activity and VWF antigen or activity in the patients with TMA did not differ from those who developed TMA, with infection or GVHD or without any complication (p>0.05). However, plasma ADAMTS13 activity decreased and the ratio of VWF antigen/activity increased significantly in patients with VOD (p<0.05). Plasma VWF multimer distribution was similar in patients with infection, GVHD or without complication, but ultralarge multimers of VWF was present in patients with TMA and VOD. Plasma levels of complement C3b was increased in patients after HSCT (198.46 ng/ml ±14.78 ng/ml) compared with healthy subjects (85.02 ng/ml±8.50ng/ml) (p<0.05), but exhibited no difference in the other groups. Plasma C3b increased significantly in patients with TMA and GVHD (p<0.05). The plasma levels of C3b were higher in the TMA group (480.70 ng/ml±66.76ng/ml) than the GVHD group (298.50 ng/ml ±32.06 ng/) (p<0.05). Also, plasma levels of C5b in patients with TMA were significantly increased (1059.49 ng/ml ±85.57 ng/ml) as compared with those before transplantation (653.19ng/ml ±44.91ng/ml) and other groups (p<0.05).

Summary/Conclusions: We conclude that plasma ADAMTS 13 activity and the ratio of VWF antigen/activity remained stable in the patients with transplant-associated TMA, but the levels of complement C3b and C5b, particularly the C5b, increased significantly, suggesting the critical role of complement pathway in the pathogenesis of TMA. C5b may be a specific biomarker for early diagnosis of TMA but C3b is a marker for both TMA and GVHD.

DONOR KIR HAPLOTYPE B EXACERBATES ACUTE GVHD IN HLA-MISMATCHED HEMATOPOIETIC CELL TRANSPLANTATION: A SINGLE-CENTER RETROSPECTIVE ANALYSIS

R Hosokai[1,*], M Masuko[2], Y Shibazaki[2], A Saitoh[1], T Furukawa[2], C Imai[1]
[1]Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, [2]Division of Stem Cell Transplantation, Niigata University Medical and Dental Hospital, Niigata-shi, Japan

Background: Following allogeneic hematopoietic stem cell transplantation (allo-HSCT), natural killer (NK) cells play a role in immune responses such as graft *versus* tumor (GVT) and graft *versus* host disease (GVHD). Killer-cell immunoglobulin-like receptors (KIR) regulate the function of NK cells by interacting with MHC class I molecules. KIR haplotype A contains only one stimulatory KIR (2DS4), whereas haplotype B contains 2 to 5 stimulatory KIR genes. Previous studies have demonstrated the effect of donor KIR haplotypes on allo-HSCT outcomes. Some investigators showed that donor KIR haplotype B augmented GVT and suppressed GVHD, consequently improving survival. However, the association between donor KIR haplotypes and clinical outcomes after allo-HSCT remains controversial.

Aims: To investigate the impact of donor KIR haplotypes on clinical outcomes in a Japanese cohort from a single center.

Methods: We retrospectively analyzed the clinical outcomes of patients with hematological malignancies who underwent allo-HSCTs at Niigata University. From 1989 to 2011, 304 HSCTs were performed. DNA samples were available for 152 donor KIR haplotypes. Of these 152, HSCTs from HLA-haploidentical family donors, umbilical cord blood, and unrelated donors with administration of anti-thymocyte globulin (ATG), as well as HSCTs for non-malignant hematologic disorders, were excluded. The remaining 106 cases, including 44 AML, 28 ALL, 14 CML, 11 NHL, and 9 MDS, were enrolled. HLA-matched sibling donors and 10/10 (HLA-A, -B, -C, -DRB1, and -DQB1) HLA allele-matched unrelated donors were defined as the HLA full-match group. Donors with at least one HLA allele mismatch were defined as the HLA mismatch group. KIR genotyping was performed with a PCR-rSSO kit.

Results: There were 61 donors with KIR haplotype A (57.5%) and 45 with KIR haplotype B (42.5%). The distribution of KIR haplotypes in this cohort was similar to that previously reported in the Japanese population. A comparison of the two groups of donors with KIR haplotypes A and B revealed no significant differences in the overall survival, cumulative incidence of relapse, and non-relapse mortality, possibly due to the small sample size and the dominance of non-AML malignancies. The cumulative incidence of grade II-IV acute (a)GVHD was not significantly different (16.4% *vs* 33.3%; P=0.051). However, grade III-IV aGVHD was significantly more frequent in patients receiving grafts from KIR haplotype B donors (4.9% *vs* 20.0%; P=0.02). The cumulative incidence of severe aGVHD was evaluated according to the degree of HLA matching. In the HLA full-match group, there was no significant difference between KIR haplotype A and B in the cumulative incidence of grade III-IV aGVHD (5.7% *vs* 8.7%; P=0.68). In contrast, in the HLA mismatch group, the cumulative incidence of grade III-IV aGVHD was significantly higher in patients receiving grafts from KIR haplotype B donors (5.3% *vs* 37.5%; P=0.02). In multivariate analysis, donor KIR haplotype B was the only significant risk factor for grade III-IV aGVHD (hazard ratio 3.92; CI, 1.04-14.75; P=0.04).

Summary/Conclusions: These findings demonstrated that donor KIR haplotype B was an independent risk factor for severe aGVHD in HLA-mismatched HSCTs using conditioning regimens without ATG. This observation suggests that genetic determinants of the functional properties of donor NK cells can affect the severity of aGVHD, which is thought to be solely induced by donor T-cells. Furthermore, it indicates that under strong T-cell alloreactivity, NK cells may have a role in worsening aGVHD.

A TWO-CENTER RETROSPECTIVE COMPARISON OF BEAM *VS* BUCYVP16 CONDITIONING PRIOR TO AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HODGKIN'S LYMPHOMA

S Singer[1,*], YA Efebera[2], Q Zhao[2], D Abounader[3], P Elder[2], CC Hofmeister[2], DM Benson[2], S Penza[2], L Andritsos[2], R Klisovic[2], S Vasu[2], W Blum[2], S Jaglowski[2], BM William[2], B Bolwell[3], B Pohlman[3], M Kalaycio[3], D Jagadeesh[3], B Hill[3], R Sobecks[3], N Majhail[3], SM Devine[2], R Dean[3]
[1]Internal Medicine, [2]Division of Hematology, The Ohio State University Wexner Medical Center, Columbus, [3]Division of Hematology, The Cleveland Clinic Foundation, Cleveland, United States

Background: High dose chemotherapy followed by autologous hematopoietic stem cell transplantation (AHSCT) is an optional treatment for patients with relapsed Hodgkin's Lymphoma (HL). A number of conditioning regimens are routinely used. However, the optimal conditioning regimen in terms of antitumor effect and toxicities remains unknown. We compare the outcomes of Carmustine, Etoposide, Cytarabine, Melphalan (BEAM) used at the Ohio State University to that of Busulfan, Cyclophosphamide, Etoposide (BUCYVP16) used at the Cleveland Clinic Foundation.

Aims: To compare the efficacy and toxicity of BEAM and BUCYVP16 conditioning regimens in patients with relapsed HL undergoing AHSCT.

Methods: We retrospectively analyzed patients treated with BEAM (n=128) or BUCYVP16 (n=105) followed by AHSCT between 2006 and 2014. Kaplan-Meier estimates were used to analyze progression free survival (PFS) and overall survival (OS). Cumulative incidence of relapse (CIR) was measured from transplant date until relapse, treating deaths as competing risks using Pepe and Mori test.

Results: Patient characteristics were similar for age (median 34 (19-73) *vs* 38 (19-69), p=0.51), disease stage (p=0.17), prior radiation exposure (p=0.21), comorbidity index (p=0.58), and response status at transplant (89.1% CR/PR *vs* 90.3%) for BEAM *vs* BUCYVP16 respectively. Differences were number of prior treatments (median 3 (1-10) *vs* 2 (1-5), p<0.01), and median CD34 dose infused (4.45 x10^6 *vs* 7.25, p<0.01) for BEAM *vs* BUCYVP16. Median follow-up from diagnosis and transplant was 7.0 years and 4.2 years respectively for BEAM and 6.5 years and 3.8 years for BUCYVP16. Median day to neutrophil engraftment was 10 (8-13) *vs* 10 (9-12) (p<0.01) and median time to platelet engraftment was 18 (13-70) *vs* 16 (7-49) (p<0.01) for BEAM *vs* BUCYVP16. Patients receiving BEAM had a lower CIR at 1, 3, and 5 years compared to BUCYVP16 (p<0.001). PFS at 1, 3 and 5 years from HSCT was 80%, 70% and 66% for BEAM *vs* 65%, 45% and 33% for BUCYVP16 respectively (P<0.001). OS from HSCT at 1, 3, and 5 years was also longer in the BEAM cohort: 94%, 88%, and 79% compared to 88%, 72%, and 54% in the BUCVY16 cohort (p<0.001, Figure 1). Grade 3/4 mucositis was higher for patients receiving BUCYVP16 (p=0.01). There were no differences in hemorrhagic cystitis, veno-occlusive disease or second primary malignancy.

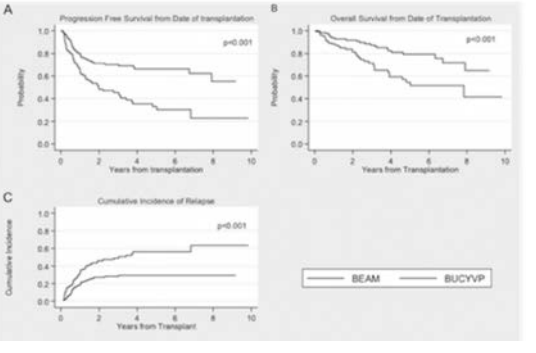

Figure 1.

Summary/Conclusions: This large retrospective study supports the use of BEAM as a conditioning regimen for AHSCT for relapsed HL. Both PFS and OS were longer for the BEAM cohort with a lower CIR.

E1514

A TWO-CENTER RETROSPECTIVE COMPARISON OF BEAM *VS* BUCYVP16 CONDITIONING PRIOR TO AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

S Singer[1,*], YA Efebera[2], Q Zhao[2], D Abounader[3], P Elder[2], CC Hofmeister[2], DM Benson[2], S Penza[2], L Andritsos[2], R Klisovic[2], S Vasu[2], W Blum[2], S Jaglowski[2], BM William[2], B Bolwell[3], B Pohlman[3], M Kalaycio[3], D Jagadeesh[3], B Hill[3], R Sobecks[3], N Majhail[3], SM Devine[2], R Dean[3]
[1]Internal Medicine, [2]Division of Hematology, The Ohio State University Wexner Medical Center, Columbus, [3]Division of Hematology, The Cleveland Clinic Foundation, Cleveland, United States

Background: High dose chemotherapy followed by autologous hematopoietic stem cell transplantation (AHSCT) has become the standard of care for patients with relapsed chemo-sensitive Non-Hodgkin's Lymphoma (NHL). Various conditioning regimens have been developed to improve outcome, but no regimen has proven superior. We compare the outcomes of Carmustine, Etoposide, Cytarabine, Melphalan (BEAM) used at the Ohio State University to that of Busulfan, Cyclophosphamide, Etoposide (BUCYVP16) used at the Cleveland Clinic Foundation.
Aims: To compare the efficacy and toxicity of BEAM and BUCYVP16 conditioning regimens in patients with relapsed NHL undergoing AHSCT.
Methods: We retrospectively analyzed patients treated with BEAM (n=269) or BUCYVP16 (n=409) followed by AHSCT between 2006 and 2014. Kaplan-Meier estimates were used to analyze progression free survival (PFS) and overall survival (OS). Cumulative incidence of relapse (CIR) was measured from transplant date until relapse, treating deaths as competing risks using Pepe and Mori test.
Results: Patient characteristics were similar for age (median 60 (20-77) *vs* 58 (27-78)), disease stage at diagnosis (p=0.29), prior radiation exposure (p=0.68), and response status at transplant (94.7% CR/PR *vs* 93.2%) for BEAM *vs* BUCYVP16 respectively. Differences were number of prior treatments (median 2 (1-8) *vs* 2 (1-13), p<0.01), comorbidity index (74.0% 0-3 *vs* 80.9%, p=0.03), and median CD34 dose infused (4.3 *vs* 6.02, p<0.01) for BEAM *vs* BUCYVP16. Median follow-up from diagnosis and transplant was 6.6 years and 4.0 years respectively for BEAM and 7.0 years and 4.3 years for BUCYVP16. Median day to neutrophil engraftment was 10 (8-19) *vs* 10 (9-15) (p<0.01) and median time to platelet engraftment was 18 (11-69) *vs* 16 (3-129) (p<0.01) for BEAM *vs* BUCYVP16. There were no statistical differences in CIR, PFS or OS. At 1, 3 and 5 years from AHSCT, PFS was 75%, 59%, and 46% *vs* 72%, 54%, and 44% (p=0.52); OS 88%, 75%, and 66% *vs* 83%, 69% and 59% (p=0.11) in the BEAM *vs* BUCYVP16 groups respectively (Figure 1). Veno-occlusive disease (VOD) was higher in the BEAM group (7 pts (2.6%) compared to none in BYCYVP16 (p<0.01)) but grade 3 or 4 mucositis was lower in BEAM (24.2%) compared to 56.1% in BUCYVP16 (p<0.01). There were no differences in hemorrhagic cystitis or second primary malignancy.

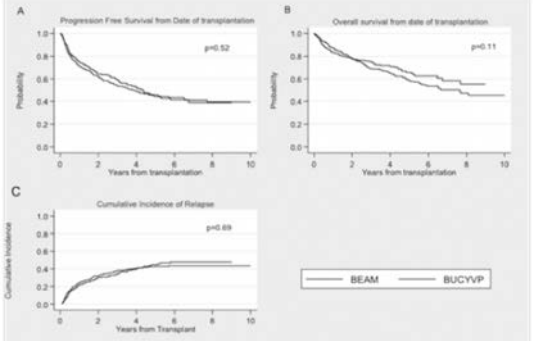

Figure 1.

Summary/Conclusions: This large retrospective study showed no statistical difference in PFS, OS, or CIR between BEAM and BUCVP16 conditioning regimens for AHSCT in relapsed NHL. Veno-occlusive disease occurred more frequently in the BEAM group, while grade 3 or 4 mucositis occurred more frequently in the BUCYVP16 group.

MINIMAL RESIDUAL DISEASE ANALYSIS USING DEEP SEQUENCING OF NPM1 AT THE TIME OF STEM CELL TRANSPLANTATION CAN PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA

SJ Alm[1,*], M Nicklasson[2], E Malmberg[1], L Palmqvist[1,3], M Brune[2], L Fogelstrand[1,3]
[1]Department of Clinical Chemistry and Transfusion Medicine, Institute of Biomedicine, Sahlgrenska Academy at University of Gothenburg, [2]Section of Hematology, Department of Internal Medicine, [3]Department of Clinical Chemistry, Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Assessment of minimal residual disease (MRD) in acute myeloid leukemia (AML) has become increasingly more important for risk stratification, early detection of relapse and monitoring after stem cell transplantation (SCT). In AML with mutation in *NPM1*, RT-qPCR (reverse transcription-quantitative polymerase chain reaction) after first-line treatment has been shown to have high predictive value. However, there are numerous recurrent mutations in the *NPM1* gene and therefore specific MRD analyses of each individual mutation would require an overwhelming number of specific RT-qPCR assays. Using targeted deep sequencing, the same assay can be applied for all described *NPM1* mutations, and serve as a cost-effective alternative for MRD analysis also in cases with rare *NPM1* mutations.
Aims: The aim of this study was (i) to investigate whether deep sequencing may provide predictive information in the SCT setting, and (ii) to analyze potential relationship between deep sequencing and chimerism analyses post SCT.
Methods: A total of 37 bone marrow samples from 19 patients with AML with mutated *NPM1* were analyzed using targeted deep sequencing before (within one month) and three months after SCT. Sequencing was performed in multiplex on the Illumina MiSeq platform, using Truseq-library preparation, with coverages ranging between x6-18x10^5, a threshold of significance of 0.006% and a between run-CV of 2.1%. Calling of mutated and wild-type *NPM1* sequences was performed using an in house-script. Based on the linearity and sensitivity of the assay, *NPM1* MRD positivity was defined as variant allele frequency (VAF) ≥0.025% and *NPM1* MRD negativity as VAF<0.025%. Chimerism analysis with STR-PCR (short tandem repeat-polymerase chain reaction) was performed on bone marrow samples taken three months after SCT. Follow-up status of patients was collected from the local stem cell transplantation registry. The study was approved by the local ethics committee.
Results: Nine out of the 37 bone marrow samples displayed *NPM1* MRD positivity. Four of these were detected pre-SCT, and five post-SCT. In samples with *NPM1* MRD positivity, the *NPM1* mutation load ranged from 0.033-1.1% in VAF. Of the 5 patients with *NPM1* positivity post-SCT, only one had mixed chimerism, defined as >1% recipient donor T cells or CD34+ cells. There was no correlation between results from chimerism analysis and *NPM1* mutation load detected with deep sequencing. In patients with *NPM1* MRD positivity either pre- or post-SCT, the relapse-free and overall survival were significantly shorter compared with patients with *NPM1* MRD negativity at both time points (p=0.002 for both). In fact, all patients relapsing (n=5) showed *NPM1* MRD positivity in at least one of the samples.
Summary/Conclusions: In summary, MRD monitoring using targeted deep sequencing of *NPM1* is a highly sensitive technique, and in this study *NPM1* MRD positivity both pre- and post-SCT was highly predictive of relapse in AML after SCT. Chimerism analysis using STR-PCR appeared in this study to be less predictive of imminent relapse, at the time points analyzed. We conclude that detection of residual leukemic cells with deep sequencing is of value for clinical monitoring before and after SCT, allowing for early relapse-preventing intervention.

Background: Diagnosing, scoring and treating chronic graft-*versus*-host disease (cGVHD) is challenging because of polymorphic manifestations and lack of biomarkers for the diagnosis and assessment of disease activity. Several guidelines have been published, however the clinical practice remains demanding.
Aims: With this study we investigated the 'real life' management of cGVHD in 32 Italian Center members of GITMO (Gruppo Italiano Trapianto Midollo Osseo).
Methods: A detailed survey with 41 multiple-choice questions about the use of guidelines, and the first and further lines of treatment and management of cGVHD has been proposed to all adult and pediatric GITMO Centers (N=60)
Results: Thirty-two Centers replied, and according to the survey's results, 29 Centers referred to published guidelines for cGVHD management (mainly those proposed by National Institute of Health, NIH), however only 13 find them fully adequate. As shown in Figure 1, the main reasons for complain were related to second line treatment. According to NIH definition, most of the Centers (N=25) started treatment when severe cGVHD occurred, whereas 4 Centers also considered bad prognostic features regardless the grading. All Centers agreed on the use of prednisone as first line treatment, which was started at the dose of 1 mg/kg in 26/33 Centers. Prednisone alone was used in 4 Centers, while in the others it was associated to extracorporeal photo-apheresis (ECP, N=25), calcineurine inhibitors (CNI, N=17) and mycophenolate mofetil (MMF, N=11). A great inter-center variety has been reported regarding the duration of treatment, as well as the indication to and the choice of steroid-sparing agents. All but 6 Centers referred to NIH criteria to define response. Objective measurements (i.e. pulmonary function and lab tests), patient reports and ability to treatment discontinuation were scored as of great importance for response judgment, whereas physician opinion was scored as medium. In case of complete response, 30/32 Centers tapered steroid slowly, but there was no uniformity on the definition of slow taper (9/32 agreed on 10% reduction/week). Treatment failure, steroid refractoriness, intolerance or dependency were the main reasons for second line therapy. Sixteen Centers stated to have a policy for the choice of second line treatment, and the choice was customized according to organ involvement and patients condition in 24/32 Centers. Seven Centers declared a policy for third line of treatment. Overall, CNI, ECP and MMF were the most used treatments for refractory cGVHD: CNI regardless the involved organ, ECP and sirolimus for skin, lung, and gastrointestinal (GI) involvement, imatinib for skin and lung, infliximab and MMF for liver and GI, and rituximab for skin. ECP was available in 25/32 Centers. Finally, all responding Centers reported a strong need and willing to participate in prospective multicenter trials for both first and second line treatment of cGVHD; only 2 of them had a protocol open for refractory GVHD.

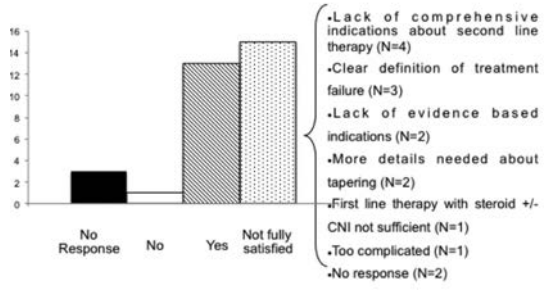

Figure 1. Are you satisfied from the current guidelines?

Summary/Conclusions: Despite the presence of guidelines, this survey showed a great disparity in the management of cGVHD, especially for refractory disease. The survey further emphasized the great interest and need for prospective trials investigating this setting.

E1517

A PHASE 2, MULTICENTER, SINGLE-ARM STUDY TO EVALUATE SAFETY AND EFFICACY OF DEFERASIROX AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH BETA-THALASSEMIA MAJOR

MA Yesilipek[1,*], G Karasu[2], Z Kaya[3], BB Kuskonmaz[4], V Uygun[1], I Dag[5], O Ozudogru[5], M Ertem[6]
[1]Pediatric Hematology, Bahcesehir University Faculty of Medicine, Antalya, [2]Pediatric Hematology, Bahcesehir University Faculty of Medicine, Istanbul, [3]Pediatric Hematology, Gazi University Faculty of Medicine, [4]Pediatric Hematology, Hacettepe University Faculty of Medicine, Ankara, [5]Novartis Oncology, Novartis Saglik Gida ve Tarim Urunleri San. ve Tic. A.S., Istanbul, [6]Pediatric Hematology, Ankara University Faculty of Medicine, Ankara, Turkey

Background: Hematopoietic stem cell transplantation (HSCT) is being increasingly used as curative therapy for severe disorders of the hematopoietic system such as thalassemia. The use of therapeutic phlebotomy post-HSCT is often difficult to perform in younger or anemic children. Deferiprone is shown to be related with bone marrow suppression and compliance to deferoxamine is low. Studies that evaluate the safety of deferasirox (DFX) in this setting, are limited.
Aims: The aim of this study is to evaluate safety and efficacy of DFX in Thalassemia Major patients in a Post Transplant setting.
Methods: This was a prospective, phase 2, multicenter, single-arm study to evaluate efficacy and safety of DFX in beta-thalassemia major (TM) patients who have undergone HSCT. The primary objective was to evaluate if DFX could provide safe chelation in patients with transfusional iron overload within a time period of 6 months to 2 years after HSCT. Transfusion independent patients aged ≥2 to<18 years old who had undergone HSCT with a washout period of at least 3 months after immunosuppressive therapies and had iron overload at screening defined by serum ferritin (SF) of >1000 µg/L or cardiac MRI T2*<20 ms or liver iron concentration (LIC, by MRI R2) of ≥5 mg/g were included in the study. Patients received DFX at an initial dose of 10 mg/kg/day with up titration every 3 months by 5 mg/kg/day per investigator judgment to the intended 20 mg/kg/day dose. Therapy continued for 52 weeks or until SF reached below 500 µg/L.
Results: Data from 27 patients enrolled (median (range) age 9.07 years (3-16), 70,4% males) were included in this analysis. One patient discontinued on week 14 due to withdrawal of consent. 20 patients were able to achieve the intended dose of 20 mg/kg/day. *Safety* From a total of 140 Adverse Events (AEs), 10 (7.1%) AEs in 4 patients were suspected to be related to study drug. The majority of AEs were of Grade I (n=81, 57.9%) or II (n=48, 34.3%). A total number of 6 (4.7%) SAE's were reported. 8 (5.7%) AEs resulted in study drug interruption or dose adjustment, 1 of which was suspected to be related to the study drug (ALT increase). On 51 (36.4%)AE's, no action was taken. Median ALT level decreased from 27 IU/L (range: 10-119) at baseline to 17 IU/L (range: 9-205) at week 52. Median AST level decreased from 35,5 IU/L (range: 17-66.5) to 26 IU/L (range:18-78) at week 52 (*Figure 1*). The median SCr was similar at baseline (0.4 mg/dL range: 0.2-0.7) and week 52 (0.4 mg/dL range: 0.2-1) Median cystatin C was similar at baseline (0.7 mg/mL range: 0.5-1) and week 52 (0.7 mg/mL range: 0.5-1) (*Figure 2*). No dose adjustments were required due to nephrotoxicity. Increased proteinuria was described in 9 (33.3%) patients, irrespective of dose at 52 weeks. No patient with proteinuria required dose adjustments. *Efficacy* SF significantly and consistently decreased through 52 weeks from a median of 1718 µg/L (range: 873.7-2919) to 845.3 µg/L (range: 146.2-2740), p<0.001. At week 52, 9 (33.3%) patients reached SF<500 µg/L, p<0.001. LIC also significantly decreased from a median of 8.60 mg/g (range: 2.8-43) to 4.1 mg/g (range 0.9-12.5), p<0.001. Cardiac T2* increased from a median of 25.95 ms (range: 4.5-51) to 28 ms (18.5-44), p=0.520.

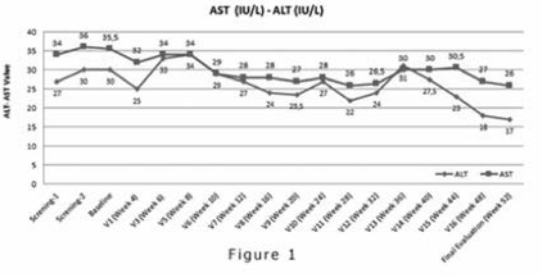

Figure 1

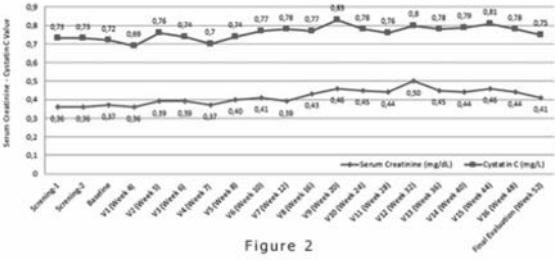

Figure 2

Figure 1.

Summary/Conclusions: Our findings suggest that DFX dose escalation up to 15-20 mg/kg/day is safe for TM patients following successful HSCT regarding nephrotoxicity and hepatotoxicity. 15-20 mg/kg/day deferasirox was also efficacious and this was evident through significant reductions of systemic and hepatic iron overload.

E1518

PARAMETERS OF PROTEIN METABOLISM AND THYROID FUNCTION AS PREDICTORS OF A SCORING SYSTEM FOR ACUTE AND CHRONIC GRAFT-VERSUS-HOST DISEASE

C Skert[1,*], A Turra[1], M Malagola[1], S Perucca[1], F Cattina[1], V Cancelli[1], B Rambaldi[1], C Filì[1], C Pagani[1,2], N Polverelli[1], A Di Palma[1], S Bernardi[1], D Russo[1]

[1]Usd Tmo adulti, [2]Ematolgia, Brescia, Italy

Background: Some "classical" patient-, donor- and transplant characteristics, such as age, gender disparity, donor type, HLA-match, and source of stem cells, have been reported as predictors for acute and chronic GVHD. However, no studies analysed these "classical" variables together with parameters of metabolic and endocrine functions that may potentially influence the immune system.
Aims: Patient-and transplant variables together with index of liver and thyroid function, and some parameters of protein and lipid metabolism were retrospectively evaluated at different time points after transplantation, in order to identify possible predictors of acute and chronic GVHD and to calculate a risk score.
Methods: Clinical and transplant characteristics, number and type of infections before and after SCT were analysed in 200 patients. The following variables were also analysed pre-SCT, at day +7,+14,+21,+28, at+3 and +6 months: LDH, parameters of liver function; parameters of protein and lipid metabolism; thyroid function tests; autoimmune parameters; body mass index. A 2-step multivariate analysis was performed using principal component analysis and Cox regression analysis. Based on the regression coefficient of Cox analysis for each significant predictor, a scoring system for acute and chronic GVHD was calculated.
Results: In multivariate analysis, diagnosis of Myelodisplastic Syndrome or Chronic Myeloid Leukemia (p=0.0004), conditioning regimen including Total Body Irradiation (p=0.0003), and pre transplantation urea >34 mg/dl with +21 day urea >54 mg/dl (p=0.0008) were predictors for acute GVHD. Score values for each factor are 2, 1, 1, respectively and the system had a score range between 0 and 4. The probabilities of acute GVHD according to the sum scores ranged from 8% (score 0) to 98% (score 4). Female donor (p=0.0008), pre-SCT TSH values ≥2 mU/L with +28 day urea ≥39 mg/dl (p=0.02), +6 month total protein<5,5 g/dl with gamma-GT ≥347 U/L (p=0.0001) resulted predictors for moderate/severe chronic GVHD. Risk of chronic GVHD at +6,5 month ranged from 3% (score 0) to 97% (score 4).
Summary/Conclusions: Our study evidenced that factors other than those "classical" may be associated to GVHD. The scoring system included routine-parameters, which are easily available in clinical practice. Urea levels depend on the balance between protein intake, endogenous catabolism and urinary excretion. The inflammatory microenvironment of GVHD promotes muscle catabolism and hence, increased urea levels. Increased urea levels could be indirect index of increased uremic toxins as well, which may stimulate the production of pro-inflammatory cytokines and the activation of leukocytes. Increased urea levels and uremic toxins could also derive from a dysregulated metabolism of the gut microbiome that may influence immune system. Our findings suggest the usefulness to study in deep the complex network between metabolic/endocrine functions and immune system for a holistic approach of the transplant management.

E1519

DEFIBROTIDE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCCLUSIVE DISEASE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE

B Antmen*, I Sasmaz, B Karagun, M Serbest
Pediatric Bone Marrow Transplantation Unit, Adana Acibadem Hospital, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hemotopoietic stem cell transplantation (HSCT) in children.
Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.
Methods: In this study, 76 patients who underwent HSCT were given defibrotide prophylaxis as 25 mg/kg per day in four divided intravenous infusions over 2h, starting on the same day as the pretransplantation conditioning regimen. The mean duration of use of defibrotide is 20 days as a prophylaxis.
Results: In this study, 76 patients were recruited, 53 male patients and 23 female patients, with the average of 9.3 years, range 1-20; 4% infants, 55% children and 41% adolescent. There were 33 patients with thalassemia major, 30 patients with leukemia, 7 patients with aplastic anemia, one patient with Diamond Blackfan anemia, two patients with congenitale dyserythropoetic anemia, one patient with osteopetrosis, one patient with famial hemophagocytic lymphohistiocytosis, and one patient with Kostman syndrome. All transplants were allogeneic. No serious side effects were seen. In eight patients developed clinical VOD (Seattle criteria). In these patients, defibrotide dose was increased to a treatment dose of 40-60 mg/kg per day. One infant patient with Kostman syndrome and one patient with aplastic anemia died due to hepatic and pulmonary veno-occlusive disease. After 24 months of follow up, 6 patients who developed VOD are being well and no patient have transplant related complications.
Summary/Conclusions: Hepatic veno-occlusive disease, which is caused by hepatocyte and sinusoidal vessel endothelium damage, can ocur early after HSCT, and in its severe form, may lead tol iver faillure, hepatorenal syndrom, portal hypertension, and eventually death from multiorgan faillure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk.

E1520

COMPARISON OF INTENSIFIED MYELOABLATIVE CONDITIONING REGIMEN WITHOUT ATG TO MYELOABLATIVE CONDITIONING REGIMEN FOR SINGLE-UNIT UMBILICAL CORD BLOOD TRANSPLANTATION IN HEMATOLOGICAL MALIGNANCIES

Y Wu, H Liu, C Zheng, B Tang, X Zhu, X Wan, L Zhang, J Tong, W Yao, X Zhang, Z Sun*
Hematology, Anhui Provincial Hospital, Hefei, China

Background: The superiority and safety of strengthening conditioning regimen for single-unit umbilical cord blood transplantation (sUCBT) in hematological malignancies remain controversial.
Aims: To define whether intensified myeloablative regimen is superior to conventional myeloablative regimen for single-unit umbilical cord blood transplantation (sUCBT) in hematological malignancies.
Methods: We retrospectively analyzed the clinical data of 251 hematological malignancies undergoing sUCBT from Apr 2000 to Dec 2014 at Anhui provincial hospital hematology department. In these patients, 216 received the intensified myeloablative conditioning regimen (IMCR), and 35 received the myeloablative conditioning regimen (MCR). We evaluated the effect of IMCR without ATG on patient outcomes. Among the IMCR group, 106 patient received TBI/Ara-C/CY regimen, 41 received Ara-C/Bu/CY regimen, 69 received Flu/Bu/CY regimen, and all received a combination of CsA and MMF for the prophylaxis of GVHD. For the MCR group, 35 patients received Bu/CY regimen using CsA/MMF±ATG or MTX for the prophylaxis of GVHD.
Results: The cumulative incidence of myeloid and platelet engraftment of the IMCR group was significantly higher than that in the MCR group (96.98% *vs* 82.81%, 85.89% *vs* 51.79%, P=0.000, 0.003, respectively). Corresponding incidences of transplantation-related mortality (TRM) by 180 days in the IMCR group and the MCR group were 19.50% *vs* 41.67% (P=0.0028), respectively. The incidence of CMV infection and pre-engraftment syndrome were significantly higher in the IMCR group compared with that in the MCR group (68.8% *vs* 40%, 82.9% vs.48.6%, P=0.001, 0.000, respectively). There were no differences in the incidence of grade II to IV aGVHD, grade III to IV aGVHD and 2-year cumulative incidence of relapse. Up to Oct. 2015,with a median follow-up of 30 months, the estimated 3-year overall survival and disease-free survival in the IMCR group were both significantly higher than that of the MCR group (62.4% *vs* 35.5%, 60.1% *vs* 35.5%, P=0.000,0.004, respectively). For 49 patients not in remission at transplantation in the IMCR group, the cumulative incidence of 2-year relapse was 21.92% (95%CI, 21.15-22.69%), which was comparable with patients in remission (P=0.115). The estimated 3-year overall survival and disease-free survival of advanced patients undergoing IMCR were 54.8% and 52.1%, respectively. For six patients older than 40 years, the incidences of myeloid, platelet engraftment and 180d TRM were not significantly different from patients between 20 and 40 year old and those younger than 20 year□100% vs.96.36% vs.96.73%, 66.67% vs.91.32% vs.84.75%, 16.67% vs.19.87% vs.18.48%, P=0.418, 0.405, 0.975, respectively).
Summary/Conclusions: This study is the first to show the superiority of intensified myeloablative regimen to conventional myeloablative regimen. A large-scale prospective study was needed to investigate its application.

E1521

TCRAB+/CD19+-DEPLETION IN HEMATOPOIETIC STEM CELLS TRANSPLANTATION FROM MATCHED UNRELATED AND HAPLOIDENTICAL DONORS IN PEDIATRIC ACUTE MYELOBLASTIC LEUKEMIA PATIENTS

L Shelikhova[1,*], Z Shekhovtsova[1], D Balashov[1], E Kurnikova[2], E Boyakova[3], Y Muzalevsky[2], A Kazachenok[2], Y Skvortsova[1], M Ilushina[1], I Shipitsina[1], D Shasheleva[1], R Khismatullina[1], E Gutovskaya[1], A Livshits[1], S Blagov[1], I Kalinina[4], A Abrosimov[1], D Baidildina[4], G Novichkova[5], A Maschan[6], M Maschan[1]
[1]HSCT, [2]Laboratory of Transplant Processing and Cell Preparations, [3]Laboratory of physiology and pathology of stem cells, [4]Department of pediatric hematology/oncology, [5]Administration, [6]Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Graft-*versus*-host disease (GvHD) and GvHD-associated morbidity and mortality are major obstacles to the success of transplantation from unrelated and haploidentical donors. Negative depletion of α/β(+) T cells and CD19+ B lymphocytes is a technology of graft manipulation with a potential to improve GvHD control and immune reconstitution.
Aims: The aim was to study retrospectively the outcomes of TCR-alpha/beta depleted transplants in a group of pediatric acute myeloid leukemia patients with the emphasis on two consequtive GVHD prophylaxis regimens.
Methods: A total of 59 pediatric patients with acute myeloblastic leukemia (17 female, 42 male, median age 9,1 years, range 0,6-22) underwent allogeneic HSCT between May 2012 and June 2015. Twenty two patients received haploidentical graft, 37 - a graft from matched unrelated donor. Disease status at transplant was CR1 in 40 pts., CR≥2 in 10 pts., active disease(AD) in 9 pts. Transplantation in CR1 was performed according to risk stratification scheme in the current institutional AML protocol. For all patients it was first HSCT.

TCRαβ+/CD19+ depletion of HSCT with CliniMACS technology was implemented in all cases. All patients received Treosulfan/Melphalan/Fludarabine as conditioning regimen. Two regimens of GvHD prophylaxis were used: regimen 1 (n=31): ATG (horse, ATGAM) 50 mg/kg and post-transplant Tacro/MTX (n=28), or no post-transplant prophylaxis (n=3); regimen 2 (n=28): ATG (rabbit, thymoglobuline) 5 mg/kg, rituximab 200mg/m^2 and post-transplant bortezomib (n= 27) or Tacro/MTX (n=1). The median dose of CD34+ cells in transplant was 7,9 x10^6/kg (range 1-21), TCRα/β - 15x10^3/kg (range 0,6-210).
Results: Primary engraftment of WBC and platelets was achieved in 58 (98,3%) patients at a median of 14 days, 1 pt. with AD had primary graft failure with no evidence of leukemia and was retransplanted from MUD. No case of graft rejection was registered. Early mortality was low with a +100-day pTRM - 3,4% (95% CI: 0,1-13.2), 3-year pTRM-10,8% (95%CI: 5-23). The 2 early deaths included viral infections (ADV), four late: bacterial sepsis in 1 pt. and viral infection(ADV and CMV) in 3 pts, all with extensive chronic GvHD. Cumulative incidence (CI) of acute GvHD grade ≥II was 20,3% (95% CI: 12-34), grade III–IV 8,5% (95%CI: 4-20) and chronic GvHD-28% (95% CI: 18-45). No correlation between graft composition and aGvHD was noted. CI of acute GvHD was significantly lower in a group with regimen 2: 7,4% (95% CI: 2-28) *vs* 31,3% (95% CI: 19-52) in group with regimen 1, p=0,028. Regimen 2 was also effective in prevention of chronic GvHD: CI at 1 year after HSCT was 14% *vs* 36%, p=0,085 Median time of follow-up for survivors is 1,9 years (range 7 months-3,5 years). CI of relapse at 3 year is 27,6% (95%CI: 18-43). Three year pEFS is 62% (95%CI: 49-75), 3-year pOS - 64% (95%CI: 50-78). There was no significant difference in survival and relapse rate according leukemia subtype, remission status and donor type.
Summary/Conclusions: We confirm that the depletion of TCR-alpha/beta and CD19 lymphocytes from the graft ensures high engraftment rate and acceptable transplant-related mortality in pediatric AML patients. All major outcomes were equivalent between transplantation from unrelated and haploidentical donor. GvHD prophylaxis including Thymoglobulin/Rituximab/Bortezomib improves GvHD control in recipients of TCRα/β- depleted grafts in comparison to ATGAM/Tacro/MTX apparently without loss of anti-leukemic activity.

E1522

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACQUIRED SEVERE APLASTIC ANEMIA

M Miao*, X Zhang, T Xu, S Jin, H Wang, X Yang, Z Pan, J He, A Sun, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Acquired severe aplastic anemia (SAA) is a life-threatening disease and allo-geneic hematopoietic stem cell cell transplantation (HSCT) is a curative treatment. Recent researches indicate that haploidentical HSCT (haplo-HSCT) is an effective therapeutic option for SAA.
Aims: To evaluate the efficiacy and safety of haploidentical hematopoietic stem cell transplantation (haplo-HSCT) in patients with acquired severe aplastic anemia (SAA), who lacked suitable related or unrelated HLA-matched donors
Methods: 39 SAA patients underwent haplo-HSCT from Jul 2012 to Jun 2015 at our center. There were 23 males and 16 females at a median follow-up of 11 (range, from 0 to 36) months. The median time from diagnosis to transplantation was 1 (range, from 0.5 to 52) months. The median ages of SAA patients and related haploidentical donor were 23 years (range, 9 to 51years) and 45 (range, from 21 to 61) years, respectively. All patients were given BuCy plus ATG conditioning regimen. GVHD prophylaxis regimen consisted of cyclosporine A (CsA), mycophenolate motetil (MMF), and short-term methotrexate.
Results: Stem cells were collected from bone marrow in 23.08% (n=9) of patients, peripheral blood in 2.56% (n=1), bone marrow plus peripheral blood in 74.36% (n=29) patients. 36 patients received haplo-HSCT combined with the third part of cord blood transfusion 92.31%. The median stem cell dose transplanted was 9.76 (range, from 4.02 to 20.10)×10^8/kg for mononuclear cells, while 3.4 (range, from 1.05 to 8.60)×10^8/kg for CD34 cells. 36 patients achieved neutrophil engraftment at a median of 12 (range, from 9 to 28), and 29 patients achieved platelet engraftment at a median of 29 (range, from 10 to 26) days. Cumulative incidence of III°~IV° acute graft *versus* host disease (aGVHD) was 8.9±4.9%. 6 patients died of transplant-related mortality (TRM), including 4 from severe infection, 1 from TMA and 1 from encephalorrhagia. The 2-year overal survival rate of all patients was 83.2%±6.4%.
Summary/Conclusions: Haplo-HSCT is likely to be an option for SAA patients without suitable related or unrelated HLA-matched donors, in consideration of the acceptable TRM and severe GVHD incidences.

E1523

EBV AND CMV INFECTION IN RECIPIENTS OF HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION RECEIVING TWO DIFFERENT DOSES OF ANTITHYMOCYTEGLOBULIN AS CONDITIONING REGIMEN

R Lin[1], Y Wang[2], T Yang[3], Y Xu[4], F Huang[1], Z Fan[1], S Zhang[2], Y Ji[2], N Xu[1], Y Gao[1], J Sun[1], X Huang[2], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Peking University Institute of Hematology, Beijing, [3]Department of Hematology, Fujian Medical University Union Hospital, Fuzhou, [4]Department of Hematology, Xiangya Hospital, Central South University, Changsha, China

Background: Antithymocyteglobulin (ATG) has been widely used to prevent acute graft-*versus*-host disease (aGVHD) in recipients receiving haploidentical hematopoietic stem cell transplantation (HSCT). Notwithstanding, immunosuppressive effect of ATG increases the risk for infections, especially viral infection. Therefore, the optimal dose of ATG which elicits adequate immune suppression and limits the development of viral infection/reactivation is needed to be studied.
Aims: To evaluate the effect of different doses of ATG on post-transplant viral infection, this multicenter prospective study was conducted to compare EBV and CMV infection in haploidentical HSCT recipients receiving 7.5 mg/kg or 10 mg/kg of ATG. Besides, the incidence of aGVHD was compared between the two arms.
Methods: Between January 2013 and August 2015, 217 consecutive patients with hematological malignancies undergoing haploidentical HSCT were enrolled in 4 hospitals. One hundred and ten patients were randomized to receive a total dosage of 7.5 mg/kg of ATG and 107 were randomized to receive 10 mg/kg of ATG.
Results: The 1-year cumulative incidence of EBV infection were 30.7±6.0% in 7.5 mg/kg of ATG arm and 43.1±6.0% in 10 mg/kg arm (*P*=0.107). CMV infection were comparable in the two arms (7.5 mg/kg arm: 79.6±3.9% *vs* 10 mg/kg arm: 84.1±3.6%, *P*=0.188). Acute GVHD grade II to IV within 100 days occurred in 35.9±5.2% of the patients with 7.5 mg/kg ATG and 19.2±4.8% of those with 10 mg/kg ATG (*P*=0.004). The incidence of aGVHD grade III to IV within day 100 were 14.1±3.9% in 7.5 mg/kg arm and 7.3±3.3% in 10 mg/kg arm (*P*=0.072). No difference in the 1-year cumulative overall survival was found (75.8±6.8% in 7.5 mg/kg arm *vs* 73.7±4.6% in 10 mg/kg arm, *P*=0.192).
Summary/Conclusions: Compared with 10 mg/kg of ATG, the application of 7.5 mg/kg might reduce the viral infection after haploidentical HSCT and not increase the risk for severe aGVHD.

E1524

AUTOLOGOUS STEM CELL TRANSPLANT WITH NON CRYOPRESERVED HEMATOPOIETIC STEM CELL IN ALGERIAN PATIENTS WITH MULTIPLE MYELOMA

A Bekadja*, S talhi, K amani, M brahimi, S osmani, N yafour, A krim, R bouhass
Hematology and cell therapy, EHU1st November, Oran, Algeria

Background: For younger patients under 65 years of age, induction followed by high-dose chemotherapy with autologous stem cell transplantation (ASCT) is the standard treatment in multiple myeloma (MM). There is limited experience with non-cryopreserved autologous hematopoietic stem cell transplantation.
Aims: We evaluated the efficacy and safety of non-cryopreserved storage of ASCT in patients undergoing ASCT for MM.
Methods: From May 2009 to December 2013, 134 patients with MM were treated in our center in Oran. The median age at ASCT was 55 years (range; 27-67). There were 80 males and 54 females. The median harvested CD34$^+$ cell count was 3,5x10^6/kg (range; 1, 22 to 13, 24). Autologous stem cell was mobilized using G-CSF alone (10 µg/kg/day for 5 days). Leukapheresis to harvest stem cells were performed on day -2 and -1. The grafts were kept in a conventional blood bank refrigerator at +4°C until reinfusion on day 0. The conditioning regimen consisted of melphalan 200 mg/m^2.
Results: All patients had engraftment on the median of day 10 (range; 7 to 17) and platelet transfusion independence on the median of day 13 (range; 9 to 24). There was no graft failure. Mucositis grade 3/4 was seen in 68% patients. Transplant related mortality at 100 days was 2.9%. The overall response to transplant was 92%. In the 130 evaluable patients, the median post-transplant overall survival had not been reached. The estimated overall survival at 75 months was 63% with 95% confidence interval and the median post-transplant disease free Survival was 35 months (0.05%). 93 (72%) patients are alive and 75 (81%) without disease activity after a median follow-up of 35 months (range; 3 to 75).
Summary/Conclusions: We conclude that high dose chemotherapy and autologous transplant with non cryopreserved ASCT is a simple, effective and safe method for MM with equivalent results, and that cryopreservation is not necessary in the treatment of MM under our work conditions in developing countries.

E1525

SECONDARY ANTIFUNGAL PROPHYLAXIS IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT: THE NIGUARDA HOSPITAL EXPERIENCE

S Ferrari*, M Zancanella, E Zucchetti, G Grillo, R Cairoli, A Nosari
Niguarda, Milan, Italy

Background: As allogeneic hematopoietic SCT (HSCT) is the only curative treatment for the majority of acute leukemia patients (pts), clinicians encounter the therapeutic dilemma of balancing cytotoxic therapy and HSCT with the risk of invasive mold infections (IMIs) relapse-related morbidity and death. Use of effective, less toxic antifungals and routine early chest CT implementation, leading to prompt intensive antifungal therapy, improved responses and survival. These developments have increased the interest regarding the efficacy of secondary antifungal prophylaxis (SAP), but data are limited.

Aims: The aim of the study was to evaluate the IMI relapse rate and associated mortality rate after allogeneic HSCT in a cohort of pts with hematological malignancies. We assessed the HSCT outcome of pts with a history of IFI and the efficacy of SAP.
Methods: We retrospectively collected data of pts with IFI treated at Niguarda bone marrow transplant center between 2004 and 2016. Among the 322 HSCT recipients we identified 36 pts, median age 49 yrs (range 16-67), with a history of IFI. The underlying malignancies were AML (26), ALL (8), myelodysplastic syndrome (2). Hematologic disease status at transplant was CR (26), PR (6) and refractory disease (4). Conditioning regimens were myeloablative in 22 pts and reduced-intensity conditioning in 14.
Results: The IFI diagnosis according to the EORTC/MSG criteria was proven, probable and possible in 6 (2 A.fumigatus, 1 A.terreus, 1 Absidia Corymbifera and 2 Mucor), 5 and 25 pts, respectively. Sites of involvement included lung (31), sinuses (3), central nervous system (1) and breastbone (1). The median duration of antifungal treatment before SCT was 110 days (10-360) and the IFI status at transplantation was CR, PR (defined as presence of residual pulmonary localizations at CT scan but no symptoms) and active in 18, 16 and 2 pts, respectively. During the peritransplant period 31 pts received SAP with liposomal amphotericin (Amb), 1 pt received both Amb and Posaconazole, 2 pts Voriconazole, 2 pts Caspofungin. After engraftment 12 pts (1 active IFI, 5 PR and 6 CR) continued antifungal therapy: 6 received Voriconazole, 1 Posaconazole, 5 Amb for a median period of a month; 3 of Amb pts continued prophylaxis with Posaconazole (2) and Voriconazole (1) up to ciclosporine suspension. By day +100, IFI progression occurred in only 1 pt with active hematologic disease and proven aspergillosis who rapidly died. No fungal recurrence was present in the other pts, also in presence of CMV reactivation (15 pts). We observed 16 cases of aGVHD (12 with possible, 1 with probable and 3 with proven IFI) and 18 cases of cGVHD, treated with steroid therapy (median duration 17 months, 1-80). Among GVHD pts only one had a possible IFI reactivation (20 months from HSCT) in absence of SAP. With a median follow-up of 37 months (1–118) 20 pts died due to leukemia relapse (10), bacterial infections (6), GVHD/transplant toxicities (3), IFI (1).
Summary/Conclusions: In our experience (1 IFI-related death and 1 possible late IFI reactivation) with a correct SAP, prior IFI may no longer be considered a contraindication for allo-SCT. However, new data are needed to guide the use of SAP and to improve the cost-effectiveness of treatment. Determination of appropriate time to discontinue SAP is one of the many areas where more data are needed. Prolonged fungal pre-transplant therapy, aiming to achieve a clinically undetectable state of infection, followed by SAP during transplant may allow the SCT with reduced fungal reactivation.

E1526

EFFECT OF DONOR KIR GENOTYPE ON THE OUTCOME OF PEDIATRIC ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

HH Koo[1,*], SH Lee[1], JW Lee[1], KH Yoo[1], KW Sung[1], ES Kang[2], SJ Kim[3], K Kim[3], JH Jang[3], CW Jung[3]
[1]Department of Pediatrics, [2]Department of Laboratory Medicine and Genetics, [3]Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Natural Killer (NK) cells have recently attracted for the potential role in graft-*versus*-tumor effect and NK cell alloreactivity was investigated in several studies.
Aims: The impact of donor killer immunoglobulin-like receptor (KIR) phenotype and genotype on the outcome following allogeneic hematopoietic stem cell transplantation (HSCT) in children was evaluated.
Methods: We prospectively evaluated the gene content and expression of the KIR in children undergoing allogeneic HSCT for malignant diseases. The incompatibility between donor KIR and recipient KIR ligand (receptor-ligand (R-L) mismatch) was defined if the donor has an inhibitory receptor for which the cognate ligand is absent in the recipient. Donors were assigned to A or B KIR haplotype donor according to their gene content. A haplotype donor was defined as the individual having only genes of the group A KIR haplotypes. All other individuals having one or more B haplotype specific genes were defined as B haplotype donor.
Results: All 42 patients received allogeneic HSCT from sibling (n=11), unrelated donor (n=20), or haploidentical donor (n=11) between January 2011 and December 2013. Seventeen transplants were performed in patients with acute myeloid leukemia, 15 in patients with acute lymphoblastic leukemia, 8 in patients with neuroblastoma, and 2 in patients with other solid tumors. Five donor-recipient pairs had KIR R-L match and remaining 37 donor-recipient pairs had KIR R-L mismatch. The 2-year relapse-free survival (RFS) was 100% in recipients with R-L match and 69.3±8.9% in recipients with R-L mismatch, respectively (P=0.18). However, recipients who received HSCT from B haplotype donor had better RFS than those who received HSCT from A haplotype donor (93.3±6.4% *vs* 58.0±12.0%, P=0.03). Furthermore, there was no relapse in four recipients who received HSCT from donors having 2 or more B gene-content motifs. Survival benefit of B haplotype donors was found in both HLA-matched and mismatched transplants. Donor KIR genotype and R-L mismatch did not have any significant effect on rates of grade III-IV acute graft-*versus*-host disease (GVHD) or chronic GVHD. In multivariate analysis, A haplotype was the only independent factor predicting increased risk of relapse (RR 16.5, 95% CI 1.3-217.4, P=0.03).
Summary/Conclusions: This analysis has identified decreased relapse and improved RFS in patients who received allogeneic HSCT from donors having B haplotype. KIR genotyping should be considered for successful selection of a NK cell alloreactive donor.

E1527

DEVELOPMENT AND CLINICAL EVALUATION OF DIGITAL PCR ASSAYS FOR SENSITIVE CHIMERISM ANALYSIS BASED ON DELETION/INSERTION POLYMORPHISMS

T Stahl[1], C Rothe[2], MU Böhme[2], S Mersmann[3,*], N Kröger[1], B Fehse[1]
[1]Department of Stem Cell Transplantation, University Medical Centre Hamburg-Eppendorf, Hamburg, [2]R&D, [3]Product Management, Biotype Diagnostic GmbH, Dresden, Germany

Background: Examination of chimerism has become a crucial means to monitor engraftment and, in the absence of specific disease markers, detect recurrence of leukemic cells after allogeneic stem cell transplantation. Various techniques have been established for chimerism analysis; the most often used STR amplification has high power of discrimination, but its detection limit is restrained to 1%>5%. Consequently, more sensitive approaches are required to ensure earlier detection of engraftment failure or relapses.
Aims: We have previously shown that digital PCR assays detecting deletion/insertion polymorphisms (DIPs) combine excellent sensitivity (routinely ≤0.1%) with accurate quantification over a large dynamic measurement range. Moreover, built on the dPCR principle, there is no need for standard curves and replicate measurements. Here we aimed at introducing a whole panel of digital-PCR based assays for routine chimerism measurement.
Methods: We selected a set of 53 DIPs and tested their suitability for duplex analysis in combination with a reference gene and a Y-chromosome specific locus. We identified 29 DIPs with high power of discrimination and good performance in duplex PCR.
Results: Assays were optimized and technically validated; applicability for diagnostics was confirmed on clinical samples in direct comparison with STR and qPCR. Finally, we established a screening plate for initial genotyping with DIP-specific digital duplex assays for convenient application of the system in every-day diagnostics.
Summary/Conclusions: In conclusion, we have developed and validated assays for regular chimerism determination including a screening plate for initial DIP assessment. The new tool ensures precise, robust and fast analysis of hematopoietic chimerism with a regular sensitivity of ≤0.1% (for ≥20 ng of genomic DNA). We propose that the new method will be highly useful for clinical routine diagnostics.

IRON-CHELATING THERAPY IMPROVES OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MDS

C Gu, C Li[*], X Chen, H Liu, J Ma, T Wang, Q Zou, J Chen, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Iron overload (IO) is general among patients with myelodysplastic syndrome (MDS). IO increased the non-relapse mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Therefore, the application of iron chelating therapy in allo-HSCT attracts the extensive attention recently. r severe HC following HSCT.
Aims: To investigate the effect of iron chelating therapy on hematopoietic reconstitution and related complications of allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with myelodysplastic syndrome (MDS).
Methods: Various clinical parameters were analyzed retrospectivly in 57 MDS patients with iron overload (IO)who received allogeneic transplantation. According to the level of serum ferritin (SF) before transplantation, we divided the patients into two groups: the effective treatment group (19 cases, SF<1000ng/ml) and iron overload group (38 cases, SF≥1000ng/ml).
Results: (1) 30/57 cases were received iron chelating treatment, 19/30 (63%) cases obtained obvious curative effect, the SF level before transplantation was<1000ng/ml, the median was 561(223-846) ng/ml. The effort of other 11/30 (37%) cases was not obvious, with the SF level before transplantation was ≥1000ng/ml,the median was 1262(1100-2352) ng/ml. 27/57 patients didn't received iron chelating therapy before transplantation, the SF level before transplantation was≥1000ng/ml,the median was 1540(1320-3112) ng/ml. (2) The rate of fully-engraftment in the effective treatment group and iron overload group was 19/19 (100%) and 34/38 (89%). And the latter group had 4/38 (11%) cases failed the hematopoietic reconstitution.The medium time of myeloid and platelet reconstitution of the 19 cases of effective treatment group was (12±2) and (16±6) days respectively, while those of 34 cases of iron overload group was (13±3)

and (18±6) days. The hematopoietic reconstruction was shorten in the former group, however the difference between the two groups had no statistical significance (*P*=0.441, *P*=0.579). (3) The infection rate of the effective treatment group and iron overload group was 7/19 (37%) patients and 28/34 (82%) patients respectively. The risk of infection of the effective treatment group was decreased significantly (*P*=0.002). (4) The incidence of aGVHD of the effective treatment group was 5/19 (26%) patients, all of which were I-II degree. The incidence of aGVHD of iron load group was 22/34 (65%) cases, with 16 cases of I-II degree, 6 cases of III-IV degree. The risk of aGVHD in the effective treatment group was significantly decreased (*P*=0.01). (5) The median disease-free survival (DFS) in effective treatment group was 28.9 (0.3-89.5) and 21.2 (0.1-81.0) months in iron load group during a median follow-up period of 22.0 (0.1-89.0) months.The DFS of effective treatment group was prolonged (*P*=0.053).
Summary/Conclusions: Effective iron chelating therapy before transplantation was helpful to hematopoietic reconstitution, and significantly reduced the incidence and degree of infection and aGVHD, decreased transplantation related mortality(TRM) and prolonged DFS, thereby improved the success rate of transplantation in MDS.

E1529

IMPACT OF CYCLOSPORINE-A CONCENTRATION IN T CELL-REPLETE HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION

X Yang*, A Sun, S Yang, X Hu, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Previous studies on HLA-identical allo-HSCT (allogeneic hematopoietic stem cell transplantation) have shown that level of blood CSA concentration during early stage after HSCT were significantly associated with risk of severe aGVHD (acute graft *versus* host disease). However, there remains a lack of data on T cell-replete haploidentical HSCT in which using ATG combined with CSA, MTX, MMF to prevent GVHD. Objective: This study was to investigate whether CSA (cyclosporine-A) levels impact on clinical outcomes of patients in the T cell-replete haploidentical allo-HSCT setting.
Aims: This study was to investigate whether CSA (cyclosporine-A) levels impact on clinical outcomes of patients in the T cell-replete haploidentical allo-sct (allogeneic stem cell transplantation) setting.
Methods: we retrospectively analyzed 140 consecutive patients who conducted T cell-replete haploidentical allo-sct in our institution to assess effect of CSA concentration in early stage on clinical outcomes including hematopoietic recovery, aGVHD (acute graft *versus* host disease), infection, DFS (disease free survival), and OS (overall survival).
Results: The median concentrations of CSA in the blood in the 1st, 2nd, 3rd and 4th week after allo-sct were 218ng/ml (rang:54-1377ng/ml), 235ng/ml (rang:27-1500ng/ml), 263ng/ml (rang:20-1500ng/ml), and 270ng/ml (rang:4-1500ng/ml); 46%, 40%, 27% and 18% of the patients had CsA blood levels below 200 ng/mL during these weeks. 39 patients developed grade 2–4 aGVHD for a cumulative incidence of 27.8% at a median of 32 days.CSA levels during 1st, 2nd, and 4th week didn't affect patients' hematopoietic recovery, aGVHD, infection, DFS, and OS significantly ($p>0.05$). However, patients having CSA concentration below 200ng/ml in the 3rd week had a higher cumulative incidence of grade 2-4 aGVHD ($p=0.02$). In a multivariate logistic regression analysis, low CSA concentration (below 200ng/ml) in the 3rd week remained the independent risk factor of grade 2-4 aGVHD ($p=0.02$). CSA level in the 3rd week was not associated with patients' engraftment, infection, DFS, and OS ($p>0.05$).
Summary/Conclusions: The analysis presented here emphasize that adequate management of CSA levels in the early stage, especially during the periengrafment period, can improve clinical outcomes in the T cell-replete haploidentical allo-sct setting.

E1530

HYPERBARIC OXYGEN THERAPY IS CLINICALLY EFFECTIVE FOR REFRACTORY VIRUS-ASSOCIATED HEMORRHAGIC CYSTITIS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y Suzuki[1,*], T Oyake[1], M Asahi[1], N Sugawara[1], Y Okano[1], Y Fujishima[1], Y Aoki[1], S Kowata[1], S Ito[2], Y Ishida[1]
[1]Hematology and Oncology, Internal Medicine, [2]Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: Late-onset hemorrhagic cystitis (HC) after allogeneic hematopoietic stem cell transplantation (HSCT) has been frequently associated with viral infection of adenovirus (ADV), BK virus (BKV), JC virus (JCV) or another viruses. Antiviral drugs are of limited efficacy, and the optimal treatment for HC has not yet been established. Hyperbaric oxygen (HBO) may benefit these patients, but efficacy and safety of HBO for HC has not been evaluated sufficiently.
Aims: To clarify the efficacy and safety of HBO therapy for viral HC, we retrospectively evaluated clinical data during the therapy.
Methods: In 199 cases of allogeneic HSCT from September 1994 to November 2015, we experienced 8 cases of refractory viral HC by ADV or JCV. We evaluated the effectiveness of HBO therapy in 8 patients with refractory HC after allogeneic HSCT at our institution.
Results: All 8 patients had macroscopic hematuria associated ADV or BKV infections. Patients received 100% oxygen in a hyperbaric chamber at 2.1 atmospheres for 90-120 min per day, 5 days per week, with 13 median treatments (range, 10-16). The 5 of 8 patients (62.5%) showed complete resolution of hematuria in 7 days. The pain during urination disappeared in all 8 patients (100%) in 5 days. Urinary DNA titers of ADV or BKV declined after HBO. Patients who started on HBO earlier after diagnosis of HC responded sooner and better than those who did on HBO later. Interestingly, 3 of 8 patients (37.5%) showed dramatic recovery from refractory acute graft *versus* host disease (GVHD) symptom accompanied by thrombotic microangiopathy (TMA), after HBO therapy for refractory virus-associated HC.
Summary/Conclusions: HBO therpy was generally well tolerated, and proved to be a reliable option for refractory viral HC cases to manage their condition.

E1531

THE INFLUENCE OF NK CELL ALLOREACTIVITY ON OUTCOME AFTER T-CELL-DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN PATIENTS WITH ACUTE LEUKEMIA

V Zakharova[1], Z Shekhovtsova[2], E Raykina[1], O Shragina[1], L Shelikhova[2], D Balashov[2], Y Skvortsova[2], A Maschan[3], M Maschan[2,*]
[1]Laboratory of molecular biology, [2]HSCT, [3]Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: HSCT from human leukocyte antigen (HLA) haplotype-mismatched family members is the only curative option for patients with high-risk acute leukemia who do not have a matched donor. Natural killer (NK) cells are the first lymphoid cell population to reconstitute after allogeneic HSCT. It is believed that NK alloreactivity is regulated by quantitative differences in activating and inhibitory signals (mediated by activating and inhibitory killer cell immunoglobulin-like-receptors (KIRs), which recognize HLA class-I alleles (KIR ligands)). A number of studies demonstrated beneficial effects of donor activating KIRs and KIR-ligand mismatches on transplant outcome.
Aims: In the present study we tested if donor KIR haplotype, particular KIR genes and KIR-ligand mismatch have an effect on relapse incidence and event-free survival (EFS) in pediatric patients with acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML).
Methods: Fifty eight patients between 1/2012 and 6/2015 in complete remission with ALL(n=26) and AML(n=32) were included in this study. Patients received T-cell-depleted haploidentical transplants after myeloablative conditioning regimen and post-transplant tacrolimus (n=24) or bortezomib (n=34) as GVHD prophylaxis. In all cases GCSF-mobilized PBSC were depleted of TCR-alpha/beta and CD19+ cells with CliniMACS Plus. All samples were typed for HLA-A,-B,-C,-DRB1,-DQB1 by sequence-based typing. KIR genotype was performed by sequence-specific primers. "Receptor-ligand" model (at least one inhibitory KIR gene expressed in the donor in the abscence of the appropriate HLA-molecules in the recipient's ligand repertoire) was used to predict NK alloreactivity. The role of donor B *vs* A KIR haplotype and the number of total, inhibitory or activating KIR in the donor was evaluated. The effect of each individual KIR gene was analyzed. Cumulative incidence estimates were used for relapse and nonrelapse mortality, because they are competing risk. The Gray test compared univariate competing risk outcome. The Kaplan-Meier method evaluated EFS.
Results: All patients had primary engraftment (median 14 days for neutrophils and 15 days for platelets). The median number of total KIR genes in donor was 10(range, 7-15), activating 3(1-6), inhibitory 7(5-9). No significant effect of KIR genotype was found in patients treated with tacrolimus and in the whole cohort of patients. Incidence of relapse decreased for patients treated with bortezomib by: donor's B/x haplotype compared to A/A, 12±6.5 *vs* 22.2±13.6, p=0.05; higher total number of KIR genes (total KIR, 0 *vs* 29.4 ±10.9, p=0.005; activating KIR, 0 *vs* 29.4 ±10.9, p=0.004; inhibitory KIR, 8.7±5.9 *vs* 27.3 ±13.2, p=0.014; Influence of particular KIR genes on the incidence of relapse was detected: KIR2DS2(10±6.7 *vs* 21.4±10.7, p=0.05); KIR2DS3(0 *vs* 22.7±8.8, p=0.028); KIR2DL2(10±6.7 *vs* 21.4±10.7, p=0.05); KIR2DL5B(0 *vs* 21.7±8.5, p=0.035). No significant influence was observed for other KIR genes. Based on clinical studies "receptor-ligand" model was analyzed in patients with AML. There was no correlation between KIR-ligand mismatch and relapse risk and EFS (p=0.97 and p=0.50 respectively).
Summary/Conclusions: There is increasing evidence that impact of donor NK alloreactivity and KIR genotype is dependent on the transplant protocol. Our results suggest that the use of bortezomib instead of prolonged tacrolimus may contribute to the beneficial effects of donor NK cells.

ETANERCEPT FOR STEROID-REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE: A SINGLE CENTER EXPERIENCE

N de Jong[1,*], L Saes[1], C Klerk[2], M van der Klift[3], J Cornelissen[1], A Broers[1]
[1]Hematology, Erasmus Medical Center, Rotterdam, [2]Hematology, VU University Medical Center, Amsterdam, [3]Hematology, Amphia Hospital, Breda, Netherlands

Background: Acute graft-*versus*-host disease (aGVHD) is a major cause of morbidity and mortality after allogeneic stem cell transplantation (alloSCT). High dose systemic glucocorticosteroids (steroids) are currently recommended as first-line treatment for grade II-IV aGVHD resulting in overall complete responses (CR) in 40 to 50 percent of patients. Currently, there is no standard second-line treatment for steroid-refractory aGVHD (SR-aGVHD). Etanercept is a recombinant human tumor necrosis receptor fusion protein which inhibits the biological activity of tumor necrosis factor alpha (TNFα) involved in the pathophysiology of aGVHD. Studies that have investigated the use of anti-TNFα as primary as well as secondary treatment in aGVHD have shown promising results.[1,2]
Aims: Here we report the results of a retrospective analysis of patients with SR-aGVHD treated with etanercept in our center.
Methods: We studied the outcome of sixteen patients following alloSCT with SR-aGVHD, who gave consent for second-line treatment with the TNFα inhibitor etanercept (Enbrel, Pfizer) between January 2009 and April 2013. Etanercept was added to the initiated first-line treatment with high dose steroids combined with cyclosporine A (CsA) or mycophenolate mofetil (MMF) and administered subcutaneously twice weekly at a dose of 25 mg for a maximum of eight weeks.
Results: aGVHD developed at a median of 61 days post-transplantation. In all cases it concerned grade 3 aGVHD of the gut. Second-line treatment with etanercept was started at a median of 13 days after the initiation of first-line treatment. First-line treatment consisted of 2 mg/kg steroids combined either with CsA in fourteen patients or MMF in two patients and was continued during treatment with etanercept until a sustained response was achieved. The overall response rate was 50%, including a complete response (CR) in three patients (18.8%) and a partial response (PR) in five patients (31,3%). Responses were reached after a median duration of treatment of 9 days (range 5-40 days). Despite a promising initial response rate, five out of eight responding patients lost their response. One CR patient developed progressive GVHD after treatment with etanercept had to be discontinued because of the development of post-transplant EBV-related lymphoproliferative disorder. In addition, four PR patients lost their response during treatment with etanercept. Clinically significant infectious complications occurred in thirteen patients, including bacterial septicemia, viral infections and invasive pulmonary aspergillosis. Eventually, all sixteen patients died at a median of 57 days (range 1 –267 days) after initiation of etanercept. Death was caused by progressive GVHD in seven cases (43.8%), opportunistic infections in six cases (37.5%), cardiac death in two cases (12.5%) and relapse of the original malignancy in one case (6%).
Summary/Conclusions: Second-line treatment of SR-aGVHD of the gut with the TNFα inhibitor etanercept did not meet the promising results reported by Busca et al.[2] While etanercept showed a promising initial response rate of 50% in our patients, survival was very poor, which was mainly due to opportunistic infections in the context of ongoing or progressive GVHD, even in patients, who initially responded.

HEMOCOAGULASE FOR THE TREATMENT OF SEVERE HEMORRHAGIC CYSTITIS FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION

M Xue*, F Chen, D Wu, S Xue
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Hemorrhagic cystitis (HC) is a common and potentially severe complication after allogeneic hematopoietic stem cell transplantation (HSCT). Despite many therapies have been tested in the treatment of severe HC, no definitive treatment has been established. Hemocoagulase is an established hemostatic agent, but its efficacy for HC has not been evaluated.
Aims: The aim of this study is to investigate the clinical efficacy of hemocoagulase for severe HC following HSCT.
Methods: We treated Twenty patients with severe HC (macroscopic hematuria with clots and macroscopic hematuria with renal or bladder dysfunction, with symptoms of cystitis) following HSCT with hemocoagulase. All the patients were initially treated with hyperhydration, forced diuresis and red cell and platelet transfusion support. For the patients with cytomegalovirus (CMV) replication in plasma determined by polymerase chain reaction, ganciclovir or foscarnet sodium was given. When patients developed macroscopic hematuria with clots, hemocoagulase was given, 1U iv twice per day for 5 days as a course. If the macroscopic hematuria disappeared at the sixth day after stopping the drug, hemocoagulase was no longer given. If not, the next course was given. During the treatment, the blood clotting factors was monitored for 2 to 3 times weekly. If the fibrinogen was decreased, the plasma or fibrinogen was transfused to correct the blood coagulation abnormality. The urine specimens reserved before and after hemocoagulase respectively were examined by naked eye and microscope to evaluate the efficacy.
Results: Patients included 12 males and 8 females with a median age of 27 years (range, 13-57years). The median time to onset of severe HC was 28 days after HSCT (range, 14 to 70 days). The HC was cured (disappearance of macroscopic hematuria without relapse) in 18 patients(2 cases were cured after 1 courses, 9 cases were cured after 2 courses, 2 cases were cured after 3 courses, 2 cases were cured after 4 courses, 2 cases were cured after 5 courses, 1 cases were cured after 9 courses), improved (amelioration of macroscopic hematuria) in 1 patients after 3 courses and uncontrolled (persistence of macroscopic hematuria with red cell transfusion requirements) in 1 patients who died of pulmonary infection and pneumorrhagia. For the patients with response, macroscopic hematuria disappeared at a median time of 28 days after the treatments (range, 4-127 days). Among 20 patients, 7 cases had no decrease of fibrinogen (2 cases were cured after 1 courses, 5 cases were cured after 2 courses), the other 13 cases had obvious decrease of fibrinogen, while after the infusion of plasma or fibrinogen, the fibrinogen recoveried. There was no patient required interruption of treatment.
Summary/Conclusions: Hemocoagulase seems to be a safe and effective drug for severe HC following HSCT.

E1534

HCT.CI PREDICTS MORBI-MORTALITY IN AUTOLOGOUS STEM CELL TRANSPLANTATION

M Berro[1,*], LA Bet[1], JI Trucco[1], MM Rivas[1], P Longo[1], MI Paganini[1], L Ballestracci[1], MC Foncuberta[2], A Vitriu[2], GD Kusminsky[1]
[1]Hematology, Hospital Universitario Austral, Pilar, [2]Hematology, Alexandre Fleming, CABA, Argentina

Background: Hematopoietic Stem Cell Transplant Comorbidity Index (HCT.CI) score, described by Sorror, is a useful tool to assess the risk for Non Relapse Mortality (NRM) after Allogeneic HSCT. The impact of this score in Autologous HSCT is still to be confirmed.
Aims: To determine the impact of HCT.Ci score in the morbidity and mortality after autologous HSCT, assessing the 100 day morbidity defined as orothraqueal intubation (OTI), dialysis or vasopressors need, early mortality (before day 100) and long term NRM.
Methods: We retrospectively reviewed 473 medical records of patients that received an autologous HSCT in our centres between October 2002 and September 2015. Median age was 49 years (range 1-74 years), 58% were male, prevalent diseases were Multiple Myeloma (37%), Non Hodgkin Lymphoma (26%) and Hodgkin Lymphoma (20%), 29% were in complete remission, 42% received one chemotherapy scheme before transplant, 46% two schemes and 12% three or more (heavily pre-treated). Regarding comorbidities, 42% had low risk (LR) HCT.CI (score 0), 47% intermediate risk (IR) (1-2) and 12% high risk (HR) (≥3). For univariate analysis we use Chi2 for dichotomic variables, Kaplan-Meier for Overall Survival (OS) and cumulative incidence for NRM; for multivariate analysis we used logistic regression for dichotomic and Cox regression for time dependant variables.

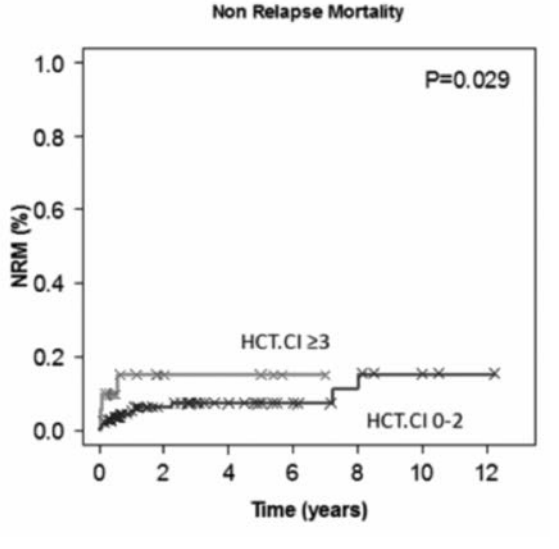

Figure 1.

Results: Median follow up was 1.3 years. Early mortality (day 100) was 4.4%, 9% required OTI, 8.5% vassopresors and 2.2% dialysis, 1-3 years NRM and OS were 7-9% and 85-79% respectively. High risk HCT.Ci patients had a significant

increase in 100 day mortality compared to low and intermediate risk (11% *vs* 4.1% *vs* 2.6% respectively, p=0.02), OTI (18% *vs* 8% *vs* 7%, p=0.02), dialysis (9% vs.2% *vs* 0.5%, p=0.001) and NRM (1-3 years HR *vs* LR/IR 15-15% *vs* 5-7%, p=0.02) (figure 1). After multivariate analysis these outcomes remain significant (comparing HR *vs* LR/IR): early mortality (OR 3.4, 95% CI 1.1-10.4), OTI (OR 2.9, 95% CI 1.3-6.7), dialysis (OR 8.8, 95% CI 2.4-32.6) and NRM (OR 2.6, 95% CI 1.05-6.6). Other than comorbidities, Multiple Myeloma patients had a significant reduction in NRM (OR 0.25, 95% CI 0.1-0.8) and OTI (OR 0.28, 95% CI 0.1-0.83); patients older than 60 years had a significant increase in NRM (OR 4.6, 95% CI 2.1-10.5) and heavily pre-treated patients had a significant increase in NRM (OR 3.3, 95% CI 1.4-7.9) and OTI (OR 2.4, 95% CI 1.1-5.6).
Summary/Conclusions: We observed that HCT.CI had a significant impact on Autologous HSCT treatment related mortality basically due to early toxicity express as 100 day mortality and the three main morbidity outcomes. This observation should be confirmed in larger series.

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR INTRAVASCULAR LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY OF THE OF THE EUROPEAN SOCIETY FOR BLOOD AND MARROW TRANSPLANTATION LYMPHOMA WORKING PARTY

J Meissner[1,*], H Finel[2], A Boumendil[2], S Dietrich[1,2], E Kanfer[2,3], G Laboure[2,4], M Abecasis[2,5], J Cornelissen[2,6], J Delage[2,7], J Finke[2,8], U Hess[2,9], H Ludwig[2,10], M Mohty[2,11], T Pabst[2,12], P Pioltelli[2,13], S Robinson[2,14], P Samaras[2,15], P Dreger[1,2]
[1]University Hospital, Heidelberg, Germany, [2]Lymphoma Working Party, European Society for Blood and Marrow Transplantation, Paris, France, [3]Hammersmith Hospital, London, United Kingdom, [4]University Hospital, Bordeaux, France, [5]Inst. Potugues Oncologia, Lisboa, Portugal, [6]Erasmus MC-Daniel den Hoed Cancer Centre, Rotterdam, Netherlands, [7]CHU Lapeyronie, Montpellier, France, [8]University Hospital, Freiburg, Germany, [9]Kantonsspital, St. Gallen, Switzerland, [10]Wilhelminenspital, Vienna, Austria, [11]Hopital Saint Antoine, Paris, France, [12]University Hospital, Bern, Switzerland, [13]Ospedale San Gerardo, Monza, Italy, [14]Bristol Oncology Centre, Bristol, United Kingdom, [15]University Hospital, Zürich, Switzerland

Background: Intravascular large B-cell lymphoma (IVLBCL) represents a rare lymphoma subtype characterized by the selective growth of malignant cells within the lumina of small vessels. The combination of rituximab and cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) is widely used as first-line therapy but with about half of the patients being progressive within 2 years, outcome is inferior to non-intravascular diffuse large B-cell lymphoma.
Aims: Since the value and timing of autologous stem cell transplantation (autoSCT) in the treatment of IVLBCL is undefined, the objective of this study was to analyze for the first time the efficacy of autoSCT for IVLBCL in a larger cohort of Western patients.
Methods: This is a registry-based retrospective multicentre study including patients aged 18 years or above with histologically verified IVLBCL who underwent autoSCT between 1 January 2002 and 31 December 2013 and were registered with the European Society for Blood and Marrow Transplantation (EBMT) database. Of 97 patients identified in the EBMT registry, a full data set could be obtained for 19 patients. After exclusion of patients with a histopathology report not confirmative for the diagnosis of IVLBCL, the final study cohort consisted of 11 patients.
Results: The median age of the 11 patients was 55 (range 34-68) years. All had stage IV disease with CNS involvement in 5 patients. First-line treatment was mainly based on R-CHOP or a CHOP-like regimen. The median time from diagnosis to transplant was 6 months. Six patients were autografted in first remission while 5 patients received more than one line of treatment prior to autoSCT. Disease status at autoSCT was complete remission in 8 patients and partial remission in 3 patients. After a median follow-up of surviving patients of 51 months (range 12-95), 8 patients were alive and free of progression. One patient (transplanted in first remission) died treatment-related whereas 2 patients relapsed 15 and 27 months post autoSCT, both with more than one previous treatment line. No relapse occurred in patients autografted in first remission. 4-year progression-free survival of all 11 patients was 71%.
Summary/Conclusions: The outcome of this to date largest patient cohort compares favorable to the outcome after standard R-CHOP and is in line with the outcome of autoSCT in small Asian case series. Furthermore our data suggest that the outcome of autoSCT performed in first remission may be superior to that of autoSCT performed after multiple lines of therapy. Consolidative autoSCT performed in first remission after R-CHOP-like therapy results in favorable long-term outcome for patients with IVLBCL and thus appears to be a valuable treatment option for fit patients up to an age of 65-70 years.

E1536

RESULTS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHRONIC MYELOGENOUS LEUKEMIA PATIENTS WHO FAILED TYROSINE KINASE INHIBITORS

V Funke[*], AC Brandao, R Savian, J Oliveira, D Setubal, L Medeiros, C Bonamin, N Farah, AL Mion, R Pasquini
Hematology, Federal University of Parana, Curitiba, Brazil

Background: Chronic Myelogenous Leukemia (CML) is a myeloproliferative neoplasm. The hallmark is the presence of a reciprocal t(9;22)(q34;q11.2)-Philadelphia chromosome (Ph), resulting in which produces a BCR-ABL fusion gene and therefore a BCR-ABL protein with constitutive tyrosine kinase activity. Tyrosine kinase inhibitors (TKI) are the first line of treatment. However, some patients are resistant. Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) is indicated for patients with Chronic Myelogenous Leukemia (CML) who develop resistance to tyrosine kinase inhibitors (TKI).
Aims: The main aim is analyzing outcomes of HSCT in 49 patients with CML resistant to TKI and identifying risk factors for overall survival (OS) and disease free survival (DFS) in those patients.
Methods: We analyzed the outcomes of 49 patients resistant to TKIs transplanted at the BMT Center of Federal University of Paraná, from January 2001 to August 2015. The study is retrospective, observational and analytical, held from data record in either STMO database or medical chart. Informed consent was waived. Kaplan-Meyer method was used to build survival curves and Log-rank test to compare them. The established level of significance was $p<0.05$. The following risk factors were analyzed: donor and recipient sex, age at HSCT, pre-HSCT imatinib, second generation inhibitors or interferon, conditioning regimen, immunoprophylaxis, donor type, stem cell source, HLA compatibility, engraftment, acute graft *versus* host disease (aGVHD), chronic graft *versus* host disease (cGVHD), disease phase and previous response to TKI (hematologic and cytogenetic). Multivariate analysis was performed using Cox Regression model to identify risk factors for overall survival and disease-free survival.
Results: Chronic graft *versus* host disease (GVHD) (n=16) was associated to a higher OS (p=0,04) whereas acute GVHD (n=13) was associated to a lower OS. Regarding to DFS, a myeloablative (MA) conditioning regimen (n=45) lead to higher survival probability (p=0.00182). BCR-ABL mutation analysis was performed before HSCT in 55% of the patients (n=27) and found in 33% (n=9). The presence of mutations was a significant risk factor for OS (p=0.00366). The median OS was 373 days (33-3677) and the median DFS was 273 days (0-3677). Five years probability of survival was 41% for entire group.
Summary/Conclusions: HSCT is an important alternative for patients with TKI resistance. Chronic GVHD was associated with a 3,6 lower probability of death, while occurence of acute GVHD had a negative impact, increasing probability of death in 3 times. Worse outcome was showed for patients with pre-transplant mutations. Myeloablative conditioning was significantly associated with better DFS.

E1537

EQUIVALENT OUTCOME OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA PATIENTS WHO HAD T (8;21) WITH AND WITHOUT ADDITIONAL ABERATIONS

H Chen[*], KY Liu, LP Xu, Q Jiang, YH Chen, HH Zhu, YY Lai, YR Liu, XJ Huang
Peking University, People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Although acute myeloid leukemia (AML) patients who had t(8;21) had favorable outcome after high-dose therapy with autologous stem cell transplantation(ASCT). It was still a heterogeneous disease. Limited data was reported about outcome in AML patients who had t(8;21) with additional cytogenetic abnormalities after ASCT.
Aims: In the current cohort study we investigated long-term survival of AML patients who had t(8;21) with and without additional aberations after ASCT.
Methods: Patients with de novel AML who had t(8;21) with or without additional cytogenetic abnormalities, younger than 60 years were eligible. G banding and FISH analysis were performed to test cytogenetic aberations. Peripheral blood stem cell (PBSC) harvesting was started if patients achieved CR1 and MRD level was less than 0.1% after 1 to 2 courses of induction therapy(3+7) and at least 2-coursrs of consolidation therapy including high-dose Ara-C. MRD was monitored using real-time PCR (RT-PCR) to quantify the RUNX1/RUNX1T, The conditioning regimen was busulphan/cytoxan.
Results: between March 2008 and March 2014, 27 eligible patients were enrolled. All enrolled patients were Chinese. Median age was 30 years (range, 13- 56 years). Fourteen patients were male and 13 were female. Eleven patients had additional aberrations, including –y (n=6), -x (n=2), del (8q) (n=1), del(9q) (n=1), del(9q) and –x (n=1). Patients' characteristics between the two groups were comparable. At the median follow-up 46 months (range,6.5 to 92 months) after consolidation therapy, the 5-year leukemia-free survival (LFS) and overall survival (OS) for the total patients were 88.9%±6.0% and 90.3% ±6.8% after consolidation therapy. For the patients with and without additional aberations, LFS were 87.5% and. 90.9%, p=0.832. OS were 90.8% and 90.9%, p=0.752, respectively. Two relapse patients after ASCT received haploidentical related transplantation and were still alive in CR after following-up 74 and 64 months.
Summary/Conclusions: AML patients who had t (8;21) with and without additional aberations had equivalent long-term survival after ASCT in Chinese, if patient achieved CR1 with MRD level less than 0.1% before transplant. Allogeneic HSCT including haploidentical related transplant is a salvage therapy for relapse patients after ASCT.

E1538

ANTIBACTERIAL PROPHYLAXIS REDUCES THE RISK OF BACTEREMIA IN PATIENTS WITH MULTIPLE MYELOMA AND LYMPHOMA UNDERGOING HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION

I Vaxman*, U Rosovski, M Moshe, L shargian, O Pasvolsky, D yahav, J Bashara, M Lahav, R Gurion, H Magen, L Vidal, G Itzhaki, A Peck, M Navon Sela, P Raanani, M Yeshurun
Beilinson, Petah Tikva, Israel

Background: Bacterial infections are a major cause of morbidity and mortality in patients undergoing autologous stem cell transplantation (ASCT). However, whether these patients benefit from antibacterial prophylaxis is unclear. The few studies which addressed this issue are limited by small sample size or the use of multiple anti-microbial agents. Current guidelines recommend considering the use of antibacterial prophylaxis in patients with anticipated neutropenia of 7 days or more. At our center, patients undergoing ASCT were given ciprofloxacin for antibacterial prophylaxis until 2012. This change in policy provides a unique opportunity to study the potential benefit of antibacterial prophylaxis in ASCT.
Aims: To explore the efficacy and adverse effects of ciprofloxacin prophylaxis in patients undergoing ASCT.
Methods: This is a single center retrospective study. Data were collected from the medical records of all patients with a diagnosis of non-Hodgkin's lymphoma, Hodgkin's disease or multiple myeloma (MM) who underwent ASCT at Rabin Medical Center between 03/2007 and 12/2015. Until 10/2012 all patients were given oral ciprofloxacin 500 mg BID starting concomitantly with the conditioning regimen (BEAM for lymphoma and melphalan for multiple myeloma) until the first febrile episode or until engraftment. After 10/2012, our treatment policy has changed and we stopped using antibacterial prophylaxis in the ASCT setting.
Results: Between 03/2007 and 12/2015 303 patients received 327 high dose chemotherapy followed by ASCT. The median age at time of transplant was 55 years (range: 16 to 72) and 186 patients (57%) were males. The diagnosis was MM in 174 patients (46%), NHL in 110 patients (34%) and HD in 43 patients (13%). 154 consecutive patients were given ciprofloxacin prophylaxis and 171 patients were not given ciprofloxacin prophylaxis before and after 10/2012, respectively. Overall, 10% (n=32) of the patients had a bacteremia, 16% (n=27) in the group of patients who did not receive prophylaxis, compared to only 3% (n=5) in the group of patients who received prophylaxis (*P*<.0001). The rates of febrile neutropenia were 84% (N=129) in patients who received prophylaxis compared to 91% (155) in patients who did not receive antibacterial prophylaxis (P=0.06). The number needed to treat (NNT) in order to prevent one episode of bacteremia is 4.9. The frequency of all other infections, the duration of hospitalization, and the rates of all cause and infection-related mortality were not significantly different between groups. Of note, ciprofloxacin prophylaxis was not associated with an increased in bacterial resistance. Patients with lymphoma were younger (median 53 years, range: 19-72) than patients with MM (median 58, range: 33-68) but similar in all other demographic characteristics. The median duration of aplasia was 6 days (range: 4 to 13) in patients with MM after high-dose melphalan and 8 days (range 5 to 14) in patients with lymphoma after BEAM (p<0.0001). However, both groups seemed to equally benefit from antibacterial prophylaxis. In a multivariable analysis ciprofolxacin prophylaxis significantly decreased the odds of bacteremia (Odds Ratio: 0.19 (Confidence interval: 0.07 to 0.52)). Age, diagnosis, and the duration of aplasia were not associated with the risk of bacteremia
Summary/Conclusions: Ciprofloxacin prophylaxis markedly reduced the risk of bacteremia and neutropenic fever in lymphoma and MM patients undergoing ASCT without increasing the incidence of resistant bacterial strains in patients receiving ciprofloxacin prophylaxis. The NNT in order to prevent one episode of bacteremia is 4.9, suggesting that antibacterial prophylaxis should be considered in ASCT.

E1539

EFFECTIVE USE OF ORAL RIBAVIRIN FOR RESPIRATORY SYNCYTIAL VIRAL INFECTIONS IN ADULT ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS

C M Gorcea[1,*], E Tholouli[1], A Turner[2], E Davies[3], E Battersby[3], M Saif[1], F Dignan[1]
[1]Department of Haematology, [2]Department of Virology, [3]Pharmacy Department, Manchester Royal Infirmary, Manchester, United Kingdom

Background: Respiratory syncytial virus (RSV) is a common cause of respiratory viral infections and is associated with increased morbidity and mortality in patients undergoing haematopoietic stem cell transplantation (HSCT). Little is known about the best management strategy in this high risk group and there is very little data on oral ribavirin treatment.
Aims: The outcome of adult allogeneic HSCT recipients with RSV infection treated with oral ribavirin was analysed at a single UK centre.
Methods: We performed a retrospective analysis of 23 consecutive RSV cases treated with oral Ribavirin between December 2010 and February 2015. Patient characteristics: male 12, median age 52 years (range 20 to 69). Underlying diagnoses: acute leukaemia 11, myelodysplasia 4, aplastic anaemia 3, multiple myeloma 3, chronic leukaemia 2. Allogeneic HSCT characteristics: 16 reduced intensity conditioning (RIC) and 7 myeloablative conditioning. RSV diagnosis was established by polymerase chain reaction (PCR) assay. At diagnosis, 7 patients presented with lower respiratory tract infection (LRTI) as defined by new infiltrate on chest X-ray (CXR), signs on auscultation or hypoxia, whereas 16 experienced upper RTI. All patients with a positive RSV PCR result received treatment. We initiated oral Ribavirin at a dose of 15mg/kg divided into 3 daily doses with no subsequent dose escalation. The median treatment duration was 10 days (range 5 to 47). Additional therapies were administered concomitantly: 3 patients received immunoglobulin replacement, 17 received antimicrobials and 3 patients also received antifungal treatment for suspected superimposed bacterial or fungal infection. Patients were retrospectively scored using the immunodeficiency scoring index for RSV (ISI-RSV) which takes into consideration neutropenia (<0.5x10^9/L), lymphopenia (<0.2x10^9/L), age (≥40 years), myeloablative conditioning regimen, graft *versus* host disease (GVHD acute/chronic), corticosteroid treatment and pre-engraftment period (or within 30 days of HSCT) to determine the risk of progression to LRTI. In our cohort, 14 patients were low risk with an ISI of 0-2 (2 patients ISI 0, 6 patients ISI 1, 6 patients ISI 2) and 9 patients were moderate risk with an ISI of 3-4 (8 patients ISI 3, 1 patient ISI 4) and therefore oral treatment was felt to have been appropriate, on retrospective analysis.
Results: The treatment was well tolerated with minor side effects in 2 patients. In total, 19 patients completed exclusively oral ribavirin treatment, whereas 4 were escalated to aerosolised ribavirin due to worsening symptoms. Only 7 patients required admission for intravenous antibiotics and/or aerosolised ribavirin. The median admission period was 7 days (range 1 to 16). None of the patients required intensive care admission. After a median follow-up of 17 months (range 4 to 48), 17 patients are alive and 6 died. One patient died of RSV pneumonitis complicated with bacterial and suspected fungal infection on the background of relapsed disease and 5 died of unrelated causes.
Summary/Conclusions: RSV in post allogeneic HSCT patients remains a challenge due to the high frequency of infection and increased morbidity and mortality associated with RSV LRTI. Prompt initiation of treatment is essential and may avoid unnecessary hospital admission. Our experience supports the use of oral ribavirin in selected adult HSCT recipients, after a careful risk assessment has been performed. Prospective studies and larger numbers of patients are needed to determine the optimal therapy for this patient group.

E1540

EFFICACY AND SAFETY OF BIOSIMILAR FILGRASTIM (ZARZIO®) AFTER AUTOLOGOUS STEM CELL TRANSPLANT: UPDATE OF A COMPARATIVE STUDY WITH LENOGRASTIM AND PEG-FILGRASTIM

F Marchesi[1,*], M Vacca[2], S Gumenyuk[1], A Pandolfi[2], D Renzi[1], F Palombi[1], F Pisani[1], A Romano[1], A Spadea[1], F Ipsevich[2], M De Rienzo[3], E Papa[1], M Canfora[4], ML Foddai[3], L Pierelli[2], A Mengarelli[1]
[1]Hematology and Stem Cell Transplant, Regina Elena National Cancer Institute, [2]Leukapheresis and Cellular Therapy Unit, S. Camillo-Forlanini Hospital, [3]Immuno-Transfusional Medicine Unit, [4]Scientific Direction, Regina Elena National Cancer Institute, Rome, Italy

Background: Biosimilar Granulocyte Colony-Stimulating Factor (G-CSF) has been approved on the basis of comparable quality, safety and efficacy as the originator product. So far, biosimilar Filgrastim Zarzio® has been approved also for autologous peripheral stem cell mobilization and for prophylaxis of sever neutropenia duration following conditioning chemotherapy and stem cell infusion. However, there is still general skepticism about safety and efficacy of Zarzio® in these setting of patients, considering the lack of prospective studies with a long follow-up.
Aims: The aim of the study was to evaluate the efficacy and the safety of Zarzio® when used as hematologic recovery after autologous stem cell transplant (ASCT).
Methods: From March 2013 to November 2015, 114 consecutive adult patients with hematologic malignancies (Plasma cell disorders n=68; Non Hodgkin and Hodgkin's lymphomas n=42; others n=4) underwent ASCT in our Institution. Zarzio® was given at the dosage of 5 mcg/Kg beginning to day 3 from infusion of stem cells and continued until neutrophilis recovery. Hematologic recovery after ASCT was defined as an absolute neutrophilis count upper than 0.5x10^9/L and a platelets count upper than 20 x 10^9/L in three consecutive checks. This cohort of patients was compared with two historical cohorts of patients in our Institution: a) 99 consecutive adult patients treated with Lenograstim (Myelostim®) at dosage of 5 mcg/Kg daily given from day 3 after infusion from January 2009 to February 2013; b) 60 consecutive adult patients treated with peg-filgrastim (Neulasta®) at dosage of 6 mg single dose at day 3 after infusion from March 2006 to December 2008.
Results: The three patient cohorts were similar for all baseline features analyzed, without any significant differences in terms of sex, median age, diagnosis, median chemotherapy lines prior ASCT, disease status at ASCT, conditioning regimen and median infused CD34+ cells. We analyzed the time of hematologic recovery after stem cell infusion, the occurrence of fever of unknown origin (FUO) in neutropenia, documented infectious episodes and needing of intra-

venous antibiotics, number of red blood and platelet transfusions, the days of hospitalization and the transplant-related mortality (TRM). The results of the study show a significantly shorter time to neutrophilis and platelet recovery (P=0.001 and P=0.007, respectively) in the cohort of patients treated with Neulasta®, whereas no difference was observed among the other two groups. As for the other analyzed parameters, we didn't observe any significant difference among the three patient cohorts for all the other analyzed parameters. In particular, we did observe a similar incidence of FUO episodes (P=0.102), microbiologically documented infections (P=0.424) and needing of intravenous antibiotics (P=0.612). Moreover, we didn't find any significant differences as for transfusional needing (P=0.099), median hospitalization time (0.102) and TRM (P=0.709). No difference in terms of drug-related adverse events was observed in the three patient cohorts with no reported serious adverse events. Similar results were obtained performing two separate sub-analysis only for lymphoma or myeloma patients.

Summary/Conclusions: Despite the limitations due to the non-randomized nature of the study, from our data biosimilar Filgrastim (Zarzio®) seems to be substantially equivalent in terms of efficacy and safety to Lenograstim (Myelostim®) and Peg-Filgrastim (Neulasta®), when used for hematological recovery after ASCT in adult patients with hematologic malignancies.

EXTRACORPOREAL PHOTOPHERESIS FOR THE TREATEMENT OF ACUTE AND CHRONIC GRAFT *VERSUS* HOST DISEASE: A RETROSPECTIVE MULTICENTRIC ANALYSIS ON 94 PATIENTS

M Malagola[1,*], V Cancelli[2], C Skert[1], P Ferremi Lealia[3], E Ferrari[3], A Tiburzi[3], ML Sala[3], I Donini[4], P Chiusolo[5], A Muffetti[6], M Battista[7], N Polverelli[1], A Turra[1], F Cattina[1], B Rambaldi[1], F Schieppati[1], A Bosi[4], S Sica[8], P Corradini[6], F Patriarca[7], M Marini[3], D Russo[1]

[1]Chair of Hematology, Bone Marrow Transplant Unit, University of Brescia, AO Civili Brescia, Brescia, Italy, [2]Experimental and Clinical Sciences, Chair of Hematology, Bone Marrow Transplant Unit, University of Brescia, AO Civili Brescia, [3]Immunohematology and Transfusion Medicine Unit, AO Cvili, Brescia, [4]Bone Marrow Transplant Unit SODc Ematologia, AOU Careggi, Firenze, [5]UO Ematologia, Policlinico Universitario A Gemelli, Università Cattolica del Sacro Cuore, Roma, [6]SC Ematologia, Istituto Nazionale Tumori, Milano, [7]Clinica Ematologica, AOU Santa Maria della Misericordia, Udine, [8]UO Ematologia, Policlinico Universitario A Gemelli, Università Cattolica del Sacro Cuore, Brescia, Italy

Background: Extracorporeal photopheresis (ECP) is considered a valid second-line treatment of both acute and chronic GVHD, which represent the most frequent causes of morbidity and mortality after allo-SCT in hematological malignancies.

Aims: According to an observational multicentric study, we report here a retrospective analysis on the use and results of ECP in 94 patients with acute and chronic GVHD, recruited in 6 italian Centres.

Methods: 94 patients with aGVHD grado ≥ 2 (n=45) and cGVHD (n=49) were submitted to ECP after first-line steroid-based therapy. ECP treatment consisted on conventional bi-weekly procedure for 4 weeks. Then, most of the patients were treated with bi-weekly procedures every 2 weeks for 4 other weeks. Response to steroid was assessed after 7 days for aGVHD and 15 days for cGVHD.

Results: aGHVD: 45 patients with aGVHD were treated with ECP. In 22 (49%) ECP was used as salvage treatment, being these patients non responsive to steroid (NR). 19/22 (86%) achieved a CR after ECP, whose median duration was 77 days (range 20-1112). The median duration of steroid therapy was 101 days (range 24-772), with a median of 22 days (range 7-80) on full steroid dose. The median duration of steroid on tapering was 82 days (range 0-756). 8/22 (36%) patients developed a cGVHD (extensive in 6 cases and limited in 2 cases). After a median follow up of 419 days (range 61-2149), 11/22 (50%) patients are alive. In 23/45 cases (51%) ECP was used earlier, being these patients partially responsive to steroid. Among these patients, 22 (96%) achieved the CR after ECP. In this setting of patients, the median duration of steroid was 88 days (range 32-719), with a median of 18 days (range 4-69) on full dose steroid therapy. The median duration of steroid on tapering was 68 days (range 0-700). The median duration of ECP treatment was 194 days (range 22-933). 7/23 (30%) patients developed a cGHVD (extensive in 6 cases and limited in 1 case). With a median follow up of 741 days (range 81-1819), 17/22 (77%) patients are alive. Among the 45 patients with aGVHD, the projected 2 years OS was 50% for the patients with steroid-refractory aGVHD *versus* 80% for the patients with steroid partially responsive aGVHD (p=0,07), and the cumulative incidence of cGVHD at 1 year was 48% *vs* 23%, respectively (p=0,32). cGVHD: 49 patients with cGVHD were treated wiht ECP. 12/49 (24%) and 37/49 (76%) had limited and extensive cGVHD, respectively. The median time of cGVHD onset was 193 days (range 43-3756), the median time from steroid to ECP was 26 days (range 0-1347) and the median duration of ECP was 276 days (range 19-2861). The median duration of steroid therapy in this group was 276 days (range 19-2861). 22/49 patients (45%) and 17/49 patients (35%) achieved a CR and PR, respectively. After a median follow up of 811 days (range 152-4676), 44/49 patients (90%) are alive, 28 of whom (64%) on immunosuppressive therapy.

Summary/Conclusions: ECP confirmed to be an effective treatment in aGVHD steroid-resistant patients as it can induce a CR in more than 80% of the cases, with 50% of these patients becoming long-term survivors. In aGVHD steroid partially-responsive patients it can probably allow a faster steroid tapering, with more than 70% of patients becoming long term survivors. In cGVHD steroid-resistant patients, ECP are associated with an overall response rate of 80%, with 90% of patients who become long-term survivors.

E1542

IMPACT OF PLERIXAFOR ON HOSPITAL EFFICIENCY: A SINGLE CENTER EXPERIENCE

N Azar*, M Ouzegdouh, S Choquet, V Leblond

Hematology department, Hôpital Pitié-Salpêtrière, Paris, France

Background: Plerixafor in combination with granulocyte colony-stimulating factor (G-CSF) has shown to increase mobilization of peripheral blood stem cells (PBSC) as compared to G-CSF alone in patients undergoing autologous stem cell transplantation (ASCT). However, up to 25% of patients treated with G-CSF alone still fail mobilization. Adding plerixafor to the regimen of poor mobilizers allows to rescue these patients from mobilization failure and to reduce the number of apheresis sessions. Furthermore, it was hypothesized that the use of plerixafor would lead to a better prediction of the number of apheresis time-slots needed and a reduction of time-slots lost. This in turn would free hospital resources which could be dedicated to other procedures.

Aims: The goal of this retrospective study was to capture the impact of plerixafor on mobilization outcome and on the efficiency of the apheresis department. Efficiency was described in terms of time-slots lost and the number of extracorporeal photopheresis (ECP) sessions carried out. ECP, whose benefit is generally recognized in patients with cutaneous T-cell lymphoma and graft *versus* host disease, is a procedure which carries some similarities with standard apheresis techniques and may therefore be carried out by the same staff provided some additional training. The demand for this procedure has steadily increased over the last years, but could not be matched by available health care resources.

Methods: Hospital records of patients treated before (2005-2008) and after (2009-2014) introduction of plerixafor were collected and analyzed retrospectively. Main outcomes were mobilization failure rate and number of time-slots lost due to insufficient mobilization, ie low CD34 count. Secondary endpoints included the number of apheresis sessions per patient, mean CD34+ cells collected, the number of ASCT and ECP sessions carried out, and costs per ASCT patient.

Results: Following plerixafor introduction, the mobilization failure rate dropped from 12% to 4% and the mean number of time-slots lost per patient dropped from 1.39 to 0.89. Additional drug costs due to plerixafor were partially balanced by a reduction in apheresis sessions, resulting in an additional cost of 700 € per ASCT candidate. More importantly, with the use of plerixafor, the availability of time-slots turned from erratic to predictable such that freed capacity could be dedicated to other apheresis procedures, and the number of ECP sessions increased from 0 in 2005 to 685 sessions in 2014 (see Figure).

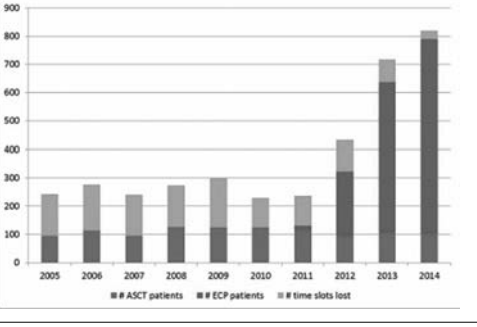

Figure 1.

Summary/Conclusions: Plerixafor not only improved mobilization outcomes for patients undergoing ASCT, but also reduced uncertainty around scheduling of apheresis sessions, leading to a decrease in time-slots lost. Freed resources were used to manage patients requiring ECP therapy, showing that the introduction of plerixafor had much wider implications beyond that of improvement in PBSC mobilization. Even though this result is not generalizable, in a climate of stretched resources it is important to consider the opportunity and redistribution investment possible with freed capacities.

E1543

A TREOSULFAN-BASED TOXICITY-REDUCED CONDITIONING REGIMEN IS SAFE AND FEASIBLE FOR CHILDREN WITH NON-MALIGNANT DISEASES BUT INCREASES REJECTION RATES IN STEM CELL TRANSPLANTATION OF HEMOGLOBINOPATHIES

C Malaval[1,*], J Feucht[1], M Döring[2], KM Cabanillas Stanchi[1], HM Teltschik[1], I Müller[3], R Handgretinger[1], P Lang[1], T Feuchtinger[2]

[1]General Pediatrics, Hematology/Oncology, University Children's Hospital Tübingen, Tübingen, [2]Pediatric Hematology/Oncology, Ludwig-Maximilians-University München - Dr.-von-Hauner'sches Kinderspital, Munich, [3]Department of Pediatric Hematology/Oncology, University Hospital Hamburg, Hamburg, Germany

Background: Hematopoietic stem cell transplantation (HSCT) as a treatment of non-malignant diseases has improved over the last decades. Less toxic chemotherapy during conditioning aims at reducing transplant related mortality with the risk of an increased rejection rate. Non-malignant disorders are chemo-naïve and carry an increased risk of transplant rejection compared to malignant diseases.
Aims: Aim of the present study was to evaluate safety and feasibility of a treosulfan-based toxicity-reduced conditioning regimen in pediatric patients undergoing HSCT.
Methods: This retrospective study analyzed the safety and feasibility of a treosulfan-based conditioning between 2009 and 2013 in 31 pediatric HSCT recipients (17 males, 14 females) with a median age of 7.8 years (range 0.1-18.2 years), undergoing allogeneic HSCT for non-malignant diseases, thalassemia (n=11), leukodystrophies (n=6), severe combined immunodeficiency (n=4), sickle cell disease (n=3), familial hemophagocytic lymphohystiocytosis (n=3) and others (n=4). The chemotherapy during the conditioning regimen consisted of fludarabine 150 mg/m^2 in 5 single doses (5 x 30 mg/m^2) between day -7 and day -3. Treosulfan was given in a dosage of 42 g/m^2 in 3 single doses (3 x 14 g/m^2) between day -6 and day -4. On day -2, thiotepa was applied in a dosage of 10 mg/kg bodyweight per day, twice a day (2 x 5 mg/kg BW). Between day -6 and day -3, patients received treatment with 4.5 mg /kg BW anti-thymocyte globulin (ATG) in 4 dosages (1 x 0.5 mg/kg BW as test dosage; 1 x 1.0 mg/kg BW; 2 x 1.5 mg/kg BW). Patients received transplants from a matched sibling donor (MSD, n=15), a matched unrelated donor (MUD, n=12), a mismatched unrelated donor (MMUD, n=1), a matched family donor (MFD, n=2), or a mismatched family donor (MMFD, n=1). The median observation period was 2.0 years (range 34 days - 5.6 years) and included the time of measurement directly before the start of conditioning until December 2014.
Results: Primary engraftment occurred in 97% of the patients, with a median time of 15 days after transplantation to reach >1000 leukocytes per µl peripheral blood and a median time of 21 days to reach platelet counts, which did not require transfusions anymore. After re-transplantation, final engraftment occurred in 67% of the patients. Graft-*versus*-Host Disease (GvHD) grade II and III-IV occurred in 6% and 9% of the patients, and chronic GvHD occurred in 0% of the patients. Rate of other grade IV side effects was low, except for grade IV stomatitis that occurred in 42% of the cases. Transplant related mortality (TRM) was observed in 7% of the patients after one year. HSCT recipients with hemoglobinopathies were accompanied by a rejection rate of 31% compared to 0% rejection rate among all other patients. Mixed chimerism occurred in 71% of the cases. Mixed chimerism >50% occurred in 42% of the cases and mixed chimerism >80% occurred in 23% of the cases.
Summary/Conclusions: In conclusion, a treosulfan-based conditioning regimen resulted in excellent engraftment rates with low toxicity in children with non-malignant diseases. However, in children with hemoglobinopathies, the rejection rate was not acceptable occurring in around one third of the cases. Future prospective controlled studies will have to clarify the long-term outcome.

E1544

POST-TRANSPLANT CYCLOPHOSPHAMIDE AS GRAFT-VERSUS-HOST DISEASE PROPHYLAXIS IN PEDIATRIC PATIENTS WITH HEMATOLOGIC MALIGNANCIES TRANSPLANTED FROM HAPLOIDENTICAL AND MATCHED UNRELATED DONORS

A Abrosimov[1,*], L Shelikhova[1], Z Shekhovtsova[1], D Balashov[1], Y Skvortsova[1], E Kurnikova[2], M Ilushina[1], I Shipitsina[1], D Shasheleva[1], R Khismatullina[1], E Gutovskaya[1], S Blagov[1], N Myakova[3], D Litvinov[4], D Baidildina[5], G Novichkova[6], M Maschan[1], A Maschan[6]
[1]HSCT, [2]Laboratory of Transplant Processing and Cell Preparations, [3]Department of oncohematology, [4]Department of of Hematology/Oncology of young adults and neurooncology, [5]Department of pediatric hematology/oncology, [6]Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Standard GvHD prophylaxis regimens impair the graft-*versus*-tumor (GVT) effect, delay immune reconstitution and are associated with high rate of infections. High-dose post-transplantation cyclophosphamide (PTCy) targets alloreactive donor T cells proliferating early after BMT, promotes regulatory T cell and permits rapid immune reconstitution.
Aims: In this pilot trial we evaluate the safety and effects of PTCy in unmanipulated haploidentical and matched unrelated transplantation (MUD) in pediatric patients with hematologic malignancies.
Methods: Twenty eight pediatric patients with high risk hematologic malignancies underwent unmanipulated allogeneic bone marrow (BM) (n=26) or peripheral blood stem cell (PBSC)(n=2) transplantation followed by PTCy between April 2014 and September 2015 with a median follow-up of 9 months (1,5-19). Nineteen patients were transplanted from haploidentical donors and 9 from MUD. The median age was 10,4 years (range 1,9-18); 14 patients with ALL, 4 AML, 8 JMML and 2 with HD; 16 patients were in remission (CR) (14-ALL, 1-AML, 1-HD), 12 had active disease (AD) (8-JMML, 3-AML, 1-HD). In 11 pts this was a second allograft. Twenty-six pts received myeloablative Treosulfan/Melphalan/Fludarabine and 2 pts - reduced-intensity Fludarabine/TAO 2Gy/Thiotepa as conditioning regimen. GvHD prophylaxis consisted of PTCy on day +3, +4 and tacrolimus from day +5 in all pts., 12 (43%) pts. also received ATG (rabbit, thymoglobuline) at 5 mg/kg/course.
Results: Primary engraftment was achieved in 27(96,4%) of 28 pts., the median time to neutrophil and platelet recovery was 20 days (14-45) and 21 days (10-97). Twenty seven (96,4%) patients were in full donor chimerism on day +30. Early mortality was 14,9% (95% CI: 6-36), causes of death included viral infections (n=3); GvHD and viral infection (n=1). Cumulative incidence (CI) of acute GvHD grade ≥II was 50% (95%CI:34-74), grade III–IV - 34% (95%CI:19-62) and chronic GvHD-19% (95%CI:8-45). No correlation between the use of ATG and acute/chronic GvHD was noted. CI of relapse was 15,4% (95% CI: 6-38) and was significantly lower in CR *vs* AD group: 0% *vs* 36% (95% CI: 17-77), p=0,015. One year event-free survival (EFS) was 69,7% (95%CI: 52-87) and overall survival (OS) - 76% (95%CI: 59-93). One year pOS was significantly lower in the ATG group 58% (95%CI: 30-86) *vs* non-ATG group 93% (95%CI: 79-100), p=0,039. One year pEFS was 87% for patients in remission and 48% for patients with active disease (p=0,028). There was no significant difference in survival and relapse rate according to donor type.
Summary/Conclusions: Our study demonstrates the high rate of engraftment with acceptable transplant-related mortality in pediatric patients with hematological malignancies after unmanipulated HSCT with posttransplant cyclophosphamide. The data need to be confirmed in a larger trial with long-term follow-up.

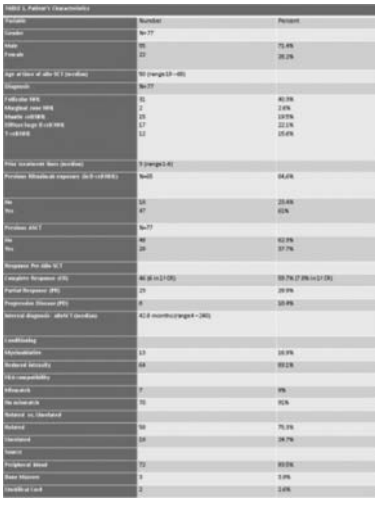
E1545

ALLOGENEIC HEMATOPOIETIC TRANSPLANTATION FOR NON-HODGKIN'S LYMPHOMAS A RETROSPECTIVE ANALYSIS OF 77 CASES

AM Picleanu[1,*], S Novelli[2], A Esquirol[2], AC Caballero[2], I Garcia[2], R Martino[2], S Saavedra[2], J Briones[2], J Sierra[2]
[1]Hematologia, Filantropia Hospital, Craiova, Romania, [2]Hematologia, Hospital Sant Pau, Barcelona, Spain

Background: Non-Hodgkin's lymphomas (NHL) are a heterogeneous group of malignancies characterized by uncontrolled proliferation of clonal lymphocytes, which have varied aggressiveness. Allogeneic stem-cell transplantation (allo-SCT) is a therapeutic option for advanced and otherwise incurable NHL. The major drawbacks associated with this therapy are graft-*versus*-host disease (GVHD) and infections. On the positive side, it is becoming clear that in the allo-SCT setting there is a graft-*versus*-lymphoma effect. Selection of the appropriate patients and donors, as well as the transplantation timing still is a matter of debate.
Aims: To investigate the factors that influenced the outcome after allo-SCT for NHL over a 20 years period in a Spanish University hospital
Methods: Retrospective analysis of patients with NHL who received an allo-SCT between January 1995 and December 2014. Statistical analyses were performed using the IBM SPSS Statistics version 21. Survival curves were estimated by the Kaplan-Meier method and compared using the log-rank test. Variables were selected based on previous studies: age (≤60 *vs* >60 years), gender (male *vs* female), previous ASCT, disease status pre allo-SCT, number of chemotherapy lines before allo-SCT, intensity of conditioning regimen (ablative *vs* reduced intensity), HLA compatibility (no mismatch *vs* mismatch), related donor *vs* unrelated donor. Cox regression method was used to develop a prognostic model of OS.

Table 1.



Results: The characteristics of the series are summarized in Table 1. Indolent NHL (iNHL) accounted for 43% of patients (n=33) and aggressive NHL 57% (n= 44). Within aggressive NHL, 16% were of T-cell origin.The median time follow-up after alloSCT was 23 months (range 0-232). The OS at median time was 53.5% and the PFS was 53.8% (only 9 progressed). The main cause of death (n= 48) were GVHD 37.5% (n=18), infections 22.9% (n=11), secondary malignancies 8.3% (n=4) and veno-oclussive disease 4.2% (n=2). Age and response pre allo-SCT had statistically significant impact on OS in multivariate analysis (p<0.01) The OS for patients ≤60 years old vs.>60 years old were 58.% and 24%, respectively.The OS for patients in CR pre allo-SCT was 60% and for patients in PR was 55%. All patients with progressive disease were death at median time of follow-up.
Summary/Conclusions: Allo-SCT is a feasible option for high risk of relapse lymphoma patients. Old patients and those with non-responsive disease before allo-SCT should be considered for alternative therapies. The results are remarkable in younger patients with sensitive NHL.

E1546

BEING OVERWEIGHT/OBESE PRIOR TO ALLOJENEIK HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT) IS RELATED TO BETTER OVERALL SURVIVAL (OS) AND DECREASED NON-RELASE MORTALITY

E Atilla*, P Ataca Atilla, S Civriz Bozdag, M Kurt Yuksel, P Topcuoglu, H Akan, M Beksac, O Arslan, O Ilhan, M Ozcan, S Kocak Toprak, G Gurman
Ankara University School of Medicine Department of Hematology, Ankara, Turkey

Background: Obesity is an increasingly important health problem in developed countries and a cause of variability in treatment outcomes. The effect of being owerweight or obese had been studied in various populations in patients undergoing Allo-HSCT. Sorror et. al reported obesity as a factor in hemetopoietic cell transplant-specific comorbidity index and increased risk of non-relapse mortality (NRM).
Aims: In this study, we evaluated the impact of obesity on acute graft *vs* host disease (aGVHD) risk, overall survival (OS), relapse rate (RR), relapse free survival (RFS) and NRM in patients undergoing Allo-HSCT.
Methods: Retrospectively, 245 patients who underwent allo-HSCT between 2000 and 2015 at Ankara University School of Medicine was included in our study. Patients were classified into four groups based on pretransplant BMI values according to World Health Organization as follows: underweight (BMI<18.5 kg/m^2, n=17), normal (18.5 ≤BMI<25 mg/kg/m^2, n=116), overweight (25 ≤BMI<30 mg/kg/m^2, n=78) and obese (BMI ≥30 mg/kg/m^2, n=34). Patients received weight adjusted chemotherapy doses. Characteristics of patients were compared using the Chi-squared test for categorical variables. The probilibity of OS was calculated by the Kaplan-Meier method.

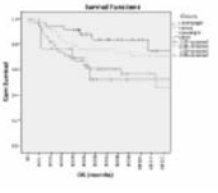


Figure 1.

Table 1.

Table 1. Patient Characteristics

	Underweight (n=17)	Normal (n=116)	Overweight (n=78)	Obese (n=34)	P
Mean Age, years	36.0	37.9	33.5	38.9	0.362
Sex (F/M)	8/7	47/69	37/41	18/16	0.428
Stem Cell Source					
BM	5	7	14	9	0.033
PBSC	10	104	61	25	
BM+PBSC		5	3		
Donor					
Related	5	56	28	5	0.093
Unrelated	10	60	50	29	
HLA Status					
Fullmatch	11	81	47	26	0.396
Mismatch	3	22	22	4	
missing	4	13	9	4	
Diagnosis					
Acute Leukemia	8	72	50	18	
Bone Marrow Failure	4	16	13	3	0.0081
CML					
Lymphoma		7	5	7	
Others	1	10	8	4	
	4	11	4	3	
Conditioning					
Myeloablative	9	89	66	29	0.803
Reduced-intensity	8	27	12	5	

Results: The patient characteristics are given in the table. Mean age of the group was 36.8 (range, 16-71). Overweight and obese patients received more bone marrow as a stem cell source (P=0.033). Bone marrow failure syndromes were more common diagnosis in normal and underweight recipients (p=0.0001). Myeloablative conditioning were prefered in overweight and obese group (p=0.002). Five year OS in underweight, normal, overweight and obese groups were as follows: 51%, 60%, 74% and 83% (P=0.005). Relaps rate was higher in underweight and normal compared to overweight and obese but not statistically different (23% *vs* 19%, P=0.53). 2-year RFS in underweight, normal, overweight and obese groups were as follows: 33%, 29%, 41%, 50%, P=0.069). The incidence of aGVHD detected higher in obese and overweight group however not statistically significant (44% *vs* 40%, p=0.6). NRM was lower in overweight and obese group (12% *vs* 31%, P=0.001).
Summary/Conclusions: Interestingly, we have demostrated that being overweight/obese improved OS and decreased NRM in our cohort. Relapse rate was higher in underweight and normal weight group however not statistically significant.

E1547

EXPRESSION OF CD143 ON CD34-POSITIVE CELLS IN PERIPHERAL BLOOD AND APHERESIS PRODUCTS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AT THE MOBILIZATION OF PERIPHERAL BLOOD PROGENITOR CELLS (PBPCS)

M Kanaeva*, I Galtseva, Y Davydova, N Kapranov, T Gaponova, L Mendeleeva, E Parovichnikova, V Savchenko
National Research Center for Hematology, Moscow, Russian Federation

Background: Angiotensin converting enzyme (CD143) is a part of the renin-angiotensin system catalyzing the cleavage of angiotensin I to angiotensin II. CD143 is expressed in blood-forming tissues of the human embryo: para-aortic splanchnopleura, yolk sac, aorta-gonad-mesonephros, liver and bone marrow. Transplantation into NOD/SCID mice and cultivation have shown that CD34+/CD143+ cell progenitors, but not CD34+/CD143-, sustain multilineage hematopoietic cell engraftment and have long-term culture-initiating cell potential.
Aims: To estimate of CD143 expression on CD34+ cells in peripheral blood and apheresis products in patients with hematological malignancies before and after the mobilization of PBPCs.
Methods: The study included 31 patients: 16 women and 15 men aged 22-68 years old (median 52). 29 patients were diagnosed with multiple myeloma and 2 - Hodgkin's lymphoma. Analysis of CD34+ cells was performed by flow cytometry (FACSCantoII, Becton Dickinson) using monoclonal antibodies: CD34 PE, CD45 FITC, and CD143 APC (Becton Dickinson). The percentage of CD34+ among CD45+ cells and the percentage of CD34+/CD143+ in CD34+ population were calculated in peripheral blood of patients before mobilization and in peripheral blood and apheresis products on the day of leukapheresis. The mobilization was performed with cytotoxic chemotherapy (cyclophosphamide - 4 g/m^2 - 24 patients, patient - 2 DHAP)+5 mg/kg G-CSF (CC+G-CSF) in 26 cases and with G-CSF (10 mg/kg) only - in 5 cases. The control group included peripheral blood samples from 10 healthy donors without mobilization.
Results: The percentage of CD34+ cells in peripheral blood before mobilization from all patients was 0.03±0.01% compared to healthy control group with 0.024±0.004% (p=0.62). The percentage of CD34+/CD143+ was 12.33±1.55% (3.42±1.43% in healthy donors, p=0.004). After the mobilization percentage of CD34+ cells in peripheral blood was 0.08±0.05% when mobilization was performed with G-CSF, and in case of using CC+G-CSF the percentage of CD34+ was 0.83±0.18% (p=0.09). The percentage of CD34+/CD143+ cells with G-CSF mobilization was 28.32±4.06%, compared to 46.07±2.96% (p=0.01) in patients with CC+G-CSF mobilization. The apheresis products contained 0.36±0.11% of CD34+ cells after mobilization with G-CSF, and 1.55±0.25% of CD34+ cells after mobilization with CC+G-CSF (p=0.048). The percentage of CD34+/CD143+ cells in apheresis products was 29.16±5.99% when mobilization was carried out with G-CSF and 47.96±2.77% (p=0.01) in patients with CC+G-CSF mobilization.
Summary/Conclusions: Thus, increase of CD34+/CD143+ cell number in peripheral blood and apheresis products after mobilization has been shown. Increase of CD34+/CD143+ cells in patients after mobilization of PBPCs with chemotherapy and G-CSF was significantly greater in contrast to the mobilization with G-CSF alone. Patients with hematological malignancies before mobilization had higher percentage of CD34+/CD143+ cells in peripheral blood then healthy donors that may be due to previous chemotherapy.

A COMPARISON OF ORIGINATOR G-CSFS *VERSUS* BIOSIMILAR G-CSFS AFTER AUTOGRAFTING IN HEMATOLOGICAL MALIGNANCIES

L Brunello[1,*], MJ Fornaro[1], L Giaccone[1], M Scaldaferri[2], V Redoglia[1], P Omedè[1], M Festuccia[1], G Ciccone[3], M Massaia[1], D Ferrero[1], F Cavallo[1], A Palumbo[4], F Cattel[2], T Francisci[5], V Tassi[5], A Evangelista[3], M Boccadoro[1], B Bruno[1]
[1]Department of Oncology, Division of Hematology, Department of Molecular Biotechnology and Health Sciences, A.O.U. Città della Salute e della Scienza

di Torino, University of Torino, [2]SC Farmacia, AOU Città della salute e della Scienza di Torino, [3]Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, [4]Myeloma Unit, Division of Hematology, University of Torino, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, [5]SC Banca del Sangue, AOU Città della salute e della Scienza di Torino, torino, Italy

Background: Autografting is widely used for the treatment of hematological malignancies, especially for lymphoproliferative diseases. In recent years, biosimilar G-CSFs (BioG-CSFs) have gradually been introduced into clinical practice to mobilize peripheral blood hematopoietic stem cells (CD34+ cells) and reduce the duration of neutropenia.
Aims: This study was designed to assess, in the setting of "real life" clinical practice, the role of BioG-CSFs and to compare them with a historical patient cohort treated with "originator" G-CSFs after autografting. The study was prompted by the growing propensity for the use of biosimilar growth factors to reduce overall costs and by the imminent implementation of other novel biosimilar molecules.
Methods: The study period was 2006-2015 during which standard policies for autografting did not change. Primary endpoints were post transplant engraftment kinetics, transfusion requirements and duration of hospitalization. Secondary objective was one-year overall survival. Day of neutrophil engraftment was defined as the first of 3 consecutive days of absolute neutrophil count ≥500/ul whereas day of platelet engraftment was defined as the first of 7 consecutive days of platelets ≥20.000/ul unsupported by transfusion.
Results: 276 patients were studied for a total of 354 transplants. Underlying diseases included multiple myeloma (n=204), non-Hodgkin lymphoma (n=56), Hodgkin lymphoma (n=9), chronic lymphocytic leukemia (n=2), acute myeloid leukemia (n=4) and histiocytic sarcoma (n=1). Seventy-eight multiple myeloma patients received double autologous transplant. Conditionings were as follows: melphalan 200 mg/m^2 for myeloma; busulfan/cyclophosphamide for acute myeloid leukemia; BEAM or FEAM-like for lymphoproliferative disorders. Overall,148 and 206 patients received originator G-CSFs and BioG-CSFs respectively. Infused CD34+ cells were 4.99 (IQR 3.77-5.05) x10^6/kg/body weight and 4.17 (IQR 3.66-5.00) x10^6/kg/body weight in the originator G-CSFs and BioG-CSFs cohorts. Cumulative incidences of neutrophil recovery at day +15 and +25 were 95.3% (95% CI 91.7% - 98.8%) and 99.3% (95% CI 97.6% - 100%) and 96.1% (95% CI 93.4% - 98.8%) and 98.5% (95% CI 96.8% - 100%) in the originator G-CSFs and BioG-CSFs groups respectively (p=0.980). These data were confirmed by Propensity Score adjustment, HR 1.03 (95% CI 0.87-1.2), p= 0.763. Cumulative incidence of platelet recovery at day +30 was 98.6% (95% CI 96.5% - 100%) and 96.1% (95% CI 93.4% - 98.8%) in the originator G-CSFs and BioG-CSFs cohorts (p<0.001). Of note, no differences between cohorts were found in a) median duration of neutropenia (median: 7 and 6 days, p=0.180) b) platelet (median 1 pool/patient in both, p=0.441) and red blood cell (median: 0/patient in both, p=0.703) transfusion requirements, hospital stay (median: 20 days in both, p=0.270). Interestingly, engraftment kinetics after the second transplant were faster for both neutrophil and platelet recoveries (HR 1.34 (95% CI 1.1-1.62), p=0.003 and HR 1.30 (95% CI 1.01-1.67), p=0.038, respectively, by multivariate models). No severe adverse reactions attributable to growth factors were documented. Finally, one-year overall survival was comparable between cohorts (p=0.901).

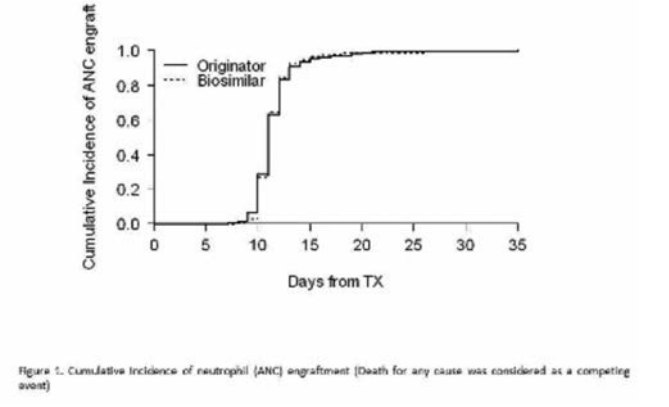

Figure 1. Cumulative incidence of neutrophil (ANC) engraftment (Death for any cause was considered as a competing event)

Figure 1.

Summary/Conclusions: In this sizable study, BioG-CSFs were as effective as originator G-CSFs. Moreover, their extensive use led to a significant cost containment.

E1549

FRONTLINE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR AGGRESSIVE B AND T CELL LYMPHOMA

TD Tan[1,*], MC Wu[1], LW Chiou[1], PY Chen[1], JS Wu[2]

[1]Hematology and Medical Oncology, [2]Radiation Oncology, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, ROC

Background: Either autologous or allogeneic haematopoietic stem cell transplantation is the salvage and even curative treatment for relapsed lymphoma. For high risk aggressive B cell or T cell lymphoma, frontline auto-transplantation can also improve survival.
Aims: We investigated the outcome between frontline *versus* salvage autotransplantation for aggressive lymphoma including B cell, T cell, and Hodgkin lymphomas.
Methods: For high risk aggressive B cell lymphoma (stage III and IV or IPI score above 3) and aggressive T cell lymphoma except ALK+ ALCL, we retrospectively compared the outcome of frontline autologous transplantation and non-transplant or salvage transplant patients.
Results: Between 2001 and 2015, we have 95 patients undergoing autologous (N=67) and allogeneic (N=28) haematopoietic stem cell transplantation. The 5-year overall survival was 70.4% and 59.1%, respectively. For high risk aggressive B cell lymphoma undergoing frontline autotransplant, the overall survival was 81.8%. During the same period, 5-year overall survival of stage III and IV diffuse large B cell lymphoma patients treated at our institute were 58% and 45%, respectively. For aggressive T cell lymphoma, 66.7% *versus* 0% of 5-year overall survival for frontline *versus* salvage autotransplant.
Summary/Conclusions: Frontline autotransplant should be considered in selected high risk aggressive B cell lymphoma patients and is very important for aggressive T cell lymphoma patients.

LB2269

PHASE 2A STUDY OF ALXN1007, A NOVEL C5A INHIBITOR, IN SUBJECTS WITH NEWLY DIAGNOSED ACUTE GRAFT-VERSUS-HOST DISEASE (GVHD) INVOLVING THE LOWER GASTROINTESTINAL TRACT

AM Alousi[1,*], B Yao[2], B Overman[1], V Ratanatharathorn[3], S Gill[4], G Socié[5], Y Dai[2], S Chasan-Taber[6], K Anderson[2], A Mujeebuddin[2], R Champlin[1], E Shpall[1], S Holtan[7]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Alexion Pharmaceuticals, Inc., New Haven, CT, [3]Karmanos Cancer Center, Detroit, MI, [4]University of Pennsylvania, Philadelphia, PA, United States, [5]Service d'Hématologie-Greffe de Moelle, Hôpital Saint Louis, Paris, France, [6]The Dartmouth Institute for Health Policy & Clinical Practice, Hanover, NH, [7]University of Minnesota, Minneapolis, MN, United States

Background: Murine models implicate complement in multiple steps of the acute GVHD cascade. Transplantation of donor T cells deficient in C3a and C5a as well as pharmacologic exposure to C5a receptor blockade have all been shown to reduce GVHD lethality in mice. In humans, complement activation has been correlated with gastrointestinal (GI) GVHD.
Aims: For this reason, we performed a multicenter Phase 2a trial (NCT02245412) of ALXN1007, a recombinant humanized monoclonal C5a antibody, in patients with newly diagnosed acute GVHD of the lower GI tract.
Methods: Between 14 Nov 2014 and 13 Nov 2015, a total of 15 patients with biopsy-confirmed acute GVHD of the lower GI tract consented, enrolled, and received weekly intravenous administration of 10 mg/kg ALXN1007, in combination with methylprednisolone at an initial dose of 2 mg/kg, through day 56. The primary objective was to assess the day 28 overall acute GVHD response rate along with safety and pharmacokinetics/pharmacodynamics (PK/PD).
Results: Median age was 60 years (range, 25-69); 60% were male, and acute myeloid leukemia was the most common diagnosis (33%). At enrollment, lower GI stages 1, 2, and 3 were present in 7, 2, and 6 patients, respectively. Day 28 overall acute GVHD response rate was 77% (2 patients were nonevaluable due to leukemia relapse at day 18 or early withdrawal). Complete GI GVHD response rates at days 28 and 56 were 69% and 77%, respectively. Day 56 overall acute GVHD response rate, day 180 nonrelapse mortality, and overall survival were 77%, 12.5%, and 69.2%, respectively. PK/PD analyses suggest that the dose may have been suboptimal with 10/13 patients achieving <90% inhibition of C5a. Day 28 response rate was higher in those achieving 90% inhibition (3/3) *versus* in those with less C5a inhibition (6/10). The drug was well tolerated with just 1 grade 2 infusion-related reaction and no grade 3 or higher adverse events attributable to the study drug.
Summary/Conclusions: The efficacy and safety data suggest that ALXN1007 is a promising therapy for patients with acute GVHD involving the lower GI tract. The level of C5a inhibition might be an important biologic parameter to predict clinical response. PK/PD analyses suggested higher doses and frequency may be needed to optimize C5a inhibition and maximize clinical response. For this reason, the trial has been amended to test 20 mg/kg weekly and twice-weekly dosing.

LB2270

RABBIT ANTITHYMOCYTE GLOBULIN *VERSUS* ALEMTUZUMAB IN ALLOGENEIC STEM CELL TRANSPLANTATIONA META-ANALYSIS

X Zhang, C Zhang[*], HJ Yan, L Gao

Department of Haematology, Xinqiao Hospital, The Third Military Medical University, Chongqing, China

Background: Rabbit antithymocyte globulin (ATG) and alemtuzumab have been used for graft-versus-host disease(GVHD) prophylaxis in allogeneic haematopoietic stem cell transplantation, but which is more efficient remain unclear.
Aims: This study is to analysize the role of rabbit antithymocyte globulin *versus* alemtuzumab in allogeneic stem cell transplantation.
Methods: we perform a meta-analysis of all studies comparing rabbit antithymocyte globulin (ATG) and alemtuzumab for graft-versus-host disease(GVHD) prophylaxis in allogeneic haematopoietic stem cell transplantation to evaluate their benefits and drawbacks. There are 7 studies (one prospective and six retrospective)for comparing ATG *vs* alemtuzumab in GVHD prophylaxis with 622 patients.
Results: Our results showed that the incidence of grade II-IV acute GVHD(RR 1.51, 95% CI 0.97-2.34, P=0.07), incidence of grade III-IV acute GVHD (RR 1.48, 95% CI 0.63-3.47, P=0.37) had a statistically non-significant reduction in alemtuzumab group, however , alemtuzumab significantly impaired OS (HR 0.61 (95% CI 0.41-0.90, P=0.01) compared with ATG. The incidence of overall chronic GVHD(RR 0.97, 95% CI 0.67-1.40, P=0.87) and the incidence of relapse(RR 1.03, 95% CI 0.72-1.47, P=0.88) were similar in the two groups.
Summary/Conclusions: We propose that using alemtuzumab for GVHD prophylaxis is beneficial for allogeneic stem cell transplantation due to the efficacy in grade III/IV acute GVHD, but OS is impaired compared with ATG group.

LB2271

A PRELIMINARY DISCUSSION ON THE RELATIONSHIP BETWEEN SERUM BIOMARKERS AND AGVHD IN PATIENTS WITH ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Tan, HJ Yan, L Gao, Y Liu, C Zhang, L Gao, X Zhang*
Department of Hematology, Xinqiao Hospital the Third Military Medical University, Chongqing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is an effective means for the treatment of a variety of hematologic malignancies. Acute graft *versus* host disease (aGVHD) is a common complication after allo-HSCT. And it seriously affects the quality of life and survival rate of patients and is also the main cause of non relapse mortality in allo-HSCT patients. The diagnosis of aGVHD mainly depends on the clinical manifestations and pathological examination of the damaged target organs. But its clinical symptoms are changeable and lack of specificity, the pathological examination often in clinical diagnosis and treatment because of various reasons can not be carried out.
Aims: To explore the relationship between serum biomarkers and aGVHD in allo-HSCT patients at different time points, and to provide theoretical basis for early intervention and prognosis evaluation of aGVHD.
Methods: Collection the serum samples of patients with allo-HSCT in November 2014 to November 2015 in the Department of Hematology, Xinqiao Hospital, Third Military Medical University . 10 patients with aGVHD were selected as the case group, and 10 patients without aGVHD were randomly selected as the control group. Protein chip technology was used to detect the content of IL-1β, IL-7, IL-8, ST2, vWF in plasma of the two groups patients in 7 days before transplantion and 7 days, 14 days, 28 days, 56 days, 100 days after transplantation.
Results: Compared aGVHD group and non-aGVHD group, 7 days and 56 days after transplantion, the level of ST2 in serum were significantly increased (P<0.05); 28 days, 56 days and 100 days after transplantion, the level of IL-7 in plasma were significantly increased (P<0.05); 56 days after transplantion, the level of IL-1β in plasma were significantly increased (P<0.05); Serum IL-8 and vWF were not significantly different between two groups in every time points.
Summary/Conclusions: The content of IL-1β, IL-7, ST2 in serum of patients with aGVHD after transplantation is higher than that of patients who were not aGVHD, and they can be used as the auxiliary diagnosis index of aGVHD and is helpful to early diagnosis and intervention of aGVHD. Monitoring of serum biomarkers for aGVHD immune targeted therapy provides a new direction.

TLR2-PI3K/AKT SIGNALING PATHWAY INVOLVED IN PLATELET ACTIVATION INDUCED BY GROUP B STREPTOCOCCI

L Ma[1,*], X Liu[2], G Zhang[2]
[1]Medicine, [2]Hematology, Sun Yat-sen Memorial Hospital, Guangzhou, China

Background: Platelets not only play an inportmant role in the initiation of hemostasis and thrombosis,but also participate in immune and inflammatory response. Most studies focus on the platelet-bacteria interaction and demonstrate that bacteria are capable of bind to,aggreating and activating platelets. Human platelets are reported to express several groups of TLRs, which particiated in the inflammation process. and monitoring host infection.Recent data from our laboratory demostrated that Group B streptococci(GBS) could induce platelet aggregation and up-regulate the expression of CD62P and further study shows that platelet TLR2 might involve in the activation.GBS,or streptococcus agalactiae,is one of the most common cause of life-threatening sepsis,pneumonia and meningitis in neonates,pregnant women,the elderly and immunocompromised adults.Therefore,illuminating the mechanisms of GBS-induced platelet activation is important for providing the basis for platelets in defense against infection and immunity.Since increasing reports have shown that the PI3-K/Akt signaling pathway regulates platelet activation and hemostasis,it is possible to research the TLR2 related signaling pathway.
Aims: Exploring whether TLR2-PI3K/Akt signaling pathway involved in the platelet activation induced by GBS.
Methods: 1. Platelets were from healthy volunteers (all genders, 25-52 years old) who had not taken any anti-platelet drugs (like aspirins, clopidogrel and abciximab) during the previous 30 days. GBS 639 were isolated from sepsis patients. 2. Platelet aggregation, the expression of platelet CD62P and PAC-1 were used as the indicator of platelet activation. GBS-induced platelet aggregation was assayed by light transmission; platelet TLR2, CD62P and PAC-1 expression were determined by flow cytometry; AKT and AKT phosphorylation expression were determined by RT-PCR or western blot assay. In some experiments, platelets were pre-incubated with PI3-K specific inhibitors LY294002 or anti-TLR2 monoclonal antibody.. 3. Statistical analysis: Data are reported as the mean±SD. Treatment groups were compared with the appropriate control (s), and statistical significance was examined using the two-tailed t-test. Differences were considered significant when P=0.05. All values were analyzed using SPSS version 17.0 software.
Results: 1. Platelet activation and TLR2 protein expression: Platelet aggregation, surface expression of TLR2, CD62P and PAC-1 induced by GBS were increased significantly on the platelets upon activation with GBS 639. However incubated with anti-TLR2 monoclonal antibody, they all decreased. 2. PI3-K/Akt signaling pathway: Real-time PCR showed that the PI3-K and Akt mRNA expression levels were increased significantly in the platelets stimulated with GBS 639. Western blot results showed that of Akt phosphorylation triggered by GBS was occurred as early as 15 min and increased gradually to reach a peak at 2 h post-infection and no significant changes were observed in total Akt protein expression during the infection. However, the expression of p-Akt, platelet aggregation and surface expression of CD62P and PAC-1 induced by GBS were significantly inhibited in the presence of a PI3-K inhibitor LY294002. 3. The relationship between TLR2 and PI3-K/Akt signaling pathway in platelet activation: Platelet p-Akt expression levels induced by GBS were significantly decreased after the activity of platelet TLR2 was blocked by anti-TLR2 monoclonal antibody, and no significant changes in total Akt protein expression.
Summary/Conclusions: GBS induced platelet activation through the TLR2-PI3-K/Akt signaling pathway in human platelets.

E1551

FUNCTIONAL ANALYSIS OF VON WILLEBRAND FACTOR IN MOUSE MODEL OF ACUTE ISCHEMIA-REPERFUSION KIDNEY INJURY

S Ono[1], H Matsui[1], M Noda[1], K Nishio[2], M Sugimoto[1,*]
[1]Regulatory Medicine for Thrombosis, [2]General Medicine, Nara Medical University, Kashihara, Japan

Background: Acute kidney injury (AKI), an abrupt loss of renal function, is often seen in clinical settings and may become fatal. The adhesive protein von Willebrand factor (VWF) plays a pivotal role in platelet thrombus formation under high shear stress conditions and is recently understood as a key protein in a cross-talk between inflammation and thrombosis.
Aims: We therefore assumed that VWF may be involved in the pathophysiology of AKI, the major cause of which could be an insufficient renal circulation and/or inflammatory cell infiltration in the kidney. To test this hypothesis, we studied the relevant role of VWF in AKI in mouse model of acute ischemia-reperfusion (I/R) kidney injury.
Methods: Mice (male, 8-12 weeks of age), whose right kidney were surgically removed 1 week prior to the kidney I/R experiment, were anesthetized with inhaled isoflurane and then placed in an abdominal position on a heating pad. Surgical incision was given on the left side of back and the left kidney was brought out and kept outside during the operation. Both renal artery and vein

were clamped at the renal hilus by a clamping clip for 30 min ischemia. Then a clip was taken off to provoke the reperfusion of renal blood flow, which was monitored by Laser Doppler flowmetry. The kidney was then put back in a body and skin incision was closed. The renal blood flow was measured again 30 h after reperfusion and mice were then sacrificed for blood collection.
Results: We compared 15 wild-type (WT) and 16 VWF-gene deleted (knock-out; KO) mice (from The Jackson Laboratory, Bar Harbor, ME). Excess blood loss was not observed in all mice (WT or KO) during whole surgical process. Although no difference was seen immediately after reperfusion, significantly ($p<0.05$) higher renal blood flow at 30 h after reperfusion was confirmed in VWF-KO mice, as compared to WT (KO; 24.0±2.3 *vs* WT; 15.1±1.46 ml/min/100g of kidney weight, and the reperfusion/base flow ratio: KO; 1.0±0.07 *vs* WT; 0.6 ±0.07). Consistent with the renal blood flow data, the serum creatinine value at 30 h after reperfusion were significantly ($p<0.05$) lower in VWF-KO mice than WT (KO; 2.77±0.11 *vs* WT; 3.15±0.11 mg/dl).
Summary/Conclusions: Our results suggest that VWF does play a role in the pathogenesis of AKI, in which VWF-dependent thrombotic or inflammatory responses may trigger thrombotic ischemia or endothelial damages of vascular bed in the kidney. Thus, proper functional regulation of VWF would be beneficial for better microcirculation and vessel functions in the kidney, suggesting a novel therapeutic potential against AKI.

INCREASED PLATELET LEUKOCYTE INTERACTIONS IN TYPE 2 DIABETIC INDIVIDUALS COMPARED TO HEALTHY CONTROLS

Z Mkandla[1,*], T Matsha[1], G Davison[1], B Nkambule[2]
[1]Department of Biomedical Sciences, Cape Peninsula University of Technology, Cape Town, [2]School of Laboratory Medicine & Medical Sciences (SLMMS), University of Kwazulu-Natal, Durban, South Africa

Background: Type 2 diabetes mellitus (T2DM) is considered as a form of low grade inflammatory response. Activated platelets are involved in inflammatory processes and bind to inflammatory cells monocytes and neutrophils to form platelet leukocyte aggregates (PLAs). Platelet bound neutrophils and monocytes become activated (expressing CD69) and undergo a phenotypic change into pro-coagulant phenotypes expressing tissue factor (CD142).
Aims: 1) To investigate the baseline levels of platelet activation in pre-diabetes and diabetes and compare this to normal controls. 2) To investigate the percentage of monocytes and neutrophils forming aggregates with platelets (PMA's and PNA's) in pre-diabetes and diabetes and comparing this to normal individuals. 3) To investigate the up regulation of pro-thrombotic and activation antigens on the surface of monocytes and neutrophils (Tissue Factor and CD69) in pre-diabetic and diabetic individuals.
Methods: Peripheral blood was collected into 4.5ml sodium citrate tubes containing 3.2% sodium citrate, samples were analysed within 1 hour of collection on the Navios 8 colour flow cytometer (Beckman Coulter, Miami, Florida). To ensure reporting on standardized results, flow check pro fluorescent labelled beads (Beckman Coulter, Miami, Florida) were used to standardise the optical path and laminar flow of the instrument. Blood was also collected into serum separator tubes (SST), heparin and EDTA for both biochemical and haematology testing. 50µl of citrated blood was incubated with 5µl of an antibody cocktail containing the antibodies CD42b-FITC, CD142-PE, CD69-PC5, CD16-PC7 and CD14-APC.After 10 minute incubation in the dark at room temperature each sample was lysed with 500µl Versalyse lysing solution for 15 minutes. 500µl of PBS was added to the sample and it was immediately analysed on the flow cytometer.
Results: Our results showed increased levels of platelet leukocyte aggregates%PLA in pre-diabetes and diabetes therefore indicating increased interactions between platelets and leukocytes in the peripheral blood of pre-DM and DM individuals. The diabetic group showed increased baseline levels of circulating platelets monocyte aggregates (%PMAs) median 49.04[36.78-62] compared to the control group 7.2[5.4-9], $p<0.0001$. Baseline platelet neutrophil aggregates (%PNAs) were significantly increased in the DM group [median 13.56(10.17-16.95)] compared to the control group [median 6.01(4.51-7.51)] $p<0.0001$. We also showed increased levels of tissue factor expression, a main part of the coagulation cascade, on the monocytes and neutrophils possibly is causing the hyper-coaguable state seen in diabetic individuals causing CVDs. Tissue factor (TF) expression on both monocytes for the diabetic group were significantly higher than the control group and correlated with increased levels of%PMAs ($r=0.6744$, $p<0.0001$).
Summary/Conclusions: In this study we showed increased PLAs in diabetic individuals than normal controls which may be responsible for the cardiovascular complications in diabetic patients. The increased tissue factor expression on monocytes and neutrophils in diabetic individuals may also contribute to the pro-coagulant state.

E1553

ANTICOAGULATION THERAPY AND A CAREFUL INTERDISCIPLINARY MANAGEMENT OF SPLANCHNIC VEIN THROMBOSIS: A SAFE AND EFFECTIVE APPROACH

S Rupoli[1,*], M Gironella[1], L Canafoglia[1], G Micucci[1], I Federici[1], G Svegliati Baroni[2], A Fiorentini[3], A Riva[4], AR Scortechini[1], L Da Lio[5], E Honorati[1], P Leoni[1]
[1]Department of Clinical and Molecular Sciences, Clinic of Hematology, [2]Department of Gastroenterology, [3]Departmemnt of Gastroenterology and Transplantation, Clinic of tropical, parassitology and chronic hepatitis Infectious Diseases, [4]Department of Gastroenterology and Transplantation, Clinic of Emerging Infectious Diseases, [5]Clinical Pathology, Polytechnic University of Marche Region, Ancona, Italy

Background: Splanchnic vein thrombosis (SVT) are unusual thrombosis that may be associated with underlying disorders either local or systemic. The optimal initial treatment of SVT is uncertain and limited data regarding safety and efficacy of anticoagulation are available at present.
Aims: In this report, we present our recent experience with SVT and discuss our treatment algorithm.
Methods: We retrospectively reviewed the records of 38 patients diagnosed as SVT that attended our anticoagulation clinic until June 2015. All clinical, laboratory, therapeutic and outcome data were collected for each patient. In patients who were not actively bleeding, anticoagulation treatment was started as soon as possible according to the platelet count. For a platelet count >50.000/mcl, we administered initial full dose low-molecular-weight heparin (LMWH) and antivitamin-K (AVK; target INR range 2-3 or 1.8-2.5 in the presence of additional risk factors for bleeding), half or prophylactic dose of LMWH for a platelet count between 30.000/mcl and 50.000/mcl and no treatment below 30.000/mcl. Moreover an appropriate prophylaxis with beta-blockers or with endoscopic therapies was extensively employed in in our cohort of cirrhotic SVT. The quality of oral anticoagulation was assessed by the time in therapeutic range (TTR). The response to initial anticoagulant therapy was evaluated as vessel recanalization and computed according to the Kaplan-Meier method. Major bleeding (ISTH definition) and vascular events (arterial and venous thrombosis) were also assessed.
Results: Thirty eight patients were included (median age 51 years; 71.1% males); portal vein thrombosis was the most common site of thrombosis (52.6%), followed by multiple venous segments involvement (34.2%). Hepatic cirrhosis was the common cause (44.7%) while myeloproliferative neoplasms were identified in four patients (10.5%). Thirteen patients (34.2%) were diagnosed incidentally. Thirty five patients (92.1%) were treated with anticoagulation (47.4% with AVK; median TTR 57%). Twenty three patients remained on anticoagulant treatment during the whole study period. During a median treatment duration of 27 months, the incidence rate of vascular events was 2.1 per 100 patient-years (1.6 and 0.8 per 100 patient-years among patients treated with LMWH alone or AVK respectively). Major bleeding occurred in one patient treated with AVK, corresponding to an incidence rate of 0.8 per 100 patient-years. Twenty six patients (68.4%) obtained vessel recanalization or thrombosis resolution. The probability of recanalization of the occluded vessels was 50% at 30 months. The median follow-up was 30.9 months (2-213); four patients (26.7%) died for causes not related to anticoagulation (cirrhosis, cancer).
Summary/Conclusions: The use of our treatment algorithm and a careful interdisciplinary management of SVT, appears to be safe and effective even for patients with major risk factors for bleeding (e.g. liver cirrhosis).

FIBRINOGEN GENETIC VARIABILITY AND COAGULATION PROCESS MEDIATE ATHEROSCLEROSIS MANIFESTATIONS AND AFFECT THE EXTENT OF THE DISEASE

Z Pallantza[*], N Papageorgiou, M Kozanitou, K Tsiligianni, M Pitsinou, M Malliotakis, E Andronopoulou, O Zoupouli, A Vlachopoulou, C Stefanadis, D Tousoulis
Athens Ippokratio Hospital, Athens, Greece

Background:
Aims: Evidence suggests that altered coagulation and fibrinogen genetic variability may contribute to atherogenesis. Therefore, we examined the combined effects of the rs1800790, rs2070011 fibrinogen polymorphisms on coagulation and endothelial function as well as the effect of coagulation on atherosclerotic manifestations.
Methods: In the present study we enrolled 422 patients with stable angina (SA) and 277 controls. The rs1800790 (G455A) and the rs2070011 (G58A) polymorphisms were detected by appropriate genotyping. Fibrinogen and D-Dimer levels, as well as factors (f) V, X activity were measured by standard coagulometry techniques. Flow-mediated dilation (FMD) was assessed by brachial ultrasound.
Results: We have shown that the 455AA homozygosity was associated with increased fibrinogen levels in both groups ($p=0.035$ controls and $p<0.001$ SA). In addition, homozygotes for the 58A allele had lower fibrinogen levels in controls ($p=0.038$). Both the 58AA ($p=0.027$) and 455AA homozygotes ($p=0.022$) had higher levels of D-Dimer in the SA group. The 455AA homozygotes had also increased fV activity in the SA group ($p=0.048$). No effects were observed on fX activity and FMD. Further analysis revealed that fibrinogen levels were strongly associated with SA (1.005 [1.003-1.007], $p<0.001$) as well as the presence of myocardial infarction (MI) (1.003 [1.001-1.005], $p=0.001$). Similarly, D-Dimer levels were also strong predictors of CAD (1.001 [1.001-1.002], $p<0.001$), but not of MI (1.000 [1.001-1.001], $p=0.083$). Surprisingly, when fV and fX activ-

ities were examined for possible associations with clinical presentations, we found that fV activity was associated with increased number of diseased vessels (1.016 [1.001-1.030], p=0.037), while fX activity was strongly related to MI (0.985 [0.973-0.997], p=0.013).
Summary/Conclusions: Our results demonstrate that the rs1800790 variant increases significantly fibrinogen, D-Dimers levels and fV activity, contributing to atherogenesis. Moreover, fibrinogen and D-Dimers levels are strong predictors of SA and MI. Interestingly, in our study we have shown for the first time that fV and fX are associated with the number of diseased vessels and the risk of MI respectively.

E1555

INTERVENTION TO OPTIMIZE VENOUS THROMBOEMBOLISM PREVENTION IN A COMMUNITY TEACHING HOSPITAL
U Goldberg*, V Patel, N Pasco, D Biobaku, M Kalavar
Kingsbrook Jewish Medical Center, Brooklyn, United States

Background: According to the U.S. Surgeon General, venous thromboembolism (VTE) affects 350,000 to 600,000 Americans each year and is implicated in over 100,000 deaths (The Surgeon General's Call to Action to Prevent Deep Vein Thrombosis and Pulmonary Embolism. Rockville, MD: Office of the Surgeon General, US; 2008.). Noting that only half of eligible patients in our inpatient medical service were receiving VTE prophylaxis (VTEP), our hospital instituted an intervention to improve performance on this critical measure.
Aims: To evaluate the efficacy of an electronic medical record (EMR)-based intervention to optimize VTEP among patients admitted to our institution.
Methods: In February of 2011, our hospital's information technology department instituted an automated prompt in the EMR system designed to increase the number of VTEP-eligible patients receiving VTEP. The prompt guides resident physicians in the process of admitting patients to a "hard stop" screen entreating them to identify VTE risk factors in the patient and to choose from a list of evidence-based VTEP therapies (including but not limited to heparin, sequential compression devices, and an option to not order VTEP if contraindicated). Concurrently, an educational presentation was offered to residents explaining the intervention and re-educating them on evidence-based VTEP guidelines. The computerized prompt remains in use today.
Results: Data covering 964 patients admitted in the month prior to the implementation of the VTEP prompt and 673 patients from after implementation were collected and analyzed. Prior to the implementation of the VTEP prompt, 49.0% of 964 patients were found to have received VTEP therapy. Following prompt implementation, that number rose 16.9% to 65.9% of patients. Data is continually collected and assessed semiannually.
Summary/Conclusions: As advances in medical technology continue to improve patient care, optimization of medication utilization becomes increasingly important. With underuse of critical medications raising the risk of iatrogenic illness, it remains the responsibility of the patient care team to engage in best practices to minimize these risks. Our intervention has demonstrated that VTEP utilization may be optimized by the use of a low-cost, easily implementable, and easily replicable intervention that effectively leverages the EMR system.

ERYTROCYTE-RELATED PHENOTYPES AND GENETIC SUSCEPTIBILITY TO THROMBOSIS
N Vilalta[1], AF Remacha[2,*], MP Sardà[2], JA Millón[1], N Pujol-Moix[3], A Ziyatdinov[3], J Fontcuberta[1], J Nomdedéu[2], JM Soria[3], JC Souto[1]
[1]Hemostasis and thrombosis, [2]Hematology Department, [3]Unit of Genomics of Complex diseases, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Venous thromboembolism (VTE) is a common disease that involves the interaction of genetic and environmental risk factors. Previous studies have estimated a heritability of approximately 60% for the risk of VTE. Using variance analysis, intermediate phenotypes related to thrombosis have identified genetic risk factors. Erythrocyte-related phenotypes are considered good risk factors.
Aims: To investigate the relationship of erythrocyte-related phenotypes with the risk of VTE.
Methods: Our study used the Genetic Analysis of Idiopathic Thrombophilia 2 (GAIT 2 Project) sample, which consisted of extended pedigrees (935 individuals). The sample had 120 subjects with thromboembolism (86 with VTE, 47 with arterial thrombosis and 13 with both). The following possible risk factors were evaluated: Red blood cell and indices, reticulocytes, serum iron, total iron binding capacity, serum ferritin, serum transferrin receptor (STFR), haptoglobin, serum vitamin B12 (B12), serum folate and red blood cell folate. Using the variance component method, heritability (h^2), the household effect and all of the phenotypic, genetic and environmental correlations with VTE were estimated.
Results: The h^2 of VTE was 0.67. Most erythrocyte parameters showed significantly high h^2. In addition, VTE was correlated with: hematocrit (0.52, p=0.01), red blood cell distribution width (RDW) (0.28, p=0.05), immature reticulocyte fraction (IRF) (0.45, p=0.008), transferrin saturation index (-0.7, p=0.05), STFR (0.4, p=0.006), and B12 (0.34, p=0.03).
Summary/Conclusions: We demonstrated a genetic relationship between erythrocyte phenotypes and VTE, and we identified 6 intermediate phenotypes as risk factors. We suggest that these risk factors will be useful in the search for thrombosis-related genes.

E1557

INTENSIVE HEMATOLOGY SCREENING FOR MYELOPROLIFERATIVE NEOPLASM AND EARLY RADIOLOGICAL INTERVENTION IS ASSOCIATED WITH EXCELLENT OUTCOMES IN BUDD CHIARI SYNDROME
A Mo[1,*], A Testro[2], J French[2], M Robertson[2], P Angus[2], A Grigg[3]
[1]Haematology, Monash Hospital, Clayton, [2]Liver Transplant Unit, [3]Haematology, Austin Health, Heidelberg, Australia

Background: Budd Chiari Syndrome (BCS) is a rare and life-threatening disorder, resulting from thrombosis of the hepatic veins. Aetiologies include prothrombotic states such as Myeloproliferative Neoplasm (MPN). Current treatment strategies involve a step-wise approach of anticoagulation followed successively by radiological and surgical interventions, and ultimately liver transplantation.
Aims: We aimed to retrospectively describe our institution's experience with the management of patients with BCS, including the diagnosis (by bone marrow biopsy and molecular testing for JAK2 and calreticulin mutations) and management of concomitant MPN.
Methods: In this retrospective study, approved by the hospital's Research Ethics committee, all cases of primary BCS, including new and recurrent presentations, presenting between January 2000 and August 2012 were identified from the hospital's computerised database.
Results: 27 patients with primary BCS presented during the study period. Twenty-four patients (89%) had identifiable risk factors, with the commonest being MPN, detected in 17/24 (71%) of the tested patients. This included 4 patients who initially presented with normal peripheral blood counts. The MPN diagnosis was made on the basis of JAK2V617F positivity (n=13), either alone (n= 8) or with a confirmatory bone marrow biopsy (n=5); or on marrow biopsy alone (n=4). The calreticulin mutation was detected in 2/9 tested patients (one patient with JAK2 negative MPN and one with ET with unknown JAK2 status). Subtypes of MPN included: Polycythaemia Vera (n=8), Essential Thrombocytosis(n=6), MPN unclassified (n=2) and Chronic Myeloid Leukaemia (n=1). An additional thrombophilic state was present in six of the MPN patients: the oral contraceptive pill (n=4), factor V Leiden heterozygosity (n=1), anticardiolipin antibody and recent in-vitro fertilisation (IVF) treatment (n=1). Of the six patients with a known diagnosis of MPN prior to BCS, three were on treatment with hydroxyurea, aspirin or venesection but none were anticoagulated prior to BCS diagnosis. Of the 11 patients with newly diagnosed MPN, additional treatment included hydroxyurea alone (n=3), venesection alone (n= 2), hydroxyurea and venesection (n=2), hydroxyurea and splenectomy (n= 1) and interferon (n= 1). Three patients with MPN were not given additional cytoreductive treatment: two in the context of normal peripheral blood counts, and one diagnosed just prior to death. All patients in the study were anticoagulated with warfarin or Low Molecular Weight Heparin, and 2 of the MPN patients also had aspirin. 25 of the 27 (92.6%) patients also had upfront radiological interventions, consisting of TIPS (transjugular intrahepatic portosystemic shunt) in 18 (67%) patients and/or angioplasty/stenting in 11 (40%). No patient developed TIPS failure. At a median follow up of 59 months (range 2 to 248 months), the overall survival was 96% at one year and 81% at five years, much greater than predicted by the patients' median Rotterdam score of 1.16 (range 0.07-2.11). No patients required liver transplantation.
Summary/Conclusions: There is a high incidence of MPN in patients with primary BCS, predominantly JAK2V617F positive, including patients with normal peripheral blood counts at the time of diagnosis. All BCS patients should therefore have JAK2 testing and, if negative, calreticulin mutation testing. A bone marrow biopsy should be considered if these are negative, in the context of unexplained polycythaemia or thrombocytosis. Furthermore, we advocate early radiological hepatic decompression as an alternative to the step-wise approach, as we have demonstrated excellent medium term outcomes with no TIPS failure and no patients requiring transplantation.

E1558

FIBRIN SHEATHS ON CENTRAL VEIN CATHETERS AS A RISK FACTOR FOR DEEP VEIN THROMBOSIS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
D Fedorova*, P Zharkov, A Sugak
Federal Research Clinical Centre Of Pediatric Hematology, Oncology And Immunology N.A. D.Rogachev, Moscow, Russian Federation

Background: Indwelling of central vein catheter (CVC) is well known as a risk factor for deep vein thrombosis (DVT) especially in patients with malignancies. The term «CVC-related thrombosis» is attributed to mural thrombosis that

involves CVC, adheres to vessel wall and partially or totally occludes the vessel lumen. However, presence of CVC in a central vein may result in emerging not only «true» mural thrombosis but so-called fibrin sheaths (FS) that envelope CVC but do not involve venous wall. Despite high FS incidence data on its clinical importance is scarce.
Aims: To investigate the role of FS in DVT development; to reveal the efficacy of anticoagulant therapy in patients with DVT with previous FS.
Methods: We analyzed data on 182 CVC inserted in 113 patients with acute lymphoblastic leukemia (ALL) aged from 1 to 19 years. Data were collected retrospectively from electronic hospital charts. The diagnosis of DVT and FS was made by means of echocardiography (ECHO) and Doppler ultrasound scanning (DUS) of extracranial brachiocephalic veins. DUS has been performed at different time after CVC implantation depending on clinical indications and physician's opinion. A «p» value<0,05 was considered statistically significant. Data were analyzed using the IBM SPSS for Windows Software. Univariant logistic regression analysis was performed for estimation of FS significance for DVT development. Between group comparisons were performed by chi-square or Fisher's exact test depending on sample value.
Results: FS were detected on 63 (35%) CVC. Incidence of FS was 2,71 events per 1000 catheter days. Catheter-related DVT was revealed in 51 (28%) cases. In 24 of them FS preceded DVT emerging. Presence of FS was significantly associated with subsequent DVT (odds ratio (OR) 2,75, 95% confidential interval (CI) 1,32-5,74, p=0,003). After detecting of FS, anticoagulant prophylaxis was started in 31 cases. In this group DVT subsequently developed in association with 15 (48%) CVC. In group that did not receive anticoagulants DVT developed in 9 (32%) cases. In both groups there was one occlusive DVT. Difference in DVT incidence between groups with and without anticoagulant prophylaxis after FS detecting was statistically insignificant (p=0,908). FS resolution occurred independently of anticoagulants usage (p=0,598).

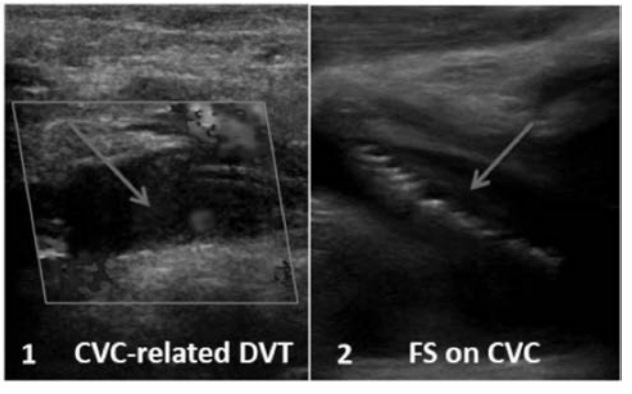

Figure 1.

Summary/Conclusions: According to our data, FS was detected on 35% of CVC. Presence of FS was associated with subsequent CVC-related DVT emerging. Efficiency of anticoagulants for FS resolving is doubtful. The question whether anticoagulant prophylaxis of DVT should be started after FS detecting remains unclear. Large prospective studies are required to resolve this issue.

E1559

FIBRINOGEN GENETIC VARIABILITY ACCELERATES ATHEROGENESIS BY ALTERING THE INFLAMMATORY PROCESS AND COAGULATION IN PATIENTS WITH DIABETES MELLITUS TYPE 2 AND HYPERTENSION
Z Pallantza*, N Papageorgiou, M Kozanitou, D Goubini, P Parigori, L Plavoukou, G Mallios, B Palioura, M Karagrigoriou, C Stefanadis, D Tousoulis
Athens Ippokratio Hospital, Athens, Greece

Background:
Aims: Hypertension (HTN) and diabetes mellitus (DM) are significant risk factors for atherosclerosis and characterised by altered coagulation and inflammatory process. In the present study we aimed to investigate the role of fibrinogen genetic variants (rs180070 and rs2070011) on coagulation and inflammation in patients with combined DM and HTN
Methods: 744 subjects (HTN and DM) were enrolled in our study. Fibrinogen polymorphisms were determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique. Fibrinogen, interleukin-6 (IL-6), high sensitivity C-reactive protein (hsCRP) CD40L, D-dimers and factors V, X activity were measured with appropriate laboratory methods.
Results: In HTN patients, hsCRP levels were higher in the group of patients with higher fibrinogen levels compared to patients with lower and intermediate fibrinogen levels [0.28 (0.12–0.42) *vs* 0.17 (0.04–0.38) *vs* 0.18 (0.09–0.39), p=0.032)]. In addition, we found a significant effect of the rs180070 polymophism on IL-6 levels among HTN and DM. In HTN, IL-6 levels were higher in AA homozygotes of the rs180070 compared to all other genotypes (AG or GG) (4.96±0.69 *vs* 3.7±0.2, p=0.046). Similarly, DM patients homozygotes for the A allele (rs180070) had higher IL-6 levels (6.72±0.99 *vs* 4.01±0.35, p=0.016). In multivariable analysis, the only independent predictor of IL-6 levels in DM was the AA genotype [β(SE): 0.216 (1.76), P=0.047]. In hypertensives, AA (rs180070) homozygosity was the only adjusted independent predictor of IL-6 levels [β(SE): 0.151 (0.642), P=0.032]. Subgroup analysis of HTN and DM patients did not reveal any differences of CD40L levels in the presence of AA genotype (rs180070) (p=0.919 for DM and p=0.144 for HTN). We did not observe any significant change in IL-6 or CD40L levels with the presence of the AA genotype of the rs2070011 among the studied subgroups. Finally, we found that the AA homozygosity (rs180070) was associated with increases D-dimer levels in both DM and HTN (DM: 741.6±109,4 *vs* 487.3±35.6, p=0.028, HTN 623.3±79.6 *vs* 388.6±23.5,p=0.048).
Summary/Conclusions: The AA homozygosity (rs180070) was associated with higher IL-6 levels and CD40L concentrations. We also showe for the first time, to our knowledge, that the AA homozygosity (rs180070) is associated with increased D-dimer levels. Our results of this study showed that higher levels of fibrinogen were associated with elevated D-dimer levels. Homozygotic status for the rs180070 polymorphism was also related to higher D-dimer levels both in HTN and DM patients.

E1560

VENOUS THROMBOSIS IN PUERPERIUM IS ALSO DOMINANTLY LOCALIZED IN LEFT LEG, BUT TENDS TO BE MORE MASSIVE THAN THROMBOSIS DURING GESTATION
J N Bodrozic[1,*], P Miljic[1,2], D Lekovic[1,2], D Sefer[1], D Vasic[3], M Gojnic Dugalic[2,4]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, [3]Clinic for Vascular and Endovascular Surgery, [4]Clinic for Gynecology and Obstetrics, Clinical Center of Serbia, Belgrade, Serbia

Background: During pregnancy and puerperium different factors play role in pathogenesis of venous thrombosis, and they may influence on localization and extent of thrombosis. Compression of iliac veins by gravid uterus is responsible for dominance of thrombosis in left leg during gestation. On the other hand, after delivery and during puerperium blood hypercoagulability plays a key role in pathogenesis of thrombosis, but little is known about anatomic distribution and extent of venous thrombosis in legs during puerperium.
Aims: To investigate the anatomic distribution and extent of deep vein thrombosis of the lower extremity during pregnancy and puerperium.
Methods: Retrospective analysis of 174 consecutive women with pregnancy related venous thrombosis of lower extremities that were referred to our institution from January 2004 to December 2015 has been performed. The localisation of thrombosis was classified as a thrombosis of left or right leg, proximal, distal or massive (proximal+distal). Thrombosis of superficial veins was excluded. All thrombotic episodes were confirmed with duplex ultrasonography. Descriptive statistics and chi square test were used for statistical analysis.
Results: Out of 174 women with pregnancy related thrombosis, 26 (15,5%) developed thrombosis during the first trimester, 23 (13,3%) during second, 37 (21,2%) during third and 87 (50%) during puerperium. Thrombosis of the left leg developed 127 (73%) women, and of the right leg 40 (23%). Bilateral thrombosis occurred in 7 (4%) of women. Prevalence of left leg thrombosis was 66%, 78%, 83%, 69% during first, second, third trimester and puerperium, respectively. Prevalence of right leg thrombosis was 33%, 13%, 13%, 26%. Left leg thrombosis was more frequent throughout gestation but also during puerperium than thrombosis in right leg (p<0,05). In our group of patients, 68 (39%) developed massive thrombosis, 81 (47%) proximal and 25 (14%) distal thrombosis. Prevalence of massive thrombosis during first, second, third trimester and puerperium was 41%, 30%, 13%, 52% respectively, of isolated proximal veins was 48%, 57%, 84%, 27%, and of distal veins 11%, 13%, 3%, 21%. The difference between different periods of pregnancy and puerperium regarding distribution and extent of thrombosis was statistical significant (p<0,05). Before the delivery most common localization of thrombosis was in proximal veins, while massive thrombosis occurred most frequently in puerperium.
Summary/Conclusions: We observed that deep vein thrombosis of the left leg occurred more frequently than thrombosis of the right leg not only during gestation but also during puerperium. This indicates that significant proportion of thromboses in pueperium might have initiated in last period of gestation and become clinically overt only after delivery. More massive thrombosis observed in puerperium points to importance of blood hypercoagulability on extent of thrombosis.

E1561

A NOVEL ADAMTS13 MUTATION IN A PEDIATRIC PATIENT WITH CONGENITAL AND ACQUIRED ADAMTS13 DEFICIENCY
K Yalçın[1,*], A Cairo[2], E Güler[1], I Mancini[3], F Peyvandi[2,3], A Küpesiz[1]
[1]Pediatric Hematology Oncology, Akdeniz University School of Medicine, Antalya, Turkey, [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, [3]Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milan, Italy

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare and life-threatening disorder caused by the deficiency of von Willebrand factor (VWF) cleaving protease, ADAMTS13. Severe ADAMTS13 deficiency (activity levels<10% of normal) can be due either to anti-ADAMTS13 autoantibodies (acquired TTP) or to ADAMTS13 gene mutations (congenital TTP).
Aims: In this report, we describe the novel mutation and clinical history of a pediatric patient with both congenital and acquired ADAMTS13 deficiency.
Methods: A 8 years old girl presented with easy bruising and thrombocytopenia. She was diagnosed with immune thrombocytopenic purpura (ITP) when she was 8 months old and followed with mild thrombocytopenia. Family history was unremarkable. At admission, blood work-up exhibited anemia, thrombocytopenia, fragmented erythrocytes, and schistocytes. Elevated serum LDH was detected. Renal function tests were impaired. TTP was diagnosed and started double volume plasma exchange (PEX) immediately. She was unresponsive to plasma exchange therapy. We used high dose methylprednisolone, acetylcysteine, cyclosporin, rituximab, vincristine and cyclophosphamide therapies unfortunately, there was no response. In spite of splenectomy, clinical status was deteriorated. We continued PEX beside all these therapies. During the treatment she had serious complications related to TTP as partial retina detachment, convulsion, renal failure and myocardial hypertrophy. During the treatment she had to be transfused with 118 units erythrocyte and despite of all efforts she died at the nineth month of TTP attack.
Results: The patient had undetectable ADAMTS13 activity (measured by FRETS-VWF73 assay) and antigen (measured by Technozym ADAMTS13 Antigen assay) and a high titer of anti-ADAMTS13 IgG. ADAMTS13 activity of the patient's mother was 60%. According to these results congenital and acquired ADAMTS13 deficiency seemed to be together in one patient. The genetic analysis identified the presence of a nonsense mutation in homozygous state on the *ADAMTS13* gene, a C to T substitution at nucleotide589 in the exon 6 (c.589C>T) leading to the substitution of the Glutamine 197 with a premature stop codon (p.Gln197X) in the metalloprotease domain in homozygous state. The mutation was also confirmed in heterozygous state in the patient's mother (her father died in an accident years ago).
Summary/Conclusions: This patient is unique with complex phenotype (congenital and acquired ADAMTS13 deficiency together) and novel mutation in ADAMTS13 gene. Similar complex phenotype is reported before and in that case ticlodipine is the trigger factor for acquired TTP. We could not detect any trigger factor for acquired TTP as drugs or infections. We also measure a high titer of anti-ADAMTS13 IgG at admission before the first plasma exchange.
The novel mutation has not been previously reported in the literature and there aren't any data from in vitro expression studies. However, due to its location within the metalloprotease domain, it is most probably responsible for the deficiency of protein product and its activity. This phenotipic complexity and mutation could be a novel type of TTP with severe clinical status and unresponsive to treatment.

E1562

PEDIATRIC VENOUS THROMBOEMBOLISM: A SINGLE CENTRE EXPERIENCE
N N Ozdemir*, G Dikme, H Kızılocak, B Koç, T Celkan
Pediatric Hematology Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Pediatric venous thromboembolism (VTE) and associated complications are rare but increasing. We reviewed our experience of pediatric VTE in 20 years.
Aims: To identify predictors of pediatric VTE, efficacy of treatment and prevalence of complications.
Methods: A retrospective chart review of patients aged 1 to 18 years with VTE was done.Data were collected on demographics, risk factors, thrombophilia work-up, treatment, and relapse. Neonatal and catheter related thrombosis cases were excluded.
Results: Sixty-five pediatric patients (M/F: 1.5) were recruited. Median age at diagnosis was 8.7 years (range: 1 month -17 years). Thrombotic locations were cerebral veins (n=34), lower extremities (n=12), upper extremities (n=7), DVT & pulmonary embolism (n=1), splenic and/or portal veins (n=7), renal vein (n=2), mesenteric veins (n=1), and purpura fulminans (n=1). In 35 patients (53%), a probable acquired risk factor was identified; the most common risks were leukemia, mastoiditis, vasculitis, congenital heart defect and infections. Thrombophilia work-up showed FV Leiden mutation (n=12), low protein C (n=12), high FVIII levels (n=10), low anti-thrombin-3 (n=4), high homocytein level (n=3), prothrombin 20210a mutation (n=3) in 33 patients (50%). Fifty-four patients received anti-coagulant therapy; the majority (n=49) received low molecular weight heparin (LMWH) and acetylsalicylic acid (n=4). Three received warfarin, one was on dabigatran study and one received rivoraxabin. Low molecular weight was given as single dose at a dose of 100 u/kg to all patients. Five had recurrent thrombosis under treatment, one was on dabigatran and the rest were on LMWH. One patient with vasculitis had post-thrombotic syndrome.
Summary/Conclusions: The etiology of pediatric venous thromboembolic disease (VTE) is multifactorial, and in most children, 1 or more clinical and inherited risk factors are present. In our experience low dose LMWH may be used with success in pediatric VTE.

E1563

ANTITHROMBOTIC EFFECTS OF ARGININ-CONTAINING GLYPROLINE
M Grigorjeva*, T Obergan, L Lyapina
Биология, Ломоносова, Москва, Russian Federation

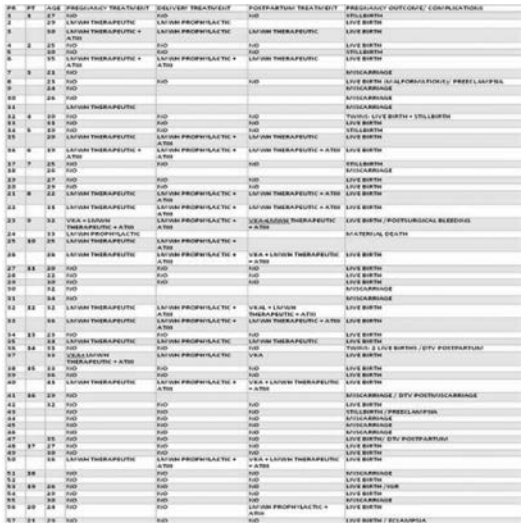
Background: It has been shown that glyproline peptides have the anticoagulant, fibrinolytic and antiplatelet action in the organism. The decrease of platelet aggregation can be enhanced by adding to the molecule of glyprolines arginine, which causes the release of NO in the bloodstream.
Aims: The aim of this study was to determine the antithrombotic effects of arginine-containing glyproline Pro-Gly-Pro-Arg (PGPR) in rats with experimental venous thrombosis.
Methods: The peptide PGPR was administered to experimental rats intranasally for 4 days in a daily dose of 1 mg/kg. Control animals similarly received saline. Then venous thrombosis (Wessler model) was simulated in rats. The degree of clot formation was assessed by weight of thrombus (mg). The state of the hemostasis system was estimated used standard methods: determination of anticoagulant activity (APTT), fibrinolytic activity on fibrin plates, ADP-induced aggregation of platelets.
Results: It is established that preliminary injection of PGPR lead to decrease of thrombus formation in experimental rats on 60%. Thrombus formation in control rats-100%. Moreover in the blood plasma of experimental animals anticoagulant and fibrinolytic activity were increased by 21% and 30% respectively. Platelet aggregation was decreased at 25% compared with the control.
Summary/Conclusions: Thus arginine-containing glyproline Pro-Gly-Pro-Arg showed anticoagulant, fibrinolytic and antiplatelet properties. Therefore this drug had significant antithrombotic effects, and prevented the thrombus formation in the organism.

E1564

IMPACT ON MOTHER AND NEWBORN OF ANTITHROMBIN III DEFICIENCY DURING PREGNANCY
D Fernandez-Jimenez[1,*], L Entrena-Ureña[1], I García-Cabrera[2], MJ Gutierrez-Pimentel[1], M Jurado-Chacon[1]
[1]Complejo Hospitalario Universitario de Granada, Granada, [2]Hospital de Santa Ana, Motril, Spain

Background: During pregnancy, the risk of suffering thromboembolic disease increases fivefold. The most significant risk factors are a prior history of thrombosis followed by the presence of thrombophilia, with ATIII deficiency associated to a greater risk of thrombosis and complications during pregnancy (including miscarriage, intrauterine growth restriction, fetal death, placental abruption, pre-eclampsia and HELLP syndrome). The ideal treatment for such women remains undefined, given that limited clinical data is available and most cases are reported on an individual basis or on a small scale. It is widely accepted that most of these patients should receive thromboembolic prophylaxis, although the dosage, duration and type of anticoagulant remains a contentious issue.
Aims: Evaluate the impact of antithrombin deficiency and the different treatments in pregnant women.
Methods: Retrospective 30-year study of pregnant women with ATIII deficiency. We analysed a total of 57 pregnancies in 21 women diagnosed with ATIII deficiency (10 due to family history, 2 due to a child having shown the deficiency and the remainder due to personal history). The average age was 29 (19-41). 4 pregnant women displayed cardiovascular risk factors (1 high blood pressure, 1 smoker, 1 dyslipidemia and the other a smoker plus sufferer of dyslipidemia) and 8 had additional thrombophilia (6 with heterozygous Factor V Leiden, one protein S deficiency and one combined homozygous factor XII deficiency and heterozygous Factor V Leiden).
Results: Of the 57 pregnant women, 2 of whom were carrying twins, 38 received no treatment as the antithrombin III deficiency was diagnosed at a later date. From this group, 22 resulted in live births, 12 miscarried, 6 suffered an intrauterine stillbirth and 2 experienced intrauterine growth retardation. In terms of maternal complications that went untreated, 2 women developed pre-eclampsia and there were 5 thrombotic events (2 pulmonary thromboembolisms, one of which with sinus-related thrombosis and 4 deep vein thromboses). As part of 6 pregnancies, patients received Acenocumarol due to a history of thromboses. 19 pregnant women received treatment: 15 low molecular weight heparin (LMWH) in therapeutic doses subject to Anti Xa control (6 received Acenocumarol previously due to a history of thromboses), 1 LMWH in intermediate doses and 3 in prophylactic doses. At the same time, ATIII 50UI/kg/72 hours was administered to 4 patients and 2 took Acenocumarol from week 12. During the peripartum period, two received LMWH, another ATIII and 13 ATIII linked to LMWH in prophylactic doses. Post-partum, 9 patients received Acenocumarol (6 having received bridging treatment via ATIII and LMWH and 3 just via LMWH) and 10 LMWH (5 of which with ATIII). From amongst the 19 pregnancies as part of which treatment was administered, 17 resulted in live births. Complications recorded included one pre-eclampsia, one miscarriage and one maternal death due to severe sinus thrombosis, all three of which occurred in patients receiving a prophylactic dose of Heparin. The only adverse effect of the treatment involved bleeding from a caesarean wound in one of the patients receiving ATIII and LMWH. 10 received an epidural with no adverse effects.

Table 1.



Summary/Conclusions: In our experience, the rate of maternal-fetal complications in patients with an ATIII deficiency is clearly higher than amongst the general population; furthermore, there is a higher number of adverse effects in the group receiving no treatment. Although in the series of cases in hand, therapy using LMWH and/or ATIII has been demonstrated as an effective and safe strategy, these patients must be subject to strict monitoring, as complications can occur throughout the pregnancy and post-partum period, particularly in the case of inadequate thromboprophylaxis. Further research is needed to establish and standardise action protocols.

E1565

REVIEW OF PATIENTS WITH CEREBRAL SINUS THROMBOSIS OVER A 7 YEAR PERIOD: SINGLE CENTRE EXPERIENCE FROM A UNIVERSITY HOSPITAL IN THE UNITED KINGDOM

I Kaddam[1,*], A Barua[1], P Gupta[2], D Chandra[1]
[1]Staffordshire Thrombosis and Anticoagulation Centre, [2]Department of Neurology, University hospital of north Staffordshire, Stoke-on-Trent, United Kingdom

Background: Cerebral sinus venous thrombosis (CVST) is a rare form of venous thromboembolism, usually affecting younger individuals. It has a wide range of clinical presentation and sometimes difficult to diagnose.
Aims: We present a retrospective review of 83 patients who were diagnosed and treated for CVST over a 7 year period at a University hospital in the United Kingdom
Methods: Electronic clinical records of all patients who were diagnosed and treated for CVST between 1st January 2008 and 31st December 2014 were reviewed.
Results: Eighty three patients (45 females, 38 males) with median age 35 years (range between 2 months - 80 years) were diagnosed and treated for CVST during this period. Headache was the most common presentation reported by 70% patients, followed by seizures (19%), motor deficit & aphasia (18%), altered sensorium (13%), confusion (7%), photophobia(6%), and cranial nerve palsy(5%). Twenty five (30%) of patients had intracranial bleed at the time of presentation. Diagnosis of CVST was confirmed by contrast head CT (14%), CT venogram (54%), contrast brain MR (16%) and MR venogram (20%). Twenty patients (24%) developed CVST during pregnancy, puerpurium or due to oral contraceptive use. Cancer (glioblastoma 1, meningioma 4, acute leukaemia 3, other cancers 8), neurosurgery (n=11), head injury (n=6) and ENT infections (n=9) were provoking factors in (50%) of the patients. No provocation could be identified in 16 patients (19%). The commonest affected site involved was the transverse sinus (62%) followed by sigmoid sinus (51%) and superior saggital sinus (44%). In over half of the patients (n=47) more than one sinus was involved with thrombosis. Patients were treated with anticoagulation (83%), hemi-craniotomy (4%), endovascular surgery (3%). No anticoagulation was given in 14 (16%) patients. After a follow-up of 24-84months, 54% of patients had a complete recovery. Residual neurologic impairment was seen in 25 patients (intracranial HT, persistent headaches, secondary epilepsy). Thirteen patients died (median age =57, range14-71 years). Cause of death was unrelated to CVST in 10 patients (progressive cancer 9; cerebral abscess 1). Adequate follow up clinical information was not available for 5 patients
Summary/Conclusions: CVST is a rare site thrombosis usually affects younger individuals and has a varied clinical presentation. Clinician should have a low index of suspicion to ensure prompt diagnosis and effective treatment. With modern management majority of patients can expect a complete recovery with no residual sequelae.

Transfusion medicine

E1566

WHAT DO FINAL YEAR MEDICAL STUDENTS KNOW ABOUT TRANSFUSION MEDICINE?

S Lovato[1,2,*], R Patel[2], J Stanger[2], A Southgate[3], A Sharif[1,3]
[1]Undergraduate education, Imperial College, [2]Haematology, [3]Undergraduate education, LNWH NHS Trust - Northwick Park and St Mark's Hospitals, London, United Kingdom

Background: Blood component transfusion is a common procedure performed among different specialities. Every year transfusion errors are reported as cause of mortality and major morbidities. To improve the safety of the procedure the staff involved have to be adequately trained. Including transfusion training in medical school can improve patient safety. In UK most medical schools undergraduate curriculum includes transfusion related topics, but there are no national survey to assess the quality of teaching or the knowledge of the students.
Aims: To investigate the knowledge of final year medical students on transfusion medicine topics and evaluate if interprofessional teaching delivered with the collaboration of a transfusion practitioner and the pathology laboratory can improve their knowledge.
Methods: Topics relevant to transfusion safety were extrapolated analysing SHOT reports. Nineteen final year medical students were offered a two hours teaching involving case based discussion, visit to the transfusion laboratory and application of the knowledge acquired through simulation. The teaching session was delivered by the local haematology teaching fellow with the help of a transfusion practitioner and the collaboration of the transfusion laboratory. Students' knowledge was tested before and after the teaching session with an open answer test.
Results: There was a significant improvement between the average score in the pre-teaching and post-teaching test (36% *vs* 73%). Topics where the difference in the percentage of students who were able to answer correctly was more evident where: patient monitoring (0% *vs* 94%), indication for irradiated products (0% *vs* 78%), blood component prescriptions (5% *vs* 100%), acute transfusion reactions (16% *vs* 94%). Improvement of knowledge was observed also for: delayed transfusion reactions (0% *vs* 44%), understanding of FFP compatibility (0% *vs* 44%) and understanding of group and save test (0% *vs* 44%), interestingly in the group that had practical teaching in the transfusion laboratory on this topic the rate of correct answer was 100%.
Summary/Conclusions: Transfusion medicine topics are covered during medical school, however when tested, this group of final year medical students were unable to answer correctly to question about essential practical aspects of the transfusion process. Improving education in transfusion medicine for medical students will help them in their future role as doctors and can improve patient safety. A short teaching session in collaboration with transfusion practitioner and transfusion laboratory was an effective way to improve students short term knowledge. Further studies are required to find the best way to improve short term and long term knowledge on transfusion medicine.

E1567

BLOOD TRANSFUSION IN CARDIAC SURGERY IS ASSOCIATED WITH WORSE PROGNOSIS

JM García-Gala[1,*], A Gonzalez-Pérez[2], E Martinez-Revuelta[1], J Zanabili Al-Sibai[3], M Argüello-Junquera[3], T Arias-Fernández[3], F García Menendez-Tevar[3]
[1]Transfusion Service, [2]Cardiac Intensive Care Unit, [3]Hematology Department, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: Transfusion has been associated with a worse prognosis in patients undergoing cardiac surgery so restrictive attitude to transfuse had been proposed.
Aims: In order to assess the impact of transfusion in patients undergoing cardiac surgery we reviewed patients admitted to cardiac ICU.
Methods: Data concerning age, sex, reason for ICU admission, type of surgery, transfusion, preoperative haemoglobin, length of stay in the ICU, ICU survival, EUROSCORE prior to surgery and extracorporeal time from patients admitted in cardiac ICU of our hospital between January 2004 and June 2014 were collected. Univariate analysis with different variables and then a logistic regression model was
Results: We analysed data from 4,315 patients (63% male / 37% female) admitted to the unit during this period. Median age of 67.88 years (0-91 years). 93% were postoperative cardiac surgery. The most common reasons for surgery were valvular surgery (34.5%) coronary surgery (28%), coronary and valve surgery (18%). 3282 of patients (76.1%) were transfused. Patients undergoing valvular surgery were most frequently transfused than those who underwent coronary surgery (77% *versus* 66%). Transfused patients had lower haemoglobin at the time of surgery than those who were transfused (12.7±1.7 *versus* 14, 51±1.33, p<0.001). Of the total patients analysed, 23.7% had Hb<12 g / dl at the time of surgery. Of these, 97% were transfused compared to 69%

who had Hb>12 g / dl (p<0.001). Patients with Hb level>12 g / dl had a survival of 95% *versus* 88% in the group with Hb<12 g / dl (p<0.001). 97% of non-transfused patients survive *versus* 88% of transfused patients (p<0.001) with a relative risk of survival of 3.87 (95% CI 2.67-5,99) within the group without transfusion. For most common types of surgery:

Table 1.

			survival		OR (IC95%) survival
coronary surgery	Transfusion	yes	94%	P < 0.001	
		no	99%		8,26 (2.12-32.15
Valvular surgery	Transfusion	yes	92%	P < 0.001	
		no	99%		20.8 (2.9-144)
Valvular + coronary surgery	Transfusion	yes	92%	P < 0.001	
		no	98%		3.83 (0.97-15)

Patients who were transfused had a shorter average length of stay in the ICU than those who were not (8.46±3.95 days *versus* 15±3.4, p<0.001)
In the logistic regression analysis, the only variable that showed significant for survival was transfusion.
Summary/Conclusions: Transfusion is associated with a negative effect on the survival of patients undergoing cardiac surgery, 24% of patients undergoing cardiac surgery have anaemia at surgery. Patients with a better hemoglobin prior to surgery have a lower risk of being transfused so it must be necessary to establish measures to improve the haemoglobin prior to cardiac surgery in order to improve outcome of this patients.

E1568

TRANSFUSION PRACTICES USED IN TERMINAL STAGE -CANCER-PATIENTS
A Argyrou[1*], A Livada[2], G Fakinos[2], A Charalambous[1], E Grouzi[2], A Gafou[1]
Blood Bank, General and Oncology Hospital "Agioi Anargyroi", [2]Blood Bank, Oncology Hospital "Agios Savvas", ATHENS, Greece

Background: Despite the increased attention to quality palliative care, dying of oncology patients often take place in the ward or intensive care unit rather than hospice and with an intensive level of medical care.
Aims: To investigate the transfusion practises for the terminally ill cancer patients as part of their medical care during the last seven days of life.
Methods: We conducted a retrospective review of the causes of consecutive deaths oncology patients who succumbed in two Oncology Hospitals between April 2015 and June 2015. Patients were categorized as: solid tumor-patients, haematological malignancy-patients and no cancer-patients. We recorded the pretransfusion tests performed for these patients (ABO grouping, detection and identification tests for unexpected alloantibodies, crossmatching), as well as the transfusion episodes per patient and the number of transfused units per transfusion episode, during the last seven days of life. X^2-test and one-way ANOVA tests were used for the statistical analysis. The number of transfused platelets corresponds to equivalent number of platelets random-donor.
Results: 211 patients [116 males (55%) and 93 females (45%)] of mean age 67 years old (range 18-92) had died during the study period. Of them, 163 (77.25%) were solid tumor-patients, 11 (5.22%) were haematological malignancy-patients and 37 (17.53%) were no cancer-patients. The number of pretransfusion tests performed and blood product units transfused, are shown in the Table.

Table 1.

	TOTAL	NO CANCER	SOLID TUMORS	HAEMATOLOGY MALIGNANCIES	p-value
PATIENTS	211	37	163	11	
PRETRANSFUSION TESTS	143 (67,7%)	17 (45,9%)	115 (70,6%)	11 (100%)	0,01
RED BLOOD CELL TRANSFUSIONS					
Patients (%)	54 (25,6%)	9 (24,3%)	37 (22,7%)	8 (72,7%)	0,02
RBC units (total)	125	18 (14,4%)	86 (68,8%)	21 (16,8%)	NS
Episodes/patient		2	1,94	2,1	NS
RBC units/patient		2	2,32	2,62	NS
RBC units/episode		1,03	1,09	1,25	NS
PLATELET TRANSFUSIONS					
Patients (%)	20 (9,5%)	0 (0%)	12 (7,36%)	8 (72,7%)	0,001
PLT units (total)	295	0	157(46,4%)	158 (53,6%)	NS
Episodes/patient		0	2,25	4,66	0,013
PLT units/patient		0	13,41	19,75	NS
PLT units/episode		0	4,66	4,26	NS
FRESH FROZEN PLASMA TRANSFUSIONS					
Patients (%)	23 (9,95%)	2 (5,4%)	17 (10,43%)	2 (18,1%)	—
FFP units (total)	122	20 (16,4%)	93 (76,23%)	9 (7,37%)	NS
Episodes/patient		3,5	2,88	2,5	NS
FFP units/patient		6	5,47	10	NS
FFP units/episode		2,9	3,02	2,25	NS

Summary/Conclusions: 1. Blood transfusion practices remained intensive in terminal stage-cancer-patients and does not seem to be different compared to non-cancer patients. 2. Patients with haematological malignancies had even more intensive transfusion practises especially regarding the platelet- transfusion- episodes. 3. Cooperation with local hospital Transfusion Medicine Committee and the Ethics Committee, and proper allocation of medical resources could result in providing the optimal end-of-life care for cancer patients. The blood is a valuable but limited source. The health services have the duty to achieve both the maximum "beneficity" by transfusing blood products to the terminally ill patients, and "justice" by not depriving other patients of necessary transfusions.

E1569

THE SHP-2/ERK2-MEDIATED SIGNALING REGULATES BRANCHED I FORMATION BY CONTROLLING THE C/EBPA BINDING TO IGNTC PROMOTER REGION IN THE ERYTHROID-DIFFERENTIATION
YC Twu[1,*], YH Lee[1,2], FL Chang[1], H Ho[1]
[1]Department of Biotechnology and Laboratory Science in Medicine, Natinal Yang-Ming University, Taipei, [2]Department of Medical Research, Mackay Memorial Hospital, New Taipei, Taiwan, ROC

Background: The straight and branched repeats of poly-LacNAc chains characterize the histo-blood group i and I antigens, respectively. In the human hematopoietic cell model, the transcription factor CCAAT/enhancer binding protein a (C/EBPa) regulates branched I antigen formation through *IGnTC* expression in both erythroid- and granulocytic-differentiation. However, the detail mechanisms for the regulation on the I synthesis along these different lineages remain unclear.
Aims: To investigate the regulatory mechanisms for branched I antigen formation during the erythroid- and granulocytic-differentiation.
Methods: The sodium butyrate (SB)- and retinoic acid (RA)-induced differentiated K-562 cells were served as the erythroid- and granulocytic-differentiation model, respectively. The wild type and mutant form of ERK2 and SHP-2-overexpressing K-562 cells were used to study the involvement of MAP kinase-mediated pathways and upstream signaling molecule in the I antigen formation. CHIP analysis was used to compare the binding affinity of C/EBPa to *IGnTC* promoter.
Results: The ERK2-mediated signaling specifically regulated the synthesis of I antigens during the erythroid-differentiation, but not for granulocytic-differentiation. SHP-2 acted as upstream regulator of ERK2 to control the phosphorylation status of Ser21 on C/EBPa, which affect the binding affinity to *IGnTC* regulatory region, and to govern the I antigen formation.
Summary/Conclusions: In this K-562 cell model when induced by SB, the SHP-2-ERK2 signaling is specific for the branched poly-LacNAc formation during erythroid-differentiation.

E1570

PEGYLATED CARBOXYHEMOGLOBIN BOVINE EXHIBITS SUPERIOR RESUSCITATIVE CAPACITY IN RODENT MODEL OF SEVERE HEMORRHAGE
R Jubin[1,*], A Abuchowski[1], P Buontempo[1], C Buontempo[1], B Song[2], W Nugent[2]
[1]Prolong Pharmaceuticals, South Plainfield, [2]Song Technologies, Baltimore, United States

Background: PEGylated Carboxyhemoglobin bovine (PEG-HbCO) is a novel biological therapy designed to release carbon monoxide and then transfer oxygen to hypoxic tissue. Prior *in vitro* cell culture and *in vivo* animal models including stroke and myocardial infarction have demonstrated the PEG-HbCO exhibits both anti-inflammatory and anti-hypoxia activities. Severe hemorrhage results in rapid hypotension and tissue hypoxia. Fluid restoration and pressors are standard of care that positively impact blood pressure and circulatory volume, but unfortunately they have minimal impact towards resolution of tissue hypoxia and systemic inflammation resulting from hemorrhagic shock.
Aims: A rat model of severe hemorrhage was developed to evaluate the effects of PEG-HbCO on cardiovascular and respiratory macro function in comparison to the colloid volume expander, Hetastarch. Additionally, microscopic measurements of microcirculation and tissue oxygenation were compared between the two resuscitative agents as well as circulating markers of inflammation and hypoxia.
Methods: Male Sprague-Dawley rats underwent a controlled 45% blood volume hemorrhage at 3.5 ml x min^{-1} x kg^{-1} through a cannulated carotid artery and were maintained in a hypovolemic, hemorrhagic shock phase for 30 minutes. Resuscitation fluids were infused at a rate of 3.5 ml x min^{-1} x kg^{-1} to a volume equal to 20% of the total estimated blood volume through a cannulated jugular vein. Systemic measurements were recorded via a cannulated femoral artery that was connected to a pressure transducer while microcirculatory parameters were collected through phosphorescence quenching and intravital microscopic examination of the exteriorized spinotrapezius muscle.
Results: Compared to baseline, the 45% hemorrhage produced a significant reduction in heart rate, blood pressure, arterial diameter and interstitial fluid oxygen partial pressure (ISF PO_2). Resuscitation with either PEG-HbCO or Hetastarch improved animal heart rate and mean arterial pressure systemic parameters towards pre-conditional baseline levels, but only PEG-HbCO -treated animals showed an improvement in ISF PO_2. The impact of improved systemic variables was evident in mortality with untreated animals (sham) expiring an hour after hemorrhage, while Hetastarch resuscitated animals expired after 4 hours. PEG-HbCO animals survived for the entire 8 hour observation period. In addition to extended survival times, PEG-HbCO animals showed steady systemic and microcirculatory parameters. Hetastarch resuscitated animals, how-

ever, developed rigor mortis in their limbs at approximately 3 hours post-hemorrhage, which was concurrent with a rapid decline in systemic variables. Additionally, only PEG-HbCO yielded reduction in hypoxia and inflammatory gene expression levels as compared to Hetastarch and sham control animals.
Summary/Conclusions: Systemic hypoxia is a major factor in trauma-related mortality and early intervention can improve survival rates. This study showed that PEG-HbCO has a unique capacity to restore macro and microcirculatory functions in addition to reducing inflammation and tissue hypoxia. Moreover, reestablishing blood pressure is acutely important for post-hemorrhage survival and restoring oxygen delivery to peripheral tissues is critical for improving long-term outcomes.

FIVE YEARS OF HEMOVIGILANCE REPORTS OF COMPLICATIONS OF THE BLOOD DONATION REPORTED AT A TERTIARY CARE CENTRE IN KARACHI

B Nepal*
Blood Bank, Dr. Ishrat ul Ebad Khan Institute of Blood Diseases, Karachi, Pakistan

Background: There is a minor chance of risk among blood donors. Even though blood donors are usually screened for the presence of risk factors, sometimes blood donations can put a person at panic.
Aims: The safety of the blood supply depends on the actions to protect both; blood transfusion recipient and the blood donor. Hemovigilance practice of learning of complications of blood donation and protecting them from such complications is the best way to minimize the risk to blood donor.
Methods: Comprehensive blood donor hemovigilance program was studied at Dr. Ishrat ul Ebad Khan Institute of blood diseases, Karachi from 2010 to 2015. Outlines of reported and communicated complications were collected after whole blood donation. Analysis was done by general logistic regression.
Results: Complications after 30,000 Whole blood donation procedures calculated 1620 total. (54 per 1,000 donations). The majority of the complications were faint and pre-faint reaction with light headedness (58.6%), Sore arm (24%), Bruises and hematoma (14.4%). Minor complications were Agitation/sweating (2%) and arterial puncture (1%). Markers of the complications were age, sex, race, weight, blood pressure and donation status. All associated independently after whole blood donation. Age and first-time status were associated with a significantly higher risk of complications with 18-22 years old at higher risk compared to 23 to 50 years old. First-time donor were at higher risk compared to repeat donor.
Summary/Conclusions: The results of this study are helpful in identifying and understanding the promoter to complication of blood donation. Donor age and status were strong predictors of complications. The remedies and specific areas of care should be provided.

E1573

A NEW METHOD FOR ACTIVATING PLATELETS IN PLATELET-RICH PLASMA TO USE IN REGENERATIVE MEDICINE: A CYCLE OF FREEZING AND THAWING

RA Çetinkaya[1], I Eker[2], S Yılmaz[3], A Ünlü[4], A Pekel[5], R Ilıkçı Sağkan[5], Z Ertaş[6], O Gürsel[2,*], HU Muşabak[5], E Yazıcı[3], S Yılmaz[3], C Açıkel[7], IY Avcı[8], F Avcu[6]
[1]Infectious Diseases, Gulhane Military Medical Faculty, Haydarpaşa Hospital, İstanbul, [2]Pediatric Hematology, [3]Blood Bank, [4]Surgery, [5]Allergy and Immunology, [6]Hematology, [7]Biostatics, [8]Infectious Diseases, Gülhane Military Medical Faculty, Ankara, Turkey

Background: Platelet-rich plasma (PRP) is a platelet-derived product, which exhibits regenerative properties and have been widely used in regenerative medicine. Platelet-rich plasma can be used with or without previous platelet activation, for what purpose is to be used. There are different ways of activating platelets. Activating platelets by freezing cycles is a new, not widely known and applied method.
Aims: The objective of the study was to assess whether and to which amount a cycle of freezing/thawing may affect the amount of growth factors in autologous platelet-rich plasma.
Methods: Fifteen ml of whole blood was obtained by venipuncture and collected in two citrated tubes from 20 healthy, male volunteer donors to obtain PRP. After preparation of PRP with standard methods, they were divided into two groups. First group was activated by adding 10% calcium gluconate to finalize PRP with volume ratio of 1:10. Second group was cryopreserved at -80°C for 24 hours. Of the obtained PRP, insulin-like growth factor-1 (IGF-1) platelet-derived growth factor (PDGF-BB), basic fibroblast growth factor (bFGF) concentrations were measures using the ELISA kit following the manufacturer's instructions.
Results: The mean platelet count of the donors and the autologous PRPs were 238,5±44,7 x 10^3 / µl and 544,7±161,5 x 10^3 / µl, respectively. Overall, there was an increase in the concentration of the insulin-like growth factor-1 (IGF-1) platelet-derived growth factor (PDGF-BB) and basic fibroblast growth factor (bFGF) after a cycle of freezing and thawing. But only the increase in PDGF levels were significant (218,90±30 and 78,95±49,42 respectively; p: 0,0001). There was not a statistically significant difference between the GF levels of freeze thawed and calcium activated PRPs. A cycle of freezing/thawing was the only independent factor associated with growth factor yield in multivariate model. In summary overall, there was an increase in the concentration of the three GFs, but only PDGF was significant. There was not a significant difference between the GF levels of post-freezed and calcium activated PRP. A cycle of freezing/thawing was the only independent factor associated with growth factor yield in the multivariate model.
Summary/Conclusions: With its features of being simple, inexpensive and easy for standardization; a cycle of freezing/thawing may be the method of choice in the future for PRP activation procedure, especially for obtaining PRPs rich in PDGF, without inducing fibrin matrix.
This study is done with the support of the Turkish Society of Hematology, with the approval number of 2014-8.

E1574

PERFORMING ELUTION TEST WITH MONOSPECIFIC ANTIHUMAN GLOBULIN UNMASKS MULTIPLE IMMUNOGLOBULIN COATING; IMPLICATIONS ON IMPROVING MULTIPLE IMMUNOGLOBULIN DETECTION SENSITIVITY IN AIHA SCREENING

Z Bezirgiannidou[1,2,*], E Kontekaki[1], S Papamichos[2], A Christoforidou[2], S Zisaki[1], K Chouchos[3], I Kotsianidis[2], D Margaritis[2], E Mantadakis[4]
[1]Blood Transfusion Center, University Hospital of Alexandroupolis, [2]Department of Haematology, Democritus University of Thrace Medical School, [3]Biomedical Engineering Department, University Hospital of Alexandroupolis, [4]Department of Paediatrics, Democritus University of Thrace Medical School, Alexandroupolis, Greece

Background: Autoimmune Haemolytic Anemia (AIHA) basic screening includes: (i) Direct Antiglobulin Test (DAT) using monospecific antihuman globulin (MAHG), namely anti-IgG, anti-IgA, anti-IgM, anti-C3c and anti-C3d, to detect the autoantibody immunoglobulin (Ig) class(es) or complement fragments on erythrocyte membrane; (ii) Indirect Antiglobulin Test (IAT) using polyspecific antihuman globulin (PAHG), comprised of anti-IgG and anti-C3d, to identify autoantibody(ies) in serum or red blood cells (RBCs) elution. Current elution techniques are valuable for allowing the identification of antibody specificity and the elimination of false positive DAT cases. The use of only anti-IgG in IAT implies that: (a) Non-IgG classes causing AIHA will be missed in elution test, rendering false negative results, (b) Elution test in AIHA caused by multiple Ig classes would allow non-IgG classes to be missed, generating misleading results.
Aims: To highlight that in DAT (+) RBCs coated with multiple Igs, DAT is not sufficient to unmask all the putative Ig classes and to suggest a method that potently unmasks multiple Ig coating.
Methods: Acid elution (DiaCidel/BIO-RAD) was performed on 59 patients' DAT (+) RBCs. The eluates were screened by IAT against a commercially available panel of RBCs (ID-DiaPanel) using PAHG Liss/Coombs gel cards (Biorad, Switzerland). An additional method using MAHG gel cards (DC-Screening I/BIO-RAD) in elution IAT was also applied. Seven patients were excluded from the study since their DAT positivity was due to alloantibodies following recent transfusion or non-specific reactions. Of the remaining 52 patients, only 21 (40.38%) fulfilled the diagnostic criteria for autoimmune haemolysis; 17 presented with AIHA and 4 with Evans syndrome. DAT positivity without haemolysis was observed in 31 (59.61%) patients, representing a random finding during pretransfusion testing.
Results: Initial screening of blood samples by DAT identified 49 warm and 2 cold autoantibodies, as well as one mixed type autoantibody. When AIHA was caused by multiple Ig classes, the use of MAHG in elution IAT allowed the identification of Ig classes that were not detected by the standard DAT. In detail, six DAT (+) and IgM (-) cases by DAT were identified as IgM (+) by elution IAT; three IgG (-) DAT (+) cases were found to be IgG (+) by elution IAT; and five DAT (+) IgA (-) cases by DAT were identified as IgA (+) by elution IAT. Overall, in 14 out of 52 cases (26.92%), the DAT missed to identify multiple Igs coating. Even though elution IAT with PAHG would identify the three IgG (-) DAT (+) cases, still 11 cases with multiple Igs (21.15%) would have been missed, a statistically significant difference (p=0.012). It is notable that 11 of the 14 missed cases (78.57%) presented with severe autoimmune haemolysis.
Summary/Conclusions: In cases of AIHA caused by multiple Ig classes, we assume that monospecific antiserums in DAT bind mainly with the dominant Ig class due to the high concentration of bound antibodies on the RBC membrane (like the prozone phenomenon). This constraint is bypassed when Igs are discarded from the RBC membrane in elution, since they are available to react with PAHG by IAT. However, the latter applies only for IgGs, since non-IgGs are not detectable by PAHG. In conclusion, we report an efficient method for unmasking non-IgGs participating in multiple Ig coating, i.e., the use of MAHG

in IAT elution. This method may have clinical implications, because AIHA is frequently severe when multiple Ig coating occurs.

E1575

BIOTINYLATION OF ERYTHROCYTES FOR CLINICAL RESEARCH

D De Back[1,*], R Vlaar[2], B Beuger[3], B Daal[4], J Lagerberg[4], D de Korte[4], M van Kraaij[5], R Bruggen[3]
[1]BCR, [2]BTT, [3]Blood Cell Research, [4]PPO, [5]UTG, Sanquin, Amsterdam, Netherlands

Background: Within Sanquin there are currently several clinical transfusion protocols in development or already realized, where the objective is to assess the efficacy and safety of erythrocyte transfusions in certain categories of patients (MDS patients, IC patients). This question arises from the fact that up to 25% of the donor erythrocytes are cleared within 24 hours after a transfusion, a phenomenon that is becoming more and more linked to side effects of transfusion in the receiver. The mechanisms that ensure that erythrocytes are cleared are to a large extent still unclear. Identification of the routes that lead to the clearance of erythrocytes are especially important for the transfusion practice.
Aims: The goal is therefore to develop a standardized labelled blood product (GMP) that can be used for clinical research and evaluation of new blood products.
Methods: The yield after transfusion is difficult to measure. Although autologous red blood cells (RBCs) have a different genetic make-up than the transfused products, it is difficult to distinguish donor from recipient RBCs. Previously, donor erythrocytes were labelled with Chromium-51, a radioactive label a procedure that is not allowed in the Netherlands. Another option is to discriminate on the basis of differences in minor blood group antigens. This, however, is laborious and not always possible. A third possibility is to label erythrocytes with biotin, also known as vitamin B8. The advantage of labelling with biotin is that different concentrations of biotin labelling can be used, allowing the detection of several RBC transfusions in 1 patient.
Results: Former studies have shown that labelling with biotin is safe, also upon multiple exposures. We found that labelling with biotin does not affect the life span or function of the RBCs, and remains stable over time, also when the erythrocyte concentrate (EC) needs to be irradiated to prevent Graft *vs* Host disease. Furthermore, labeling with different densities of biotin gives reliable identification of different populations of donor RBCs. However, about 12,5% of healthy volunteers may develop antibodies against biotin, without clinical consequences, and resolve spontaneously within a year time. Lastly, biotin can be stored in different concentrations, in bags that are compatible with blood bags, without loss of quality, and with preservation of properties.
Summary/Conclusions: Having arrived at the end of the validation study, it shows that EC that are labeled with biotin, can be produced in a standardized manner under GMP conditions, and can be used for clinical research and evaluation of new blood products.

E1576

KNOWLEDGE, ATTITUDE AND PRACTICE ABOUT THE VOLUNTARY BLOOD DONATION AMONG THE YOUNG STUDENT POPULATION OF KARACHI

B Nepal*
Blood Bank, Dr. Ishrat ul Ebad Khan Institute of Blood Diseases, Karachi, Pakistan

Background: Safe blood is a crucial and irreplaceable component in the medical management of many diseases. The Voluntary non-remunerated blood donation is the ideal sources of quality blood, which forms less than 15% of the demand of the blood in Pakistan. Motivation among the youth, particularly students, is essential to make voluntary blood movement more successful.
Aims: To assess the knowledge, attitude and practice regarding the voluntary blood donation among the young student population of Karachi so that an effective approach can be made regarding motivation enrollment of voluntary non remunerated blood donors in future in Pakistan
Methods: A cross sectional prospective study was conducted among 600 students from different universities and colleges of Karachi. A well-structured and pre-tested questionnaire, in English, was used to access the knowledge, attitudes and practices about voluntary blood donation. A scoring mechanism was used to understand overall knowledge level. The participants were given a briefing about the objectives of the study and confidentiality about the personal data. Obtained data was analyzed by using statistical package of social sciences (SPSS) version 17.0 in computer. Statistical significance level was set at p=0.05.
Results: The sample population consisted of 54% male and 46% female students in the age group of 18-28 years. Only 65% of the students have heard about voluntary blood donation and 28% of the students have given blood once in their lifetime and among them 19% are blood donors at the moment. 42% of the participants believed that there is a specific reason why they don't donate blood and 59% believed that there is a risk involved for the donors, when donating blood. 80% students wanted to promote voluntary blood donation. Fear and lack of awareness on blood donation are the reasons for not donating blood. Students gather information about voluntary blood donation from several sources mostly schools, colleges, family and friends.
Summary/Conclusions: This study showed that myths and misconceptions are leading the youngsters not to donate blood. Study also showed how increasing awareness and marketing through different ways can boost the culture of voluntary blood donation in society. Student population can be motivated to participate in different ways. There is a dire need to mobilize the electronic media for educating our youth about voluntary blood donation due to its access to masses.

E1577

CURRENT STATUS OF INCIDENTS CAUSED BY HEMOSIDEROSIS IN PATIENTS WITH HEMATOLOGIC DISEASES: RESULTS FROM SPANISH HAEMOVIGILANCE SYSTEM

P Romero García, E Morente Constantin, MDP Garrido Collado, MA García Ruiz*, M Jurado Chacón
Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The Blood Safety System (Haemovigilance - HV) enables to collect and analyze incidents related to donation, preparation of blood components and transfusion. The purpose is to know the complications and adverse reactions occurred during the transfusion process, to establish effective control measures that can prevent these events. HV should cover the entire transfusion chain. Among transfusion-related complications, the Hemosiderosis is an incident characterized by a very low level of reporting. We have analyzed Hemosiderosis at national state and inside our CCAA (Andalusia). Post-transfusion hemosiderosis is a frequent complication of hematologic diseases, as well as part of their treatment. It is defined as the accumulation of iron in organs and tissues in patients who are receiving regular transfusions of packed red blood cells. Malignant hematological diseases will require regularly transfusions, iron overload, therefore, will be a common side effect in these patients. It is directly related to the number of transfusions received. After transfusing 10 bags, iron is deposited in tissues, after 20, the risk of developing a secondary hemochromatosis increases.
Aims: We intend to investigate the percentage of hemosiderosis reports to the Spanish Haemovigilance system. In the European Union, there are various HV systems, to note: French Haemovigilance system: Is governmental, with a complex structure, notification of all adverse effects and mandatory reporting. English Haemovigilance system (SHOT): notification of serious adverse effects and voluntary reporting. Spanish system (HV): a simpler structure model, voluntary reporting of adverse events and reactions. Notifications are virtually nonexistent except in the French system. Although reporting of post-transfusion hemosiderosis is mandatory in the French haemovigilance network since 1994, existing data is limited.
Methods: We reviewed the transfusion incidents caused by iron overload which have been reported to the Spanish HV system and the Andalusia HV system of, comparing them with the ones notified by our hospital from 2013 to 2015 and their underlying hematologic diseases. Cases in Spanish HV system: 2007: 3. 2008: 15. 2009: 10. 2010: 10. 2011: 16. 2012: 10. 2013: 88. Andalusia: 2007-2012: 0. 2013: 71. (Figure 1).
Results: In 2013 we identified 57 cases, 32 men and 25 women, from 20 to 87 years old, average of 56, who have been transfused with packed red blood cells. The results vary from 10 CH to 73 CH transfused (average of 25 CH per patient). Postransfusional ferritin levels were over 1000 mg/l (average of 2869 mg/l). In 2014 we have notified 76 cases, 50 men and 26 women, from 24 to 83 years old) (average of 56). The number of CH transfused varied from 10 to 130 (average of 31 CH). The number of post-transfusion ferritin ranged between 1,041 and 15,190 mg/l. In 2015, 42 cases have been reported: 18 women and 24 men, between the ages of 17 and 81, with an average of 51 years old. The number of CH transfused ranged from 10 to 107 (average of 33.3 CH). Post-transfusion ferritin ranged between 1.274 and 8.858.4 mg/l. Firstly, the largest number of hyperferritinemia cases was found in patients with acute myeloid leukemia. Secondly, in patients with monoclonal gammopathies found. And thirdly, in patients with non-Hodgkin lymphoma. Other diagnoses were myelodysplastic syndrome, chronic lymphocytic leukemia etc. (Figure 2).

Figure 1.

Summary/Conclusions: The most frequent cause of hemosiderosis secondary to transfusion in our hospital has been acute leukemia, with a predominance of acute myeloid leukemia over acute lymphoblastic leukemia. It is very important to properly track ferritin levels in patients undergoing multiple transfusions in order to establish chelation therapy when necessary and to prevent the organic damage of secondary hemochromatosis. In the results published by the Andalusian HV system in 2013, we can highlight the increase of notifications

of post-transfusion hemosiderosis to the Hemovigilance system, as well as the increasing number of near-miss reported in 2013. This is valued as an improvement in the notification of such events. Communication of Hemosiderosis cases to the Hemovigilance System helps to create protocols for polytransfused patients because of hematologic diseases. Hemovigilance in Spain is, today, a fully integrated tool within the activities carried out by Transfusion Hospital Centers and Services. Among the remaining challenges we highlight: Getting a more uniform level of notification and to Advance in the optimal use of blood and blood components: safe, effective and efficient.

E1578

USE OF OCTAPLASLG IN THE TREATMENT OF THROMBOTIC MICROANGIOPATHIES (TMA)

S McGuckin*, C Vendramin, F Alwan, JP Westwood, M Thomas, M Scully
Department of Haematology, University College London Hospital, London, United Kingdom

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare and acute disorder and plasma exchange (PEX) remains the life-saving therapeutic procedure in patients with TTP and other thrombotic microangiopathic anemias (TMA). OctaplasLG (Octapharma), a virally inactivated prion reducing plasma, has replaced the Solvent-Detergent Fresh-Frozen Plasma (Octaplas®; Octapharma) to improve the safety of plasma.
Aims: Aim of this study was to assess safety of OctaplasLG administration for patients undergoing PEX.
Methods: We performed a prospective study of 90 patients, treated with PEX for TMAs from a single institution over a 36 month period, January 1st 2013-December 31st 2015. We recorded: virology on admission and in remission for all patients, allergic reactions to plasma, citrate toxicities associated with PEX, venous thrombotic events (VTE) rates and incidence of central venous access (CVA) line sepsis (which can result in exacerbation of TTP).
Results: Over the 36-month period, a total of 981 PEX procedures were performed (median 9, range 0-37). 62 patient episodes were TTP: 45 females (median age: 47 years; range: 15-89) and 17 males (median age: 49 years; range: 21-79); 51 patient episodes were De Novo presentations (43 idiopathic, 5 HIV, 1 Congenital and 2 Pancreatitis) and 11 were relapsed presentations. 17 patient episodes were HUS / aHUS, of which 12 females and 5 males. 11 patient episodes were 'Other TMAs' (8 females and 3 males). Citrate toxicity was 5.3% of PEX, (facial and limb tingling). Plasma reactions were 1.7% of PEX (hives and facial swelling) relieved by anti-histamines. No episodes of anaphylaxis and no TRALI were reported. Two cases of line associated sepsis were recorded and 11 cases of VTE were diagnosed (5 PE; day of PE (range): 5-35; platelets count (range): 35-228; 6 DVT; day of DVT (range): 6-43; platelets count (range): 86-264). Virology was checked for all patients. On admission for Hepatitis B they were subdivided into different groups: 57 patients had no evidence of infection or immunisation, 12 patients had evidence of previous immunisation and 9 patients had previous evidence of Hepatitis B infection. No viral transfer was documented following treatment. HCV Ab on admission: 89 negative, 1 positive. There was no antibody transfer post treatment. Pre PEX HIV: 5 positive, 85 negative. No seroconversion was detected post treatment.
Summary/Conclusions: Citrate toxicities are reduced in severity, likely due to shortened PEX with the Optya. Reactions with Octaplas remain minimal, with no severe anaphylaxis noted. VTE events, despite prophylactic LMWH starting when platelets are >50x10^9/L, occurred in 12% of cases, with 50% completed PEX when VTE was recorded. Adherence to our CVA line policy has resulted in a further reduction to our line related infections. In plasma high volume users, virology is important on admission to establish viral profile of the patients and in the follow-up for checking eventual infectious transmission. To date no viral transfer or antibody transfer or seroconversions were reported post treatment, likely due to safety of OctaplasLG.

E1579

DRUG-INDUCED IMMUNE HEMOLYTIC ANEMIA ASSOCIATED WITH ROMIPLOSTIN

HJ Campo Palacio*, A Salamanca Cuenca, C Blazquez Goñi, MA Correa Alonso
Haematology, Hospital Jerez de la Frontera, Jerez de la Frontera, Spain

Background: Drug-induced immune hemolytic anemia (DIIHA) is a rare condition with an estimated incidence of about one per million patients per year. The exposure to a specific drug induces a sudden drop in circulating red blood cells (RBCs). Many drugs have been implicated in causing red cell (RCBs) destruction, with the most common being second and third generation cephalosporins. The initial serologic presentation is not fully appreciated, causing the disorder to be underdiagnosed. Romiplostim is a thrombopoietin receptor agonist approved for adult patients with chronic immune thrombocytopenic (ITP) who have been refractory to other treatments. It has also been used in some hyporegenerative thrombocytopenia cases. Here we report the case of a patient who gradually developed DIIHA with Romiplostim-related antibodies
Methods: CASE REPORT: A 67-year-old female was diagnosed with acute myeloid leukemia in February 2014. She received induction chemotherapy (QT) with Idarubicin and Cytarabine (3+7) achieving complete remission (CR) without hematological recovery. Persistent pancytopenia did not allow consolidation QT. In June 2014, she initiated erythropoietin (EPO) and Romiplostim treatment. EPO was suspended two months later and Romiplostin dose, which had come to 4 µg/kg/week was reduced to 0.5 µg/kg/week, keeping platelets count >100 X 103/µL. Subsequent bone marrow aspirations confirmed maintained complete remission. In October 2015, hemoglobin (Hb) concentration was 12.8 gr/dL (normal range 13.5-16.5 gr/dL) and platelets count 133 x 103/µL (normal range 130-400 x 103/µL). Four weeks later the patient referred asthenia. Laboratory tests showed Hb 9.7gr/dl. We ruled leukemia relapse and discontinued romiplostim. Ten days after last dose of romiplostim, laboratory analysis was notable for the following: Hb 10.2 gr/dl, reticulocytes 9.3%, LDH 513 mg/dl, bilirrubin 0.63 mg/dl and haptoglobin 117 mg/dl. Peripheral blood smear showed anisocytosis, polychromasia and spherocytes. Based on her clinical history and laboratory evaluation there was a high suspicion of a potential inmune hemolytic process. Serologic findings showed a strong positive DAT with polyspecific antiglobulin sera (3+) and monospecific anti-C3d sera (2+), being negative with monospecific anti-IgG sera. Eluate with group O RBCs was nonreactive and IAT (indirect antiglobuling test) was negative. Cold agglutinin anti-I was detected in patient´s plasma, titer 32 and thermal activity<20ºC. Patient´s plasma was strong reactive (2+) with romiplostin-treated RBCs (ID-Card LISS/Coombs, BIORAD). Eluate reacted weakly with romiplostim treated RBCs but did not react with the untreated RBCs. Both of them, plasma and eluate, were non reactive with saline-suspended untreated RBCs. After discontinuating the drug, Hb concentration and reticulocyte count were normalized. At the present time, her Hb concentration is 13.5gr/dl and DAT is negative.
Summary/Conclusions: This case highlights the importance for clinicians to maintain high index of suspicion for DIIHA in patients with unexplained hemolysis. It is also important to provide of specialized serological testing to clarify the suspected diagnosis. Romiplostim should be considered as a possible risk factor in development of immune hemolytic anemia. To our knowledge, this is the second report that implicates Romiplostim as a drug inducing DIIHA, being the other one in a patient with ITP.

E1580

ANALYSIS OF DATA CONCERNING PLATELET TRANSFUSIONS DURING A TWO-MONTH PERIOD IN A TERTIARY CARE HOSPITAL

V Voulgaridou*, F Girtovitis, E Ntinopoulou, V Bakaloudi, A Konstantinidou, M Pape, M Chatzikyrkou, O Perperidou, E Hassapopoulou-Matamis
Blood Center, AHEPA University General Hospital, Thessaloniki, Greece

Background: Blood Centers should constantly evaluate their policy, get informed about the impact it has in clinical practice and eventually reinforce or modify some attitudes. Platelet transfusions are a subject of controversy concerning the importance of ABO matching, of providing single donor platelets rather than random donor etc.
Aims: The purpose of our study was to analyze data on all platelet transfusions performed in our Institution, in order to draw information about the age of the patients, the type, the blood group and the age of the platelet units issued.
We ultimately wanted to examine to what degree the current practice conformed to the principles of our Blood Center, concerning ABO and Rhesus blood group matching, administration of plateletpheresis units (SDPs) rather than random donor platelets (RDPs), issue of units as fresh as possible, avoiding outdating.
Methods: Having defined as one «transfusion event» the administration of one or more platelet units in a 24-hour period for each patient, we registered all platelet transfusion events in our Tertiary Care Hospital in the two month period May-June 2015. For each patient transfused, we registered the age (in order to separate to two categories: adults and pediatric) as well as the type (SDP or RDP) and the «age» of the units. Differences in the ABO and Rh group between the patients and the platelet units they received, were registered and analyzed.
Results: In the two-month period 258 platelet transfusions were performed, 198 in 38 adults (27 men and 11 women, aged 63±17 years) and 60 transfusions in 10 children (5 boys and 5 girls) aged 6,9±2,4 years. In total, 1482 platelet units were administered, of which 1438 RDPs and 44 SDPs. The adults were given SDPs in 9.09% of the transfusion events (18/198). In the remaining transfusion events 1285 platelet units from random donors were administered, in average 7.5±1.98 units per adult patient. The children were given SDPs in 43.33% of the transfusion events (26/60) and RDPs in the remaining transfusion events, with an average of 4.5±1.4 units per child. All SDPs were of ABO and Rh group identical to the patients', while 31,7% of RDPs were of different ABO group. The following table shows how fresh the platelet units were. In the same 2-month period, disposal of 137 out of 1619 platelet units produced, was registered: 136 (8.4%) RDPs and 1SDP (0.061%). 79/137 RDPs and 1 SDP were destroyed due to expiration, 14/137 due to positive serologic and/or molecular testing, 11/137 due to confidential unit exclusion (CUE) and 32/137 RDPs due to other reasons.

Table 1.

Day since the unit was produced	1st day	2nd day	3rd day	4th day	5th day
Units from random donors (n=1482)	475 (**32.05%**)	446 (**30.09%**)	256 (17.27%)	222 (14.98%)	83 (5.6%)
SDPs (n=44)	15 (**34.09%**)	10 (**22.72%**)	6 (13.63%)	7 (15.9%)	6 (13.63%)

Summary/Conclusions: The strategy of the Blood Center to provide platelet units of identical ABO blood group to the patient's, was accomplished 100% in the case of SDPs, but only in 68.2% of the transfusion events during which RDPs were administered. The already satisfactory percentage of «fresh» units (more than 2/3 of units administered, were less than 3 days old) can probably be further improved. It is advisable to investigate whether it would be helpful to increase the proportion of SDPs for adults, at least to the same extent as for pediatric patients. With better planning and better collaboration with the other Blood Centers, the number of units outdated could be minimized.

E1581

ASSESSING THE OUTCOMES OF PATIENTS FOLLOWING GRANULOCYTE TRANSFUSION

D Rodger[1], O Varsou[2], R Soutar[2,*]
[1]University of Glasgow, [2]SNBTS, Glasgow, United Kingdom

Background: The use of granulocytes in transfusion medicine is not a new concept. Despite continual advances in the process and over half a century of recorded use in clinical practice, the efficacy of these blood products continues to be the subject of much debate. Authors worldwide have reported differing results regarding the outcomes of patients following such transfusions and our understanding of the clinical course of patients receiving transfusions today is largely at the same level as the original pioneers in this field.
Aims: The aim of this project was to assess the use of granulocyte transfusions in the West of Scotland in recent years and evaluate the outcomes of the patients who received these transfusions.
Methods: A retrospective single-arm case series study was carried out with the data being collected for the time period between January 2012 and October 2015.
Results: In total, 20 patients (10 [50%] women and 10 [50%] men) were included. Granulocyte transfusions were discontinued in 8 patients (40%), as there was clinical improvement. This included the patients requiring granulocytes for: severe neutropenia with a non-healing dental extraction (deceased due to end stage AML); severe neutropenia with an infected haematoma (deceased with cause unknown); neutropenic sepsis (alive); pancytopenia (alive); pneumonia (alive); peri-anal abscess (alive); necrotising fasciitis (alive); and lung fungal infection (alive). Eight patients (40%) also deteriorated and for this reason the granulocyte transfusions were stopped. This included the patients that required granulocytes for the following reasons: two patients with neutropenic pyrexia (both deceased with the cause of death being respiratory failure for one patient and a chest infection refractory to treatment for the other patient); severe neutropenia with pericarditis and a fungal infection (deceased due to neutropenic sepsis); neutropenic sepsis (deceased due to neutropenic sepsis); neutropenic sepsis with lung abscess (deceased from chest infection that was refractory to treatment); pancytopenia (deceased due to haemodynamic instability); nasal sinus fungal infection (deceased from neutropenic sepsis); and *Klebsiellaoxytoca* sepsis (deceased due to respiratory failure). Interestingly, from the patients that deteriorated the following pathogens were noted in microbiological testing: *Amoeba* (querying *Acanthamoeba*), throat and sputum *Candida*, heavy yeast growth, *Klebsiellaoxytoca*, and *Pseudomonas aeruginosa* along with *Staphylococcus hominis* in the blood. When comparing the above two groups (i.e. 8 patients showing clinical improvement *versus* 8 patients deteriorating), the median age was 40 years (IQR=47.5; minimum age=2; maximum age=64; 6 women [75%]; 2 men [25%]) for the patients that improved and 60 years (IQR=39.25; minimum age=0.92; maximum age=66; 2 women [25%]; 6 men [75%]) for the patients that deteriorated.
Summary/Conclusions: The data confirms the variable outcomes in patients receiving granulocyte transfusions. However those patients who showed clinical improvement were noted to be younger than those who deteriorated while there was also a discrepancy between the sexes with women typically having better outcomes than men. Atypical organisms were also associated with poorer outcomes suggesting a multifactorial cause for a less successful outcome. Although this is a non-randomised study the patient outcomes are encouraging considering their clinical severity. We therefore continue to use granulocyte transfusions derived from Buffy coats in these situations.

E1582

THE USE OF ERYTROCYTE-APHERESIS FOR THE TREATMENT OF HEREDITARY HEMOCHROMATOSIS: OUR EXPERIENCE

A Bruzzese[1,*], A Bruzzese[2], R Forgione[3], P Orlando[3], V Bruzzese[3]
[1]Dipartimento di Biotecnolgie ed Ematologia, Università "La Sapienza", Roma, [2]UOC Nefrologia e Dialisi, Policlinico Universitario, Messina, [3]U.O. Emodialisi, ASP 5 RC, Taurianova, Italy

Background: The erytrocyte- apheresis has proved advantageous for the treatment of patients with hereditary hemochromatosis (HH) and iron overload, rather than the traditional "bloodletting", allowing a less frequent treatment and more personalized. It would lead to a greater decrease in serum ferritin for single treatment procedure, without a major reduction in Hepcidin. This may be clinically relevant, being able to prevent an increase in intestinal iron uptake and a vicious circle resulting in the need for frequent treatments. The accessibility to the method, however, is hindered by the lack of access to the extracorporeal circulation, required to achieve it.
Aims: To facilitate access of the erytrocyte- apheresis to a population of subjects suffering from hemocromatosis, we made available the expertise in the field of extracorporeal circulation, the staff of a hemodialysis center. After an activity of about 10 years, we have conducted a retrospective observational study, comparing with some parameters, subjects undergoing erytrocyte-apheresis with a control group that continued to be subjected to bloodletting.
Methods: Over a period of 10 years, we treated, 37 patients with hematological diagnosis of hereditary hemochromatosis with erytrocyte- apheresis. We have selected among the patients with the same diagnosis that continued to be subjected to bloodletting, a "control" group of 38 patients with similar nosographic characteristics. The retrospective assessment has been focused on the following parameters: hematocrit, levels of blood ferritin, number of treatment procedures, length of intervals between a treatment and another. We also evaluated the costs of treatment.
Results: The mean number of treatment / year procedures was significantly lower for patients treated with erytrocyte- apheresis compared to those treated with bloodletting. The average time interval between two consecutive treatments is a result of 2.3 times longer for the erytrocyte- apheresis compared to bloodletting. The interval between two consecutive procedures of erytrocyte- apheresis has shown a tendency to a progressive increase in the longer time interval of time between a drain and the other. The average annual cost of treatment with erytrocyte- apheresis was about twice compared to those of bloodletting.
Summary/Conclusions: The erytrocyte- apheresis reduced, in our experience, significantly the number of treatment procedures rather than the bloodletting. We believe that, where there is easily available the acces to the extracorporeal circulation for cell separation, the erytrocyte- apheresis procedure could become the treatment of choice for patients suffering from hemochromatosis.

E1583

THE OUTCOME OF PREOPERATIVE TRANSFUSION GUIDELINE ON SICKLE CELL DISEASE PATIENTS AT KING FAHD HOSPITAL-JEDDAH (KSA)

DS Felemban[1,*], A Qadi[2], R Chatterjee[3], R Bajoria[4]
[1]Blood bank and transfusion medicine, [2]Medical Department, King Fahd Hospital Jeddah, MOH, Jeddah 21472, Saudi Arabia, [3]MSc in Haemoglobinopathy, [4]Director of MSc in haemoglobinopaty, institute for women's haelth, London WC1E 6HX, United Kingdom

Background: We have developed a local hospital preoperative transfusion guidelines for sickle cell disease (SCD) patients to reduce the perioperative and the postoperative complications.
Aims: This study was conducted to evaluate the outcome of practice on SCD patients undergoing surgeries in our institution.
Methods: A retrospective review of 75 SCD patients undergoing surgery at King Fahd Hospital, Jeddah, Saudi Arabia was conducted between April 2005 and May 2010. The medical records were reviewed to define the perioperative risks and the postoperative complications in relation to the type of transfusion modality selected.
Results: The medical record of 75 SCD patients who undergoing surgeries were reviewed. Preoperatively, 25.3% had complete exchange transfusion (CETX), 17.3% had partial exchange transfusion (PETX), 26.7% had simple top up transfusion (STX) and 30.7% had no transfusion (NTX). The postoperative complications were 20% vaso-occlusive crises (VOC), 2.7% acute chest syndrome (ACS), and 16% had fever. There was 33.3% patients with prolonged duration of the hospital stay. There was no significant difference in the outcome of postoperative fever, VOC, ACS, and the length of hospital stay between all types of transfusion modalities. However, The correlation was highly significant between the pre-operative haemoglobin (Hb) level and postoperative fever (P=.001) and VOC (P =.002). Interestingly, SCD patients who received hydroxyurea were observed to have less postoperative complication like fever (P=.015) and vaso-occlusive crises (P=.011), while those who received prophylactic heparin in the postoperative period were found to have a reduced length of hospital stay (P=.005) and vaso-occlusive crises (P=.001).
Summary/Conclusions: The guidelines for preoperative transfusion in SCD patients was effective in reducing the postoperative morbidity and mortality. However, this guidelines establish the surgical situations where preoperative transfusion is needed and the optimum regimen for different surgical types.

E1584

FREQUENCY OF REACTIVE BLOOD DONORS IN A TERTIARY CARE HOSPITAL, KARACHI, PAKISTAN

B Nepal[*]
Blood Bank, Dr. Ishrat ul Ebad Khan Institute of Blood Diseases, Karachi, Pakistan

Background: Human Immunodeficiency Virus (HIV), hepatitis C virus (HCV), and hepatitis B virus (HBV) are blood-borne viruses and share transmission routes among at-risk populations, specifically injection drug use and remote blood transfusions before modern donor screening for these pathogens, making co-infection common. Morbidity and mortality from infection with HCV in HIV-infected patients are increasing and have become a major challenge in the management of such patients. In recent years, number of patients infected with HBV or HCV or HIV or co-infected with either of the two viruses, has increased tremendously in Karachi population. IDUs (intravenous drug users), MSM (Men who have Sex with Men) and individuals having unsafe sex are among the people who are identified as groups at higher risk of contracting these infections than others. But these studies does not give an exact picture of prevalence and frequency of these infection in Karachi's population as focus of most of these studies were individuals already involved in behaviors (intravenous drug use and unsafe sex) regarded as high risk behaviors.
Aims: To find the frequency of different types of reactive healthy blood donors at a tertiary care hospital, Karachi, Pakistan.
Methods: The retrospective observational study carried out on both male and female healthy blood donors. Data from complete blood screening from January 2013 to December 2014 were collected and frequency of various types of reactive blood donors was sorted out to get an actual picture. All the blood products were screened for HBV and HIV Using enzyme linkedimmunosorbent assay (Elisa plate washer version 3 and Elisa plate reader stat fax 3200). HCV screening was performed on Architect 2000 SR Chemiluminescent micro plate immune assay (CMIA). Malarial parasite tested by making thick and thin smear seen under microscope. Syphilis was tested by ICT method.
Results: A total number of 6996 healthy donors were received and about 624 were found to have blood screening positive in various combination. The highest numbers of isolates was HbsAg reactive 214, HCV 213, VDRL 170, HIV 26 and 1 case of malarial parasite. More prevalent in male population. In this study there were seven donors found with HCV –VDRL co infection and five co infected with HCV and HbsAg two donors with HIV and HbsAg infected and two donors were HbsAg and VDRL reactive.
Summary/Conclusions: This study supports that HBV, HIV and syphilis prevalence is high and HIV prevalence is low in healthy blood donors.

E1585

MASSIVE TRANSFUSION IN SON ESPASES UNIVERSITY HOSPITAL FROM 2010 TO 2015: A SINGLE CENTRE EXPERIENCE

S Ruiz*, A Perez, L Garcia, A Gutierrez, A Sampol
Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain

Background: The definition of massive transfusion (MT) is the need of at least 10 packed red blood cells units (PRBCs) in 24 hours in response to a situation of uncontrolled bleeding. However there is still no consensus for the clinical management of these situations.
Aims: The aim of this study was to analyze the events of MT in our center and variables associated to mortality within 24 hours and 30 days after MT.
Methods: The records of the Transfusion Service of the Son Espases University Hospital were retrospectively reviewed for cases of patients who required at least 10 PRBCs units within 24 hours during the period of 2010-2015. Their demographic and clinical-biological data were collected.
Results: A total of 93 episodes of MT were identified between 2010 and 2015. The median age of patients was 56 years (15-88) with 69 (74%) males and 24 (26%) females. Descriptive consumption data were: total units transfused in our MT cases were 1444 PRBCs, 537 plasma units and 233 pooled platelets. Median transfusion counts were 13 (10-36) PRBCs, 6 (0-14) plasma units and 2 (0-9) pooled platelets. Median ratio PRBCs/plasma and ratio PRBCs/platelets were 2.7 (1.1-14) and 6 (1.3-23), respectively. We analyze the influence of various variables related to survival at 24 hours and 30 days of the MT. Mortality at 24 hours and 30 days of MT were respectively 28% and 38%, with no differences according to sex (p=NS) or age (p=NS). However these mortalities were significantly higher in politrauma patiens (46% and 43%) compared to aortic pathology (30% and 37%) and other causes (23% and 20%) (p=0.046 and p=0.007), for mortality at 24 hours and 30 days respectively. Variables significantly influencing mortality at 24 hours and 30 days were the number of PRBCs (p=0.008 and p=0.015) and the ratio of PRBCs/plasma transfused (p=0.003 and p=0.049), respectively. Median number of transfused PRBCs was respectively 13 (10-30) and 16 (10-36) for patients surviving and non-surviving after 24 hours and 30 days. Median PRBCs/plasma ratio was respectively 2.5 (1.1-14) and 3.9 (1.5-9) for patients surviving and non-surviving after 24 hours and respectively 2.55 (1.2-14) and 3.3 (1.1-13) for patients surviving and non-surviving after 30 days.
Summary/Conclusions: The MT is accompanied by high mortality rates and involves a high consumption of blood components. In our series, we found an increased mortality in the first 24 hours and in the first 30 days, in patients receiving higher number of PRBCs and with higher PRBCs/plasma ratios. It would be necessary to establish protocols for massive transfusion in each center to unify treatment criteria and optimize the ratio PRBCs/plasma.

E1586

CLINICAL EFFECTS OF CHRONIC RED BLOOD CELL EXCHANGE AND DIFFERENT TYPES OF RED CELL CONCENTRATES IN PATIENTS WITH SICKLE CELL DISEASE

S Cabibbo*, C Fidone, V Spadola, G Garozzo, A Antolino, O Manenti, M Poidomani
Immunohematology and Transfusion Medicine Service, ASP 7, Ragusa, Italy

Background: For patients with severe SCD not eligible for hydroxyurea, two major therapeutic options are currently available: blood transfusion, and bone marrow transplantation. Either urgent or chronic red blood cell transfusion therapy, is widely used in the management of SCD but determines a progressive increase of ferritin level and is also limited by the development of antibodies to red cell antigens. The introduction of chronic red blood cell exchange and prestorage filtration to remove leucocytes and the use of techniques for multicomponent donation could be a good solutions.
Aims: Thus, the aims of our studies were to evaluate the clinical effects of the different blood components in terms of annual transfusion needs and the intervals between transfusion, moreover we evaluated the efficacy of chronic red blood cell exchange (manual or automatic with cell separator) in preventing SCD complications and limiting iron overload.
Methods: In our center we follow 78 patients affected by Sickle Cell Disease. We selected 36 patients occasionally treated with urgent red blood cell exchange because they had less than 2 complications/Year**,** and 42 patients regularly treated with chronic red blood cell exchange because they had more than 2 complications /Year with Hospital Admission. Moreover among these we selected 10 patients for fulfilling the criteria of continuous treatment at the Centre for at least 48 months with no interruptions, even sporadic and absolute transfusion dependency. All 10 patients were evaluated for a period of 4 years, during which two different systems of producing RCC were used. In the second two the patients were transfused with RCC obtained from filtering whole blood prestorage or with RCC from apheresis filtered prestorage. These products differed from those used in the preceding two years, during which the leucodepletion was obtained by bed-side filtration
Results: For all the patients we performed 782 automatic red blood cell exchanges and 4421 units of RCC were transfused. The exchange procedures were extremely well-tolerated by the patients and adverse effects were limited to symptoms of hypocalcaemia during automatic red blood cell exchange with cell separator. After every red blood cell exchange we obtained HbS level<30%. The10 patients selected received respectively a mean of 6.9 and 6.1 units of RBCs exchanged per automatic procedure, in the first two years and in the second two years. Alloantibody developed in 14 patients but only 2 clinically significant and about the observed frequency of transfusion reactions it was very low. All patients treated with chronic red blood cell exchange had an improvement of the quality of life with a reduced number of complications/year (<2/year) and good compliance and moreover patients had limited iron overload making chelating therapy easier.
Summary/Conclusions: In conclusion this study was focused on the most suitable characteristics of blood components for use in sickle cell disease patients and the choice of systematically adopting *prestorage filtration of whole blood*, enabled us to have RCC with a higher Hb concentration than standard. Moreover chronic manual or automatic red blood cell exchange as an alternative approach to simple long-term RBC transfusions give many advantages by being more rapid and tolerable as well as clinically safe and effective and minimize the development of iron overload especially when procedure was carried out with an automatic apparatus. To note that the clinical advantages for patients derived from good selection of the donor and good practices in the production of the blood components.

E1587

FREQUENCY OF RED CELL ANTIGENS AND ANTIBODIES IN THE POPULATION OF NORTH-EASTERN REGIONS OF RUSSIAN FEDERATION

E Butina*, G Zaitseva, T Koryakovtseva, A Karavaeva
Immunogematology, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: Providing immunological compatibility of donor and recipient can prevent the development alloimmunization, the occurrence of hemolytic transfusion reactions and increase the effectiveness of transfusion therapy. The frequency of red blood cell (RBC) antigens and alloantibodies is different in populations from different races and geographic areas.
Aims: To study the frequency of Rhesus phenotypes and RBC alloantibodies in donors and recipients of blood components residing in north-eastern regions of the Russian Federation.
Methods: Data from 8087 donors and 2648 patients with hematological diseases were analysed in 2009-2015. Research blood samples was carried out by erythrocyte-magnetized technology (Diagast, France) and gel agglutination assay (BioRad, USA).
Results: Established following frequency of Rhesus phenotypes: CcDee -

30.35%, CCDee-19.39%, CcDEe-15.88%, ccddee-15.34%, ccDEe-13.00%, ccDEE-3.24%, ccDee-1.72%, Ccddee - 0.90%, ccddEe-0.07%, CCddee-0.05%, CcDEE-0.05%, CCDEe-0.02%, CCDEE-0%, CCddEE-0%. The incidence of RBC antibodies in blood donors is very low (0.49%) compared with the incidence in patients with hematological diseases, who received transfusion therapy (1.93%) ($p<0.01$). The most common specificities of antibodies in donors were anti-D (0.22%), in recipients - anti-E (0.3%), anti-K (0.26%), anti-D (0.23%). Differences in the frequency of anti-E and anti-K antibody in donors and recipients are significant ($p<0.01$) (table).

Table 1. Frequency and specificity of RBC alloantibodies in blood donor and patients with hematological diseases

Specificity of RBC alloantibodies	Frequency of RBC alloantibodies (%)	
	donors	patients with hematological diseases
D	0.21	0.23
DC	0.02	0.08
C	0.01	0.08
c	0	0.08
E	0.05	0.30*
C*	0.02	0.04
K	0.02	0.26*
M	0.02	0.11
Le^a	0.02	0.11
Le^b	0.02	0.08
Lu^a	0	0.08
Fy^a	0	0.04
Fy^b	0.01	0
Jk^b	0.01	0

** - The differences between the groups of donor and patients were significant (p <0.01).*

Summary/Conclusions: In the population of north-eastern regions of Russian Federation the most frequent phenotypes CcDee, CCDee, ccddee, CcDEe and anti-D, -E, -K alloantibodies. Analysis of immunohematological parameters of donors and recipients allows targeted collection, banking and storage of blood components.

LB2272

SEROLOGICAL AND MOLECULAR CHARACTERIZAZATION OF RHD VARIANTS

B Foglieni[1,*], L Raffaele[1], I Guarnori[1], M Spreafico[1], F Rossi[2], P Lanzini[3], L La Rosa[4], D Prati[5]
[1]Dept. of Transfusion Medicine and Hematology, ASST Lecco - A. Manzoni Hospital, Lecco, [2]SIMTI, ASST Monza, Monza, [3]SIMT, ASST Valtellina e Alto Lario, Sondrio, [4]SIMT, ASST Vimercate, Vimercate, [5]ASST Lecco - A. Manzoni Hospital, Lecco, Italy

Background: RhD is the most important, immunogenic and polymorphic Rh antigen, which plays a key role in transfusion medicine. Anti-D antibodies remain the leading cause of the hemolytic disease of the newborn, and antigen D compatible units are chosen when transfusions are needed. Screening tests are based on panels of monoclonal antibodies developed to identify the majority of D variants, but Rh D typing is a constant challenge in donor routine testing, since in presence of RHD blood group polymorphisms of RH partial D or weak D phenotypes may vary according to reagent and method used. In January 2015, the Lombardy transfusion system has been deeply reorganized, and screening tests performed by 27 transfusion centers have been centralized into 8 centers. In our department, we are now testing for ABD about 85,000 units per year.
Aims: The aim of the study was to describe the findings of ABD typing performed with a different system based on agglutination on solid phase technology, different from the ones previously used, based on gel-card technology.
Methods: From March 2015 to March 2016, AB0/Rh typing of blood donations were performed by solid phase technology with a completely automated system (Capture-R Ready-Screen, Immucor). Results were compared with data obtained by gel-card. Samples with negative or weak anti-D reactivity were screened for the presence of RhD variants with different anti-D sera and advanced serological kits such as ID-Partial RhD Typing (Biorad), and, furthermore, they were analyzed for DAT testing. Discrepant or inconclusive samples were selected for further investigation with molecular techniques, based on allele specific PCR for the detection of 14 RhD weak and 48 RhD partial variants (Inno-Train, Essemedical).
Results: A total of 82,000 blood donations, collected from 38,515 donors, were analyzed for AB0 and RhD blood groups. In 130 donors (0.3%) a weak or discrepant RhD typing with different anti-sera were obtained. All of them were analyzed for the presence of RhD variants by molecular approach, which identified: 117 weak D alleles (91 type 1, 7 type 2, 6 type 3, 1 type 4, 1 type 5, 10 type 11, 2 compound heterozygote type 1+4 and type 2+4) and 12 partial D alleles (9 DFR, 1 DNB, 2 DV). In 2 subjects none of the RhD variants analyzed were found. All RhD variants were identified by both gel-card and solid phase technologies, except the weak D type 11 (885G>T) variant carried by 10 subjects, which showed a completely negative results with all monoclonal gel-card antisera used, and only the D weak cells analysis on Immucor microplates revealed a weak reactivity. This RHD variant is commonly classified among the Del phenotype, since it can be only identified by adsorption and elution techniques. The RhD typing of blood component of these 10 blood donors were changed from Rh negative to Rh positive. Moreover, all the RhD variants identified showed a strong correlation between serological reactivity obtained with different anti-sera and molecular results. All RHD variants were identified in subjects with Cc or Ee phenotype, and a linkage disequilibrium between RHD variants and RHCE phenotypes were observed.
Summary/Conclusions: Solid phase methods were highly sensitive in detecting very weak RhD expression variants, such as DEL, which is important for the prevention of anti-D post-transfusion or newborn immunizations. Molecular methods help in the differentiation and definition of partial D and weak D types, providing additional information for transfusion procedures.

LB2273

HBV VACCINATION PROGRAM IN ITALIAN BLOOD DONORS: EFFECTIVENESS AND POTENTIAL THREAT OF VACCINATION FAILURES TO THE SAFETY OF BLOOD SUPPLY

M Spreafico*, F Fumagalli Maldini, L Raffaele, B Foglieni, A Berzuini, I Guarnori, D Prati
Department of Transfusion Medicine and Hematology, Azienda Socio-Sanitaria Territoriale (ASST) di Lecco, Lecco, Italy

Background: In Italy, vaccination against HBV in newborns, extended to 12-year-old children, was mandated in 1991. Recombinant HBsAg of A2 genotype, aimed to protect across all genotypes, is used. However, occasional reports of infection with non-A2 HBV genotype in vaccinated blood donors presenting with occult HBV infection (OBI: HBsAg negative, HBV DNA positive) raised concerns about the broad genotype efficacy of vaccines as well as to the safety of blood supply. OBI is a potential risk factor for post-transfusion hepatitis, hepatocellular carcinoma, cirrhosis and HBV reactivation.
Aims: The aim of the study was to investigate the efficacy of HBV vaccination in Italy, where HBV D genotype is prevalent.
Methods: In March 2015 we started 12 month project among Italian blood donors vaccinated at 12 years of age (group A) or in infancy (group B). Donors were enrolled and tested for HBsAg, anti-HBc, anti-HBe, anti-HBs titre and HBV DNA. Dilution and avidity tests were performed on anti-HBc positive samples to confirm true positive results. The persistence of anti-HBs according to the time elapsed from vaccination was also evaluated.
Results: Out of 1055 enrolled blood donors, 295 were vaccinated in infancy (28%) and 760 (72%) at 12 years. No anti-HBc positive result was found in group B, whereas 5 donors (0,7%) in group A were anti-HBc positive, HBsAg and HBV DNA negative (p=0.3). Avidity testing confirmed the anti-HBc positivity in 3/5 donors (anti-HBc specificity: 99.72%), all with high avidity. None of them have detectable circulating HBV DNA. One of them, vaccinated at 13 years of age, was also anti-HBe positive. Anti-HBs titres were<10 IU/mL in 381 (36%) subjects, corresponding to 64% of donors vaccinated in infancy (n=189) and 25% of vaccinated at 12 years of age (n=192). Age at vaccination was an independent predictor of low anti-HBs titer (R2: 0.048; 95% CI: 11.14-19.24) by logistic regression analysis.
Summary/Conclusions: In Italy, HBV vaccination program in newborns seems to be effective to ensure protection against HBV infection. The prevalence of anti-HBc positivity among donors vaccinated at 12 years of age was low, but further studies are needed to clarify whether vaccinated anti-HBc positive donors are threat for transfusion safety. Vaccination in adolescence results in more prolonged immunogenicity than vaccination in infancy, reflecting a more developed immune system.

LB2274

RED CELL AND HAEMOGLOBIN ABNORMALITIES ARE POTENTIAL BARRIERS TO BLOOD DONATION IN PERSONS OF SUB-SAHARAN ETHNICITY

A Berzuini*, B Foglieni, M Spreafico, D Prati
Hematology and Transfusion Medicine Department, Ospedale Manzoni, Lecco, Italy

Background: A substantial increase of persons affected by Sickle Cell Disease (SCD) is expected in European countries, due to migratory flows from Sub-Saharan (SSA) and other endemic areas. Blood transfusion is the essential treatment for people affected by SCD but, due to an intrinsic susceptibility, at least 1/3 of them develop red blood cell (RBC) alloimmunization, which is also favoured by the peculiar antigen patterns found in SSA. For these reasons SCD patients should receive fully matched blood starting from early childhood, and the only way to reach this objective is to include in the donor pool persons of the same ethnicity, who are also at risk of having congenital red cell and haemoglobin (Hb) defects. The conditions are potentially harmful for blood recipient due to increased risk of hemolysis and/or veno-occlusive crises after transfusion.
Aims: The aim of this study was to assess the prevalence of RBC and Hb defects in an apparently healthy population of first generation foreign citizens native of SSA areas.

Methods: In March 2014 we started a 24-months program for the recruitment of foreign citizens to become blood donors in the area of Lecco, Italy. Of 450 potentially eligible persons, 175 (65 f, 110 m), gave their informed consent to undergo clinical and behavioural pre donation assessments according to the European regulation, as well as to the glucose-6-phosphate dehydrogenase (G6PDH) concentration and Hb electrophoresis.
Results: G6PDH concentration could be determined in 169 persons, allowing us to identify 55 (33%) with reduced enzyme concentration, including 25 (15%) with severe deficiency (i.e. <5 u/gHb). Despite the X-linked transmission, 8% of females had severe deficiency. Hb electrophoresis could be assessed in 173 persons. The overall prevalence of Hb variants was 32%: 28 subjects (21% f, 12% m), were carriers of HbS; 19 (11%) had beta thalassemia trait, and 8 (5%) were HbC carriers. Coexpression of G6PDH deficiency and HbS was found in 5% of subjects.
Summary/Conclusions: Despite the clinicians expectations of an increased availability of donors from SSA to provide a better matched blood supply for SSD patients, a substantial proportion of candidate donors will be carrier of RBC and/or Hb abnormalities, representing a major contraindication to blood components preparation.

INHIBITORY EFFECTS OF QUERCETIN ON ANGIOGENESIS IN T-ALL CELL LINES AND ZEBRAFISH *IN VIVO*

LJ Shen*, FY Chen, HY Liu, JH Zhong, H Zhong,xLi
Hematology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Microvessel dendity was significantly increased in organs from patients with T cell acute lymphocyte Leukemia (T-ALL). Notch1 activating mutations was identified in more than 60% of T-ALL case, and has been demonstrated as one of the most important pathways in angiogenesis. Quercetin, a kind of polyphenolic bioflavonoid, has showed strong anti-tumor effects and antiangiogenesis on various cancers.
Aims: we constructed *Notch1* overexpression transgenic zebrafish, then, treated zebrafish embryos and T-ALL cell lines (A3 and Molt-4) with quercetin to explore its role in anti-angiogenesis of T-ALL.
Methods: Quercetin (>95% pure) was dissolved in <0.1% dimethylsulfoxide. Using T lymphocytes specific promoter Rag2, we introduced human intracellular domain *Notch1* (*ICN1*) gene into *Tg(fli1:EGFP)* zebrafish, tagged with RFP gene. In previously work, we vertified that these fish are closely resemble the main aspects of human ALL. Zebrafish embryos were collected and treated with various concentrations of quercetin (0, 80, 160, 240μM) dissolved in 4mL egg water and incubated in six-well plates (20 embryos per well) at 28.5°C from 14 hours post fertilization (hpf) to 86 hpf. Morphological changes and vessel density were observed and imaged with fluorescence microscope. The subintestinal vessels (SIVs) and intersegmental artery (ISV) of the zebrafish were chosen for the measurement of the length by image analyse software Image-Pro Plus 6.0. Cell line growth inhibition assay was performed at different concentrations of quercetin (0, 15, 30, 60, 90, and 120μM) with Cell Counting Kit-8. A3 and Molt-4 cells apoptosis was measured with AnnexinV-FITC/PI Apoptosis Detection Kit after treated with 30μM or 60μM of quercetin at 24, 48 and 72h. Quantitative real-time PCR and western blot analyses were used to detect the changes of angiogenic factors after dosing. All statistical analyses were carried out in Graphpad Prism 5.
Results: It showed that quercetin can significantly block the SIVs and ISV formation in *Notch1* transgenic zebrafish model. Two of the T-ALL cell lines (A3 and Molt-4) have high expression of Notch1. The IC50 at 48h for quercetin in A3 and Molt-4 were (35.17±1.46)μM and (33.24±2.35)μM, respectively. Their proliferation was significantly inhibited by quercetin in a dose- and time-dependent manner. Furthermore, the mRNA and protein levels of VEGF, DLL4, Notch1 and Hes1 were gradual inhibited with the concentration and exposure time increasing. After treatment with various concentrations (30μM and 60μM) of quercetin for 48h, the maximal apoptosis rates were (70.24±3.58)% in A3 cells, (61.05±2.37)% in Molt-4 cells, respectively. In contrast, less than 5% of untreated cells underwent apoptosis under the same conditions (Figure 1).

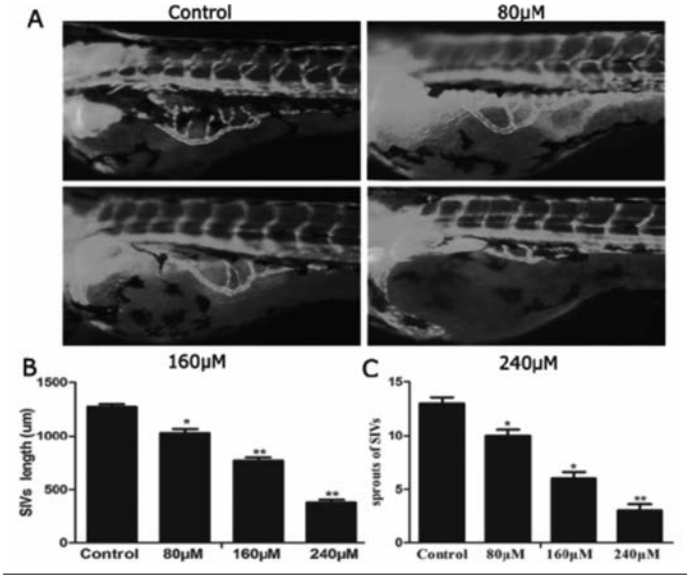

Figure 1.

Summary/Conclusions: These finding suggested that quercetin could inhibit angiogenesis by targeting VEGF regulated DLL4/Notch signaling pathway and supposed to be a potential drug candidate for T-ALL therapy.

PB1589

THE TERAPEUTIC POTENTIAL OF EMBRIONARY SIGNALING PATHWAYS INHIBITION IN ACUTE LYMPHOBLASTIC LEUKEMIA

A Pires[1,2], J Jorge[1,2], R Alves[1,2,3], AC Gonçalves[1,2,3], AB Sarmento-Ribeiro[1,2,3,4,*]
[1]Laboratory of Oncobiology and Hematology, Faculty of Medicine, [2]Center of Investigation in Environment, Genetic and Oncobiology (CIMAGO), Faculty of Medicine, [3]Center of Neurosciences and Cell Biology/Biomedical Institute of Investigation of Light and Image (CNC.IBILI), University of Coimbra, [4]Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Embrionary signaling pathways, such as Wingless (WNT), Hedgehog (Hh), and Notch pathways, are essential for differentiation and self-regulation of stem cells, and their deregulation have been associated with several hematological neoplasias. Acute lymphoblastic leukemia (ALL) is characterized by the abnormal proliferation and accumulation of immature lymphoid cells within the bone marrow and lymphoid tissues, which can arise from the aberrant activation of embryonic signaling pathways. Therefore, these pathways may constitute new therapeutic targets for ALL treatment.
Aims: Evaluate the therapeutic potential of IWR-1, GDC-0449, and Gamma Secretase XXI inhibitor (GSXXI), inhibitors of WNT, Hh and Notch signaling pathways, respectively, in ALL *in vitro* models.
Methods: For this purpose, we used two ALL cell lines, CEM as a T cell ALL model, and KOPN-8 as a B cell ALL model. Both cell lines were cultured in absence and presence of different concentrations of IWR-1, GDC-0449 and GSXXI. Trypan blue assay was used to evaluate the effect of these inhibitors on cell viability and density. Cell death was determined by optical microscopy (May-Grunwald Giemsa staining) and by flow cytometry (FC) using the Annexin V and Propidium Iodide double staining. FC was also used to measure levels of apoptosis modulators, BAX and BCL-2, cell cycle (PI/RNase assay) and mitochondrial membrane potential (through the fluorescent probe JC1).
Results: Our results showed that IWR-1 reduces only the viability and proliferation of KOPN-8 cells in a time and dose dependent manner (being the maximal inhibitory concentration, IC50, approximately 50 μM at 48 hours of exposure), having no effect in CEM cells. On the other hand, GDC-0449 and GSXXI reduces cell viability and proliferation in a time, dose and cell line dependent manner, being the KOPN-8 cells the most sensitive. We found that the IC50 at 48 hours to GDC-0449 was 75 μM and 150 μM and to GSXXI was 25 μM and 30 μM, for KOPN-8 and CEM cells, respectively. All inhibitors induced cell death by apoptosis, confirmed by the BAX/BCL-2 ratio, morphological analysis, and mitochondrial membrane depolarization. The analysis of cell cycle progression revealed that all inhibitors induce cell cycle arrest in G_0/G_1 phase in both cell lines, except in CEM when incubated with IWR-1
Summary/Conclusions: In conclusion, our results suggest that IWR-1, GDC-0449 and GSXXI could be a potential new targeted therapy in acute lymphoblastic leukemia; however, the therapeutic efficacy is cell type-dependent.

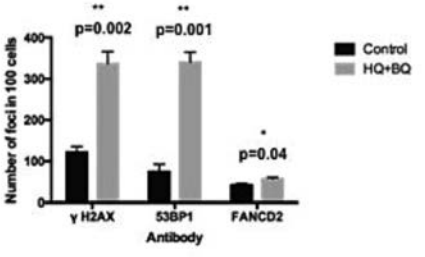
TRANSPLACENTAL CARCINOGEN EXPOSURE INCREASES THE LEVELS OF DNA DAMAGEA IN HUMAN UMBILICAL CORD BLOOD AND MOUSE C57BL/6 BONE MARROW CELLS

N Zareian[1,*], A Kaidi[2], N Brown[3], T Phillips[1], C Badie[3], P Case[1]
[1]School of Clinical Sciences, [2]School of Cellular & Molecular Medicine, University of Bristol, Bristol, [3]Radiation Effects Department, Centre for Radiation, Chemical and Environmental Hazards, Public Health England, Didcot, United Kingdom

Background: Acute leukaemia is the principal subtype of paediatric cancer and, despite success in treatment, its aetiology remains unclear. Maternal exposure to radiation and benzene metabolites during foetal development has been implicated in its aetiology as the first hit in the context of a minimal two-hit model of the natural history of the disease. Although there might not be an exclusive cause, an abnormal immune response to childhood infections has been proposed as the plausible aetiology. We have previously shown that a human placental barrier responds to different types of toxic challenge and oxidative stress by secreting molecules that cause DNA damage and chromosome aberrations in different cell types distal to the barrier including human fibroblast and human embryonic stem cells.
Aims: We aimed to investigate: *a.* the aetiology of childhood leukaemia by focusing on the role of the placenta in foetal leukaemogenesis; *b.* the effect of nanoparticles (NP) as drug delivery molecules on preventing DNA lesions during pregnancy.
Methods: *In vitro*. Human umbilical cord blood (UCB) cells were exposed indirectly to 30 μM hydroquinone (HQ) and benzoquinone (BQ) across bilayered cell barriers of human trophoblast choriocarcinoma-derived cell line BeWo grown on transwell inserts (pore size, 0.4 mm). Media with no HQ and BQ was the control. *Ex vivo*. To investigate the effect of radiation-induced bystander

mechanism and pharmacological treatment on preventing DNA damages, female C57Bl/6J mice at day 12 gestation were exposed to a whole body exposure non-irradiated, 100 mGy or 1 Gy X-irradiation (AGO, United Kingdom, dose rate 0.5 Gy/min (250 kVp and 13 mA)); the placentae were removed 4 hrs post-irradiation and cultured with 3 conditions: with no drug additive, with MitoQ bound to NP (MQNP) and with blank NP (BNP) as the control for MQNP. Total bone marrow (BM) from age-matched female C57Bl/6J was exposed to conditioned media. DNA damage was measured using quantitative immunocytochemistry for a panel of DNA damage markers including γH2AX and 53BP1 (DNA double-strand break (DSB)) and FANCD2 (interstrand crosslinks (ICL)). The experiments were carried out in triplicate.
Results: Exposure of UCB to HQ and BQ across BeWo barrier increased level of DNA damage. UCB cells showed significantly more damage after 24 hrs exposure (γH2AX (p=0.002), 53BP1 (p=0.001) and FANCD2 (p=0.04), Figure 1). Exposure of murine BM cells to conditioned media with no drug additive increased DNA DSB and ICL. BM γH2AX-positive cells showed increased DNA DSB at 1 Gy (p=0.006) but the difference was not statistically significant at 100 mGy (p=0.07). BM 53BP1-positive and BM FANCD2-positive cells showed significantly more DNA damage compared to their control counterparts at both 100 mGy and 1 Gy doses (p=0.01 and p=0.001, p=0.02 and p=0.0001, respectively). MQNP prevented DNA damaging secretions in BM treated cells however this effect was more pronounced in BM 53BP1-positive and BM FANCD2-positive cells at both 100 mGy and 1 Gy doses (γH2AX (p=0.1 and p=0.06), 53BP1 (p=0.002 and p=0.02) and FANCD2 (p=0.02 and p=0.1), respectively).



Evaluation of DNA damage in human umbilical cord blood (UCB) cells following indirect transplacental exposure to carcinogens hydroquinone (HQ) and benzoquinone (BQ). Compared with the control, transplacental exposure of human UCB cells across bilayered cell barriers of BeWo cell line to HQ and BQ caused significant DNA double strand break as indicated by γH2AX and 53BP1 and interstrand cross link as indicated by FANCD2 antibodies. Bars represent the mean with S.E.M of triplicates. P values are shown above the bars.

Figure 1.

Summary/Conclusions: Our data show that transplacental exposure of human UCB and murine BM cells to carcinogens BQ/HQ and irradiation increases levels of DNA damage presumably leading to increased genome instability. Furthermore, a marked increased phosphorylation of histone H2AX, 53BP1 and FANCD2 in BM cells indicates the effect of a radiation-induced bystander mechanism. DNA damaging secretion conferred by irradiation exposure in the *ex vivo* model could be prevented by applying nanotechnology-based drug delivery molecules to the placental conditioned medium and further investigations are ongoing. These findings suggest the importance of placenta as a barrier in DNA damage signal propagation during embryo development and provide new insights into the link between placental signaling and foetal leukaemogenesis. Whether these events lead to the accumulation of further genetic aberrations in the context of a minimal two-hit model for leukaemia initiation remains to be further elucidated.

CROSSTALK OF NOTCH1 AND NOTCH2 SIGNALING IN T-ALL CELL LINES
Y Okuhashi[1,2,*], S Tohda[2], S Hosogaya[1]
[1]Medical technology, Tokyo University of Technology, Ota, [2]Laboratory Medicine, Tokyo Medical and Dental University, Bunkyo, Japan

Background: Notch signaling is crucial for the growth of leukemia cells. We reported the effects of γ-secretase inhibitors (GSIs), which block Notch activation, on the growth of leukemia cells. GSIs suppressed the growth through induction of apoptosis in most of cell lines. Conversely, the growth of some cell lines were promoted by GSI treatment. For example, we previously reported GSI-XXI treatment suppressed the growth of KOPT-K1 cells while it promoted that of Jurkat cells, both of which are T-lymphoblastic leukemia (T-ALL) cells with constitutive Notch activation. However, the mechanisms of this phenomenon have not been fully clarified.
Aims: In this study, we investigated the mechanisms focusing on the crosstalk between NOTCH1 and NOTCH2 signaling in Jurkat cells.
Methods: Two T-ALL cell lines (KOPT-K1 and Jurkat) were used. The cells were transfected with siRNAs targeting *NOTCH1* (siN1), *NOTCH2* (siN2) or control siRNA by using the pipette tip chamber-based electroporation system. The effects of siN1 and siN2 on the expression levels of mRNA and protein of NOTCH-related molecules were examined by quantitative RT-PCR and immunoblotting, respectively. The effects of siN1 and siN2 on short-term growth were examined using a colorimetric WST-8 assay. To examine the effects of siRNA on morphological differentiation and apoptosis, cytospin preparations were prepared from harvested cells stained with Wright stain.
Results: Transfection with siN1 and siN2 selectively suppressed the expression of *NOTCH1* and *NOTCH2* mRNA and protein, respectively. *NOTCH1* knockdown as well as *NOTCH2* knockdown suppressed the growth and induced apoptosis of KOPT-K1 while they promoted the growth of Jurkat. In Jurkat, *NOTCH1* knockdown increased the level of NOTCH2 protein. On the other hand, *NOTCH2* knockdown increased the level of NOTCH1, cleaved NOTCH1 fragment (active form of NOTCH1), HES1 and MYC protein in Jurkat. In KOPT-K1, the expression of these protein was not significantly affected by siN1 and siN2. The knockdown *NOTCH1* and *NOTCH2* did not affect the expression of mTOR, Hedgehog and Wnt signal-related proteins in both cell lines.
Summary/Conclusions: Using siRNA-mediated knockdown experiments, we found that not only NOTCH1 knockdown but also NOTCH2 knockdown affected the growth of these *NOTCH1*-mutated, *NOTCH2*-unmutated T-ALL cell lines. The growth suppression by NOTCH2 knockdown did not involve the suppression of MYC expression, which was suppressed by NOTCH1 knockdown. We also found the crosstalk between NOTCH1 and NOTCH2 in Jurkat, which suggests that Jurkat might have reciprocally compensating system between two NOTCH. It might cause the resistance to GSIs. To our knowledge, this is the first report to show the interaction between NOTCH1 and NOTCH2 expression in T-ALL cell lines.

ACTIVATION OF IRS1/ BETA-CATENIN AXIS IN ACUTE LYMPHOBLASTIC LEUKEMIA
JC Fernandes[*], APN Rodrigues Alves, JA Machado-Neto, R Scopim-Ribeiro, B Alves Fenerich, F Borges da Silva, B Pinto Simões, E Magalhães Rego, F Traina
University of São Paulo - USP, Ribeirão Preto, Brazil

Background: Acute lymphoblastic leukemia (ALL) is an aggressive cancer of immature progenitors that shows aberrant activation of signaling pathways. Insulin-like growth factor 1 (IGF1) and its receptor regulate normal cell growth and contribute to transformation and growth of malignant cells. In solid tumors, IGF1 has the ability to activate a cascade of downstream phosphorylation events including translocation of beta-catenin to the nuclei, and activation of the target gene *MYC*. In fibroblasts, IGF1 was found to induce nuclear IRS1 translocation, IRS1/beta-catenin association and *MYC* transcription. When highly expressed, MYC may acts as oncogene, contributing to the development of cancers, including hematopoietic neoplasm.
Aims: We herein aimed to investigate the IRS1/beta-catenin axis in ALL cells.
Methods: Bone marrow or peripheral blood samples were obtained from 58 patients with ALL and 13 healthy donors. T-ALL cell lines, Jurkat and MOLT-4, and B-ALL cell lines, Namalwa and Raji, were obtained from ATCC. Gene expression was measured by quantitative real-time PCR; relative expression was calculated using the expression of *beta-actin* as an endogenous control. The Mann-Whitney test was used to compare the median of gene expression among normal donors and patients with ALL. Protein expression, associations and cellular localization were evaluated by immunoprecipitation, immunoblotting and western blotting analysis, subcellular fractionation and confocal microscopy. To evaluate the effects of IGF1 upon IRS1 and beta-catenin cellular localization, cells were submitted to starvation in serum-free medium for 24 hours, followed by IGF1 stimulation (20 ng/mL) and/or IGF1R pharmacological inhibition (OSI-906; 20 μM), for 24 hours.
Results: *IRS1*, *beta-catenin*, and *MYC* relative gene expression were significantly higher in ALL patients compared to normal donors (*IRS1*, ALL: median=1.10 [minimum=0.01 - maximum=9.96] *vs* normal donors: 0.34 [0.19 - 1.49], p=0.01); (*beta-catenin*, ALL: 1.12 [0.23 - 5.18] *vs* normal donors: 0.56 [0.01 - 1.57], p=0.002); (*MYC*, ALL: 1.78 [0.06 - 28.37] *vs* normal donors: 0.33 [0:13 - 1.13], p=0.0003). A positive correlation between *beta-catenin* and *MYC* mRNA expression (p=0.002, r=0.39) and between *IRS1* and *MYC* expression (p=0.02, r=0.29) was found. In ALL cell lines (Jurkat, MOLT-4, Namalwa and Raji) high expression of IGF1R, IRS1, beta-catenin and MYC protein were observed. IRS1 and beta-catenin was found to be located in the nuclei and the cytoplasm of ALL cell lines by subcellular fractionation and western blotting analysis. The confocal microscopic analysis reveals elevated co-localization of IRS1/beta-catenin in both nuclei and cytoplasm of ALL cell lines (r≥0.69). In Jurkat cells, the constitutive protein interaction IRS1 and beta-catenin were observed; IGF1 stimulation increased nuclear translocation of IRS1 and beta-catenin. The IGF1R inhibitor OSI-906 decreased IGF1R tyrosine phosphorylation, decreased nuclear beta-catenin translocation and MYC protein expression in Jurkat cells.
Summary/Conclusions: *IRS1*, *beta-catenin* and *MYC* mRNA expression were elevated in ALL patients compared to normal controls. The IRS1/beta-catenin protein association observed in ALL cell lines, together with the data that IGF1 modulates IRS1 and beta-catenin nuclear translocation and MYC expression

indicate that the IRS1/beta-catenin axis is activated in ALL cells, which may represent an important signaling pathway involved in the pathophysiology of the disease.

WHOLE EXOME SEQUENCING OF RELAPSED PEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

K Karrman[1,*], A Biloglav[1], K Paulsson[1], B Johansson[1], A Castor[2]
[1]Division of Clinical Genetics, Department of Laboratory Medicine, [2]Department of Pediatrics, Skåne University Hospital, Lund University, Lund, Sweden

Background: Acute lymphoblastic leukemia (ALL) is the most common malignancy of childhood responsible for a quarter of all pediatric cancers. T-cell ALL (T-ALL) makes up 10-15% of childhood ALL. Close to 80% of children diagnosed with T-ALL survive the disease if treated according to standard protocols. However, one in five T-ALL patients relapse and for this group the outcome is very dismal, less than half of the patients are cured.
Aims: We undertook exome sequencing of matched diagnostic, remission and two relapse (relapse 1 and 2) DNA samples from a pediatric T-ALL patient.
Methods: Agilent SureSelect exome capture was used and each capture library was sequenced on the HiSeq2000 platform. >98% of the targets were sequenced with at least 20x coverage.
Results: In total, 66 somatic single nucleotide variants (SNVs) were detected in the three samples. Almost half of the SNVs detected at diagnosis were also seen at relapse 1 and/or 2 (7/15, 47%). This result hence indicates that the relapse evolves from a clone present at diagnosis. *STAT5B* mutations, including N642H, were recently implicated as a putative drivers of T-ALL. We identified the N642H mutations in a homozygous state in both diagnostic and relapse samples, further validating the role of *STAT5B* in T-cell leukemogenesis. Two separate *NOTCH1* mutations were seen in minor subclones at diagnosis. Interestingly, these mutations were not seen in the relapse samples, however relapse 2 acquired a *FBXW7* mutation which could render the leukemic cells renewed aberrant *NOTCH1* activity. The vast majority of identified SNVs (51/66, 77%) were selectively seen in the relapsed samples. Notably, some relapse-specific mutations were detected in genes responsible for drug resistance; *ABCA2* and *NT5C2*.
Summary/Conclusions: To elucidate genes involved in relapsed T-ALL could hopefully result in new targeted treatments.

PB1594

INCOMPLETE IGH GENE REARRANGEMENTS (DH-JH) AS A MINIMAL RESIDUAL DISEASE TARGET IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

L Sedlackova[1,*], M Ondrackova[1], L Zejskova[1], R Plachy[1], A Zavrelova[2], J Horacek[2], V Petecukova[3], M Karas[4]
[1]Laboratory for Molecular Diagnostics, synlab czech s.r.o., Prague, [2]4th Department of Internal Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, [3]Internal Clinic of Hematology, University Hospital Kralovske Vinohrady, Prague, [4]Department of Hemato-Oncology, University Hospital in Plzen, Pilsen, Czech Republic

Background: Monitoring of minimal residual disease (MRD) is an important prognostic tool in acute lymphoblastic leukemia (ALL) patients. Currently, one of the most widely used techniques to detect and quantify MRD is allele-specific real-time polymerase chain reaction (qPCR) based on clonal rearrangement of immunoglobulin heavy chain (IGH) or T-cell receptor genes. These molecular targets can be detected in approximately 90% of adult B-cell precursor ALL at initial diagnosis. In patients, where it is not possible to detect a clonal complete IGH rearrangement, additional MRD targets, such as immunoglobulin light chain (IGL) or incomplete IGH (DH-JH) rearrangements, could be also used. The first step in the recombination process of the IGH locus is a rearrangement of DH and JH segments which represents one of the earliest events in B-cell development. Incomplete DH-JH joints were observed in 20 – 25% of B-cell precursor ALLs. Therefore, in adult ALL patients without clonal complete IGH rearrangement, incomplete DH-JH rearrangements could be potentially used as MRD target.
Aims: The goal of our work was the application of clonal incomplete DH-JH rearrangements as MRD targets in routine laboratory practice.
Methods: Since 2010, we have performed clonal complete IGH rearrangement analysis in 45 patients with ALL suspicion in effort to obtain suitable MRD target. In 18 patients, where it was not possible to detect clonal complete IGH marker, screening by the multiplex PCR using BIOMED-2 primer sets for the detection of clonal DH-JH rearrangement was made as the next step. After sequencing of the clonal DH-JH rearrangement, allele-specific oligonucleotides were designed for each MRD target on the basis of the sequence data of the junctional regions. Tests for MRD were conducted by qPCR using TaqMan technology (Rotor-Gene Q, Qiagen).
Results: Clonal incomplete DH-JH rearrangements were detected and sequenced in 11 out of 18 ALL patients at initial diagnosis. Two out of 11 patients had another available molecular target for MRD monitoring (BCR/ABL, MLL/ENL) and for additional 3 patients MRD analysis was not requested. The qPCR assays were developed for 6 patients who were subsequently monitored for MRD. From February 2011 to January 2016 we examined 59 samples from bone marrow (n=57) or peripheral blood (n=2). The assay detection sensitivity achieved the threshold of 10^{-4} to 10^{-5} (1 leukemic cell in 10 000 cells to 1 leukemic cell in 100 000 cells). The MRD levels of residual leukemic cells correlated with clinical outcome. The clonal DH-JH markers found in these patients and used for the MRD analysis were the only option for residual leukemic cells monitoring with sensitivity of at least four orders of magnitude.
Summary/Conclusions: Clonal incomplete DH-JH gene rearrangement targets are applicable for routine MRD testing of ALL patients as a reliable sensitive method for MRD assessment and should be considered as a complementary target for PCR-based clonality assessment and MRD monitoring.

WHOLE EXOME SEQUENCING (WES) IN PHILADELPHIA NEGATIVE (PH-) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) EXTRAMEDULLARY RELAPSES IDENTIFIED COMMON JAK2 MUTATIONS

A Ferrari[1,*], C Papayannidis[1], V Robustelli[1], A Ghelli Luserna di Rorà[1], M Manfrini[1], A Padella[1], E Imbrogno[1], C Venturi[1], G Marconi[1], C Sartor[1], MC Abbenante[1], V Guadagnuolo[1], MC Fontana[1], A Gazzola[2], A Laginestra[2], C Mannu[2], N Testoni[1], J Shira[3], G Martinelli[1]
[1]University of Bologna, Institute of Hematology "L. e A. Seràgnoli", [2]University of Bologna, Department of Experimental Hematopathology and Hematology Sections, Diagnostic and Specialty Medicine, S. Orsola-Malpighi Hospital, Bologna, Italy, [3]FASTERIS, Genève, Switzerland

Background: Acute lymphoblastic leukemia (ALL) is a complex disease with multiple factors related both to the disease itself and host biology that significantly affect outcome. Appropriate risk stratification and a better understanding of the genomic landscape underlying this disease have led to improvement in overall survival in children. Even with these advances, outcome remains unsatisfactory in adults, mainly in the Philadelphia chromosome negative subgroup. Here we report a 22-year-old man with pre-B ALL who was negative for the recurrent known molecular rearrangements (*E2A-PBX, TEL, AML1- MLL-AF4*). The patient (pt) received different therapeutic regimens and allogenic stem cell transplantation but he did not achieve a remission. Fourteen months after diagnosis (dx), leukemia extramedullary relapsed at the breast and later at lymph node in the groin (CD34+, TdT+,PAX5+, CD19+, CD22+, CD3-).
Aims: to dissect the genetic landscape in order to predict treatment failure and identify targets amenable to inhibition by targeted therapies we compared the genomic profile of 3 different tissues.
Methods: Whole exome sequencing (WES) was performed on dx bone marrow (BM), breast (BR) and lymph node (LN) samples at the time of relapse using the Illumina Hiseq2000 platform. Matched samples of primary tumour and germline DNA from buccal swab were also analyzed. The post-transplantation BR and LN samples were further matched with donor peripheral blood DNA. MuTect and Varscan tools to call mutations (Single Nucleotide Variants=SNVs and/or INDELs) were used. 3 sample SNP array analysis were also performed.
Results: WES analysis from 3 samples identified 522 point mutations and 35 indels that occur in 474 genes (Table 1). The number of total mutations at the time of relapse is higher both in BR and LN samples compare to dx BM. The majority of mutations occurred on genes localized on chr1 (74); the mean number of mutations/chr is 24 (2-74). BR and LN sample have 57 mutations in common (5 in BM and BR, 2 in BM and LN). Mutect identified 26 mutations in both relapsed samples. They include a mutation in *FAAH* gene, which is also found fused with *NSUN4* at the dx (RNASeq). This analysis revealed some other fused genes that were detected mutated with WES. Nine genes are confirmed to be mutated in all 3 samples: 7 nonsynonymous SNVs (*ACHE, COL4A2, LOC554223, NPHS1, SLC36A1, TMEM89* and *JAK2*), 1 stopgain mutation (*NTNG2*) and 1 indel (*HELZ2*). Excluding *JAK2*, no direct relations between these genes and leukemia were reported so far. The *JAK2* mutation S1032Y were detected in all 3 samples, instead the R683G one in the BM and BR. *CD8* is and presents 2 mutations in both BM and BR. SNP array analysis also reveals that this gene was deleted in heterozygosity in the BM and LN. One copy of *EBF1, INPP4B, ZCCHC7* genes are deleted in all 3 samples (SNP array). *EBF1* is described to be associated to ALL. So far, we confirmed *ZCCHC7* is fused with *PAX5* in BM and BR, as previously described (Roberts KG, 2012).

Table 1.

Sample	N.Low Frequency SNVs (Mutect)	N. Other SNVs (Varscan)	INDELs (Varscan)	Tot
BM	35	64	5	**104**
BR	26	225	20	**271**
LN	26	146	10	**182**
Tot	**87**	**435**	**35**	**557**

Summary/Conclusions: The Ph- ALL extramedullary relapses show higher genetic instability, with similar low frequency mutation profile. WES suggest

that *JAK2* alterations are driver mutations. This finding could be helpful for a targeted therapy. Supported by: ELN, AIL, AIRC, PRIN, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project.

PB1596

NOTCH1 INHIBITION REGULATES EVOLUTIONARY CONSERVED MIRNAS IN T-CELL LYMPHOBLASTIC LEUKEMIA

V Saccomani[1,*], E Piovan[1,2], A Grassi[2], J Yu [3], F Bordin[1], S Minuzzo[1], P Zanovello[1], V Tosello[2]
[1]Università degli Studi di Padova, [2]Istituto Oncologico Veneto IOV-IRCCS, Padova, Italy, [3]Herbert Irving Comprehensive Cancer Center,Columbia University, New York, NY 10032, United States

Background: Activating mutations in the NOTCH1 ligand-activated transcription factor oncogene are found in over 60% of human T-cell lymphoblastic leukemia (T-ALL), where they result in high levels of NOTCH1 signaling. Among multiple functions of oncogenic NOTCH1, there are evidences of the role of non-coding RNAs in NOTCH-induced leukemia. MicroRNAs (miRNAs) are short, single-stranded RNA molecules of approximately 22 nucleotides in length that regulate gene expression by directing their target mRNAs for degradation or translational repression. Dual translocations, that simultaneously affect the 17-92 cluster and *NOTCH1,* highlight the oncogenic importance of this interaction in T-ALL. Moreover, miR-19 was found to play a crucial role in promoting leukemogenesis in NOTCH1-induced T-ALL. In addition, miR-451 and miR-223 have been described to play an important role downstream NOTCH1 in T-ALL cells both in mouse and human models. Beside these relevant discoveries, data regarding the miRNAs that are significantly regulated following NOTCH1 inhibition are still ill-defined.
Aims: In this study we analyzed NOTH1-regulated miRNAs following NOTCH1 inhibition in T-ALL cells in view of future therapies that may combine NOTCH1 inhibition with microRNA based therapy. Specifically we pursued the following aims: - To generate microarray profiles of NOTCH1-regulated microRNAs from T-ALL cells using a mouse model of NOTCH1-induced leukaemia; - To combine analysis of NOTCH1-regulated microRNAs and gene expression profiling following *in vivo* inhibition of NOTCH1 signalling pathway; -To identify and validate evolutionary conserved differentially regulated miRNAs.
Methods: We thus used a mouse model of NOTCH1-induced leukemia, that carries a NOTCH1 mutation recurrently found in human T-ALL patients (L1601P/DPEST). NOTCH1 inhibition was performed *in vivo* using a gamma secretase inhibitor (DBZ) and the treatment schedule was sufficient to determine a significant reduction of cleaved-NOTCH1. miRNAs profiling was performed using a mouse array (8X60K release 19.0; Agilent) that detected 1,247 mouse miRNAs. In parallel, gene expression analysis was performed using SurePrint G3 Mouse Gene Expression v2 array (Agilent) for the identification of about 27000 genes and 4578 lncRNAs.
Results: MYC and NOTCH signature resulted strongly down-regulated following NOTCH1 inhibition by Gene Set Enriched Analysis (GSEA) demonstrating the efficacy of our experimental model. From the miRNAs prolife, we obtained 27 up-regulated and 22 down-regulated miRNAs following NOTCH1 inhibition. Notably, among the NOTCH1 down-regulated miRNAs, we found the miR-17-92 cluster, previously reported highly expressed in T-ALL samples. Their regulation was also confirmed in another mouse model of NOTCH1-induced T-ALL and in human T-leukemia cells. Notably, we identified miR-34a-5p, miR-22a-3p, miR-199a-5p and miR-29a-3p significantly up-regulated following NOTCH1-inhibition suggesting a putative role as tumor suppressors in NOTCH1-driven leukemia. In particular, miR-22a-3p resulted significantly up-regulated following NOTCH1 inhibition both in mouse and human T-ALL cells.
Summary/Conclusions: In conclusion, the cluster 17-92 resulted to have a prominent role amongst the down-regulated miRNAs both in mouse and human T-ALL cells. Importantly, we identified novel up-regulated miRNAs downstream NOTCH1 inhibition. In particular, miRNAs 22a-3p resulted significantly up-regulated in human T-ALLs upon GSIs treatment. Further bioinformatics and functional analysis will be performed to elucidate the role of these novel miRNAs in NOTCH1-induced leukemia.

PB1597

ACUTE LYMPHOBLASTIC LEUKEMIA: A REPORT OF TWO CASES WITH THE RARE E1A3 BCR/ABL FUSION PROTEIN

F Sartori[*], B Lopez Andrade, MA Duran Pastor, JC Amat Medina, JJ Martinez Serra
Hematology, Hospital Son Espases, Palma de Mallorca, Spain

Background: The Philadelphia chromosome is the result of a reciprocal translocation between chromosome 22 and chromosome 9 that juxtaposes the breakpoint cluster region (BCR) to the Abelson tyrosine kinase protein. Several variants exist depending of the breakpoint in the BCR gene, being the more known ones p210, p230 and p190 bcr-abl which is the most frequently associated with ALL. Other rare variants exists (e1a3, b2a3, e6a2) the e1a3 is created by the fusion of BCR exon 1 to ABL exon 3. The molecular prognostic of these rare variant forms is still unclear.
Aims: We report two cases of adult B-ALL Ph+bearing the rare BCR/ABL fusion protein e1a3. It is important that our lab is able to detect these variants of unclear prognosis.
Methods: The first patient is a 43 years old man who presented this blood test: leukocytes 136,00x10 3/uL, Hemoglobin 11,70gr/dL, platelets 39,70x10 3/uL. In the peripheral blood smear 93% of small-medium sized lymphoblasts. The bone marrow aspirate confirmed the infiltration of 90% lymphoblasts; the immunophenotype was: CD19+CD10+CD34+TdT+DR+CD79 alfa+CD20-Cytoplasm IgM negative CD33+. The cytogenetic analysis of the BMA revealed the karyotype: 46,XY,del(9)(p22)t(9;22)(q34;q11),del(20)(q13) which confirm the diagnosis of B-ALL Ph+.Patient underwent induction chemotherapy plus imatinib reaching a morphological CR with persistence of Ph+. Currently is candidate to an allogenic SCT as consolidation. The second patient is a 65 year old man whose blood test revealed: leukocytes 223,00 10 3/uL, hemoglobin 11,60 gr/dL and platelets 118 10 3/uL. In the peripheral blood smear: 80% lymphoblasts confirmed by the immunophenotype CD19+CD34+ DR+CD10+CD22+low intensity CD20- TdT+Cytoplasmatic IgM negative CD33+. The BMA confirmed an infiltration of 25% lymphoblasts. The cytogenetic analysis showed the karyotype: 46,XY,t(9;22)(q34;q11). He started induction therapy plus imatib; because of refractory disease is currently ongoing reinduction. He's not candidate to SCT because of his un-fit status.
In both cases the molecular analysis detected the presence of the BCR-ABL e1a3 variant. Our lab procedure isolates patient RNA from peripheral blood and is subjected to a two round multiplex RT-PCR reaction. In order to avoid RNA quality and/or handling errors, we included an internal positive control in which a 690-bp segment of the ubiquitously expressed transcription factor E2A mRNA was amplified. The primers and PCR conditions used in the first and second round of the nested PCR reaction are described by Pallisgaard *et al.* We identified an atypical amplification band of approximately 100 bp. In order to confirm the presence of a BCR-ABL transcript this band was extracted from the agarose gel, purified and then analyzed by DNA sequencing. cDNA sequence confirmed the presence of the e1a3 BCR-ABL transcripts.
Results: Reviewing the literature we found 20 cases bearing the e1a3 fusion proteins already described: 14 patients with B-ALL, 5 with CML and 1 patient first diagnosed with CML who experienced a B-ALL type blast crisis. Among the B-ALL patients, 8 are reported dead. It should be studied if this variant correlates to a worse prognosis, which is currently unknown (Figure 1).

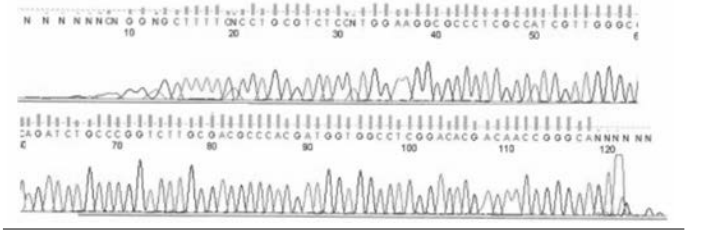

Figure 1.

Summary/Conclusions: We add to the literature two new cases of patients with B-ALL bearing the rare BCR/ABL fusion protein underlining the importance of detecting it; this variant could be missed in the laboratory testing giving a false negative; its role is unclear but seems to have a worse prognosis. More studies have to be done in order to understand the prognosis of this rare variant.

PB1598

ABERRANT DNA METHYLATION-INDUCED GENE INACTIVATION IS ASSOCIATED WITH THE T-CELL LEUKEMIAS DIAGNOSIS AND/OR THERAPY

EJ Kim[*], M Lee, YR Jung
Kirams, Seoul, Korea, Republic Of

Background: Aberrant hypermethylation of tumor suppressor genes is known to play an important role in the development of many tumors, and aberrant DNA hypermethylation was recently identified in hematologic malignancies, where it is thought to hold relevance in leukemogenesis.
Aims: These observations led us to focus on our comprehensive study to examine the prevalence of aberrant promoter methylation in a selected panel of genes that could be potentially involved in T-cell leukemia. In addition to identifying new biomarkers, exploration of methylation patterns could be used to guide T-cell leukemia therapies.
Methods: Here, we used pyrosequencing (a sensitive, easy and effective real-time sequencing-by-synthesis technique) to assess changes in the methylation levels of individual genes between normal peripheral blood (in which they are not normally methylated) and two T-cell keukemia cell lines (in which they are hypermethylated).
Results: We report that there are differences in the DNA methylation patterns seen in normal peripheral blood and two T-cell leukemia cell lines. We identify nine genes (CLEC4E, CR1, DBC1, EPO, HAL-DOA, IGF2, IL12B, ITGA1, and LMX1B) that are significantly hypermethylated in T-cell leukemias cell lines,

and suggest that aberrant hypermethylation of these normally unmethylated genes may induce their transcriptional and expressional silencing. Furthermore, we observed that the expression levels of DNMT1 and DNMT3a were significantly decreased by 5-aza-2'-deoxycytidine (5-Aza-dC), which is a demethylation agent known to deplete DNA methyltransferases (DNMTs) in leukemia cancer cells and restore the expression levels of their target genes in Jurkat cells.
Summary/Conclusions: Together, our results show that aberrant hypermethylation is an important molecular mechanism in the progression of T-cell leukemias, and thus could prove useful as a prognostic and/or diagnostic marker. Moreover, 5-Aza-dC might be a promising candidate for the treatment of T-cell leukemia.

PB1599

EVALUATION OF WNT AND HEDGEHOG SIGNALING PATHWAYS IN PEDIATRIC B ACUTE LYMPHOBLASTIC LEUKEMIA - A PRELIMINARY STUDY

M Coucelo[1,2,*], A Pires[2,3], AC Gonçalves[2,3,4], AT Simões[1], J Azevedo[1], MJ Brito[5], S Silva[5], ML Ribeiro[1], AB Sarmento-Ribeiro[1,2,3,4]
[1]Clinical Hematology Unit, Centro Hospitalar Universitário de Coimbra, CHUC, [2]Laboratory of Oncobiology and Hematology, [3]Center of Investigation in Environment, Genetic and Oncobiology (CIMAGO), FMUC, [4]Center of Neurosciences and Cell Biology/Biomedical Institute of Investigation of Light and Image (CNC.IBILI), Faculty of Medicine, University of Coimbra (FMUC), [5]Pediatric Oncology Unit, Hospital Pediatrico, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Deregulation of signaling pathways such as Wingless (Wnt) and Hedghehog (Hh) that participate in normal hematopoietic stem-cell self-renewal, differentiation and proliferation have been implied in the leukemogenic process.
Aims: Our goal was to establish the activation patterns of Wnt and Hh signaling pathways in pediatric B-ALL patients in order to identify novel prognostic markers and new targets for therapeutic strategies.
Methods: We studied 9 bone marrow samples from pediatric patients with B-ALL, 8 at diagnosis and 1 at relapse (average age 10,2y, 4F:5M). Seven B-ALL had no recurrent genetic alterations (group 1, n=6), including the relapsed patient (group 2, n=1), and 2 B-ALL had a t(4;11) (MLL-AF4) (group 3, n=2). Three bone marrow samples without neoplastic disease were used as controls (average age 9y, 3F). All samples were submitted to a gene expression array that included 84 genes for each signaling pathway, Wnt (RT2 Profiler PCR Array, Qiagen) and Hh (Hedgehog Signaling Pathway, Biorad). Results were analyzed by RT2 Profiler PCR Array Data Analysis v3.5 (Qiagen) and considered statistically significant when $p \leq 0,05$.
Results: In B-ALL patients Wnt signaling pathway genes were tendentiously downregulated. Group 1, comparing with control group, showed downregulation of *WNT* (*WNT1/2B/5B/6/7A/7B/10A/10B/16*) ($p \leq 0,05$) and *FZD* (*FZD4/5/7/9*) ($p \leq 0,05$) family genes, Wnt negative regulators (*DKK3,KREMEN1,SFRP4*) ($p \leq 0,05$) and cell cycle target genes (*CCND1,RHOU*)($p \leq 0,05$). Group 3, when compared with group 1 revealed upregulation of WNT (*WNT1,WNT10B*) ($p \leq 0,05$), FZD (*FZD3,FZD5,FZD9*) ($p \leq 0,05$), negatives regulators (*WIF1, KREMEN1*) ($p \leq 0,05$)and target genes *WISP1* and *FOSL1* ($p \leq 0,05$). B-ALL patients at relapse, when compared with the other groups, showed a tendency for Wnt upregulation, including *LEF-1*.
Hh signaling pathway results were more heterogeneous. Group 1, comparing to controls, presented a downregulation of some ligands (*SHH*) and receptors genes (*PTCHD1,BOC,LRP2*) ($p<0,05$) and upregulation of others (*CDON,PTCHD2,RAB23)* ($p<0,05$), with downregulation of some important Hh regulators and target genes (*GLI2,ZIC2,FGF9,OTX2,GREM1,SFRP1, VEGFA*)($p<0,05$) and upregulation of others (*CSNK1E, BCL2,*$p<0,05$). Both, group 3 and the B-ALL patient at relapse, showed a tendency for downregulation of Hh ligands, target genes and transcription factors, when compared to group 1.
Summary/Conclusions: Our results, although very preliminary, suggest that B-ALL pediatric patients with no recurrent genetic alterations tend to present downregulation of Wnt signaling pathway genes and abnormal expression of Hh signaling pathway. Present results suggest that these pathways may provide novel prognostic markers and therapeutic targets, and are currently being validated in a larger patient cohort.

PB1600

SERUM PROFILE OF CYTOKINES, CYTOKINE RECEPTORS AND ADHESION MOLECULES IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LYMPHOBLASTIC LEUKEMIA AND IN HEALTHY SUBJECTS

JM Horacek[1,*], T Kupsa[1], J Vanek[2], L Jebavy[1], P Zak[3]
[1]Department of Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, [2]Department of Informatics and Quantitative Methods, University of Hradec Kralove, Faculty of Imformatics and Management, [3]4th Department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Czech Republic

Background: Cytokines and adhesion molecules have been studied as markers of immune system activation in various diseases including hematological malignancies. The knowledge gained from multiple cytokine and adhesion molecule analysis could allow better diagnosis and disease management.
Aims: The aim of our study was to evaluate serum profile of cytokines, cytokine receptors and adhesion molecules in patients with newly diagnosed acute lymphoblastic leukemia (ALL) and in healthy subjects. Correlations between analytes were evaluated separately in both groups.
Methods: Serum samples of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) and 15 healthy subjects (median age 41, range 25–58 years, 11 males) were analyzed. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and Matrix Metalloproteinase-9. From cytokines, we measured Interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15, IL-23), Epidermal Growth Factor (EGF), Granulocyte Macrophage Colony Stimulating Factor (GM-CSF), Interferon-γ (IFN-γ), Macrophage Inflammatory Protein-1α (MIP-1α), Monocyte Chemotactic Protein-1 (MCP-1), Tumour Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor (VEGF) and soluble receptors for IL-2 (sIL-2Rα), IL-6 (sIL-6R), TNF-α type I and II (sTNFR-1,2). From soluble adhesion molecules, we measured E-Selectin (E-SEL), L-Selectin (L-SEL), P-Selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All analytes were measured by biochip array technology on Evidence Investigator analyzer (Randox). Statistical evaluation was done by a professional statistician using software R 3.2.3 (R Core Team 2015). Probability values (p) <0.05 were considered statistically significant.
Results: Comparing cytokine and adhesion molecule levels in newly diagnosed ALL and healthy subjects, we found significant increase in ALL in serum levels of IL-6, IL-8, IL-15, MIP-1α, MCP-1, sIL-2Rα, sIL-6R, sTNFR-1, sTNFR-2, L-SEL, ICAM-1 and VCAM-1 ($p<0.01$). Furthermore, we found in ALL significant decrease in serum levels of IL-3, IL-4 and GM-CSF ($p<0.01$). Serum levels of other evaluated analytes were without significant differences. In the group of ALL patients, we found statistically significant correlations between sTNFR-1 and sTNFR-2 ($r=0.805$; $p<0.0001$), IL-1α and IL-4 ($r=0.700$; $p=0.008$), sTNFR-2 and MIP-1α ($r=0.657$; $p=0.037$), sTNFR-2 and VCAM-1 ($r=0.652$; $p=0.044$). In the control group of healthy subjects, we found statistically significant correlations between EGF and IL-7 ($r=0.876$; $p=0.009$), EGF and IL-8 ($r=0.856$; $p=0.022$). Other correlations between analytes did not reach statistical significance.
Summary/Conclusions: Our results show that serum levels of some cytokines, cytokine receptors and adhesion molecules are significantly altered in patients with newly diagnosed ALL, reflecting activity of the disease. We found statistically significant correlations between some analytes within ALL and control group. Further studies are needed to establish if the alterations observed in the levels of these molecules could be used as a clinically relevant biomarker for ALL.
The work was supported by a long-term organisation development plan 1011 (FMHS).

PB1601

WILM'S TUMOUR GENE (WT1) EXPRESSION IN PEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N Mikhael[*]
Clinical pathology department, Alexandria Faculty of Medicine, Egypt, Alexandria, Egypt

Background: The Wilms Tumor gene (WT1) encodes a transcription factor involved in kidney development and malignancy. WT1 expression in a subpopulation of early CD34+cells has suggested its involvement in hematopoiesis. Wilms' tumor gene 1 (WT1) is overexpressed in the majority of adult acute leukemias and has been identified as an independent adverse prognostic factor. Acute lymphoblastic leukemia (ALL) is the most common childhood cancer representing 23% of pediatric cancers. Previous reports show controversial results regarding utility of WT1 expression as a prognostic and MRD marker in childhood ALL.
Aims: The aim of this work was to study the impact of WT-1 gene expression at diagnosis in a group of Egyptian children with ALL relating it to prognosis, also determine the efficacy of using this marker in minimal residual disease monitoring as compared to standard immunophenotyping methods.
Methods: This study was conducted on 70 children with newly diagnosed as ALL, assessment of WT-1 gene was done by real time PCR in BM samples at diagnosis and at day 28 of treatment**.**
Results: Positive WT-1 gene expression was positive in 48 cases (68.6%) and negative expression in 22 cases (31.4%). There was statistically significant difference between positive and negative WT-1 gene expression groups regarding immunophenotyping, where all cases that showed aberrant expression of CD13 and CD33 were positive for WT1($p=0.028$). There was significant correlation between WT1 expression at diagnosis and response to induction chemotherapy, 12/48 cases positive for WT-1 gene expression, showed MRD at d 28 while in negative WT1 group none were positive for MRD ($p=0.029$). There was a correlation between WT1 level expression at day 28 and MRD as detected by immunophenotyping. ($p=0.021$).
Summary/Conclusions: WT-1 gene expression is important prognostic factor related to response to therapy as defined by d28 MRD. WT1 level can be used as MRD marker by itself for follow up and comparable to standard immunophenotypic methods.

PB1602

PROGNOSTIC IMPACT OF ABERRANT SURFACE MARKERS EXPRESSION IN T- ACUTE LYMPHOBLASTIC LEUKEMIA

S Adnan Awad[1,*], L Fathalla[1], I Eldesouky[2], N Elsharkawy[1]
[1]Clinical Pathology Departement, [2]Clinical Oncology Department, National Cancer Institute - Cairo University, Cairo, Egypt

Background: Immunophenotyping is very important in diagnosis, and risk stratification of T-ALL with MRD proven to be the strongest prognostic indicator. Few small-scale studies have reported aberrant CD markers (CD10-CD34-CD13/CD33) in T-ALL with much conflict about its prognostic impact.
Aims: To study aberrant expression of CD10, CD34 and myeloid associated antigens (CD13/CD33) in T-ALL patients and to investigate its correlation with clinical and biologic features, treatment response (MRD) and overall survival.
Methods: This study included 62 newly diagnosed T-ALL patients from the National Cancer Institute (NCI) in Egypt during the time period from September 2012 to December 2014. All patients had undergone full history, thorough clinical examination, complete blood count (CBC), and BM aspiration. Immunophenotypic markers and minimal residual disease (MRD) at fixed time points in BM aspirate samples were studied by four-color flowcytometry EPICS XL (Coulter Corporation, Hialeah, FL, USA).
Results: Patients were classified into three phenotypes based on their immunophenotyping characteristics (CD3 cytoplasmic/surface, CD1a, CD4/CD8 expression): early T (16/62, 25.8%), T-intermediate (39/62, 63%), and T- late (7/62, 11.2%). Comparisons of different phenotypes regarding clinical factors (Age, Sex, initial mediastinal mass), hematological (Hemoglobin, leucocytes counts (TLC), Platelet counts, initial BM blast%), aberrant CD markers (CD10, CD34, CD13/CD33), MRD (Day 15, 33 and 56) and overall survival revealed significant variations regarding: TLC where the highest was T-late phenotype (P=0.014), MRD D33 (P=0.039) and MRD D56 (P=0.007) where T-late phenotype shows a better outcome. CD10 was expressed on 17/62 (27.4%), CD13 and/or CD33 on 10/62 (16.1%), CD34 on 15/62 (24.2%) of cases and co-expression of CD10 and CD34 on 5/62 (8%). Significant associations were found aberrant markers and different phenotypic groups where CD10+CD34+phenotype and CD13/CD33 occur almost exclusively in early-T groups (P=0.007 and 0.002 respectively). CD10 shows borderline significant better MRD outcome at D33 (P=0.057) and also slightly better overall survival. CD34 shows significantly worse MRD D33 (P=0.045) but no correlation with OS. Though all five patients with CD10+CD34+phenotype shows MRD<0.01 by D33 and then after, no significant correlation was found with MRD nor OS; which maybe be explained by small patient number. CD13/CD33 expression shows significant correlation with worse MRD D33 (P=0.017) with worse -but not significant- OS (Table 1).

Table 1. Clinical, biological and prognostic criteria of T-ALL phenotypes.

Positive in CD expression: >20% of blasts are positive for this CD marker, (*n); number of the patient' samples recruited at this specific time point

	T-ALL (n=62)			P value
	T-early (25.8%, n=16)	T-intermediate (63%, n=39)	T-late (11.2%, n=7)	
Age (years) Median, (range)	18, (2-60)	20, (3-42)	15(3-17)	ns
Sex (M:F ratio)	2.2:1	3.33:1	1:1.33	ns
Mediastinal mass (Positive/negative)	(2/14)	(5/34)	(2/5)	ns
Hemoglobin gm/dl (Mean+ SD)	8.7+2.44	9.99+ 2.88	8.47+ 3.22	ns
Platelet count ($X10^9$/L) Median, range	51 (3-410)	54 (6-380)	76 (17-225)	ns
Leucocyte count ($X10^9$/L) Median, range	72.2 (2.2-553)	51.6 (1.1-761.3)	263 (13-660)	P=0.014
Aberrant expression: (Positive/negative)				
1. CD10	4/12 (25%)	8/31(20%)	5/2(71%)	P=0.02
2. CD34	9/7 (56%)	4/35 (10%)	2/5 (29%)	P=0.001
3. CD10+CD34+	4/12 (25%)	0/39 (0%)	1/6 (14%)	P=007
4. CD13/CD33	7/9 (44%)	3/36 (7.7%)	0/7 (0%)	P=0.002
MRD (Positive/negative)				
D15 (n*=35)	4/2 (66.7%)	12/8(66.7%)	3/2(66.7%)	ns
D33 (n*=23)	3/2(60%)	4/9 (30.8%)	0/5 (0%)	P=0.039
D56 (n*=17)	4/1 (80%)	1/8(11.1%)	0/3(0%)	P=0.007
1 year OS	81.2%	82%	100%	ns

Summary/Conclusions: Immunophenotypic groups and aberrant expression (CD10, CD34, CD10+CD34 and CD13/CD33) have an important prognostic value in T-ALL, which is evident by their effect on MRD D33, D56 and OS.

PB1603

BOTANICAL ALKYL HYDROQUINONE HQ17(3) INDUCES ENDOPLASMIC-RETICULUM STRESS AND AUTOPHAGY BEFORE THE ONSET OF CYTOTOXICITY ON THE T(9;22) PHILADELPHIA CHROMOSOME POSITIVE SUP-B15 ALL CELLS

CW Chen[1], YJ Chang[1], LI Lin[1], DT Lin[2], CY Hu[1,*]
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, [2]Department of Pediatrics, National Taiwan University Hospital, College of Medicine, National Taiwan University, Taipei, Taiwan, ROC

Background: Acute lymphoblastic leukemia with Philadelphia chromosome (Ph^+-ALL)(t(9;22)*BCR-ABL*) is a very high risk (VHR) hematological neoplasm. Constitutively active BCR-ABL oncoprotein together with multiple genetic lesions contribute to a very aggressive clinical cause that tyrosine kinase inhibitors (TKIs) combined with multi-agent chemotherapy fail to convey long-term disease control. Searching for agents selective to leukemias and investigating the molecule mechanisms involved in the inhibitory effects on leukemic cells will help to develop new anti-leukemic therapeutics for the Ph^+-ALL. HQ17(3) [10'(Z),13'(E),15'(E)-heptadecatrienyl-hydroquinone], a natural product isolated from the sap of *Rhus succedanea*, exhibited very effective cytotoxic effect on the TKI-refractory Ph^+-ALL SUP-B15 (IC_{50}:1.9 μM) and other ALL cell lines, but spared normal peripheral blood mononuclear cells. Combination of HQ17(3) and Imatinib has synergistic cytotoxic effect on SUP-B15 cells.
Aims: To investigate the characters of, and the molecular pathways involved in the HQ17(3)-induced cytotoxic effects in Ph^+-ALL SUP-B15 cells.
Methods: HQ17(3)-treated and control SUP-B15 cells were stained and analyzed by flow cytometry: membrane lipid disturbance was analyzed by Annexin V/PI stain, DNA fragmentation was defined as sub-G1 fraction of cellular DNA content after the PI staining, mitochondrial membrane potential (MMP) loss were stained by DiOC6(3). Pan-caspase inhibitor (zVAD-fmk), receptor interacting protein 1 (RIP1) inhibitor (necrostatin-1, Nec-1), iron-chelator (deferroxamine, DFO), 3-methyladenine (3MA) or chloroquine (CQ) (autophagy inhibitors), and lysosomal protease inhibitors were used in combination with HQ17(3) in some experiments. Acridine orange stain and confocal microscopy are used to visualize the changes of lysosomes in the presence of HQ17(3). Autophagic flow in response to HQ17(3) was revealed by accumulation of LC3B-II visualized by western blot analysis and aggregation of ectopically expressed GFP-LC3 indicator.
Results: Introduction of HQ17(3) induced extensive cell death within 24 hours characterized by losing plasma membrane integrity (PI^+) concomitant with PS exposure (Annexin V^+), which was not prevented by zVAD-fmk and/or Nec-1. Cell death displayed MMP loss and profound nuclear DNA fragmentation that could be attenuated by ROS scavengers. Acidic vesicles were significantly increased 4 hours after treatment of HQ17(3) then diminished when cell death was evident. Lysosomotropic DFO abolished the HQ17(3)-induced acidic vesicles and subsequent cell death. Application of AEBSF (serine protease inh.) and/or pepstatin/CA074-Me (cathepsin D/B inh.) did not rescue cells from death. Autophagy markers were enhanced in HQ17(3)-treated cells. Autophagy inhibitors (3MA and CQ) showed a modest protective effect. Further, HQ17(3) treatment gave rise to early and sustained AKT and mTOR activation and induced ER stress as shown unfolded protein response markers eIF2a phosphorylation and upregulated ER chaperon Grp78.
Summary/Conclusions: Naturally-derived HQ17(3) displayed significant cytotoxicity on Ph^+-ALL SUP-B15 cells. HQ17(3) leads to ER stress and induces iron-dependent autophagy followed by necrotic-like, caspase-independent cell demise that is different from RIP1-mediated necroptosis or lysosomal protease-mediated cell death. These results suggest that agents selectively induce or sustain ROS in leukemic cells may induce ER stress and autophagy-associated cell death, and would potentially augment the treatment for VHR-ALL with t(9;22) translocation.

PB1604

COMPARATIVE ANALYSIS OF CLONAL IG AND TCR GENE REARRANGEMENTS IN ADULT PH-NEGATIVE ALL AT THE DIAGNOSIS AND AT THE RELAPSE

S Smirnova[1], J Sidorova[1], B Biderman[1], K Sychevskaya[2], E Parovichnikova[3], N Ryzhikova[1], A Sudarikov[1,*]
[1]Department of Molecular Hematology, National Research Center for Hematology, [2]The faculty of fundamental medicine, Moscow State University, [3]Department of Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Clonal rearrangements of immunoglobulin (IG) and T-cell receptor (TCR) genes are the targets for minimal residual disease (MRD) assessment. The level of the MRD is an independent prognostic factor and its monitoring is important to identify patients with high risk of relapse. One of the pitfalls of MRD detection by means of IG and TCR gene rearrangements in ALL is clonal evolution possibly caused by V(D)J recombinase activity. Several studies have showed that the pattern of IG and TCR gene rearrangements in ALL patients may change during the course of disease. In relapse some gene rearrangements may be lost while new gene rearrangements may occur.

Change of clonal rearrangements, during tumor progression may lead to the loss of a target for MRD studies and false-negative results.
Aims: Studying the phenomenon of clonal heterogeneity in adult patients with ALL at the diagnosis and relapse of disease.
Methods: We have determined T- and B-cell clonality in six adults with Ph-negative ALL at the time of diagnosis and at the relapse. B-cell clonality was assessed by immunoglobulin heavy chain gene rearrangements IGH (VH – JH) and light kappa chain gene rearrangements IGK (Vk – Jk/Vk – KDE/Intron RSS – KDE). T-cell clonality was assessed by T-cell receptor gamma chain TCRG (VG – JG), beta chain TCRB (VB – JB /DB – JB) and delta chain TCRD (VD – JD/DD2 – JD/ VD – DD3/ DD2 – DD3) gene rearrangements. Multiplex BIOMED-2 primer system for PCR and Gene-Scan analysis have been used.
Results: In two patients with B-cell ALL one of clonal rearrangement presented at the diagnosis was lost at the relapse of disease while new rearrangements emerged. In one patient with a diagnosis of early T-ALL clonal rearrangements of the genes TCRD, TCRB and TCRG, identified at the diagnosis were exactly the same in relapse. In one patient all the rearrangements identified at the diagnosis were preserved at the relapse and several new rearrangements appeared. In one case five rearrangements disappeared at the relapse of disease out of seven identified at the diagnosis (Figure 1). In one patient only one clonal rearrangement was revealed at the diagnosis of B-cell ALL and at the relapse of the disease this rearrangement was preserved, but there were a few new. To analyze initial ALL samples for possible presence of minor clones that lately we have found in relapse we used appropriate family-specific primers to V and J-region instead of multiplex primer mixtures. Despite increased to 10^{-2}-10^{-3}sensitivity no detectable cell populations of these subclones were found.

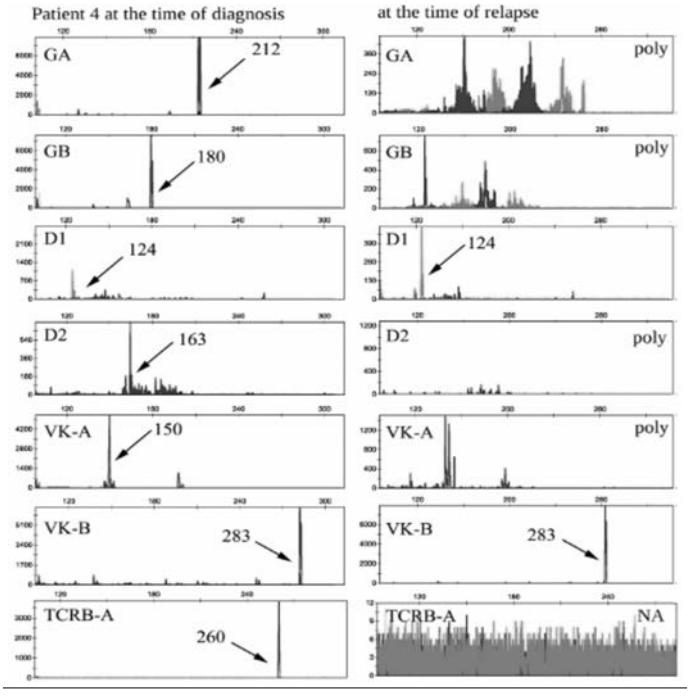

Figure 1.

Summary/Conclusions: Mismatch in clonal rearrangements at the diagnosis and at the relapse of disease was identified in five of six (83%) patients, indicating clonal instability during the course of treatment. Clonal evolution and diversity of clonal IG and TCR gene rearrangements could be one of the features of tumor progression. Also it could be speculated that many clonal IG and TCR gene rearrangements may present at different amounts at the diagnosis, however less abundant clones could be "invisible" due to the limitation of measuring sensitivity. Later major clones may disappear under the influence of chemotherapy while others could gain proliferation capacity. Study of the clonal evolution and heterogeneity in ALL and their impact on treatment efficacy should help to develop new prognostic factors and therapeutic strategies.

POTENTIAL GOOD TARGET FOR IMMUNOTHERAPY – PRAME ANTIGEN HAS SELF-ACTIVATING ABILITY

V Misyurin[1,2,*], A Misyurin[1,2], A Misyurina[2,3], Y Finashutina[1,2], N Lyzhko[1,2], O Solopova[1], L Kesaeva[1,2], N Kasatkina[1], E Misyurina[4], E Pushkova[2], A Uvarova[1], A Inshakov[1], O Burova[1], M Baryshnikova[1]
[1]FSBI « N.N. Blokhin Russian Cancer Research Center», [2]«GeneTechnology» LLC, [3]National Research Center for Hematology, Ministry of Health of Russia, [4]City Clinical Hospital No52, Moscow, Russian Federation

Background: According to literature, PRAME (preferentially expressed antigen in melanoma) protein may be exposed on extracellular membrane. Interestingly, that PRAME is structural homolog of TLR2 protein. TLR2 activates NF-kB signaling pathway and NF-κB activates an expression of TLR2. As a result, TLR2-mediated activation of expression TLR2 is possible event. If PRAME is similar to TLR2, it's possible to suggest PRAME-mediated activation of its own expression. PRAME protein is expressed in a wide range of cancers. In addition, this protein is non-active in cells of somatic tissues and is highly immunogenic. If PRAME is expressed in a tumor cell, it's possible to increase an expression level of PRAME; this can lead to higher immunogenicity of tumor cells. This method could be a powerful in context of specific anti-PRAME immunotherapy.
Aims: To show that intracellular PRAME protein expression level is increased in case of binding anti-PRAME antibody with cell membrane.
Methods: We created a mouse monoclonal antibody 5D3F2, specifically recognizing PRAME antigen. Tree cell lines were used for incubation with anti-PRAME antibody: acute monocytic leukemia cell line THP-1, acute myeloid leukemia cell line NOMO-1 and disseminated melanoma cell line mel IBR. Expression level of PRAME gene was evaluated by RQ-PCR. Cell lines THP-1 and NOMO-1 were incubated in RPMI 1640 with addition of anti-PRAME antibody. Antibody concentration was 10 ug/ml, and amount of cells counted 10000/ml. Samples of cells was analyzed after 1, 2 and 4 hours and after 1, 2 and 3 days of incubation. Number of PRAME-expressing cells was determined by flow cytometry using a FITC-labeled antibodies 5D3F2. All experiments were repeated 3 times.
Results: PRAME gene expression level was 1,67% in THP-1; 0,46% in NOMO-1 and 963% in mel IBR relative of ABL expression level before experiment. According to flow cytometry data, number of PRAME-expressing cells THP-1 and NOMO-1 before experiment was 11,4% and 3,6%, respectively. Intensity of PRAME-expressing cells in THP-1 fluorescence after incubation with antibody 5D3F2 was 101,21% (after 1 hour), 75,79% (2 hour), 88,45% (4 hour), 421,28% (1 day), 433,33% (2 day) and 820,37% (3 day). Fluorescence intensity of PRAME-expressing cells in NOMO-1 after incubation with antibody 5D3F2 was 93,88% (1 hour), 87,07% (2 hour), 74,67% (4 hour), 175,45% (1 day), 562,67% (2 day) and 146,33% (3 day).
Summary/Conclusions: PRAME protein is expressed on THP-1 and NOMO-1 cell surface. Antibody 5D3F2 binds with cell membrane and it could explain decrease of fluorescence intensity in first hours. FITC-labeled 5D3F2 show this reduction because many PRAME epitopes are closed by non-labeled 5D3F2. But after 1 and more days number of PRAME epitopes on cell surface grows, and flow cytometry reaction displays it. This finding suggests that it is possible to develop an anti-PRAME monoclonal antibody for therapy PRAME-positive disease. Moreover, PRAME expression level may be increased during therapy with these antibodies. It can be useful, because PRAME-expressing cell becomes more immunogenic after binding with a potential therapeutic anti-PRAME antibody. We did not investigate the role of NF-kB, but it will be our next challenge.

ABERRANT IMMUNOPHENOTYPES IN B-ACUTE LYMPHOBLASTIC LEUKEMIA

F Ceran, M Falay, Y Kalpakci, S Dagdas, G Ozet, DN Avci*
Hematology, Ankara Numune Education and Research Hospital, Ankara, Turkey

Background: Recently immunophenotyping has a critical role for diagnosis and classification of leukemia and lymphoma. Immunophenotyping is used increasingly for identification of some subtypes, treatment follow-up of minimal residual disease (MRD) and even for prognostic purposes. Also, myeloid and T cell aberrant antigen expressions help to distinguish B acute lymphoblastic leukemia (B-ALL) from hematogones.
Aims: The aim of this study was to evaluate myeloid and T cell aberrant expressions in B-ALL patients who had been referred to our flow cytometry center.
Methods: We retrospectively analyzed the flow cytometry data of newly diagnosed 417 B-ALL samples which were collected in our laboratory between the years 2002-2016. We used a large panel of monoclonal antibodies against lymphoid, myeloid and precursors antigens.
Results: Aberrant antigens were detected in 143/417 (34.29%) of B-ALL patients. Expression of myeloid antigens was a common aberrancy in B-ALL. The leukemic lymphoblasts exhibited aberrant expression of 4 myeloid antigens and 5 T-cell antigens. The most frequently expressed antigen was CD33 (74/143), followed by CD13 (57/143), MPO (2/143), and CD11b (1/143). Dual expression of CD13 and CD33 was seen in 24 patients. Expression of T-cell aberrant antigens was observed in only 8 patients. CD2 was positive in 3 patients, CD5 was positive in 2 patients, and CD3, CD7, CD56 were positive separately in 3 patients.
Summary/Conclusions: Aberrant antigen expression is important in MRD follow-up, also it is reported to be associated with prognosis and cytogenetic abnormalities. In literature, adult B-ALL cases expressing CD13 and CD33 have been reported to be related to BCR-ABL positivity. MPO aberrant antigen expressions are very rare and BCR-ABL has been reported mostly negative in MPO positive patients. We have detected MPO aberrant antigen expression in 2 patients, none of them has BCR-ABL positivity. Expression of T-cell antigens

has rarely been reported in B-ALL, and the significance of this aberrant antigen expression is unclear. Several studies showed that T-cell aberrant expression leads higher relapse risk and it is associated with adverse cytogenetic abnormalities.

PB1607

THE EXPRESSION LEVEL OF HLS5 IS CORRELATED WITH THE CLINICAL OUTCOMES OF ACUTE LYMPHOID LEUKEMIA (ALL) PATIENTS

J Huang[1,*], J CHEN[2], J JIN[3]
[1]Hematology, the Fourth Affiliated Hospital, College of Medicine,Zhejiang University, Yiwu, [2]Institute of Hematology, Zhejiang University, [3]Department of Hematology, the Fourth Affiliated Hospital, College of Medicine,Zhejiang University 2Department of Hematology, the First Affiliated Hospital, College of Medicine and3 Institute of Hematology, Zhejiang University, Hangzhou, China

Background: HLS5 belongs to the RBCC (Ring-finger, B-box, coiled-coil) family, a family of tumor suppressive genes including Pm, Tif1-α,Herf and Rfp, it has been reported to regulate erythroid differentiation, to be activated during the conversion of J2E erythroleukemic cells to monocytoid cells, and assumed to be a tumor supressor. However, the role of HLS5 in acute lymphoblastic leukemia has never been explored.
Aims: To identify the expression of HLS5 and the relationship to the clinical outcom to ALL.
Methods: Bone marrow of 63 *de novo* ALL patients were collected, the mononucleated cells separated, RNA extracted and the HLS5 expression level detected using real-time quantitative PCR. SPSS 16.0 used for data analysis.
Results: The high HLS5 expression level (the higher 25% of all the patients) is correlated with longer overall survival and event free survival (both $p<0.05$), but the correlations between HLS5 expression level and blast count, WBC, Hb level, platelet count, IK6 status and Ph chromosome status are not significant.
Summary/Conclusions: The expression level of HLS5 in *de novo* ALL patients may associate with the clinical outcome, but the exact mechanism needs further investigation.

COMPARISON OF THE PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE AND THE CONVENTIONAL PROGNOSTIC FACTORS IN THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA PATIENTS

S Lozenov[1,*], B Spassov[1], Y Petrov[1], V Stoeva[1], T Yankova[1], K Ignatova[1], Y Zhechev[1], M Staneva[1], T Mihailova[1], D Peichev[1], S Simeonov[1], D Nihtyanova[1], M Guenova[2], G Balatzenko[3], M Donchev[1], G Arnaudov[1], G Mihaylov[1]
[1]Clinical hematology department, [2]Hematopathology department, [3]Molecular biology and cytogenetics laboratory, Nshathd, Sofia, Bulgaria

Background: During the past couple of decades the response rates, the leukemia free survival and the 5 year overall survival (OS) in adult patients with acute lymphoblastic leukaemia (ALL) have improved significantly. There is an ongoing trend to improve further OS through better risk assessment. The risk stratification in different treatment protocols is usually based on groups of conventional prognostic risk factors, such as – white blood cells count (WBC) at diagnosis, immunophenotype, cytogenetic and molecular abnormalities, achievement of CR and time to achievement of CR, age with some variations among the different study groups. To improve the results of risk stratification through the conventional risk factors, the evaluation of the level of minimal residual disease (MRD) and its use for treatment decision making have been introduced. Several studies have already established the contributory role of MRD levels for the prediction of relapse and continuous complete remission (CCR) in the ALL patients. Despite the growing involvement of MRD evaluation in the risk stratification of adult ALL patients, there is a continuing need to better address the specific role MRD examination should play among other ALL prognostic factors and to better establish the best time point for ALL MRD evaluation.
Aims: With the present retrospective assessment we aimed to compare the impact of minimal residual disease and a group of conventional prognostic factors on the overall survival of adult ALL patients.
Methods: We analyzed retrospectively 81 patients with adult ALL, that were treated in the National Specialized Hospital for Active Treatment of Hematology Diseases (NSHATHD) between 1.1.2009 and 1.1.2016, of them 53 were CR achievers. The minimal residual disease (MRD) levels of the patients were measured through 8-color flow cytometry and through semiquantitative RT-PCR, following the BIOMED 1 program protocol for the patients with a MLL-AF4 and BCR-ABL fusion transcripts chromosome. MRD negativity or molecular complete remission (molCR) was defined as a level of less than 10^{-4} ALL cells or lack of expression of fusion transcripts.
Results: MRD negativity had a statistically significant impact on OS 70.3% *vs* 10.7% for the MRD negativity non-achievers. The conventional risk factors did not seem to convey greater prognostic significance with differences between conventional risk groups in terms of OS not reaching statistical signifcance and the multivariate analysis demonstrating significance only of MRD status, WBC and PSECOG with hazard ratios of 5.241, 3.070, 2.061, respectively. Allogeneic hematopoietic stem cells transplantation significantly improved OS in the patients who did not achieve MRD negativity with 3-year overall survival of 38.9% *vs* 11.7%.
Summary/Conclusions: The impact of molCR status on survival will probably lead to new risk stratification strategies based to a greater extent or even exclusively on the MRD status. The optimal time for MRD risk stratification remains to be established.

PB1609

PROGNOSTIC IMPACT OF CD20 EXPRESSION IN ADULTS WITH PHILADELPHIA CHROMOSOME NEGATIVE PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

I Djunic[1,2,*], M Virijevic[2], N Kraguljac-Kurtovic[2], V Knezevic[2], T Dragovic-Ivancevic[2], A Novkovic[1,3], M Mitrovic[1,2], N Colovic[1,2], A Vidovic[1,2], N Suvajdzic-Vukovic[1,2], D Tomin[1,2]
[1]Medical Faculty of Belgrade University, [2]Clinic for hematology, Clinical Center of Serbia, [3]Clinical Hospital Center "Zemun", Belgrade, Serbia

Background: Prognostic influence of immunophenotypic markers in acute lymphoblastic leukemia (ALL) is well recognized. The prognostic significance of CD20 expression in precursor B-cell acute lymphoblastic leukemia (ALL) has been investigated first in childhood and than in adult with conflicting results.
Aims: The aim of this study was to determine the prognostic impact of CD20 expression on outcome in adult patients with Philadelphia chromosome negative (Ph-) precursor B-cell ALL. The second goal was to estimate, in comparison to the results, is there a need to incorporate monoclonal anti CD20 antibody (Rituximab) in routine treatment of these patients, where it is not available, to improve their outcome.
Methods: This single center study involved 122 patients with *de novo* Ph- precursor B-cell ALL diagnosed in period 2003 – 2015, with follow-up period of 72

months. For CD20 antigen expression, detected by flow-cytometry, the cut-off value ≥20% was taken as positive (CD20+). As risk factors for rate of complete remission (CR) and overall survival (OS) in months in this cohort of patients the following were evaluated: age, leukocytosis (<30x10^9/L *vs* ≥30x10^9/L) and CD20 expression. In period of 2003 – 2006, the patients were treated with regimen LALA 94, while in period 2007-2015 they were treated with protocol Hyper-CVAD. The applying of monoclonal anti CD20 antibody (Rituximab) with chemotherapy was no available.

Results: The mean age of the patients was 42 years (range 19-77). The CD20+was recorded in 41 (33.6%) of patients. The estimated risk factors had no influence to achievement of CR. However, the univariate analysis showed that age ≥55 years (p=0.035) and CD20+(p=0.042) had significant impact on poor OS. Multivariate analysis indicated CD20+as the most important risk factor for poor OS: p=0.001, HR=3.853(95% CI=1.755-8.461.

Summary/Conclusions: This study showed the negative impact of CD20 expression in Ph- precursor ALL on outcome of these patients. Also, we point out the importance of incorporation monoclonal anti CD20 antibody (Rituximab) in combine with chemotherapy in routine treatment of these patients to improve its outcome.

PB1610

CLINICOPATHOLOGIC CHARACTERISTICS ASSOCIATED WITH NATURAL KILLER CELL ACTIVITY BY MEASUREMENT OF INTERFERON-GAMMA IN HEMATOLOGIC MALIGNANCIES

S Park[1], YC Mun[2], CM Seong[2], HJ Huh[3], J Huh[1,*]
[1]Laboratory Medicine, [2]Internal Medicine, Ewha Womans University College of Medicine, Seoul, [3]Laboratory Medicine, Dongguk University, Ilsan Medical Center, Ilsan, Korea, Republic Of

Background: Natural killer (NK) cells play a key role in innate immune responses and an important component of anti-cancer defenses. Evaluation of NK cell activity could be invaluable to estimate the status and the outcome of cancers. Defects in NK cell cytotoxicity have been reported in hematologic malignancies. Conventional methods such as 51Cr release assay and CD107a degranulation assay may be useful to determine NK cell activity, but they require complex experimental setups and are not appropriate for routine laboratory test. Recently, a commercialized kit for measurement of NK cell activity was developed, which measure released interferon-gamma secreted by *ex vivo* stimulated NK cells in whole blood.

Aims: The purpose of this study was to investigate clinicopathologic characteristics associated with NK cell activity by measurement of interferon-gamma.

Methods: The study group included 134 patients (61 at diagnosis and 73 at follow up) diagnosed as having hematologic malignancies between Mar 2015 and Jan 2016. The NK cell activity was measured by commercialized kit (NK Vue assay, ATgen, Sungnam, Korea), which is a quantitative sandwich ELISA to measure released interferon-gamma secreted by NK cells in whole blood collected in PROMOCA tube (an engineered recombinant cytokine that specifically activates NK cells). NK cell activity was expressed as ratio which patient's result was divided by upper normal level. NK cell activity was analyzed using 294 specimens obtained from patients at diagnosis or follow up.

Results: The median ratio value of NK cell activity was 1.27 (range: 0.03-8.0). Comparing with NK cell activity of 61 patients at diagnosis (12 AML, 5 ALL, 3 CML, 2 MDS/MPN, 11 MM, 25 lymphoma, 3 solid cancer), ALL patients had significantly decreased NK cell activity (median: 0.16, range: 0.16-0.26) than lymphoma patients (median: 1.05, range: 0.03-2.35, *P*=0.0196). No significant differences were found among other hematologic malignancies at diagnosis.

Among the total patients including at diagnosis and follow up, NK cell activity was positively correlated with percentage of lymphocytes (r=0.346, *P*<0.0001), whereas NK cell activity showed weak negative associations with total WBC counts (r=-0.126, *P*=0.0324), neutrophil counts (r=-0.155, *P*=0.0083) and NLR (neutrophil/lymphocyte ratio) (r=-0.227, *P*<0.0001). Of particular, NK cell activity had positive correlations with percentage of lymphocytes in patients with AML (r=0.693, *P*=0.0125), lymphoma (r=0.502, *P*<0.0001) and multiple myeloma (r=0.427, *P*=0.0011). The regression analysis between NK cell activity and lymphocyte subsets identified by flow cytometry (CD56+NK cell, CD3+T-cell, CD4+T-cell and CD19+B-cell) did not show significant associations except for CD8+T cell counts (r=0.159, *P*=0.0083). The CRP didn't show a significant association with NK cell activity(r=0.126, *P*=0.6076).

Summary/Conclusions: This study showed that the NK cell activity was significantly decreased in ALL patients, comparing with that of lymphoma patients and NK cell activity was not correlated with NK cell counts identified by flow cytometry. NK cell assay by measurement of interferon-gamma secreted by *ex vivo* stimulated NK cells in whole blood, could be useful to evaluate and monitor the NK cell activity in hematologic malignancies.

PB1611

MINIMAL RESIDUAL DISEASE: COMPARISON BETWEEN TWO METHODS IN A CLINICAL DIAGNOSTIC LABORATORY.

A Lemes[*], L Torres, D Fiallo, DLI Silvia, C Bilbao, GC Maria Teresa, T Molero
Hematología, Hospital Universitario de Gran Canaria Doctor Negrín, Lasd Palmas de Gran Canaria, Spain

Background: Flow cytometry and molecular techniques are the most important methods for monitoring minimal residual disease (MRD) in leukemia.

Evaluation of specific molecular markers represents the most sensitive and specific analysis in MRD leukemia, however the existence a small number of markers which in few cases are valid to follow the course of the disease is a limiting factor. Because of this, there is the necessity to identify new widely represented markers in AML and that could predict relapse

On the other hand, immunophenotype associated to leukemia (LAIP) have been proved to be very useful in the detection of MRD and it can be used up to 85% of patients.

Aims: The aim of this study was to compare the concordance of MRD measured by flow cytometry with standardized molecular techniques including NPM1, Inv16 and AML1-ETO. Furthermore, we also analyzed the behavior of WT1 at this respect in order to determine whether overexpression of WT1 could be a new MRD marker.

Methods: A total of 35 samples of bone marrow from patients with AML in different stages of the disease were assessed. We analyzed NPM1, Inv16 and AML1-ETO by using the gold standard quantitative PCR techniques and these results were compared first with the results obtained by flow cytometry, and then with WT1 levels measured through non standardized quantitative PCR.

In order to analyze antigen expression by flow cytometry, we used a combination of eight monoclonal antibodies, according to the panels and procedures suggested by EuroFlow Group. We analyzed about 1,000,000 events to asses MRD with a sensitivity of 10^{-4}, so MRD was registered as positive when we detected at least 100 events with LAIP, (MRD=0.01%).

Results: Our results revealed:- High concordance between MRD by Flow Cytometry and standardized molecular techniques, with a sensitivity of 88% and a specificity of 72% (Table 1). However, when we compared standardized *vs* non standardized techniques, WT1 showed a sensitivity of 100% and specificity of 47% (Table 2).

Table 1.

MRD	Molecular Markers +	Molecular Markers -	
FC +	15	2	17
FC -	5	13	18
	20	15	35

Table 2.

MRD	Molecular Markers +	Molecular Markers -	
WT1 +	4	0	4
WT1 -	11	10	21
	15	10	25

Summary/Conclusions: 1. Flow cytometry is a useful tool for detecting MRD in AML. However, it is important to establish cutoffs to predict relapse in the different stages of the disease.2. The results regarding WT1 may reflect the lack of standardization in the quantification of the marker, although it shows high specificity for the presence of disease.

PB1612

SEASONAL CLUSTERING OF ADULT ACUTE LEUKEMIAS IN A SUB-TROPICAL AREA OF BRAZIL

I Lorand-Metze[1,2,*], RA Pereira[3], KB Pagnano[2], K Metze[3]
[1]Internal Medicine, [2]Hematology/Hemotherapy Center, [3]Pathology, University of Campinas, Campinas, Brazil

Background: Seasonal peaks in the diagnosis of acute leukemias have been reported in different countries all over the world. These peaks may be caused by temporal changes in environmental factors (pollutant agents, allergens, pathogens) or by the known seasonal changes in the human immune system. Particularly, childhood acute lymphoblastic leukemia (ALL) has been studied, but results are inconsistent. Winter peaks have been found in Sweden, Finland, Iran, and South Africa, but a summer peak has been described in England. Brazil is a large country with latitudes ranging from the equator to sub-tropical areas. The Tropic of Capricorn passes near the city of São Paulo. So, the state of São Paulo has a hot and rainy summer, and a dry winter with days of low temperatures in the night.

Aims: We examined the seasonal trends in adult acute leukemia in our region analyzing the relation between the number of newly diagnosed cases of ALL and AML per month and maximum and minimum temperatures, as well as pluvimetric data during the last 25 years.

Methods: We examined the monthly number of newly diagnosed cases of AML and ALL (age <18 years) and its relation to monthly maximal, minimal and median temperatures as well as the amount of rainfall.

Results: During this period, 1303 AMLs and 236 ALLs entered the study. Concerning ALL, there was a significant positive correlation between the absolute minimum monthly temperature, the pluviometric index of the month of diagnosis, as well as these features in the 3 previous months. In a multiple regression analysis, only the pluvimetric index of the month before diagnosis entered into the final model (r=0.177; p=0.001). Concerning AML, there was a significant positive correlation (r=0.12; p=0.01) only with the absolute maximum temperature of the month of diagnosis. None of the other variables examined were found to be significant.
Summary/Conclusions: We observed a seasonal variation in the diagnosis of adult ALL related to temperature and especially to rainfall in the months preceding the diagnosis. This may be associated with a higher incidence of environmental allergens or infections in the more humid months of the year, leading to the outbreak of the disease, as has also been postulated for childhood and adult ALL in other countries. Concerning AML, a clear relation was found only with actual high temperature peaks. Perhaps, the temperature stress could provoke decompensation of an already existing bone marrow failure making the patients seek for medical assistance. This does not exclude that other environmental factors related to the pathogenesis of AML may act with different intensities in different climatic conditions.

PB1613

PROGNOSIS OF CHILDREN WITH ACUTE HYPERLEUKOCYTIC LYMPHOBLASTIC LEUKEMIA TREATED WITH MODIFIED ST JUDE TOTAL XV PROTOCOL

M Cetin*, S Aytac, C Dogancay Karahan, B Kuskonmaz, S Unal, F Gumruk, M Tuncer
[1]Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: Acute leukemias with high white blood count (greater than or equal to 100,000/mm3) have a poor prognosis with an increased risk of early morbidity and mortality.
Aims: In this study we aim to analyse outcome of all complications due to hyperleucocytosis including tumor lysis syndrome, hyperuricemia, renal failure, disseminated intravascular coagulation and treatment modalities of these complications during remission induction beside long term outcome.
Methods: Between January 2008 to December 2015, 206 children with ALL were diagnosed at Hacettepe University Faculty of Medicine, Ihsan Dogramaci Children's Hospital. However 33 were excluded from the study (infant leukemia (n=11), relapse ALL referred to our center and/or initialy treatment was given by another center (n=6), secondary ALL(n=1), mature B cell ALL(n=7), early death (n=7), lost to follow up(n=1)). 173 remained in the study and 20 out of 173 were diagnosed as hyperleukocytic high risk acute ALL.
Results: There were 8 female,12 male with a median age of 5 years old (between 1 to16,7 years). Mean initial WBC conunt is $206x10^3$/µl ($119\text{-}462x10^{-3}$/µl). 9 were T cell immunophenotype however 8 were Calla+B cell and 3 were Calla-B cell phenotype. Initial CNS involvement was 33% among these hyperleukocytic ALL patients. Translocation (9;22) was found to be positive in 2 and they received allogeneic hematopoeitic stem cell transplantation. MRD status by flowcytometer was done on the 15th day of remission induction and all except one was found to be under <0.1%. Relapse was observed 3 out of 20 (15%) in this group(combined relapse BM+CNS(n=1), isolated CNS(n=1), isolated bone marrow (n=1)). However all patients including 3 HSCT patients and relapse patients were in complete remission and alive.
Summary/Conclusions: In our study hyperleukocytic high risk All patients did show slightly improved survival when compared with the literature.

PB1614

THE POTENTIAL EFFECT OF CATHEPSIN B ON THE CLINICAL COURSE OF CHILDHOOD ALL

B Zalewska-Szewczyk[1,*], P Gorniak[2], W Justyna[1], S Janczar[1], K Wyka[1], W Mlynarski[1]
[1]Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, [2]Department of Hematological Diagnostics, Institute of Hematology and Transfusiology, Warsaw, Poland

Background: Cathepsins belong to the ubiquitous family of lysosomal cysteine proteases responsible for the conversion and degradation of intracellular proteins. In many types of cancer increased overexpression of cathepsin B (CTSB) was observed, in some solid tumors, overexpression of cathepsin B and L is considered a negative prognostic factor. Published pilot data showing a relationship between an increased expression of cathepsin B and L (CTSB, CTSL) and a worse outcome in acute myeloblastic leukemia.
Aims: The aim of this study was to evaluate the potential significance of CTSB expression in childhood ALL.
Methods: CTSB expression was evaluated in bone marrow cells collected at the time of diagnosis in 32 children aged 1.4 to 17.9 years, mean 7.16, 17 boys with newly diagnosed acute lymphoblastic leukemia who were treated at a single center according the protocol ALL IC 2002. In the bone marrow samples taken at the diagnosis RNA was isolated, in a further step of reverse transcription reactions were carried out using a commercially available kit (Applied Biosystems, USA). Determination of the expression was performed by real-time PCR.
Results: For the further analysis the expression above the upper quartile was defined as high. It was observed that the children with high CTSB expression were diagnosed at a younger age (median 6.51 *vs* 2.41 years, p=0.047). There was no correlation between the level of expression of CTSB in leukemia cells and WBC at baseline (p=0.31). The CTSB expression level in leukemia cells had no effect on the activity of L-asparaginase after the first dose (median of 89.42 IU/L *vs* 93 IU/L, p=0.226), early response (status bone marrow 15th day of induction, p=0.256), the response to steroid therapy (p=0.53) and the status of the CNS (p=0.37).
Summary/Conclusions: In summary, this pilot study may suggest the potential importance of CTSB in acute lymphoblastic leukemia in children. Further analysis in a larger study group is needed.

PB1615

HEPATIC VENOOCCLUSIVE DISEASE DURING TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA MANAGED WITH DEFIBROTIDE

H Kızılocak, N Ozdemir*, G Dikme, T Celkan
Pediatric Hematology Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Hepatic venoocclusive disease (VOD) which is the non-thrombotic obliteration of small intrahepatic veins, presents with the clinical triad of jaundice, hepatomegaly, and/or upper right quadrant pain and ascites. Definitive diagnostic tests are not available.
Aims: VOD is a common complication of cytoreductive therapy used for hematopoietic stem cell transplantation (HSCT). However, it may develop during conventional-dose treatment of acute lymphoblastic leukemia (ALL), and even more rarely, during induction treatment.
Methods: We describe four patients in whom VOD developed during induction treatment for ALL.
Results: All of the four cases, three male and one female, were diagnosed with B-cell ALL. One of them developed VOD at the end of his first protocol phase-1 (P1F1), day 31 of his treatment and presented with hepatomegaly, direct hyperbilirubinemia and increased liver transaminases. The patient's ultrasonography of the liver with doppler studies showed minimal ascites and reversal of flow in the portal veins which suggests the presence of VOD. Other three cases developed VOD at second cytarabin (ARA-C) block of the protocol 2 phase 2 (P2F2) and presented with abdominal distension, weight gain, hepatomegaly, ascites, direct hyperbilirubinemia, severe thrombocytopenia, anemia, increase of liver transaminases and abnormalities of coagulation. Defibrotide was started at a dose 25 mg/kg/day and VOD recovered both with clinical and laboratory findings at all patients.
Summary/Conclusions: Hepatic venoocclusive disease not only develops after HSCT, but also may develop during treatment for ALL. All patients with elevated liver enzymes, ascites, hepatomegaly, hyperbilirubinemia and severe thrombocytopenia must be evaluated for VOD.

PB1616

STUDY OF BONE DENSITY AND OSTEOCALCIN LEVEL IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A Elsharkawy[1,*], M Salama[1], K Moghazy[2], A Elhadidy[3], M Youssef[1]
[1]pediatrics, [2]Radiology, [3]Clinical Pathology, Alexandria university, Alexandria, Egypt

Background: Leukemias are the most common malignant neoplasms in childhood, with acute lymphoblastic leukemia (ALL) accounting for 75% of all childhood leukemias and 30% of all childhood cancers. An increasing number of children survive ALL, approaching approximately 80% over the last 2 decades, as a result of improved and more intense chemotherapy. Musculoskeletal abnormalities are well recognized in children with ALL at diagnosis, during treatment, and persist as long-term sequelae after treatment. Osteotoxic chemotherapy, steroid exposure, poor nutrition, low vitamin D, and poor muscle mass contribute to the development or worsening of bone pathology during therapy that may result in osteoporosis, fracture, and osteonecrosis. Risk-directed therapy has substantially improved treatment outcomes for pediatric ALL, with 5-year survival rates approximating 80% . Given success of this magnitude, it is important to address the management and prevention of bone toxicity. The current study evaluated the bone density and alterations in biochemical mineral status in children with ALL at time of diagnosis, during chemotherapy and after finishing chemotherapy.
Aims: To study Bone density and serum osteocalcin level in children with acute lymphoblastic leukemia.
Methods: Serum osteocalcin and DXA scan were evaluated in 45 children with ALL,15 at diagnosis and before starting chemotherapy, 15 during chemotherapy and 15 after completing their treatment regimen.
Results: From the total 45 patients, 23 (51.1%) had low osteocalcin level and

36 (80%) had low bone mineral density (48% had osteopenia and 32% had osteoporosis).
Summary/Conclusions: Musculoskeletal abnormalities are present in children with ALL at diagnosis, during treatment, and persist as long-term sequelae after treatment.

EARLY IDENTIFICATION OF CALM-AF10 MUTATION BY MOLECULAR PROFILING HELPS TO RISK STRATIFY HIGH RISK T-ALL FOR EARLY VUD ALLOGENEIC BONE MARROW TRANSPLANT

A Dicu[1], J Russell[2], D Shor[1], T Klemencickozul[3], S Wedderburn[4], W Knibbs[1], B Manasse[5], D Bloxham[6], J Morgan[1], H Warner-Charlick[7], A Hodson[8], M Prahladan[9,*]
[1]Haemato Oncology, [2]Haemato-Oncology, Ipswich Hospital, Ipswich, [3]Haemato Oncology, Ipswich Hospital, Cambridge, [4]Haemato Oncology, Ipswich Hospital NHS trust, Ipswich, [5]Haemato Oncology Diagnostic centre, Addenbrookes Hospital, [6]Haemato oncology diagnostic centre, Addenbrookes Hospital, Cambridge University Hospital NHS Foundation trust, [7]Haemato Oncology, Ipswich Hospital/ Adddenbrookes Hospital, Cambridge UNiversity Hospital NHS Foudation Trust., [8]Haemato Oncology, Ipswich Hospital/ Addenbrookes Hospital, Cambridge University Teaching Hospitals NHS Foundation Trust., [9]Haemato Oncology, Ipswich Hospital/Addenbrookes Hospital, Cambridge University Teaching Hospital NHS Foundation Trust, Cambridge, United Kingdom

Background: The t(10;11)(p12;q23) and t(10;11)(p12;q14) translocations, which encode the clathrin-assembly protein-like lymphoid myeloid leukemia gene (PICALM)- MLLT10 (formerly CALM-AF10), are recurrent chromosomal rearrangements found in some patients with T-cell acute lymphoblastic leukemia (T-ALL), and are associated with poor outcomes to standard chemotherapy. PICALM-MLLT10-positive cases often have positive expression of CD13, CD33 or CD34, but negative expression of the T-lineage markers CD5, TdT, cCD3 and CD7.
Aims: Mutational analysis on RT-PCR in conjunction with flow cytometry, fluorescent *in situ* hybridization (FISH) and metaphase karyotyping, increases the sensitivity for detecting primary and secondary cytogenetic abnormalities in patients with high-risk T-ALL.
Methods: We report a 34-year-old lady with T-ALL who presented with a mediastinal mass. Blast cells in the bone marrow aspirate demonstrated strong expression of CD7, CD13, CD56, HLA-DR, cytoplasmic CD3, and equivocal expression of CD99. No other T-cell-associated antigens were detectable (including CD1a, CD2, surface CD3, CD4, CD5, CD8, CD16, CD57, CD34 and TdT). The T-Lymphoblastic Leukaemia FISH panel was negative. Chromosomal analysis showed 46,XX,t(10;11)(p13;q14)[5]/46,XX, with balanced reciprocal translocation between the short arm of chromosome 10 and the long arm of chromosome 11. Genome molecular profiling showed recurrent translocation PICALM-MLLT10 [CALM-AF10];t(10;11)(p13;q14) with no disruption of the MLL (11q23) locus, confirming the negative MLL FISH result. The patient achieved complete remission following phase-two induction on the UKALL14 protocol and elected to have a volunteer unrelated donor (VUD) myeloablative allogeneic bone marrow transplant. She remains in complete remission 14 months post-transplant.
Results: The positive outcome for our patient, following allogeneic transplant, reflects similar reports from the UKALLXII/ECOG2993 trial for patients with the MLLT10 [CALM-AF10];t(10;11)(p13;q14) mutation. The use of mutational analysis on RT-PCR early in the diagnostic process, in this case, allowed prompt detection of a high-risk cytogenetic abnormality and more accurate risk stratification that guided the decision to proceed to allogeneic transplant.
Summary/Conclusions: Early identification of high risk cytogenetic abnormality incorporating mutational analysis using RT -PCR along with immunophenotype, FISH and karyotype help to risk stratify patients for allogeneic bone marrow transplant resulting in successful outcome in patients with in high risk T-ALL.

PB1618

THE INCIDENCE OF ACUTE LEUKEMIA IN SOME REGIONS OF THE RUSSIAN FEDERATION

A Zalina[1,*], S Kulikov[1], M Rusinov[1], E Zotina[2], L Gavrilova[3], A Pristupa[4], N Vopilina[5], E Borisenkova[6], E Parovichnikova[1]
[1]National Research Center for Hematology, Moscow, [2]Kirov Clinic Hospital, Kirov, [3]Mordovia Republic Hospital, Saransk, [4]Ryazan Regional Clinical Hospital, Ryazan, [5]Tambov Regional Clinical Hospital, Tambov, [6]Kaluga Regional Clinical Hospital, Kaluga, Russian Federation

Background: The incidence of acute leukemia (AL) in US and European countries is about 5 per 100000 according data from cancer registries. Russian Federal Cancer Register (RFCR) reported AL incidence rate across the country as about 3 per 100000.
Aims: To evaluate the age-gender specific incidence, profile and other epidemiologic characteristics AL in Russia regions.
Methods: Russian Hematology Society in 2013 initiated the AL population based registry study in which participated 5 regions of Russia Federation. The primary goal was to pre-registry patients for clinical studies, and secondary - to evaluate the epidemiology of AL. 5 regions were included into analysis of epidemiology statistics. The criteria were the fullness and reliability of AL cases registration. Also, only regions with one big hematological center accumulating all AL cases were chosen. All new cases were recorded on-line into special Web based data capture system.
Results: The registry was started at 1st April of 2013 and is ongoing. 216 new ALL cases from Kirov, Ryazan, Kaluga, Tambov regions and Mordovia republic (4,7 M of population) were included into analysis. The distribution by AL subtypes was following: AML - 131 (60,6%), ALL - 40 (18,5%), APL - 8(3,7%), other - 37 (17,1%). Median age was for AML - 59 (17-85), ALL - 38 (16-80), APL 55 (38-79) years. Gender female/male proportions 121\95.
The incidence rate estimates by region are listed in Table1.

Table.1 Incidence of adult AL in 5 Russian regions.

Region	Adult population (10^6)			Registered cases			Duration	Incidence		
	All	M	F	All	M	F	(y)	All	M	F
Kirov	1.15	0.52	0.63	47	22	25	2.14	1.90	1.98	1.84
Mordovia	0.72	0.33	0.40	52	29	23	2.06	3.49	4.31	2.81
Ryazan	1.01	0.45	0.56	45	17	28	1.90	2.34	1.98	2.63
Kaluga	0.88	0.39	0.48	33	15	18	2.03	1.84	1.86	1.83
Tambov	0.95	0.43	0.52	39	12	27	1.98	2.06	1.41	2.60

The frequencies of AL cases in age strata are distributed as following: 5 (2,3%) - in 15-19 age group; 39 (18%) - in 20-39 age group; 78 (36,1%) - in 40-59 age group; 89 (41,2%) - in 60-79 age group; 5 (2,3%) - in 80-99 age group.
Summary/Conclusions: AL patients registered in the Russian Federation are younger then AL patients of European registries (AML -58years *vs* 71years; ALL - 38 years *vs* 54years, respectively). The significant percentage of unidentified variants AL (17.1%) is a significant problem. We should emphasize that the recorded incidence of AL in our study is quite low. It's close of morbidity estimations of RFCR, but notably lower than European and American registers. This discrepancy can be explained by significantly reduced registration activity and primary diagnostics of AL in the older age groups.

PB1619

PRIMING REGIMENTS BASED ON IDARUBICIN, OR ACLACINOMYCIN OR PIRARUBICIN COMBINING WITH CYTARABINE AND G-CSF FOR REINDUCTION OF REFRACTORY/RELAPSED ALL

J Zhu[1], Y Miao[2], Y Zhang[3], Y Zhu[4], H Zhu[4], Z Wu[1], G He[4,*], J Li[4]
[1]Department of Hematology, the People's Hospital of Taizhou, Yangzhou and Nantong University, Taizhou, [2]Department of Hematology, The First People´s Hospital of Yancheng, Yancheng, [3]Department of Hematology, The Second People´s Hospital of Huaian, Huaian, [4]Department of Hematology, JiangSu Province Hospital,The First Affilated Hospital of NanJing Medical University, Nanjing, China

Background: Acute lymphoblastic leukemia (ALL) is one of the most common leukemias with complete remission(CR) rate between 70% and 90%. While the refractory/relapsed ALL is more difficult to treat with poor prognosis. CAG regiment was used for for 6 refractory/relapsed T-cell ALL patients and received high CR rate. So how about CAG regiment for B-cell ALL? What is the situation after the expansion of the cases ? Whether the response rate, adverse reactions would be improved if we use other anthracyclines, such as idarubicin and pirarubicin instead of aclacinomycin for the refractory/relapsed ALL? In our study, the IAG, CAG or PAG regiments were used for refractory/relapsed acute lymphoblasticleukemia respectively The response rate and adverse reactions were elevated.
Aims: To compare the therapeutic effects and adverse reactions of the chemotherapies which were based on idarubicin, aclacinomycin or pirarubicin combining cytarabine and granulocyte-colony stimulating factor as IAG, CAG, and PAG regimens respectively, for refractory/relapsed acute lymphoblastic leukemia.
Methods: The priming reinduction regiment was used to 43 cases with refractory/relapsed acute lymphoblastic leukemia (ALL). IAG, CAG and PAG regiments were non-randomly used to 13, 18 and 12 cases respectively. The clinical effects and adverse reactions of three regiments were evaluated..The factors which might affect the clinical effects were evaluated according to different ages, immunophenotypings and white cell counts.
Results: he overall response rate (ORR) of the priming regiments was 62.8%, with 46.5%(20) of complete remission (CR), 9.6% (7) of partial remissions (PR) and 37.2% (16)of non-remission (NR). 7 (53.8%) CR and 2 (15.4%) PR were observed in the IGA group with the ORR at 69.2%. In the CAG group, there were 8 CR cases (44.4%) and 3 PR cases (16.6%) with the ORR at 61%. While in the PAG group 5 CR cases (41.7%) and 2 PR cases (16.6%) with the ORR at 58.3% were observed. There was no statistical difference of ORRs among the three groups (P=0.837); no statistical difference of the ORRs between the patients over and under 60 years old.(60.0% *vs* 54.3%; P=0.272); no statistical difference was showed of the ORRs between the T-cell ALL and B-cell ALL patients (68.4% *vs* 54.1%; P=0.542) and between hyperleukocytic group and

non- hyperleukocytic group (50% *vs* 64.9%; P=0.808). Major adverse reactions, including bone marrow suppression, infection, gastrointestinal reaction and liver function impairment were tolerable after anti-infection, blood cell increasing and transfusion therapy. 6 patients survived and 12 died in the CAG group, 5 cases survived and 8 died in the IAG group, and in the TAG group, the numbers were 7 and 5. No statistical difference of survival time was found when compared in pairs or simultaneously for the three groups.
Summary/Conclusions: Preliminary results show that the priming chemotherapy regimens based on small doses of different kinds of anthracyclines were effective on refractory/relapsed ALL patients with good tolerance, minor non-hematological toxicity and side-effects.

PB1620

TEL-AML1 POSITIVE CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA-SINGLE CENTRE EXPERIENCE
M Kourti[1,*], V Sgouropoulou[1], A Athanassiadou[2], E Papakonstantinou[2], A Taparkou[3], D Koliouskas[1]
[1]Pediatric Oncology Department, Hippokration General Hospital, [2]Hematology Department, Papanikolaou General Hospital, [3]First Pediatric Department, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: The reciprocal translocation t(12;21)(p13;q22) is the most frequent chromosomal rearrangement in childhood B-cell precursor acute lymphoblastic leukaemia (ALL), which results in a chimeric transcription factor TEL-AML1 (ETV6-RUNX1) and is associated with favorable prognosis.
Aims: We performed a retrospective analysis of B-cell ALL patients who were treated in the last five years in our department in order to investigate the incidence, the clinical characteristics and cytogenetic features of TEL-AML1 positive patients.
Methods: Pretreatment bone marrow (BM) samples were successfully analyzed by reverse transcriptase-polymerase chain reaction (RT-PCR) for the molecular detection of the TEL/AML1 fusion gene. BM samples were also cultured and analyzed by standard cytogenetic methods. The immunophenotype was determined using a panel of monoclonal antibodies (MoAbs) with flow cytometry.
Results: A total of 51 patients with ALL displayed G-banded karyotypes and were informative for molecular analysis and were included for analysis. All patients were treated according to ALLIC-BFM 2009 protocol. On the basis of EGIL classification, the immunophenotype analysis permitted the characterization of 32 cases (62.7%) as pre-B ALL, 10 (19.6%) as common ALL and 9 (17.7%) as pro-B ALL. The TEL-AML1 fusion gene was identified in 11 patients of which 7 (63.6%) had pre-B, 3 (27.3%) pro-B ALL and 1 (90.1%) common ALL. The incidence of TEL-AML1 fusion gene was 21.6% (11/51 patients). The TEL-AML1 positive patients were studied with regard to their gender and it revealed that 7 were females and 4 males with median age of 4.16 (range:3.41-13.16 years). The median leucocyte count was $8.3x10^9$/L (range $2.6\text{-}67x10^9$/L) According to the presenting features, 91% of the TEL/AML1-positive cases were enrolled in the IR group and 9% in the SR. Moreover, all TEL/AML1-positive cases lacked evidence for BCR/ABL and MLL/AF4 fusion mRNAs. No structural chromosomal changes were noted in TEL-AML1 positive children. Hyperdiploidy of 47-48 chromosomes was encountered in 18.18% (2/11) of the children with TEL-AML1 rearrangement; however, none of TEL-AML1 positive patients had hyperdiploidy of more than 50 chromosomes. All cases were prednisone good responders and they were all very early good responders (minimal residual disease <10-3 at day 15. All patients are in continuous complete remission with event-free and overall survival of 100%.
Summary/Conclusions: Conclusions: The TEL-AML1 fusion gene is a common genetic anomaly in childhood ALL patients and our results are consistent with literature. Further investigation with a larger sample size and for a longer time is warranted.

PB1621

MATRIX METALLOPROTEINASES 2 & 9 AND TISSUE INHIBITOR OF MATRIX METALLOPROTEINASE 1 AS MAJOR PLAYERS IN CLINICAL COURSE OF EGYPTIAN PEDIATERIC ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS
E Kandel[1], M Saleh[1,*], M Khalil[1], E Ebeid[2], N Alieldin[3]
[1]Clinical Pathology, [2]Pediatric oncology, [3]Biostatistics and Cancer Epidemiology, National Cancer Institute of Egypt, Cairo, Egypt

Background: Acute lymphoblastic leukemia (ALL) is the most frequent acute leukemia affecting pediatric patients. Gelatinase B/matrix metalloproteinase - 9 (MMP9) as well as MMP-2 (gelatinase-A) and their inhibtor Tissue inhibitor of matrix metalloproteinases (TIMP)-1 play a crucial role modulating the biology of the cancer stem cell niche.
Aims: Study the impact of expression of MMP2, MMP9 and TIMP1, as well as, MMP2/TIMP1 and MMP9/TIMP1 ratios on different facets of disease progression in pediatric ALL in terms of laboratory and clinical parameters having prognostic significance, disease-free and overall survival .
Methods: Bone marrow samples were drawn from 53 Egyptian pediatric ALL patients presented to Pediatric Oncology Department, National Cancer Institute, Cairo University. An informed consent in accordance with the Declaration of Helsinki was obtained. Intracytoplasmic MMP-9 FITC, MMP-2 PE and TIMP-1 FITC was done. MoAbs were supplied from R&D system(614 McKinley Place NE, Minneapolis, MN 55413) analysis was done within 24 hours of sampling. Sample analysis was done by multicolor flow cytometry (Coulter Epics XL, Hialeah, USA). Gating strategy was applied using dim CD45/side scatter. Data analysis was done on Winlist 6 (Verity Software House, Topsham, ME).
Results: The study included 53 pediatric ALL patients, 34 males and 19 females, age ranged from 1-18 year with a median of 6 years. A significantly higher total leukocyte count (TLC) among TIMP-1 positive ALL cases and a borderline significantly higher TLC among MMP9 positive ones (P=0.03 and 0.06, respectively) were found. As regards clinical parameters, hepatomegaly was higher among MMP-9 positive cases (P=0.03). Regarding the relation of MMP2 and MMP9 in to their inhibitor; MMP2/TIMP1 ratio was significantly correlated to MMP9/TIMP1 ratio *(p<0.001)*.
ROC curve using MMP2/TIMP2 ratio as greater than or equal to 0.02 will detect MRD D42 response (negative or <0.01) with a sensitivity of 73.7%, specificity of 72.7%, positive predictive value 82.4% and negative predictive value of 61.5%. A low MMP2/TIMP1 ratio correlated significantly with presence of splenomegaly (*p<0.02)*. Patients with MMP2/TIMP1 ratio <2.0% had shorter overall survival with mean 48±3.4 months as compared to those with ratios ≥2.0% *(p=0.04)*.
Summary/Conclusions: MMP2, MMP9, TIMP1expression as well as, MMP2/TIMP1 and MMP9/TIMP1 ratios had influential implication on disease progression and clinical course on pediatric acute lymphoblastic leukemia.

PB1622

OUTCOME OF ADULT PHILADELPHIA ACUTE LYMPHOBLASTIC LEUKEMIA IN THE IMATINIB ERA IN THE SOUTH OF TUNISIA
I Frikha[1,*], M Medhaffer[1], S Hadiji[1], O Kassar[1], S Mnif[2], H Bellaaj[1], M Ghorbel[1], F Kallel[1], N Ben Abdeljalil[3], H Sennana[4], M Elloumi[1]
[1]Hematology, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, [2]Pasteur Institute, [3]CNGMO, Tunis, [4]cytogenetic laboratory, Sousse, Tunisia

Background: The Philadelphia chromosome (Ph), t(9;22), is seen in about 20 to 30% of adults diagnosed with acute lymphoblastic leukemia (ALL). It has been associated with poorer prognosis. Tyrosine kinase inhibitors (TKIs) targeting the *BCR-ABL* oncogenic protein from this translocation have been incorporated into treatment regimens used to treat patients with Ph-positive ALL. In this study we analyzed the clinical, biological features and therapeutic results of patients with Ph ALL treated with chemotheray and Imatinib.
Aims: Determinate the outcome of Philadelphia acute lymphoblastic leukemia in the era of Imatinib in the South of Tunisia
Methods: From January 2007 to March 2015, 10 patients aged 21 to 55 years diagnosis with *de novo* Philadelphia chromosome–positive acute lymphoblastic leukemia, in the department of clinical hematology of Hedi Chaker Hospital, and treated according to the GRAAPH protocol. Cytogenetic analysis and Bcr-Abl transcript was performed for all patients. Imatinib was associated with chemotherapy since 2007 at a dose of 600-800 mg/day. Hematopoietic stem cells transplantation (SCT) was indicated in patients aged under 45 years in complete remission and have a sibling related donor.
Results: Ten patients with *de novo* Ph ALL were treated with the GRAAPH protocol. The median age at the diagnosis was 44 years (21 to 55 years), 6 patients were aged under 45 years. Sex ratio (M/F) was 0,43. The median WBC was 28G/L (3,4 to 104 G/L). Nine patients had a transcript Bcr-Abl positive and one patient had only the t (9,22) without transcript Bcr-Abl. Eight patients (80%) achieved complete remission (CR). Among the 4 patients in CR and with indication to allogeneic SCT, only 3 patients were allograft. Among them, 2 patients are alive in good molecular response after a follow up of 4 and 2 years and the other patient died in post allogeneic transplant with acute graft *versus* host disease (GVHD). The 5 patients who were not allograft, 2 are alive in good molecular response after a follow up of 4 and 6 years and the other 3 patients died with disease progression .
Summary/Conclusions: In the pre-imatinib era, treatment outcomes of adult patients with Philadelphia chromosome (Ph)-positive acute lymphoblastic leukemia (ALL) were dismal. However, imatinib, in combination with conventional chemotherapy, has dramatically changed outcomes, producing approximately 95% complete remission, 80% in our study and 50% overall survival with or without allogeneic SCT.

PB1623

NK-CELL LYMPHOBLASTIC LEUKAEMIA/LYMPHOMA: CLINICAL AND LABORATORY FEATURES, AND PROGNOSIS
A Antipova[1,*], O Baranova[1], M Frenkel[2], N Kupryshina[2], A Shirin[1], N Tupitsyn[2]
[1]Hematology, [2]Immunology, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: NK-cell lymphoblastic leukemia/lymphoma (NK-LL) is a rare type of acute leukemias. According to the WHO Classification of Tumors of Haematopoietic and Lymphoid Tissues NK-LL is reviewed in chapter "Acute leukaemias of ambiguous lineage".
Aims: To determine clinical and laboratory features and prognosis of NK-LL.
Methods: From 2000 to 2014 only in 1 of 161 (0.6%) patients treated in the department of Hematology of N.N. Blokhin Russian Cancer Research Center was diagnosed NK-LL. Over the same period a diagnosis of NK-LL has been set additionally 3 patients in the Laboratory of Immunology Hematopoietic of N.N. Blokhin Russian Cancer Research Center more. The disease was diagnosed in accordance to the 2008 WHO classification. The differential diagnosis was carried out with other CD56-positive tumors – AML-M0, blastic plasmacytoid dendritic cell neoplasm, T-ALL, and neoplasms of mature NK cells. In the group NK-LL were 4 patients: 3 men and 1 woman. The median age was 52.5 years (ranged from 29 to 82 years).
Results: All patients stated the total bone marrow blast metaplasia (>70%), common extramedullary lesion: generalized lymphadenopathy, hepatosplenomegaly, lesions of skin, tonsils, mediastinal, central nervous system (CNS) by type neuroleukemia. Blasts cytochemical reaction on myeloperoxidase, lipids and nonspecific esterase were negative. In all cases the blast cells were strong positive to CD56 (69.8-99.1%) and the T-associated antigen CD7 (66.2 - 92%), and negative to myeloid, T- and B-lymphoid antigens. PCR identified the lack of gene rearrangement chain T-cell receptor in one patient. Cytogenetic study was not performed. Induction therapy of patients with NK-LL carried out mainly by the program of treatment of acute lymphoblastic leukemia (ALL). CR was achieved in 2 patients, however, proved to be of short-term (1 and 7 months.). The longest remission duration (20 mo.) was obtained using a combined regimen RACOP for the treatment of relapse. Overall survival in the group did not exceed 3 years (1-29 mo.).
Summary/Conclusions: The analysis indicates the low efficiency of current regimens NK-LL. Success in treatment of patients depends on prompt and accurate diagnosis, as well as the development of new therapeutic approaches.

Acute myeloid leukemia - Biology

TECHNICAL VALIDATION OF A NEXT-GENERATION SEQUENCING PANEL FOR ACUTE MYELOID LEUKEMIA DIAGNOSIS

M Llop[1,*], CM Alonso*[2], M Ibañez[1], J Cervera[1,3], E Such[1,3], L Pedrola[1], I Martin[1], E Onecha[4], R Ayala[4], MA Sanz[1,3], E Barragan[1,5]
[1]Instituto de Investigación Sanitaria La Fe, [2]Hematology Department, Hospital Arnau de Vilanova, [3]Hematology Department, Hospital Universitari i Politècnic La Fe, Valencia, [4]Hematology Department, Hospital 12 de Octubre, Madrid, [5]Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: Recurrently mutated genes have been described for acute myeloid leukemia (AML). However, only a few (*NPM1*, *CEBPA*, *FLT3*) have prognostic and clinical implications and are systematically analysed, usually by individual assays. The development of high throughput techniques as next-generation sequencing (NGS) allows a parallel detection of these markers and enables the inclusion of novel molecular targets.
Aims: Our aim is to validate the clinical applicability to routine laboratories of a hotspot NGS panel that includes recurrently validated mutated genes and other potentially actionable targets.
Methods: We included 130 *de novo* AML samples previously characterized for *FLT3*-D835, *NPM1*-T288, *DNMT3A*-R882, and *CEBPA* mutations by conventional molecular biology techniques (CMBT). We tested the Ion Ampliseq AML community panel (Life Technologies) (IAACP) which requires 40 ng of DNA per sample and includes hotspots of *ASXL1, BRAF, CBL, FLT3, IDH1, IDH2, JAK 2, KIT, KRAS, NRAS, PTPN11, RUNX1* and *WT1;* and the entire coding sequence of *CEBPA, DNMT3A, GATA2, TET2 and TP53*. The design does not include the *FLT3*-ITD region. Libraries were sequenced in the Ion PGM (n=12) and the Ion Proton platforms (n=118). For comparison, 3 patients were sequenced in both platforms. To determine if the hotspot approach is adequate, a subset of 25 patients was also analyzed with a custom panel (Sure Design Tool (Agilent)) that included the complete coding sequence of the genes included in the IAACP except from *CBL* and *GATA2*. Libraries were prepared with 250 ng of DNA per sample and sequenced in an Illumina platform.
Results: The IAACP sequenced in the Proton platform yielded a mean depth of 5916 reads, mean uniformity was 92.19% and mean on-target reads 89.05%. Two amplicons (RUNX1_239.66909 and ASXL1_235.1.76662) showed a strong strand bias (x5) towards the forward strand systematically. The PGM platform yielded a mean depth of 2500 reads, mean uniformity of 91.86% and mean on-target reads of 93.39%. GATA2_47.1.16110 and DNMT3A_23.66955 amplicons showed a strong bias towards the forward strand (100X) and the reverse strand (42X), respectively. For both platforms we observed intra-run differences regarding read depth and strand bias, however, none of the 239 amplicons showed a mean depth lower that 250X (Figure 1). Patients sequenced in both platforms yielded the same mutations. IAACP found 100% of the previously known mutations by CMBT plus 11 extra mutations that were negative by CMBT. These mutations were reconfirmed by Sanger sequencing. Among the 25 patients analysed with the custom panel, 53 variants were found. Fifty (95%) were also detected with the IAACP. The remaining 3 variants (5%) were located outside the hotspot regions in genes with poor clinical significance. Additionally, the IAACP detected 13 variants in the overlapping regions not found by the custom panel.

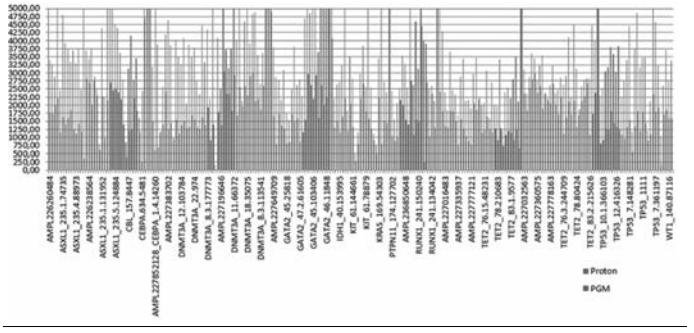

Figure 1.

Summary/Conclusions: In conclusion, the IAACP is reliable and reproducible for routine diagnosis. It allows detection of known important mutations with increased sensibility compared with CMBT, and also detection of complementary mutations with potential clinical implications. The main limitation of its design is the absence of amplicons covering *FLT3*-ITD region. The hotspot approach yields a higher mean read depth than the whole coding sequence analysis without significant losses and it requires less input DNA. Moreover, analysis of strand bias and low coverage regions is mandatory to assess sequencing quality and to perform extra assays if necessary.

MUTATIONAL ANALYSIS OF ACUTE MYELOID LEUKEMIA WITH A NEXT-GENERATION SEQUENCING PANEL

CM Alonso[1,*], M Llop[2], M Ibañez[2], J Cervera[2,3], E Such[2,3], L Pedrola[2], I Martin[2], E Onecha[4], R Ayala[4], P Montesinos[2,3], MA Sanz[2,3], E Barragan[2,5]
[1]Hematology, Hospital Arnau de Vilanova, [2]Instituto de Investigación Sanitaria La Fe, [3]Hematology Department, Hospital Universitari i Politècnic La Fe, Valencia, [4]Hematology Department, Hospital 12 de Octubre, Madrid, [5]Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: In the last years numerous recurrently mutated genes have been described for acute myeloid leukemia (AML). Although only *CEBPA*, *NPM1* and *FLT3-ITD* have been incorporated to risk stratification algorithms, other genes like *RUNX1*, *ASXL1, DNMT3A* or *TP53* are currently being evaluated and could be soon incorporated. Furthermore, *FLT3*, *IDH1/2* or *KRAS* are being tested as potential therapeutic targets. Next generation sequencing (NGS) assays allows a parallel detection of these genes.
Aims: The aim of this study is to characterize the mutational status of a series of "*de novo*" AML patients using a NGS panel that includes the hotspots of most recurrently mutated genes and other potentially actionable targets.
Methods: We studied 130 AML patients diagnosed from June 1999 to June 2014 in a single centre. Inclusion criteria were age <65 years, diagnosed with non-promyelocytic AML, treated according PETHEMA AML clinical protocols and with available DNA sample at diagnosis. Ion Ampliseq AML community (IAAC) panel was employed for mutation detection. This panel includes hotspots of *ASXL1 (*exon 12*), BRAF* (V600E)*, CBL* (exons 8-9)*, FLT3* (codons 676, 830-850)*, IDH1* (exon 4)*, IDH2* (exon 4)*, JAK 2* (exon 14*), KIT* (exons 8, 10, 11 and 17)*, KRAS* (exons 2-4)*, NRAS* (exons 2-4)*, PTPN11* (exons 3,7,8,13)*, RUNX1* (exons 3-8) and *WT1* (exons 7 and 9)*,* and the entire coding sequence of *CEBPA, DNMT3A, GATA, TET2 and TP53*. Libraries were amplified with Ion Torrent Ampliseq 2.0 beta and sequenced in the Ion PGM or Proton platforms. Variant annotation was carried out with the Ion Reporter Software (Life Technologies). Polymorphisms, synonymous, low depth read mutations (<100X) and low read% variants (<5%) were filtered out. Moreover, regions with intrinsic strand bias or low coverage were curated with the Integrative Genomics Viewer (IGV). *FLT3*-ITD mutations, which are not included in the panel design, were detected by capillary electrophoresis (Thiede 2002 Blood).
Results: Regarding cytogenetics, 9 patients showed favourable risk, 82 with intermediate risk (70 normal karyotype) and 23 unfavourable risk. For the remaining 6 patients cytogenetics could not be assessed. The IAAC panel found 322 variants in 125 patients. In brief, 59 *NPM1* mutations, 49 in *DNMT3A* (30/49 mutations (61,22%) were the R882 mutation), 36 in *TET2*, 31 in *CEBPA* (13 patients showed biallelic mutations), 21 in *RUNX1*, 18 in *NRAS*, 16 in *IDH2*, 15 in *FLT3*, 15 in *TP53*, 11 in *GATA2*, 11 in *PTPN11*, 11 in *ASXL1*, 8 in *WT1*, 7 in *IDH1*, 7 in *KRAS*, 4 in *KIT*, 2 in *CBL* and 1 mutation in *BRAF* (Figure 1). Moreover, 31 *FLT3*-ITD mutations were detected by conventional techniques. The average of mutations per patient was 2.71 (range 0-8). Only 5 (3.8%) remained wild type. *NPM1*, *DNMT3A* and *FLT3* (including *FLT3*-ITD) mutations were significantly enriched in the intermediate risk group (p<0.001 p=0.002, p=0.004, respectively), while *TP53* mutations aggregated in the unfavourable karyotype group (p<0.001). *NPM1* mutations significantly concurred with *DNMT3A* and *FLT3* mutations (p<0.0001, p<0.0001, respectively), and these three genes are mutually exclusive with *TP53* (p<0.001; p=0.005, p=0.011) and *RUNX1* (p=0.001, p=0.018, p=0.047) mutations. *NPM1* and *FLT3* were also mutually exclusive with *GATA2* (p=0.010 and p=0.016). *NPM1* and *CEBPA* were mutually exclusive (p=0.036), as well as *FLT3* with *NRAS* (p=0.014), and *ASXL1* with *NRAS* (p=0.038). *NPM1* and *PTPN11* mutations showed concurrence (p=0.012) (Figure 2).
Summary/Conclusions: IAAC panel detects mutations with validated prognostic relevance (*NPM1* and *CEBPA*) and other mutations with probable diagnostic or prognostic value and/or potential therapeutic targets are also studied and identified in one assay. The parallel study of numerous mutations allows the identification of recurrence and exclusivity patterns.

PB1626

MYELOID-SPECIFIC EXPRESSION OF SOX4 INDUCES EXPANDED MYELOPOIESIS WITH RETARDED CELL DIFFERENTIATION - A NOVEL ZEBRAFISH LEUKEMIA MODEL

LI Lin[1], JW Lu[1,*], MS Hsieh[1], HA Hou[2], CY Chen[2], HF Tien[2]
[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, ROC

Background: SOX4 belongs to a family of Sox (SRY-related HMG-box) transcription factors, including Sox4, Sox11, and Sox12. Abnormal expression of SOX4 is related to malignant transformation and cancer metastasis. Overexpression of SOX4 is associated with clonal dominance of hematopoietic stem cells, repopulation advantage of various stem/progenitor cells, block in differentiation of myeloid progenitor cells, and induction of myeloid leukemia. Recently, the expression of SOX4, as a direct target of C/EBPα, is reported to inversely correlate with C/EBPα activity. Downregulation of SOX4 attenuates self-renewal capability of leukemic cells and restored their normal differentiation process. SOX4 overexpression resulting from C/EBPα inactivation contributes to the development of leukemia with a distinct leukemia-initiating cell (LIC) phenotype. In addition, several fusion proteins resulting from chromosomal aberration, such as *MOZ-TIF2*, *AML1-ETO*, *UNP98-HOXA9*, were closely linked to SOX4 upregulation, further suggesting the significance of SOX4 in leukemogenesis. Zebrafish is a popular animal model in biomedical researches. Here, we add to its strength for leukemia research by providing a novel transgenic SOX4 zebrafish model.
Aims: To establish SOX4 transgenic zebrafish research model.
Methods: By using Multisite Gateway system® and Tol2 transposon technology, we established a construct including *spi1* promoter, human *SOX4* gene and *EGFP*. This construct was then injected into zebrafish embryos. After a series of fluorescent selection, stable transgenic *SOX4* zebrafish - Tg(CG-*spi1-SOX4-EGFP*)were generated. The expression of hematopoiesis-related transcription factors were evaluated by quantitative real-time polymerase chain reaction (qRT-PCR) or whole-mount *in situ* hybridization (WISH) technique. The histological pictures of kidney marrow (KM) were examined by light microscope
Results: We found that *SOX4* could be detected at 20 hpf (0.2~1.7x10^3 copies), and then increased gradually during development. At 5 dpf, level of *SOX4* was up to 2~10x10^3 copies. However, there were no significant differences in the expression of hematopoiesis-related transcription factors, such as *csf1r*, *cebpa*, *l-plastin*, *mpeg1*, *mpo*, *runx1* and *c-myb* in spite of the expression of *SOX4*. These results indicated that the *SOX4* transgenic zebrafish had normal hematopoiesis in the larval stage. However, in comparison with age-matched AB-wild type fish, the KM of 5-month old transgenic zebrafish Tg(CG-*spi1-SOX4-EGFP*) had a greater number of myeloid progenitors (9.24±2.75% *vs* 5.27±0.74%; p<0.05); those of 9-month old had a greater number of myeloid progenitors (18.00±8.78% *vs* 5.73±0.64, p<0.01), less number of mature erythroid cells (19.55±5.98% *vs* 27.93±6.03%, p<0.05) and greater M:E ratio (10.39±7.81 *vs* 3.72:1±0.53, p<0.05); those of 12-month old had significant difference in all blood components (17.61±8.07% *vs* 7.00±1.10% in myeloid progenitors; 62.06±7.82% *vs* 42.07±3.18% in myelomonocyte/neutrophil; 4.11±0.72% *vs* 16.20±1.12% in lymphocytes; 5.44±1.45% *vs* 10.06±2.55% in immature erythroid cells;10.78±3.40% *vs* 4.61±0.64% in mature erythroid cells and M:E ratio of15.77±5.34 *vs* 4.61±0.64, p<0.05 for all above).
Summary/Conclusions: These results indicate that *SOX4* transgenic zebrafish develops a gradual expansion of myeloid cells, which fail to differentiate, and ultimately transform into myeloid leukemia.

A COMBINED APPROACH TO DETECT RARE FUSION EVENTS IN ACUTE MYELOID LEUKEMIA

A Padella[1,*], G Simonetti[1], G Paciello[2], A Ferrari[1], E Zago[3], C Baldazzi[1], V Guadagnuolo[1], C Papayannidis[1], V Robustelli[1], E Imbrogno[1], N Testoni[1], M Cavo[1], M Delledonne[3], I Iacobucci[1], CT Storlazzi[4], E Ficarra[2], G Martinelli[1]
[1]Seragnoli Institute, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, [2]Dept. of Control and Computer Engineering DAUIN, Politecnico di Torino, Torino, [3]Personal Genomics, Personal Genomics, Verona, [4]Department of Biology, University of Bari, Bari, Italy

Background: A complex network of events characterizes Acute Myeloid Leukemia (AML), including point mutations, epigenetic modification, copy-number alterations, gene-expression alterations and fusion events. A recent study revealed that 45% of AML patients carry one fusion gene and 50% of detected fusions were novel and not recurrent events (TCGA, N Engl J Med; 2013). However, the leukemogenic potential of these fusions and their prognostic role are still unknown.
Aims: The aim of the study was to identify rare gene fusions having a causative role in leukemogenesis and which may be a target for personalized therapy in AML cases with rare chromosomal translocations.
Methods: RNAseq was performed on 4 AML patients (#59810, #20, #84 and #21, Hiseq1000 Illumina) and deFuse and Chimerascan was used to detect fusions. Putative chimeras were prioritized according to cytogenetic analysis. In addition, we exploited Pegasus and Oncofuse to select biologically relevant fusions cryptic at cytogenetic analysis. Selected fusions were validated with Sanger sequencing.
Results: The reliability of our bioinformatic analysis was confirmed thanks to the detection of the CBFβ-MYH11 transcript in the sample #84 associated to the inv(16). We detected two in-frame fusion genes in sample #20: CPD-PXT1

which appeared as the reciprocal fusion product of t(6;17) translocation, and SAV1-GYPB, which remained cryptic at cytogenetic analysis. The first chimera involved a metallocarboxypeptidase and a partner whose biological function is unknown. The second chimera involved the oncogene SAV1, a central player of the Hippo pathway, which controls the proliferation and promotes the apoptosis. The fusion event causes the loss of the protein-protein interaction domain of SAV1, which is fundamental for its stability. Sample #21 carried an in-frame fusion transcript involving the genes *OAZ1* and *MAFK*. The first gene is involved in the polyamine synthesis, while the latter one is a transcriptional regulator. The putative fusion protein was formed by the *cis*-acting elements sensitive to polyamine levels of *OAZ1* and the bZIP domain of *MAFK*. We detected two fusion transcripts in sample #59810: ZEB2-BCL11B, associated with translocation t(2;14), and CNOT2-WT1, associated with t(11;12). In particular, three different isoforms of the in-frame chimera ZEB2-BCL11B were expressed: the full length (Isoform 1), the Isoform 2 with one exon of *BCL11B* spliced and the Isoform 3 with 2 exons of *BCL11B* spliced. Gene expression profiling showed an upregulation of *ZEB2* and *BCL11B* transcripts in the patient's blasts, compared to 53 AML samples with no chromosomal aberrations in the 14q32 region. On the contrary, CNOT2-WT1 was an out-of-frame gene fusion and the reciprocal of the fusion revealed the intron retention of *CNOT2*.

Summary/Conclusions: Our data suggest that fusion events are frequent in AML and different approaches, including G-banding, molecular biology, bioinformatics and statistics, need to be integrated in order to better understand AML pathogenesis. The lack of recurrence in the landscape of AML gene fusions confers heterogeneity to the pathogenesis of the disease and we are further investigating the pathogenetic potential of the identified translocations, in order to identify common patterns of oncogenic events, which may be exploited to stratify patients and tailor personalized therapies.

PDCD1 EXPRESSION AND SNP ANALYSES IN AML, MDS AND S-AML PATIENTS

J Zaleska[1,*], M Zajac[1], A Siwiec[2], O Jankowska-Lecka[3], R Mlak[4], M Ciesielka[5], T Gromek[3], N Grzasko[6], M Soroka-Wojtaszko[3], A Szudy-Szczyrek[3], M Majdan[2], M Hus[3], K Giannopoulos[1,6]

[1]Department of Experimental Hematology, [2]Department of Rheumatology and Connective Tissue Diseases, [3]Department of Hematooncology and Bone Marrow Transplantation Unit, [4]Department of Human Physiology, [5]Department of Forensic Medicine, Medical University of Lublin, [6]Department of Hematology, St. John's Cancer Center, Lublin, Poland

Background: One of the potential mechanism responsible for evading cytotoxic T lymphocytes by tumor cells might be the programmed death-1 receptor (PD-1) signaling pathway. PD-1 and its ligand PD-L1 play a key role in tumor immune escape and the formation of tumor microenvironment, promoting tumor development. Recent findings showed elevated expression of PD-1 and PD-L1 on CD34+cells in acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) patients suggesting that deregulation of PD-1/PD-L1 axis may contribute the MDS pathogenesis. Moreover, in patients treated with epigenetic therapy PD-L1 and PD-1 expression was upregulated indicating that induction of PD-1 and PD-1 ligands may be involved in hypomethylating agents (HMAs) resistance. *PDCD1* polymorphisms are associated with susceptibility to several types of cancer.

Aims: We aim to characterize the *PDCD1* expression and six *PDCD1* polymorphisms in AML, MDS and s-AML patients samples as well as determine whether expression of PD-1 in those patients is driven by the genetic background.

Methods: *PDCD1* mRNA expression was assessed in bone marrow mononuclear cells (BMMC) of 62 MDS, 54 AML and 8 s-AML patients samples using qRT-PCR method. Six SNP for PD-1 that demonstrate relevant associations with a higher risk of developing autoimmune diseases were assessed in AML, MDS and s-AML patients as well as 100 healthy volunteers (HVs): PD-1.1 (rs36084323), PD-1.3 (rs11568821), PD-1.5 (rs2227981), PD-1.6 (rs10204525), PD -1.7 (rs41386349), PD-1.9 (rs2227982). Moreover, immunohistochemical (IHC) stainings of 12 AML and 8 MDS bone marrow smears for PD-1 protein were performed.

Results: We observed significant decreased *PDCD1* expression in AML group compared to HVs and MDS, (median: 0.0001 *vs* 0.0003, p<0.001 and 0.0001 *vs* 0.0003, p<0.001) but no differences in MDS and s-AML groups compared to HVs. IHC stainings showed PD-1 expression on blast cells in 6/12 AML and 6/8 MDS cases ranging from 1-92%. AML patients were stratified into three genetic groups according to prognosis: favorable risk, intermediate I risk and intermediate II/adverse risk and *PDCD1* expression was compared between these groups. No significant differences were found between these groups. MDS patients were divided according to IPSS scoring systems into two groups: first with IPSS ranging from 0.0 to 0.5 and second with IPSS from 1 to 3. No significant difference were observed between these groups in case of *PDCD1* expression (median: 0.0004 *vs* 0.0002, p=0.11). We observed significant differences in *PDCD1* expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 *vs* 333 days, HR=35; p=0.0188).

Summary/Conclusions: We found significant differences in *PDCD1* expression in AML and MDS patients that might indicate deregulation of a signal transduction through the PD-1/PD-L1 axis. By IHC stainings we were able to determine PD-1 expression on blast cells in 6/12 AML and 6/8 MDS bone marrow smears. Moreover, SNP analysis in AML patients revealed potential prognostic impact of PD-1.1.6 polymorphism.

MOLECULAR CYTOGENETIC ANALYSIS OF COMPLEX KARYOTYPES IN PATIENTS WITH MDS AND AML

L Grebenyuk[*], T Obukhova, G Alimova, L Shishigina, V Troitskaya, E Parovichnikova, V Savchenko

[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Cytogenetic findings at diagnosis are among the most important independent prognostic factors in patients with MDS and AML. Complex karyotype involving three or more chromosome abnormalities is associated with poor prognosis and disease progression. Precise identification of chromosome abnormalities in complex karyotype by conventional cytogenetic analysis (CCA) is limited due to low resolution of this method. Molecular cytogenetic techniques such as fluorescence *in situ* hybridization on interphase cells nuclei (FISH), multicolor fluorescence *in situ* hybridization on chromosomes (mFISH) and multicolor banding (mBAND) have significantly higher sensitivity and allow to identify complex chromosome abnormalities, marker chromosomes, submicroscopic deletions and specify chromosomes breakpoints.

Aims: The aim of our study is to characterize complex karyotypes in patients with MDS and AML using combination of molecular cytogenetic techniques.

Methods: Over a 2-year period CCA of bone marrow samples was performed in 234 patients with MDS and 83 patients with AML at diagnosis. Complex karyotypes were revealed in 20 patients (9 males and 11 females, median age 55 years), 11 patients with MDS (4.7%) and 9 patients with AML (10.8%). mFISH (24XCyte, MetaSystems) was performed in all 20 patients. Based on the results of CCA and mFISH we analyzed abnormal chromosomes using FISH with locus-specific and centromere DNA probes (LSI EGR1/D5S23, D5S721 Dual Color Probe Set in 12 cases, TP53/CEP 17 FISH Probe Kit in 10 cases, D7S522/CEP 7 FISH Probe Kit in 9 cases, CEP 8 SpectrumOrange DNA Probe Kit, ATM/CEP 11 FISH Probe Kit, LSI MLL Dual Color, Break Apart Rearrangement, D20S108 FISH Probe Kit, 1p36 Microdeletion Region Probe – LSI p58 (1p36)/TelVysion 1p/LSI 1q25 in each case one, ABBOTT), as well as mBAND probe (XCyte mBAND 5, XCyte mBAND 7, XCyte mBAND 15, XCyte mBAND 17, MetaSystems).

Results: CCA revealed an average of 4 karyotype abnormalities (from 3 to 14). Structural chromosome rearrangements were found in 20 cases: random translocations in 5 cases (25%), all of them were defined as simple reciprocal translocations, additional material of unknown origin in 12 cases (60%), marker chromosomes in 11 cases (55%). Non-random structural rearrangements were found in 3 patients: t(6;9) – 1, del5q31 -1 and del7q31 - 1 case. Most frequent numerical abnormalities were typical for MDS and AML trisomy 8 – 5 cases (25%), monosomy 5 - 8 (40%), 7 - 7 (35%) and 17 - 3 cases (15%). Molecular cytogenetic analysis revealed additional chromosome aberrations and/or additional chromosome breakpoints in 17 of 20 cases (85%). Translocations were found in 18 cases (90%): 9 (50%) – simple reciprocal translocations, 4 (22%) – complex translocations involving 3 chromosomes, 3 (16,5%) - complex translocations involving more than 3 chromosomes. In karyotype of 17 patients (85%) we found abnormalities of chromosomes 5 (60%), 7 (50%), 11 (20%) and 17 (45%). Except one case, chromosome breakpoints were identified in typical regions of known or potential genes: 5q31, 7q31, 11q23 and 17p13. Deletions 5q and 7q were confirmed in both cases. Monosomy 7 was confirmed in two of seven cases only. In all other cases with monosomy 5, 7, and 17 on the results of conventional analysis mFISH revealed fragments of these chromosomes involved in translocations. Based on the results of FISH all of these translocations, except one case, were combined by deletion of loci 5q31, 7q31 and 17p13. All marker chromosomes and chromosomes with additional material of unknown origin were recognized as complex translocations or derivative chromosomes with breakpoints in both arms.

Summary/Conclusions: In our study applying of molecular cytogenetic methods allowed to identify all numerical and structural abnormalities, unrecognized at CCA, clarify chromosome breakpoints and determine markers chromosomes origin. True monosomy 7 was confirmed in 10% only, and for chromosomes 5 and 17 true monosomy is not found. Combination of conventional and molecular cytogenetic techniques (FISH, mFISH and mBAND) is necessary for precise characteristic of complex karyotypes in MDS and AML and determination of exact breakpoints loci of potential oncogenes and tumor suppressor genes.

GENOMIC CHARACTERIZATION OF PATIENTS WITH LOW-RISK ACUTE MYELOID LEUKEMIA (AML)

MI Prieto-Conde[1,*], C Jiménez[1], M Alcoceba[1], M García-Álvarez[1], ME Sarasquete[1], A Balanzategui[1], M Hernández-Ruano[1], E Sebastián[1], R Corral[1], L Marín[1], F Ramos[2], A Godoy[3], A Bárez[4], NC Gutiérrez[5], R García-Sanz[5], M González-Díaz[5], MC Chillón[5]

Background: Not all acute myeloid leukemia (AML) patients classified at diagnosis as cytogenetic and/or molecular favorable risk display a good outcome. In fact, up to 40% of patients with core binding factor (CBF) AML will relapse and not all may be cured. In the same way, a half of NPM1 mutated patients have a relapse during the first 3 years after diagnosis and only biallelic disruption of *CEBPA* (biCEBPA) is required for a favorable outcome that not avoid a relapse rate of 44%. However, mutations responsible for poor outcome in these previously low-risk classified subsets have not been clearly defined.
Aims: 1) To determine the mutational profile of favorable risk AML: CBF-AML, NPM1-mutated AML lacking FLT3-ITD and biCEBPA AML. 2) To identify mutations at diagnosis responsible for poor outcome by comparing patients who experiment relapse *vs* patients who do not relapse.

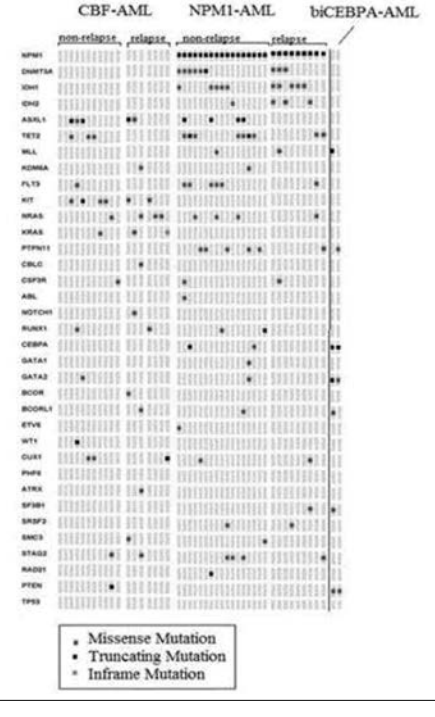

Figure 1.

Methods: A cohort of 46 patients with favorable-risk AML (median age 55 years) (PETHEMA AML-99-2010) (Table 1). FLT3-ITD mutations were analyzed by fluorescent PCR and capillary electrophoresis. None of the patients harbored FLT3-ITD. A total of 54 genes were targeted by 568 amplicons that ranged from 225 to 275 bp. The combined coverage was 141 kb in sequence length. Amplicon libraries were prepared by TruSight Myeloid sequencing panel (Illumina, CA) and paired-end sequencing runs were performed on a MiSeq (Illumina) genome sequencer. Minimum depth for reliable analysis was fixed in 100x. Sequences obtained were analyzed with the Variant Studio v2.1 software (Illumina).
Results: We found 144 mutations in 44 of 46 patients of the global series (3.3 (0-8 mutations/patient) with a mean read depth of 8230x. Only 2 patients remained wild-type for all analyzed genes. Figure 1 displays the mutational distribution of the patients who suffered relapse and patients who do not relapse in the three groups studied. The CBF group (n=18) showed a high frequency of KIT mutations (33%) that were not present in the other low-risk groups. Seven patients harbored NRAS/KRAS mutations (39%), showing a great involvement of RAS pathway in this subset. Other relevant genes affected were ASXL1 and CUX1 (28% and 17%, respectively). The NPM1 mutated group (n=26) presented a high incidence of DNMT3A, IDH1 and IDH2 mutations, as described previously (35%, 38% and 15%, respectively). Moreover, a 23% of these patients carried mutations in the phosphatase PTPN11 and a 15% in the cohesin complex gene STAG2. The two biCEBPA mutated patients showed altered variants in the transcriptional regulator GATA2. Regarding the prognostic value of these alterations, we found that patients with a better course of the disease had a lower frequency of mutations in NRAS/KRAS genes. Therefore, we analyzed the prognostic value of these variants in the CBF group and it was correlated with a trend to a shorter relapse free survival (3 years, 86% *vs* 42% p=0.125). With respect to KIT mutations we did not find significant differences in their clinical adverse impact since 5 of the 6 mutated patients were in first complete remission probably because they underwent stem cell transplantation. Concerning the NPM1 group, mutations were similar in patients with a good outcome and patients who relapse.
Summary/Conclusions: This technology is able to find altered variants with high accuracy in AML patients. Although based on small numbers of patients, we observed a clear alteration of the RAS pathway in CBF patients, which suggests the need of further studies about new alternatives to standard chemotherapy in NRAS/KRAS mutated patients.

CLINICAL RELEVANCE OF RECURRENT ALLELE-SPECIFIC RECOMBINATION EXPRESSING THE WNT10BIVS1 ALLELE VARIANT IN ACUTE MYELOID LEUKEMIA

A Beghini[1,*], F Lazzaroni[1], L Del Giacco[2], O Soderberg[3], D Biasci[4], M Turrini[5], L Prosperi[2], R Brusamolino[6], U Landegren[3], R Cairoli[7]
[1]Dept. of Health Science, [2]Department of Biosciences, University of Milan, Milan, Italy, [3]Department of Immunology, Genetics and Pathology, Uppsala Universitet, Uppsala, Sweden, [4]Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom, [5]Department of Internal Medicine, Valduce Hospital, Como, [6]Department of Pathology, [7]Department of Oncology, Hematology Unit, Niguarda Hospital, Milan, Italy

Background: The WNT/β-catenin pathway play a critical function in the regulation of cell proliferation, differentiation, and apoptosis, playing a major role in fueling stem cell activity and sustaining tissue regeneration in a dose dependent manner in several adult stem cell niches including bone marrow. Previous results obtained by our research team provided direct evidences that WNT/β-catenin signaling is diffusely activated in the $AC133^+$acute myeloid leukemia (AML) cells. The mRNA *in situ* detection analysis revealed that WNT10B results to be expressed in leukemic blasts as well as in stromal-like cells, suggesting an autocrine/paracrine mechanism of Wnt signaling induction in the leukemic bone marrow microenvironment. Conversely, the activation of Wnt signaling, marked by expression of the dephosphorylated β-catenins, is restricted only to a smaller subpopulation of $AC133^{bright}$ cells.
Aims: In the present study, focusing our attention on the major locus associated in hematopoiesis to the regenerative function, we provide evidences for a recurrent rearrangement involving the WNT10B locus within intron 1 (IVS1). Moreover, we demonstrated the consequent expression of a non-physiological transcript variant, $WNT10B^{IVS1}$, retaining 77 nucleotide of IVS1 and lacking exon1, and we analyzed the significance in AML.
Methods: In order to provide accurate quantification of mRNA levels of WNT10B and the related $WNT10B^{IVS1}$ transcript variant and analyze the clinical relevance of their expression, we carried out the gene expression analysis by Droplet Digital™ PCR on mononucleated cells derived from n=125 AML patients [*de novo*, N=118 (intermediate-adverse risk N=70; favorable risk N=48); therapy-related, N=7, informed consent was obtained]. Analyzing patients according to the three main scoring systems, formerly the Medical Research Council (MRC), European LeukemiaNet (ELN), and National Comprehensive Cancer Network (NCCN), we were able to distinguish groups of patients at different outcomes with a statistically significant wise.
Results: We observed that canonical WNT10B mRNA was highly expressed in all *de novo* AML patients here examined, while $WNT10B^{IVS1}$ mRNA transcript levels resulted undetectable in patients classified with favorable-risk (p <0.001).

Furthermore, we demonstrated absence of both WNT10B and WNT10B^{IVS1} expression in therapy-related patients (p <0.005). Moreover, we have also evaluated the effects of transient *wnt10b* overexpression on early hematopoiesis in the zebrafish model and therefore, to this aim *wnt10b* synthetic mRNA was microinjected in the zebrafish zygote to mimic, *in vivo,* the Wnt signaling overexpression we had previously observed in AC133^{bright} AML cells. Interestingly, an increase of erythromyeloid progenitors, and a simultaneous reduction in the number of circulating neutrophils is detected.
Summary/Conclusions: The results presented here provide compelling evidence that regeneration-associated Wnt signaling exceeds the homeostatic range in the majority of human AML cases. Taking these issues into consideration, we revealed that it is possible to recognize three distinct WNT10B/ WNT10B^{IVS1} patterns, suggesting a potential role of WNT10B^{IVS1} transcript as a marker for the intermediate-adverse risk AML patients. These findings, if confirmed in a larger population of patients, may help to refine diagnostic or prognostic criteria for previously described neoplasms, and to introduce newly recognized disease entities possibly characterized by distinct causative pathogenic mechanisms.

ANALYSIS OF CLONAL IMMUNOGLOBULIN AND T-CELL RECEPTOR GENE REARRANGEMENTS IN ACUTE MYELOID LEUKEMIA

Y Huang[1,*], Z Xie[1], A Jacobsen[1], D Duong[1], J Panganiban[1], W Huang[1], B Patay[1], D Hubbard[2], T Le[2], G Pawlowsky[3], NC Adams[3], J Thornes[1], JE Miller[1,2,3], T Stenzel[1]
[1]Invivoscribe, [2]LabPMM LLC, San Diego, United States, [3]LabPMM GmbH, Martinsried, Germany

Background: Acute myeloid leukemia (AML), the most common form of leukemia, carries a high mortality rate and economic burden. In 2015, approximately 39,130 individuals were diagnosed in the United States and Europe with roughly half that number dying from the disease (1,2). With the advent of more sensitive molecular assays, the complex architecture and functional heterogeneity of AML has become appreciated though not yet fully elucidated. Fundamentally, understanding the hematopoietic stem cell (HSC) self-renewal and differentiation model will aid in this goal. Initial hierarchical hematopoietic models focused on the lymphoid and myeloid lineage groupings to be segregated. Recently studies suggest that lineage commitment of hematopoietic progenitors may be both multidirectional and reversible with changes in lineage caused by both intrinsic and environmental factors (3). Though AML is classified as a myeloid neoplasm, we were interested in determining the prevalence of clonal rearrangements within the immunoglobulin heavy (*IGH*) and light chain (*IGK*), T-cell receptor gamma (*TRG*) loci in AML patient samples.
Aims: Assess the frequency of *IGH*, *IGK*, and *TRG* rearrangements in AML patient samples.
Methods: DNA was extracted by QIAcube from a random sampling of 200 AML anonymized patient residual peripheral blood (PB) or bone marrow (BM) specimens. DNA was quantified by NanoDrop and normalized. Each DNA sample was tested for 6 different PCR master mixes: IdentiClone *IGH* Tubes A, B, C, which target the framework (FR) 1, 2, and 3 regions, respectively; *IGK* Tube A, *IGK* Tube B, and *TRG* 2.0. Amplicon products were analyzed using the ABI 3500 XL instrument. Based on the florescent signals, clonal (positive) or polyclonal (negative) were assessed per instructions of use accompanying the IdentiClone assay.
Results: The IdentiClone *IGH* assay identified 23 (12%), 14 (7%) and 16 (8%) clonal positive samples for FR 1, 2 and 3, respectively. Combining all three *IGH* tubes increased the clonal detection rate to 28 (14%) with 172 (86%) samples determined to be negative. The IdentiClone *IGK* assays identified 39 (20%) and 29 (15%) clonal positive samples for Tube A and Tube B, respectively. Combining the two *IGK* tubes increased clonal detection to 56 (28%), with 143 (72%) determined to be negative. Combining all 5 *IGH+IGK* tubes, 65 (33%) clonal positive samples and 135 (68%) clonal negative samples were identified. The *TRG* 2.0 assay detected 85 (43%) clonal positive samples and 114 (57%) clonal negative samples. Overall, using 6 tubes of PCR MM across *IGH*, *IGK* and *TRG* assays, 113 (57%) samples were identified as clonal positive and 87 (44%) samples were identified as clonal negative.
Summary/Conclusions: Over 50% of AML samples demonstrated at least one clonal IG or *TCR* gene rearrangement. Although clonal rearrangements occur in individuals over 60 years of age, clonal rearrangement assays combined with outcome data for AML patients may provide clinical utility and further elucidate functional heterogeneity.

GPC4, THE GENE OF SIMPSON-GOLABI-BEHMEL SYNDROME, IS AMPLIFIED ON EXON 9 AND REVEAL A POSSIBLE PATHOGENETIC ROLE FOR APL PROGRESSION OR RELAPSE.

S Lo Monaco[*], MC Fontana, M Manfrini, C Papayannidis, G Marconi, S Paolini, V Guadagnolo, A Padella, G Simonetti, A Ghelli Luserna Di Rorà, S Parisi, C Sartor, MC Abbenante, M Cavo, G Martinelli
Istituto Seragnoli, Bologna, Italy

Background: Cytogenetical and molecular analysis of acute promyelocytic leukemia (APL) have improved the knowledge about the genomic mechanism at the origin of this pathology identifying t(15;17) and the fusion gene PML-RARa. New targeted therapies were introduced in treatment of APL, as all-trans retinoic acid (ATRA) and arsenic trioxide. Even though these therapies, a 10% of patients (pts) still relapse. Single Nucleotide Polymorphism (SNP) microarray can detect cytogenetic lesions mostly involving structural alterations with losses or gains of chromosomic material. These abnormalities could be predictive of response and can help define therapeutic strategies. SNP microarray can also detect copy-neutral loss of heterozygosity (CN-LOH) or Uniparental Disomy (UPD), relevant to induce oncogene duplication, tumor suppressor inhibition and epigenetic reprogramming.
Aims: To improve conventional cytogenetic analysis and identify new genomic abnormalities that underlie the pathogenesis of APL, we perform SNP array-based genotyping.
Methods: We performed SNP 6.0 and Cytoscan HD Array (Affymetrix) in 23 APL (21 *de novo* and 2 relapsed) and then analyzed by Nexus Copy Number (BioDiscovery, v.7.5) and R-Bioconductor. This method reveal Copy Number Alteration (CNA) and CN-LOH that standard cytogenetic analysis could not detect. Briefly, CNA were filtered for variants already annotated in Database of Genomic Variants (DGV). Furthermore, CNA less than 1 kb were removed. Significant (p<0.05) genes in which CNA events occur were summarized per patients. Moreover, commons CNV regions among patients were detected.All the pts in our cohort were treated at the hematological Institute of Bologna. Each patient was affected by newly diagnosed or relapsed APL, in accordance with WHO 2008 classification. All of them were treated with ATRA-IDA schedule of therapy.
Results: By Nexus Copy Number, we found that the relapsed pts presented more CNA than the newly diagnosis, in particular 3 out of 23 pts (a newly diagnosis and 2 relapses), showed interesting alteration on GPC4 (exon 9) and in the q26.2region of GPC3. We found that this group of 3 pts presented a minimal common region of amplification of GPC4 (chr X: 132,432,100-132,435,915) with a significant p value (p<0.05).Moreover, GPC3 q26.2 region presented significant abnormalities with more copy number gain and copy number loss, which may play a role in the pathogenesis of APL. Also UPD were found for both GPC4 (5/23 pts) and GPC3 (6/23 pts) genes, with a p value of 0.0264 for GPC4 and 0.009 for GPC3.
Summary/Conclusions: GPC4 and GPC3 are coding genes for glypicans, heparan sulfate proteoglycans which have a role in the control of cell growth and cell division. Alteration of these genes are described as first events in the pathogenesis of Simpson-Golabi-Behmel syndrome, characterized by abnormal cellular proliferation and augmented cancer risk. Our suggestion is that these two genes may play a role in the improvement of pathogenesis and resistance of APL pts. Further studies will be necessary to confirm and validate these data in order to understand the role of these genes in APL.

PROGNOSTIC IMPACT OF COMPLEX KARYOTYPE ON OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA WITH CHROMOSOME 5 AND/OR 7 ABNORMALITIES

TL Gindina[*], N Mamayev, S Bondarenko, A Alyanskiy, O Slesarchuk, A Borovkova, S Razumova, E Nikolaeva, Y Gudozhnikova, L Zubarovskaya, B Afanasyev
R.M. Gorbacheva Memorial Research Institute of Pediatric Oncology, Hematology and Transplantation, 1st Pavlov State Medical University of Saint Petersburg, Saint-Petersburg, Russian Federation

Background: Chromosome 5 and 7 abnormalities often occur in acute myeloid leukemia (AML) both as a single chromosomal aberration and a part of the complex karyotype (CK), and constitute a high-risk group. Breems *et al.*, 2008 have identified a monosomal karyotype (MK), defined by the presence of at least 1 autosomal monosomy and 1 structural chromosomal abnormality or at least 2 autosomal monosomies, which associated with dismal outcome in AML patients. However, whether or not the prognostic impact of MK and CK remains relevant for patients who have undergone allogeneic hematopoietic stem cell transplantation (allo-HSCT) is still unclear.
Aims: To evaluate the prognostic impact of chromosome 5 and 7 abnormalities both as a single chromosome aberration and a part of the complex or monosomal karyotype on outcome of allogeneic hematopoietic stem cell transplantation in AML patients.
Methods: In this study, outcomes in 44 AML patients with 5q-, 7q-/monosomy 7, who were transplanted in our University between 2008 and 2015, were analyzed. All patients and transplant characteristics are listed in Table 1.
Results: CK and MK were identified in 19 (43%) and 8 (18%) cases, respectively. The median follow-up was 525 (46-2186) days. Overall survival (OS) was 39% (95% CI 22-55) and event free survival (EFS) was 20% (95% CI 8-35) at 3 years estimated with Kaplan-Meier method. In univariate analysis, prognostic factors associated with increased OS and EFS were age (>18 *vs* <18 years; p=0.01, p=0.05, respectively), the disease status at transplant (complete remission *vs* active diease; p=0.10, p=0.01, respectively), complex karyotype (CK- *vs* CK+; p=0.05, p=0.002, respectively), and stem cells source (bone

marrow *vs* other source; p=0.03 for OS only); monosomal karyotype (MK- *vs* MK+; p=0.009 for EFS only). Other factors including variant of AML, patient sex, donor type, conditioning regimen, number of transplanted CD34+cells, and type of chromosome abnormality were not associated with survival. In multivariate analysis, age (HR-3.67; P=0.01), the disease status at allo-HSCT (HR-2.64; P=0.03), the stem cell source (HR-3.04; P=0.02), and complex karyotype (HR-2.48; P=0.03) remained statistically significant for OS. Moreover, age (HR-2.63; P=0.01), the disease status at transplant (HR-2.63; P=0.01) and complex karyotype (HR-3.29; P=0.002) were independent predictors of EFS (Figure 1).

Table 1.

Number of patients	44 (100%)
AML	
De novo AML	27 (61%)
Secondary AML	17 (39%)
Patient sex, n (%)	
Male	22 (50%)
Female	22 (50%)
Age at HSCT, median, (range) years	31.2 (1.2-67)
Age group	
≤18 yo	15 (34%)
≥18 yo	29 (66%)
Cytogenetics, n (%)	
5q	15 (34%)
-7/7q-	24 (55%)
5q- together with -7/7q-	5 (11%)
Complex karyotype -	25 (57%)
Complex karyotype+	19 (43%)
Monosomal karyotype –	36 (82%)
Monosomal karyotype+	8 (18%)
Clinical stage at HSCT, n (%)	
CR1≥	13 (30%)
CR2	7 (16%)
Active disease	24 (54%)
HSC source, n (%)	
Bone marrow	24 (55%)
Peripheral blood	15 (34%)
Both	5 (11%)
Conditioning regimen, n (%)	
MA	10 (23%)
Non-MA	34 (77%)
Donor type, n (%)	
HLA-id sibling	13 (30%)
Matched unrelated	20 (45%)
Haploidentical	11 (25%)
Number of transplanted CD34+ cells, mediana (range) x10^6/kg	6.3 (1.6-17.9)

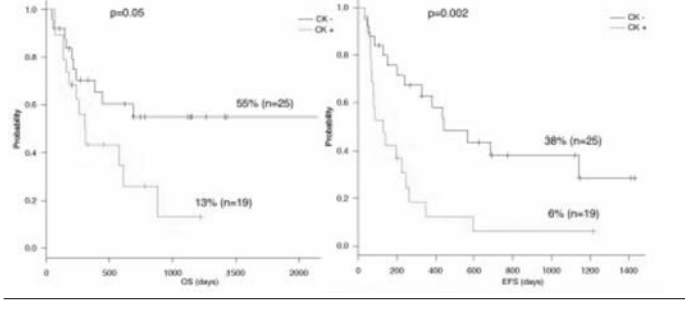

Figure 1.

Summary/Conclusions: The results indicate, that chromosome 5 and 7 abnormalities as a part of the complex karyotype but not monosomal karyotype is high-risk factor in AML patients undergoing allo-HSCT.

MUTATIONAL PROFILE BY NEXT-GENERATION SEQUENCING IN ACUTE MYELOID LEUKEMIA (AML): A SINGLE CENTER EXPERIENCE

G Piras*, R Asproni, M Monne, AD Palmas, A Uras, N Marziliano, G Latte

Laboratorio Specialistico di Ematologia, Hematology, San Francesco Hospital, ASLNuoro, Nuoro, Italy

Background: AML is a clonal disorder of hematopoietic stem and progenitor cells caused by acquired and occasionally inherited genetic alterations. Cytogenetic aberrations together with gene mutations are powerful prognostic markers and the mutational profile can be incorporated in the decision making processes to treatment.
Aims: A real-life cohort of AML patients from Sardinia (Italy) was analyzed to evaluate the usefulness of a next-generation sequencing (NGS) gene panel for the detection of mutations associated with AML in a context of routine diagnostic molecular workup.
Methods: Thirty AML patients, 15 males and 15 females with median age of 60 years (range 18-88 years) were enrolled for the study. DNAs were screened with IonAmpliseq AML panel (ThermoFisher) on IonPGM platform. The panel includes hotspots mutations of the genes: *ASXL1* (exon 12), *BRAF* (V600E),*CBL*(exons 8-9), *FLT3*(codons 676,830-850), *IDH1*(exon 4), *IDH2*(exon 4), *JAK2* (exon 14), *KIT* (exons 8, 10, 11 and 17), *KRAS* (exons 2-4), *NRAS* (exons 2-4), *PTPN11* (exons 3,7,8,13), *RUNX1* (exons3-8), *WT1* (exons 7,9), and the entire coding sequence of *CEBPA*, *DNMT3A*, *GATA*, *TET2* and *TP53* genes.The panel design does not include the *FLT3*-ITD gene region. Genomic libraries were prepared using Ion AmpliSeq™2.0 (ThermoFisher) chemistry and library clonal amplification was performed by emulsion PCR using Ion PGM™Template HiQ OT2 Reagents. Combination of 5 libraries on an Ion 318™Chip resulted in >2500X average coverage depth with >97% of the target bases covered at 500X. Genomic variants were filtered and analysed through AmpliseqAML single 5.0 workflow.
Results: The mean count of sequencing reads obtained per sample was 0.73 million and the mean sequencing depth was over 2500X with 91% uniformity. Seventy-five mutations in 19 genes were detected in 31 samples with an average of 2.3 mutations per sample. *TP53* mutations were found in 4 patients of whom one with unfavorable cytogenetics.The AML panel detected 15 mutations (20%) in *NPM1*, 6 (8%) *TET2,* 10 (13%) *DNMT3A*, 6 (8%) *CEBPA*, 5 (7%)*TP53*, 3 (4%) *RUNX1*,4 (5%) *FLT3*, 4 (5%) *IDH2*, 2 (3%) *ASXL1*, 5 (7%) *GATA2*, 6 (8%) *PTPN11* and 3 (4%) *KIT* genes. Only one patient remained wild-type for these genes. Based on mechanism of action, genes involved in signal transduction and DNA methylation were the most frequently mutated, accounting for the 39% and 32% of detected mutations, respectively. The AML gene panel identified 100% of previously identified mutations by conventional molecular biology techniques in *FLT3*(TKD), *NPM1*, *IDH1-2* and *CEBPA* genes. Mutational profiles obtained by NGS allowed to refine cytogenetic classification in the normal karyotype subgroup shifting a large proportion of patients (24 out of 30) from the intermediate to poor risk category. In one patient we were able to assess clonal dominance over the course of the disease treatment. A female 50 y.o. diagnosed with AML-M2 presented at diagnosis *IDH2* p.R172K mutation, *DNMT3A* p.F640fs*11 and *CEBPA* p.P196_P197insHP at frequencies of 42%, 49% and 20%, respectively. Monitoring of mutation levels in two consecutive bone marrow samples during treatment according to AML1310 protocol, demonstrated treatment associated clonal responses. *IDH2* mutation had a frequency of 7.3% after 4 weeks of therapy and resulted absent after 8 weeks (not detected over 6500 reads), while *DNMT3A* and *CEBPA* mutations were present at the levels of 30% and 47%, respectively. Longitudinal monitoring of three mutations indicated the presence of independent clones behaving discordantly during therapy.
Summary/Conclusions: A targeted multi gene panel analysis can provide in a short turnaround time a pretreatment mutational profile as well as the MRD status helping decision of intensity and type of induction therapy and modulation of post remission strategies.

PB1638

MRD MONITORING AND DETECTION OF MOLECULAR RELAPSE IN PEDIATRIC AML USING STANDARDIZED QPCR ASSAYS

MK Holz[1,*], C Walter[1], M Hansen[2], C von Neuhoff[1], H Hasle[2], D Reinhardt[1], N von Neuhoff[1]

[1]Pediatric Hematology and Oncology, University Children's Hospital Essen, Essen, Germany, [2]Department of Clinical Medicine - Paediatrics, Aarhus University, Aarhus, Denmark

Background: Acute myeloid leukemia (AML) is one of the most life threatening malignancies in children and adolescents. In current multi-center treatment protocols, the remission status of a patient is still determined morphologically and/or by flow cytometric as the percentage of AML blasts in the bone marrow. Although introduced in ALL for more than 10 years, no AML study group so far has been able to systematically perform real-time quantitative polymerase chain reaction (qPCR) as one of the most senstive methods to detect the presence of leukemic cells down to levels of 1:10^6.
Aims: The aim of the present study was to develop the methodology for monitoring the residual levels of AML blasts over time for patients with defined genetic aberrations enrolled in the AML-BFM 2012 clinical trial or in the study registry. These aberrations included t(8;21), t(9;11), inv(16) and NPM1 Mutation A. All patients were treated according to the AML-BFM study protocols.
Methods: We performed qPCR on mRNA isolated from bone marrow biopsies

and peripheral blood samples of pediatric AML patients. Bone marrow specimen were collected at initial diagnosis and after therapy blocks as indicated in the protocol. If possible, peripheral blood was collected every 4 weeks during maintenance therapy. We collaborated with a diagnostic laboratory in Denmark to develop and optimize standard operation procedures (SOPs) and to further standardize the MRD-monitoring methodology. Mutation-specific TaqMan probes were used and validation was performed by exchanging and analysing samples and data in parallel in both laboratories using the ΔΔCt method. *ABL proto-oncogene 1*(*ABL*) and *beta-2-microglobulin* (*B2M*) were selected as reference genes for amplification.
Results: Out of 159 patients with newly diagnosed pediatric AML from 06/2014 to 02/2016, 44 patients had genetic aberrations that could be detected and monitored using qPCR with specific primers. This included 12 patients with t(8;21), 16 patients with t(9;11), 12 patients with inv(16) and 4 patients with NPM1 mutation A. For 36 patients, we were able to analyze samples from at least 3 time points. We were able to reach sensitivity levels from 10^{-3} to 10^{-6} depending on both the quality of the bone marrow specimen as well as the specific assay.
Summary/Conclusions: We demonstrated here that qPCR for four defined genetic aberrations during and after therapy is a useful tool to prospectively monitor the AML blast levels. Due to the high sensitivity of this methodology it is possible to detect a molecular relapse at an earlier time point compared to standard morphological or flow cytometric analysis. We also showed that the successful standardization of the qPCR allowed to directly compare the MRD results from different laboratories.

PB1639

AMPLICON BASED PANEL TARGETED RESEQUENCING WITH THE TRUSIGHT MYELOID PANEL IN 100 PEDIATRIC AML PATIENTS
C Walter*, D Reinhardt, N von Neuhoff
Pediatric Hematology and Oncology, University Children's Hospital Essen, Essen, Germany

Background: Acute myeloid leukemia (AML) is one of the most threatening malignancies in children and adolescents. The accumulation of mutations in leukemia stem cells (LSC) is believed to lead to the development of leukemia. Cyto- and molecular genetics already identified several aberrations which are relevant in leukemogenesis, prognosis and therapy. Nevertheless, the molecular landscape and clonal evolution of AML and its clinical relevance, especially for pediatric patients, is not yet well described. Next Generation Sequencing as an emerging sequencing technology provides the possibility to generate sequence data of high quality and detect genetic aberrations in a minimum of time.
Aims: The aim of this study was to apply amplicon based panel targeted resequencing by using the TruSight Myeloid Panel (Illumina) on a MiSeq Dx System (Illumina) to analyse 100 children with suspicion of AML at the time of initial diagnosis to detect the genetic variants.
Methods: All the patients analysed in this study were screened in order confirm or exclude the diagnosis of AML. With the confirmation of AML, the patients were treated according to the AML-BFM therapy protocols. Next Generation sequencing (NGS) with the TruSight Myeloid panel on a MiseqDX was performed. The sequencing panel is designed to identify somatic mutations associated to myeloid malignancies in 54 genes. Validation was initially performed using data for 10 patients obtained from Sanger-Sequencing from 7 diagnostically relevant mutations and compared to the data obtained from NGS. The genes actually relevant for prognosis and treatment stratification are *CEBPA, FLT3, GATA1, KIT, NRAS, NPM1* and *WT1*.
Results: Every variant detected with Sanger Sequencing could be recovered in the NGS data. In 4 patients we could even detect additional mutations. Variants were detected and analysed using two different analysis software (Variant studio *vs* Sophia DDM) and the results were compared. Almost all variants were detectable in both software, although great insertions and deletions are detectable only by Sophia DDM. We could detect *CEBPA* mutations in 16 patients, *FLT3* ITD in 10 patients, *FLT3* TKD mutations in 2 patients, *GATA1* mutations in 6 patients, *KIT* mutations in 25 patients, *NPM1* mutations in 7 patients, *NRAS* mutations in 14 patients and *WT1* mutations in 24 patients. In 26 patients, we could not detect any mutation in these 7 genes. 23 patients had two different mutations at the same time and even three mutations could be detected in 4 patients. The analysis of variants detected in the 47 other genes covered in the panel is still ongoing.
Summary/Conclusions: Amplicon based panel targeted resequencing with the TruSight Myeloid panel provides the possibility to detect mutations in 54 genes associated to myeloid malignancies within 3 days after the sample arrived at our lab. The aim now is to adapt the report of the clinical findings to the detected variants, especially for variants in genes that were not yet diagnostically relevant. The confirmation of pathogenicity of variants in a broad range of genes could promote the possibilities of personalized targeted therapy.

PB1640

EMBRYONIC STEM CELLS ANTIGEN (ESCA) EXPRESSION IN ACUTE MYELOID LEUKEMIA CELLS
T Picot[1,*], C Aanei[2], A Fayard[3], E Tavernier-Tardy[3], P Flandrin-Gresta[2], S Tondeur[2], M Gouttenoire[3], E Wattel[4], D Guyotat[3], L Campos-Catafal[2]
[1]Laboratoire d'Hématologie, CHU de Saint Etienne, [2]Laboratoire d'Hématologie, CHU de Saint-Etienne, [3]Département d'Hématologie, Institut de Cancérologie Lucien Neuwirth, Saint-Priest-en-Jarez, [4]Laboratoire de Biologie de Modélisation de la Cellule, Lyon Sud, Lyon, France

Background: Acute Myeloid Leukemia (AML) is characterized by the expansion and resistance to apoptosis of poorly differentiated myeloid cells. This disease occurs when genetic and epigenetic processes transform an immature hematopoietic stem or progenitor cell, which reacquire self-renewing properties, and retain an undifferentiated state. Long term propagation of the disease is mainly due to a subset of proliferative, undifferentiated population, termed leukemic stem cells (LSC), which give rise to the leukemic clone. The frequency of LSC in the bulk of leukemic cells is highly variable. Several studies have suggested that LSC belongs to the $CD34^+CD38^-$ compartment and represent the malignant counterpart of normal hematopoietic stem cells (HSC). LSC can be identified by aberrant expression or down regulation of differentiation markers expressed by normal HSC. Self-renewal and lack of differentiation are also features of stem cells and has been associated with the expression of genes including those known as "Yamanaka's factors". The products of these genes are surface receptors (SSEA1 and SSEA3) and transcription factors (OCT¾, SOX2, and NANOG). There are some data concerning the abnormal expression of these proteins in solid tumors, but very few data are available in AML.
Aims: The aim of our study was to evaluate the expression of 5 ESCA (SSEA1, SSEA3, NANOG, OCT¾ and SOX2) in leukemic cell lines, and in hematopoietic stem cell (HSC) subsets ($CD34^+CD38^-$ and $CD34^+CD38^+$) from normal bone marrows (NBM) and in 106 samples from AML patients.
Methods: The expression of 5 ESCA was assessed by Multicolor Flow Cytometry and was confirmed by Reverse Transcriptase Polymerase Chain Reaction (RT-PCR).
Results: We observed a high expression of ESCA in AML cell lines (Mean Fluorescence Intensity Ratio MFIR>10, Cycle threshold Ct<40). Their expression was evaluated in $CD34^+$, as well as in the remaining $CD45^{+low}$ "blasts" after basophils and dendritic cells removal. We observed an up-regulation of the transcription factors OCT¾ and SOX2 with 2-fold higher expression ($p<0.05$) in AML cells as compared to normal cells. These results were associated with the up-regulation of SSEA3. Conversely, SSEA1 protein was down-regulated in LSC (1.7-fold higher expression in normal cells compared to leukemic cells, $p<0.05$). The expression of OCT¾, SOX2 and SSEA3 was higher in $CD34^+CD38^-$ than in CD34+CD38+subsets in HSC as well as in leukemic cells. The level of SSEA1 and NANOG were higher in more differentiated ($CD34^+CD38^+$) cells. Significant correlations were observed with recurrent molecular abnormalities. The expression of OCT¾ and SOX2 was lower in promyelocytic leukemia (APL) ($p<0.005$). SOX2 was also lower in AML with RUNX1-RUNX1T1 rearrangements (but not in AML with CBFβ-MYH11). Instead SSEA1 levels were higher in AML with CBF rearrangements ($p<0.001$), but not in APL. There was no correlation with other biological characteristics (WBC, other genetics subtypes). We also evaluated the prognostic value of ESCA expression in the 69 patients who received an intensive treatment. The rate of complete remission was not influenced by the level of expression of ESCA. There was a trend ($p=0.06$) for better overall and leukemia-free survival for patients with high OCT¾ and SOX2 levels, that was unexpected because of the inverse correlation with favourable genetic subtypes.
Summary/Conclusions: In conclusion, these results prompt us to evaluate the potential role of ESCA in leukemogenesis and to test the relevance of these markers for better LSC identification. Prognostic value should be assessed in larger series by multivariate analysis.

PB1641

ASSOCIATION BETWEEN POLYMORPHISM OF FOLATE AND METHIONINE METABOLISM GENES AND ABERRANT DNA METHYLATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME
Z Sidorova[1,*], S Kapustin[1], I Kostroma[2], S Gritsaev[2], A Chechetkin[3]
[1]Laboratory of biochemistry, [2]Hematological Clinic, [3]FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", Saint-Petersburg, Russian Federation

Background: Aberrant DNA methylation of tumor-supressor genes may be involved in the development of acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). Polymorphism of folate and methionine metabolism (FMM) related genes can influence the methylation processes and, therefore, operated on both AML and MDS development.
Aims: The aim of this study was to assess the association between polymorphism of FMM related genes and aberrant methylation of promoter regions of several tumor supressor genes in AML and MDS patients.
Methods: Fifty-seven patients with AML (20 men and 37 women, mean age 51.0 yrs) and 51 patients with MDS (24 men and 27 women, mean age 62.4 yrs) were genotyped for the MTHFR C677T, MTHFR A1298C, MTR A2756G, MTRR A66G and MTHFD G1958A polymorphisms by PCR-RFLP technique. The differences in allele and genotype frequencies were assessed by Fisher's exact test with computation of odds ratios (OR), their 95% confidence intervals (CI) and p-values. Methylation-specific PCR was used to study the methylation status of promoter regions of *SOX7*, *p15^{INK4b}*, SFRP1, SFRP4 and SFRP5 genes.

Results: Thirty patients AML (10 men and 20 women) and 21 patients MDS (9 men and 12 women) had aberrant methylation of 0-2 genes (0-2 MG group AML and MDS respectively). Twenty seven patients AML (10 men and 17 women) and 30 patients MDS (15 men and 15 women) had aberrant methylation of 3-5 genes (3-5 MG group AML and MDS respectively). In MDS group, hypermethylation of all 5 genes was found in 5 men and was not found in female patients (20.8% *vs* 0.0%, respectively, OR=15.5, 95%CI: 0.8-297.0, p=0.02). At the same time, aberrant methylation of all 5 genes was found in 8 AML patients (4 men and 4 women, 20.0% *vs* 10.8%, respectively, OR=1.9, 95%CI: 0.4-8.2, p=0.45). The presence of the MTHFR 1298C allele was increased in male patients AML from the group 0-2 MG when compared to male MDS patients in the 0-2 MG group (73% *vs* 43%, respectively, OR=3.7, 95%CI: 1.1-11.9, p=0.042). The presence of the MTHFR 677T allele was increased in female AML patients from the group 3-5 MG when compared to female AML patients in the 0-2 MG group (76.5% *vs* 35.0%, respectively, OR=6.0, 95%CI: 1.4-25.7, p=0.02), but was not different between women from 3-5 MG and 0-2 MG groups MDS patients (46.7% *vs* 33.4%, respectively, OR=1.8, 95%CI: 0.4-8.4, p=0.7). It is interesting, that positivity for the MTHFR 677T allele was significantly increased in male MDS patients from the group 0-2 MG when compared to male 3-5 MG group (100.0% *vs* 46.7%, respectively, OR=21.5, 95%CI: 1.2-437, p=0.01). In male patients with MDS, the MTHFD 1958 AA genotype was more frequently seen in the group 3-5 MG than in the group 0-2 MG (33.0% *vs* 0.0%, respectively, OR=9.9, 95%CI: 0.5-205.0, p=0.12). This genotype was also overrepresented in the group 3-5 MG of women with AML when compared to group 0-2 MG of female AML patients (29.4% *vs* 5.0%, respectively, OR=7.9, 95%CI: 0.8-76.3, p=0.08).
Summary/Conclusions: We conclude that polymorphism of the FMM genes could have an important role in mechanism of epigenetic disturbances at AML and MDS, associated with aberrant methylation of CpG islands of tumor-supressor genes.

PB1642

LOCALIZATION OF FLT3-ITD IS ASSOCIATED WITH RESPONSE TO INDUCTION CHEMOTHERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U Schnetzke*, M Fischer, B Spies-Weisshart, M Fleischmann, I Hilgendorf, A Hochhaus, S Scholl
Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: FLT3-ITDs (internal tandem duplications) represent the most frequent molecular aberrations in acute myeloid leukemia (AML) that are both virtually patient-specific and associated with a higher probability of relapse. Several studies addressed the question whether the diversity of FLT3-ITD affects the clinical outcome of AML patients. We present patient-specific sequence analysis of FLT3-ITD-positive AML patients and its correlation with clinical data.
Aims: FLT3-ITD sequence analysis focused on ITD localization and the presence of distinct amino acid motives. We sought to establish a relationship between the localization of the internal tandem duplication in FLT3 and response to therapy.
Methods: 43 patients (26 female, median age 57 years, 84% with *de novo* AML) diagnosed and treated in a single center were retrospectively analysed.All patients received intensive induction chemotherapy according to one of the following protocols of the Ostdeutsche Studiengruppe für Hämatologie und Onkologie (OSHO): AML96 or AML2002 protocol containing idarubicine for patients up to 60 years old and AML97 or AML2004 protocol containing mitoxantrone for elderly patients.
Results: FLT3-ITD localization more downstream can be correlated with impaired leukemia-free survival (LFS) while the level of significance is not reached in our small cohort of AML patients. In contrast, all investigated amino acid motifs (*e.g.* YVDFREY) had no impact on the clinical outcome. Importantly, the probability to achieve a complete remission (CR) after AML induction chemotherapy is affected by the localization of the internal tandem duplication. In detail, CR rate is significantly higher in those patients who present with FLT3-ITD localized towards the N-terminus (86.4% *vs* 57.1%, p=0.045, Chi squared test).
Summary/Conclusions: We hypothesize that FLT3-ITDs that are located closer to the C-terminus of FLT3 are associated with an unfavorable prognosis due to a lower CR rate following induction chemotherapy of AML.

MITOCHONDRIAL SPECIFIC ROS HYPEROXIDATION VIA PEROXIREDOXIN III HAS IMPORTANT ROLES ON ARSENIC TRIOXIDE INDUCED APOPTOSIS IN ACUTE PROMYELOCYTIC LEUKEMIA

CM Seong[1,*], YC Mun[1], JY Ahn[1], ES Yoo[2], KE Lee[1], E Nam[1], SN Lee[1], HA Woo[3], SG Rhee[4]
[1]Department of Internal Medicine, [2]Pediatrics, Ewha Womans University School of Medicine, [3]Graduate School of Pharmaceutical Sciences, Ewha Womans University, [4]Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Despite that the Arsenic trioxide (ATO) is an effective therapeutic drug for acute promyelocytic leukemia (APL), some APL cells are resistant to ATO treatment. Previous studies reported that the apoptotic processes by ATO treatment was due to the accumulation of ROS in the cells and its balance of redox enzymes. However, not only the mechanisms of apoptosis via reactive oxygen species (ROS) and peroxiredoxin (PRX) but its resistance during ATO treatment remain elusive.
Aims: Aims of current study are to elucidate that the upregulation of ROS production and the changes of redox enzyme may be major players of anti-leukemia effect in APL-derived NB4 cells during ATO treatment and to find ways to potentiate of the anti-leukemic effects by maniplating ROS and its redox enzymes.
Methods: NB4, one of the human acute promyelocytic leukemia cell lines, was treated with 2 μM arsenic trioxide to induce apoptosis for 16-48 hours in RPMI-1640 medium supplemented with 10% FBS in CO2 humidified atmosphere at 37°C. Apoptosis was measured by staining with 7-amino-actinomycin D (7-AAD) with flow cytometry. 2, 7-dichlrodihydro-fluorescein-diacetate (H2DCF-DA) and MitoSOX Red were used to detect cellular and mitochondrial levels of ROS. SO2 form for PRX I, PRX II, and PRX III were detected by western blot assay. Steady state level of sulfiredoxin (SRX) and caspase 3, 9 were also studied by western blot analysis. To evaluate of the effect of SRX depletion, NB4 cells were transfected with small interfering RNA (siRNA).
Results: Intracellular ROS of NB4 cells was increased significantly after 16 hour of ATO treatment but decreased after 24 hour of ATO treatment. Mitochondrial ROS of NB4 cells was increased significantly after 39 hour of ATO treatment. Apoptosis of NB4 cell after ATO treatment was increased as time elapsed (24% on 16hr, 26% on 24hr, 48% on 39hr, and 60% on 48hr). Increased cysteine sulfinic acid (Cys–SO2H) of PRX III, oxidized form, was observed as a hyperoxidation reaction in NB4 cells after ATO treatment in concordance with mitochondrial ROS increment of NB4 cells. Increased expressions of cleaved caspase-9 and cleaved caspase-3 were also observed during NB4 cell apoptosis by ATO treatment. Meanwhile, SRX expression was increased in NB4 cells after ATO treatment which was rather unexpected observation. Down regulation of SRX by siRNA promoted ROS generation and apoptosis in ATO-treated NB4 cells.
Summary/Conclusions: These findings suggest that ATO-induced anti-leukemic activity can be down regulated by an enhancing oxidized PRX III reduction after ATO-induced SRX activation and that down regulation of SRX can enhance the apoptosis in ATO-treated NB4 cells. This result might provide the insights for finding novel ways in the development of strategies, which may potentiate ATO-induced apoptosis in APL cells.

PB1644

HIGH EXPRESSION OF TIM-3 ON BLAST CELLS IS ASSOCIATED WITH GOOD PROGNOSTIC FACTORS IN *DE NOVO* NON-M3 AML

X Wu*, L Xu, J Xu, M Zhu, C Fu, Y Han,xTang, H Qiu, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: T-cell immunoglobulin and mucin domain-containing molecule3 (Tim-3) represents a novel mechanism of T-cell dysfunction and exhaustion. Tim-3 has also been identified in various solid tumors. However, the role of Tim-3 expression on blast cells in acute leukemia is not well understood.
Aims: In this study, we aimed to explore the role of Tim-3 in patients with *de novo* acute leukemia and the correlation between Tim-3 and clinicopathological prognosis.
Methods: The study cohort consisted of 121 patients including 76 cases with *de novo* non-M3 AML and 45 cases with ALL. These patients' bone marrow samples were collected and then bone Marrow mononuclear cells (BMCs) were isolated for flow cytometry to detect Tim-3 expression on blast cells. E_LINK3">clinicopathological prognosis.
Results: According to FAB type, 76 AML patients were diagnosed as M0(n=2), M1(n=16), M2(n=20),M4(n=20),M5(n=16) and M6(n=2), respectively. And ALL group were comprised of 38 cases with B-cell ALL and 7 cases with T-cell ALL. The results came out that Tim-3 expression on blasts in *de novo* AML patients significantly increased compared with that of ALL patients (P=0.00). Moreover, the frequency of Tim-3 high expression was higher in M4 patient than that in other AML patients according to FAB type (P=0.00). Tim-3 high expression was also closely associated with inv(16) (P=0.01) and C/EBPA mutation (P=0.03). The mutations of the following six genes, *i.e.*, FLT3-ITD, NPM1, C-KIT, IDH1/IDH2, DNMT3A, had little to do with the expression of Tim-3. Additionally, it is more likely to find higher level of Tim-3 in low-risk group than in intermediate- and high-risk groups (P=0.04). The expression of Tim-3 was positively correlated with CD13 (r=0.33,P=0.02), CD34 (r=0.51, P=0.00), CD7 (r=0.40, P=0.00) in AML patients. As for the ALL patients, Tim-3 expression significantly increased in the T-ALL group than in the B-ALL group (P=0.00). The expression of Tim-3 in ALL patients was positively correlated with CD34(r=0.32, P=0.00), CD7(r=0.56, P=0.01) and negatively with CD10(r=-0.35,P=0.02), CD19(r=-0.24,P=0.00), CD20(r=-0.31,P=0.01). Tim-3 expression was not significantly associated with potential prognostic factors, including age or cytogenetic risk in ALL patients. AML patients with high Tim-3 expression achieved significantly high CR rate (P=0.01) and then their Tim-3 expression significantly decreased after CR (P=0.00), but such trend did not occur in ALL patients.

Summary/Conclusions: These findings suggest that high Tim-3 expression on blast cells is associated with good prognosis and detection of Tim-3 expression may be helpful to predict clinicopathological prognosis in non-M3 AML patients.

PB1645

MEIS1 IS ESSENTIAL FOR THE MAINTENANCE OF HUMAN ACUTE MYELOID LEUKEMIA BLASTS INDEPENDENT OF MLL REARRANGEMENTS

J Liu*, YZ Qin, S Yang, Y Wang, YJ Chang, T Zhao, Q Jiang, XJ Huang
Peking University People's Hospital, Beijing, China

Background: Acute myeloid leukemia (AML) is one of the common hematopoietic malignancies with high mortality. Although the outcome of patients with AML has improved by optimized chemotherapy regimens and bone marrow transplantation, leukemia relapse remains one of the most challenging problems during clinical treatment. Sustained existence of AML blasts is a fundamental determinant for the leukemia development and resistance to therapy. Recent evidences suggest that Meis1 is tightly associated with the self-renewal capacity of normal hematopoietic stem cells. Meis1 was also found to be essential for the development of mixed lineage leukemia (*MLL*)-rearranged leukemia. Whether Meis1 functions independently of *MLL* abnormality in the context of leukemia is of major interest.
Aims: To elucidate whether Meis1 functions independently of *MLL* abnormality in the maintenance of leukemia blasts.
Methods: We performed siRNA-mediated gene silencing experiments in the cultured human AML cells without *MLL* rearrangements. Next, we detected the expression levels of Meis1 in the bone marrows from 95 patients with newly diagnosed AML excluding promyelocytic leukemia and 30 healthy donors. All patients did not express a set of recognized AML-associated fusion genes. The association between the Meis1 levels and the response to chemotherapy was further explored.
Results: Deficiency of Meis1 expression impaired the maintenance and survival of cultured human AML blasts, which is independent of *MLL* abnormality. In the patients with newly diagnosed AML and without *MLL* rearrangements, high levels of Meis1 expression were found in 64 of 95 (67.4%) AML patients whereas 31 of 95 (32.6%) patients showed the dramatically low levels, compared with the median level of Meis1 expression in healthy donors. We further demonstrated that high levels of Meis1 expression were associated with the poor response to conventional chemotherapy, compared with the group with low Meis1 levels (p=0.028).
Summary/Conclusions: We identified a distinct expression pattern of Meis1 levels in patients with newly diagnosed AML and highlighted a role of Meis1 in regulating maintenance and survival of human AML cells without *MLL* abnormality. These results implicate Meis1 functions as an important regulator and could be an independent prognostic factor during the progression of human AML.

ACTIVATION OF AMP-ACTIVATED PROTEIN KINASE AMELIORATES CYTARABINE-INDUCED OVEREXPRESSION OF NUCLEOPHOSMIN AND DRUG-INDUCED-CHEMORESISTANCE IN HL-60 AML CELLS

D Kim[1,*], YH Kwon[2], BH Choi[1], DH Lee[1], JH Kang[1], HG Yi[3], CS Park[1]
[1]Department of Pharmacology, Inha University School of Medicine, [2]Inha Research Institute for Medical Sciences, [3]Deparment of Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of

Background: Nucleophosmin (NPM or B23) is a ribosomal protein located mainly in nucleolus, and multifunctional enzyme in cancer cell growth and protein synthesis. Particularly, it has been suggested that NPM plays a role in the positive regulation of cell proliferation, thus observed the over-expression levels in pathological higher grades of tumor and actively proliferating cells than normal cells. On the other hand, AMP-activated protein kinase (AMPK) is a critical energy sensor to regulate homeostasis and plays a potential role for anti-cell proliferating activity.
Aims: We investigated the effects of AMPK activation on the cell death (apoptosis) and NPM expression in AML (acute myeloid leukemia) cells (HL-60) treated with low or high dose of an antileukemic drug cytarabine to understand the mechanisms responsible for AML cells chemoresistance.
Methods: Cell viability was assessed using MTS assay. Apoptosis and cell cycle progression were evaluated by flow cytometry assay. Protein and mRNA expressions were detected with real time-PCR and Western blot assay.
Results: Interestingly, we found that the level of NPM expression was increased significantly in cytarabine-treated cells without dose-dependency of cell death, indicating the drug-induced cell resistance. In the same point, cytarabine also inhibited the phosphor-activity (Thr172) and expression level of AMPK, which has mTOR-p70S6K pathway-repressor activity. As expected, single cytarabine treatment increased the ratio of p-mTOR/mTOR and p-p70S6K/p70S6K. Co-treatment of AMPK activator (phenformin or AICAR) in cytarabine-treated HL-60 AML cells inhibited significantly the induction of NPM expression level with the decrease of phosphor-activities of mTOR and its substrate p70S6K, resulted in the accelerated cell apoptosis.
Summary/Conclusions: Our results suggest that AMPK activation might be used to sensitize AML cells to cytarabine with the control of NPM expression levels, thus the lower therapeutic dose and the less adverse effects.(Correspondence to HG Yi and CS Park; Medical Research Center no. 2014009392)

SERUM LEVELS OF CYTOKINES AND SOLUBLE ADHESION MOLECULES IN ACTIVE ACUTE MYELOID LEUKEMIA AND COMPLETE REMISSION: EVIDENCE OF ENDOTHELIAL CELL ACTIVATION

T Kupsa[1,2], J Vanek[3], P Zak[2], L Jebavy[1,2], JM Horacek[1,2,*]
[1]Department of Military Internal Medicine and Military Hygiene, Faculty of Military Health Sciences, [2]4th Department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, [3]Department of Informatics and Quantitative Methods, University of Hradec Kralove, Faculty of Informatics and Management, Hradec Kralove, Czech Republic

Background: Acue myeloid leukemia cell are highly resistant to therapy. The presumed molecular basis of this resistance is the effect Tumor Necrosis Factor-α (TNF-α) and other cytokines on endothelial adhesion molecule expression.
Aims: The aim of this study was to test the hypothesis that cytokines and soluble adhesion molecules are involved in endothelial cell activation in acute myeloid leukemia (AML).
Methods: A total of 84 AML patients were studied. Two subgroups comprising 84 samples collected in active disease and 45 samples collected at AML complete remission (CR) were evaluated. Samples obtained after allogeneic stem cell transplantation were not included. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α,IL-1β,IL-2,IL-3,IL-4,IL-5,IL-6,IL-7,IL-8,IL-10,IL-12,IL-13,IL-15), Epidermal Growth Factor (EGF), GM-CSF, IFN-γ, Macrophage Inflammatory Protein-1α (MIP-1α), Monocyte Chemotactic Protein-1 (MCP-1), TNF-α, Vascular Endothelial Growth Factor (VEGF), E-selectin (E-SEL), P-selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor-α (sIL-2Rα) and soluble receptors for IL-6 (sIL-6R) and TNF-α type I and II (TNFR-1,2). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox). Probability values (P)<0.05 were considered significant.
Results: In active disease, the levels of VCAM-1 correlated with ICAM-1 (P<0.0001), E-SEL (P=0.0011), leukocyte count (P=0.0006), TNF-α (P<0.0001), TNFR-2 (P<0.0001), TNFR-1 (P=0.0047), LDH (P<0.0001), IL-2Rα (P=0.0224) and IL-6R (P=0.0240). The ICAM-1 levels correlated with E-SEL (P=0.0285), TNFR-1 (P=0.0007), LDH (P=0.0344) and IL-6 (P=0.0646). E-SEL correlated with P-SEL (P<0.0001), leukocyte count (P<0.0001), LDH (P<0.0001), TNFR-1 (P=0.0152), TNFR-2 (P=0.0202). CRP levels correlated with IL-6 (P<0.0001), ICAM-1 (P=0.0122) and negatively with albumin levels (P=0.0175). The platelet count correlated with IL-7 (P<0.0001), EGF (P<0.0001) and VEGF. There was no correlation of age or haemaglobin levels with any evaluated analyte. In CR the levels of IL-7 (P<0.0001), EGF (P<0.0001) and VEGF (P<0.0001) were higher, which was related to normalized platelet count. The levels of IL-6 were lower in CR with no significant correlation with CRP levels. The levels of VCAM-1, ICAM-1, E-SEL and P-SEL were decreased compared to active disease, which was not significant after Bonferroni correction of P. The P-SEL correlated with platelet count (P<0.0001) and IL-8 (P<0.0001), which was not observed in active disease. VCAM-1 correlated with ICAM-1 (P=0.0027), but not with E-SEL or P-SEL. The E-SEL did not correlate with P-SEL.
Summary/Conclusions: Our findings are in agreement with the results of studies showing that cytokine and chemokine expression are largely independent of variables, such as age, gender and haemoglobin levels. In active disease the adhesion molecule levels are influenced as a whole and correlate with leukocyte count, LDH and levels of TNF-α, TNFR-1 and TNFR-2. Understanding the relationship of evaluated analytes in active AML and CR is more important than simple comparison of their levels. Endothelial cells can release both E-SEL and P-SEL. This happens in active disease, where the correlation of E-SEL and leukocyte count is significant. In CR there was no significant correlation of E-SEL with P-SEL or leukocyte count. Platelets release only P-SEL and are the major source of P-SEL in CR. We interprete these data as direct evidence of endothelial cell activation in active AML.
The work was supported by a long-term organisation development plan 1011 (FMHS).

ARE TP53BETA AND TP53GAMMA EXPRESSION LEVELS CORRELATED TO NPM1/FLT3 MUTATIONAL STATUS?

K Matiakowska*, A Bartoszewska-Kubiak, E Bielinska, M Morgut-Klimkowska, O Haus
Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: *TP53* encodes a tumor suppressor protein which consists of transactivation, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells. p53β binds to *BAX* promoter

and can induce apoptosis independent from p53 wt. It also regulates p53 activity. In AML high expression of p53β and p53γ proteins may play role in response to treatment by enhancing cells sensitivity to chemotherapy. It has been showed that patients have longer survival after treatment. *NPM1* (nucleophosmin gene) mutations are frequent alterations in normal karyotype AML (NK AML). Until now 56 different mutations of exon 12 of *NPM1* have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, including p53 and ARF. While patients with *NPM1* mutations are stratified to favorable risk group, internal tandem duplications (ITD) in the fms-like tyrosine kinase-3 gene *(FLT3) (i.e. FLT3ITD)* are poor prognosis factors.
Aims: The aim of the study was to assess mutational status of *NPM1/FLT3* in association with *TP53*beta and *TP53*gamma expression levels.
Methods: 56 NK AML patients with *NPM1* and/or *FLT3*ITD mutations were included in the study. Analysis of *TP53*β and *TP53*γ expression levels was possible only in 36 patients. Relative expression results were analyzed with ΔΔCt method, with *ABL* as a control gene and K562 cell line as a calibrator.
Results: In all 36 cases, *TP53*β and *TP53*γ transcripts were detected. 17 patients were *NPM1+/FLT3-*, 14 were *NPM1+/FLT3+*and 5 were *NPM1-/FLT3+*. Assessed median expression level of *TP53*β was much higher (ΔΔCt 43,87) than *TP53*γ (ΔΔCt 10,52; p=0,000027). Furthermore, according to statistical analysis, expression level of *TP53*γ was significantly associated with *NPM1/FLT3* mutations (p=0,008). We also classified patients according to median expression value of *TP53* to two groups: with overexpression or with small expression. Median WBC count in patients with overexpression of both isoforms was higher (75,4 G/L) than in group where expression of both isoforms was below median value (30G/L). Expression level of *TP53*γ was also correlated to WBC (p=0,05) and patients' age (p=0,015).
Summary/Conclusions: Obtained results may indicate a clinical importance of analysis *TP53* isoforms expression together with clinical data of patients.

Aims: To evaluate impact of additional cytogenetic aberrations on outcome of allogeneic hematopoietic stem cell transplantation in patients with *RUNX1-RUNX1T1* acute myeloid leukemia
Methods: In this study, outcomes in 25 *RUNX1-RUNX1T1*-positive AML patients (pts), who were transplanted in a single institution between 2008 and 2015, were analyzed. All patients and transplant characteristics are listed in Table 1.
Results: The median follow-up was 566 (8 – 2127) days. Overall survival (OS) was 33% (95% CI 14-53) and relapse free survival (RFS) was 26% (95% CI 9-45) at 4 years estimated with Kaplan-Meier method. In univariate analysis, prognostic factors associated with increased OS and RFS were age (>18 *vs* <18 years; p=0.03, p=0.0006, respectively), donor type (match related *vs* match unrelated *vs* haploidentical; p=0.0003, p=0.02, respectively), disease status at transplant (complete remission *vs* active disease; p=0.0002, p=0.005, respectively), the interval from diagnosis to transplant (<360 *vs* >360 days; p=0.008, p=0.9, respectively), ACA (ACA- *vs* ACA+; p=0.02, p=0.009, respectively) (Figure 1), complex karyotype (CK- *vs* CK+; p=0.004, p=0.0003, respectively). In multivariate analysis, the ACA (HR-13.5; P=0.04), the donor type (HR-6.86; P=0.01), the interval from diagnosis to HSCT (HR-6.80; P=0.02) remained statistically significant for OS. Moreover, age (HR-0.11; P=0.004) and the donor type (HR-4.16; P=0.04) were independent predictors of RFS.

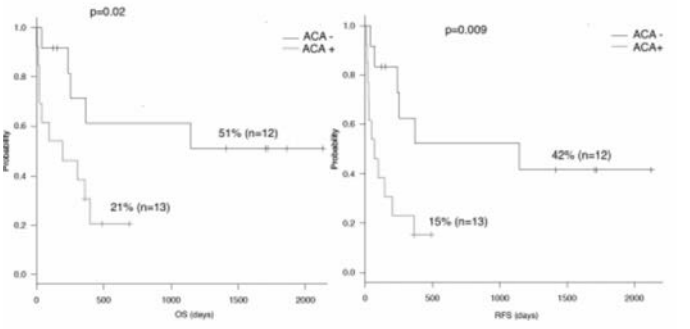

Figure 1.

Summary/Conclusions: The study demonstrates that the ACAs are independent prognostic factor for *RUNX1-RUNX1T1*-AML in transplanted pts. Since chemotherapy and cytotoxic conditioning regimen may be responsible for production of new ACAs, these regimens should be change by substitution of more toxic alkylating agents to less toxic.

PB1650

ABERRANT METHYLATION OF PROMOTER REGIONS OF SOX7, P15INK4B AND WNT PATHWAY ANTAGONIST GENES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

Background: Aberrant methylation of CpG islands of tumor-supressor genes may be involved in the development of acute myeloid leukemia (AML) and be associated with the natural history of the disease.
Aims: To reveal the features of aberrant methylation of promoter regions of *SOX7, p15^{INK4b}* and Wnt pathway antagonist genes in AML patients.
Methods: The data of 57 AML patients with median age of 51.0 years were analyzed. Next AML variants were diagnosed: 2 patients with M0, 7 M1, 23 M2, 4 M4, 8 M5, 3 M6 and 10 with myelodysplasia. Cytogenetic data were available in 56 patients. Normal karyotype was identified in 31 (54.4%) patients. Other 25 patients had different chromosomal aberrations including complex karyotype in 8 patients. Methylation-specific PCR was used to study the methylation status of promoter regions of *SOX7, p15^{INK4b}* and Wnt pathway antagonist genes.
Results: The frequency of aberrant methylation was next: *SFRP1* 68.4%, *p15^{INK4b}* 63.2%, *SOX7* 47.4%, *SFRP4* 42.1%, *SFRP5* 35.1%. Absence of aberrant methylation was found in 5 (8.8%) patients. The most frequent finding was methylation of 2 and 3 genes simultaneously: 29.8% and 21.1% accordingly. Half of the patients with aberrant methylation status of all 5 studied genes had AML with dysplasia. The most part of patients with complex karyotype (62.5%) had aberrant methylation of 3-5 genes. The difference in the number of patients with complex or normal karyotype who had aberrant methylation of all 5 studied genes was significant: 50.0% *vs* 9.7% OR=9.3 95% CI 1.5-58.0; *p=0.022*. The patients with normal karyotype and without *FLT3* and *NPM1* mutations were separated according to the number of genes with aberrant

methylation: 0-2 *vs* 3-5. There was no significant difference in overall and relapse free survival between these groups.
Summary/Conclusions: Aberrant methylation of *SOX7, p15^{INK4b}* and Wnt pathway antagonist genes is recurrent biologic phenomenon in AML patients. More often this finding occurs in AML patients with myelodysplasia and complex karyotype.

PB1651

INCIDENCE AND MAIN CHARACTERISTICS OF T(12;22)(P13;Q12)/MN1-ETV6-POSITIVE ADULT BULGARIAN ACUTE MYELOID LEUKEMIA PATIENTS: A SINGLE INSTITUTION EXPERIENCE
G Balatzenko[1,*], S Angelova[1], Y Georgieva[2], B Spassov[3], K Ignatova[3], G Mihailov[3], S Toshkov[1], M Guenova [2]
[1]Laboratory of Cytogenetics & Molecular Biology, [2]Laboratory of Hematopathology & Immunology, [3]Department of Clinical Hematology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Background: Translocation t(12;22)(p13;q12) is a recurrent, but rare genetic abnormality in acute myeloid leukemia (AML). To our knowledge, only 14 cases of t(12;22)-positive AML have been published so far. This translocation results in the *MN1-ETV6* fusion gene formation, however, in only 5 of the reported t(12;22)-positive AMLs, the presence of *MN1-ETV6* fusion gene was confirmed molecularly [1;2;3]. Due to the rareness of the disease data about the clinical and laboratory features of t(12;22)-positive AML patients are still limited.
Aims: To determine the incidence and the main characteristics of t(12;22)-positive AML.
Methods: Bone marrow aspirates of 645 adult AML patient were tested in the Laboratory of Cytogenetics and Molecular Biology of the National Specialized Hospital for Active Treatment of Hematological Diseases – Sofia during a 10-years period. Successful karyotypes were obtained in 555 patients (86%). In all cases with t(12;22), the presence of *MN1-ETV6* rearrangement was additionally tested by fluorescence *in situ* hybridization (FISH) and reverse transcription polymerase chain reaction (RT-PCR). The AML diagnosis and subclassification were performed according to the World Health Organization Classification criteria (2008).
Results: Overall, t(12;22) was detected by conventional cytogenetics in three patients (0.54%). In all of them the translocation was identified as a sole chromosome abnormality and the *MN1-ETV6* fusion was confirmed by FISH and RT-PCR. None of the patients was positive for *BCR-ABL1*, *CBFb-MYH11, AML1-ETO, FLT3-ITD, JAK2 V617F*, and *NPM1* mutations. Two of the patients were male and one was female, aged 60, 65 and 71 years, respectively. White blood cell counts varied from 4.6x10^9/L to 77.5x10^9/L, platelet counts from 14x10^9/L to 104x10^9/L, and hemoglobin from 81 g/L to 125 g/L. Morphology was myelomonocytic in all patients, associated with granulocytic dysplasia in one of the cases and presented as a hypoplastic leukemia in another. Bone marrow blasts accounted for 58%>88%. Flow cytometry revealed CD34 positive expression and aberrant myelomonocytic phenotypes in all three patients, with CD56 positive and CD4 positive immune labeling in 2 patients each. Aberrant expression of other lymphoid-associated antigens (CD7/CD19) was also detected in one case. No splenomegaly was found in all of the patients, while mild liver enlargement was observed in one of them. Two of patients received conventional cytarabine/antracycline-based induction therapy. Unfortunately, early death occurred in both cases. The third patient refused chemotherapy and was lost of follow up.
Summary/Conclusions: Our study confirmed the low incidence of t(12;22)/*MN1-ETV6*-positive AML. Though heterogeneous in terms of clinical and laboratory presentation, the reported patients were characterized by absence of additional chromosomal aberrations, aberrant myelomonocytic phenotype and a high induction-induced death rate.

INCREASED RISK OF TUBERCULOSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA IN AN ENDEMIC AREA: A NATIONWIDE POPULATION-BASED STUDY
CJ Liu[1,*], YM Zheng[2], P Hsu[2], YC Liu[1], JP Gau[1], LT Hsiao[1], YB Yu[1], CH Tzeng[1], PM Chen[1], TJ Chiou[3], JH Liu[1]
[1]Division of Hematology and Oncology, [2]Department of Medicine, [3]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ROC

Background: To date, few studies have investigated the association between tuberculosis (TB) and acute myeloid leukemia (AML).
Aims: We therefore aim to assess the impact and the risk factors of TB in patients with AML for a better risk stratification strategy.
Methods: We conducted a nationwide population-based study using data retrieved from Taiwan's National Health Insurance Research Database to determine the incidence of TB and to analyze the risk factors for TB in patients with newly diagnosed AML. From 2000 to 2011, we identified 6,771 AML patients and the same number of subjects without AML matched for sex, age, and comorbidities. Cox proportional hazards models were applied for further analysis. AML-related therapies were assessed as time-dependent covariates to avoid immortal time bias.
Results: Compared with the matched cohort, AML patients exhibited a higher risk for TB (adjusted hazard ratio [HR] 4.31, 95% confidence interval [CI] 3.27–5.67, p <0.001), with an increased risk for both pulmonary (adjusted HR 4.22, 95% CI 3.13–5.69, p <0·001) and extrapulmonary (adjusted HR 4.86, 95% CI 2.40–9.84, p <0.001) TB. Adjusted HRs of TB occurrence for follow-up periods of <1, 1–2, 2–5, and ≥5 years were 9.61 (95% CI 5.69–16.25), 5.40 (95% CI 2.88–10.13), 1.89 (95% CI 0.94–3.79), and 1.81 (95% CI 0.71–4.63), respectively. Multivariate analysis showed that being male (adjusted HR 1.47, 95% CI 1.06–2.04, p=0.020) and having liver cirrhosis (adjusted HR 2.08, 95% CI 1.17–3.70, p=0.012) were identified as independent risk factors for developing TB in AML patients. However, treatment with idarubicin, daunorubicin, high-dose cytarabine, or hematopoietic stem cell transplantation did not increase the risk of TB development. AML patients who developed TB had a higher mortality rate than those who did not (adjusted HR 1.63, 95% CI 1.33–1.99, p <0.001) (Figure 1).

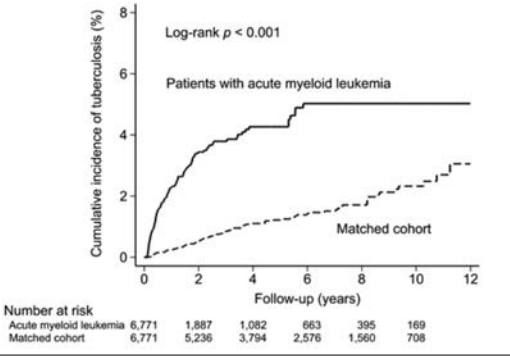

Figure 1.

Summary/Conclusions: Patients with AML had a higher risk of TB, especially within two years of diagnosis. Being male and having liver cirrhosis were independent risk factors for TB in AML patients. Physicians should be aware of the TB situation among their respective populations, particularly those in endemic areas.

DECREASING EARLY DEATHS IN ACUTE PROMYELOCYTIC LEUKEMIA (APL) IN AN ACADEMIC CENTER IN THE US BY USING A SIMPLIFIED TREATMENT ALGORITHM AND DEDICATED APL EXPERTS
A Jillella[1,*], M Mody[2], G Harpaul[2], M Arellano[1], H Khoury[1], Z Al-Kadhimi[1], M McLemore[1], E Winton[1], M Gaddh[1], L Heffner[1], L Bernal-Mizrachi[1], J Galipeau[1], A Langston[1], K Sitchenko[1], V Jonnalagadda[1], K Bradley[3], V Kota[1]
[1]Department of Hematology and Oncology, Winship Cancer Institute of Emory University, [2]Department of Medicine, [3]Department of Pathology, Emory University School of Medicine, Atlanta, United States

Background: APL is a highly curable malignancy with reported survival above 90% in many large co-operative group studies. Treatment of low and intermediate risk patients showed an expected survival of 99% with retinoic acid (ATRA)/Arsenic (ATO) combination *versus* 91% with ATRA/chemotherapy at 2

years. These spectacular results are not evident in the general population. US SEER data showed that 1 and 5 year relative survival in APL patients is 71% and 65%. Studies from Swedish Cancer Registry and Brazil showed that early deaths (ED) can be approximately 30%. This is in contrast to observation in clinical trials where the early mortality is approximately 5%. Common causes of death are hemorrhagic complications (HC), differentiation syndrome (DS), infection and multi-organ failure (MOF). It is now agreed that the most common cause of treatment failure in APL is ED; and decreasing ED will improve population wide survival in this most curable leukemia. We report our institutional experience that showed a decrease in ED by using a streamlined set of guidelines and expert advice as needed.

Aims: To identify the impact of streamlined guidelines

Methods: We reviewed charts of patients with newly diagnosed APL and treated at our institution between January 2007 and August 2013 (earlier group). We compared these outcomes with those diagnosed from September 2013 to January 2016 (newer group) when we put in place a set of streamlined guidelines to improve ED. In addition to the guidelines, three faculty members with an interest in APL provided input as needed in the management of all newly diagnosed patients.

Results: From 01/2007 to 01/2016, 108 patients were treated; 75 patients managed prior to and 33 after establishment of guidelines. One Jehovah's Witness patient was excluded from the newer group for refusing transfusions and subsequently died. Median age was similar at 45 years in both groups (range 19-86 and 21-81 respectively). Patients above 60 years were approximately 30% (23/75 and 10/32) and platelet count (29 and 30) were similar in both groups. In the earlier group, median white cell count (WBC) (4.2 and 2.2) and proportion of high risk (WBC >10,000/ml) patients (36% *vs* 21%) were higher. In the earlier group, induction regimen consisted of ATRA in combination with anthracycline (50, 66%), arsenic (12, 16%), other chemotherapy (8, 10%) or single agent ATRA in (5, 6%) patients. In contrast in the newer group, ATRA with ATO was the preferred induction regimen in 24 (75%) and anthracycline based treatment was used in 6 (18%) patients. 2 patients received ATRA alone. Overall the ED rate was higher in the earlier group with 19 patients (25%) dying in the first month. The causes of death were DIC (9), DS (7) and infection/MOF (3). 5 patients presented with large intracranial bleeds and were extremely ill. Excluding the patients that were referred late, the mortality was 18%; similar to some single institution studies but more than what is seen in clinical trials. After the institution of our algorithm, mortality was reduced to 9.4% (3/32 ED). Cause of ED was DS (2) and DIC (1). The incidence of severe DS (18% *vs* 6%) and sepsis (28% *vs* 16%) were lower in the newer group. The improved outcomes (25% *vs* 9.3%) is probably multifactorial due to lower number of high risk patients, more frequent arsenic based induction, use of streamlined guidelines and advice by dedicated APL experts.

Summary/Conclusions: Our experience shows that a streamlined treatment algorithm along with input from experts will result in better outcomes in this most curable hematological malignancy even at academic centers. We believe our experience warrants large scale implementation of our model and is presently approved as an ECOG/ACRIN trial.

PB1654

CLINICAL SIGNIFICANCE OF IMMUNOPHENOTYPIC CHANGES AT THE FIRST RELAPSE IN ADULT ACUTE MYELOID LEUKEMIA PATIENTS

H Shimizu[1,*], T Ishizaki[1], T Mitsui[1], N Hatsumi[2], S Takada[2], T Saitoh[1], A Yokohama[1], T Sakura[2], H Handa[1]
[1]Department of Hematology, Gunma University, [2]Leukemia Research Center, Saiseikai Maebashi Hospital, Maebashi, Gunma, Japan

Background: Immunophenotypic changes (IPC) between diagnosis and the first relapse are found in up to 90% of relapsed acute myeloid leukemia (AML) cases, and are considered as a result of major clone shift and/or clonal evolution of AML cells, just like additional cytogenetic abnormality (ACA) which we reported that was the strongest negative prognostic factor in relapsed AML patients.

Aims: Because the clinical significance of IPC has not been elucidated in adult AML patients, we conducted a large-scale retrospective study to address this unsolved issue.

Methods: Of the 375 adult patients diagnosed with non-APL AML between 1990 and 2010, 108 relapsed patients whose immunophenotypic data both at diagnosis and at the first relapse were available were included in this study. All these patients underwent intensive chemotherapy. AML cells were sorted with usual CD45/SSC gating, and CD7, CD19, CD13, CD33, CD34, HLA-DR, and CD56 were analyzed. IPC was diagnosed when more than 50% increase or decrease of at least one antigen-positive from diagnosis to the first relapse was observed. Overall survival (OS) was defined as the interval from the date of the first relapse to the date of death. Fisher's exact test was used to compare binary variables. OS was estimated with the Kaplan-Meier method and compared using the log-rank test. Multiple logistic regression analysis and the Cox proportional hazard model were used for multivariate analysis of predisposing factors and prognostic factors, respectively. Values of $p < 0.05$ were considered to indicate statistical significance.

Results: Of the 108 patients included in this study, 65 patients were male, and 43 were female. The median age was 56 years (range, 18–78 years). According to the definition described above, 46 patients (43%) experienced IPC at the first relapse. With univariate analysis, t(8;21) was extracted as a statistically significant predisposing factor for IPC at the first relapse (69%). Multivariate analysis revealed t(8;21) and M4/5 as independent predisposing factors. Excluding one patient that directly proceeded to allo-SCT without re-induction chemotherapy, the 107 patients with IPC showed a similar second remission rate when comparing with those without IPC (42.1% *vs* 44.0%, respectively; p=0.848). Additionally, among all 108 patients, there was no significant difference in the 2-year OS rates after the first relapse between patients with and without IPC (34.4% *vs* 29.3%, respectively; p=0.212). Multivariate analysis extracted ACA, high-risk karyotype, fewer than 12 months duration of the first remission, and no allogeneic stem cell transplantation (allo-SCT) after the first relapse, but not IPC. Of the 46 patients with IPC (median age: 55, range; 18–78 years), 18 underwent allo-SCT after the first relapse. The 2-year OS rates after the first relapse were significantly different between patients undergoing allo-SCT after the first relapse and those treated only with chemotherapy (62.7% *vs* 17.9%; p <0.001). With multivariate analysis, undergoing allo-SCT after the first relapse was identified as an independent prognostic factor, in addition to ACA and duration of the first remission.

Summary/Conclusions: These findings suggested that IPC had no prognostic impact in relapsed AML patients, unlike acquisition of ACA. As t(8;21) was extracted as an independent predisposing factor for IPC as well as ACA, susceptibility for clonal evolution might be high in t(8;21) AML patients. Clarification of the biological background of IPC may contribute to the development of novel therapeutic strategies and improved treatment outcomes in adult AML patients.

HIGH FREQUENCY OF OCCULT CENTRAL NERVOUS SYSTEM INVOLVEMENT IN BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM AT DIAGNOSIS: ROLE FOR INTRATHECAL PROPHYLAXIS?

L Martin-Martin[1,*], J Almeida[1], H Pomares[2], E González-Barca[2], P Bravo[3], T Giménez[4], C Heras[5], JA Queizán[6], E Pérez-Ceballos[7], V Martínez[8], N Alonso[9], C Calvo[10], R Álvarez[11], MD Caballero[12], A Orfao[1]
[1]University of Salamanca, Salamanca, [2]Institut Catalá d'Oncologia, Barcelona, [3]University Hospital of Fuenlabrada, Madrid, [4]University Hospital Joan XXIII, Tarragona, [5]Infanta Leonor Hospital, Madrid, [6]Hospital of Segovia, Segovia, [7]University Hospital Morales Meseguer, Murcia, [8]Hospital of León, León, [9]University Hospital of Santiago, Santiago de Compostela, [10]University Hospital Miguel Servet, Zaragoza, [11]General Yagüe Hospital, Burgos, [12]University Hospital of Salamanca, Salamanca, Spain

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare aggressive myeloid neoplasm which shows a high rate of central nervous system (CNS) recurrence (≈30%) and a short overall survival (OS), usually <1 year. Despite this, screening for CNS involvement is not routinely performed at diagnosis and intrathecal (IT) prophylaxis is not regularly administered in BPDCN patients.

Aims: To analyse the incidence of CNS involvement in BPDCN patients at diagnosis and to evaluate the potential benefit of intrathecal prophylaxis administration.

Methods: Forty-one stabilized cerebrospinal fluid (CSF) samples from 13 consecutive BPDCN patients were evaluated for the presence of CNS involvement by next generation flow cytometry immunophenotypic studies. Cases were evaluated at diagnosis (n=10) or at relapse (n=3) and subsequently, after IT therapy. The 10 patients studied at diagnosis received high-risk acute lymphoblastic leukaemia (ALL)-type treatment, including one dose of triple intrathecal therapy (TIT), as CNS prophylaxis at each treatment phase. For CSF-positive cases, additional IT treatment was given until two consecutive CSF-negative samples were obtained. In order to validate the impact of CNS involvement and CNS-directed therapy on patient outcome, an independent validation cohort of 23 BPDCN was retrospectively analysed. Informed consent was obtained from all patients.

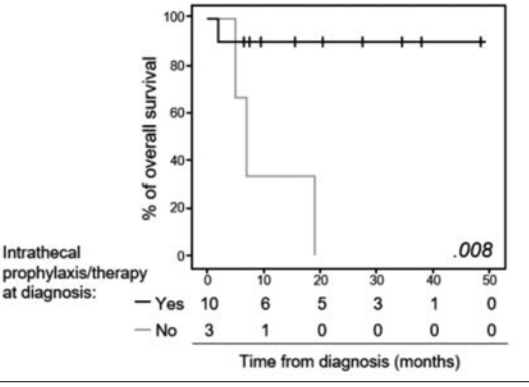

Figure 1. Prognostic impact on OS of intrathecal prophylaxis/therapy administration at diagnosis in BPDCN patients.

Results: Despite none of the patients presented with neurological symptoms at disease staging, occult CNS involvement was detected in 6/10 cases evaluated at diagnosis and 3/3 studied at relapse/progression. Detection of tumour cells in CSF at diagnosis was associated with a ≥20% bone marrow infiltration by tumour cells. BPDCN patients evaluated at diagnosis received IT treatment -either CNS prophylaxis (n=4) or active therapy (n=6)- and all but one remain alive (median follow-up of 20 months). In contrast, all three patients assessed at relapse/progression died (Figure 1). Follow-up CSF samples obtained after TIT showed absence of tumour cells in 6/6 CSF^{+}cases studied at diagnosis, either after one -5/6 cases- or 4 doses of therapy (6/6 cases). The potential benefit of IT treatment administered early at diagnosis on OS and CNS recurrence-free survival (RFS) of BPDCN was further confirmed in a retrospective cohort of another 23 BPDCN patients. Univariate analysis of prognostic factors performed in the whole patient cohort (n=36) showed a favourable impact on CNS-RFS and/or OS for children, patients receiving ALL-type therapy, allogeneic hematopoietic stem cell transplant and IT prophylaxis/treatment at diagnosis, the later variable emerging as the only independent (favourable) prognostic factor for CNS-RFS (p=.02, hazard ratio [HR]=11.2, 95% confidence interval [CI]: 1.4 – 88.8) and OS (p=.001, HR=7.6, 95% CI: 2.2 – 25.9).
Summary/Conclusions: Our findings show that BPDCN patients studied at diagnosis frequently display occult CNS involvement; moreover, these data also indicate that treatment of occult CNS disease might lead to an improved outcome for BPDCN. These results suggest that the CNS could be a persistent blast-cell sanctuary in BPDCN patients with leukemic presentation, due to the limited power of cytostatic drugs to cross the blood-brain barrier into the CSF and brain parenchyma. This reservoir of leukemic cells may also contribute to the high rate of bone marrow/systemic disease recurrence observed in these patients.

PB1656

APPLICABILITY OF THE PATIENT'S "FITNESS" CRITERIA IN ELDERLY AML IN CLINICAL PRACTICE

M Virijevic[1,*], I Djunic[1,2], M Mitrovic[1,2], A Novkovic[3], N Colovic[1,2], A Vidovic[1,2], N Suvajdzic-Vukovic[1,2], D Tomin[1,2]
[1]Clinic for hematology, Clical Center of Serbia, [2]Medical Faculty of Belgrade University, [3]Clinical Hospital Center "Zemun", Belgrade, Serbia

Background: The prognosis for acute myeloid leukemia (AML) patients older than 65 years of age is poor. Besides age, comorbidities, a proper assessment of patient's fitness represents a important step in the therapeutic decision-making process in elderly AML patients. Recent study proposed a set of objective criteria to define pts fit or unfit to conventional intensive chemotherapy (i-CT), non-intensive chemotherapy (ni-CT) or best supportive care (BSC)(Ferrara *et al.,* Leukemia, 2013).
Aims: The aim of this study was to investigate: a) applicability of "fitness" criteria; b) the concordance between "fitness" categorization of pts and the type of treatment they actually received; c) the outcome of pts according to "fitness", to the prognostic stratification of European Leukemianet (ELN) and to the treatment received.
Methods: This single-center study involved 201 adult patients with nonpromyelocytic *de novo* AML aged ≥65 years (median age 70 years, range 65-83 years) diagnosed between January 2009 and December 2015. Pts were categorized according to "fitness" criteria, retrospectively: as fit to i-CT (FIT), unfit to i-CT (UNFIT), or unfit even to ni-CT (FRAIL). According to ELN recommendation, pts were at low-risk (6 pts: 3.2%), intermediate-I (91 pts: 48.4%), intermediate-II (39 pts: 20.7%), or high risk (52 pts: 27.7%). The patients were treated with i-CT 89 (44.5%), 66 pts (33%) ni-CT, such as low-dose cytarabine and 45 pts (22.5%) BSC, including cytoreductive therapies (hydroxyurea) and/or transfusion.
Results: Among 201 pts, 98 (49%) were FIT, 79 (39.5%) were UNFIT, and 23 (11.5%) were FRAIL. Their median age was 67, 73 and 72 years. Median overall survival (OS) of FIT, UNFIT and FRAIL pts was 4, 3 and 1 months, (FIT *vs* others: p<0.0001, UNFIT *vs* FRAIL: p=0.012). Overall concordance between "fitness criteria" and the treatment actually received by pts were 77% in FIT, 84% in UNFIT and 96% in FRAIL pts. Median OS of pts receiving i-CT, ni-CT or BSC was 6, 3 and 3 months in FIT (p=0.001); 2,3,4 months in UNFIT (p<0.047). Median OS in FRAIL pts receiving ni-CT or BSC was 1 *vs* 2 months, (p<0.107). CR rate was 50% in LR, 40% in Int-I, 25.6% in Int-II, 25.5% in HR, (p=0.039). OS rate was 5 in LR/Int-I *vs* 3 months in Int-II/HR pts (p<0.0001). Comprising ELN prognostic stratification with fitness, the use of i-CT obtained a significantly better median OS of 12 months in FIT pts at ELN LR/Int-I compared to 4 months in pts at Int-II/HR (p=0,008).
Summary/Conclusions: This study has shown that a fitness was significantly related to patient's outcome. Applying the fitness criteria could be useful in clinical practice for therapeutic decision-making in elderly AML patients.

PB1657

CHARACTERIZATION AND PROGNOSTIC IMPACT OF FLT3-ITD MUTATIONS IN INTERMEDIATE RISK ACUTE MYELOID LEUKEMIA

M Amorim[*], E Aguiar, P Gomes, M Lopes, M Soares, J Bastos, R Damas, M Gomes, C Marini, F Trigo, J Guimarães
Serviço Hematologia Clínica, Centro Hospitalar São João, Porto, Portugal

Background: The adverse impact of internal tandem duplications (ITDs) of the *FMS-like tyrosine kinase 3 gene (FLT3)* in acute myeloid leukemia (AML) has been related to specific ITD characteristics such as the *FLT3*-ITD/wt allelic ratio (AR), length of mutation and insertion site.
Aims: To evaluate *FLT3*-ITD mutations, as well as *NPM1* mutations, and the prognostic impact of the *FLT3*-ITD AR, size, number and the insertion site of ITDS in AML patients with intermediate-risk karyotype.
Methods: This single-centre study included 148 AML patients with intermediate-risk karyotype according to the European LeukemiaNet criteria. Screening of *FLT3*-ITD and *NPM1* mutations was performed in diagnostic bone marrow samples by PCR with labeled primers and GeneScan-based fragment-length analysis. In *FLT3*-ITD patients, size and number of ITDs were collected and *FLT3*-ITD AR was calculated. The ITD insertion site was determined by direct sequencing of PCR products in a subgroup of patients. For survival analysis, median (Md) value was used to dichotomize continuous variables.
Results: *FLT3*-ITD mutations were found in 29% (43/148) of patients. The majority of patients (36/43) had a single ITD, four patients – two ITDs and one patient - three ITDs. Median ITD size was 42 bp (range, 18 to 108 bp). The *FLT3*-ITD AR varied from 0.02 to 13.48, with a median of 0.57. DNA sequence analysis of 26 single *FLT3*-ITDs patients revealed that the insertion site was localized in juxtamembrane domain (JMD, amino acids 572-609) in 77% patients and in tyrosine kinase I domain (TKD1, amino acids 610-615) in 23% of patients. A trend for worst overall survival (OS) was noted for patients with insertion site in TKD1 (*P*=.09). *FLT3*-ITD was significantly longer in cases with an insertion site in TKD1 compared with ITD insertion in JMD (69 *vs* 36 bp, *P*=.008). Concerning pretreatment patients characteristics, white blood counts (*P*<.001), serum lactate dehydrogenase (*P*=.002), and bone marrow blasts (*P*=.03) differed significantly with increasing AR. Regarding clinical outcome, only patients candidates to intensive chemotherapy were included (N=128). *FLT3*-ITD patients with high mutant level (AR>0.57) had significantly worst OS, median of 7.6 months, than low mutant level and wt patients (25.6 *vs* 23.2 months, *P*=.003). A trend for worst Disease Free Survival (DFS) was noted for patients with AR>0.57 (Md=5.7 months) compared with low ratio (Md=15.6 months) and wt patients (Md=23 months), *P*=.05. When the analysis was restricted to *NPM1*mut AML patients (60/146), *FLT3*-ITD patients with high AR had significantly worst OS (Md=7.6 months) than low mutant level (Md=34.7 months); OS for wt patients was not reached (*P*<.001). *FLT3*-ITD patients with high AR had a DFS significantly lower (5.8 months) than low AR (15.6 months) and wt type patients (37.9 months), *P*=.01. No significant difference was observed between low ratio and wt patients for DFS (*P*=.09), whereas for OS was (*P*=.02). No significant difference was observed in DFS and OS regarding insertion site, size and number of ITDs.
Summary/Conclusions: We confirmed that *FLT3*-ITD allelic ratio was the only ITD characteristic with significant prognostic marker for OS and DFS within our cohort of *FLT3*-ITD intermediate-risk AML patients. Nevertheless we were able to identify a trend for worst OS in patients with ITD insertion site in TKD1. Moreover, we were able to show that, among patients with concomitant *NPM1* mutation, DFS was not significantly different between ITD low burden and wt patients.

POST-TRANSPLANTATION MONITORING OF ACUTE MYELOID LEUKEMIA BY SERIAL MEASUREMENT OF WT1 GENE EXPRESSION LEVELS

Y Gudozhnikov[*], Y Gudozhnikov[*], N Mamayev, I Barkhatov, V Katerina, S Bondarenko, O Slesarchuk, T Gindina, L Zubarovskaya, B Afanasyev
Raisa Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of Saint Petersburg, Saint Petersburg, Russia, St. Petersburg, Russian Federation

Background: The major problem in the treatment of acute myeloid leukemia (AML) with allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the relapse of the underlying disease, poorly responsive to chemotherapy. For its early detection, molecular monitoring methods were introduced, of which serial measurement of Wilms Tumor-1 (WT1) gene expression levels is considered to be the most efficient (Candoni *et al.*, 2011; Zhao *et al.*, 2011; Mamaev *et al.*, 2015).
Aims: We aimed to estimate the molecular monitoring potential for early detection of relapse and the quality of its treatment in AML patients after allo-HSCT.
Methods: A serial measurement of WT1 gene expression levels by quantitative real-time polymerase chain reaction (PCR) was conducted in 65 AML patients in the post-transplant period. The threshold for identification of WT1 gene overexpression was above $250x10^4$ copies of the ABL gene. The clinical and laboratory characteristics of AML patients after allo-HSCT are presented in Table 1.
Results: The maximum initial level of WT1 gene expression ranged from 259 to 56884 copies/10^4 copies of ABL gene (9869 copies on average). Its expression hardly depended on the cytological type of AML or the cytogenetic type of the cells. According to the obtained data on WT gene expression, two groups of patients were formed. The first group consisted of 28 patients with stable normal WT1 gene expression during the post-transplantation period; the second group consisted of 37 patients with impaired WT1 gene expression. In the period after transplantation WT1 gene expression levels were consistent with or

surpassing those of specific markers of minimal residual disease in parallel analysis. Our data showed that in one-third of the patients WT1 overexpression preceded the increase in blast cells in the bone marrow, thus predicting a relapse. For post-transplantation relapse therapy hypomethylating agents in combination with or without donor lymphocyte infusion were applied in 31 patients. The therapy results were not encouraging. In 22 patients mortality was due to the relapse of the underlying disease. Complete remission was only achieved in 6 patients with AML. Three of them later died from GVHD, acute heart failure and sepsis on D+101, D+541 and D+350 after allo-HSCT respectively.

Table 1.

Number of patients	65
AML	
AML *de novo*	51 (0-4, 1-6, 2-12, 3-1, 4-20, 5-6, 6-1, 7-1)
Secondary AML	14
Patient sex, n	
Male	36
Female	29
Age at HSCT (mediana)	26 (4-56)
Cytogenetics, n	
Favorable	0
Intermediate	50
Infavorable	15
Molecular markers, n	
Yes	16
No	49
HSC source, n	
Bone marrow	34
Peripheral blood	31
Conditioning regimen, n	
MA	44
Non-MA	21
Donor type, n	
HLA-id sibling	12
Matched unrelated	41
Haploidentical	12
Number of transplanted CD34+cells (mediana)	$4,78*10^6$ (2,2-11,9)

Summary/Conclusions: Molecular monitoring of acute myeloid leukemia after allo-HSCT using serial measurement of WT1 gene expression levels allows to reveal cytological relapses at an earlier stage and may soon be used to assess the treatment of prognostically adverse post-transplant relapses of AML.

PB1659

EFFICACY AND SAFETY OF ADJUSTED CAG IN COMBINATION WITH DECITABINE IN NEWLY DIAGNOSED OR REFRACTORY/RELAPSED ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

B Chen, C Guan,xShao, P Xu, Y Yang, R Zhou, J Xu, J Li, Y Xu,xXu, M Zhou, T Xie,xWang, J Ouyang*
Hematology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Priming regimen(*e.g.*, CAG) combined with Decitabine is increasingly being used to treat acute myeloid leukemia, especially in elderly patients. However, the particular mode of administration and dosage of Decitabine has not been unified.
Aims: This pilot study was designed to evaluate the efficacy and safety of adjusted CAG (aCAG) regimen combined with Decitabine treatment for elderly patients with newly diagnosed or refractory/relapsed acute myeloid leukemia (AML).
Methods: All patients (age≥60 years, PS≤2) in this study were treated with aCAG-D regimen: Cytarabine (10mg/m^2/12h, days 1-8), Aclarubicin (5-7mg/m^2/day, days 1-8), Granulocyte colony-stimulating factor (300μg/day, days 0-8 or stopped when WBC count >20×10^9/L) and Decitabine(25mg/m^2/day, days 5-8) for two cycles.
Results: The median age of the twelve patients (seven men and five women) able to be evaluated, which contained nine *de novo* patients and three refractory/relapsed patients, was 67 years (range of 60-75 years). A total of nine patients (75.0%) achieved complete remission (CR) after the aCAG-D treatment, including eight of whom achieved CR after only one treatment cycle. In nine newly diagnosed patients eight cases achieved CR (88.9%) and another got partial remission (PR). Meanwhile, three other refractory/relapsed patients achieved CR/ partial remission (PR)/no response (NR) respectively. The overall response rate (ORR) and CR after two treatment cycles were 91.6% and 75.0%, respectively. In patients with CR, the median time was 24.2 days (range of 16-43 days) for granulocyte recovery and 17.9 days (range of 11-37 days) for platelet recovery. After a median follow-up of 11 months (range of 4.5-22 months), one patient died due to secondary infections; one patient showed a relapse; five patients died due to progression of the disease; five patients maintained CR. The median overall survival (OS) of 13 months(range of 4.5-22 months) for those who achieved CR was significantly longer than that of patients who did not achieved CR(5 months). The main adverse events were grade IV bone marrow suppression(12/12 patients) and grade I-IV secondary infection(11/12 patients). There was no treatment-related mortality during remission induction (Figure 1).

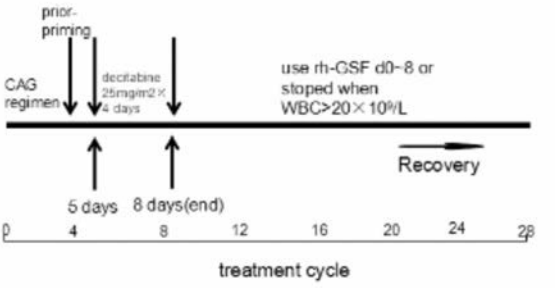

Figure 1.

Summary/Conclusions: The regimen combined aCAG and Decitabine, which designed to use CAG scheme for priming firstly, then add Decitabine to target tumor cells in the S-phase of the cell cycle, demonstrates good efficacy for elderly AML patients, especially in *de novo* patients. Meanwhile, this regimen didn't give rise to serious myelo-suppression and secondary infection. In general, aCAG-D regimen was well tolerated by the elderly patients with *de novo* or relapsed/refractory AML and showed promising clinical efficacy.

PB1660

HOME CARE ADMINISTRATION OF SUBCUTANEOUS AZACITIDINE (AZA) AND DOMICILIARY MANAGEMENT OF FRAIL PATIENTS AFFECTED BY ACUTE MYELOID LEUKEMIA/MYELODYSPLASTIC SYNDROME: A FEASIBILITY STUDY

C Cartoni[1,*], I Carmosino[1], GA Brunetti[1], R Latagliata[1], C Minotti[1], G Palumbo[1], SG Morano[1], S Grammatico[1], G Annechini[1], M Breccia[1], F Mandelli[2], R Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Policlinico Umberto I, [2]AIL, Italian Association against Leukemias, Lymphomas and Myeloma, Roma, Italy

Background: Home delivery of parenteral antineoplastic agents may allow an appropriate treatment for frail or disable patients (pts) with acute myeloid leukemia (AML)/myelodysplastic syndrome (MDS), whose management would be otherwise hampered by clinical barriers or conditioned by hospitalization requirements.
Aims: To describe the feasibility of a home care (HC) program that provides a managing package capable of supporting pts with their parenteral AZA therapy at home.
Methods: A retrospective analysis of the clinical features, use of resources, follow-up and HC satisfaction rating of frail homebound pts affected by AML or intermediate-high risk MDS with a clinical frailty scale score >4, who received at home subcutaneous AZA (75 mg/sqm/7 days).
Results: Overall, 106 pts with AML/MDS received AZA therapy; in 13 out of 31 pts (4%) with AML and in 7 out of 75 pts (9%) with MDS, the drug was administered at home. Reasons for the HC solution were: i) disability in 15 pts (11 AML/4 MDS), ii) early discharge from the ward in 5 (2 AML/3 MDS). The pts' median age was 76 yrs (range 59-83), Karnofsky PS 50% (range 40-60%), Activity Dayly Living score 4 (range 1-6), Charlson co-morbidity index 2 (range 1-3). The mean No. of AZA courses in AML and MDS patients was 3 (1-6) and 2 (1-4), respectively. At home, 409 units of packed red cells were transfused, with a mean No. of 20 units transfused/per patient (range 0-94). During AZA therapy, 13 pts had infections with a mean No. of infections/patient of 1.9 (range 0-7). In 37 out of 38 cases (97%), infections were managed at home with i.v. antibiotic administration. Overall, hospitalization occurred in 8 out of 20 pts (40%). AZA therapy at home was started as a first course in 6 pts, whereas it was continued in 14 pts following courses already delivered at hospital, with a mean No. of 2.8 courses (range 1-4) and 2.1 (range 1-6), administered respectively. In 83% of cases, pts rated HC as more than good. Eighteen pts discontinued HC AZA: 15 due to disease progression and 3 because of an infection-related hospitalization. The median length of HC after AZA interruption was 111 days (1-343). Two pts are still on treatment with AZA, 18 pts have died: 11 at home or at a hospice, 7 while hospitalized. The pts median survival time from the start of AZA was 143.2 days (range 5-284) for AML pts and 229.7 days (range 49-411) for MDS pts.
Summary/Conclusions: Home administration of AZA proved feasible through the availability of a domiciliary service that guaranteed a high number of transfusions, blood sampling and i.v. antimicrobial therapy, combined with an approach of palliative care. Pts with poor prognosis AML/MDS had the opportunity of undergoing a specific epigenetic treatment at home, while living a con-

siderable time interval outside the hospital with a high satisfaction level for HC. Inappropriate hospitalizations were reduced, with an overall median time at home of nearly 5 months for AML and 7.6 months for MDS pts. Death during the hospice care occurred in 61% of cases.

PB1661

ELANE MUTATION C233TER PREDISPOSES PATIENTS WITH SEVERE CONGENITAL NEUTROPENIA TO ACUTE MYELOID LEUKEMIA

D Dale[1,*], AA Bolyard[1], M Kelley[1], V Makaryan[1], L Boxer[2], MA Bonilla[3], M Cavieres[4], P Tan[5], F Firkin[6]
[1]Medicine, UNIVERSITY OF WASHINGTON, Seattle, WA, [2]Pediatric Hematology/Oncology, University of Michigan, Ann Arbor, MI, [3]Pediatric Hematology/Oncology, St. Joseph's Childrens Hospital, Paterson, NJ, United States, [4]Hematology, Hospital Luis Calvo Mackenna, Santiago, Chile, [5]Hematology, Hollywood Medical Centre, Nedlands, [6]Medicine, St. Vincent's Hospital, Fitzroy, Australia

Background: Mutations in *ELANE* are the most frequent cause for cyclic and congenital neutropenia. In a genotype-phenotype study, we previously reported that mutations G214R which replaces glycine (nonpolar, neutral) with the much larger arginine (polar, strongly basic) amino acid, and C151Y which disrupts the second disulfide bond of the protein are associated with severe outcomes. (Makaryan *et al.,* Curr Opin Hematol 2015;22:3-11) Termination mutations were associated with leukemic transformation, but the number of these patients was relatively small.
Aims: To investigate the natural history and long-term consequences of mutations in *ELANE*.
Methods: The Severe Chronic Neutropenia International Registry (SCNIR) has enrolled 3 patients with the termination mutation C223ter. All three have developed acute myeloid leukemia.
Results: Patient #1 is a 38 year old female residing in Michigan USA. She was diagnosed with SCN in 1989 at age 11. She started G-CSF in 1989, 11.5 mcg/kg/day. Because of a poor response, G-CSF was gradually increased to 24 mcg/kg/day. After 15 years, she was switched to peg G-CSF, 3 mg every 10 days for the next 11 years. In February 2015 at age 37, she had blasts in the blood and marrow revealing 65.8% blasts. Ten months ago, she underwent HSCT, GvHD has resolved, platelets are holding at 59K without transfusions and she receives darbepoetin alfa to maintain hemoglobin. Patient #2 is a 25 year old female residing in Western Australia. She was diagnosed with SCN in 1991 at age 4.5 months. She was started at age 5 months on G-CSF at 5 mcg/kg/day and the dose increased to 20 mcg/kg/day because of a poor response. After 12 years, she was switched to peg G-CSF 6 mg q 14 days after 12 years because of her poor neutrophil response. She received Neulasta 6 mg every 14 days for 11 years. She became pregnant in May 2015 having had 3 previous pregnancies (2 terminations and one live birth). In the second month of her fourth pregnancy, she appeared to be losing her response to peg G-CSF. About two months later, she was found to have hypertrophied gums with infiltration of immature myeloid cells, consistent with the abnormal cells also found in her bone marrow. She was maintained on G-CSF, prednisone, and blood products because without the growth factor she was severely ill. With this approach, she delivered a healthy male infant at 30 weeks via C-section. She had a HSCT five weeks after delivery and is now 2 months post-transplant, in serious condition with the donor marrow beginning to respond. Patient # 3 was a 6 year old female who resided in Chile. She was diagnosed with SCN in 1997 at 10 months and started G-CSF at 15 mcg/kg/day. There was a poor response requiring an increase of G-CSF to 37.5 mcg/kg/day. After 3 years on G-CSF, she developed AML presenting with increased blasts, anemia and thrombocytopenia. She received chemotherapy; HSCT was not available. She died from complications of AML in 2002. Mutations in G214R, C152Y and C223ter have no obvious common features in terms of effects on the active site, glycosylation sites, or disulfide bonds of the enzyme. These mutations and others associated with evolution to AML are often relatively resistant to treatment with G-CSF, but the biological basis for resistance to G-CSF as well as the risk of evolution to AML is not known.
Summary/Conclusions: Understanding the biological basis for the diversity of genotype-phenotype relationships for mutations in *ELANE*, particularly how some mutations predispose to a high risk of AML, is critical for improving the diagnosis and treatment of this form of hereditary neutropenia.

PB1662

ACUTE MYELOID LEUKEMIA IN THE ELDERLY TREATED AGGRESSIVELY IN A NON-TRANSPLANT CENTER: A SINGLE CENTER OF EXPERIENCE

D Mota[*], J Carda, P César, M Pereira, E Cortesão, A Crisóstomo, L Ribeiro
Clinical Haematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Most cases of Acute Myeloid Leukemia (AML) occur in older patients in whom, considering biological variation associated with chemoresistance and comorbidities, defines a challenging population. While overall survival (OS) in patients with AML decreases with age, most studies performed in elderly patients showed Complete Remission (CR) rates between 50 and 60% if they are treated aggressively.
Aims: This study aims to characterize an elderly population with a diagnosis of AML (considering age subgroups, cytogenetic risk groups, type of intended treatment and use of consolidation) and to analyze the impact of different treatment approaches on complete response (CR) and their overall survival (OS).
Methods: We analysed 157 patients aged over 60 years with the diagnosis of AML (excluding acute promyelocytic leukemia, according the 2008 World Health Organization classification) treated agressively. Retrospective analysis of clinical and laboratory data, between 1st January 2005 and 31st December 2015.
Results: Of all patients, 55% were male. The median age at diagnosis was 67 years and 68% of patients were over 65. In this population 49% (N=77) of AML were secondary to another haematological disorder (40%, N=63), or as consequence of prior chemotherapy for another malignancy (9%, N=14). According to the French-British-American classification, the most frequent subtypes were M4 (23%), followed by the M2 and M1 subtypes (22% each) and M5 (19%). We obtained conventional karyotype cytogenetic results in 64% of our patients, of whom 4% were of low risk, 45% of intermediate risk and 15% of high risk. We choose an aggressive treatment strategy in these 157 patients, pre-selected according to age, performance-status and comorbidities, attaining a CR rate of 52%. The main induction regimens were MIC/MICE (N=113), ICE/3+7 (N=30), ARA-C (N=12). OS was respectively 43%, 49% and 8% at 10 months, with significant difference between MIC/MICE and ICE/3+7 when compared with ARA-C regimen ($p<0.05$). During hematological recovery, 62% presented febrile neutropenia, 10% presented mucositis (grade ≥3) and 8% presented palmar-plantar rash with cytarabine. The median days to hematological recovery was 28. The use of consolidation therapy after CR in this age group didn't improve overall survival (62 *vs* 53% at 12 months, p=N.S.). OS was 15% at 12 months and 10% at 24 months with a statistically significant difference in survival between the 60-65, and over 65 age groups at 12 months (20% *vs* 12%; $p<0.05$). Progression of the haematological malignancy was the primary cause of death in 43% of patients and infection in 22%; 6% died from bleeding complications.
Summary/Conclusions: Although we concluded that a significant proportion of patients treated aggressively obtain CR, in our series the use of consolidation didn't improve OS. However aggressive treatment strategies may induce several complications so treatment decisions should be individualized to each patient, according to risk factors, such as age and cytogenetics, performance status and co-morbidities. The recommendation is to whenever possible enroll the patient in a clinical trial.

PB1663

ACUTE PROMYELOCYTIC LEUKEMIA: A CONTEMPORARY SINGLE-INSTITUTION EXPERIENCE

M Hessenauer[1,*], N Farhadfar[2], N Gangat[2]
[1]Internal Medicine, [2]Hematology, Mayo Clinic, Rochester, United States

Background: Acute promyelocytic leukemia (APL) is a rare hematologic malignancy, with an incidence of 600-800 cases per year in the United States. At our institution, fewer than 10 patients with a new diagnosis of acute promyelocytic leukemia are treated each year.
Aims: We aim to describe our experience with patients treated for acute promyelocytic leukemia at our institution over the last 15 years.
Methods: After Mayo Clinic institutional review board approval, we searched our institutional electronic database for those 18 years and older with a new diagnosis of acute promyelocytic leukemia between January 1, 2000 and December 31, 2015. We meticulously gathered all patient information through electronic chart review.
Results: Out of a total of 89 patients reviewed, 59 patients had complete data available. The median age at diagnosis was 61 years (range: 18-80 years). 34 patients were male, and 25 were female. 9 patients (15.3%) presented with high-risk disease, 27 (45.8%) had intermediate-risk disease, and 23 (39.0%) had low-risk disease. 5 patients (8.5%) had received chemotherapy for prior malignancies. 50 patients (84.7%) received ATRA with anthracycline-based chemotherapy, and 9 received ATRA and arsenic induction. 58 of 59 (98.3%) patients achieved complete remission after induction chemotherapy. One patient died during induction due to diffuse alveolar hemorrhage. After a median follow-up of 51 months (range: 1-180 months), 53 of 59 (89.8%) patients remain alive. 2 patients died of causes related to APL, 1 of a non-APL-related cause, and 3 died of unknown causes. Among 9 patients treated with ATRA and arsenic induction, all achieved complete remission and were alive at the time of last follow-up. 28 patients (47.5%) presented with disseminated intravascular coagulation (DIC) at diagnosis. Out of 28 patients with DIC, 9 (32.1%) experienced hemorrhage, and 19 (67.9%) experienced thrombotic events. 23 of 59 patients (40.0%) developed differentiation syndrome; 3 of 9 patients (33.3%) treated with arsenic and 20 of 50 patients (40.0%) treated with chemotherapy. 6 of the 9 patients (66.7%) treated with ATRA-arsenic had grade 3 or 4 neutropenia for 15 days or more during induction therapy. 46 of 50 patients (92.0%) treated with ATRA-chemotherapy had grade 3 or 4 neutropenia during induction. Infection was documented during induction therapy in 5 of 9 patients (55.6%) treated with arsenic and 26 of 50 patients (52.0%) receiving chemotherapy. 4 of the 6 patients (66.7%) who developed hepatic toxicity were receiving arsenic. Overall,

7 of 59 patients (11.9%) have relapsed, and 10 of 59 patients (16.9%) developed a secondary malignancy in our cohort.
Summary/Conclusions: Herein, we summarize our single-institution experience with acute promyelocytic leukemia treated over the last fifteen years. A comparison of the adverse events and efficacy of ATRA and chemotherapy *versus* ATRA and arsenic needs further exploration.

PB1664

SUCCESSFUL BL-8040 TREATMENT FOR RELAPSED AML PATIENTS SINGLE CENTER EXPERIENCE

J Rowe*, Y Pereg
Hematology, Rambam Medical Center, Jerusalem, Israel

Background: BL-8040 is a high-affinity antagonist of CXCR4, a chemokine receptor that is directly involved in tumor progression, angiogenesis, metastasis, and cell survival. BL-8040 binds to CXCR4 on leukemic cells, inhibiting its function, thus releasing them from the protective microenvironment of the bone marrow (BM) resulting in amplification of their sensitivity to chemotherapy. BL-8040 also has a direct anti-tumor effect by selectively inducing apoptosis of malignant cells.
Aims: To assess the effectiveness of BL-8040 in combination with cytarabine (Ara-C) in three patients with relapsed AML who were treated under compassionate protocol.
Methods: Treatment of relapsed AML patients with SC BL-8040 1.25mg/kg on days 1-7 together with Ara-C 1.5 gr/m^2 from day 3-7.
Results: Case 1: A 75 year old male with relapsed AML, 7 years after initial diagnosis. At the time of diagnosis he had normal karyotype and treated successfully with 7+3 followed by consolidation with Ara-C. At time of relapse he presented with dysplastic changes and additional chromosome 13 karyotype. At relapse the patient was treated with Ara-C and BL-8040. On day 35 his BM was in complete remission (CR) with less than 5% blasts. Maintenance therapy with azacitidine began three months later. Nine months post induction the patient is still in CR. Case 2: A 23 year old male with a history of Hodgkin lymphoma at age 17. At the age of 20 he was diagnosed with AML with the t(8;21) chromosomal abnormality. He was treated with 7+3 followed by consolidation with Ara-C. A year later he relapsed and received an allogeneic transplant (allo-HSCT). Two years post-transplant the patient relapsed with intra and extramedullary disease represented by a large chest wall mass. He was treated with BL-8040 and Ara-C as a salvage treatment. There was some resolution of the extramedullary mass on the first 2 days of monotherapy treatment with BL-8040 (before the onset of Ara-C). The patient experienced severe injection site pain and generalized muscle pain which required narcotics for analgesia. The patient entered CR on day 34 and underwent a second allo-HSCT. Almost a year and half post BL-8040 salvage treatment the patient is still in CR. Case 3: A 66 years old female with relapsed AML, 14 months after first diagnosis. At the time of diagnosis she presented with a complex karyotype. She received induction treatment followed by allo-HSCT but relapsed 3 months later. She was then treated with Ara-C and donor lymphocyte infusion (DLI) reaching CR; 7 months later she relapsed again. A second salvage treatment with BL-8040 and Ara-C was provided. During treatment she suffered from severe muscle pain (chest and legs). The patient didn't reach response showing 52% myeloblasts on day 24 BM examination. Two days later the patient died. The direct cause of her death is likely to be disease related.
Summary/Conclusions: Three patients were treated with BL-8040 and Ara-C as salvage therapy for relapsed AML. The safety profile was similar and the adverse events were well managed. These were characterized by injection site reactions and severe muscle pain. BL-8040 in combination with Ara-C can be administered safely to relapsed, heavily pretreated, AML patients. BL-8040 in combination with Ara-C has been shown to be an effective regimen for bone marrow as well as extramedullary AML. BL-8040 in combination with Ara-C should be considered as a bridging therapy for allo-HSCT.

PB1665

IMPACT OF GRANULOCYTE COLONY STIMULATING FACTOR FOR OUTCOMES OF NON-M3 AML PATIENTS TREATED WITH ANTHRACYCLINE-BASED INDUCTION (7+3 REGIMEN) CHEMOTHERAPIES

KW Kang[1,*], DS Kim[1], SR Lee[1], HJ Sung [1], SJ Kim[2], CW Choi[1], BS Kim[1], Y Park[1]
[1]Department of Internal Medicine, Korea University School of Medicine, [2]Department of Internal Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Currently most guidelines recommend primary granulocyte colony-stimulating factor (G-CSF) prophylaxis in patients with solid cancer who have an approximately 20% or higher risk for febrile neutropenia. However, these recommendations are not as clear for patients with acute myelogenous leukemia (AML).
Aims: To identify the role of G-CSF in induction treatment in patients with newly diagnosed AML, we analyzed the efficacies of administration based on clinical situations such as the development of neutropenia or fever, and investigated the impact of G-CSF exposure on the anti-leukemic efficacies of induction chemotherapy.
Methods: A total of 285 patients enrolled in the Korea University AML registry from September 2001 to March 2015 were analyzed and classified based on G-CSF administration: (1) no G-CSF exposure during induction (no G-CSF group), (2) administration initiated immediately after the development of neutropenia (absolute neutrophil counts, <1000/μL) but before the development of febrile neutropenia (preemptive group), and (3) administration initiated after the development of febrile neutropenia (therapeutic group).
Results: G-CSF administration resulted in faster ANC recovery compared to that in the no G-CSF group (p <0.001), but did not significantly affect the duration of neutropenia or chemotherapy-induced febrile neutropenia (CIFN) in both the preemptive and therapeutic group. In treatment-related mortality (TRM) multivariate analysis, the therapeutic group had higher TRM than the preemptive group (OR 5.921, 95% confidence interval 1.316–26.634, p=0.020), with no significant difference between the preemptive and no G-CSF groups (OR 2.454, 95% CI 0.482-12.495, p=0.280). Only quinolone prophylaxis was shown to be effective in reducing the incidence of CIFN (p=0.001). There were no significant differences in remission rate, cumulative incidence of relapse, overall survival, and relapse-free survival among the groups (Table 1).

Table 1. Univariate and multivariate analysis for risk factors associated with treatment-related mortality.

Factors	Treatment-related mortality			
	Univariate	Multivariate		
	P value	OR	95% CI	P value
Group(Ref. Pre-emptive G-CSF)	**0.040**			**0.022**
Pre-emptive G-CSF vs. No G-CSF	0.076	2.454	0.482 – 12.495	0.280
Pre-emptive G-CSF vs. Therapeutic G-CSF	**0.014**	5.921	1.316 – 26.634	**0.020**
Age< 60 (Ref.) vs. Age≥ 60	**<0.001**	2.366	0.979 – 5.716	0.056
Sex	0.139			
ECOG 0-1(Ref.) vs. ECOG≥ 2	**0.001**	3.392	1.239 – 9.288	**0.017**
CCI 0-1(Ref.) vs. CCI ≥ 2	**0.001**	2.813	1.093 – 7.237	**0.032**
Cytogenetic risk	0.558			
Type of anthracyclin	0.481			
Prophylactic quinolone	0.836			

Abbreviations: G-CSF, Granulocyte-stimulating factor; CCI, Charlson comorbidity index; HR, Hazard ratio; CI, Confidence interval; NA, Not applicable

Summary/Conclusions: G-CSF administration during induction chemotherapy in non-M3 AML patients can accelerate neutrophil recovery without affecting treatment outcomes. It is best administered at least before the development of febrile neutropenia in order to prevent TRM. Quinolone prophylaxis might be effective in reducing CIFN.

PB1666

ADULT BIPHENOTYPIC ACUTE LEUKEMIA: THE EGYPTIAN NATIONAL CANCER INSTITUTE EXPERIENCE

A Darwish[1,*], M Samra[1], N Alsharkawy[2], O Gaber[1]
[1]Medical Oncology, [2]Clinical Pathology, National Cancer Institute, Cairo, Egypt

Background: Biphenotypic acute leukemia is a rare form of leukemia. Knowledge concerning the clinical and biological presentation, as well as the outcome of treatment, in adult is limited
Aims: Our objective was to analyze the biological features and outcome of patients diagnosed with BAL in our institute.
Methods: This is a retrospective analysis of the clinical, biological, and immunophenotypic features of 30 biphenotypic acute leukemias (BALs), fulfilling modified EGIL's score, and treated in the medical oncology department at the National Cancer Institute (NCI-Cairo) between 2005& 2010. Myeloid and T-lineage features were demonstrated by cytoplasmic myeloperoxidase and CD3; B-lineage features were demonstrated by CD19, CD22 and CD10.

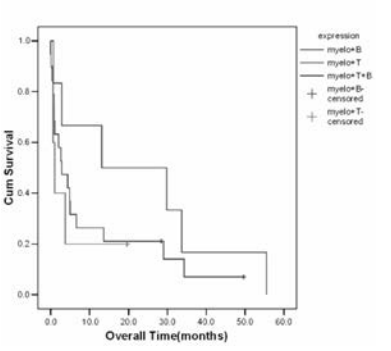

Figure 1.

Results: There were 18 men and 12 women; all were adult with a male to female ratio 3:2. The median age of the patients at diagnosis was 40 years (range, 19-62).The median white blood cell (WBC) count, hemoglobin concentration and platelet count were 31x10^3/dl (range, 2-275), 7g/dl (range, 4.1-11) and 53x10^3/dl (range, 14-539), respectively. Morphological assessment showed myeloid features in 14, and undifferentiated in sixteen patients. According to the EGIL classification, there were 20 cases of myeloid+B-lymphoid leukemia (66.7%), 5 cases of myeloid+T-lymphoid (16.7%), and 5 cases of trilineage myeloid+B+T-lymphoid leukemia (16.7%). The most common phenotypic feature was the expression of CD45 antigen which was positive in 27 (93.1%) patients. Cytogenetic results were available for only 4 patients. Eight patients received ALL-tailored therapy, 14 received AML-tailored therapy while 8 were either unfit for chemotherapy or died before induction treatment. Patients that received ALL-tailored chemotherapy had a better CR achievement rate (87.5%) over the patients that received AML-tailored chemotherapy (35.7%). The 6, 12 & 24 months overall survival (OS) were 33.3%, 30.0% & 26.6% respectively. Although patients with trilineage phenotype had better OS at 6, 12 & 24 months this was not of statistical significance (Figure 1).
Summary/Conclusions: Biphenotypic acute leukemia is a poor-risk disease. Despite the progress in the treatment of acute leukemia there are no uniform criteria about whether to treat BAL patients as ALL or AML. Further prospective collaborative studies are needed to investigate proper treatment protocols for this entity.

PB1667

SALVAGE REGIMENT WITH FLAT FOR REFRACTORY AND RELAPSED AML: EXPERIENCE A SINGLE CENTRE

A Salamanca*, D Madrigal, R Saldaña, E Martin, S Garzon
Haematology, Hospital Jerez de la Frontera. Área Sanitaria Norte de Cádiz., Cadiz, Spain

Background: Outcomes in patients with acute myeloid leukemia (AML) who are primary refractory or early relapsed are dismal, and there is not one standard therapy for all patients. Allogeneic hematopoietic stem cells transplantation (HSCT) is the treatment with the highest probability of cure when is possible to reduce the leukemia burden with salvage chemotherapy regimen prior to transplantation.
Aims: In this study, we report our experience of salvage chemotherapy regimen with fludarabine 30 mg/m^2, cytarabine 2 g/m^2 and topotecan 1.5 mg/m^2 on days 1 to 4 (FLAT), for refractory or relapsed AML treated in our institution.
Methods: Analytical, observational and retrospective study. We included all patients treated with FLAT from 2008 to 2016 in our center. We studied disease status prior to salvage therapy (refractoriness to one or two previous regimens *Vs* early or late relapse), cytogenetic risk profile (favorable, intermediate or adverse), response (complete response [CR], partial response [PR] or refractory disease [RD]) and survival (overall survival [OS]).
Results: Twenty-four patients were treated with FLAT in the last eight years in our center. Median age at time of treatment was 55 years old (range 39-69). AML was the underlying condition in all individuals. Cytogenetic risk profile at diagnosis (ELN) was favorable in 2 patients, intermediate in 10 and adverse in 9 of them. It was not determinate in 3 patients. Ten patients received FLAT salvage course for primary refractory AML, 1 for secondary refractory AML, 11 for relapsed AML after chemotherapy and 2 for relapsed AML after stem cell transplant (allo-SCT). Median OS was 16 months (range 1-86), with median follow up of 41 months. OS in primary refractory AML was 20 months (1-84) and 14 months (3-86) in relapsed AML. RC rate after FLAT was 45.8% (11 patients), higher in refractory disease (7 out of 11). Treatment related mortality was 16%. After reaching CR or PR, 7 patients underwent allogeneic transplantation. In this group, OS was 23 months (2-84). Four patients did not undergo transplantation despite reaching CR because of infection complications or early relapse while unrelated donor search was activated. Four patients underwent a sequential approach with a third salvage chemotherapy and allo-SCT despite refractoriness to FLAT; two of them could reach CR with this approach.
Summary/Conclusions: FLAT is an efficient salvage regimen for refractory and relapse AML. An acceptable CR rate allowed patients to continue with allogeneic-SCT and a longer overall survival. This combination has an acceptable safety profile, even for the patients who were treated after transplant.

PB1668

KINETICS OF WT1 OVER-EXPRESSION IN ACUTE MYELOID LEUKEMIA PATIENTS WHO RECEIVED STANDARD CHEMOTHERAPY OR UNDERWENT ALLOGENEIC STEM CELL TRANSPLANTATION

N Eisa[1,2,*], S Shamaa[1,2], M Khalaf[3], E Azmy[1,2], A Agm[4], M Samra[5], Z Emarah[2,6]
[1]Clinical Hematology Department, Oncology Center, Mansoura University, [2]Internal Medicine, Faculty of Medicine, Mansoura University, Mansoura, [3]Clinical Hematology Department, [4]Clinical Pathology Department, Hematology and Oncology Hospital, Maadi Armed Forces Medical Compound, [5]Medical Oncology Department, National Cancer Institute, Cairo University, Cairo, [6]Medical Oncology Department, Oncology Center, Mansoura University, Mansoura, Egypt

Background: Wilms' tumor 1 (WT1) gene expression is well-known pan leukemia marker which overexpressed in more than 90% of newly diagnosed acute myeloid leukemia patients. However, the clinical utility of WT1 monitoring has been somewhat controversial.
Aims: The aim of this study is to compare WT1 transcript level kinetic changes in patients with AML either received standard chemotherapy (Arm A) or underwent allogeneic stem cell transplantation (Arm B).
Methods: Peripheral blood samples collected from 26 patients diagnosed with AML at initial diagnosis. Further samples collected from 9 patient who received standard chemotherapy (Arm A) at post-induction and post-intensification time points. Further samples collected from 8 patients who underwent allogeneic stem cell transplantation (Arm B) before conditioning, at day 30 and at day 100. The remaining 9 patients were not included in the analysis due to either early death or a negative WT1 at diagnosis. Quantitative RT-PCR detection of WT1 gene transcript level using Ipsogen WT1 profile Quant was performed on peripheral blood samples in both arms at the different time points mentioned before.
Results: We observed significant difference in the median values of WT1 transcript level at the 3 time points for patients with Arm A (P value 0.011) while for allogeneic arm B the median values were nearly the same at the 3 time points (P value 0.687). We found that WT1 level post-induction correlates with morphologic response (P value: 0.04). The median values for WT1 level were more for relapsed rather than non-relapsed cases in both arms at the 3 time points, but this difference was statistically insignificant except at D100 in arm B (P-value 0.046) and about to be significant at post-intensification (P value was 0.064) in arm A (Figure 1).

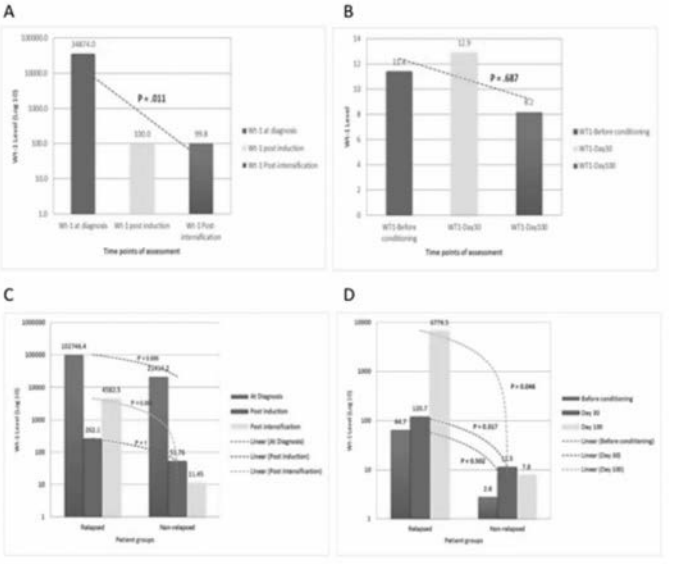

Figure 1. WT1 kinetics. A: WT1 kinetics for arm A. B: WT1 kinetics for arm B. C: WT1 transcript level between relapsed and non-relapsed case in arm A. D: WT1 transcript level between relapsed and non-relapsed case in arm B.

Summary/Conclusions: We identified a positive correlation between WT1 transcript level and morphological response. Therefore, elevation or rising WT1 transcript levels after intensifications or beyond day 100 post-transplant may be a marker of impending relapse that if validated in larger studies, may warrant either close observation or pre-emptive intervention. Although our results are poorly reaching the level of significance, probably due to the small sample size, WT1 transcript level showed dynamic changes with treatment and may be a marker for relapse. We recommend further studies with larger number of patients in different centers to confirm these results.

PB1669

STANDARD INDUCTION CHEMOTHERAPY IN CHILDREN WITH MLL-AF9 ACUTE MYELOID LEUKEMIA AND SEVERE DISSEMINATED INTRAVASCULAR COAGULATION IS ASSOCIATED WITH HIGH MORTALITY

A Colita[1,2,*], M Asan[3], A Gheorghe[3], C Zaharia[3], L Radu[2], M Safta[2], M Dragomir[3], C Jardan[2], A Colita[2]
[1]Pediatric Hematology & BMT, Fundeni Clinical Institue, [2]Carol Davila University of Medicine, [3]Fundeni Clinical Institue, Bucharest, Romania

Background: MLL-AF9 AML is a rare subgroup of unfavorable prognostic leukemia secondary to t(9;11)(p22;q23) with particular clinical aspects, mainly severe coagulopathy.
Aims: To analyze the clinical, hematological and coagulation parameters at diagnosis and correlation with the outcome after chemotherapy initiation in children with MLL-AF9 leukemia treated according to a BFM 2004 AML protocol in a single center.

Methods: Six consecutive patients with MLL-AF9 AML were identified by fluorescence *in situ* hybridization and Nested PCR in our center in the last 10 years. The diagnostic was completed by bone marrow morphology and immunophenotyping, standard kariotype and coagulation tests (AP, aPTT, INR, D-Dimers, PDF, Fbg, PC, PS, AT III). Patients were treated according to the BFM 2004 AML protocol. All patients received fresh frozen plasma. Informed consent has been obtained from parents.
Results: Between 2006-2015 we treated 74 patients with AML, 6 (8,1%) being diagnosed with MLL-AF9 AML, fusion type 6A in all cases. The kariotype has been performed in all patients, but we obtained interpretable result only in 2 patients, all of them without abnormal cytogenetics. The patient characteristics are shown in Table 1. All patients had laboratory signs of variable degrees of DIC at diagnosis documented by prolonged coagulation times, presence of fibrin degradation products (FDP) and elevated D-Dimer levels. Three patients developed during the first 2 days after chemotherapy initiation a respiratory distress syndrome and seizures associated with cerebral hemorrhage with fatal outcome in the next 2-5 days. The initial hemostasis/coagulation analysis in these patients showed platelet counts $30x10^9$/L, $70x10^9$/L, respectively $165x10^9$/L, but with high D-Dimer levels 1670, 2430, respectively >60.000 µg/L (upper detection limit for our laboratory). The other 3 patients completed the induction chemotherapy without special complications. The BM aspirate and MLL-AF9 monitoring confirmed the complete remission (CR). The hemostasis/coagulation analysis in these patients showed similar platelet counts (60 $x10^9$/L, 54 $x10^9$/L, 30 $x10^9$/L), but associated with lower levels of D-Dimers (1070, 960, 1020µg/L).

Table 1.

Patient characteristics	No. 6 cases
Sex ratio M/F	5/1
Age median	2y 6 mo
FAB type	M1:1/M5:3/M7:2
Hg median	7.6 g/dl
PLT median	$62x10^9$/L
WBC median	$19.13x10^9$/L
Blasts median	$13.88x10^9$/L
Hepatomegaly	4/6
Splenomegaly	3/6

Summary/Conclusions: MLL-AF9 is a poor prognostic AML subtype, associated with a higher mortality at induction treatment. Half of the patients in our cohort had a severe DIC associated at onset, with high D-Dimers levels (more than twice upper normal limit) that worsened after chemotherapy initiation leading to respiratory failure and cerebral hemorrhage in absence of severe thrombocytopenia. For our cohort the presence of significant coagulopathy at onset is associated with poor prognosis, suggesting a clinical evolution of this syndrome that is similar with AML M3 outcome in the absence of all-trans retinoic acid associated chemotherapy.

PB1670

CD34 POSITIVE CELL COUNT DETECTED BY MULTI-COLOR FLOW CYTOMETRY (MFC) AFTER FIRST INDUCTION THERAPY IN ACUTE MYELOID LEUKEMIA (AML) EFFECTS ON SURVIVAL AND RELAPSE

E Atilla*, P Ataca Atilla, S Civriz Bozdag, M Kurt Yuksel, P Topcuoglu, O Arslan, M Beksac, M Ozcan, O Ilhan, H Akan, K Dalva, G Gurman, S Kocak Toprak
Ankara University School of Medicine Department of Hematology, Ankara, Turkey

Background: Minimal residual disease (MRD) is defined as detection of low levels of leukemic cells and had been shown to correlate with an increased risk of relapse and shortened survival in Acute Lymphoblastic Leukemia. However there is a controversy in definition of MRD in AML.
Aims: Our aim is to evaluate the effects of CD34 positive cell count of >1.0% after first induction therapy on survival and relapse in AML in our cohort.
Methods: CD34 positive cell count of >1.0% was measured in newly diagnosed 148 AML (excluding acute promyelocytic leukemia) patients by multi-color flow-cytometry (MFC) based detection after first induction regimen in between 2007 and 2015. Chi-square test and kaplan-meier curves were used for statistical analysis. P<0.05 was considered statistically significant.
Results: The median age was 47 (range, 21-82). 78 (52%) of patients were male. AML risk stratification at diagnosis were as follows; low risk (21%), standart risk (38%), high risk (22%). For the induction regimen, 11 geriatric patients received azacytidine and 137 patients got standart 3+7 (ARA-C/daunorubicin). 23.5% of patients (35/148) were not in remission and received reinduction therapy. CD34 positive cell count>1.0% was detected in 49.7% patients (74/148) after induction. High dose ARA-C consolidation treatments (mean 2 cycles, range 1-6) were administered and 87 patients (58%) underwent allogeneic-stem cell transplantation due to their risk status. The relapse rate of patients with CD34 positive cell count >1.0% was significantly higher than CD34 positive cell count lower than 1.0% (58% *vs* 32%, P=0.01). RFS rate at 12 months was higher in CD34 positive cell count lower than 1.0% (72% *vs* 41%, P=0.1). 2 year OS significantly improved in patients with in CD34 positive cell count lower than 1.0% (83% *vs* 66%, P=0.049) (Figure 1).

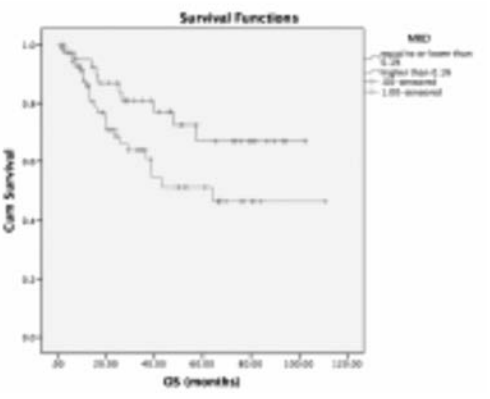

Figure 1.

Summary/Conclusions: CD34 positive cell count >1.0% detected by MFC after first induction is related to higher risk of relapse and decreaced OS. Despite techniques for detection of MRD in AML evolve rapidly, MFC remains a useful tool.

PB1671

ACUTE MYELOID LEUKEMIA WITH MYELODISPLASIA-RELATED CHANGES: A REVIEW OF 58 CASES AT A SINGLE CENTRE

S Martin-Batista*, B Soria, BJ González-González, T Martín-Santos, A Martín-Martín, C De Bonis, S Afonso, B Esquivel, L Gutiérrez-Murillo, MJ Rodríguez-Salazar, S Iraheta, S Lakhwani, P Machado, MT Hernández-García, JM Raya
Hospital Universitario de Canarias, La Laguna, Spain

Background: The WHO-defined category (2008) of acute myeloid leukemia with myelodysplasia-related changes (AML-MRC) includes cases with 20% or more blasts in the peripheral blood or BM and (1) dysplastic morphology in 50% or more of the cells in two or more myeloid lineages and/or (2) a preceding MDS or MDS/MPN phase and/or (3) specific myelodysplasia-related genetic abnormalities. In consecuense, this is a heterogeneous disorder defined by morphologic, genetic, or clinical features.
Aims: Our objective was to analyze the main characteristics of patients with a diagnosis of AML-MRC who were treated and followed in our institution.
Methods: We have retrospectively studied all the cases of AML-MRC that were seen at our hospital in the last fiveteen years. Main recorded data included age, sex, a previous diagnosis of myelodysplastic síndrome (MDS), peripheral blood cell counts, serum lactate-dehydrogenase level, bone marrow aspirate features, cytogenetics, immunophenotype by flow cytometry, therapeutic approach, response to treatment, overall survival and mortality. Statistical analysis was performed using the SPSS 17.0 version.
Results: From 2001 to 2015, 58 patients were diagnosed with AML-MRC at our hospital. Mean age at diagnosis was 72 years (median 75, range 23-90) and 60,3% were men. A previous diagnosis of MDS was noted in 43 patients (74%), with the following distribution: refractory cytopenia with multilineage dysplasia, 22 cases (38%); RAEB-1 or 2, 17 (29%); refractory anemia, 3 (5%); and refractory anemia with ring sideroblasts, 1 (1,7%). According to WHO criteria, cytogenetic abnormalities sufficient to diagnose AML-MRC were found in 7/31 patients with a conclusive caryotypic result (22,6%). A diagnosis of AML-MRC based only in morphological findings was performed in 9 patients (15,5%).
With respect to the findings on blood at diagnosis, leukopenia was present in 53% and leukocytosis in 28%; anemia in 93% (macrocytic 30%) and thrombopenia in 84%. Pancytopenia was found in 47% of cases and a high level of serum lactate-dehydrogenase in 42%. The more frequent phenotypic markers of blast cells, analysed by flow cytometry, were HLA-DR (80% of cases), CD34 (74%), CD33 (72%), CD13 (68%), CD117 (68%), CD38 (62%) and MPO (48%). Some aberrant expressions were found, being CD7 positivity the most frequent (34% of cases); positivities for CD56 (10%) and CD4 (3%) were also observed. The "3+7" induction regimen was applied in 24% of patients, while 5-azacytidine was the drug of choice in 21%. Paliative or supportive treatment was used in the majority of cases (55%). Nine of 14 patients (64%) obtained complete remission after "3+7" scheme (four still alive), and only one (8%) among those treated with 5-azacytidine. At the moment of closing this study, 52 patients had died (89,7%), with a mean overall survival of 14 months (range 0-60), and 6 were still alive after a mean follow-up of 53 months (range 16-168). Mean age of survivors at diagnosis was 57.5 years, compared with 74 years of that who have died. Among the recorded data, those associated with a better outcome were younger age (p=0.028), positivity for CD56 (p=0.005) and intensive treatment (p=0.026).

Summary/Conclusions: In our experience, AML-MRC occurs mainly in elderly patients and is associated with a poor prognosis. The age at diagnosis (and therefore, the probability of receiving intensive chemotherapy) seems to be a strong determinant of prognosis; also, CD56-positive cases exhibited a lower mortality rate than those negative. Further studies are needed to confirm these findings and new therapeutic strategies should be investigated to improve outcome in this group of patients.

PB1672

THE ROLE OF DAILY ECG-MONITORING IN THE MYOCARDIAL INJURY DIAGNOSIS ON THE BACKGROUND OF ANTHRACYCLINE LOW CUMULATIVE DOSES IN PATIENTS WITH ACUTE LEUKEMIA IN COMBINATION WITH ISCHEMIC HEART DISEASE

T Lymanets*, I Skrypnyk, G Maslova
Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: Anthracycline-induced cardiotoxicity is a complicated problem of treating patients with acute leukemia (AL), which can lead to the acute cardiac events development. Ischemic heart disease (IHD) is one of the cardiotoxicity risk factors, which requires monitoring of changes in myocardial bioelectric activity on the background of anthracycline low cumulative doses (CDs) in these patients.
Aims: To assess the nature of electrocardiogram (ECG) changes on the background of anthracycline low CDs in patients with AL taking into account concomitant ischemic heart disease.
Methods: The study involved 93 patients with newly diagnosed AL (acute lymphoblastic leukemia – 21 pts, acute myeloid leukemia – 72 pts), mean age 16-72 years, 48 (51.8%) men, 45 (48.2%) women, ECOG I-II. Their polychemotherapy (PCT) programs included anthracyclines. According to the presence of concomitant IHD patients were divided into two groups: I (n=57) – AL patients without concomitant IHD; II (n=36) – AL patients with concomitant IHD. The standard 12-lead ECG and daily ECG-monitoring were performed for patients of both groups in achieving the CD from 100 to 200 mg/m^2 for doxorubicin, which amounted 179.5±24.11 mg/m^2 and 172.1±23.15 mg/m^2 in patients of groups I and II respectively.
Results: The sinus tachycardia, repolarization processes violations and QRS complex voltage reduction were registered in 16 (28%) pts of group I according to the standard 12-lead ECG. In 29 (80.5%) pts of group II on the sinus tachycardia background the following changes were revealed: right bundle branch block – in 2 (5.6%) pts, left anterior fascicular block – in 2 (5.6%) pts, first-degree atrioventricular block – in 2 (5.6%) pts, supraventricular extrasystoles – in 4 (11.1%) pts, lower voltage and repolarization processes reduction – in 8 (22.2%) pts. The ST segment depression was registered in 13 (36.1%) pts, the Q-T interval prolongation – in 6 (16.6%) pts, T wave changes – in 6 (16.7%) pts of group II. According to the daily ECG-monitoring in 28 (49%) pts of group I with minimal physical activity on the tachycardia background the episodes of solitary supraventricular extrasystoles were detected. In all 36 (100%) patients of group II the periods of tachycardia were recorded, that were accompanied by the increasing number of single supraventricular extrasystoles, episodes of paired and group supraventricular extrasystoles – in 24 (66.6%) pts, single episodes of ventricular extrasystoles – in 19 (52%) pts and increased number of clinically significant ST segment depression periods – in 29 (80.5%) and Q-T prolongation – in 14 (38.8%) patients.
Summary/Conclusions: Low CDs up to 100-200 mg/m^2 for doxorubicin in AL patients without ischemic heart disease are accompanied by the cardiotoxic effects development in the form of arrhythmias: sinus tachycardia, supraventricular extrasystoles. In case of concomitant ischemic heart disease presence the complex of myocardial bioelectric activity disorders develops, such as arrhythmias, conduction abnormalities and silent myocardial ischemia. With the purpose of early anthracycline-induced cardiotoxicity diagnosis in patients with AL receiving PCT it is necessary to conduct daily ECG-monitoring, which has greater sensitivity compared with standard 12-lead ECG.

PB1673

MOLECULAR DIAGNOSTIC ON BONE MARROW BIOPSY SPECIMEN: AN INNOVATIVE CLINICAL TOOL WITH MAJOR IMPACT ON CLINICAL DECISIONS.

M Gavillet*, S Mathieu, O Spertini
Hematology, CHUV, Lausanne, Switzerland

Background: Genetics is currently central to diagnosis, prognosis and measure of response to therapy (minimal residual disease, MRD) for patients with acute leukemia, myeloid or lymphoid. These tests are usually conducted on bone marrow aspirate by various techniques (karyotype, fluorescence *in situ* hybridization, reverse transcription polymerase chain reaction, or DNA sequencing). In case of a dry tap these most valuable information are often lost.
Aims: Since January 2014, we implemented a method for DNA and RNA extraction from bone marrow biopsy specimen in case of a dry tap at diagnosis or during follow up. Here we present the method, results and relevance of the analysis conducted so far.
Methods: Bone marrow biopsy is immediately sunken in either RNAlater (QIAGEN, as for other products listed below) for transcript expression analysis such as acute myeloid leukemia (AML) recurrent genetic anomaly or MRD determination. In case DNA-based analysis is warranted, such as analysis of BCR rearrangements and NOTCH mutations, the biopsy specimen is put into phosphate buffer saline (PBS). Biopsy material is then manually crushed and solved in Qiazol for RNA and PBS for DNA. Manual extraction according to the phenol/chloroform is performed prior to RNA purification, quantification and reverse transcription according to manufacturer's instruction. DNA purification and quantification is performed similarly. Analyses are performed according to established standards for bone marrow aspirates.
Results: We retrospectively identified 32 analysis from 20 patients with either acute lymphoid leukemia (ALL, n=6), acute myeloid leukemia (AML, n=12) or high risk myelodysplastic syndromes (MDS, n=2). Dry tap occurred either at diagnosis (n=11) or during follow up (n=21), regardless of diagnosis (lymphoid or myeloid neoplasia), blast count (median 5%, range: 1-95%) or marrow fibrosis (median 2, range 0-4). In seven samples, this technique allowed to identify a mutation in NMP1, with impact on diagnosis and prognosis, which is not amendable to other techniques (karyotype or FISH). Seventeen more samples allowed to quantify minimal residual disease (levels of WT1 or BCR-ABL transcripts), which is either not possible or less refined by alternative cytogenetic methods. Seven patients had more than one sample, which allowed correlation with and refinement of response assessment by histology. On 11 occasions (37.5%) the result of molecular analysis had a major impact on therapy (mostly distinction of Philadelphia positive *vs* negative ALL n=5, targeted therapy for FLT3-ITD transcript n=1, identification of relapse/refractory disease n=2, decision between autologous *vs* allogeneic transplantation for consolidation n=2).
Summary/Conclusions: The method presented here is a readily accessible variant of the commonly used molecular diagnostic techniques. Its use can confirm, expand and usually refine the analysis available on the bone marrow biopsy specimen, and in one third of the cases, have a significant impact on therapy options.

PB1674

ACUTE MYELOID LEUKEMIA IN OLDER PATIENTS: COMPARISON OF THE EFFECTIVENESS OF THERAPY AND SURVIVAL ANALYSIS. A SINGLE CENTER EXPERIENCE

A Klak-Skubis[1], K Kapelko-Slowik[1,*], J Dybko[1], D Urbaniak-Kujda[1], M Biernat[2], S Stapor[1], K Kuliczkowski[1]
[1]Hematology, Blood Neoplasms and Bone Marrow Transplantation, [2]MIcrobiology, Wroclaw Medical University, Wroclaw, Poland

Background: Acute myeloid leukemia (AML) is disease of older adults with median age over 65 years. The effect of age and severe comorbidities are associated with high incidence of early death, low rate of complete remission (CR) and poor survival. Treatment options for elderly patients include: intensive chemotherapy, less-intensive regimens, best supportive care as well as enrollment in clinical trials. Therapeutic decisions in older AML patients are highly challenging and need to be individualized since the outcome in this group remains still unsatisfactory.
Aims: The aim of the study was to compare results of different treatment strategies in elderly patients with AML and to analyze overall survival in examined patients.
Methods: Patients. We describe a single center experience of 101 patients (41 females and 60 males) with diagnosis of AML, hospitalized in the Department and Clinic of Hematology, Blood Neoplasms, and Bone Marrow Transplantation, Wroclaw Medical University between 2007 and 2014. Median age was 70,6 years (range, 60-90 years). In 85 patients AML was diagnosed *de novo*, whereas 16 patients had secondary AML. Adverse, intermediate and favorable karyotype was found in 14, 82 and 5 patients, respectively. All patients were enrolled into therapeutic procedures according to the age, karyotype, performance status and comorbidity index. Fifty-five patients were treated with intensive chemotherapy regimen based on daunorubicin and cytarabine (DA, "3+5-7"), 22 patients obtained azacitidine (AZA), 14 patients were treated with low-dose cytarabine (LDAC), and only 10 patients received best supportive care (BSC). We estimated percent of CR, early mortality rate, leukemia free survival (LFS) and overall survival (OS).
Results: CR was achieved in 24 patients (44%) who received DA, and in 10 patients (28%) with less-intensive therapy. LFS was comparable in both these groups (5 *vs* 4 months), but superior in patients who received DA. Eight-week early mortality rate was up to 15% after intensive induction therapy and 10% after AZA and LDAC regimens. Nevertheless, median OS in patients treated with DA was marginally superior (5 month) than in patients who received low intensive treatment (4 month) and significantly longer than in patients with BSC (1 month).
Summary/Conclusions: The DA regimen remains still a best standard therapy in older AML patients with good performance status and low comorbidity index. Low-intensive treatment strategies (azacitidine, low-dose cytarabine) seem to be good therapeutic options for older patients with severe comorbidities.

PB1675

ARSENIC TRIOXIDE AS THE FIRST LINE THERAPY FOR PATIENTS WITH SECONDARY MITOXANTRONE-RELATED ACUTE PROMYELOCYTIC LEUKEMIA ON THE BACKGROUND OF MULTIPLE SCLEROSIS

T Lobanova[1,*], V Troizkaya[1], A Sokolov[1], S Kravchenko[1], L Plastilina[1], O Gavrilina[1], A Sidorova[1], G Galstyan[2], E Parovichnikova[1]
[1]Hematological Oncology and BMT, [2]Intensive care unit, National Research Center for Hematology, Moscow, Russian Federation

Background: Mitoxantrone (MT) is a topoisomerase II inhibitor which impairs DNA repair mechanisms. It is well known to induce acute leukemia with absence of myelodysplastic phase. MT therapy is often associated with translocation t(15;17), which defines the development of acute promyelocytic leukemia (APL). MT remains an effective drug for treatment of remitting progressive phase of multiple sclerosis (MS). The APL risk in patients with MS depends on MT dose (≤60mg/m^2, ≥60mg/m^2). Long MS anamnesis, severity of somatic status and evolvement of therapy-related acute leukemia (TRAL) in such patients requires new approaches to treatment.
Aims: To describe the optimal treatment protocols for MS patients with APL, taking into account the patients somatic status.
Methods: From January 2014 to February 2016 in the Department of Hematological Oncology and BMT 15 pts with APL were treated, and 2 of them (39 and 58 y.o.) were with long anamnesis (over 15 years) of MS (remitting progressive phase, cerebral-spinal form). First patient (pt) due to fast progression of MS got MT therapy several times a year, in total≥60mg/m^2, second pt received MT with 60mg in total. Both pts developed APL after 2 years of MT injections. Severity of somatic status was determined by hemorrhagic syndrome (skin and mucosa), coagulation disturbances, granulocytopenia and lower paraparesis with pelvic organs dysfunction due to MS. Pts had intermediate risk APL, cytogenetic analysis showed translocation t(15;17), molecular – bcr1 transcript in both cases.
Results: For the first patient we started all trans-retinoic acid (ATRA) therapy with arsenic trioxide (ATO). Good tolerance to treatment was stated. After 1 month of treatment APL molecular remission was established. The neutropenia period lasted 6 days; catheter-associated sepsis, vaginal and urinary infections, QTc lengthening to 0,48ms were diagnosed. The course of treatment was completed according to ATRA and ATO protocol (E. Estey, 2006). APL remission retains for 16 months. Neurologic symptoms of MS stay stable since the start of APL therapy. The second pt was started with chemotherapy protocol (AIDA), on day 14 he developed septic shock, severe pneumocystis pneumonia with acute respiratory failure. In 2 days he was transferred to the intensive care unit for prolonged invasive mechanical ventilation. Due to long lasting cytopenia (30 days), severe infectious complications, the polyneuropathy deteriorated and tetraplegia developed after status stabilization. ATO therapy with further combination ATRA+ATO was started. Morphological complete remission (CR) and cytogenetic CR were achieved after chemotherapy, molecular CR – after 28 days of ATO. 5 courses of ATO and ATRA+ATO treatment completed. No severe complications were noted and the duration of CR is 8 months. Upper limbs function has recovered, lower limbs – only partially.
Summary/Conclusions: Our experience shows high toxicity of chemotherapy protocol in APL patients with MS. Such protocols cause severe infectious complications due to long period of immunosuppression and may worsen the neurologic status. ATO and ATRA combination as the first line therapy of therapy-related APL in such pts allows to achieve molecular remission with lower toxic effects and without deterioration of MS course.

PB1676

THE ACUTE CLINICAL AND LABORATORY CONSEQUENCES OF ORAL MUCOSITIS DEVELOPED AFTER REMISSION INDUCTION CHEMOTHERAPY IN ACUTE LEUKEMIA PATIENTS

A Yigit[1], N Guler[2,*], P Buyukkaya[2], M Turgut[2], D Ozatli[2]
[1]Internal Medicine, [2]Hematology, Ondokuz Mayis University, School of Medicine, Samsun, Turkey

Background: Chemotherapeutic (CT) agents frequently cause oral mucositis (OM) as a side effect during the treatment of acute leukemia. Patients with OM are generally more predisposed to intraoral infections. OM also affects the nutrition, swallowing, and quality of life.
Aims: To analyze the consequences of post chemotherapy developed OM in acute leukemia patients.
Methods: Seventy-two adult patients with newly-diagnosed Acute Myeloblastic leukemia (n=59), Acute Lymphoblastic Leukemia (n=13) were included. CTs were 7+3 ARA-C+idarubicin (n=43), Azacitidine (n=13), idarubicin+ATRA (n=2), low dose ARA-C (n=1), Hyper-CVAD (n=8), CALGB (n=5). Patients divided into two groups as post-chemotherapy OM or not. Evaluation was performed by same physician daily according to WHO (World Health Organization) OM classification. Stage 1: Oral soreness, erythema; stage 2: Oral erythema, ulcers, solid diet tolerated; stage 3: Oral ulcers, liquid diet only; stage 4: Oral alimentation impossible.
Results: OM occurred in 27 (37%) of 72 patients. Appearance time of the OM after the initiation day of the CT was 6.3±3.4 days and OM were continued for 9.7±5.8 days. There were no significant differences in sociodemographic data, type of leukemia, CT protocol, and smoking status between the two groups. Mostly OM were stage 2 (40.7%, n=11). Others were stage 1 (14%, n=4), stage 3 (29.6%, n=8), stage 4 (14.8%, n=4). Microorganisms in the oral mucositis swab cultures were detected in 12 out of 27 patients with OM. They were Pseudomonas aeruginosa (n=4 patient, 14.8%), Streptococcus viridans in (n=2; 7.4%), Enteroccus faecium in (n=2), Candia albicans (n=1; 3.7%), Acinetobacter baumannii (n=1), Morganella morganii (n=1), Enterobacter cloacae (n=1). Microorganisms in blood cultures of patients with OM were detected in 7 (25.9%) out of 27 patients. This ratio was low as 11% (5 out of 45) in patients without OM. There wasn't any relationship between microorganism in swab culture and blood culture as same in patients. Microorganism in blood cultures of patients with OM were: Staphylococcus hominis (n=2 patients, 7.4%), ESBL Negative E.coli (n=2; 7.4%), Acinetobacter baumannii (n=1; 3.7%), Staphylococcus Epidermidis (n=1), Coagulase negative staphylococcus (n=1). Microorganisms in blood cultures of patients without OM were such as: Staphylococcus Epidermidis (n=2; 4.4%), ESBL Negative E.coli (n=1; 2.2%), Staphylococcus capitis (n=1), Staphylococcus hominis (n=1). The mean duration of neutropenia in OM group was 32 days compared to 22 days in the without OM group (p=0.02). The pre-treatment level of serum albumin was lower, and the levels of CRP and LDH during mucositis were higher in the patients with OM (p<0.001, p<0.001and p=0.002, respectively). Mortality was higher in the group with OM, 9 (6 patients with stage 3 or 4 OM; 3 patients with stage 1) in 27 *vs* 6 in 45 patients (p=0.04). Six of 12 patients who developed severe mucositis (stages 3 and 4) died. The fever appeared on day 7.1±0.87 of the CT in the patients with OM, whereas fever was observed on day 4.1±0.67 in the patients without OM (p=0.002).
Summary/Conclusions: The development of OM may have a role about prognostic value in the patients receiving CT because of the extended duration of neutropenia, higher levels of LDH and CRP, and a higher rate of mortality in patients with OM. Furthermore, we would like to highlight that the patients with low levels of albumin prior to chemotherapy should be more closely followed for OM.

PB1677

ACUTE MYELOID LEUKEMIA IN ELDERLY PATIENTS. ANALYSIS OF 102 CASES

H Ionita[1,*], I Ionita[1], M Cheveresan[1], C Ionita[2], D Calamar[1], D Oros[1], M Ionita[3]
[1]Hematology, [2]Surgery, [3]Internal Medicine, University of Medicine and Farmacy Victor Babes Timisoara, Timisoara, Romania

Background: Acute myeloid leukemia (AML) is more frequent in elderly patients and the prognosis is very poor. There is no established standard treatment, since the survival of patients treated with intensive chemotherapy is 15% at 3 years. Most patients are not candidates for intensive treatment due to age, comorbidity or other biological characteristics. The management of old patients with AML remains controversial, specially in those cases affecting very old patients (aged ≥70).
Aims: It is presented the experience of our centre (single centre experience) with a group of patients from the period 1995-2014.
Methods: We conducted a retrospective analysis of 102 consecutive patients 65years of age or older, diagnosed for AML between January 1995 and December 2014, in Department of Hematology, County Hospital, Timisoara, Romania. Without selection (33.1%) had evolved from prior myelodysplastic syndrome. Patients were divided into 3 groups according to the treatment: no treatment (supportive treatment), low intensity treatment (low doses Ara-C: 10 mg/m^2/12h s. c. days 1-21) and high intensity treatment (Idarubicin 10 mg/m^2 days 1 and 3; Ara-C 100 mg/m^2/12h days 1-3; Etoposide 100 mg/m^2 days 1-3).
Results: Total number of subjects was 57 men and 45 women. Median patient age was 73 years (range, 65-87 years); mean Karnofsky index was 70; 72 patients received treatment and 30 of them did not; M3 subtype was excluded, overall survival was 6,2 months, significant differences were observed in the mean overall survival between the treated and no-treated groups (12,5 *vs* 2,5 months respectively; p=0,015). The patients treated with supportive therapy had a median length of hospital stay of 16 days, while the patients treated with chemotherapy had a median length of hospital stay of 75 days. In the low intensity group (45 patients) an overall response of 30% was observed; in the high intensity one (27 patients), overall response was 50% no statistical differences were observed between both groups considering all subgroups of response (p=0,14).
Summary/Conclusions: Overall survival in the treated group is higher than in the non-treated one, differences reached statistical significance. Comparing both arms of treatment no statistical differences were observed in the quality of response, though a higher proportion of complete responses were observed in the high intensity group. An adequate selection of patients for chemotherapy treatment leads to a low mortality rate. Further research is needed to establish optimal management and improve outcomes of elderly patients with AML.

Aggressive Non-Hodgkin lymphoma - Clinical

PB1678

HIGH DOSE THERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION RESULTS IN EXCELLENT LONG TERM SURVIVAL IN PRIMARY MEDIASTINAL B CELL LYMPHOMA

T Struessmann*, K Fritsch, A Zober, A Baumgarten, J Duyster, J Finke, R Marks
Hematology, Oncology, and Stem-Cell Transplantation, Medical Center - University of Freiburg, Freiburg, Germany

Background: Primary mediastinal B cell lymphoma (PMBL) is a rare subtype of diffuse large B cell lymphoma and has some clinical and pathologic features of classical nodular sclerosing Hodgkin lymphoma. Patients are predominantly young women and often present with a locally invasive anterior mediastinal mass. The optimal treatment of PMBL is unknown and differs in clinical practice. Standard immunochemotherapy alone is inadequate and has resulted in routine consolidation with mediastinal radiation. There is only a paucity of prospective data and best results were achieved with rituximab based regimens combined with radiotherapy or dose intensified therapy (DA-EPOCH-R) without radiation. Here we present a single center 10 year retrospective survey indicating that high dose therapy with autologous stem cell support (HDT/ASCT) results in excellent long term outcome.
Aims: Aim of this study is to investigate the infrequent population of PMBL patients, as a single center survey, regarding treatment strategies and long-term outcome.
Methods: All patients with PMBL who presented at Freiburg University Medical Center since 2005 were evaluated according to their baseline characteristics, treatment modality and treatment outcome. From 2005 on patients were treated with upfront HDT/ASCT after R-CHOP induction and R-VCPE (rituximab, epirubicin, etoposide, cisplatin, cyclophosphamide) intensification. Conditioning regimen was BEAM (group A). From 2011 onwards patients were treated with an early intensified protocol: Dense R-MTX/CHOP-14 (6 cycles CHOP-14, dose dense rituximab on days 0, 1, 4, 8, 15, 22, 29, 47, 61 and 75. High-dose MTX was administered on days 30 and 76 right before standard CHOP). Patients who did not achieve a complete metabolic response were intensified as described above (group B). Radiotherapy consolidation was not routinely performed in both treatment groups.
Results: 25 patients were identified. Median age was 32 y (range 19-57y), with predominantly females (64%). Disease stage was mostly III/IV (76%). All patients presented with bulky disease and elevated LDH. 36% had an ECOG-Score of ≥2. 72% of patients presented with more than one extranodal site involvement. 88% presented with high-intermediate or high risk aaIPI. Nine patients were intended to receive upfront HDT/ASCT (group A). Of these patients one was primary refractory to R-CHOP-21 and died early in the course of disease. Three patients received consolidating radiotherapy. 2-year PFS and OS were 88.9%, respectively. 14 patients were treated with upfront dense R-MTX/CHOP-14 (group B). Six patients achieved only partial remission and received HDT/ASCT as consolidation. Five patients received additional mediastinal radiotherapy. 2-year PFS and OS were 85.7% and 100%. In addition to both groups, two patients were treated with six cycles of R-CHOP-21+2xR (group C). With a median follow-up of 35.9 months estimated 3-year progression-free and overall survival for all patients were 83.2% and 83.6%, respectively. Despite a complete metabolic response after R-MTX/CHOP-14 induction two relapses were observed in this group. One relapse was observed after six cycles R-CHOP-21 and mediastinal radiation. Patients who underwent upfront HDT/ASCT or received HDT/ASCT consolidation in addition to dense R-MTX/CHOP-14 induction had an excellent long-term outcome with a 3-year PFS and OS of 100%, respectively. According HDT/ASCT or no-HDT/ASCT survival curves do significantly differ (Figure 1). There was no transplant related mortality. No second malignancies were observed yet.

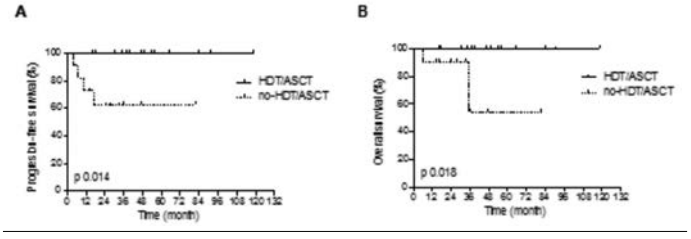

Figure 1. Kaplan-Meier curve for A) progression-free survival and B) overall survival stratified by high dose treatment (HDT/ASCT) or no high dose treatment (no-HDT/ASCT) for all PMBL patients.

Summary/Conclusions: Our results support that dose intensification is necessary in PMBL patients. Regarding the role of HDT/ASCT our data suggest that an approach using upfront HDT/ASCT (group A) or as intensification for patients failing complete metabolic response after induction (group B) is safe and results in excellent long term survival.

PB1679

THE REVISED INTERNATIONAL PROGNOSTIC INDEX IS MORE USEFUL IN COMBINATION WITH SERUM INTERLEUKIN-2 RECEPTOR LEVEL FOR DETERMINING THE PROGNOSIS IN DIFFUSE LARGE B-CELL LYMPHOMA

S Kuwahara[1,*], H Kaneko[1,2], T Fujino[1], M Ohshiro[1], Y Tsutsumi[1,3], T Iwai[1], H Uchiyama[1], J Kuroda[4], M Taniwaki[4]
[1]Department of Hematology, Japanese Red Cross Kyoto Daiichi Hospital, [2]Department of Hematology, Aiseikai Yamashina Hospital, [3]Department of Hematology, Japanese Red Cross Kyoto Daini Hospital, [4]Department of Hematology and Oncology, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: The current standard of care for diffuse large B-cell lymphoma (DLBCL) is rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP). The International Prognostic Index (IPI) was developed to predict the outcome prior to the availability of rituximab. The addition of rituximab to CHOP dramatically improved clinical outcomes in patients with DLBCL. Therefore, some major modifications to the IPI have been reevaluated in the rituximab era. The revised IPI (R-IPI), a clinical tool used to predict patient outcome, has been implemented and validated; however, it has not been established for general practical use. Serum soluble interleukin-2 receptor (IL-2R) level has been identified as a marker of poor outcome in patients with DLBCL.
Aims: In this study, we analyzed to determine whether incorporation of serum IL-2R level into the factors of R-IPI allow for wider differentiation of outcomes.
Methods: The clinical records of 227 consecutive patients in our center with DLBCL diagnosed between 2003 and 2013 who received rituximab were retrospectively analyzed. Data for IPI factors (age >60 years, stage III/IV disease, elevated serum lactate dehydrogenase level, Eastern Cooperative Oncology Group performance status ≥2, and >1 extranodal site of disease) and serum IL-2R level upon diagnosis were collected retrospectively. The normal upper limit of serum IL-2R level was set at 519 U/mL using an enzyme immunoassay system. The R-IPI segregated patients into 3 outcome groups. A combination of R-IPI and serum IL-2R level identified 6 groups. The survival period was calculated from treatment initiation and estimated using Kaplan-Meier method. Death from any cause or relapse was defined as an event. Survival was compared between risk groups using the log-rank test. This study was conducted in accordance with the Declaration of Helsinki and its amendments. The protocol was approved by the Ethics Committee of the Japanese Red Cross Kyoto Daiichi Hospital.
Results: A total of 227 patients with DLBCL were enrolled, and 54 patients had normal serum IL-2R levels, on the basis of which, 12 were categorized as a very good prognostic group, 39 a good prognostic group, and 3 a poor prognostic group according to the R-IPI; similarly 173 patients had elevated serum IL-2R levels, on the basis of which, 4 were categorized as a very good prognostic group, 81 a good prognostic group, and 88 a poor prognostic group. With a median observation period of 39 months (range, 1 - 205), the 3-year overall survival (OS) was 72.9% for all patients. and 100%, 94.4%, and 100% for 3 prognostic groups of patients with normal serum IL-2R levels, according to the R-IPI. Similarly, the 3-year OS for patients with elevated serum IL-2R level was 100%, 81.7%, and 68.7%, respectively (p=.002). Moreover, 12 patients with a very good prognostic group per the R-IPI showed favorable prognoses regardless of serum IL-2R level (100% 3-year OS). However, serum IL-2R level significantly differed between with good and poor prognostic groups. According to the serum IL-2R level, 3-year OS was 94.4%, and 81.7%, respectively, for patients with the good prognostic group (p=.02) and 100% and 60.5%, respectively, for those with the poor prognostic group (p=.02).
Summary/Conclusions: A new scoring system is needed for better risk stratification and establishing the appropriate therapeutic strategy in the rituximab era. R-IPI is a useful prognostic marker, particularly in patients with elevated serum IL-2R levels. The combination of serum IL-2R level with R-IPI might provide a more precise risk stratification and serve as a useful prognostic predictor in DLBCL patients to identify candidates for experimental therapy other than R-CHOP.

PB1680

SALVAGE TREATMENT WITH R-IEV (RITUXIMAB, IFOSFAMIDE, EPIRUBICIN, ETOPOSIDE) AND AUTOLOGOUS STEM CELL TRANSPLANT FOR RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA

S Gumenyuk[1,*], F Marchesi[1], P Anticoli Borza[2], D Renzi[1], F Palombi[1], F Pisani[1], A Romano[1], A Spadea[1], M Canfora[3], E Papa[1], A Mengarelli[1]
[1]Hematology and Stem Cell Transplant, Regina Elena National Cancer Institute, [2]Hematology, San Giovanni-Addolorata Hospital, [3]Scientific Direction, Regina Elena National Cancer Institute, Roma, Italy

Background: The better salvage treatment before Autologous Stem Cell Transplant (ASCT) for relapsed/refractory Diffuse Large B-Cell Lymphoma (DLBCL) hasn't been still definitively established. The phase III CORAL study, comparing R-ICE (Rituximab, Ifosfamide, Carboplatin, Etoposide) *versus* R-DHAP (Rituximab, Dexametasone, Cisplatin, Cytarabine) in relapsed DLBCL patients didn't demonstrate a significant difference in terms of response rate and Progression-Free Survival (PFS) between the two groups. Therefore, the ESMO (European Society of Medical Oncology) guidelines recommend the use of R-ICE or R-DHAP or R-GDP (Rituximab, Gemcitabine, Dexamethasone, Cisplatin) as

salvage regimen for relapsed/refractory DLBCL, considering the similar efficacy of all these treatment schemes.
Aims: The aim of the study was to evaluate the efficacy and safety of salvage treatment with R-IEV (Riruximab, Ifosfamide, Epirubicin, Etoposide and Dexamethasone) followed by ASCT in relapsed/refractory DLBCL patients.
Methods: From July 2007 to December 2015, 42 consecutive adult patients with relapsed (n=17) or refractory (n=25) DLBCL patients underwent a salvage treatment with three courses of R-IEV (Rituximab 375 mg/m^2 on day 0, Ifosfamide 2500 mg/m^2, Etoposide 150 mg/m^2, Dexamethasone 20 mg, on days 1-3, Epirubicin 100 mg/m^2 on day 1) every 21 days in two different Hematology Institutions of Rome (Regina Elena National Cancer Institute, n=20; San Giovanni Addolorata Hospital, n=22). For all patients we planned a Peripheral Blood hematopoietic Stem Cell (PBSC) harvest after the second or the third course of chemotherapy, if the bone marrow wasn't or was involved at salvage treatment start, respectively, using Filgrastim or Lenograstim 5 mcg/Kg. All patients underwent a febrile neutropenia prophylaxis with Filgrastim (n=14), Lenograstim (n=18) or Pegfilgrastim (n=10) in all courses of treatment. All patients underwent a baseline evaluation of Performance Status (PS) and comorbidities, and left ventricular ejection assessment.
Results: The median age of patients at the start of salvage treatment was of 48 years (range: 23-62). At diagnosis, 38 patients (90%) were in advanced (III-IV) Ann-Arbor stage and 18 (43%) presented intermediate-high IPI score. Moreover, 35 patients (83%) had a 0-1 ECOG PS and 15 (36%) had not any relevant comorbidities. As first line treatment, 29 patients (69%) were treated with R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin, Vincristine and Prednisone), whereas the remaining 13 with other chemotherapeutic regimens. At the time of salvage treatment start, 25 patients (59%) were defined as refractory, 7 (17%) were relapsed within 12 months from the end of previous treatment line and 10 (24%) were relapsed after more than 12 months. After the end of R-IEV, a Complete Remission (CR) was obtained in 30 patients (71%), 9 patients were in Partial Response (PR, 21%), whereas the remaining 3 patients (8%) were defined as refractory to salvage treatment. PBSC collection was successfully performed in 40 patients, whereas in the remaining two wasn't carry out for early progression (n=1) or harvest failure (n=1). Actually, 37 patients underwent ASCT after BEAM (Carmustine, Etoposide, Cytarabine, Melphalan) conditioning chemotherapy. Out of 40 patients in which a PBSC collection was successfully performed, three patients didn't undergo ASCT for progression of disease (n=1), clinical choice (n=1) and patient refusal (n=1). A grade 3-4 neutropenia and a febrile neutropenia occurred in 78% and 31% of patients, respectively. However, we didn't observe any cases of toxic death or cardiac relevant complication. After a median follow-up of 36 months (range: 3-116), the 2-year-PFS and OS (2y-PFS and 2y-OS) from the start of salvage treatment were of 73.8% and 83.3%, respectively.
Summary/Conclusions: From our experience, R-IEV salvage regimen with consequent ASCT was highly effective in relapsed/refractory DLBCL patients, permitting to obtain an impressive 2y-PFS, with a good safety profile. Further prospective randomized studies comparing R-IEV with other standard salvage regimens should be useful to establish the better therapeutic approach for these patients.

PB1681

A COMPARISON STUDY BETWEEN ALLOGENEIC AND AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT FOR HIGH-RISK PERIPHERAL T-CELL LYMPHOMAS (PTCL)

H Huang*, Q Wang, Z Jin, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Peripheral T-cell lymphomas (PTCLs) are heterogeneous malignancies sharing common elements of chemotherapy resistance and poor outcome with standard treatments. Attempts to improve outcomes have included autologous or allogeneic hematopoietic cell transplantation (autoHCT or alloHCT). both modalities lead to durable remissions in recurrent disease settings and might be important in consolidating first remission. However, key questions remain, including relative efficacy of autologous *versus* allogeneic approaches, and HCT timing (first-line consolidation v relapse).
Aims: Herein, we analyzed outcomes of 60 cases recieved autoHCT or alloHCT in our center.
Methods: From July 2007 to July 2014, Outcomes of 60 patients undergoing autologous HCT (autoHCT) or allogeneic HCT (alloHCT) were analyzed retrospectively. Primary outcomes were nonrelapse mortality (NRM), relapse/progression, progression-free survival (PFS), and overall survival (OS).
Results: All 60 patients were at high risk group (carried with IPI≥3), with a median age of 31 (13-55) years old. Of the 60 cases, 22 were PTCL-not otherwise specified (PTCL-NOS), 22 with ALK negative anaplastic large cell lymphoma (ALK-negative ALCL) and 16 with angioimmunoblastic T-cell lymphoma (AITL). Before receiving transplantation, 40/60 patients were in complete remission (CR) and 20/60 patients were not remission (NR). Twenty-one (21/60) received allo-HSCT and thirty-nine patients (39/60) received auto-HSCT. In the 20 NR patients before transplant, 11 patients received allo-HCT and 9 patients received auto-HCT. After a median follow-up of 39 (range 1-96) months, the K-M analysis showed that the 5-year PFS for auto-HSCT and allo-HSCT were 61% and 60% (*P*=0.724). 1-year NRM was higher (22.5% *vs* 7.8%) for alloHCT. The 5-year OS for auto-HCT and allo-HCT were 62% and 61% (*P*=0.724). There were no statistically significant differences between the auto-HSCT and allo-HSCT. However, autoHCT recipients were more likely in complete remission (CR; 76.9% *vs* 47.6%; P <0.01) and with chemotherapy-sensitive disease.

Table 1. Baseline characteristics of the patients.

Parameters	Auto-HCT	Allo-HCT
Number	39	21
Histological subtypes		
PTCL-NOS	12	4
ALK-negative ALCL	13	4
AITL	7	9
NK/T	7	4
Conditioning regimen		
BEAM	39	0
BUCY	0	11
TBI+BUCY	0	10
Donor source	N	
Matched unrelated donor		8
Matched sibling donor		4
Haploid donor		8
Cord blood		1
Disease status before HCT		
CR	30	10
PR	2	0
NR	7	11
Disease status after HCT		
CR	35	19
PR	0	0
NR	4	0
Uncertain	0	2

Summary/Conclusions: Both autoHCT and alloHCT approaches can benefit patients with PTCL. We did not find a difference in PFS and OS between auto-HCT and alloHCT, although NRM increased significantly in alloHCT. However, our results suggest that outcomes of alloHCT are better for refractory and relapsed patients with PTCL. nd overall survival (OS).

PB1682

PROGNOSTIC SIGNIFICANCE OF SARCOPENIA IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH RITUXIMAB PLUS CHOP (R-CHOP)

SI Go[1], MJ Park[2], HG Kim[1], MH Kang[1], GW Lee[1,*]
[1]Internal Medicine, [2]Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia, defined as the loss of skeletal muscle mass and strength, is one of the criteria for cancer cachexia. A computed tomography (CT) scan has been accepted as one of the most preferred tools toassess sarcopenia. Measuring the extent of sarcopenia by CT in patients with malignancy has severaladvantages, including accurate quantification of muscle mass, precise differentiation between fat andmuscle, and wide availability as a routine diagnostic tool in cancer. Sarcopenia evaluated by CT isknown to be related to an increased risk of chemotherapy toxicity, poorer functional status, andreduced survival in malignancy.
Aims: In this study, we investigated the prognostic impact of sarcopenia in all age groups of patients with DLBCL using an extended cohort. Additionally, a new prognostic model, including sarcopenia and other significant prognostic factors, was constructed using a nomogram.
Methods: In total, 187 consecutive DLBCL patients treated with induction R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone) immunochemotherapy were reviewed.Sarcopenia was defined as the lowest sex-specific quartile of the skeletal muscle index, calculated bydividing the pectoralis muscle area by the height. Clinical outcomes were compared between thesarcopenic and non-sarcopenic groups. A nomogram was constructed from the Cox regression model for overall survival (OS).
Results: Treatment-related mortality (21.7% *vs* 5.0%, p=0.002) and early discontinuation of treatment(32.6% *vs* 14.9%, p=0.008) were more common in the sarcopenic group than in the non-sarcopenic group. The 5-year progression-free survival (PFS) rates were 35.3% in the sarcopenic group and 65.8% in the non-sarcopenic group (p <0.001). The 5-year OS rates were 37.3% in the sarcopenic group and 68.1% in the non-sarcopenic group (p <0.001). Sarcopenia and the five variables of the International Prognostic Index (IPI) were independent prognostic factors in a multivariate analysis for PFS and OS, and were used to construct the nomogram. The calibration plot showed good agreement between the nomogram predictions and actual observations. The c index of the nomogram (0.80) was higher than those of other prognostic indices (IPI, 0.77, p=0.009; revised-IPI, 0.74, p <0.001; National Comprehensive Cancer Network-IPI, 0.77, p=0.062).

Summary/Conclusions: This study demonstrates the role of sarcopenia as a poor prognostic marker in DLBCL patients. We suggest that dose adjustment and intensive supportive care should be considered in DLBCL patients with sarcopenia receiving induction R-CHOP immunochemotherapy. Further prospective studiesare warranted to confirm the prognostic role of sarcopenia and to externally validate the nomogramincluding sarcopenia in DLBCL.

PB1683

GOOD RESULTS WITH R-CHOP-14 THERAPY IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMAS. THE CHEMOKINE TARC IS AN EXCELLENT MARKER OF TUMOR ACTIVITY AND IN TREATMENT EFFECTIVITY IN MEDIASTINAL LYMPHOMAS.

T Schneider[1,*], B Deák[1], Z Molnár[1], E Szaleczky[1], E Várady[1], F Varga[1], E Tóth[2], J Strausz[2], K Kajáry[3], É Jederán[4], O Csuka[5], I Gaudi[6], A Rosta[1]
[1]Center for Lymphomas, [2]Surgical and Molecular Tumour Pathology Centre, National Institute of Oncology, [3]Pozitron-Diagnosztika Health Centre, [4]Department of Radiological Diagnostics, [5]Department of Pathogenetics, [6]Department of Epidemiology, National Institute of Oncology, Budapest, Hungary

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is a rare disease that belongs to the group of aggressive, diffuse large B-cell lymphomas and is associated with a characteristic clinical feature. Data from evidence-based treatments are not available. Retrospective studies suggest that the so called third generation treatments are more effective than the previous standard treatment with 21-day cycles R-CHOP. Nowadays, dose-dense DA-EPOCH-R treatment is well tolerated by young patients and appears to be even more effective.
Aims: Our research shows that dose-dense R-CHOP-14 treatment is as effective as the more aggressive DA-EPOCH-R. There is no earlier data for the role of TARC (thymus activation-regulated chemokine) in PMBCL as a disease activity marker. The change of TARC level during the treatment was monitored.
Methods: Between July 2005 and June 2015, 56 newly diagnosed, untreated PMBCL patients were subject to treatment with R-CHOP-14. The average age of the 33 (59%) female and 23 (41%) male patients was 32 years (range: 21-53 years). Using the R-IPI, 9 patients were the very good, 46 patients were the good and one patient was in the worse prognostic group. The combination of CHOP-14 and rituximab administered in 14-day cycles was used as treatment; the treatment regimen also included preventive administration of filgastrim. The average number of cycles of the chemotherapeutic treatments was 6.6 (range: 4-8). After the final R-CHOP-14 treatment high energy photon radiation was used to the residual mediastinal abnormalities in 46 cases as consolidation treatment. Before diagnosis could be performed two patients received life-saving irradiation. Since May 2013 we have investigated the role of TARC to follow the disease activity in 13 cases.
Results: The planed treatment was completed in 55 (98.2%) patients and in 54 (96.4%) patients we achieved complete remission verified by PET/CT. One patient, who did not get complete remission, was cured with high-dose chemotherapy and autologous stem cell transplantation. One patient died after the fourth cycle R-CHOP-14, due restrictive pulmonary disease and ARDS. The average duration of the follow-up period was 57 months (range: 10-126 months), during which time only one relapse was shown. The relapse free survival is 98.1%. One patient did not wish to receive further oncological treatment, she was only one who died due lymphoma. The lymphoma specific mortality is 98.2%. Two young female patients (with hereditary mental retardation) died in lung tuberculosis 9 and 13 month after the end of the treatment. The overall survival rate is 92.9%; the event free survival is 91.1%. Before the treatment all but one out of 13 cases extremely high TARC level was found. The TARC levels were dropped quickly in the normal range due the treatment effect.
Summary/Conclusions: In the treatment of PMBCL the R-CHOP-14 was found highly effective, short-term and well tolerable. Further investigation and research is needed to find out if radiation therapy is necessary. The TARC proved to be a very good marker in PMBCL which signs the activity of disease and the effectivity of treatment well and early.

PB1684

PROGNOSTIC VALUE OF PRETREATMENT ADVANCED LUNG CANCER INFLAMMATION INDEX (ALI) IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH R-CHOP CHEMOTHERAPY

YH Park[1,2,*], JH Lim[2], HG Yi[2], MH Lee[2], CS Kim[2]
[1]Department of Hematology and Oncology, Hanil General Hospital, Seoul, [2]Department of Hematology and Oncology, Inha University Hospital, University of Inha College of Medicine, Incheon, Korea, Republic Of

Background: It has become evident that cancer-related inflammation plays an important role in the development and progression of various types of cancer and adversely influences response to anti-cancer therapy. Advanced lung cancer inflammation index (ALI), a novel inflammation-based prognostic system, has been demonstrated to be a prognostic factor of survival in some solid cancers. However, the prognostic usefulness of ALI has not been investigated in lymphoma.
Aims: The authors investigated the ability of ALI to predict response to chemotherapy and survival in patients with diffuse large B-cell lymphoma (DLBCL).
Methods: The records of 212 patients with newly diagnosed DLBCL treated by R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone) chemotherapy were reviewed. ALI values were calculated by dividing the product of body mass index and blood albumin level by peripheral blood neutrophil/lymphocyte ratio. Patients were allocated to a low pretreatment ALI group (n=82, 38.7%) or a high pretreatment ALI group (n=130, 61.3%) using on optimal ALI discriminatory cutoff value for survival of 15.5 as determined by receiver operating curve analysis.
Results: The proportion of older patients (aged >60 years) was significantly higher in the low ALI group than in the high ALI group (63.4% *vs* 36.2%, p<0.001). More patients had advanced disease (Ann Arbor stage III/IV) in low ALI group at initial diagnosis (72% *vs* 54.6%, p=0.014). Poor Eastern Cooperative Oncology Group performance status (ECOG PS, p=0.001), presence of B symptoms (p=0.002), and high-risk of International Prognostic Index (IPI, p=0.029) were observed more frequently in the low ALI group. Complete remission rates in the low and high ALI groups after completing R-CHOP chemotherapy (after 6 to 8 cycles) were 54.9% (45/82) and 75.4% (98/130), respectively (p=0.008). During a median follow-up of 54 months (range, 6-92 months), patients in the low ALI group had shorter 5-year PFS (58.1% *vs* 77.3%, p=0.006) and OS (64.2% *vs* 80.2%, p=0.008) than patients in the high ALI group. Multivariate analysis showed advanced disease (hazard ratio [HR] 2.425, 95% confidence interval [CI] 1.514-3.128, p=0.013), bulky disease (diameter ≥10 cm, HR 1.568, 95% CI 0.678-4.287, p=0.043) and low pretreatment ALI (HR 1.927, 95% CI 0.893-3.598, p=0.021) were significantly associated with poorer PFS. Regarding OS, age >60 (HR 2.298, 95% CI 1.628-6.118, p=0.015), ECOG PS ≥2 (HR 1.814, 95% CI 0.874-6.521, p=0.024), high-risk IPI (HR 2.872, 95% CI 1.658-5.723, p<0.001), advanced disease (HR 2.431, 95% CI 1.422-6.249, p=0.002) and low pretreatment ALI (HR 2.645, 95% CI 1.542-5.974, p=0.001) were all found to be independently associated with shorter OS. Interestingly, a low ALI before R-CHOP chemotherapy reverted to a high ALI during treatment in 58 patients (27.4%) and median OS of these patients (not reached) was better than that of patients whose ALI remained low (n=24, 25 months; p<0.001). Conversely, patients with a persistent low ALI during treatment showed worse survival.
Summary/Conclusions: This study shows a significant association exists between pretreatment ALI and response to R-CHOP chemotherapy and prognosis in DLBCL. Changes in ALI during the course of chemotherapy might also provide additional information about survival, particularly for patients with a low pretreatment ALI. Our findings suggest ALI is an inexpensive, potential prognostic marker in patients with DLBCL that can be readily used in routine practice.

PB1685

FACTORS RELATED TO NON-HODGKIN'S LYMPHOMA LONG-TIME TO TREATMENT INITIATION AND IMPACT ON SURVIVAL IN A POPULATION BASED STUDY IN FRANCE: IS THERE A ROLE OF SOCIOECONOMIC STATUS?

S Le Guyader-Peyrou[1,2,*], S Orazio[1,2], O Dejardin[3], M Maynadie[4],xTroussard[5], A Monnereau[2,6]
[1]Registre des Hémopathies malignes de la Gironde, Réseau Repih, Institut Bergonie, [2]INSERM U1219 Epidemiology of Cancer and Environmental Exposure, Isped, Bordeaux, [3]U1086 INSERM_UCBN, Cancers et Preventions, Caen, [4]Registre des Hémopathies malignes de Cote d'Or, EA 4184, Université de Bourgogne, Réseau REPIH, Dijon, [5]Registre des hémopathies malignes de Basse Normandie, Réseau REPIH, Caen, [6]Registre des Hemopathies malignes de la Gironde, Institut Bergonie, Bordeaux, France

Background: Diffuse large B cell lymphoma (DLBCL) is one of the most frequent non-Hodgkin's lymphoma histological subtype for which care management is well codified and remaining still an aggressive disease potentially curable with a combination of anthracycline-based chemotherapy. In this context, time to treatment initiation (TTI) could be having an impact on the patient's survival.
Aims: The aim of this study was to identify the socioeconomic and medical factors predicting a long TTI and determine the impact of a long delay on overall (OS) and relative (RS) survival (excess mortality due to lymphoma) for DLBCL patients.
Methods: We performed a population-based "high-resolution" study including all patients diagnosed with DLBCL in three registry-areas in France (Gironde, Côte d'Or and Basse-Normandie) between 2002-2008. Medical and socioeconomic factors (GP's density, rural area, distance to the nearest reference centre, index deprivation) were collected. TTI was the delay in days between diagnosis and treatment initiation. A long TTI was considered for 75thpercentile and very long TTI for the 90th percentile. Three multivariate analysis logistic regressions were performed for the first aim using median, 75th and 90th percentiles TTI as dependant variables. For each patient, the follow-up period continued from the date of diagnosis to the death or until June, 30, 2013. For survival outcome we fitted a multivariate cox model for OS and an Esteve model for RS (3 and 5 years). Net survival (NS) using Pohar Perme unbiaised method was also calculated for 1, 3 and 5 years.
Results: We included 1084 DLBCL patients (median age 71(9-99) years) and sex ratio H/F 1.12.The median TTI was 27 days, interquartile (15-42); The long

TTI was 42 days and a very long TTI was considered >63 days. Each dependant variable has been analysed in details. Among these variables in multivariate logistic regression, adjusted on age and sex, we first confirmed that elevated serum lactate dehydrogenase and disseminated stage of disease were independently associated with a TTI>63 days (OR: 0.37 IC 95%: 0.22-0.63 and OR: 0.59 IC 95%: 0.37-0.93, respectively). The registry areas and outpatient diagnosis were both independently associated with a long TTI (OR: 1.89 IC 95%: 1.38-2.60 for patients of north of France; OR: 1.55 IC 95%: 1.01-2.39 for outpatients). In contrast, the socioeconomic status (European Deprivation Index) was not associated with the delay of treatment initiation. Median of follow up was 5 years. For the respective long TTI groups, 5 years OS estimates were 55% and 60.5%; 5 years NS estimates were 62.3% and 67.7%. We found no association between a TTI>63 days and overall survival or relative survival.

Summary/Conclusions: This study shows that medical factors such as LDH and stage of disease influence a longer delay of treatment. To be diagnosed in the same place of care management that treated seems to be also a factor of earlier treatment. Socioeconomic status is not associated with TTI whatever the delay. Finally, our results emphasize disparities according to France area. This retrospective cohort suggest that time to treatment initiation don't may influence outcomes.

R-CHOP-21 PLUS LOW DOSE ETOPOSIDE *VERSUS* DA-EPOCH-R IN PATIENTS WITH AIDS-RELATED GCB DIFFUSE LARGE CELL B CELL LYMPHOMA; SINGLE CENTRE EXPERIENCE

I Kozlov[1,*], V Kozlov[2], N Strembitska[2], O Ryzhak[2], L Batyuk[2], M Chupryna[2], V Leonov[2], H Chikalova[2]
[1]Internal Medicine #1 with additional course of cardiovascular diseases, Odessa National Medical University, [2]Odessa Regional Clinical Hospital, Odessa, Ukraine

Background: Treatment of AIDS-related diffuse large cell B cell lymphoma (DLBCL) with low CD4 count (<100 mm3) remains a great challenge for hematologists. Balancing between competing needs of lymphoma treatment and HIV management is crucial for achieving long term survival. Previous studies have shown strong advantage of DA-EPOCH-R *versus* R-CHOP in AIDS-related lymphomas. However hematological toxicity profile of this regimen is quite considerable especially in patients with AIDS with decreased bone marrow reserves. Combination of standard R-CHOP with low dose etoposide (R-CHOEP) could be effective alternative option in AIDS-related GCB-type DLBCL management.
Aims: The aim of our study was to evaluate if R-CHOEP benefit of R-DA-EPOCH in patients with AIDS-related GCB DLBCL considering hematological toxicity.
Methods: Thirty one patients (pts) with AIDS-related GCB DLBCL have been enrolled in study. All pts had low CD4 count with mean amount 78 cells/mm3 and did not receive HAART before the enrolment. They have been divided into two arms. First arm (n=14) received standard R-CHOP with 50 mg/m2 etoposide infusion on days 1-3. Second arm received DA-EPOCH-R as it has been described in previous studies. FDG-PET scans have been done before and after the treatment.
Results: Complete response (CR) has been achieved in 93% in DA-EPOCH-R arm and in 85% in R-CHOEP arm. Hematological toxicities have been observed in both arms in all cycles of treatment. However in DA-EPOCH-R arm neutropenia mean period was 16 days when in R-CHOEP arm 11 days; thrombocytopenia period was 11 and 3 days respectively. Septic complications in DA-EPOCH-R arm have been observed in 53% when in R-CHOEP arm in 31%.
Summary/Conclusions: Patients treated with R-CHOEP had shorter periods of neutropenia and thrombocytopenia in comparison with DA-EPOCH-R group, where periods of neutropenia and thrombocytopenia were longer and resulted in higher rate of infectious complications. Considering comparable CR rate in both groups R-CHOP plus low dose etoposide could be effective option with lower hematological toxicity profile in AIDS-related DLBCL with CD4 count less than 100 cells/mm3.

THE PROGNOSTIC IMPACT OF SERUM ALBUMIN IN DOUBLE HIT/DOUBLE EXPRESSING AGGRESSIVE B CELL LYMPHOMAS: A PILOT STUDY EVALUATING SAAB SCORING SYSTEM

C Talati[1,*], J Sandoval-Sus[1], S Dalia[2], B Shah[3], C Bello[3], P Chervenick[3], E Ayala[3], F Locke[3], M Kharfan-Dabaja[4], E Sotomayor[5], L Sokol[3], J Chavez[3]
[1]Moffitt Cancer Center, University of South Florida/Moffitt Cancer Center, Tampa, [2]Mercy Clinic, Mercy Clinic, Joplin, [3]Malignant Hematology, [4]Bone Marrow Transplantation, Moffitt Cancer Center, Tampa, [5]Malignant Hematology, George Washington University, Washington, DC, United States

Background: Double hit lymphomas (DHL) [rearrangements of MYC and BCL2/BCL6, and double expressing lymphomas (DEL) [expression of MYC and BCL6/BCL2 by immunohistochemistry] represent a subset of diffuse large B-cell lymphoma (DLBCL) with poor overall survival (OS). Several prognostic scores have been tested to clinically stratify these patients with the double hit score (DHS) being the most recently developed model (Petrich 2014).
Aims: We explored the use of serum albumin (SA) as prognostic factor in DHL as previously shown in DLBCL (Dalia 2013).
Methods: We included 100 patients from Moffitt Cancer Center database from January 2008 to December 2015 with DHL and performed a retrospective chart review. Recorded clinical data included SA, hemoglobin, age, International Prognostic Index (IPI), DHS, and lymphopenia. Pairwise Cox Comparison was used to develop a weighted scoring system. Kaplan-Meier method with Cox proportional hazard model was used to determine OS.
Results: The median age was 63 (18-87), stage III/IV in 73.1%, bulky disease (>10cm) in 47.4%, B symptoms in 41.67%, CNS involvement in 14.1%, extranodal (EN) involvement in 34.7% of the patients. Patients with DHL and DEL were 60.2% and 39.8%, respectively. The median OS for the cohort was 15 months. Multivariate analysis identified Age >60 (1 point), SA <3.7 (4 points), bulky disease (2 points) and Stage III/IV (1 point) as prognostically significant. LDH and EN dropped from the model. SAAB scoring consisted of 3 groups: Very good (0-2), Good (3-5), Poor (6-8). The 3-years OS was compared among scoring systems (Table 1).

Table 1.

Score (N=100)	3 Year-OS	P-value
SAAB		0.005
Very good (SAAB=0-2)	45%	
Good (SAAB 3-5)	30%	
Poor (SAAB=6-8)	NA*	
R-IPI		0.437
Very Good (R-IPI=0)	100%	
Good (R-IPI=1-2)	30%	
Poor (R-IPI=3-5)	32%	
Double Hit Score (DHS)		0.281
Low (DHS=0)	26%	
Intermediate (DHS=1)	29%	
High (DHS=2 or more)	27%	

**Highest survival was 18 months.*

Summary/Conclusions: Compared to the R-IPI and DHS, the new SAAB score better discriminated prognostic groups in DHL/DEL. Confirmation in a larger and multicenter study is needed to validate these findings. SA might represent a surrogate of comorbid status and worse biology in patients with DHL/DEL.

PB1689

CLINICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA TREATED WITH INTENSE SHORT-PULSE CHEMOTHERAPY, R-CHOP OR R-DA-EPOCH A RETROSPECTIVE OBSERVATIONAL STUDY

K Mors[1,*], S Döring[2], S Fuhrmann[1], C Gerecke[1], H Stein[3], I Anagnostopoulos[4], WD Ludwig[1], A Pezzutto[5], R Ratei[6]
[1]Hematology, Oncology, Helios Klinikum Berlin Buch, [2]Hematology, Oncology, Charite, University Medicine Berlin, [3]Pathology, Pathodiagnostik Berlin, [4]Pathology, Charite, University Medicine Berlin, [5]Hematology, Oncology, Charité University Medicine Berlin, Berlin, [6]Hematology, Oncology, Carl-Thiem-Klinikum Cottbus, Cottbus, Germany

Background: Primary mediastinal large B-cell lymphoma (PMBL) is a locally highly aggressive tumour and accounts for approximately 2.4% of adult non-Hodgkin's lymphoma (NHL). Overall survival rates (OS) between 46 – 79% have been reported but optimal treatment regimens remain to be defined.
Aims: Retrospective, longitudinal assessment of clinical risk factors and outcome of three different treatment regimens for patients with primary mediastinal large B-cell lymphoma.
Methods: We performed a longterm longitudinal retrospective study to analyze the clinical characteristics and the treatment outcome of 63 adult patients with primary mediastinal large B-cell lymphoma in two large hematology departments in Berlin. The study was approved by the Charité Ethic Committee. Between 1996 and 2016 patients were registered at the time of treatment start and data on demographics, clinical features and laboratory parameters were recorded during treatment and follow up. The prognostic impact of IPI-value, pleural or pericardial effusion, LDH, gender and presence of bulky disease was analyzed with univariate analysis with respect to overall survival (OS) and event-free survival (EFS). Survival analyses were performed with the Kaplan-Meyer method and the log-rank test for comparison using SPSSÒ.
Results: Between 1996 and 2016 37 female patients with a median age of 31 years and 26 male patients with a median age of 36 years were registered. Initial presentation in Ann Arbor stage I: 22%, stage II: 41%, stage III: 9% and

stage IV: 28%. B-symptoms: 42%. Bulky disease with a tumor >10cm was present in 36.2% of all patients. Extranodal manifestations were detected in 30% and either pleural or pericardial effusions was present in 56% of all patients. 16 pts. (26%) were treated according to an intensive short-pulse B-NHL type chemotherapy protocol without Rituximab (B-NHL) and 22 patients (36%) with Rituximab (R-B-NHL), respectively. R-CHOP and R-DA-EPOCH was administered in 12 pts. (20%) and 6 pts. (10%), respectively. 4 pts. received either CHOP without Rituximab or R-ACVBP. Almost all patients received adjuvant involved field radiotherapy after completion of chemotherapy, usually with a total dose of 36 Gy. The probability of event-free survival (pEFS) and OS at 5 years for all patients was 73.5±6.7% and 81.3±6.0%, respectively. For 16 pts. treated with a short-pulse B-NHL type protocol without Rituximab 5-year EFS and OS was 64.3±12.8% and 78.7±11.0%, respectively. With the addition of Rituximab the 5-year EFS and OS (22 pts.) increased with this therapy to 79.4±10.7% and 91.7±8.0%, respectively. Treatment with R-CHOP for 12 pts. led to a 5year EFS and OS of 77.1±14.4% and 75.0±15.3%, respectively. 5-year survival analysis for the 6 pts. treated with R-DA-EPOCH was not calculated due to short follow up (Figure1). Except for IPI-value there was no significant prognostic impact of pleural or pericardial effusion, LDH, gender or presence of bulky disease.

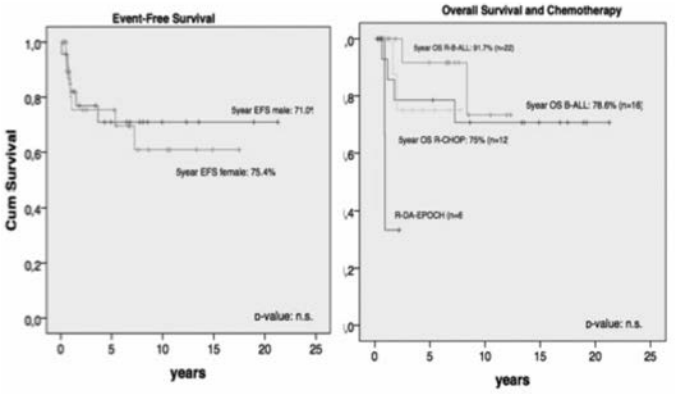

Figure 1.

Summary/Conclusions: The addition of Rituximab to the intensive short-pulse B-NHL type chemotherapy protocol led to an improved 5 year EFS and OS. Treatment with R-CHOP seems to be slightly inferior with respect to clinical outcome. We did not find a higher predilection of young female patients and there was no significant prognostic impact of bulky disease, pleural or pericardial effusion, elevated LDH or gender. The best treatment regimen for this rare entity of B-cell lymphoma remains be determined in a randomized multicenter trial.

PB1690

POSITRON EMISSION TOMOGRAPHY COMPUTED TOMOGRAPHY FEATURES OF TYPE II ENTEROPATHY ASSOCIATED T CELL LYMPHOMA

T Chan[1,*], E Lee[2], PL Khong[2], YL Kwong[1], E Tse[1]
[1]Medicine, Queen Mary Hospital, Hong Kong, [2]Diagnostic radiology, The University of Hong Kong, Hong Kong, Hong Kong

Background: Type II enteropathy associated T cell lymphoma (EATL) is a rare malignancy in the West and the only form of EATL in the East. 18F-fluorodeoxyglucose (FDG) positron emission tomography computed tomography (PET/CT) findings have not been described for type II EATL.
Aims: Type II EATL is increasingly recognized as a separate entity from type I EATL, we report herein the PET/CT findings of in a large cohort of patients, so that more can be known for this new disease entity.
Methods: Consecutive patients with type II EATL diagnosed between January 2008 and July 2015 were studied. The diagnosis was based on typical histopathological and immunophenotypical features. Standard clinical and biochemical evaluations for staging and response assessment were undertaken. Treatment protocols evolved over this period and were heterogeneous.
Results: Six men and four women with type II EATL investigated by PET/CT at diagnosis and relapse were retrospectively analysed. On presentation, the primary involved sites were the small bowel (N=8), stomach (N=1) and large bowel (N=1). The uninvolved small bowel did not show undue FDG-avidity to suggest enteropathy. Distant lymph nodes and organs were involved in four cases (40%). The primary lesions were hypermetabolic except in one case, where the colonic lesion was eumetabolic. At relapse, the stomach and large bowel might be involved even if the primary tumours arose from the small bowel, and multiple extra-intestinal metastases occurred. Interestingly, the lung and the brain were frequently involved (40% and 20% respectively).
Summary/Conclusions: These findings showed that in contrast to classical EATL, where the small bowel is the exclusive primary site (owing to its origin from coeliac disease associated enteropathy) and distant metastases even during relapse are exceptional, type II EATL could on presentation and during relapse involve any part of the gut, and metastasize to multiple extra-intestinal sites. These observations support the proposition of classifying this lymphoma as a distinct clinicopathological entity (monomorphic epitheliotropic intestinal T-cell lymphoma) to differentiate it from classical EATL.

PB1691

THE INFLUENCE OF GENETIC POLYMORPHISMS BCL-2 AND C-MYC IN PATIENTS WITH DLBCL TREATED WITH RCHOP TO ACHIEVE COMPLETE REMISSION

S Sretenovic[1,*], S Mitrovic[2], B Mihaljevic[3], S Đukic[1]
[1]Clinic of Haematology, [2]Center of pathology, Clinical Centre Kragujevac, Kragujevac, [3]Clinic of Haematology, Clinical Centre Srbia, Belgrade, Serbia

Background: Non -Hodgkin's diffuse large B- cell lymphoma (DLBCL) represents a heterogeneous group of aggressive lymphomas, which are characterized by the presence of large, transformed B cells. DLBCL with both translocations C-MYC and BCL-2 provides *double-hit* lymphoma and is characterized by poor response to standard therapy with an aggressive clinical course.
Aims: What is the influence of BCL-2 and C-MYC in DLBCL treated with RCHOP to achive complete remission.
Methods: We analyzed the population of 62 patients primary DLBCL, treated with immunochemotherapy R-CHOP/21 day. Testing BCL-2 and C-MYC was conducted with classical FISH analysis. Complete remission (CR) was defined as the absence of disease after the therapy. We tested the sensitivity and specificity, and statistical analysis was performed in Windows SSPS (22.00), a statistical significance defined as p <0,05.
Results: The study group consisted of 32 men and 30 women, mean age was 59.76+/- 14,38. The patients were in CS III and IV in 81.9%. After applying the first therapeutic line RCHOP, 30 patients or 48.7% achieved a complete remission. The frequency of FISH/BCL2+in the group with complete remission was 40% and in the group without a complete remission of 46.2%. Achieving complete remission was not statistically significantly different between subjects FISH/ BCL-2 positive and negative (χ 2 test, p=0,585). Frequency FISH/C-MYC in the group with complete remission was 36.7%, while in the group without CR it was 43.8%. Achieving complete remission was not significantly different between patients FISH/ C-MYC positive and negative (χ 2 test, p=0,570). The frequency of both positive FISH/ BCL-2 and C-MYC, with the presence of at least one positive polymorphism and negative both, it is not statistically significantly different in comparison to achieving a complete remission (χ 2 test, p=0,600). Respondents with BCL-2 and C-MYC negative were slightly over-represented in the group with the complete remission of 43,3%, compared to the patients without complete remission of 31,3%. A bit higher frequency BCL-2 positive patients 31,3% was observed in group without achieving the complete remission, but in patients with complete remission of 20%. The sensitivity observed in the presence of both polymorphisms as well as the sensitivity of FISH positive BCL-2 or C-MYC findings was the same, about 45%. Specificity was the same in the presence BCL-2 or C-MYC gene polymorphism at about 60%, while it was the lowest in the presence both genetic polymorphism
Summary/Conclusions: In our study, the sensitivity observed in the presence of both or single mutation was the same, about 45%. Specificity in all observed parameters was relatively small, which means that the absence of the observed risk factors does not mean the emergence of the complete remission. The existence C-MYC and BCL-2 is not a good predictor of achieving complete remission in the era of rituximab.

PB1692

ANAPLASTIC LARGE CELL LYMPHOMA IN ADULTS: RESULTS AND NEW APPROACH OF TREATMENT

L Gorenkova[*], S Kravchenko
National Research Centre of hematology, Moscow, Russian Federation

Background: Anaplastic Large Cell Lymphoma (ALCL) represents supgroupe of peripheral T-cell lymphoma and constitutes 10-12% of this groupe. According to WHO classification 2008 ALCL is subdivided by two types depending on presence of *ALK* gene rearrangement: ALK-positive (ALCL ALK+) and ALK-negative (ALCL ALK-). ALCL ALK+has a favorable prognosis with CHOP in patients without adverse prognostic factors and event free survival (EFS) reaches 70-75%. ALCL ALK- has worse treatment results: when using CHOP overall survival (OS) and EFS doesn't reach more than 50%. Autologous stem cell transplantation (auto-SCT) in first complete remission takes an advantage.
Aims: to estimate an efficacy of intensive chemotherapy in treatment of ALCL ALK+and ALCL ALK-
Methods: The study included 64 patients with ALCL (38 ALCL ALK+26 ALCL ALK-)
Results: 36 patients with ALCL ALK+were treated according NHL BFM-90: OS and relapse-free survival were 90% and 83%, respectively, median survival was 67 months. In 16 patients with ALCL ALK- was used NHL-BFM-90 protocol – common response (CO) was achieved in 8 from 16 patients (50%), however 6 patients had disease progression and 3 had a relapse. Thus, OS and EFS were 37,5% and 31% respectively. 8 patients were treated by TL-REZ-09 protocol.

Complete/partial remission were acieved in 4 patients, 3 had disease progression. The highest efficacy was observed in 5 patients underwent auto-SCT in first complete remission: 4 from 5 patients alive in remission and one in relapse.
Summary/Conclusions: Patients with ALCL ALK+have favorable prognosis and high treatment results on NHL BFM-90 protocol. Selection of induction chemotherapy regimen before auto-SCT in patients with ALCL ALK- continue to be unsolved question. In patients who didn't achieve a common response like second line therapy could be DexaBEAM protocol with subsequent auto-SCT.

PB1693

DOSE ADJUSTED REPOCH IN UNTREATED *DE NOVO* DIFFUSE LARGE B CELL LYMPHOMA - A SINGLE CENTRE SINGAPORE EXPERIENCE

ACY Tso*, VS Sampath, KH Ong
Haematology, Tan Tock Seng Hospital, Singapore, Singapore

Background: The current standard of care for untreated Diffuse Large B Cell Lymphoma (DLBCL) remains as Rituximab plus CHOP chemotherapy (RCHOP). Some studies suggested that certain subtypes of DLBCL respond better to dose adjusted REPOCH. However, data comparing the efficacy of RCHOP with REPOCH is scarce.
Aims: To compare the outcome of untreated *de novo* DLBCL of dose adjusted REPOCH chemotherapy with historical controls.
Methods: This is a retrospective analysis of all patients between age 18 – 70 with any stage of treatment naïve *de novo* DLBCL; who received RCHOP chemotherapy between 2009 to 2013, and REPOCH chemotherapy between 2013 to 2016. DLBCLs that were transformed from low grade lymphomas were excluded. Demography, histology, stage, immunohistochemistry biomarkers for cell of origin (GCB *versus* ABC using Hans algorithm), cytogenetics, details of chemotherapy, responses and duration of follow-up were included for analysis. 2 years overall survival (OS) and progression free survival (PFS) were calculated.
Results: 46 evaluable patients were followed up between 2009 and 2016 with 20 in the RCHOP cohort and 26 in the REPOCH cohort. The characteristics between the RCHOP and REPOCH groups were comparable: average age were 54 and 53.9 years respectively, 15 of 20 (75%) and 18 of 26 (69%) patients had stage 3 or 4 disease respectively. 50% and 20% of the RCHOP group; and 73% and 23% of the REPOCH group have the ABC and GCB subtypes of DLBCL respectively. The median follow-up period for the RCHOP and REPOCH groups were 40.5 (range 8 -70) and 16 (range 3 - 35) months. Kaplain Meier survival curves showed that the OS and PFS of REPOCH were greater than that of RCHOP, although they were not statistically significant (OS Log-rank test: z=0.71, p=0.48; PFS Log-rank test: z=1.52, p=0.13). The 2 years OS of the RCHOP and REPOCH groups were 89% and 100% respectively; and the 2 years PFS of the RCHOP and REPOCH groups were 75% and 95% respectively (Figure 1).

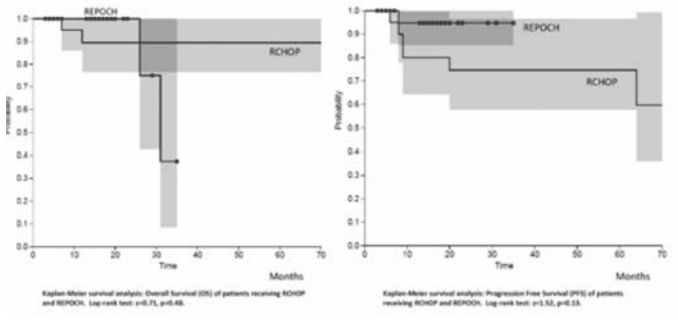

Figure 1.

Summary/Conclusions: In the literature, the GCB subtype is generally more than twice as common as the ABC subtype and confers a better overall outcome. In our institution, the ABC subtype was around 3 times more prevalent than the GCB subtype, suggesting the biology of the disease may differ with ethnicity and imply a more aggressive phenotype. Although our data suggests REPOCH to be superior to RCHOP in treatment naïve *de novo* DLBCL patients, a longer follow-up period may be required to observe a statistical difference in the OS and PFS. Further prospective randomized comparison between these two regimens in the Asian population is warranted.

BASELINE RENAL FUNCTION AS A PROGNOSTIC INDICATOR IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP IMMUNOCHEMOTHERAPY

J Hong[1,*], S Lee[1], J Park[1], JY Ahn[2], JY Jung[1], JH Lee[1]

[1]Department of Internal Medicine, [2]Department of Laboratory Medicine, Gachon University College of Medicine, Incheon, Korea, Republic Of

Background: Recently the prognostic value of baseline renal impairment (RI) has been evaluated in patients with newly diagnosed cancers: baseline RI assessed by blood urea nitrogen showed significant relationship to overall survival (OS) of patients with advanced non-small cell lung cancer (Zhang *et al.,* Int J Cancer 2015;136:382) or to early mortality among patients with resectable pancreatic adenocarcinoma (Sohal, *et al.,* Cancer 2015;121:1779).
Aims: In this study, we evaluated the prognostic value of baseline RI in patients with diffuse large B-cell lymphoma (DLBCL) uniformly treated with conventional three-weekly rituximab plus cyclophosphamide, adriamycin, vincristine, and prednisolone (R-CHOP21) immunochemotherapy in single institution.
Methods: Patients with newly diagnosed *de novo* DLBCL treated with ≥1 cycle of R-CHOP21 were included. Glomerular filtration rate (GFR) was calculated using serum ceratinine level from pre-treatment serum chemistry data and other clinical information. RI was defined as a GFR of <60 mL/min/1.73 m^2according to the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula.
Results: 185 patients treated from Mar. 2006 to Jan. 2015 were included and analyzed. For the median follow up period of 44.1 months (95% CI, 37.5 - 50.7), 53 patients (28.6%) underwent any event and 44 (23.8%) died. 3-year Event-free (EFS) and OS were 71.1% and 76.5%, respectively. Both standard and the NCCN-IPI showed good prognostication. However, NCCN-IPI more efficiently separated patients of low-intermediate *vs* high-intermediate risk compared to standard IPI, and the patients of high risk group according to NCCN-IPI showed poorer OS compared to those according to standard IPI. 19 patients had RI according to CKD-EPI formula: 5 patients had pre-existing CKD, 2 had post-renal acute kidney injury (AKI) caused by DLBCL, and another 2 had hypercalcemia and/or hyperuricemia, suggesting AKI due to the electrolyte imbalance due to lymphoma. We could not define the reason of RI of the other 10 patients: they were aged ≥70 years (range 71 – 89) except 2 patients with 49 and 69 years, respectively. Patients with RI showed inferior OS compared to those without RI (3-yr OS 26.7% *vs* 81.8%, p <0.001). There was no difference of OS between patients with a GFR of ≥90 *vs* ≥60 - 89 mL/min/1.73 m^2 (3-yr OS 82.4% *vs* 76.7%, p=0.436), suggesting that only RI defined by GFR below 60 mL/min/1.73 m^2 is a meaningful prognostic indicator of OS. In multivariate analysis, RI was an IPI-independent prognostic biomarker (Table 1). Among patients with high or high-intermediate risk according to standard IPI, patients with neither anemia of Hb <10 g/dL nor RI had superior OS *vs* patients who had one of them or *vs* those with both of them. These findings were maintained when the analysis was restricted to patients with high risk according to standard IPI. Use of NCCN-IPI instead of standard IPI showed same result.

Table 1. Univariate and multivariate analysis for event-free and overall survival.

Parameters	For overall survival	
	HR* (95% confidence interval)	*p*-value
Univariate analysis		
High-intermediate or high risk by standard IPI†	6.3 (3.3 – 12.0)	< 0.001
Age > 60 years	2.5 (1.4 – 4.7)	0.003
Elevated lactose dehydrogenase	3.6 (1.8 – 7.2)	< 0.001
Ann Arbor stage III or IV	3.6 (1.8 - 7.2)	< 0.001
ECOG‡ performance status ≥ 2	13.0 (6.6 – 25.0)	< 0.001
≥ 2 extranodal sites	4.4 (2.4 – 8.0)	< 0.001
High-intermediate or high risk by NCCN§-IPI	8.3 (4.0 – 17.3)	<0.001
Presence of B symptom	3.4 (1.9 – 6.1)	< 0.001
Bone marrow involvement	5.2 (2.8 – 9.6)	< 0.001
Hemoglobin < 10 g/dL	4.9 (2.7 – 8.9)	< 0.001
Bulky lesion	0.9 (0.5 – 1.9)	0.845
Non-germinal center B-cell type by Hans	1.4 (0.7 – 2.9)	0.376
Renal impairment	5.6 (2.9 – 11.0)	< 0.001
Multivariate analysis; IPI as separate 5 marker		
Elevated lactate dehydrogenase	-	-
ECOG performance status ≥ 2	9.6 (4.7 – 19.4)	< 0.001
Hemoglobin < 10 g/dL	2.5 (1.3 – 4.7)	0.006
Renal impairment	2.3 (1.1 – 4.7)	0.025
Multivariate analysis; with standard IPI as a single marker		
Hemoglobin < 10 g/dL	2.3 (1.1 – 4.5)	0.020
Renal impairment	4.1 (1.9 – 8.6)	< 0.001
High-intermediate or high risk by standard IPI	5.1 (2.5 - 10.1)	< 0.001
Multivariate analysis; with NCCN-IPI as a single marker		
Hemoglobin < 10 g/dL	2.8 (1.5 – 5.3)	0.002
Renal impairment	2.0 (1.0 – 4.2)	0.050
High-intermediate or high risk by NCCN-IPI	5.8 (2.7 – 12.7)	< 0.001

*HR, Hazard Ratio, †IPI, International Prognostic Index, ‡ECOG, Eastern Cooperative Oncology Group, §NCCN, National Comprehensive Cancer Network

Summary/Conclusions: Patients with baseline RI had inferior OS compared to those without RI. Because RI was an independent prognostic factor for OS in multivariate analysis whereas age >60 years (or ≥70 or even ≥75 years instead) was not, RI might have a role of the biological age-indicator of patients with DLBCL and therefore affect to OS. In combination with Hb <10 g/dL, RI enhanced prognostication in patients classified as higher risk group according to either standard or NCCN-IPI.

PB1695

INCIDENCE AND PROGNOSIS OF EPSTEIN-BARR VIRUS-POSITIVE DIFFUSE LARGE B-CELL LYMPHOMA IN VERY ELDERLY PATIENTS (AGED OVER 80 YEARS)

T Tomikawa[1,*], M Tokuhira[1], R Watanabe[1], T Tabayashi[1], Y Tanaka[1],

Y Takahashi[1], Y Kimura[1], M Sagawa[1], T Anan-Nemoto[1], M Higashi[2], JI Tamaru[2], M Kizaki[1]
[1]Department of Hematology, [2]Department of Pathology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Epstein-Barr virus (EBV)-positive diffuse large B-cell lymphoma (DLBCL) of the elderly is a newly-described lymphoproliferative disorder (LPD) as a provisional entity in the 2008 WHO classification. The definition is a clonal B-cell proliferation associated with EBV, age at diagnosis over 50 years, and no secondary immune deficiencies. The prognosis is reportedly significantly inferior compared with EBV-negative DLBCL.
Aims: The aim of this study was to clarify the incidence of EBV infection and its related clinical features in very elderly patients with DLBCL.
Methods: We retrospectively analyzed 190 DLBCL patients diagnosed in our institute from January 2008 to December 2013. Diagnoses were immunohistochemically confirmed and the *in situ* hybridization detection technique for EBV-encoded small RNAs (EBER) was performed in all cases. EBV results were compared with clinical and immunochemical data according to age.
Results: The median age was 70.0 (22.7-97.1) years, and the median follow-up duration was 33.6 (0.2-96.5) months. The average EBER positivity was 4.6% in all patients. The mean EBV positivity of tumor samples in age groups were: 20-49 years (n=25), 0%; 50-59 years (n=32), 3.6%; 60-69 years, (n=38), 3.8%; 70-79 years (n=61), 8.9%; and over 80 years (n=34), 3.4% (1/34). The 5-year overall survival (OS) of all 190 patients was 58.2%, and that of EBV-positive patients (n=8) was 62.5%; the difference was not significant.
Summary/Conclusions: The reported incidence of EBV-positive DLBCL among patients of Asian and Latin American origin ranges from 9 to 15%, and the incidence of EBV-associated LPD increases with advancing age (Castillo JJ, *et al*. Oncologist 2011; 16: 87-96). Only 4.6% of the current DLBCL patients were EBER-positive; the reported peak (8.9%) was in the 70-79 years group, whereas the peak in that group in our cohort was only 3.4%. The immunophenotypic analysis results were similar in each age group, suggesting the patient population of this study was not deviated. In contrast to previous reports, the prognosis for EBV-positive and -negative DLBCL was similar. In conclusion, the characteristics of the EBV-positive DLBCL of the elderly identified in this study differ in several ways from that previously reported, and may be a new subtype of B-cell lymphoma; further studies to examine this possibility are warranted.

PB1696

OLDER PATIENTS WITH DLCLB-SHOULD ALL BE TREATED WITH INTENT TO CURE?

M Purić*, B Živković, D Ristić, N Milanović
Department of medical oncology; Chemotherapy of haematological malignancy and bone sarcomas, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia

Background: The incidence of diffuse large B cell lymphoma (DLCLB) increases in the elderly. Older age is associated with the presence of concomitant disease making the therapy difficult. Concidering the results of earlier studies, age itself should not be a justification for a paliative care decisions or reduced intensity chemotherapy. However, elderly patrients as more fragile, do not always receive the right treatment. So, the best method for identifying non-fit patients is not known.
Aims: To evaluate if Age Adjusted Carlson score (AACS) at diagnosis can predict clinical outcome in older patients with DLCLB receiving the first– line chemotherapy.
Methods: Patients at the Institution for Oncology and radiology of Serbia between 2005 and 2015 who were diagnosed and received first-line chemotherapy for DLCLB, older than 65 years were enrolled. Clinical and treatment data were recorded including AACS at the diagnosis. Survival time was estimated using the Kaplan- Meier (KM) method, and Cox proportional hazard model was used to evaluate the risk factors significance for survival. A p-value <0.05 was considered significant.
Results: 87 patients were included in the study. 23 (26.44%) patients were older than 75 years, 52 (59.77%) were female, 38 (43.67%) were Ann Arbor stage 1 and 2, 28 (32.18%) were International prognostic index (IPI) score 0-1; and 38 (43.68%) were intermediate high or high risk. 44 (50.57%) patients were AACS≤5 and 43 (49.43%) patients were AACS≥6. Extronadal involvement was present in 65 (74.71%) patients at diagnosis. 60 (68.97%) patients were treated with Rituximab. 38 (43.68%) patients received CHOP, 27 (31.03%) mCHOP, 12 (13.79%) CVP and 10 (11.49%) CEOP regimen, with or without Rituximab. Statistically significant difference for overal responce rate (ORR) was registered between CHOP and CVP arm (p=0.004), as for mCHOP and CVP arm (p=0.001). CEOP was not inferior to CHOP (p=0.37) and mCHOP(p=0.47) in term of ORR. Complete responce rate (CRR) was significantly better in CHOP (73.68%), m CHOP (74.07%) and CEOP (80%) groups, than in CVP group (25%). ORR and CRR were better when Rituximab was used (ORR and CRR were 100% and 79.31%/78.26% for RCHOP/RmCHOP, but 88.89%/50% and 55.56%/50% for CHOP/mCHOP). There was no difference in toxicity among chemotherapy regimens. After a median follow-up of 43 months (range, 1-128), median overal survival (OS) times were 91 months (54-not reached) for CHOP, 8.5 months (2- not reached) for CVP. Median OS was not reached for mCHOP and CEOP arm. The CVP regimen was associated with a significantly worse OS and PFS than was the CHOP regimen (p=0.0002) or mCHOP regimen (p=0.0006). CHOP was uncommon in AACS≥6 group (p=0.003). There was no difference between AACS≤5 and AACS ≥6 groups in the frequency of other chemotherapy regimens. ORR was significantly better in AACS≤5 (p=0.005). Median OS were not reached for AACS≤5 and 43 months (20- not reached) for AACS≥6. Patients with AACS≥6 had significantly shorter PFS (p=0.006) and OS (p=0.001) than patients with AACS≤5.
Summary/Conclusions: AACS≤5 was associated with a significant reduction in the risk of death among older patients with DLCLB treated with different chemotherapy regimens. This study suggests that AACS may predict responce to chemotherapy and survival in older patients with newly diagnosed DLCLB. As predictive biomarker and clinical prognostic indicator for OS and PFS, AACS may be useful in defining the group of older DLCLB patients that would have more benefit from best supportive care instead of chemotherapy.

PB1697

THE PROGNOSTIC NUTRITIONAL INDEX AS A PREDICTOR OF PROGNOSIS IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

V Periša[1,*], L Zibar[2], A Knezović[3], I Periša[4], J Sinčić-Petričević[1], I Aurer[5]
[1]Hematology, [2]Nephrology, University Hospital Centre Osijek, Osijek, [3]Community Health Centre Đakovo, Community Health Centre Đakovo, Đakovo, [4]Community Health Centre Vinkovci, Community Health Centre Đakovo, Vinkovci, [5]Hematology, University Hospital Centre Zagreb, Zagreb, Croatia

Background: The prognostic nutritional index (PNI), an indicator of nutritional status and systemic inflammation, is associated with short- and long-term outcomes of various malignancies. The prognostic value of the PNI in diffuse large B cell lymphoma (DLBCL) remains unknown.
Aims: The aim of present study is to determine the prognostic value of baseline PNI in DLBCL patients.
Methods: We retrospectively analyzed data from 76 DLBCL patients treated with R-CHOP or R-CHOP-like regimens. We evaluated the significance of PNI as a predictor of response to treatment, overall survival (OS) and event-free survival (EFS).
Results: Lower PNI levels were found in patients with advanced Ann Arbor clinical stage (47.56±6.97 *vs* 53.28±5.43, *P*<0.001) and in those with poor response to therapy (41.63±6.1 *vs* 51.08±6.11, *P*<0.001). Patients with PNI≤44.55 (cut-off was calculated by receiver operating chararacteristics) had significantly worse 5-year OS (35% *vs* 88.8%, P<0.001, log rank test) and 5-year EFS (28% *vs* 81.3%, *P*<0.001, log rank test). Cox regression analysis showed that PNI≤44.55 was an independent prognostic factor for OS (HR 4.729, 95% CI 1.327-16.854) and EFS (HR 3.024, 95% CI 1.037-18.819).
Summary/Conclusions: PNI is an important prognostic factor in DLBCL, in addition to and independent of the International Prognostic Index. PNI may emerge as a simple, fast, easy to use and inexpensive new prognostic marker for DLBCL patients in routine clinical practice.

PB1698

ROLE OF PET/MRI IN HEMATOLOGIC MALIGNANCIES: PRELIMINARY OBSERVATIONS

GD Mendez de Paz[1,*], A Serrano Maestro[1], ML Bengochea Casado[1], L Garcia Canamaque[2], V Perez Duenas[3], J Perez de Oteyza[1]
[1]Department of Hematology, [2]Department of Nuclear Medicine, [3]Department of Radiology, Hospital HM Norte Sanchinarro, Madrid, Spain

Background: Hybrid imaging using simultaneous PET/MRI could be a valuable diagnostic modality for the staging and follow-up of patients with hematologic malignancies. Since the availability of this technique is currently restricted to a small number of centers, data available in this setting is still limited.
Aims: Our objective is to analyze the results and potential advantages of PET/MRI in hematologic malignancies.
Methods: A total of 30 PET/MRI studies were performed at our institution using a Biograph mMR device. Informed consent, which included use of clinical data, was obtained before every procedure. PET/MRI was performed 45 minutes after injection of 18F-FDG. Images were obtained from orbital region to proximal third femur. Magnetic Resonance was obtained by HASTE sequencing.
Results: A total of 21 patients were studied. Median age was 62 years (range 35-89).Patients' diagnoses were: Diffuse Large B Cell Lymphoma (8 patients); Follicular Lymphoma (3); Multiple Myeloma (2); Primary Central Nervous System Lymphoma (2); Hodgkin Lymphoma (3); Plasmacytoma (1) and other Low grade Lymphomas (2). In 7 patients (23%) PET/MRI was used for initial staging, and in 11 patients (37%) it was used for follow-up, comparing previous results with other staging techniques (CT scan/PET-CT). In 3 patients (12%) the PET/MRI was used to study possible relapse of the disease. In 9 patients (30%) a second PET/MRI was performed for either follow-up (6 patients, 20%), or to evaluate potential relapse (3 patients,10%). Of all procedures performed, PET/MRI was useful for establishing initial stage (6 patients, 20%); confirm response to therapy (14 patients. 46%); and prove disease relapse (3 patients

10%). Finally, in 7 patients (23%) in whom conventional imaging had shown residual disease, PET/MRI was able to demonstrate complete remission.
Summary/Conclusions: Taken together, our results suggest that PET/MRI is a promising technique which may improve diagnostic accuracy, with a reduction of radiation dose in patients with hematologic malignancies. Further studies are needed in order to validate this technique for clinical use.

PB1699

DOSING OF CHEMOTHERAPY IN OBESE ADULT PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES: A SURVEY OF PRACTICE IN THE UK

A Preston[1,*], N Duncan[2], S Robinson[1], J Braybrooke[1]
[1]Bristol Haematology & Oncology Centre, University Hospitals Bristol NHS Foundation Trust, Bristol, [2]Pharmacy Department, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Background: With obesity levels increasing to epidemic proportions, treating obese patients optimally with chemotherapy is a significant issue. There is accumulating evidence of increased cancer risk in obese patients and obesity related co-morbidities can compromise relative total dose intensity, resulting in poorer overall survival in some tumour types.
In 2010 the American Society of Clinical Oncology (ASCO) convened an expert panel to review the literature on chemotherapy dosing in obesity. The panel concluded that up to 40% of obese patients received "capped" doses because of clinicians' concerns regarding toxicity. They concluded that there was no evidence of increased toxicity in such patients and released a Clinical Practice Guideline recommending that obese patients should be dosed on their actual (full) body weight.
Aims: To investigate UK clinical practice in this area and establish whether it has changed as a result of the ASCO Clinical Practice Guideline.
Methods: A questionnaire was completed by 81 specialist cancer services pharmacists from the British Oncology Pharmacy Association. The questionnaire assessed: 1) criteria used for defining obesity, 2) if dose adjusting for obesity was undertaken at individual hospitals and if so what methodology it was based on, 3) if practice had been influenced by the ASCO guideline and 4) what formulae/ methods were being used to assess body surface area (BSA), ideal body weight (IBW) and glomerular filtration rate (GFR).
Bone marrow transplant conditioning and treatment of leukaemia were excluded to reflect ASCO's guideline; treatment of Non-Hodgkins and Hodgkins Lymphoma were included.
Results: Of the 73 pharmacists who fully responded, just less than half (47%) stated that their hospitals follow ASCO's recommendations and dose on actual body weight. The most common reasons for non-adherence included the lack of robust evidence and a need for clinical teams to discuss the guidelines and reach a consensus of how to adapt locally. Of the 53% who confirmed that they reduce doses in obese patients, 30% dose reduced in all obese patients and 70% in selected patients where 'capping' decisions were based on treatment goal (100%) and the pharmacokinetics of the individual drugs (38%).
There was no uniformity in formulae used for BSA, IBW or GFR calculations. Methodology varied for defining obesity, adjusting the dose, assessing GFR and some centres used IBW in GFR formulae, some actual body weight. This lack of uniformity is not unique to the UK and is likely to be a widespread issue.
Summary/Conclusions: Further research is needed to clarify chemotherapy dosing in obese patients to aid clinicians and pharmacists in these decisions. Pharmacokinetic and pharmacogenetic studies would provide a more personalised approach to treatment, and can be undertaken in the context of large prospective trials. Until evidence is available for specific cancers, a unified approach to dosing in obesity based on current guidance should be encouraged.

PB1700

RITUXIMAB DURING INDUCTION THERAPY MIGHT NOT IMPROVE OVERALL SURVIVAL OF VERY ELDERLY JAPANESE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

Y Miyata[1,*], T Yano[2], Y Abe[3], S Okamura[4], M Otsuka[5], M Hidaka[6], K Sunami[7], N Inoue[8], M Sawamura[9], T Ito[10], S Yoshida[11], T Shimomura[12], K Kitano[13], H Iida[1], T Naoe[1], H Nagai[1]
[1]Hematology, Nagoya Medical Center, Nagoya, [2]Hematology, Tokyo Medical Center, Tokyo, [3]Hematology, Kyushu Cancer Center, [4]Hematology, Kyushu Medical Center, Fukuoka, [5]Hematology, Kagoshima Medical Center, Kagoshima, [6]Hematology, Kumamoto Medical Center, Kumamoto, [7]Hematology, Okayama Medical Center, Okayama, [8]Hematology, Osaka Medical Center, Osaka, [9]Hematology, Nishigunma National Hospital, Shibukawa, [10]Hematology, Kure Medical Center, Kure, [11]Hematology, Nagasaki Medical Center, Omura, [12]Hematology, Hiroshima-nishi Medical Center, Otake, [13]Hematology, Matsumoto Medical Center, Matsumoto, Japan

Background: As aging of population is advancing, the number of the elderly patients with diffuse large B-cell lymphoma (DLBCL), most common type of lymphoma, is increasing. In addition to difficulty to treat patients age 80 and over due to comorbidities and poor organ functions, the optimal treatment of these patients with DLBCL remains unclear since there was no well-controlled, randomized trial to confirm clinical benefits of rituximab during induction therapy for these patients, unlike younger patients.
Aims: In this study, we assessed clinical contribution of rituximab during induction therapy on survival of Japanese patients with DLBCL age 80 and over, especially in actual practical setting.
Methods: Previously, we reported that rituximab-containing remission induction therapy improved the outcome of Japanese patients with mature B-cell lymphoma newly diagnosed at 20 National Hospital Organization hospitals from January 2000 to December 2004. A retrospective study was conducted using this database, although it lacks detailed information on treatment, *e.g.* combinations of drugs, dose intensities of each drug, and the number of treatment cycles.
Results: From database, we identified 100 patients age 80 and over (12.5%) from 798 DLBCL patients. Only 15 patients (15.0%) didn't receive an anthracycline-containing regimen, and were excluded from further analyses. This ratio was statistically higher, compared to younger patients ($p<0.0001$). Among 85 patients who received anthracycline-containing regimens, 45 deaths were observed during follow-up period, and 8 deaths (17.8%) were due to other than lymphoma. This was not significant, compared to younger patients ($p=0.859$). Based on administration of rituximab in remission induction therapy, 85 patients were divided into two groups since patients didn't receive rituximab during induction until its approval for DLBCL in September 2003 in Japan. Sixty-two patients (72.9%) were treated without rituximab (R- group) and 23 patients (27.1%) with rituximab (R+group). Median follow-up periods were 38.7 months and 21.8 months, respectively. No significant difference of patient characteristics, age, sex, disease stage, extranodal involvement, B symptom, PS, LDH, IPI and AA-IPI, were observed between two groups. Better response was observed in R+group than R- group (CRR 56.5% *vs* 43.5%, ORR 82.6% *vs* 66.1%), but these differences were not significant ($p=0.3337$ and $p=0.183$ respectively). Estimated 2-year progression-free survival of R+group was significantly higher than R- group (50.4% *vs* 25.6% $p=0.030$), but 2-year overall survival was similar (45.3% *vs* 42.3% $p=0.344$). The same trends were seen when deaths of other than lymphoma were censored ($p=0.260$). R- group was further divided into 2 groups, patients who never received rituximab throughout their lifetimes (R-R- group n=48) and those who received rituximab during salvage therapies (R-R+group n=14). Median survivals of these groups were similar (19.2 months *vs* 21.8 months $p=0.900$), and there was no significant difference from R+group ($p=0.351$ and $p=0.486$ respectively).
Summary/Conclusions: Rituximab during induction therapy didn't improve overall survival of Japanese patients with DLBCL age 80 and over, unlike younger patients. However, later administration of rituximab during salvage therapies could improve prognosis. Large-scale studies are further needed to confirm these results.

PB1701

PROGNOSTIC ROLE OF NTPROBNP LEVELS AT DIAGNOSIS IN ELDERLY PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)

V Bozzoli[1,*], MC Tisi[2], E Maiolo[2], E Alma[2], AM Leone[3], D Francesco[2], S Hohaus[2]
[1]Hematology, Ospedale Vito Fazzi, Lecce, [2]Hematology, [3]Cardiology, Catholic University S. Cuore, Rome, Italy

Background: Immunochemotherapy using the R-CHOP regimen (Rituximab, Cyclophosphamide, Doxorubcin, Vincristine and Prednisolone) represents the standard treatment of elderly patients (pts) with Diffuse Large B Cell Lymphoma (DLBCL), but treatment can be complicated by cardiac side effects often attributed to the cytotoxic drug doxorubicin. NTproBNP levels in plasma are typically increased in patients with left ventricular dysfunction and have been proposed as a marker for cardiac injury during cytotoxic treatment.
Aims: The aim of this study was to investigate the prognostic role of NTproBNP at diagnosis in elderly DLBCL pts.
Methods: We conducted a retrospective analysis, including 130 elderly (≥65 years) pts, median age 74 years (range 65-91), diagnosed with DLBCL from 2009 to 2014 in our institution for whom NTproBNP levels at diagnosis were available. The impact of NTproBNP levels on response and survival was evaluated in 126 patients who either received anthracycline-containing immunchemotherapy (92 pts) or immunochemotherapy without anthracyclines (34 pts). Anthracycline consisted in standard doxorubicin in 52 pts and liposomal doxorubicin in 40 pts.
Results: At diagnosis, 82/130 pts (63%) showed elevated NTproBNP levels. NTproBNP levels correlated positively with age (*p=0.0001*), and creatinine values (*p=0.001*) and negatively with levels of albumin (*p=0.0001*), and hemoglobin (*p=0.0001*). Poor performance status (ECOG ≥2) was associated with higher levels of NTproBNP (*p=0.0004*). Pts with a previous history of hypertension and ischemic heart disease had increased NTproBNP levels (*p=0.006*, and *p=0.02,* respectively). There was no correlation between NTproBNP and left ventricular ejection fraction at diagnosis (Spearman's rank coefficient p=0.7, p_s=-0.05). In a multivariate analysis, albumin levels <4 g/dl retained the significant association with elevated NTproBNP levels (*p=0.004*). Patients with normal NTproBNP levels at diagnosis had a higher probability of complete

responses (91 *vs* 70%, *p=0.02*). Higher NTproBNP levels were associated with inferior event-free and overall survival both in univariate (*p<0.001*) and multivariate analysis including IPI and anthracycline-containing chemotherapy as significant parameters (Table 1).

Table 1. Multivariate Cox regression analysis for event-free survival.

Parameter	Haz. Ratio	P-value	[95% Conf. Interval]
Anthracycline, No vs. Yes	4.200275	0.000	2.040647 8.645453
IPI, 3-5 vs 0-2	2.867061	0.008	1.318712 6.233381
NTproBNP, unit increase	1.000168	0.018	1.000029 1.000307

Summary/Conclusions: NTproBNP levels at DLBCL diagnosis are frequently elevated in elderly patients with DLBCL, predict poor outcome and are associated with a number of patient characteristics reflecting "host-related factors", such as age, history of cardiac injury, performance status and laboratory abnormalities as low hemoglobin and albumin values. Studies on mechanisms that lead to increased NTproBNP levels in addition to wall stress on myocardiocytes are warranted.

PB1702

AGGRESSIVE LYMPHOMA: DEMOGRAPHICS, DIAGNOSTIC PATTERNS AND OUTCOMES IN GROOTE SCHUUR HOSPITAL IN CAPE TOWN, SOUTH AFRICA

C Levetan[1,*], E Verburgh[2], N Novitzky[2], C du Toit[2], Z Mohamed[3]
[1]MEDICINE, [2]Haematology, [3]Oncology, University of Cape Town, Cape Town, South Africa

Background: The high rate of HIV in South Africa led to an increasing incidence of aggressive non Hodgkin lymphoma (NHL) and Hodgkin lymphoma (HL), but also of infection with Mycobacterium tuberculosis (TB) which may mimic lymphoma. We have observed in Cape Town that lymphoma patients present with advanced disease and that their route to diagnosis is often markedly delayed.
Aims: This study describes the demographic distribution of aggressive lymphomas in our Cape Town institution as well as examine survival outcomes as impacted by documented time delays along the diagnostic pathway.
Methods: We studied 163 patients diagnosed and treated for aggressive lymphoma by Radiation Oncology and Haematology at Groote Schuur Hospital Cape Town in 2013/14. We collected diagnostic and outcome data from hospital records and patient interviews. We constructed a pathway to diagnosis as previously described by Howell DA *et al.,* in BMC Hematology 2013 Oct 31;13(1):9. Delays along the diagnostic pathway were divided into three time frames. 1. Patient delay (time from first symptoms until first contact with a medical practitioner) 2. Diagnostic delay (time from first medical contact to diagnostic biopsy). 3. Treatment delay (time from biopsy to referral to our unit and initiation of therapy).
Results: NHL was diagnosed in 122 (74.8%) and HL in 41 (25.2%). In the NHL cohort 29 patients (23.8%) were HIV positive and in HL 18 patients (43.9%), p=0.014. There was no significant association between HIV status and stage at presentation and HIV positive patients did not have a significantly poorer overall survival (OS) (59.6% *vs* 69%, p=0.251). There was, however, a significant association of HIV with progressive disease in the alive group at time of data analysis (8 patients (28.6%) *vs* HIV negative 10 patients (12.5%), p=0.05). HL had better OS compared to NHL (35 (85.4%) *vs* 73 (59.8%), p=0.003). The HL cohort was more likely to present with high-risk disease (80.5%), lymphadenopathy (82.9% *vs* 56.6% p=0.001) and B-symptoms (73.2% *vs* 54.1% p=0.032). Despite presenting at this advanced stage, they waited significantly longer for referral from first doctor's visit to diagnostic biopsy (125 days *versus* 43 days p=0.01) and from first symptoms to treatment (271 *versus* 97 days p=0.004). Investigations for the diagnosis of TB as well as empiric TB treatment had a major impact on this delay. Empiric TB treatment was given to 26% of the HL cohort prior to diagnosis of lymphoma, compared to 4.9% in the NHL cohort (p=0.00). Fine needle aspiration (FNA) was carried out in 63 (61%) prior to excisional biopsy and in 17 (27%) FNAs were repeated. Only 10 of 88 FNA studies (11%) suggested lymphoma. Time delay between FNA and diagnostic biopsy median 22 days (IQR 9.8-64). Longer delay from first doctors visit to referral for diagnostic biopsy was associated with an increased mortality (alive: median 40 days (IQR 23-69), dead: median 64 days (IQR 27-154), p=0.04). This is also true for time from first doctor's visit to treatment (alive: median 59 days (IQR 29-122), dead: median 97 (51-205), p=0.03) and for time from first symptoms until treatment (alive: median 103 days (61-178), dead: median 131 (IQR 73-299), p=0.04).
Summary/Conclusions: In aggressive lymphoma diagnosis the period between first patient contact with a health professional and the diagnostic biopsy is crucial. FNA examination is often the first step in the diagnostic pathway of lymphadenopathy in South Africa due to the high rate of TB and poor access to diagnostic biopsy. This led to an inappropriately long 3-week median delay from first FNA to diagnostic biopsy. These three key areas - use of FNA, poor access to excisional biopsy and treatment with empiric TB therapy – significantly delayed diagnosis resulting in severe consequences with increased patient mortality.

PB1703

TRANSGASTRIC ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION BIOPSY FOR LYMPHOMA DIAGNOSIS OF ISOLATED SPLENIC LESIONS

A Cuccaro[1,*], F Attili[2], F D'Alò[1], A Larghi[2], MC Tisi[1], S Bellesi[1], S Sica[1], LM Larocca[3], S Hohaus[1]
[1]Institute of Hematology, [2]Digestive Endoscopic Unit, [3]Institute of Patology, Catholic University of Sacred Heart, Rome, Italy

Background: Isolated splenic lesions are relatively infrequent, but represent a diagnostic challenge, as tissue sampling for histologic analysis may be difficult, in particular if the size of the lesion is small. Percutaneous image-guided splenic biopsies are rarely performed due to the perceived high risk of hemorrhage that could lead to urgent splenectomy, and diagnostic splenectomy is often preferred as primary diagnostic procedure. Endoscopic ultrasonography (EUS)-guided fine needle aspiration (EUS-FNA) biopsy allows sampling of tissue which is adjacent to the stomach wall. EUS provides a good imaging of the spleen through the gastric wall. There have been only few cases of successful histopathologic diagnoses by EUS-guided splenic biopsies reported in the literature. We report our experience with trans-gastric EUS-FNA in the investigation of patients with isolated splenic lesions suspicious for lymphoma.
Aims: We retrospectively assessed the diagnostic performance and safety of EUS-FNA to elucidate the tissue diagnosis of splenic abnormalities suspicious for lymphoma.
Methods: Between 2009 and 2016, we evaluated nine patients with splenic lesions detected by CT, Positron Emission Tomography (PET) and US in our Institution. We used a linear echo-endoscope and 19/20 gauge needles for transgastric EUS-FNA biopsy. Patients were admitted to the hospital to guarantee an overnight monitoring after the procedure. Platelet counts were in the normal range and INR was <1.5.
Results: The age of the patients was 40–83 year (average 58.6 year); five patients were male and four female. All patients presented focal splenic lesions that varied in size from 17 to 100 mm (average 41 mm). Bone marrow biopsy was negative for lymphoma localization, and lymph node involvement was absent or minimal. There was no evidence of bleeding or other complications related to the procedure after splenic EUS-FNA biopsy. In seven patients tissue sampling was sufficient for a pathological diagnosis (78% sensitivity). Diagnoses were Hodgkin Lymphoma in two patients, and Diffuse Large B-cell Lymphoma (DLBCL) in five patients. Only two patients required further diagnostic procedures, including laparoscopic spleen biopsy in one patient and splenectomy in one patient. In both cases final diagnosis was DLBCL.
Summary/Conclusions: Transgastric EUS-FNA biopsy of splenic lesions is a safe diagnostic procedure with high sensitivity for the diagnosis of lymphoma, reducing the need for splenectomy.

PB1704

THE LYMPHOCYTE COUNT AND THE MONOCYTE COUNT AND THE LYMPHOCYTE TO MONOCYTE RATIO AT DIAGNOSIS WERE A PROGNOSTIC PARAMETERS IN DIFFUSE LARGE B-CELL LYMPHOMA: RESULTS FROM A LARGE MULTICENTER STUDY

A Bekadja[1,*], H Touhami[2], Z Zouaoui[3], N Mesli[4], N Mehalhal[5], A Bachiri[6], M Talbi[7]
[1]Hematology and cell therapy, University hospital Oran, [2]Hématologie, CHU Oran, Oran, [3]Hématologie, CHU Bel Abbès, Bel Abbès, [4]Hématologie, CHU Tlemcen, Tlemcen, [5]Hématologie, EPH Mascara, Mascara, [6]Hématologie, HMRU Oran, Oran, [7]Hématologie, CHU Béchar, Béchar, Algeria

Background: There is increasing evidence that tumor microenvironment and host immunity play an important role in lymphoma progression. The absolute lymphocyte count (ALC) and the absolute monocyte count (AMC), calculated from the complete blood count, were considered a surrogate for host immunity.
Aims: The aim of this collaborative multicenter study was to verify the prognostic significance of ALC, AMC and ALC/AMC ratio in a large cohort of newly diagnosed patients with DLBCL and we also examined whether ALC and AMC could be utilized as a simple Independent prognostic factors for survival.
Methods: It is a retrospective and multicenter study carried-out by seven hematology departments in the western of Algeria. 467 patients with DLBCL had been diagnosed during an eight years period (2007-2014). All patients, older than 16 years, were included in the study. The median age at the diagnosis was 54 years (16 to 89). There were 265 males and 202 females. The localized stage (I-II) was 43% and the advanced stage (III-IV) was 57%. The performans status (PS≥2) was 41%. LDH increased level in 47%. The number of extra-nodal involved sites was as follows: 0=26%, 1=43%, 2=19%, ≥3=12%. The IPI score were as follow: low risk=41%, intermediate low risk=23%, intermediate high risk=24% and high risk=12%. The IPI-R score were as follow: very good=11%, good=52%, bad=37%. The overall survival (OS) and progression free survival (PFS) were calculated according to Kaplan and Meier method and the survival curves were compared using the Log Rank test. The multi-factorial survival analysis was performed by the use Cox regression test. The end point date was the December the 31st 2015. The median of follow up was 24 months (6-109).
Results: The mono-factorial analysis of OS (comparison of the survival curves)

showed: Age (≥60 *vs* <60) (p=0.5); sex (M *vs* F) (p=0.04); Performans Status (0-1 *vs* ≥2) (p=0.06); the Ann Arbor (localized *vs* advanced stage (p=0.008). Bulky *vs* no Bulky (p=0.32); B symptoms (A *vs* B) (p=0.05); LDH (Normal *vs* Increased) (p=0.4); IPI score (p=0.046); IPI-R score (p=0.16- p=0.002 and p=0.001); ALC (>1000µl *vs* <1000µl) (p=0.082); AMC (>630/µl *vs* <630/µl) (p=0.001). ALC/AMC ratio (≥2.11 *vs* <2.11) (p=0.001). The mono factorial analysis of PFS showed: Sexe (p=0,247); PS>=2 (p=0,325); the Ann Arbor localized *vs* advanced stage (p=0,089); IPI score (p=0,709); IPI-R score (p=0,581); LDH>Normal *vs* Increased (p=0,465); AMC >630 (p=0,778); ALC>1000 (p=0,155) and the ALC/AMC ratio ≥2.11 *vs* <2.11(p=0, 03). The multi-factorial analysis of the overall survival showed that the most discriminative prognostic factors were: Age>60 years old (HR=1.77, p=0.002); Female sex (HR=0.58, CI 95% 0.41-0.82, p=0.002); PS<2(HR=0.58, CI 95% 0.41-0.81, p=0.002), ALC>1000 (HR=1.28 IC 95% 0.68-2.42, p=0.043), AMC>630 (HR=0.72 IC 95% 0.45-1.15, p=0.018), ALC/AMC ratio>11 (HR=1.54 IC 95% 0.72-3.02, p=0.02).
Summary/Conclusions: This study shows that a simple parameters like absolute lymphocyte count (>1000/mm3) and monocyte count (>630/mm3) and the lymphocyte to monocyte ratio at the diagnosis can easily be used routinely in the evaluation of newly diagnosed diffuse large B-cell lymphoma to identify high –risk patients with a worse survival in the rituximab era.

THE ABSOLUTE MONOCYTE AND PLATELET COUNTS IN PRIMARY GASTRIC DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH RITUXIMAB AND CHOP

B Spassov*, D Vassileva, S Nikolov, P Ganeva, G Mihaylov, G Balatzenko, M Guenova
NSBALHZ, Sofia, Bulgaria

Background: Primary gastric lymphoma (PGL) accounts for 3% of gastric malignancies and 10% of lymphomas. The most common histological subtype of PGL is the primary gastric diffuse large B cell lymphoma (PGDLBCL). The standard of care of PGDLBCL patients (pts) is the combination rituximab-CHOP immunochemotherapy (R-CHOP). Recently serum albumin (SA), β2-microglobulin (B2M), hemoglobin level (Hb), absolute neutrophil (ANC), lymphocyte (ALC), monocyte (AMC) and platelet counts (PC) etc have been introduced into the clinical practice for better pts' stratification. However the data regarding the prognostic significance of these markers are limited.
Aims: Therefore, we decided to access the possible prognostic impact of SA, B2M, Hb, ANC, ALC, AMC and PC in R-CHOP treated PGDLBCL pts.
Methods: We retrospectively reviewed the clinical outcome of 42 R-CHOP treated PGDLBCL pts with median age 56.7 years and 54.76% male. The laboratory levels of SA, Hb, ANC, ALC, AMC and PC were recorded. Serum B2M levels were measured radioimmunologically. The best cut off values of SA, B2M, ANC, ALC, AMC and PC to predict overall survival (OS) by Kaplan-Meier method were calculated by a receiver operating characteristic (ROC) curve analysis. Univariate and multivariate analyses were performed by the log rank and Cox proportional-hazards methods, respectively.
Results: The estimated 5-year OS of the whole group was 80.9%. The median values of SA, B2M, Hb, ANC, ALC, AMC and PC were 39.1 g/L, 2.95 mg/L, 121 g/L, 4.69 G/L, 1.79 G/L, 0.51 G/L and 324 G/L, respectively. By applying the best cut off values of SA, B2M, Hb, ANC, ALC, AMC and PC that were 33.9 g/L, 2.6 mg/L, 105 g/L, 6.12 G/L, 1.77 G/L, 0.518 G/L and 335 G/L, respectively, it was observed that only Hb, ANC, AMC and PC correlated with OS. The independent prognostic significance, however, was confirmed in multivariate analysis only for AMC and PC (hazard ratios 15.482 and 13.525; p=0.012 and p=0.017, respectively). The dichotomized AMC and PC generatedthe AMC/PC prognostic index (PI) and stratified patients into3 risk groups: very good (AMC <0.518 G/L and PC <335 G/L),good (AMC <0.518 G/L or PC <335 G/L) and poor-risk (AMC ≥0.518 G/L and PC ≥335 G/L) populations. For both the very good and good-risk groups median OS has not been reachedwith estimated 5-year OS of 100% and 86.4%, respectively whereas the median OS for poor-risk pts was 4 months with an estimated 5-year OS of 28.6% (p<0.001).
Summary/Conclusions: AMC and PC are independent prognostic markers to predict survival in PGDLBCL patients. AMC/PC PI could provide additional prognostic information for better stratification of these pts.

PB1706

TWENTY YEARS' EXPERIENCE OF TREATMENT OF ADOLESCENTS AND YOUNG ADULTS WITH NON-HODGKIN LYMPHOMA – A SINGLE CENTER EXPERIENCE

R Ratzon[1,2,*], S Tzadok[2], P Raanani[1], R Gurion[1,2]
[1]Institute of Hematology, Davidoff Cancer Center, Beilinson Hospital, Rabin Medical Center, Petah Tikva, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Adolescents and young adults (AYAs) with non-Hodgkin lymphomas (NHL) comprise a unique group of patients, under-represented in clinical trials. Furthermore, the prognosis of these patients is inferior to that of younger patients with hematological malignancies. Therefore, many questions regarding the biology and treatment strategies of this group remain unanswered.
Aims: We aimed to determine the characteristics of AYA NHL patients in the last 20 years in a single tertiary center. Also, we intended to identify risk factors for poor prognosis in this population.
Methods: We reviewed retrospectively the database of our NHL patients at the Rabin Medical Center between the years 1995-2014 and identified patients who met the following criteria: age 18-40 years old, a confirmed histological diagnosis of NHL and treatment in our institution, with at least one year follow-up. In order to define prognostic factors we used the Mann-Whitney U test to compare between the group of patients with poor outcome and those with better outcome. 3-year event free (EFS) and overall survival (OS) were calculated according to the Kaplan-Meier analysis.
Results: A total of 85 patients with confirmed diagnosis of NHL were included in this study. Median age was 32 (range, 18-40) years with 42% male. 74 patients (87%) were diagnosed with aggressive lymphoma and 11 (13%) with indolent lymphoma. The histologic subtypes included diffuse large B-cell lymphoma - 50%, primary mediastinal B-cell lymphoma - 28%, Burkitt lymphoma - 9%, follicular lymphoma - 12%, marginal zone lymphoma - 1%. Due to the small number of patients with indolent lymphoma, this group of patients was not analyzed. B symptoms were present in 32 patients (43%) and 48 had bulky disease (68%). More than half of the patients had advanced stage disease. The IPI score was low (0-1) in 40 patients (56%), low-intermediate (2) in 12 patients (17%) and intermediate-high (3) in 19 patients (27%). Half of the patients were treated with CHOP like regimen (CHOP, R-CHOP, CHOEP), 30% were treated with MACOP\VACOP-B with or without rituximab and 16% received intensive regimens (hyper-CVAD & GMALL). Most patients (74%) received rituximab as part of their treatment regimen. 92% of the patients achieved complete remission (CR), 19% of them relapsed. 14 patients (19%) underwent stem cell transplantation: 12 autologous and 2 allogeneic. Overall, 7 patients died during follow - up, 6 of them with DLBCL and 1 with PMBCL. All died due to progressive disease. 3-year EFS and 3-year OS for the whole group was 74% and 90%, respectively, for patients with DLBCL-67% and 86%, respectively and for patients with PMBCL- 90% and 96%, respectively (Figure 1). The results of Mann-Whitney U test revealed that the group of patients with worse outcome had higher IPI (p=0.03), higher aaIPI (p=0.03) and lower use of rituximab in the treatment regimen compared to those with better outcome (p=0.05).

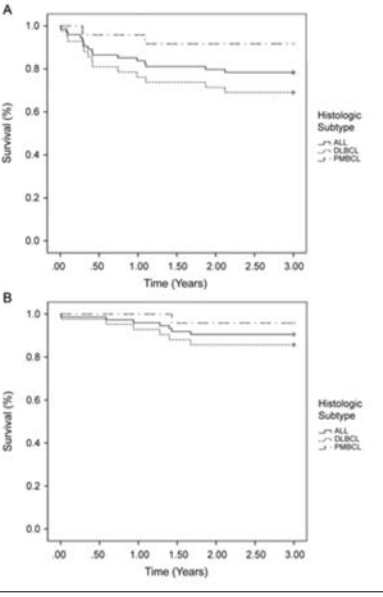

Figure 1.

Summary/Conclusions: In our cohort of AYA patients with NHL, DLBCL was the most frequent subtype of lymphoma followed by PMBCL. This is in accordance with previous reports. The 3 year EFS and OS of AYA patients with DLBCL in our cohort were lower or similar to other studies of AYA patients while results for patients with PMBCL were superior to those in the literature. The aaIPI/IPI score was validated in our cohort as a reliable prognostic index. As in adults, the inclusion of rituximab in a combined regimen was associated with better outcomes than chemotherapy alone.

PB1707

PRETREATMENT CRP LEVEL IN DLBCL PATIENTS: AN IMPORTANT PREDICTOR OF TREATMENT RESPONSE IN RESOURCE CONSTRAINT SETTINGS

N Jain[1,*], G Prakash[1], MU Sachdeva[2], P Malhotra[1], N Varma[2], S Varma[1]

[1]Clinical Hematology, [2]Hematopathology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: The currently available prognostic model for Diffuse Large B Cell Lymphoma (DLBCL) is not sufficient to predict the outcome of this heterogenous group of DLBCL. There is a need to find better prognostic markers for optimal risk stratification of DLBCL patients.
Aims: This study aimed to evaluate the prognostic significance of proinflammatory markers in pretreatment peripheral blood sample of patients of DLBCL.
Methods: We measured levels of CRP and Th1 and Th2 cytokines (IL2, IL4, IL6, IL10, IFN gamma and TNF alpha) in the pretreatment serum of 46 newly diagnosed DLBCL patients and in 10 healthy controls. CRP was measured by nephelometry and cytokines were measured using flowcytometric bead array assay. We compared the levels of these proinflammatory markers between cases and control groups. We evaluated the correlation of levels of these proinflammatory markers with disease characteristics like B symptoms, Ann Arbor stage, IPI and with treatment response.
Results: The median age of cases was 55 years (range 13-80 years) while that of controls was 46 years. Among DLBCL patients 72% were males and 28% were females. According to the IPI scoring the low, intermediate and high risk groups comprised of 28%, 28%, and 44% patients respectively. Of the 41 patients who received treatment, 58% achieved CR, 12% achieved PR and 24% had progressive disease respectively after frontline treatment with chemotherapy. In this study we found that the levels of CRP, IL4, IL6, IL10 and IFN gamma were significantly elevated in DLBCL patients as compared to the control group as shown in Table 1. The pretreatment serum level of CRP in DLBCL patients was significantly elevated in those with B symptoms and high risk IPI group as compared to those without B symptoms and low risk IPI respectively. It was also noted that IL2 showed a significant inverse correlation with stage and IPI of DLBCL patients. The median serum value of CRP was 30.5mg/l and 81mg/l in patients who achieved complete remission (CR) and those who did not achieve CR respectively after the frontline chemotherapy (p value - 0.007). The median serum level of IL6 was 31.5pg/ml and 14pg/ml respectively in those who achieved overall response (OR) and those who did not achieve. Thus OR was significantly lower in those patients with elevated IL6 (p value - 0.05).

Table 1. Comparison of cytokine levels between cases and controls.

Cytokine	Cases(n 46) Median (Range)	Controls(n10) median	Cases Mean ± SD	Controls Mean +SD	P Value*
IL2 pg/ml	0 (0 – 8)	1.48 (0 – 5.29)	1.30 ± 1.82	2.34 ± 1.24	0.414
IL4 pg/ml	1 (0 -8)	0 (0 -2)	1.77 ± 2.04	0.16 ± 0.53	**0.002**
IL6 pg/ml	15 (0 -8625)	1.50 (0 -4.67)	220.11 ± 1268.96	1.96 ± 1.45	**<0.001**
IL10 pg/ml	4 (0 – 181)	0.63 (0 – 1.21)	19.88 ± 41.75	0.54 ± 0.50	**0.001**
TNF alfa pg/ml	0 (0 – 419	0 (0 -4.02)	10.85 ± 61.82	0.40 ± 1.27	0.175
IFNgamma pg/ml	1.45 (0 – 24.69)	0 (0 - 0)	2.30 ± 4.07	0	**0.001**
CRP mg/l	44.5 (1 – 338)	1.95 (1 - 5)	82.30 ± 87.13	2.34 ± 1.24	**<0.001**

*Mann Whitney U Test

Summary/Conclusions: Pro inflammatory markers can be used to predict treatment outcome in DLBCL patients. Our work concludes that there is alteration in cytokine profile of patients with DLBCL with inclination towards heightened Th2 response. CRP has shown a significant correlation with adverse disease characteristics and treatment response. It can emerge as a readily available and cost effective prognostic marker to predict treatment response in DLBCL patients especially in resource constraint settings.

PB1708

PROGNOSTIC IMPACT OF MYC/BCL-2 PROTEIN OVEREXPRESSION IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN THE RITUXIMAB ERA: A SINGLE-INSTITUTION EXPERIENCE

L García-Sanchis[1,*], F ANTONIO[2], T Anabel[3], P Jose Luis[3], S Carlos[3], TM Jose[3]
[1]Hemathology, Hospital General Castellón, Castellón, [2]Pathology, [3]Hematology, Hospital Clinico de Valencia, Valencia, Spain

Background: Protein overexpression and rearrangements of myc and bcl-2 genes have been related with an adverse prognosis in diffuse large B-cell lymphoma (DLBCL) patients in the rituximab era. But data are not always consistent and sometimes contradictory.
Aims: To analyze the incidence of MYC and BCL2 protein overexpression in DLBCL as well as to evaluate the prognostic impact in terms of time to progression (TTP) and overall survival (OS).
Methods: We carried out a single institution study with tissue biopsies obtained from patients diagnosed of DLBCL in the period 1994-2011. Tissue fixation and processing were performed using standard methods. Tissue microarrays (TMAs) that contained two representative 2-mm cores from each tumor were prepared. Immunohistochemical stainnings were performed using fully automated protocols. We used the following antibodies: MYC (clone Y69;Roche), BCL2 (clone 124; DAKO). The cut-off level for BCL2 and MYC expression was 50% and 10% respectively. MYC and BCL2 expression were evaluated by an pathologist expert as well as an hematologist. At the same time, MYC and BCL2 expression was evaluated using computerized image analysis with Image Pro Plus 6.0. A mean number of 1000 cells were analyzed per case. TTP and OS curves were built by the Kaplan_Meier method and compared by the log-rank test. Impact of TTP and OS was studied by the Cox regression test. Results: 140 DLBCL patients were included, median age was 70 (23-76), male/female ratio 73/67, Ann Arbor stage III or IV: 73 (52%), high LDH 72 (51%), high β2-microglobulin 62 (44%) low risk IPI 53 pt, int-low 26pt (19%), int-high 31pt (23%), high 28pt (20%) IPI ≥3: 59pt (42.1%). 45 patient were treated with CHOP-like regimens and 95 with rituximab-CHOP schedules. Median follow-up (alive pts) was 49 months(12,135).
Results: We observed MYC overexpression (≥10%) in 101pt (72%), BCL2 overexpression (≥50%) in 71pt (50%) and both in 56pt (40%). We did not observe any correlationship between MYC, BCL2 or both overexpression and clinical-biologic baseline characteristics. Patients with MYC and BCL2 overexpression had a lower complete response rate than the rest: 62% *versus* 76% (p=0.09). Patients with both markers had a worse 5 year TTP: 67% *versus* 83% (p0.09) and also a worse 5 year OS: 60% *versus* 79% (p0.05),. When we restricted the analysis to the rituximab-treated patients, patients with both markers had a worse 5-y TTP and OS than the rest (57% *vs* 73%, p=0.05) and (58% *vs* 85%, p=0.002). In the multivariate analysis including the IPI variable and myc/bcl-2, myc/bcl-2 overexpression showed an independent prognostic value on OS, HR 3,876(1.58, 9.51), p=0.003.
Summary/Conclusions: In our experience the protein overexpression of MYC and BCL-2 had a negative impact on the outcome, specially in the rituximab era with a lower CCR and a significant worse TTP and OS. Further studies on these area are required.

PB1709

DOUBLE - HIT NON- HODGKIN'S LARGE B-CELLS LYMPHOMAS IS MORE FREQUENT THAN WE THINK, BUT IPI SCORE IS NOT THE PREDICTOR GOOD ENOUGH TO RECOGNIZE THIS TYPE OF LYMPHOMA

S Sretenovic[1,*], S Mitrovic[2], B Mihaljevic[3], D Jovanovic[1]
[1]Clinic of Haematology, [2]Center of pathology, Clinical Centre Kragujevac, Kragujevac, [3]Clinic of Haematology, Clinical Centre Serbia, Belgrade, Serbia

Background: Diffuse large B-cell lymphoma (DLBCL) exhibits various morphologies, immunophenotypes, genetic aberrations, and clinical courses. These features vary across geographic regions, suggesting geographic heterogeneity as a characteristic of this type of lymphoma. DLBCL constitutes 31–34% of all non-Hodgkin's lymphomas in western countries, but in poor countries up to 50%. DLBCL is classified as the lymphoma with different entity in the recently published classification of the World Health Organization (WHO classification). Double-hit lymphomas (DHLs), as currently defined by the World Health Organization classification, are those lymphomas expressing the co-occurrence of *MYC* and *BCL2* or *BCL6* rearrangement as detected by fluorescence *in situ* hybridization (FISH) or standard cytogenetics.
Aims: Is the IPI score good predictor for recognize Double Hit in DLBC lymphomas.
Methods: We studied 62 patients with *de novo* DLBCL over the last six years and investigated the prognostic relevance of BCL-2 and C-MYC rearrangements positivity found by FISH. The prognostic significance of BCL-2 and C-MYC expression was evaluated within the context of DLBCL different subtypes and IPI score, but all treated with R-CHOP/ 21 day. Statistical analysis was performed by *SPSS for Windows (22.0*) and significance of p<0,05.
Results: We studied 62 patients with DLBCL, male 32 and female 30, mean age was 59,76+14,38 year. 58% of patients had high and intermediate high IPI score, whilst 42% of patients had low IPI score. With CS IV and III was 82% and only 18% had CS I and II. Patients with BCL-2 and C- MYC positivity found by FISH (13/62) – double hit, had a bad outcome and median OS was only 14 months. ECOG performance status 0 and 1 had 71% patients. No statistically significant differences in the frequency of BCL-2+between the group with low *vs* high IPI risk, (χ2-test, p=0,492). There was no statistically significant difference in the incidence of C-MYC+between the group of high and low IPI risk, (χ2-test, p=0,426). Intergroup analysis of the group of high *vs* low risk IPI, both positive, both negative or at least one negative gene polymorphism did not show statistically significant difference,(χ2-test, p=0,884).
Summary/Conclusions: Although currently available techniques such as

immunohistochemistry may still be used, whole genomic analytic techniques like FISH will likely play a major role in the evaluation of patients in the future to determine optimal personalized treatment, but FISH is exspensive and IPI score is not good enough to recognize double-hit.

PB1710

EFFICACY OF GEMCITABINE AS SALVAGE THERAPY FOR RELAPSED/ REFRACTORY AGGRESSIVE NON HODGKIN LYMPHOMA PATIENTS

M Zlotnick[1], A Avigdor[2], E Ribakovsky[2], A Nagler[2], M Kedmi[2,*]
[1]Department of Medicine E, [2]Division of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center, Ramat Gan, Israel

Background: High-dose therapy with stem-cell support (ASCT) is the standard treatment for relapsed non-hodgkin lymphoma (NHL), but is not feasible for elderly or frail patients. Gemcitabine-based salvage regimens were previously shown to be an effective treatment option with response rates as high as 80% accompanied by a relatively benign toxicity profile. Our local policy is to use these regimens either for frail patients that are not eligible for ASCT, or for relapse post ASCT.
Aims: Since we had the clinical impression that our success rates are lower than the reported, we decided to retrospectively analyze the outcome of NHL patients that were treated with gemcitabine-based regimens in our institute.
Methods: Based on local pharmacy query we annotated 35 patients that were treated with gemcitabine-based regimens between 1/2007-1/2015 for relapsed/refractory aggressive NHL. Clinical features and outcomes were evaluated using thorough medical record review. Statistical analysis was done using Chi square test and Kaplan-Meier method.
Results: The study cohort included 23 males and 12 females. Median age was 67.2 (28-83). Median follow-up from gemcitabine initiation was 8.7 months (0.4-48.7). The most frequently used protocol was gemcitabine-oxaliplatinum (77%, n=27). Eighty percent of patients (n=28) received full dose while 20% (n=7) received reduced dose regimens. Twenty-seven patients had B cell and 8 had T cell lymphoma. All patients received a median of 2 prior regimens (1-5), of which at least 1 was anthracycline-based therapy. Seventeen patients (49%) had relapsed while 18 (51%) had refractory disease. Overall response rate (ORR) was 37%, with 29% (n=10) CR, 8% (n=3) PR, and 63% (n=22) PD or SD. Of the 13 responders, 8 patients (61%) experienced relapse or progression during follow up. Median PFS was 61 days (range 12-1318), median OS was 23.7 months (0.4-48.7). Sixteen patients (45%) deceased during follow up. Grade 3-4 hematological-toxicity was reported in 17 patients (49%). Hospitalization due to treatment induced toxicity occurred in 12 patients (34%). Eight due to infections, 2 due to bleeding, 1 due to trauma and 1 due to abdominal pain. Several factors were tested as predictors of PFS: number of previous treatement regimens, dose intensity (full *vs* reduced), cell of origin, length of prior remission and relapsed *vs* refractory disease. The only predictor for better PFS was relapsed *vs* refractory disease (median 151 *vs* 41 days p=0.017) (Figure 1).

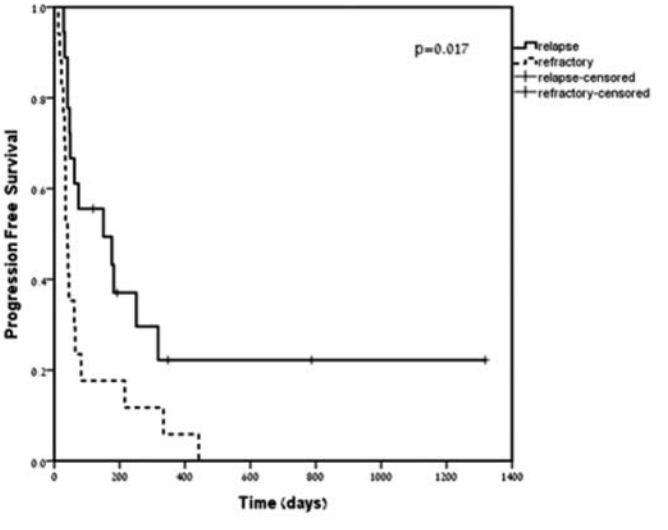

Figure 1.

Summary/Conclusions: compared to previous published data in relapsed/ refractory aggressive NHL, we observed less favorable outcome along with worse toxicity. Although ORR was 37%, the median PFS after gemcitabine-based regimens was dismal (61 days). The only predictor for better PFS was relapsed as oposed to refractoy disease. Notabely, the 4 long term survivors were all treated in first (n=3) or second relapse (n=1) and received full dose regimen. Our single institution results are inferior than the published literature. The admnistration of gemcitabine based therapy as salvage regimen for patients with relasped /refractory NHL was with limited success. Innovative therapies are urgently in need for this devastating patient population as well as randomized studies.

PB1711

EFFICACY OF ESHAP REGIMEN IN THE ABSENCE OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN RELAPSED/REFRACTORY T-CELL LYMPHOMA

L Norasetthada*, A Tantiworawit, T Rattanathammethee, S Hantrakool, C ChaiAdisaksopha, E Rattarittamrong
Division of Hematology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: After relapse, prognosis of patients with peripheral T-cell lymphoma (PTCLs) was poor. Currently, there was no standard salvage regimen for PTCLs. ESHAP regimen, consisting of etoposide, methylprednisolone, high-dose Ara-C, and cisplatin, is one of the well accepted regimens for relapsed or refractory (R/R) lymphoma. However, the efficacy of ESHAP have been examined in the cohorts of various subtypes of R/R NHL, not specifically described the outcome in those with PTCLs.
Aims: The purpose of this study was to determine the efficacy and safety of ESHAP as first salvage regimen, not followed by stem cell transplantation (SCT), in R/R PTCLs.
Methods: According to institute's treatment plan, ESHAP was recommended as first salvage regimen for R/R PTCLs. We retrospectively evaluated the efficiency and safety of ESHAP in patients with PTCLs who progressed after one prior therapy and did not undergo salvage SCT. Disease status at first relapse/progression was categorized as early relapse (relapsed within 12 months after the completion of frontline therapy), late relapse (relapsed after 12 months of frontline treatment) and refractory disease (achieving less than partial response after frontline chemotherapy).
Results: From 2004 to 2014, 33 patients with R/R PTCLs received ESHAP as first salvage regimen at Chiang Mai University hospital. Overall response rate was 46% with complete responses (CR) of 39%. Median duration of response was 18 months with the longest duration of 131 months. Patients with PTCL-NOS, the most common subtype treated in this cohort (n=18), had ORR of 50% (CR/CRu 44%). None of the patients with HSTL and EATL type II responded to ESHAP. Reponses were independently influenced by disease status at first relapse/progression (Odd ratio; OR 2.7, 95%CI: 1.46-5.15) and secondary IPI (OR 2.12, 95%CI: 1.06-4.29). Median second progression-free (PFS) and overall survival (OS) were 8.0 and 11.0 months, respectively. Patients having late relapsed disease after frontline treatment had more favorable OS than those having early relapsed or refractory disease with a median OS of 21, 17 and 3 months, respectively (*P*=.001). The corresponding figures for median second PFS were 16, 8 and 2 months, respectively (*P*=.001). Patients achieving CR after ESHAP had significantly better median OS (39, 7 and 5 months, *P*<.0001) and second PFS (33, 2 and 2 months, *P*<.0001) than those achieving PR or having progressive disease. By multivariate analysis, the only factor affected OS was the response to ESHAP (HR 4.7, 95%CI 2.2-10.0, P<.0001) while second PFS was affected by the response to ESHAP (HR 5.9, 95%CI 2.4-14.6, *P*<.0001) and disease status at relapse/progression (HR 3.4, 95%CI1.2-9.7, *P*-value=.025). Grade 3-4 neutropenia (45.5%) and thrombocytopenia (33.4%) were common but manageable. Grade I-II transient rising of serum creatinine was observed in 36.4% of patients.
Summary/Conclusions: ESHAP has acceptable efficacy and toxicity for R/R PTCLs. It offers a long-term survival in patients with chemosensitive relapse who are not suitable for SCT.

PB1712

PRALATREXATE IN COMBINATION WITH BORTEZOMIB FOR RELAPSED OR REFRACTORY PERIPHERAL T CELL LYMPHOMA IN ELDERLY PATIENTS: A PILOT TRIAL

SS Lee*, SH Jung, JS Ahn, YK Kim, JJ Lee, HJ Kim, DH Yang
Department of Hematology and Oncology, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of

Background: Peripheral T cell lymphoma (PTCL) is a heterogeneous group of aggressive lymphoma with poor prognosis and there is no efficacious standard regimen for the relapsed or refractory disease. Particularly, elderly patients generally have impaired bone marrow function, altered drug metabolism, comorbidities, and poor functional status. Therefore, the treatment of elderly patients with relapsed or refractory PTCL remains a challenge for clinicians.
Aims: A recent report demonstrated that the combination of pralatrexate and bortezomib enhanced efficacy compared with that of either agent alone *in vitro* and *in vivo* models of T cell malignancy. Hence, we performed a pilot study that evaluated the response rate, duration of response and safety profile of this combination regimen in elderly patients with relapsed or refractory PTCL.
Methods: Five elderly patients (age ≥65 years) with relapsed or refractory PTCLs, who progressed following one or more prior chemotherapy, were investigated. The histological subtypes were consisted of 2 PTCL-NOS, 2 AITL, and 1 NK/T cell. Two patients were previously treated with methotrexate-containing chemotherapy. Pralatrexate (15 mg/m^2) and bortezomib (1.3mg/m^2) were administered intravenously on day 1, 8 and 15 and repeated every 28 days for 4 cycles. Concomitant medications were included that vitamin B12 (1 mg) was

injected within 14 days before pralatrexate infusion and oral 45mg of leucovorin was taken during entire days of chemotherapy. The interim and final response were assessed according to the revised International Workshop Criteria (IWC).
Results: All 5 patients are men with median age of 71 years (range: 67 – 74). The number of prior systemic therapies ranges 1 to 5. Of 5 patients, two achieved partial response (PR) after 2 cycles and one achieved complete response (CR) after 4 cycles which have lasted 8 months until now. Another patient with interim PR progressed after 3 cycles. Two responders had no history of prior methotrexate-containing treatment and histologically all PTCL-NOS. Three other patients progressed after one or 2 cycles. The most common adverse events were mucositis and anorexia. Four patients complained of mucositis, but only 1 week delay of treatment was required for grade 3 mucositis in one patient. Generally most patients tolerated combination therapy. All patients were treated with planned pralatrexate without dose reduction or discontinuation due to toxicity. Only one dose of bortezomib was omitted due to peripheral neuropathy among all patients and one episode of herpes zoster occurred. None of the patients postponed treatment due to hematologic adverse events.
Summary/Conclusions: Combination therapy with pralatrexate and bortezomib could be used effectively and safely as a salvage therapy for relapsed or refractory PTCL in elderly patients. Larger studies are needed for evaluating benefit of combination therapy over single pralatrexate therapy.

PB1713

TREATMENT OUTCOME OF DIFFUSE LARGE B CELL LYMPHOMA IN RITUXIMAB ERA AND THE PROGNOSTIC VALUE OF R-IPI SCORE AT A CANCER CENTER IN TAIWAN: SINGLE INSTITUTION EXPERIENCE
MT Sung*, WH Wu, LW Chiou, AC Feng, MC Wu, PY Chen, WH Liu, HH Cheng, TD Tan
Multidisciplinary Teams of Lymphoma & Leukemia, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, ROC

Background: The treatment outcome of diffuse large B cell lymphoma showed major improvement in rituximab era. The predictor of outcome is still under investigation.
Aims: To review and analyze the treatment experience of newly diagnosed diffuse large B cell lymphoma in rituximab era in our institution.
Methods: We retrospectively reviewed medical records from Jan 2005 to Dec 2014 from our institution. We figured out patients with newly diagnosed diffuse large B cell lymphoma. Clinical characteristics, treatment response, treatment modality, and survival were analyzed.

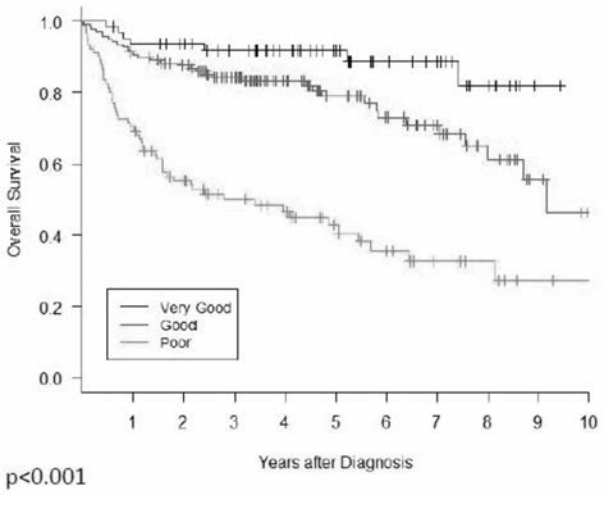

Figure 1. 2005-2014 overall survival of DLBCL by R_IPI.

Results: From Jan 2005 to Dec 2014, there were 292 newly diagnosed diffuse large B cell lymphoma in our institution. Median age was 57 years old. 50.7% of patients had advanced stage (stage III&IV), and 7.9% had poor performance status(ECOG2-4). According to revised International Prognostic Index score(R-IPI score), 21.6% had very good prognosis (score 0), 47.2% had good prognosis (score 1 or 2), and 31.2% had poor prognosis(score 3,4 or 5). According to primary site,62.3% had lymphadenopathy, 8.2% had mediastinum disease, 16.1% had gastrointestinal disease. Ki67 was available in 59.9% of patients. According to cell origin, germinal center B-cell-like(GCB) was 11.7% and non-GCB was 9.9%.78.4% of patients did not perform the test. HBsAg was positive in 25.3% of patients. 81.3% of patients were treated with RCHOP-like regimen. Complete remission(CR) was achieved in 79.4% of patients. 3-year event free survival(EFS) and overall survival(OS) were 70% and 75.3%, respectively. 5-year event free survival(EFS) and overall survival(OS) were 64.9% and 70%, respectively. The 5-year OS was 92.7%,77.5%,66%,47.3% in stageI/II/III/IV, respectively(p<0.001). The 5-year OS was 91.8%, 78.9%,42.8% in R-IPI very good group, good group and poor group, respectively(p<0.001). CR, treated with R-CHOP-like regimen, R-IPI score predicted the outcome of the patient. Primary site, Ki67, GCB were not associated with outcome in our cohort. Though Taiwan is in HBV endemic area, HsAg was not associated with outcome in our cohort (Figure 1).
Summary/Conclusions: Diffuse large B cell lymphoma has good prognosis for majority of patients in rituximab era. R-IPI score has significant prognostic value in Asian population. However, for patients with higher stage and higher IPI score, further investigation to improve outcome is still required.

PB1714

TREATMENT PECULIARITIES OF NON-HODGKIN'S LYMPHOMAS IN CHILDREN WITH NIJMEGEN BREAKAGE SYNDROME
K Olena[1,*], TV Irina[2], S Olga[3], L Volodimir[3]
[1]hematology, Western Ukrainian Specialized Children's Medical Centre, Institute of Blood Pathology and Transfusion Medicine, [2]hematology, Western Ukrainian Specialized Children's Medical Centre, [3]Institute of Blood Pathology and Transfusion Medicine, Lviv, Ukraine

Background: Nijmegen breakage syndrome (NBS) is rare autosomal recessive disorder, typically characterized by increased chromosome fragility phenomenon, immune deficiency, hypersensitivity to radiation and high predisposition to malignancy.
Aims: To investigate the effectiveness of cytostatic treatment of non-Hodgkin lymphomas (NHL) in children with NBS.
Methods: 1992 through 2014 one hundred children in the Hematology Department of Lviv Children hospital were first diagnosed with, 9 (9%) out them with NBS. The median age of this children group was 8 years and 8 months (from 4 years 4 months to 14 years 11 months old). Male to female ratio was 3:2. The diagnosis of NBS was based on specific phenotype features, results of clinical, genetic (657del5 *NBN* gene mutation) and laboratory investigations. The diagnosis of NHL was based on clinical symptoms, morphological and immunological analysis of tumor substrate. Patients received treatment according to BFM-group protocols (NHL-BFM-90/95, NHL-DGLLU-2000).
Results: The NHL types were established as follows: lymphoblastic lymphoma (LBL) in 3 patients, diffuse large B-cell lymphoma (DLBCL) in 6 patients. In most cases the primary manifestations were nodal: peripheral lymph nodes - in 9 patients, mediastinal – in 7, abdominal lymph nodes - in 3, and spleen – in 7 children. Involved extranodal sites included liver (6 patients), lung and pleura (5), skull bones (2), kidney (1), CNS (1). Atypical cells (L1/L2 and L3-type lymphoblasts according to FAB-classification) in the bone marrow were found in 2 patients with LBL, 1 – with DLBCL. Cytostatic treatment was initiated in 8 patients. One patient was in the terminal state and died before the specific treatment. Three patients died upon the completion of first chemotherapy cycles, due to serious infectious complications (pneumonia, pneumothorax, enteropathy, necrotic stomatitis, palatal fistula). In a 4 year old boy with DLBCL, after 2 cycles, the tumor didn't go into regression. The salvage therapy (ICE+rituximab) was not effective; the child died of lymphoma progression. In 4 patients the cytostatic treatment was successful. Three children with LBL received a full course of protocol treatment without reducing the doses of cytostatic and are in remission at present (duration of remission in months – 215, 39, 30). In one girl with DLBCL the treatment was discontinued after the 5th cycle (AA N2) of NHL-DGLLU-2000 protocol, because of coccyx area soft tissue necrosis, thus the last BB cycle was not conducted. After 11 years of remission in this patient a secondary tumor (meningioma) was diagnosed, her treatment with the CyberKnife radiosurgery was effective.
Summary/Conclusions: The complexity of the clinical course of NHL in NBS patients was preconditioned by the presence of concomitant infections on the background of combined immunodeficiency, which caused death of 4 patients at the beginning of the treatment. One patient died from lymphoma progression. Specific NHL treatment in NBS patients is possible and effective, given the individual correction of doses and schedules of applied cytostatic agents, and if adequate supportive therapy is provided concomitantly. Nonetheless, after successful NHL treatment in children with NBS, the risks of secondary tumor development still run high.

Abstract withdrawn.

PB1716

VARIATION IN R-CHOP REGIMENS FOR PATIENTS WITH STAGE II-IV DIFFUSE LARGE B-CELL LYMPHOMA IN THE NETHERLANDS
M Brink[1,*], DE Issa[2], AG Dinmohamed[1,3,4], ME Chamuleau[5], O Visser[1]
[1]Department of Research, Netherlands Comprehensive Cancer Organisation, Utrecht, [2]Department of Hematology, Jeroen Bosch Hospital, 's Hertogenbosch, [3]Department of Hematology, Erasmus MC Cancer Institute, [4]Department of Public Health, Erasmus University Medical Center, Rotterdam, [5]Department of Hematology, VU Medical Center, Amsterdam, Netherlands

Background: The 2014 Dutch national clinical practice guideline for diffuse

large B-cell lymphoma (DLBCL) recommends 8x R-CHOP21 or 6x R-CHOP14 followed by 2 additional cycles of rituximab (2R) as first line therapy for stage II-IV DLBCL patients with an age-adjusted International Prognostic Index (aaIPI) of 1-3. However, international guidelines tend to promote 6x R-CHOP21 as the preferred first line treatment.
Aims: The aim of this population-based study was to evaluate which treatment regimens were applied in the Netherlands.
Methods: We selected 840 patients diagnosed in 2014 with stage II-IV DLBCL and aaIPI 1-3 (median [range] age 69 years [18-99]; 55% male) from the nationwide population-based Netherlands Cancer Registry. All patients were treated outside clinical trials. In this study, first line treatment was defined as 6x or 8x R-CHOP14/21, and, in case of 6x R-CHOP14/21, with or without 2R. Overall response rate (ORR) was defined as achieving complete or partial response, *i.e.* CR(u) or PR. Data were analyzed for the total cohort, as well as stratified by age and treatment regimen.
Results: Treatment with R-CHOP14/21 was initiated in 651 (78%) patients, while 103 (12%) patients received other (chemo)therapeutic regimens. The remaining 86 (10%) patients received no therapy. Of those who received R-CHOP14/21, 508 (78%) completed 6x or 8x, 122 (19%) received less than 6x, and 21 (3%) received 7x. Of the patients who completed treatment (6x+/- 2R or 8x), 6x R-CHOP21, 6x R-CHOP21+2R and 8x R-CHOP21 regimens were provided in 21%, 20% and 45% of patients, while 6x R-CHOP14, 6x R-CHOP14+2R and 8x R-CHOP14 in 3%, 3% and 8% of patients, respectively. Of note, 8x R-CHOP14/21 was most commonly applied (53%; N=269). Patients aged <65 years (N=233) more often received 8x (82%), whereas patients aged ≥65 years more often received 6x (72%). As for patients aged 65-74 years (N=160), 39 (24%) patients received 6x R-CHOP21, 49 (31%) 6x R-CHOP21+2R and 55 (34%) 8x R-CHOP21. Only 17 (11%) patients received 6x R-CHOP14+/- 2R or 8x R-CHOP14. For patients aged ≥75 years (N=115), all but one received R-CHOP21 regimens, of which 43% received 6x, 39% 6x with 2R and 17% 8x. The ORR was 88% (448/508) for patients who completed treatment. Further, the ORR was 87% for 8x R-CHOP21, 83% for 6x R-CHOP21 and 94% for 6x R-CHOP14+2R and this was irrespective of age group.
Summary/Conclusions: Our results show that treatment with R-CHOP was initiated in 78% of patients with stage II-IV DLBCL and an aaIPI of 1-3. Three-weekly regimens were applied to 85% of patients who completed treatment. Although based on modest patient numbers, the ORR for 6x R-CHOP21, which is the internationally preferred R-CHOP regimen, was 83%. That value compares somewhat lower to the ORRs in the 8x R-CHOP21 and 6x R-CHOP14+2R groups, *i.e.* 87% and 94%, respectively. Collectively, these population-based analyses demonstrate that there is variation in the provision of R-CHOP regimens in daily practice, which could be related to the ongoing debate among clinicians in the Netherlands whether 6x or 8x R-CHOP21 should be the standard of care as first line therapy for stage II-IV DLBCL patients with an aaIPI of 1-3.

PB1717

DIFFERENT IMMUNOCHEMOTHERAPY REGIMENS FOR PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY ON 86 PREVIOUSLY UNTREATED PATIENTS

I Ilyasova*, M Kichigina, E Medvedovskaya, O Trofimova, E Osmanov, G Tumyan, N Falaleeva, P Zeynalova
N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMBCL) arising from thymic medulla B cell, occurring more often in young females and characterized by a locally invasive anterior mediastinal bulky mass that often causes cough, dyspnea and a superior vena cava syndrome. Previous retrospective studies have suggested that it may respond better to more intensive chemotherapy regimens than to standard CHOP. The prognostic role of PET/CT scan and the feasibility of consolidation with radiotherapy (RT) on residual mediastinal mass still remain unclear.
Aims: To assess the impact of different immunochemotherapy regimens on survival outcomes in newly diagnosed patients with PMBCL.
Methods: We identified 86 pts with PMBCL treated in N.N. Blokhin Russian Cancer Research Center during last 10 years (2004-2014). The median age was 29 years (15-63), 56% were female, 62% had I/IIE stages, LDH elevated in 81% pts. Patients received three different regimens chemotherapy (CT): MACOP-B+R- 52 pts (group 1), R-CHOP -18 pts (group 2), R-EPOCH - 16 pts (group 3). After completion of CT, PET/CT scan was performed on 56 of 86 pts and in 20 of 56 (36%) it was abnormal. Radiation therapy to the mediastinum received 69 pts (80%).
Results: With a median follow 34 months, progression-free survival (PFS) was 80%, overall survival (OS) - 86%. There is no significant differences in PFS and OS depending on the CT regimens (p=0.1). It should be noted that none of the 16 patients treated on EPOCH-R, had relapse or disease progression. 4-year PFS was 91% in patients who were PET negative before RT regardless of the CH regimens,
Summary/Conclusions: Immunochemotherapy combined with local irradiation remains the standard treatment for PMBCL. Perhaps, more number of patients will be able to demonstrate significant benefit one chemotherapy regimens over the other and define the role of consolidation RT in patients with PET-negative mediastinal mass after standard chemoimmunotherapy.

PB1718

TREATMENT OF HIGH RISK AGGRESSIVE B CELL LYMPHOMAS WITH DA EPOCH R– A RETROSPECTIVE ANALYSIS

M Panny[1], K Troppan[2], P Neumeister[2], T Nösslinger[1], K Holzer[1], H Greinix[2], F Keil[1,*]
[1]Department of Hematology and Oncology, Hanusch Hospital, Vienna, [2]Department of Hematology, Medical University of Graz, Graz, Austria

Background: Promising results in patients suffering from high risk DLBCL, Burkitt`s lymphoma (BL), gray-zone lymphoma (GZL) and primary mediastinal B cell lymphoma (PMBCL) treated with DA-EPOCH R have been reported.
Aims: To evaluate retrospective toxicity and efficacy in DA EPOCH R treated patients.
Methods: In our centres high risk DLBCL - defined as double-hit/double hit score 2 or high/ high-intermediate risk NCCN IPI - BL, MGZL and PMCL are treated with DA EPOCH R. Retrospective analysis of toxicity and efficacy in DA EPOCH R treated patients.
Results: So far 39 previously untreated patients with a median age of 54a (28a – 76a) have been treated with a total of 190 cycles of DA EPOCH R: 16 DLBCL, 9 GZL, 8 PMBCL, 6 BL. 37 Patients have finished treatment, 2 are stilll on treatment. Targeted ANC <500/l occurred in 46%, thrombocytopenia <25.000/l in 20% and anemia <8g/dl in 12,5% of all cycles. Dose escalation was possible in 27 (73%) patients – but only in 5 (38%) of 13 patients >65a. 15 (63%) of 24 patients aged <65a received at least dose level 3 (144% increased dose of Etoposide, Doxorubicin, Cyclophosphamide). Due to peripheral sensory neuropathy, Vincristine had to be dose reduced in 52% of all cycles. Other CTCAE grade III/IV non-hematopoietic toxicities were infrequent and manageable. After a median follow up of 10 month (range: 1-25) overall survival (OS) rate is 74%. 2 patients in PR were (1 PMBCL, 1 GZL) bridged to allogenic stem cell transplantation, 1 patient in CR had to be switched to a less toxic regimen due to repeated febrile neutropenia after 3 cycles of. In 18 high risk DLBCL patients (8 DHS2/DHL, 8 high/high intermediate NCCN IPI) OS is 80% after a median follow up of 12 month. From 8 (4GZL, 2 DLBCL, 1 BL, 1 PMBCL) relapsed/ refractory patients 7 died. Causes of death were: 2 infectious complications (1 DLBCL HIV associated, 1 GZL) and 5 progressive disease
Summary/Conclusions: Although still preliminary data DA EPOCH R seems to be a feasible treatment with acceptable toxicity and a promising response rate. Dose escalation is age dependent. Especially in patients with high risk DLBCL DA EPOCH R is an alternative to insufficient induction therapy with R CHOP.

PB1719

SINGLE-HIT LYMPHOMA PATIENTS HAD MORE PRONOUNCED BENEFIT FROM DOSE-INTENSIFIED CHEMOTHERAPY THAN DOUBLE-HIT LYMPHOMA PATIENTS. SINGLE-CENTER EXPERIENCE.

A Misyurina[1,2,*], E Baryakh[3], S Kravchenko[1], A Kovrigina[1], T Obukhova[1], V Misyurin[4], J Mangasarova[1], L Plastinina[1], E Nesterova[1], A Magomedova[1], E Penskaya[1], A Vorobiev[1]
[1]National Research Center for Hematology, [2]"GeneTechnology" LLC, [3]City Clinical Hospital № 52, [4]N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: B-cell lymphomas with *c-MYC* rearrangement are characterized by aggressive clinical behavior and poor prognosis when R-CHOP-21 is used. An efficacy of intensified chemotherapeutic regimens continues to be debatable.
Aims: To represent treatment results of *MYC*+agressive B-cell lymphomas with dose-intensified chemotherapy.
Methods: Since 2007 till 2015 years in National Research Center for Hamatology 23 cases of *c-MYC* rearranged non-Burkitt B-cell lymphomas (5 DLBCL and 18 BCLU intermediate between DLBCL and BL) were diagnosed. Ratio between men and women was 9:14. Median age was 51 years old (30-70). ECOG ≥2 was in 18 (78%) cases; 19 (83%) of pts had III-IV stage according Ann-Arbor classification; 17 (74%) had more than one extranodal site: 7 (30%) - bone marrow involvement, 2 (9%) - CNS; 18 (78%) pts had IPI 3-5. In 15 cases *c-MYC* translocation partner was locus of *IGH* gene, in 4 cases – locus of *IGL* or *IGK* gene, in 4 cases – undefined. In 8 cases with available karyotype were revealed complex abnormalities. *MYC+/BCL2*+double-hit lymphoma (DHL) was in 6 cases, *MYC+/BCL6*+DHL was in 3 pts, others 14 pts had single-hit lymphoma (SHL). In all cases dose-intensified treatment strategy was initially chosen: in 4 cases - R-DA-EPOCH and in 19 cases – protocol BL-M-04 consisted of A-C-A-C 4-6 courses (Course A: dexa 10 mg/m^2 1-5 days; Mtx 1500 mg/m^2 1st day12-hours infusion; ifosfamide 800 mg/m^2 1-5 days; vincristine 1 mg/m^2 1st day; doxorubicine 50 mg/m^{2}3rd day; AraC 150 mg/m^2 4-5 days bid; etoposide 100 mg/m^2 4-5 days, iv. Course C: dexa 10 mg/m^2, 1-5 days; Mtx 1500 mg/m^{2}1st day12-hours infusion; vinblastine 5 mg/m^2 1st day; AraC 2000 mg/m^{2}2-3 days bid; etoposide 150 mg/m^{2}3-5 days, iv. AraC 30 mg,

Mtx 15 mg, dexa 4 mg 1st day of each course, intrathecally). Rituximab was indicated in 12/19 cases. AutoSCT was performed in 5 cases. Kaplan-Meier method and log-rank test were used to estimate treatment results (SAS 9.3).
Results: 9/23 (39%) pts had a complete remission, 6/23 (26%) pts had a partial remission, 7/23 (30%) pts had disease progression (in one case after autoSCT), one pt (4%) died from infectious. In one case (4%) of DLBCL early relapse had occurred. 2-year overall survival (OS) and event-free survival (EFS) were 51% (median - 9,0 months (0,6-89,1)) and 40% (median 7,3 months (0,1-89,1)), respectively. DHL pts had worse treatment results compared with SHL pts: 2-year OS was 30% (median – 8,2 months (0,6-54,1)) *vs* 64% (18,6 months (1,1-89,1)) in DHL *vs* SHL groups, respectively (p=0,06) (Figure 1). 2-year EFS was 13% (median – 3,5 months (0,3-21,4)) *vs* 56% (median 17,4 months (0,1-89,1)) in DHL *vs* SHL groups, respectively (p=0,03) (Figure 1).

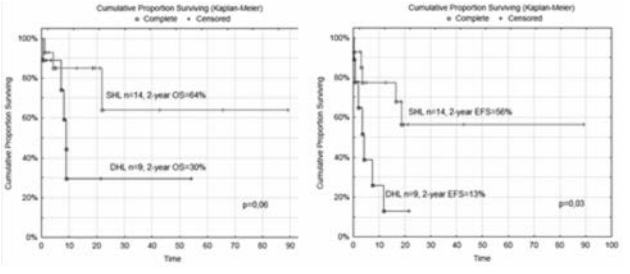

Figure 1.

Summary/Conclusions: Single-hit lymphoma patients have more pronounced benefit from dose intensification compared with miserly results in double-hit lymphoma patients.

PB1720

DICEP IS AN EFFECTIVE CHEMOTHERAPEUTIC REGIMEN FOR PATIENTS WITH RELAPSED OR REFRACTORY LYMPHOMAS WHO FAILED PRIOR SALVAGE CHEMOTHERAPIES

A Al Garni*, P Kaloyannidis, N Al Mulhem, M Ali, A Al Bahrani, A Al Sagheir, K Al Anazi, H Al Hashmi
Adult Hematology and SCT, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: The outcome of patients (pts) with relapsed or refractory Hodgkin's (HL) and Non Hodgkin lymphomas (NHL) post failure of response to 1st salvage treatment tends to be very poor even after autologous stem cell transplantation (ASCT). Though several 2nd line salvage regimens have been used, the optimal treatment still remains an issue of clinical investigation and there is an unmet need for salvage chemotherapies, sufficiently strong to reduce the tumor burden with acceptable toxicities to allow safe yet successful ASCT.
Aims: We herein evaluated the DICEP regimen [Dose Intesified Cyclophoshamide (1,750 gr/m^2), Etoposide (350 mg/m^2) and Cisplatin (35 mg/m^2), days 1-3] in terms of safety and efficacy regarding disease response and stem cell mobilization and collection.
Methods: We retrospectively analyzed the data of 21 (10 HL, 11 NHL) pts with a median age of 26 (16-60) yrs who had refractory or relapsed disease after ABVD or R-CHOP regimens (6-8 cycles) and received as 1st line salvage chemotherapy at least 2 cycles of ESHAP (13 pts), ICE (3 pts), ESHAP+ICE (2 pts) and other regimens (3 pts). Two out of 21 achieved complete remission (CR) post 1st salvage, 17 partial remission (>50% response, PR) while 2 had stable or progressive disease. A single cycle of DICEP was administered either as mobilization chemotherapy (in 2 pts with CR), or as 2nd salvage treatment for patients with PR, stable or progressive disease.
Results: DICEP was well tolerated and no lethal or major organ toxicities were observed. Nevertheless, all patients experienced hematological toxicity (gr 3-4 WHO) and 18/21 developed febrlile neutropenia (3/18 experienced septicemia), however that completely resolved with the appropriate antibiotic therapy not requiring admission to intensive care unit. The hospitalization period was 20 (11-25) days. All patients were successfully mobilized and a medium of 7,9 (2,8 -33,5)x10^6/kg CD34+cells were collected after a median of 1 (1-3) days of apheresis procedure. Post DICEP administration, a further overall disease improvement of 42% was observed (6 additional CRs and 2 PRs), whilst in 1 pt the disease proved to be refractory. Finally 20/21 pts underwent ASCT. The 3,5yrs overall survival (OS) and progression free survival (PFS) from DICEP administration were 50% for the whole cohort of patients. Specifically, for HD pts the 2 yrs OS and PFS were estimated to be 75% and 65% respectively, while for NHL the 3,5 yrs OS and PFS were 45% and 50% respectively.
Summary/Conclusions: Taking into account the limitations of the retrospective nature of the present study, it seems that DICEP regimen is a sufficient salvage treatment demonstrating acceptable toxicity without negatively affecting the collection process. The promising overall response rates post DICEP in combination with the encouraging OS and PFS rates achieved post ASCT in that heavily pretreated group of patients, strongly support the rationale to use DICEP regimen not only as a "bridge" to a successful ASCT but also as 1st line salvage regimen in selected pts.

PB1721

THE COMPARISON OF THE PROGNOSIS SCORING SYSTEMS BETWEEN EVENT-FREE SURVIVAL AT FIRST 24 MONTHS AND OVERALL SURVIVAL IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

M Maden[1,*], M Demir[1], A Gokyer[2], V Bas[2], K Sacar Kubuc[2]
[1]Trakya University, Hematology Department, [2]Trakya University, Internal Medicine Department, Edirne, Turkey

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma (NHL). R-CHOP (Rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) is curative in the majority of DLBCL patients. However, about one-third of patients will have refractory disease or relapse following the therapy. Therefore, risk stratification at diagnosis for patients with DLBCL is of great clinical interest. Recently, it is shown that event-free survival (EFS) at first 24 months from the time of diagnosis in patients who received rituximab-based chemotherapy onwards the similar survival rates with healthy patients in their own age group and gender. Recently, the scoring system for prognosis called IPI24 is effective to predict the first 24-month EFS (EFS24) in DLBCL patients.
Aims: In this study, we aimed to compare the risk stratification anticipated by IPI24, IPI and NCCN-IPI for patients treated with RCHOP in the first EFS24 and overall survival in Trakya University Medical Faculty Hematology department and identify the prognosis scoring system which makes best risk stratification.

Table 1.

A Event free survival at first 24 months, Cox regression analysis

	P	HR	95%CI	
			Lower	Upper
IPI	0.135	0.715	0.461	1.108
IPI24	0.034	1.038	1.003	1.074
NCCN-IPI	<0.001	6.070	3.026	12.175

B Overall survival at first 24 months, Cox regression analysis

	P	HR	95%CI	
			Lower	Upper
IPI	0.143	0.709	0.448	1.123
IPI24	0.082	1.034	0.996	1.074
NCCN-IPI	<0.001	7.403	3.368	16.272

C Overall event free survival, Cox regression analysis

	P	HR	95%CI	
			Lower	Upper
IPI	0.148	0.725	0.470	1.118
IPI24	0.064	1.032	0.998	1.067
NCCN-IPI	<0.001	6.039	3.043	11.983

D Overall survival, Cox regression analysis

	P	HR	95%CI	
			Lower	Upper
IPI	0.132	0.718	0.468	1.130
IPI24	0.136	1.028	0.991	1.067
NCCN-IPI	<0.001	7.319	3.387	15.797

Methods: Clinical and laboratory data of 284 patients who have been diagnosed with NHL in our center since 2004 were retrospectively analyzed. The patients who were under the age of 50 and over the age of 85 and also receiving chemotherapy except for R-CHOP, apart from DLBCL were subtracted from the study and 103 patients (57 M, 46 F) were enrolled in the study. Clinical and laboratory data of the patients were obtained by scanning files. According to IPI and NCCN-IPI, patients were analyzed depending on 4 risk groups (low, low-intermediate, high-intermediate, high) which are created on using age, LDH, ECOG score, extranodal organ involvement and Ann Arbor stage. But the risk of events on the first 24 months calculated by IPI24 were calculated with the QX

calculator using age, sex, absolute lymphocyte count, bulky lymph node masses (>10cm), LDH, ECOG score and Ann Arbor stage. Data were analyzed with SPSS statistical software. Whether the prognostic scores were independent indicators or not in terms of survival and event-free survival was examined using Cox regression analysis. P<0.05 was considered significantly.
Results: The mean age of 103 patients in our study was 60±9 years and in%48 of them had extranodal disease,%64 of the patients had advanced disease,%24 of the patients had solid disease. In%37 of the patients ECOG score was ≥2.%38 of the cases were dead. NCCN-IPI was the most successful prognostic model to predict EFS24 in the patients (p<0.001). While IPI24 was statistically significant to predict EFS24 (p=0.03), IPI was not sufficient (p=0.13) (Table 1A). While the best prognostic model was NCCN-IPI to predict the overall survival in 24 months (p<0.001), IPI and IPI24 were insufficient (with order p=0.08, p=0.7) (Table 1B). To predict the overall EFS and overall survival in the patients, the best prognostic model was NCCN-IPI (p<0.001), but IPI and IPI24 were insufficient (p>0.05) (with order Table 1C-D).
Summary/Conclusions: In DLBCL patients before treatment, while NCCN-IPI was superior to IPI 24 as a prognostic scoring system to predict EFS24, IPI was insufficient. Similarly to predict overall survival, NCCN-IPI was the best prognostic model. Due to the mean age of our patients was high and the number of the patients was not enough IPI24 could be insufficient when compared to NCCN-IPI to predict EFS24 and overall survival. It would be useful to do more studies to show the effectiveness of IPI24 for determining the risk factors before the treatment on DLBCL patients.

PB1722

EFFICACY OF SPLENECTOMY IN DIFFUSE LARGE CELL LYMPHOMA
Y Yevstakhevych[1,*], J Vygovska[2], I Yevstakhevych[1], M Semerak[1], V Loginskiy[3]
[1]Surgery and Transfusion Medicine, [2]Heamatology, [3]SI "Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine", L'viv, Ukraine

Background: Diffuse large cell lymphomas (DLCL) are often associated with splenomegaly. Large-size spleen causes both abdominal discomfort, cytopenia, regional portal hypertension and a decreased efficacy of chemotherapy. This is why splenectomy is indicated in such cases.
Aims: To retrospectively analyze the efficacy of splenectomy in patients with diffuse large B-cell lymphoma (DLBCL) and diffuse large T-cell lymphoma (DLTCL).
Methods: 43 patients with DLBCL and two patients with DLTCL underwent splenectomy.
Results: Splenectomy was performed in 25 male and 18 female patients aged 25-76 years with DLBCL. Indications for splenectomy included splenomegaly (in all patients), hyperslenism (anemia, leukopenia, thrombocytopenia) – in 25 patients (58.1%), regional portal hypertension – in 20 (46.5%) patients; inefficacy of chemotherapy – in 18 (41.9%) patients, and concomitant autoimmune hemolytic anemia (warm type) – in two patients. Splenectomy proved effective in 40 (93%) patients with DLBCL: abdominal syndrome, anemia and leukopenia were reverted, hemolysis in AIHA relieved, and the platelet count was normalized in patients with concomitant thrombocytopenia. The following complications were observed postoperatively: bilateral pneumonia (1 patient), chronic adrenal insufficiency (3 patients), acute thrombophlebitis of superficial veins of the right leg (1 patient), acute pancreatitis (4 patients), and thrombosis of residual limb of the splenic vein (3 patients). One patient died immediately following splenectomy. This lethal outcome was caused by acute cardiovascular insufficiency, which developed within 4 days after operation. Splenectomy did not prove effective in patients with DLBCL. The surgery did not result in normalization of concomitant cytopenia in one female patient who died within 1 month after splenectomy due to both progression of illness and chronic adrenal insufficiency. Another female patient achieved a short-term recovery following surgery (hemoglobin level as well as leukocyte and platelet count normalized) but she developed a cytopenia after 30 days and passed away due to a rapid deterioration of illness and multi-organ insufficiency. As shown by a retrospective analysis of long-term results of splenectomy in patients with DLBCL, the overall survival post splenectomy reached 63.9 months, and the mean treatment-free survival reached 36.8 months. 11 patients did not require administration of chemotherapy following splenectomy at all. 17 patients with DLBCL (39.5%) developed a relapse of illness at different timepoints after surgery. Splenectomy was performed in two patients with DLTCL. In both cases, surgical treatment proved ineffective, and the patients died within 1 month following intervention due to a relapse of cytopenia, rapid deterioration of illness and multi-organ insufficiency.
Summary/Conclusions: Splenectomy remains to be an effective treatment option in non-Hodgkin lymphomas. In DLBCL, the surgery helps relieve both abdominal discomfort and hypersplenism; symptoms of regional portal hypertension alleviate; there is less or no need in administration of chemotherapy; and there is no more hemolysis in concomitant AIHA. In DLTCL, splenectomy is ineffective and should be thus avoided.

DONOR-TRANSMITTED TRIPLE-HIT LYMPHOMA IN A RENAL ALLOGRAFT RECIPIENT
L Biavati[1,*], E Orciuolo[2], S Galimberti[3], MI Ferreri[4], F Basolo[5], G Buda[6], F Caracciolo[2], E Ciabatti[3], S Grassi[3], U Boggi[7], M Petrini[3]
[1]Scuola Superiore Sant'Anna, [2]Hematology Unit, Azienda Ospedaliero-Universitaria Pisana, [3]Clinical & Experimental Medicine, University of Pisa, [4]Laboratory of Cytogenetics, Azienda Ospedaliero-Universitaria Pisana, [5]Unit of Pathological Anatomy, University of Pisa, [6]Hematology Unit, Azienda Ospedaliero-Universitaria Pisana, [7]General & Transplant Surgery, University of Pisa, Pisa, Italy

Background: Donor cancer transmission is a rare long-term complication of kidney transplantation that carries an estimated risk of approximately 0.05%. Diagnosis and management of these malignancies are difficult because of their rarity and the need for an individualized approach to treatment. CM is a 30-years-old man with a medical history significant for chronic kidney disease who underwent kidney transplantation in May 2015 with his mother as the donor. In July 2015, the donor presented with an abdominal mass diagnosed as a triple-hit lymphoma (THL), a subset of highly aggressive B-cell lymphomas characterized by the overexpression of MYC, BCL2 and BCL6. Initial staging with PET/CT and bone marrow biopsy showed widespread disease with no marrow involvement, while circulating tumor DNA (ctDNA) assay confirmed a clonal B-cell proliferation. Analysis of ctDNA was performed on recipient's plasma, but ctDNA levels were undetectable. In September 2015, CM developed a perigraft mass that was identified as a THL as well. The peculiar clinical presentation and the histochemical similarities of the two THLs raised the suspicion that the same lymphoma had been transmitted from the donor to the recipient during the transplant procedure.
Aims: This case describes donor transmission of THL with kidney transplantation and points out difficulties in diagnosis and management.
Methods: Lymphoma biopsy specimens from both donor and recipient were obtained and prepared for histological and immunohistochemical (IHC) studies and stained for the identification of Ki67, CD20, BCL6, BCL2, MYC, CD10, MUM1/IRF4, CD5, cyclin D1, CD3, EBV-LMP1 and TdT. DNA was extracted from the biopsies of both donor and recipient THL with standard methods. Samples were assessed for nine microsatellite loci and a segment of the X-Y homologous gene amelogenin by PCR with use of a kit for chimerism determination. Fluorescent in-situ hybridization (FISH) studies were performed on specimen sections using probes for sex determination. B-cell clonality analyses targeting the IGH gene for rearrangements were conducted on ctDNA obtained from plasma of both donor and recipient and from the recipient's bone marrow.
Results: Histology and IHC showed identical findings in both donor and recipient. In particular, MYC, BCL2 and BCL6 were positive and the proliferative index was more than 90%. FISH recognized an XX pattern in both samples. Microchimerism analysis pointed out that the donor and the recipient biopsies had identical profiles considering discriminant alleles and amelogenin (see Figure 1). Moreover, the recipient sample profile was significantly different from his basal allelic profile obtained from peripheral lymphocytes at the time of the diagnosis. B-cell clonality in the donor sample was detected at the time of the diagnosis, however ctDNA levels assessed on recipient's sample were undetectable. The same clonal band was persistently detected by ctDNA analysis of the recipient plasma and bone marrow only after September 2015.

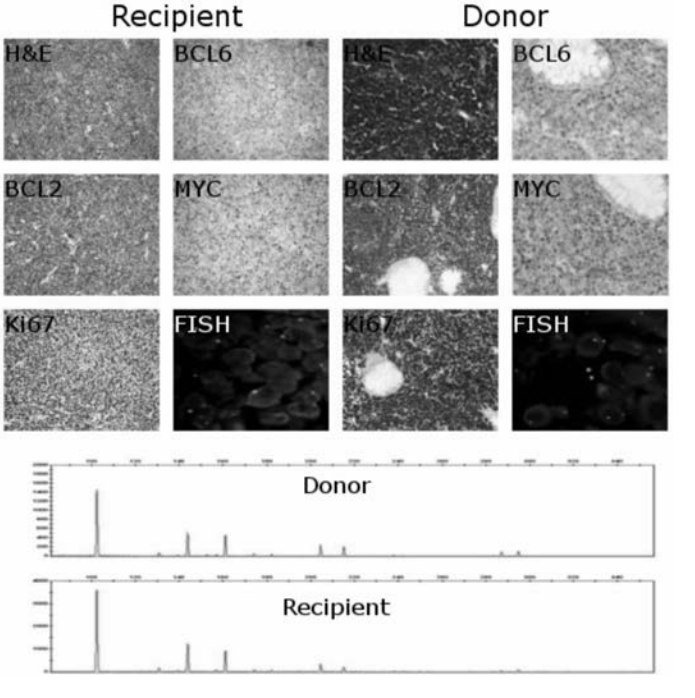

Figure 1.

Summary/Conclusions: We describe the transmission of a highly aggressive B-cell non-Hodgkin lymphoma by kidney transplantation. The THL was transplanted along with the renal graft, while immunosuppressive therapy and immunological impairment enabled its growth and expansion. The patient went on to complete the full course of 2 cycles of R CODOXM/IVAC and associated withdrawal of immunosuppression achieving a complete remission and preserving graft function. The donor underwent the same intensive regimen and achieved a complete response as well.

PB1724

TREATMENT OF C-MYC/BCL2 DOUBLE EXPRESSER DLBCL WITH R-CHOP CHEMOIMMUNOTHERAPY: AN AUSTRALIAN SINGLE CENTRE EXPERIENCE

TF Ng[1,2,*], A Whiteside[3], H Rose[1], D Kipp[1], B Tawfik[3], P Campbell[1,4]
[1]Clinical Haematology, University Hospital Geelong, Geelong, [2]Haematology, Fiona Stanley Hospital, Perth, [3]Anatomical Pathology, St John of God Pathology, [4]School of Medicine, Deakin University, Geelong, Australia

Background: Co-expression of c-myc and BCL2 in Diffuse Large B-cell Lymphoma (DLBCL), (increasingly known as 'double expresser' DLBCL), is associated with inferior outcome with standard-of-care R-CHOP immunochemotherapy.
Aims: To retrospectively identify patients with 'double expresser' immunophenotype within our patient cohort of DLBCL, and to analyze their outcomes following treatment.
Methods: Chart review of patients with DLBCL treated with RCHOP chemoimmunotherapy between 2007 and 2014 at our institution. We retrospectively performed immunohistochemical staining for c-myc and BCL2 on pre-treatment tumor tissue blocks to identify patients with 'double expresser' immunophenotype. Other prognostic factors including the revised international prognostic index (R-IPI) score, initial bulky disease (>7.5cm) and cell of origin were also recorded and analyzed. Progression-free survival (PFS) were analyzed using Kaplan–Meier curves and statistically tested with the Gehan-Breslow-Wilcoxon test. 2-tailed chi-square test was used to compare incidence of various prognostic factors in subgroup analysis.
Results: 89 patients were included in the study. Patients with high risk R-IPI score, bulky disease, and elevated serum lactate dehydrogenase level (LDH) showed reduced progression-free survival (p=0.03, p=0.04, p=0.002 respectively). In particular, LDH above 2 times of upper limit of normal (ULN) was associated with a 56% reduction in PFS. There was no significant difference in PFS between 'germinal center' and 'non-germinal center' cell of origin subtypes of DLBCL. 34 patients were found to have 'double expresser' immunophenotype. They showed a higher rate of disease progression (32% *vs* 16%, p=0.03), than the remaining DLBCL patients, with progression occurring predominantly within 24 months of treatment. The 'double expresser' subgroup also had a higher incidence of bulky disease (50% *vs* 13%, p=0.01), and LDH above 2xULN (35% *vs* 11%, p=0.005), at presentation. All patients with normal LDH levels and non-bulky disease (n=7) remained in remission at a median follow-up of 32 months (Figure 1).

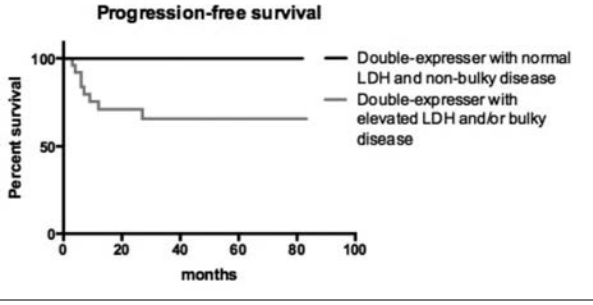

Figure 1.

Summary/Conclusions: We present a small single center series of 'double expresser' DLBCL. Patients with the double expresser phenotype had a higher incidence of bulky disease and markedly elevated LDH level, which was associated with higher risk of disease progression. Knowing this, it may be reasonable to adopt a more intensive treatment approach for these patients. Interestingly, having a normal LDH level at diagnosis and absence of bulky disease (known good prognostic factors) retained their protective influence even in patients with 'double expresser' phenotype.

PB1725

METRONOMIC CHEMOTHERAPY IMPROVES SURVIVAL IN RESPONDING PATIENTS WITH RECURRENT/REFRACTORY LYMPHOMA

B Sanchez-Gonzalez[1,*], MP Ferraro[1], F Garcia-Pallarols[1], D Lopez-Aventin[2], E Gimeno[1], E Torres[1], L Martinez-Serra[1], A Senin[1], F Gallardo[2], A Salar[1]
[1]Hematology, [2]Dermatology, Hospital del Mar, Barcelona, Spain

Background: Metronomic chemotherapy (MC) consists of continuous administration of oral chemotherapy at low, potentially less toxic doses without prolonged drug-free breaks. MC might be a useful for many patients with recurrent or refractory lymphomas that are unable to tolerate intensive therapies.
Aims: The aim of this study was to retrospectively analyze the efficacy and toxicity of MC in recurrent or refractory lymphomas in our Institution.
Methods: Retrospective analysis of patients with lymphoma treated with MC from 2009 to2014 in our Institution. The metronomic scheme consisted of oral 50 mg of prednisone, 50 mg of cyclophosphamide, 50 mg of etoposide, and/or 50 mg of procarbazine evenly distributed throughout the day. Clinical response, duration of response, progression-free survival (PFS) and overall survival (OS) was evaluated. Clinical response was defined as improvement of the symptoms of lymphoma and/or shrinkage of tumours (lymph nodes or affected organs) by physical examination and/or imaging.
Results: *Patient demographics and characteristics*: 28 lymphoma patients consecutively treated with MC were included. 10 patients had diffuse large B-cell lymphoma (DLBCL), 6 cutaneous T-cell lymphoma (CTCL), 5 peripheral T-cell lymphoma (T-NHL), 4 Hodgkin lymphoma (HL), 1 mantle cell lymphoma, 2 other types of non-Hodgkin lymphoma. Median number of prior regimens was 3 (range 1-8). 26 patients (93%) had refractory disease to prior treatment.
Efficacy: Clinical response was observed in 23 patients (82%) with a median duration of response 6 months (95% CI, 0-11 months). No differences were found in clinical response rate, duration of response, PFS and OS among the aggressive or indolent lymphomas. With a median follow-up of 14 months, median OS was 6 months. Of note, responders to MC showed a significantly increased OS (median OS of 11 months in responders *vs* 1 months in non-responders (p<0.001) (Figure 1). Remarkably, PFS was also significantly higher in responders, 42% of cases were progression-free at 6 months in responders *vs* 0% in non-responders (p<0.001). Twenty patients died: progressive disease (n=15), infection (n=4) and non-related (n=1). *Toxicity*: Seventeen patients (61%) had adverse events grade 3/4, mainly hematologic. A total of 6 patients had infections grade ≥3: urinary tract infection (n=2), pneumonia (n=2), multiresistant *Pseudomonas aeruginosa* bacteremia+*Cytomegalovirus* infection (n=1) and *Escherichia coli* sepsis (n=1). The main cause of treatment discontinuation was progressive disease. Only one gastrointestinal adverse event grade 4 led to MC discontinuation (3.6%). Dose modifications of MC drugs was performed in 15 patients (54%) and 12 patients required use of granulocyte colony stimulating factor (G-CSF). 54% of patients received cotrimoxazole as primary or secondary prophylaxis.

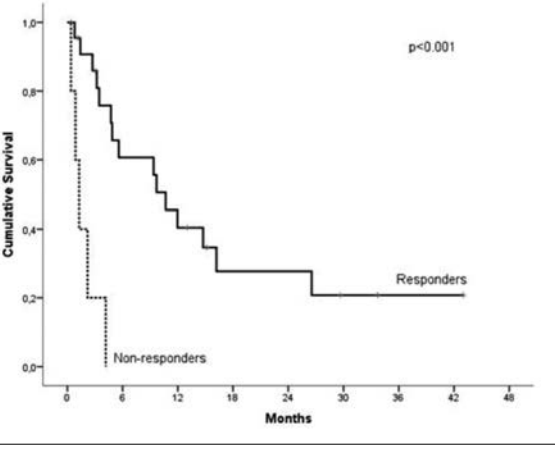

Figure 1.

Summary/Conclusions: Our study supports the anti-tumor activity of MC in patients with advanced lymphoma chemo-resistant and relapsed to multiple therapies with no other therapeutic alternatives. Clinical responses were observed in all lymphoma subgroups and the toxicity profile was acceptable, even in heavily pretreated patients. Even most of our cases had been considered refractory to prior treatment, responding patients to MC had an improved PFS and even OS.

PB1726

RELATIVE TOTAL DOSE INTENSITY OF TREATMENT WITH R-CHOP IN OBESE *VERSUS* NON OBESE LYMPHOMA PATIENTS DOSED ON ACTUAL BODY WEIGHT: A SINGLE CENTRE EXPERIENCE

A Preston[1,*], S Robinson[1], P Mehta[1], N Duncan[2]
[1]Bristol Haematology & Oncology Centre, University Hospitals Bristol NHS Foundation Trust, Bristol, [2]Pharmacy Department, University Hospitals Birmingham, Birmingham, United Kingdom

Background: The number of obese patients in the UK is growing to epidemic

proportions and due to an aging population the incidence of cancer is also increasing. To ensure good patient outcomes it is imperative that we optimally treat obese patients, particularly in the curative setting for diseases such as diffuse large B-cell lymphoma (DLBCL). In 2012 the American Society of Clinical Oncology (ASCO) released a Clinical Practice Guideline recommending that obese patients should be dosed on their full body weight. It is recognised however that clinicians in the UK continue to dose adjust (or 'cap' doses) in fear of excess toxicity.

Aims: This study aims to assess whether dosing on actual body weight in obese patients with R-CHOP chemotherapy for DLBCL affects relative total dose intensity of treatment (RTDI).

Methods: A retrospective analysis was performed of 77 consecutive patients who had received treatment with R-CHOP chemotherapy for DLBCL from 2006 to 2010. After exclusions for insufficient individual patient data or modifications to the regime *e.g.* addition of etoposide (R-CHOEP), the remaining number of patients for analysis was 66 (obese patients dosed on full body weight; n=18 and non-obese; n=48). Baseline characteristics were recorded. Weight and height measurements within 1 month of treatment initiation were used to calculate body surface area (BSA) and body mass index (BMI). Patients were defined as obese if BMI ≥30kg/m^2 as per WHO classification. IBW was calculated for obese patients using the BJ Devine formula. RTDI was calculated using previously published methods. It is the ratio of Actual Total Dose Intensity (ATDI) and Planned Total Dose Intensity (PTDI) expressed as a percentage *i.e.* RTDI (%)=ATDI/ PTDIx100. PTDI is the planned dose intensity over the entire treatment duration, averaged across the chemotherapy agents used. For permanent treatment discontinuation for a reason other than disease progression, relapse or death, the remaining cycles are calculated with planned length and zero dose. In cases of disease progression, relapse or death PTDI is calculated based on number of cycles completed. ATDI is the actual average dose intensity over the real treatment duration *i.e.* actual total dose (mg)/duration of therapy (weeks). RTDI therefore takes into account the effects of treatment delays as well as dose reductions, and premature cessation of therapy due to reasons other than disease progression or death. It is a surrogate marker of survival and multiple studies have demonstrated that achieving an average RTDI >90% is associated with improved long term outcomes. The chi squared test for trend was used to test for a trend in the number of patients being dose reduced at baseline between the two groups. Univariate analysis was performed for age, gender, performance status (PS), baseline characteristics including renal function, hepatic function, full blood count, line of treatment, and GCSF usage using chi-squared tests, t-tests and Mann-Whitney tests. Multivariable linear regression was performed to adjust for confounding factors.

Results: Before adjusting for confounding factors, there was a non-significant difference in average RTDI for R-CHOP between obese and non-obese patients of 7.22%. After adjusting for age, gender, performance status, and whether patients were dose modified in the 1st cycle, a multivariable linear regression showed a reduction in this difference to 5.67% . There was no evidence to suggest a difference in RTDI between the two groups (Table 1).

Table 1.

	Obese N=18	Control (non-obese) N=48	P-value
Average RTDI Mean (sd%)	94.05 (7.13)	86.83 (16.05)	0.071 (t-test)

Summary/Conclusions: These findings, although of limited value due to small patient numbers, would reassure clinicians and pharmacists that full weight based dosing in obese patients should not lead to excess toxicity. In conjunction with the broader published literature and ASCO's Clinical Practice Guideline they support dosing on actual body weight for R-CHOP for obese patients with DLBCL.

[1]Department of Medicine, University Hospital Dubrava, [2]Department of Medicine, University Hospital Center Zagreb, Zagreb, [3]Department of Medicine, University Hospital Center Rijeka, Rijeka, [4]Department of Medicine, University Hospital Merkur, [5]Department of Medicine, University Hospital Center Sestre Milosrdnice, Zagreb, [6]Department of Medicine, University Hospital Center Split, Split, [7]Department of Medicine, University Hospital Center Osijek, Osijek, Croatia

Background: Approximately half of the patients with diffuse large B-cell lymphoma (DLBCL) are older than 60 years and their outcome is inferior in comparison to younger patients.

Aims: We aimed to assess the impact of age, risk factors and the type of treatment on event-free survival (EFS) and overall survival (OS).

Methods: In this retrospective study, 304 patients with DLBCL older than 60 years or equal were included. A total of 218 patients were included in an observational study of patients treated with rituximab conducted at 15 general and university hospitals in 2007 and 2008. Additional patients were recruited from two clinical centers.

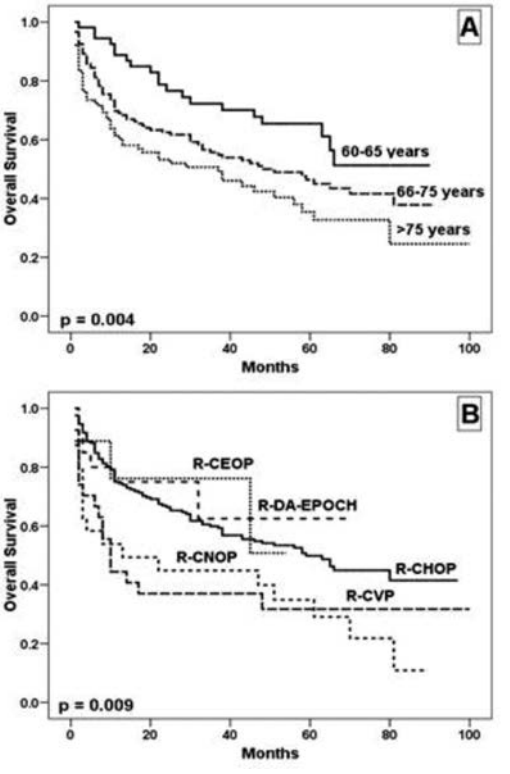

Figure 1.

Results: The median age was 73 years (range 60-90), 144 were men and 160 women. 205 patients were treated with R-CHOP, 27 with R-CVP, 24 with R-CNOP (mitoxantrone instead of doxorubicin), 20 with R-DA-EPOCH, 9 with R-CEOP (etoposide instead of doxorubicin), and 19 patients received other regimens or no chemotherapy. After a median follow up of 52 months for survivors, the estimated 5-year EFS and 5-year OS were 43% and 47%, respectively. Half of the patients are alive at the time of last follow up. Lymphoma, infections, and cardiac events were the leading causes of death. A total of 52% patients died during first-line treatment, 24% died in remission, and 24% died in relapse. There were 16 secondary malignancies reported. The aaIPI significantly correlated with EFS (p=0.002) and OS (p=0.001). Gender, bulky disease (>5cm), and extranodal involvement were not associated with survival, whereas B symptoms were significantly predictive of EFS (p=0.002) and OS (p<0.001). Age had a negative impact on survival: patients between 60 and 65 years fared well (5-year OS 65%), patients from 66 to 75 years of age worse (5-year OS 46%), and those older than 75 years the worst (5-year OS 38%); p=0.004 (Figure 1A). Treatment choice also influenced EFS and OS: R-CVP and R-CNOP had worst outcomes worst, whereas those of R-CEOP and R-DA-EPOCH were at least comparable to R-CHOP; p=0.025 for EFS, p=0.009 for OS (Figure 1B).

Summary/Conclusions: R-CHOP remains the standard of care in elderly patients with B-LCL. The aaIPI and presence of B symptoms influence prognosis. Survival decreases with age; cut-offs at 65 and 75 years are discriminative. R-CNOP has only modest efficacy, similar to R-CVP. Etoposide may serve as an alternative to anthracyclines for patients with cardiac comorbidities, and R-DA-EPOCH may represent a good option for high-risk patients.

PB1728

TREATMENT TOXICITIES AND OUTCOME OF AN INTENSIVE IMMUNOCHEMOTHERAPY REGIMEN (FAB LMB96) FOR ADULT AGGRESSIVE B CELL NON-HODGKIN LYMPHOMAS (BNHL) AT RISK FOR OR WITH CENTRAL NERVOUS SYSTEM INFILTRATION

J Desterro*, M Koehler, J Lobato, R Coutinho, F Pierdomenico, S Carvalho, MJ Frade, A Nunes, M Gomes da Silva

Serviço de Hematologia, Instituto Português de Oncologia Francisco Gentil Lisboa, Lisboa, Portugal

Background: The treatment of diffuse large B cell lymphomas (DLBCL) at risk for CNS infiltration is not well established but may benefit of regimens including systemic drugs crossing the blood-brain barrier. Furthermore, different studies have showed that patients with lymphomas with features intermediate between DLBCL and Burkitt (Int-BNHL) and MYC-rearranged lymphomas have inferior

outcomes when treated with R-CHOP compared to more intensive regimens. Treatment toxicity is a major concern in this setting where a superior efficacy has yet to be prospectively established.
Aims: We retrospectively reviewed the clinical and genetic characteristics, treatment toxicities and outcomes of DLBCL patients at risk for CNS infiltration and Int-BNHL selected for aggressive treatment at our institution between 2009 and 2013.
Methods: Selection was based on age, performance status, ≥2 extranodal sites (ENS) plus elevated LDH, CNS infiltration at diagnosis or MYC-rearrangement. Fab LMB96 regimen includes alkylator/anthracycline/high-dose methotrexate-based induction and high-dose cytarabine/etoposide or cytarabine/methotrexate-based consolidation, followed by maintenance; intrathecal chemotherapy is administered at induction and consolidation. Toxicities were graded according to CTCAE. Response was defined by conventional criteria and overall survival (OS) determined from diagnosis until death or last follow up. Treatment toxicities and outcomes of stage IV, intermediate-high and high-risk IPI DLBCL patients receiving R-CHOP during the same period were reviewed for reference.
Results: 15 patients with DLBCL (9) or Int-BNHL (6), median age 48 (23-65) yo, 6 men, with stage IV disease were treated with the LMB96 protocol to which Rituximab was added at the beginning of the induction and consolidation cycles. 10/11 evaluable patients had MYC rearrangements detected by FISH (MYC+). CNS involvement at presentation occurred in 3 patients and bone marrow infiltration in 6. 93% of the patients had ECOG performance status 0-1 and 12 had IPI 3-5; the other 3 patients had either CNS infiltration or MYC+. 74% and 43% of 94 treatment cycles were complicated by grade 3-4 hematological and infectious toxicities, respectively. These toxicities occurred mostly during induction and consolidation. All patients were admitted for induction/consolidation cycles and required transfusion support, myeloid growth factors and IV antibiotics. Serious neurological (1%) and gastrointestinal (13%) toxicities were also observed. Dose reductions/premature interruptions occurred in 6 patients Complete response occurred in 13/14 (93%) evaluable patients. With a median follow-up of 37.8 months, 3 patients (20%) died, 2 of toxicity (13%) and 1 with progressive lymphoma; median OS was 36 months. In 40 patients with stage IV DLBCL patients aged ≤65 yo diagnosed in the same period and treated with R-CHOP (75% IPI 3-5, 90% high LDH, 65% ≥2 ENS), CR rate was 67.5%. 18/40 (45%) patients died, 14 of NHL and 2 (5%) of toxicity; median OS was 27 months.
Summary/Conclusions: In this retrospectively analyzed, single-center study we show that an intensive immunochemotherapy regimen is feasible and highly effective in selected patients with high-risk BNHL. R-CHOP, although widely applicable, demonstrated poor disease control in the reference sample. Large prospective studies are vital to assess the impact of intensive regimens in the outcome of unselected patients with aggressive lymphomas.

PB1729

MANAGEMENT OF PRIMARY HEPATIC NON-HODGKIN'S LYMPHOMA (PHL)

C Cerchione[1,*], A De Renzo[2], M Masarone[3], C Cimmino[1], R Della Pepa[1], M Di Perna[1], C Mainolfi[4], I De Sio[5], G Ciancia[6], M Persico[3], F Pane[1]
[1]Hematology, [2]Ematologia e trapianto/au federico ii, Napoli, [3]Hepatology, Ospedale di Salerno, Salerno, [4]Medicina Nucleare, Università Federico II, [5]Medicina Interna, Seconda Università di Napoli, [6]Anatomia Patologica, Università Federico II, Napoli, Italy

Background: Primary Hepatic (PHL) is a rare form of NHL, characterized by the exclusive involvement of the liver at the moment of the diagnosis, whereas other localizations, such as lymph nodes, spleen, bone marrow and peripheral blood, or other tissues are free of disease at least for 6 months after diagnosis. Even if its occurrence is rare, PHL should enter in the differential diagnosis of every space-occupying liver lesion, in particular if they are present in concomitance with normal levels of AFP and/or CEA and in absence of liver cirrhosis.
Aims: Only small series of PHL have been investigated in literature, nevertheless a non-fortuitous association with Hepatitis C Virus (HCV) infection has been reported among these series. The prognosis is believed to be dismal, with early recurrence and short survival.
Methods: Patients diagnosed with PHL at our institution between 1990 and 2014, among a population of 600 NHL, were retrospectively analyzed. 11 PHL were defined, 10 patients had a B-cell lymphoma, DLBCL in 6. The prevalence of HCV infection was 72%. Combination CHT was the mainstay of treatment for PHL. 10 patients were treated with CHT (10/11 : 90%). In 7 patients, the multi-drug regimen we used consisted of the CHOP or a CHOP-like scheme; in 2 of them (diagnosed after 2002) rituximab was added, at standard schedule. In the indolent types a fludarabine-based scheme was used. One patient with a single-focal lesion underwent to surgical treatment, with a CR. 11/11 patients achieved complete remission of the disease after the frontline therapy (six CHT courses/surgical treatment) (CR : 100%). Only one patient, 47 years old, Diffuse Large B-Cell Lymphoma, relapsed 144 months after CR: she underwent to retreatment with Rituximab+CHOP with the result of SD, so she underwent to third line treatment with R-Bendamustine, but, due to cardiotoxicity, she had to stop treatment and in the same month died for heart failure.
Results: At time, 10/11 (90%) of patients are alive with a median overall survival (OS) was 123 months (r. 40-228) and median disease- free survival (DFS) was 120 months (range 36-223), no statistically significant differences were found between PHL and other types of NHL in terms of OS and DFS. HCV infection did not appear to influence the results of therapy.
Summary/Conclusions: Our study confirms the rarity of PHL, shows a high prevalence of HCV infection, and demonstrates that the outcome of patients with PHL may be favorable.

PB1730

LEUKEMIZATION OF FOLLICULAR LYMPHOMA: DIAGNOSTIC FEATURES AND CLINICAL COURSE OF A RARE FORM OF THE DISEASE

E Nesterova[1,*], AM Kovrigina[1], EA Baryakh[2], AE Misyurina[1], YK Mangasarova[1], LV Plastinina[1], TN Obuhova[1], EG Gemdzhian[1], IA Vorobyev[3], AI Vorobyev[1], SK Kravchenko[1]
[1]Moscow, National Research Center for Hematology, [2]Moscow, City Clinical Hospital №52, [3]Moscow, Moscow State University named after Lomonosov, Moscow, Russian Federation

Background: Follicular lymphoma is a frequent lymphoid neoplasm, accounting for 22 percent of all non-Hodgkin's lymphoma in Russia. At diagnosis, some patients with FL manifest a detectable leukemic phase – leukemization (FL-LP), but this feature has been seldom described and has poorly prognosis.
Aims: to characterize a group of patients with FL with leukemization and evaluate the efficacy of therapy (R-CHOP /R-FMC/high dose therapy (HDT)).
Methods: Among 250 patients diagnosed with FL in National Research Center for Hematology, 18 (7, 2%) had characteristic FL-LP (by cytological blood smears and flow cytometry analysis). 8/18 patients had extranodal foci: lung, stomach, spleen, lumbar muscles, upper jaw, vertebrae. 17/18 patients had bone marrow involvement. Morphologically in biopsies of tumors in the majority of patients had a indolent FL (10/18 pts were diagnosed with I-II cytological grade of FL, nodular tumor growth and nodular-diffuse tumor growth in 14/18 pts). As first line therapy we used standard therapy (R-CHOP or R-FMC) or HDT with autoSCT.
Results: Median follow-up was 66 months (range 12–217). The 5-year overall survival (OS) and progression-free survival (PFS) were: 70% (standard error 10) and 35% (15), respectively (Figure 1A-B), Median OS was not reached, median RFS was 3 years.

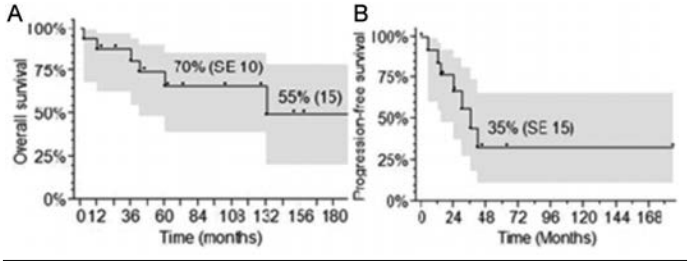

Figure 1.

Summary/Conclusions: FL with leukemization characterized by a low overall and disease-free survival. The most effective treatment regimens of this group are: R-CHOP with autoSCT or R-FMC. These courses allow a greater degree to achieve complete eradication of the tumor clone in the bone marrow. Given the recurrent course of the FL, the most expedient to conduct autoSCT in first-line therapy.

PB1731

DIFFUSE LARGE B-CELL LYMPHOMA IN HIGH RISK AAIPI 2-3 YOUNG PATIENTS: CLINICAL PRESENTATION AND SURVIVAL AFTER FIRST LINE STANDARD R-CHOP THERAPY

MQ Salas Gay[1,*], E Domingo-Domenech[1], S Mercadal[1], V Paredes[1], A Oliveira[1], C Aguilera[1], F Climent[2], M Encuentra[3], A Fernandez de Sevilla[1], A Sureda[1], E González Barca[1]
[1]Hematology, Hospital Duran i Reynalds, [2]Patologist, Hospital Universitario de Bellvitge, [3]UIC, Hospital Duran i Reynalds, Barcelona, Spain

Background: The outcome of diffuse large B-cell lymphoma (DLBCL) has substantially improved with the addition of Rituximab (R) to chemotherapy regimens although there is not a randomized trial comparing R-chemotherapy *versus* chemotherapy alone in high risk young patients.
Aims: We aim to present a retrospective study of the clinical, immunohistochemical features (IHC), and survival of patients≤60 years with aaIPI 2-3 treated with 6 cycles of standard R-CHOP in a single center.
Methods: Three hundred sixty seven patients were diagnosed of DLBCL from January of 2004 to June of 2015 in our centre, 119 (32.4%) were ≤60 years and 63 (52.9%) of them had aaIPI 2-3. Cases were classified as germinal center (GB) or activated B-cell (ABC) subtype according with the IHC Hans's algorithm.

Clinical and biological features, progression free survival (PFS) and overall survival (OS) were analyzed. Survival curves were estimated using the Kaplan-Meier method and compared using the log-rank test.
Results: Sixty three young patients with aaIPI 2-3 DLBCL were included. Median age was 50 years (range 21-60), 29 (46%) were male. Clinical characteristics at presentation were: ECOG ≥2 in 45 (67.2%), Ann Arbor stage III-IV 53 (84.1%), B symptoms 27 (42.9%), Bulky >5cm mass 19 (30.2%), extra nodal disease 43 (68.3%), CNS involvement 3 (4.8%), high LDH 37/53 (69.8%), high B2M 12/25 (48%), aaIPI2 48 (71.6%) and aaIPI3 15 (23.8%).Thirty-six cases had data to be classified by IHC: 22 (61.1%) CGB and 14(38.9%) ABC. Sixty-two (98.4%) patients started treatment: 58 (92%) with 6 cycles of R-CHOP and 4 (8%) of R-CHOP-like (2 R-CNOP, 1 R-Bortezomib-CAP and 1 GA101-CHOP). Nine (14.2%) patients did not complete treatment, 5 due to adverse events (2 not recorded, 2 severe infections, 1 cardiac event) and 4 due to progression. Intrathecal prophylaxis was administered in 10 (16.1%) cases and as therapy in the 3 patients with CNS involvement. Response was evaluated with PET/CT in 41 (71.8%) patients. Intention to treat response rate was: CR 46 (73%), PR 4 (6.3%), refractory disease 9 (14.3%), not evaluable 4 (6.3%). With a median follow-up of 44 months PFS was 69% and OS was 70%. PFS was 75.2%in patients with aaIPI 2 and 46.7% in patients with aaIPI3 (p=0.02). OS was 77.4% and 38.7% respectively (p=0.01). Sixteen patients relapsed or progressed[AS1], 4 were lost of control and 12[AS2] were treated with a second line regimen in our center (9 R-ESHAP, 1 MTX-ARAC, 1 Burkitt regimen and 1 DHAP). Only 3 patients achieved enough response (2 CR and 1 PR) to[AS3] undergo an autologous stem cell transplant. After second line therapy, median PFS was 2 months and median OS was 4 months.
Summary/Conclusions: Six cycles of R-CHOP is an effective first line regimen for young patients with aaIPI2, but alternative therapies are needed for patients with aaIPI3. Moreover, only a small percentage of patients who fail first line therapy are rescued. Clinical trials with new drugs are needed especially for the very high risk population.

PB1732

ANALYSIS OF RISK FACTORS FOR CENTRAL NERVOUS SYSTEM RELAPSE IN DIFFUSE LARGE B-CELL LYMPHOMA: THE EXPERIENCE OF A TERTIARY HOSPITAL

M Vara[1,*], M Puente[1], E Amutio[1], A Balerdi[1], I Olazabal[1], H Díez[1], L Posada[1], C Gómez[1],xMartín[1], L Martínez-Indart[2], J Escudero[2], MÁ Gil[3], J García-Ruiz[1]
[1]Hematology department, Cruces Universitary Hospital, [2]Biocruces Health Research Institute, [3]Pharmacy department, Cruces Universitary Hospital, Barakaldo, Spain

Background: Central nervous system (CNS) relapse is an uncommon (5%) unfavorable complication of diffuse large B-cell lymphoma (DLBCL). Independent predictors at diagnosis have been described to establish higher-risk groups that benefit from CNS prophylaxis: IPI ≥3, elevated serum LDH levels, B symptoms, bulky mass, CD5+, MYC rearrangement, >1 extranodal involvement, ECOG >1 and absence of Rituximab in systemic treatment. Many studies have demonstrated that the frequency of CNS relapse varies from 10% to 50%, depending on risk factors.
Aims: Analyze triple intrathecal therapy to prevent CNS relapse in DLBCL with high risk factors.
Methods: We analyzed retrospectively, from 2009 to 2015, 75 patients with newly diagnosed DLBCL. The decision to administer them all triple intrathecal therapy (TIT) (metotrexate, cytarabine, hydrocortisone) was based on the CNS relapsing risk factors in DLBCL described above. Systemic therapy was CHOP-*like*. Qualitative variables are described in percentages and quantitative variables are described with means and standard deviations. We use Chi square test to compare different categorical variables with CNS relapse. The overall survival is tested with Kaplan-Meier tables.
Results: Of 75 patients, 41 were male. Median age at diagnosis was 62 years. 6 (8%) patients experienced CNS relapse. The mean Overall Survival (OS) was 62 months CI 95% (55-69). OS at 6 months was 90.4%, at 2 years 80.5% and at 5 years 72%.Table 1 shows comparison between parameters described and CNS relapse.

Table 1.

Risk factors at diagnosis	Frequency (n)	CNS relapse (%)	P value
B symptoms (Yes/No)	37/38	10.8/5.3	0.430
Bulky mass (Yes/No)	19/56	10.5/7.1	0.640
Ann-Arbor Stage (I-II/III-IV)	11/64	9.1/7.8	0.999
Serum LDH levels (elevated/non-elevated)	46/29	8.7/6.9	0.999
Extranodal sites (0-1/>1)	42/33	4.8/12.1	0.395
IPI (0-2/3-5)	30/35	6.7/8.9	0.999
CNS involvement at diagnosis (Yes/No)	2/73	50/6.8	0.155
Rituximab (Yes/No)	73/2	8.2/0	0.999
CD5 (Positive/Negative)	4/53	0/9.4	0.556
MYC rearrangement (Negative/Not realized)	6/69	16.7/7.2	0.405

Summary/Conclusions: Spanish GELTAMO group has recently published the Guideline for diagnosis, prevention and therapeutic management of CNS involvement in DLBCL. In our experience, TIT was effective to prevent CNS relapse (8% compare to 10-50% described in literature in high risk patients). However, patients with very high risk factors could benefit from combination therapy recommended by GELTAMO based on inmunochemotherapy+TIT+ High Dose Metotrexate.

PB1733

ANALYSIS OF THE TOXICITY AND EFFICACY OF LIPOSOMAL CYTARABINE IN THE PROPHYLAXIS AND TREATMENT OF CNS LYMPHOMATOSIS: THE BALEARIC LYMPHOMA GROUP EXPERIENCE

M Garcia-Recio[1,*], A Cladera[2], L Bento[1], J Dominguez[2], S Ruiz de Gracia[1], F Sartori[1], R Del Campo[2], L García[1], C Ballester[1], J Bargay[2], A Sampol[1], A Gutierrez[1]
[1]Hematology, Univerity Hospital Son Espases, [2]Hematology, Hospital Son Llatzer, Palma, Spain

Background: CNS lymphomatosis is a generally fatal complication of aggressive NHL. Without specific CNS prophylaxis the risk of CNS relapse is higher (20-30%) in patients with very aggressive NHL such as burkitt or lymphoblastic lymphoma/leukemia. DLBCL has a lower risk (around 5%) but several factors have been identified that increase the incidence of CNS relapse to levels similar to very aggressive NHL. All above mentioned patients are candidates for CNS prophylaxis. However there is no consensus about which is the best way of administering CNS prophylaxis. Best results seem to be associated to the use of intravenous (iv) high-dose methotrexate (HDMTX) but with significant toxicity. Other options are intrathecal (IT) administration of MTX, cytarabine or liposomal cytarabine (ITLC). However no randomized trial has been performed to test which is the best option in terms of tolerance and efficacy.
Aims: We aim to analyse the experience of the centres of the Balearic Lymphoma Group about the tolerance, toxicity and efficacy of ITLC in the prophylaxis and therapy of CNS lymphomatosis.
Methods: We retrospectively reviewed all cases treated with ITLC in Son Espases and Son Llatzer Hospitals. Standard diagnostic, response assessment and follow-up data was obtained from medical records. All cerebrospinal fluid (CSF) samples were evaluated through 8-colours flow cytometry. Survival analysis was done using Kaplan-Meier curves and the Log-rank test.
Results: From 2005 to 2015, 58 patients received ITLC. They received a total of 180 ITLC injections. Toxicity was as follows: 33% headache, 20% neurological deficits, 11% nausea, 9% dizziness, 4% vomiting, 4% fever, 2% transient blindness and 2% photophobia. In the prophylactic cohort (n=26) with a median follow-up of 55 months (17-81) only 3 CNS relapses (11%) were observed in a testicular DLBCL, Burkitt and plasmablastic lymphoma. This represents a cumulative incidence of CNS relapse of 8%, 14% and 20%, respectively for DLBCL, Burkit/lymphoblastic and plasmablastic lymphoma. In the treatment cohort (n=32), complete clearance of CSF was obtained in 77% of cases (86%, 62% and 100% of respectively DLBCL, Burkit/lymphoblastic lymphoma and Primary CNS lymphoma). Median OS was 6 months (0-16). Causes of death were lymphoma progression in 19 patients (79%), treatment toxicity in 2 and other non-related in 3 (12%) (Table 1).

Table 1.

Characteristics	Global group(n=58)	Prophylaxis cohort (n=26)	Treatment cohort(n=32)
Median age (range)	53 (10-85)	47 (12-85)	55 (10-81)
Gender:			
·Male	44 (76%)	19 (73%)	25 (78%)
· Female	14 (24%)	7 (27%)	7 (22%)
Diagnostic:			
DLBCL	31 (53%)	17 (65%)	14 (44%)
Lymphoblastic or Burkitt	16 (27%)	7 (27%)	9 (28%)
Primary CNS Lymphoma	6 (10%)	1 (4%)	5 (16%)
Mantle Cell Lymphoma	3 (5%)	1 (4%)	2 (6%)
Peripheral T-cell lymphoma	1 (2%)	0 (0%)	1 (3%)
Follicular Lymphoma	1 (2%)	0 (0%)	1 (3%)
First line treatment:			
· Intensive treatment ALL-like	14 (24%)	7 (27%)	7 (22%)
·Intensive treatment for CNS	11 (19%)	1 (4%)	10 (31%)
·Conventional CHOP-like	23 (40%)	17 (65%)	6 (19%)
Other	10 (17%)	1 (4%)	9 (28%)

Summary/Conclusions: The toxicity profile was good especially when concomitant IT and oral dexamethasone was administered. In the prophylactic cohort the incidence of CNS relapse was low in the DLBCL group similar to previously reported for iv HDMTX and much better than IT MTX. ITLC may be a good alternative for CNS prophylaxis but randomized clinical trials are needed. Patients in treatment cohort had a high rate of clearance of CSF but survival is still poor in CNS lymphomatosis.

PB1734

CHARACTERIZATION OF HEPATITIS C VIRUS ASSOCIATED B-CELL NON-HODGKIN LYMPHOMA IN MANSOURA REGION (EGYPT), ANRS 12263 STUDY

Z Emarah[1,2,*], H Abdel-ghaffar[3], D Canioni[4], S Shamaa[1], M El-Zaafarany[1], H Ghazy[1], S Abdel-Aziz[3], M Mofreh[3], L Tharwat[3], E Eladle[5], A Abdelaziz[6], O Hermine[7], C Besson[8]
[1]Medical Oncology, Oncology Center, Mansoura University, [2]Internal Medicine, [3]Haematology Unit, Clinical Pathology Department, Faculty of Medicine, Mansoura University, Mansoura, Egypt, [4]Department of Pathology, Paris 5 Descartes University, Paris, France, [5]Department of Pathology, [6]Faculty of Medicine, Mansoura University, Mansoura, Egypt, [7]Department of Adult Hematology, Paris 5 Descartes University, [8]Department of Internal Medicine and Clinical Immunology, Paris Sud University, Paris, France

Background: The prevalence of Hepatitis C virus in Egypt is 14.7%, which is considered the highest in the world. Genotype 4 represents about 93.1% of cases which is considered among the highest prevalence areas of genotype 4 all over the world. Non-Hodgkin lymphoma is the 5th most common cancer in both male and female in Egypt. The association of HCV infection and development of B-cell lymphoproliferative especially the causative relationship not yet clear in Egypt.
Aims: the aim of this primary pilot study is to evaluate the incidence and clinical characteristics of HCV associated lymphoma in Egypt.
Methods: Between January 2012 and January 2013, we enrolled 110 adult patients with newly diagnosed B cell NHL. HCV infection was defined by the detection of anti-HCV antibodies by enzyme-linked immunosorbent assays with or without viraemia at initial diagnosis. Patients with Hepatitis B virus co-infection could be included but not those with HIV co-infection. Anti HCV positive samples, underwent HCV-RNA testing at disease diagnosis beside a rheumatoid factor screen.
Results: The incidence of B cell non-Hodgkin lymphoma associated with HCV infection was 60.9% (67/110 patients) which is considered the highest reported value in the literature. The incidence of cases presented with viraemia was 80% (32/40 patients). As regard histology, the majority of HCV associated lymphoma were DLBCLs (71.6%), SLL/CLL (13.4%), marginal zone (7.5%) and follicular (7.5%).
Summary/Conclusions: B cell lymphomas are highly associated with HCV infection (In Egypt incidence=60.9% *vs* 2.5% in France). The difference in genotype distribution may be responsible for different incidence and behavior of HCV associated lymphoma. Further studies is needed to have a molecular signature for this unique environmental and genetic background.

PB1735

PRIMARY BONE LYMPHOMA (PBL) - "REAL WORLD" EXPERIENCE OF A SINGLE CANCER HOSPITAL. CLINICAL CHARACTERISTICS, PROGNOSTIC FACTORS AND MANAGEMENT OF TWELVE PATIENTS.

D Stoumbos[1,*], I Patsias[1], G Papageorgiou[1], E Fergadis[1], C Gkekas[1], EE Christaki[1], E Asmanis[1], P Lampropoulou[1], A Tsakiridou[1], P Repousis[1], A Megalakaki[1], I Skouras[2], A Petridis[3], M Kotsopoulou[1]
[1]Hematology, [2]Radiology, [3]Radiation Oncology, Metaxa Cancer Hospital, Peiraias, Greece

Background: PBL was first described as a distinct clinopathological entity on 'reticulum cell sarcoma of bone' in 1939 by Parker and Jackson. It is a very rare condition which constitutes less than 1% of all malignant lymphomas, less than 2% of all bone tumors and less than 5% of extra-nodal lymphomas. A number of studies have been reported, but most with a limited number of patients. Being an uncommon entity, there is a lack of experience in paramaters such as clinical characteristics and optimal management.
Aims: To determine patient characteristics, prognostic and treatment factors that could affect outcome measured by overall survival (OS) and complete remission (CR).
Methods: Herein, we retrospectively review 12 patients diagnosed with PBL and treated at our institution from 2001 to present.
Results: The demographic and clinical characteristics of the 12 patients at the time of diagnosis are summarized in Table 1. The median age of the patients was 49 years old (range, 31-81 years). Eight (70%) patients were female and 4 (30%) male. The histological type of all 12 patients (100%) was Diffuse Large B-Cell Lymphoma. Ten patients (83%) were presented with Ann Arbor Stage I or II disease. Two patients (17%) had high stage disease. The median follow-up after achieving CR (without relapse) to date was approximately 80 months (range, 0-170 months). Our analysis demonstrated that age less than 47 years normal LDH level, Ann Arbor Stage I or II and female gender were found to be favorable prognostic factors for achieving CR and OS. Notably, the pelvis was the most frequently primary involved site of the bone (5; 41.5%). All twelve patients underwent chemotherapy with most of them (10; 83%) receiving six to eight cycles of the RCHOP regimen. The majority (11; 92%) of them received radiotherapy. After front line chemotherapy followed by radiotherapy most patients (9; 75%) achieved CR. Among the remaining three patients, the one died before completing first line chemotherapy due to an infection while in chemotherapy-induced neutropenia. The other patient is undergoing autologous stem-cell transplantation due to refractory PBL. The third one achieved CR after he underwent autologous stem-cell transplantation due to refractory PBL. Both patients that had refractory disease were male and initially diagnosed with high stage PBL. The median OS was 89,5 months (range, 6-178 months).

Table 1. Patient demographic and clinical characteristics.

	Median	Range
Age	49 years	31 - 81
Gender M/F	4 (30%)/8 (70%)	
Serum LDH	250 IU/L	137 - 857
Clinical Stage I & II	10 (83%)	
Pelvis as primary involved site of the bone	5 (41,5%)	
Initial CTx: RCHOP	10 (83%)	
Response to initial treatment CTx+RT: CR	9 (75%)	
ASCT	2 (17%)	
Follow up after CR (without relapse)	80 months	0 - 170
OS	89.5 months	6 - 178

Summary/Conclusions: Although the total number of patients was relatively small, the data from our study supports that most PBL patients have had early stage disease (IE-IIE) on diagnosis which also was the most important favorable prognostic factor. Overall, patients with primary lymphoma of the bone with DLBCL have an excellent prognosis and only a limited number of patients underwent autologous stem-cell transplantation in order to achieve CR.

PB1736

PRIMARY BONE DIFFUSE LARGE B CELL LYMPHOMA: EXPERIENCE AT A SINGLE CENTER IN JORDAN

M Ayesh (Haj Yousef)[1,*], Z Audat[2], K Alwaneh[1], Y Khader[3]
[1]Medicine, [2]orthopedic, [3]Public health, Jordan University of Science and Technology, Irbid, Jordan

Background: Diffuse large B cell lymphoma (DLBCL) is the most common type of non-Hodgkin's lymphoma, although there may be geographical and ethnic differences with respect to DLBL; these differences are associated with particular clinicopathologic features and outcomes. Primary bone diffuse large B cell lymphoma (PBDLBL) comprises 4–5% of all extranodal non-Hodgkin lymphoma (ENHL) cases and less than 1% of all malignant lymphomas. PBDLBL is so rare that many of its characteristics remain unknown, with no data at all available from Jordan.
Aims: To examine the epidemiology and clinical features of PBDLBL in Jordanian patients as a model for other Middle East countries in which such data are scarce.
Methods: Between September 2002 and December 2015, 112 patients aged 16 years and above were diagnosed with DLBL and treated at King Abdullah University Hospital.Patients with ENHL were included in the study only if they had a tissue diagnosis of DLBL at the site of involvement. According to the site of ENHL involvement at the time presentation Clinical stage was defined according to the Ann Arbor classification. Disease involving the lymph nodes, spleen, and Waldeyer's ring were defined as "nodal".
Results: This retrospective study included 114 patients with DLBCL (54 females and 60 males; age range, 16 to 94 years; mean (SD), 51.0 (18.7) years). Of these, 66 (57.9%) presented with heterogeneous extranodal organ involvement. Of all extranodal sites, bone was involved in nine (14%) cases. Of these cases, 33% were female and 67% were male. The mean age of patients with extra nodal involvement was 46.7 (20.6) years. There was no significant difference between those with nodal and those with extranodal lymphomas in terms of gender (p=0.656) or age (p=0.158). The spine was the most common site of extranodal involvement with DLBL in six patients, the pelvis in one patient, the clavicle in one patient, and the scapulae in one patient. Back pain was the most common presenting symptom (six (67%) patients). A pathological fracture was noted in one patient (11%), a shoulder mass in one patient, and lower limb paralysis in one patient. No B symptoms were present in any patient. Serum lactic dehydrogenase (LDH) levels were elevated in only one patient.
Summary/Conclusions: PBDLBL was the second most common extranodal manifestation of DLBL (14%), with the spine being the most frequent site.the most common extranodal site was the gastrointestinal tract (18%). Back pain was the main presenting symptom, with an absence of B symptoms. LDL levels were normal in most patients. The present study highlights geographic and ethnic variations in the primary disease site in patients with DLBL.

PB1737

THE INFLUENCE OF CARDIOVASCULAR COMORBIDITIES ON THE THERAPEUTIC RESPONSE AND PROGNOSIS OF PATIENTS DIAGNOSED WITH AGGRESSIVE NON HODGKIN LYMPHOMA

P Monica[1,*], SR Cristina[1], PO Ovidiu[1], B Ema-Cristina[1], O Dacian[1], J Cristian[2], I Ioana[1], I Maria[1], I Hortensia[1]

[1]Hematology, Municipality Emergency Hospital of Timisoara, [2]Onco-hematology and Bone Marrow Transplantation, Emergency Children's Hospital LOUIS TURCANU, III. Clinic of Pediatrics, Timisoara, Romania

Background: The NHLs are a heterogeneous group of lymphoproliferative malignancies with different patterns of behavior and responses to treatment. The aggressive type of NHL has a shorter natural history, but a significant number of these patients can be cured with intensive chemotherapy regimens.
Aims: The aim of this study was to determine to what extent cardiovascular comorbidities influence choice of therapy, treatment response and survival of patients diagnosed with NHL.
Methods: We have retrospectively analyzed clinical data of 47 aggresive NHL patients who were consecutively diagnosed at the Hematology Department of the Municipality Hospital of Timisoara,between 2009 and 2015. Disease stage and treatment were established after collecting clinical,laboratory, and pathological data. Survival analysis was estimated by means of the Kaplan-Meier curves and comparison of survival between subgroups was performed using the log-rank test. IBM SPSS Statistics 23 was the software that was used.
Results: There were 20 patients males and 27 females, averaging the age of 53.82 years, a median age at diagnosis of 56 years and a standard deviation of 15.49. The estimated overall survival at 5 years for the whole group of patients is 45% while the free survival disease at 5 years is 38%. In the case of patients diagnosed with high blood pressure (HBP), the overall survival is 45% at 5 years compared to the 43% for the patients who did not show HBP while the free survival disease for the patients diagnosed with HBP at 5 years is 45% compared to those who did not indicate the presence of HBP (37%). As for the coronary artery disease (CID), there were found differences both for the overall survival at 5 years (59% *versus* 41%) and for the free survival disease at 5 years (58% *versus* 32%). Also, for the patients diagnosed with heart failure the overall survival at 30 months proved to be 0% compared to the overall survival for those who did not show this pathology (65%), and this is the same for the free survival disease found at these patients (p=0.025).
Summary/Conclusions: All the patients were subjected to polychemotherapy of R-CHOP or R-CNOP type. Referring to the associated cardiovascular commomorbidty neither the high blood pressure nor the coronary artery disease prove to be factors of negative prognosis, neither did they influence the survival and nor required the diminution of the chemotherapy dosages. Only the heart failure influenced the survival.

PB1738

LATE MYELOTOXICITY OF INTENSIVE MODIFIED PROGRAM NHL-BFM-90 IN ADULT POOR-PROGNOSIS PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

E Dorokhina*, A Magomedova, V Dvirnyk, I Galtseva , S Glinkina, S Kulikov, T Obuchova , S Kravchenko
National Reserch Center of Hematology, Ministry of Health of Russia, Moscow., Moscow, Russian Federation

Background:
High dose chemotherapy showed to be more effective compared with standart dose therapy in DLBCL patients with poor prognosis, but late myelotoxicity wasn't estimated enough.
Aims: To evaluate late myelotoxicity of intensive modified program NHL-BFM-90 (mNHL-BFM-90) in adult poor-prognosis patients with diffuse large B-cell lymphoma (DLBCL).
Methods: Results of complex clinical, laboratory and instrumental examination, including cytological, histological and standard cytogenetic bone marrow study of 40 patients with DLBCL which received mNHL-BFM-90 protocol in the Hematology Research Center in the period since 2002 till 2009 years were analyzed. Group consisted of 20 men, 20 women, median age – 57 (31-76) years at the time of survey. Comparison group included 19 patients (8 men and 11 women), median age – 70 (39-80) years at the time of survey, who received CHOP /R-CHOP-21 therapy. Median follow-up after completion of treatment - 6 years. Results of study of bone marrow were analyzed before chemotherapy and after 5-10 years after treatment. Cellularity of bone marrow, the amount of erythroid, granulocytic and megakaryocytic germs, signs of dysplasia, and dysplastic changes of stroma were determined by histologically and cytologically. Also performs standard cytogenetic bone marrow examination to identify karyological violations. As late myelotoxicity were considered signs of toxic damage of bone marrow, which appeared first time in late period after chemotherapy . Cases with initially presented and preserved after chemotherapy myelotoxicity signs, as well as presence and absence of baseline after chemotherapy – weren't taken into account.
Results: Cytopenia (with no signs of myelodysplasia and substitutive transfusions of blood components need) were detected in 52% of patients with high-dose group, 46% of cases are accounted for thrombocytopenia. Reduced cellularity of bone marrow in 15 (38%) patients, p=0.02, reducing of erythroid and megakaryocytic germs in 13 (33%), p=0.01, and 19 (48%), p=0.009, respectively, stroma changes in 17 (43%) patients, p=0.02, were revealed like signs of late myelotoxicity in patients after high-dose chemotherapy for mNHL-BFM-90 program. Standard cytogenetic study of bone marrow was performed for first six patients, all had a normal karyotype, without any karyological abnormalities, therefore further study wasn't performed.
Summary/Conclusions: Long-term myelotoxicity of high-dose program mNHL-BFM-90 exceeds significantly toxicity of standard therapy CHOP/R-CHOP-21. However, myelodysplastic syndromes or cytopenia requiring transfusions of blood components wasn't observed.

PB1739

ANALYSIS OF CLINICAL PARAMETERS, ABSOLUTE LYMPHOCYTE AND ABSOLUTE MONOCYTE COUNT IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

J Jelicic[1,*], M Torodovic Balint[1], D Antic[1], B Andjelic[1], O Markovic[2], I Petkovic[3], A Sretenovic[1], J Bila[1], V Vukovic[1], V Djurasinovic[1], M Smiljanic[1], I Pejicic[3], B Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [2]Clinical Hospital Center "Bezanijska Kosa", Belgrade, [3]Clinic of Oncology, University Clinical Centre Nis, Nis, Serbia

Background: The results of gene expression profiling (GEP) analysis of diffuse large B cell lymphoma (DLBCL) confirmed existence of two subtypes of DLBCL with different outcome. In order to reproduce GEP findings several studies have investigated the potential role of absolute lymphocyte count (ALC), absolute monocyte count (AMC) and ALC/AMC as surrogate markers. However, the contradictory data were reported.
Aims: The aim of this study was to evaluate prognostic significance of clinical parameters, laboratory parameters: ALC, AMC and ALC/AMC on the overall survival (OS) and event free survival (EFS).
Methods: A total of 583 patients (295 females/288 males) with the median age of 60 years (range 18-89) were included in the study. According to the Ann Arbor classification, stage I, II, III and IV had 74 patients (12.7%), 212 (36.4%), 110 (18.9%) and 187 (32.1%), respectively. Bulky disease was present in 190 patients (32.6%) and B symptoms in 370 patients (63.5%). Bone marrow involvement was present in 77 patients (13.2%). Low Revised International Prognostic Index (R-IPI) was presented in 97 patients (16.6%), intermediate in 307 (52.7%) and high in 174 (29.8%). Median ALC at diagnosis was $1.35x10^9$/l (range 0.07-$17.8x10^9$/l), AMC $0.60x10^9$/l (range 0.06-$8.58x10^9$/l) and ALC/AMC 2.5 (range 0.07-$37.0x10^9$/l). Cut off values for LAC, AMC and ALC/AMC were used as previously published and included $1.1x10^9$/l, $0.62x10^9$/l and $2.6x10^9$/l for ALC, AMC and ALC/AMC, respectively. Regarding cell of origin according to Hans algorithm, 45.3% of patients had GC (germinal center) type, while 64.7% had non-GC type. All patients were initially treated with rituximab plus CHOP or CHOP like protocols.
Results: Complete remission (CR) was achieved in 425 patients (72.9%), partial remission (PR) in 79 (13.6%), stable disease (SD) in 19 (3.3%) and progressive disease in 60 (10.3%). Disease relapse was confirmed in 88 patients (15.1%). The patients with B symptoms of disease had inferior OS (Log Rank=11.27, p=0.001) and EFS (Log Rank=12.62, p=0.001) compared to those without B symptoms. Furthermore, presence of bulky disease influenced OD (Log Rank=10.58, p=0.001) and EFS (Log Rank=11.35, p=0.001). The prognostic value of R-IPI was highly statistically significantfor both OS (Log Rank=62.3, p<0.0001) and EFS (Log Rank=56.83, p<0.0001). The patients with GC type had better OS (Log Rank=7.44, p=0.006) and EFS (Log Rank=6.34, p=0.012) compared to non-GC type. However, there was no influence of ALC, AMC and ALC/AMC neither on OS nor EFS. Multivariate analysis among significant parameters (presence of B symptoms, bulky disease, R-IPI and cell of origin GC *vs* non-GC type), has pointed out the major impact of R-IPI on OS (HR 1.75, p<0.0001) and (HR 1.44, p=0.0001) along with the presence of B symptoms (OS, HR 1.51, p=0.01; EFS, HR 1.58, p<0.008).
Summary/Conclusions: ALC, AMC and ALC/AMC failed to prove influence on survival of DLBCL patients indicating the need for new potential surrogate markers of GEP results. Moreover, R-IPI as clinical prognostic score may help to differentiate risk groups within DLBCL patients.

PB1740

OUTCOME AND PROGNOSTIC FACTORS IN DIFFUSE LARGE B-CELL LYMPHOMA: AN INSTITUTIONAL EXPERIENCE OF A TERTIARY CARE CENTRE FROM INDIA

R Mahajan[1,*], BS Yadav[1], S Kumar[1], A Gupta[1], S Ghoshal[1], SC Sharma[2], R kapoor[1], N Kumar[1]
[1]Radiotherapy and Oncology, Post Graduate Institute of Medical Education and Research, Chandigarh, [2]Radiotherapy And Oncology, Mmu, Mullana, Ambala, India

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common non-Hodgkin's lymphoma(NHL), accounting for approximately 30% of all new diagnoses. We conducted the retrospective study in our institution to analyze the main clinical features at diagnosis, response to therapy and the outcome of patients diagnosed with DLBCL.
Aims: To analyze the prognostic factors, response to therapy and the outcome of patients with DLBCL.

Methods: This study enrolled 74 patients with histologically confirmed diagnosis of DLBCL treated from January 2003 to December 2014. Complete clinical patient and disease related details were recorded. All patients were treated with chemotherapy with or without radiotherapy. Clinical features, treatment response and impact of different prognostic factors on clinical outcome were analyzed. Bulky disease was defined as any mass greater than 10cm in diameter.

Table 1.

Characteristic:		Number(%)
Age	<=60	55(74.3)
	>60	19(25.7)
Site	NODAL	40(54.1)
	EXTRANODAL	34(45.9)
Nodal sites	<4	34(45.9)
	=>4	6(8.1)
B symptoms	NO	70(94.6)
	Yes	4(5.4)
Number of sites	ONE	40(54.1)
	TWO	22(29.7)
	THREE	7(9.5)
	FOUR OR MORE	5(6.8)
Bone marrow	NOT INVOLVED	70(94.6)
	INVOLVED	4(5.4)
Stage	I	36(48.6)
	II	20(27)
	III	13(17.6)
	IV	5(6.8)
IPI	LOW	58(78.4)
	INTERMEDIATE	9(12.2)
	HIGH INTERMEDIATE	7(9.5)
Treatment	CCT	31(41.9)
	CCT+RT	43(58.1)

Results: Median age of presentation was 50 years (range 18-85 years). 55(74.3%) of the patients were ≤60 years age and 19(25.7%) were >60 years age. Out of 74 patients, 53 were males and 21 were females. Ann Arbor clinical stage at diagnosis was 36(48.6%) stage I, 20(27%) stage II, 13 (17.6%) stage III, and 5(6.8%) stage IV respectively. Bulky disease was present in 6 patients (8.1%). Nodal disease was present in 40(54.1%) patients and 34(45.9%) had extranodal disease presentation. Supradiaphragmatic disease was seen in 44(59.5%) and 15(20.3%) had infradiaphragmatic as well as disease on both sides of the diaphragm. Most of the patients (93.2%) received either CHOP or R-CHOP chemotherapy. 43(58.1%) patients received consolidative radiotherapy. The median follow-up period was 22 months (range, 2 to 147 months). Complete response was seen in 51(68.9%) patients. With addition of radiation 9.4% improvement in local control was seen. Relapses was seen in 10(13.5%) patients, out of which 5(6.8%) had nodal and 5(6.8%) had visceral relapse. At 22 months, disease free survival (DFS) and overall survival (OS) was 66% and 81.5% respectively. Stage, International prognostic index (IPI), supradiaphragmatic disease, number of sites, extranodal diasease and number of nodal sites involvement were important prognostic factors having significant impact on response, DFS and OS (Table 1).

Summary/Conclusions: This study represents the largest Indian experience to treat DLBCL. Stage, IPI, supradiaphragmatic disease, number of sites, extranodal disease and number of nodal sites were the important prognostic factors for response, DFS and OS.

PB1741

STUDY OF DISPARITIES BETWEEN SERUM LDH AND SOLUBLE INTERLEUKIN-2 RECEPTOR (SIL-2R) IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS

T Okatani[1,*], H Asaoku[2], K Toishigawa[1], T Ochi[1], R Imanaka[1], K Kyo[1], M Itagaki[1], K Shinya[1], Y Katayama[1], K Iwato[3], K Taiichi[1]

[1]Division of Hematology, [2]Division of Laboratory, [3]Division of Transfusion, Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima city, Japan

Background: Serum LDH or serum interleukin-2 receptor (sIL-2R) are two of the most important tumour markers of malignant lymphoma, and of diffuse large B-cell lymphoma (DLBCL), which is the most common histological types of non-Hodgkin lymphoma. We usually find elevated values of both in DLBCL patients; however, sometimes there are cases where, unexpectedly, only one value does not exhibit an abnormal level, while the other does.

Aims: To analyse the clinical characteristics of cases where serum LDH and sIL-2R are not correlated.

Methods: We retrospectively analysed 556 patients that visited our hospital from March 1994 to June 2012 and who were diagnosed for the first time as having DLBCL. We drew a distribution chart of the ratio of serum LDH and normal level (LDH/N) and serum sIL-2R. (Figure 1.) The median LDH/N was 1.04 (0.38-20.59), and sIL-2R was 1,420 (119-40,000). Then, we decided two groups; group I was LDH/N >2, sIL-2R <2,000U/ml, and group II was LDH/N <1, sIL-2R >3,000U/ml.

Results: The median age of the DLBCL patients was 67 years (19-97). Thirteen patients were in group I (six female and seven male), and a total of 13 patients were diagnosed as being at an advanced clinical stage of disease. There were five patients aged over 60 (38%), but there were nine cases (69%) in which Performance Status (PS) was over 2. Twelve patients (92%) belonged to the higher-risk group, in which International Prognostic Index (IPI) was over 3. As for incidence, there were four (31%), primary mediastinal cases, seven (54%) extra-nodal onset cases, and bulky mass was observed in nine (69%). We were able to review six cases for pathological diagnosis; three were of the GCB type and three were the non-GCB type. On the other hand, 15 patients were in group II (seven female and eight male), 10 cases (67%) were over 60 years of age, but there were only four (27%) cases in which PS was over 2, and finally there were three (20%) in the higher-risk group. Ten cases (67%) had retroperitoneal mass and seven (47%) showed bone marrow involvement. Pathological diagnosis could be reviewed again in six cases; two were the GCB type and four were non-GCB type.

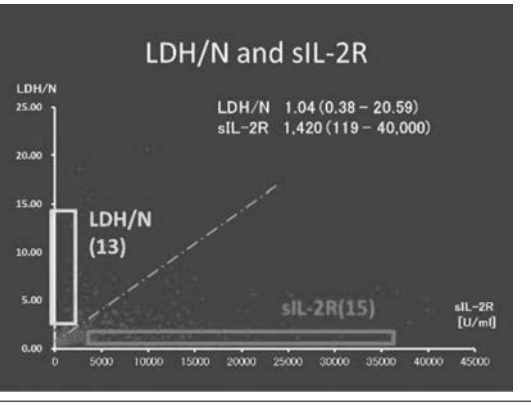

Figure 1.

Summary/Conclusions: DLBCL is a heterogenous disease. By analysing cases of disparity biomarkers between LDH and sIL-2R, we showed the possibility of identifying subgroups.

PB1742

DIFFUSE LARGE B-CELL LYMPHOMA IN THE ELDERLY: REAL-WORLD OUTCOMES OF IMMUNOCHEMOTHERAPY IN ASIAN POPULATION

JO Lee[*], JM Byun, SM Bang, JS Lee

Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: The International Prognostic Index (IPI) has been the primary scoring system for predicting the survival in diffuse large B-cell lymphoma (DLBCL). However, the validity of IPI in the era of immunochemotherapy is somewhat uncertain, and the age cut-off for defining "elderly" patients remains especially controversial. Moreover, elderly DLBCL patients frequently do not receive adequate treatment, compromising the chance of complete remission.

Aims: We sought to evaluate real-life outcomes of immunochemotherapy in elderly DLBCL patients from a homogenous Asian population.

Methods: This was a single-center, retrospective study of 192 DLBCL patients over 60 years of age treated with first line rituximab – cyclophosphamide, doxorubicin, vincristine, and prednisone between May 2004 and July 2014. Treatment schedule, adverse events and survival outcomes were analyzed overall and by four age groups (over 60 to 64, 65 to 69, 70 to 74, 75 and above).

Results: Patients of 75 years of age and older were associated with significantly lower complete remission (CR) rate (86.5% *vs* 81.4% *vs* 82.0% *vs* 51%; P<0.001) and higher treatment related mortality (TRM) (5.4% *vs* 9.3% *vs* 13.1% *vs* 33.3%; P=0.001). Advanced age was also related to dose reductions (24.3% *vs* 39.5% *vs* 73.8% *vs* 100%; P<0.001) and less likelihood of completing planned chemotherapy cycle (73% *vs* 79.1% *vs* 78.7% *vs* 51%, P=0.005). Significantly poorer progression free survival (PFS) (3-year PFS rate, 45.9% *vs* 44.2% *vs* 44.3% *vs* 11.8%; P=0.043) and overall survival (OS) (3-year OS rate, 64.9% *vs* 58.1 *vs* 55.7% *vs* 23.5%; P<0.001) were observed for patients aged ≥75 years old. Multivariate regression analyses identified age ≥75 and initial ECOG performance status as potential risk factors associated with OS.

Summary/Conclusions: In conclusion, elderly patients <75 years old or those with better performance status were tolerable to standard immunochemotherapy, with acceptable survival profiles. In Asian elderly DLBCL population, 75 years seems to be judicious cut-off age for predicting the treatment outcomes. Treating patients aged ≥75 years requires more innovative therapy options and not just dose reductions.

PB1743

EXPERIENCE WITH R-MINICHOP IN CLINICAL PRACTICE IN THE OLDEST PATIENTS WITH AGGRESSIVE NON HODGKIN'S LYMPHOMA

C De Ramon Ortiz*, M Monsalve, B Diaz Jordan, A Muñoz Gama, P Gomez Prieto, A Lopez de la Guia, P Baltasar, V Jimenez Yuste, M Canales
Hematologia y Hemoterapia, HOSPITAL UNIVERSITARIO LA PAZ, Madrid, Spain

Background: About 40% of aggressive Non Hodgkin's Lymphoma (NHL) are diagnosed in patients older than 70 years. However, the experience in the treatment of this group of patients is very limited. The encouraging results of the GELA group (Peyrade *et al.,* Lancet Oncol 2011) with the R-miniCHOP regimen in patients older than 80 years suggest that a substantial proportion of them can be cured, and therefore it is recommended as the standard therapy in this population.
Aims: The aim of this study is to analyse our experience in using this regimen in elderly patients with aggressive lymphoma.
Methods: We retrospectively analysed patients consecutively diagnosed with aggressive NHL, older tan 70 years, treated with R-miniCHOP regimen (rituximab 375 mg/m2, cyclophosphamide 400 mg/m2, doxorubicin 25 mg/m2, vincristine 1 mg, prednisone 60 mg/day) in our center, from August 2010 to December 2015.

Table 1. Patient's characteristics

Characteristics	n=30
Age, median	81 yo (73-85)
Women	18
Comorbidities	
- Cardiovascular	15
- HBV	4
- HCV	3
- Previous neoplasia	5
Histology	
- Diffuse large B-cell lymphoma	25
- Mantle Cell	2
- Burkitt	3
Stage III-IV	21
IPI	
- Low	3
- Intermediate/low	4
- Intermediate/high	5
- High	18

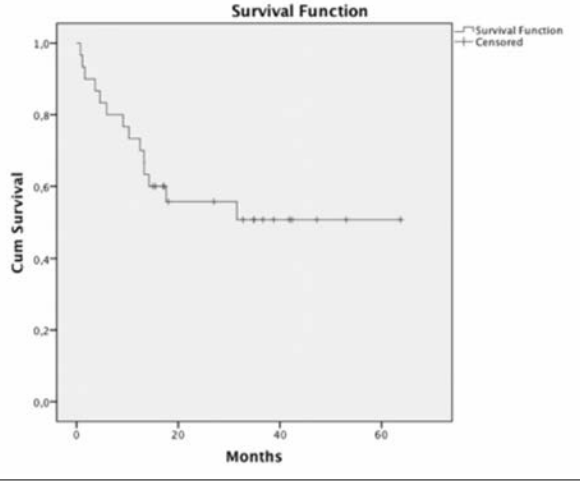

Figure 1.

Results: Thirty patients who received at least 1 course of treatment were included in our analysis. Clinical characteristics are summarized in Table 1. It is remarkable the poor prognosis of our patients, with median age of 81 years, the associated comorbidities and the high IPI. The median of treatment cycles received was 6 (1-8), 50% of cases received 6 cycles. Nine patients received prephase (Vincristine 1 mg and/or prednisone). Four patients received radiotherapy. Most frequent toxicity was hematological (grade 2 anemia and grade 3 afebrile neutropenia), ocurring mostly during the first cycle. Only one death occurred due to treatment toxicity (grade 4 neutropenia and sepsis). In seven patients, at least one cycle was postponed because of toxicity. The overall response rate was 63,3%, with 63,1% of patients achieving a complete response. During treatment, 11 patients experienced progression, 10 died and one reached partial response after salvage therapy with R-GEMOX (5 cycles). One death occurred because of other causes (arterial hemorrhage secondary to traumatism). During follow-up, three patients relapsed, with a median duration of response of 29.3 months. With a median follow-up of 17.15 months, median survival has not yet been reached (Figure 1).
Summary/Conclusions: R-miniCHOP represents an effective and safe regimen in this group of patients, confirming the previous experience of the GELA group. Toxicity observed in the first cycle shows the need of administering prephase in all patients.

PB1744

PROGNOSTIC FACTORS AND TREATMENT OUTCOME OF PEDIATRIC ANAPLASTIC LARGE CELL LYMPHOMA TREATED AT THE CHILDREN CANCER HOSPITAL EGYPT

H Abdelrahman Sayed[1,*], S El Semary[2], I Atteya[3], M Sedky[1], S Talaat[1], O Hassanain[4]
[1]Pediatric Oncology, National Cancer Institute, Cairo University, Cairo, [2]Pediatric Oncology, Bany Sweif University, Bany Sweif, [3]Pediatric Oncology, National Cancer Institute, [4]Research, Children Cancer Hospital, Cairo, Egypt

Background: Anaplastic large cell lymphoma (ALCL) belongs to the group of high-grade non-Hodgkin's lymphomas (NHLs) and typically presents as an aggressive systemic disease, with or without extranodal involvement. ALCL cells are characterized by the expression of the CD30/Ki-1 and more often by a T-cell phenotype. Frequently; ALCL is associated with the t(2;5)(p23;q35) chromosomal translocation, which gives rise to the fusion gene NPM–ALK. Recent data suggest that t(2;5) positive ALCL respond better to therapy and have a higher survival rate than translocation negative ALCL, thus implying that NPM–ALK expression may have a significant prognostic impact
Aims: The aim of the current study is to report the clinico-epinediologic data, prognostic factors and treatment outcome of pediatric ALCL treated at the Children Cancer Hospital Egypt during 8 years period.
Methods: A retrospective study including all patients diagnosed and treated as ALCL from july 2007 till July 2014 at CCHE. The diagnosis of ALCL was based on established morphologic and immunohistochemical criteria. ALK1 antibody directed to the NPM/ALK protein was used to detect the t(2;5) translocation.
Results: Forty-three patients were enrolled in our study, forming 5.4% of all NHL patients treated at CCHE within this period. They were 26 males (60.5%), and 17 (39.5%) females. Mean age was 11.5 years, median 11.7, range (3.7 to 17.2 years).The most common tumor primary site was generalized lymphadenopathy (62%). ALK status was available in 65% of the cohort (28 patients), of which 75% (21 patients) was positive and 25% negative. Bone marrow was free in all patients, while 5 patients (11.6%) had CNS involvement. Stage II and III were 37.2% each (16 patients), while stage IV was 14% (6 patients). Evaluation of tumor response post induction showed 25 (58%) of patients in complete remission (CR), 15 (34.9%) had partial remission (PR), 2 (4.7%) were progressive (PD), and 1 (2.4%) stationary disease (SD), while at the end of treatment 83.7% were in CR, 11.6% PD and 4.7% relapsed. At the end of the study period, 81.4% (36 patients) were alive, and (8 patients) 18.6% died. The mean FU period was 50months (range 12-96). The 4 years OS and EFS is 80.9% and 71.1% respectively.
Summary/Conclusions: Results of treatment of ALCL in our center are comparable to most of the reported studies. Salvage for relapsing and progressing patients is difficult, and the outcome is extremely poor, hence the need to identify biologic or clinical prognostic factors including minimal residual tumor to better evaluate chemotherapy response.

PB1745

CLINICAL OUTCOME AND PROGNOSIS IN 49 PATIENTS WITH MANTLE CELL LYMPHOMA TREATED WITH ROUTINE CLINICAL PRACTICE

G Tumyan*, P Zeynalova, N Falaleeva, I Ilyasova, V Larionova, E Osmanov
N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Mantle cell lymphoma (MCL) is a distinct subtype of non-Hodgkin's lymphoma (NHL) that has commonly an aggressive clinical course and a poor prognosis. Current frontline intensive therapies have improved the outcome for patients (pts). Although these regimens have high response rates, most pts eventually have a relapse. There is not always possible to find a relationship between the intensity of treatment and survival outcomes of pts with MCL.
Aims: To assess the impact of treatment intensity on survival outcomes in newly diagnosed patients with MCL.
Methods: We conducted a retrospective analysis for pts with MCL diagnosed between 2004 and 2014 through our institutional databases. Frontline treatment modalities were categorized into 2 groups: high intensity (R-HyperCVAD or equivalent and/or stem cell transplant) and moderate intensity therapy (R-CHOP, R-B or equivalent). Median progression free survival (PFS) and overall survival (OS) for each treatment group were estimated using the Kaplan-Meier (KM) method and compared using the log rank test. Cox regression was used to identify univariate predictors of survival.

Results: A total of 49 pts MCL were identified. Median age was 58 yrs (31-78), 69% were male, 94% had advance stages and 59% bone marrow involvement; MIPI low (54%), int. (26%), high (20%). High and moderate intensity treatment accounted for 19 (39%) and 30 (61%) of pts. 53% pts in moderate group followed by R maintenance. Intensively treated patients were more likely to be young and have B symptoms (58% *vs* 20% respectively). With a median follow-up of 48 months, median PFS was 42 mos and OS not yet reached. Despite median duration of response with high and moderate intensity treatment was 57 mos *vs* 30 mos, there was no statistically significant difference in PFS (p=0,46) and OS (p=0,16) by treatment strategy. This lack of survival difference was true for all pairwise log-rank comparisons between treatment groups. No significant correlation with OS was observed with age (p=0,56), MIPI risk (p=0,13), or treatment intensity (p=0.30).
Summary/Conclusions: In our retrospective analysis, we were not able to validate the hypothesis, that frontline intensive treatment may improve OS in MCL. These data highlight the lack of a "standard of care" in MCL, and provide further rationale for the use of novel agents in newly diagnosed MCL.

PB1746

PREVALENCE OF LYMPHOPROLIFERATIVE DISEASES IN PATIENTS WITH AUTOIMMUNE DISORDERS

V Djurasinovic[1,*], P Djuradjevic[2,3], D Antic[1,4], B Andjelic[1,4], A Sretenovic[1], V Vukovic[1], J Bila[1,4], J jeličić[1], M Todorovic-Balint[1,4], B Mihaljevic[1,4]
[1]Institute of hematology, Belgrade, [2]Medicall faculty, University of Kragujevacdic, [3]Clinical center Kragujevac, Kragujevac, [4]Medical faculty University of Belgrade, Belgrade, Serbia

Background: Lymphoproliferative disorders can be found in patients with previously diagnosed autoimmune disorder.
Aims: We have evaluated type of lymphproliferative disease in population of pts with autoimmune disorders and differences between genders.
Methods: Data from national registry for lymphoproliferative diseases were analysed. From 1992-2015. there was 45pts, male 9(20%) and female 36(80%), median age 57(33-76)years.
Results: 42(93%) of pts previously had autoimmune disesase with average 7,63(0,7-27) years. There were: systemic lupus erythematosus (SLE) 22/36(61%), reumathoid arthritis (RA) 8/36 (22%) and systemic sclerosis (SS) 6/36(17%) in women and SS 5/9 (56%), SLE 2/9(22%), RA 1/9(11%), polimiozitis 1/9(11%) in men.40(89%)pts had non Hodgkin lymphoma (NHL), multiple myeloma (MM) 3(7%) and Hodgkin lymphoma 2(4%). In NHL group 20 were DLBCL, indolent 18- NHL foll. and 2 very agressive.
Summary/Conclusions: The most frequent autoimmune disorder was SLE in women and SS in men.NHL DLBCL was the most common lymphorpoliferative disease. Pts with these condiotions had higher stage of disease at the diagnosis and there was no difference in survival between male and female pts.

Bleeding disorders (congenital and acquired)

PB1747

SUCCESSFUL SEQUENTIAL THERAPY USING RFVII WITH A NOVEL AGENT (PLASMA-DERIVED FACTOR FVIIA AND FACTOR FX MIXTURE) TO CONTROL PERIOPERATIVE BLEEDING IN A PATIENT WITH SEVERE HEMOPHILIA A AND INHIBITORS

K Isobe[1,*], K Koh[1], T Uehara[1], M Yanagi[1], Y Ikeda[1], C Oyama[1], K Sasaki[1], K Watanabe[1], M Mori[1], Y Arakawa[1], H Taketani[2], R Hanada[1]
[1]Department of Hematology/Oncology, Saitama Children's Medical Center, Saitama, [2]Department of Joint Surgery, Research Hospital of the Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background: The bypass therapy is usually performed to control bleeding in patients with hemophilia and inhibitors; however, approximately 10% cases are resistant to that using a single agent in the perioperative period. The plasma-derived factor FVIIa and factor FX mixture (pd FVIIa/FX), containing human serum-derived FVII and FX in a 1: 10 ratio, was recently developed in Japan as a novel bypassing agent. The bypass effect induced by FVII is enhanced under a high concentration of FX. We hypothesized that pd FVIIa/FX would induce a stronger bypass effect than conventional sequential therapy using aPCC and rFVII. Here we report our experience of sequential therapy using pd FVIIa/FX and rFVII as a bypass therapy during the perioperative period in a patient with severe hemophilia A and inhibitors.
Aims: To determin optimal dose of of rFVII and pd FVIIa/FX based on a preoperative PK study.
Methods: A pharmacokinetics (PK) study used by pd FVIIa/FX was performed a week before surgery. FX and FVII level was measured 15 minutes, 6 hours and 24 hours after pd FVIIa/FX (120 mcg/kg) was administered. FX level was measured at Kaketsuken Co. (Japan) by activated partial thromboplastin time assays under a high concentration of FVII. The Based on the PK study, FVII and FX activity levels were simulated to determine the optimal dose and interval of rFVII when rFVII and pd FVIIa/FX were administered. Thromboelastography (ROTEM^R) was used to rapidly allow to monitor the coagulation intra-operatively. Case: A 10-year-old male was diagnosed with severe hemophilia A at 8 months old. At 13 months old, inhibitor to factor FVIII (maximum 1625 BU/ml, the most recent: 19.2 BU/ml) was detected. He received immune tolerance induction therapy using rFVIII or VWF/FVIII for 2 years but with no response. At 4 years, he was started on prophylactic aPCC as a bypass therapy. At 10 years, he experienced frequent spontaneous intra-articular hemorrhage, particularly in the left knee and right ankle. Therefore, he was transferred to our institution to receive arthroscopic synovectomy of these joint. When the surgery started, the following sequential therapy was also initiated in accordance with the simulation: pd FVIIa/FX (120 mcg/kg) was administered three times every 36 h and rFVII (60mcg/kg) every 2 h. The interval of rFVII administration was gradually extended. Six days after surgery, the sequential therapy was switched to prophylactic aPCC administration.
Results: 1) Coagulation: The measured activity levels of rFVII and FX were almost the same as the simulation data. The INTEM^{R}assay, in the ROTEM^R, used to monitor the intrinsic pathway showed that coagulation was recovered by sequential therapy. 2) Safety: In accordance with the product document, pd FVIIa/FX (120 mcg/kg) every 36 h was administered and no thrombotic events were detected. 3) Efficacy: Little bleeding was observed during surgery, and no sign of intra-articular hemorrhage was observed on physical examination after surgery. 4) Cost: This regimen contributed to a 45% cost reduction compared with that with single agent bypass therapy using rFVII.
Summary/Conclusions: Sequential pd FVIIa/FX and rFVII as a bypass therapy during the perioperative period is feasible and effective for patients with severe hemophilia A and inhibitors. It is necessary to determine the optimal dose of rFVII based on a preoperative PK study.

PB1748

CONTINUOUS INFUSION FOR LIFE THREATENING HEMORRHAGE OF HEMOPHILIA PATIENT

K Lee[1,*], J Kim[1], J Seo[1], S Hyun[2]
[1]Pediatrics, Kyungpook National University School of Medicine, Daegu, [2]Internal Medicine, Yonsei University Wonju College of Medicine, Wounju, Korea, Republic Of

Background: Continuous infusion (CI) compare to bolus infusion has a merit of factor concentrate saving as much as 30% with same hemostatic effect. All biologic products will drcrease its activity even *in vitro*.
Aims: According to the instruction of inside package the factor concentrate recommend to administer within 3 hours of reconstitution at room temperature. Universally 24 hours' volume of CI were reconstituted at one time in almost all hospital. We applied this CI for life-threatening hemorrhage with a different method since 1996.
Methods: Thirty five of life threatening hemorrhage or major surgery from 28 patients were enrolled in this study for 15 years. All patients received FVIII con-

centrates with initial loading dose of FVIII 50U/kg and then the continuous infusion, 3 U/kg/hr for 3 days, and then gradually decreased the amount for 2 weeks. We empirically prepared the material of CI with every 2-4 hours reconstitution to keep a desired *in vivo* factor level. To verify of this we checked *in vitro* factor activity of 3 drugs as time goes on recently.
Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean; 24.8 yr). Severity was severe (16), moderate (7) and mild (5). We confirmed *in vivo* factor activity within permissible level in all patients. All recovered from hemorrhage or surgery and are healthy, but one had limping gate and one had mild neurologic sequelae for more than 10 years. The mean *in vitro* factor activity at 2, 4, 6, 8 and 24hours of reconstitution were gradually decreased to 97.7%, 95.3%, 92.9%, 90.6 and 73.0% respectively in all 3 drugs.
Summary/Conclusions: All biologic products decrease their activity as time goes on even *in vitro*. Empirically, we reconstitute the concentrate every 2-4 hours for CI since 1996. And we confirmed the *in vitro* activity will decrease as time goes on. In continuous infusion we have to reconstitute the concentrate every 2-4 hours to make a desired *in vivo* factor level.

PB1749

THE GENETIC ANALYSIS OF TWO PATIENTS WITH CONGENITAL COAGULATION FACTOR XI DEFICIENCY
R Zhou*, N Zhou, J Ouyan
Haematology, The Affiliated Nanjing Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Factor-XI deficiency (FXID) is a rare inherited autosomal recessive disord.
Aims: To analyze genetic mutation and explore its molecular pathogenesis for two patients with congenital coagulation factor XI deficiency
Methods: Two patients were found to have prolonged activated partial thrombin time (aPTT), then their activity of coagulant factors were tested and aPTT mixing test with incubation were performed. Low activity of the FXI (FXI: C) was found in both. Two patients' blood was collected, and their DNA was extracted. Polymerase Chain Reaction (PCR) was used to amplify all exons and exon-intron boundaries, and then the products of PCR were sequenced directjy. The mutation was determined through alignment of the normal FXI genomic DNA sequence by software chromas. The segment with mutation was sequenced backward.
Results: aPTT and FXI:C was 109.6s and 0.4% for patient 1 and 50.1s and 6.7% for patient 2,respectively.The results of aPTT mixing correction test and activities of other coagulant factors were all in normal range for both patients. The results of sequencing showed that a de novel homogenous nucleotide 18A deletion (18delA) mutation in exon2 was detected in patient1, leading frame shift mutation (Val-13TrpfsX15), and that combined heterogenous mutation, a nucleotide 738G>A transition in exon7 and a nucleotide 1021G>A transition in exon9, resulting a Trp228stop substitution and a Glu323Lys substitution,respectively, were detected in patient 2.
Summary/Conclusions: These mutations might be the molecular pathogenesis for two patients with congenital coagulation factor XI deficiency, respectively.

PB1750

A NOVEL FIBRINOGEN VARIANT: DYSFIBRINOGENEMIA ASSOCIATED WITH ΓASP185ASN SUBSTITUTION
R Zhou*, N Zhou, J Ouyan
Haematology, The Affiliated Nanjing Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Congenital dysfibrinogenemia is a qualitative congenital fibrinogen disorder characterized by normal antigen levels of a dysfunctional fibrinogen.
Aims: A patient with abnormal coagulation test was diagnosed as congenital dysfibrinogenemia. In this study, the causative mutations responsible for dysfibrinogenemia were detected in proband and her child.
Methods: The proband from Nanjing, China was presented with low fibrinogen and prolonged thrombin time (TT) during prenatal routine medical examination but with asymptoms. Her son also had low fibrinogen and prolonged TT. After extraction, genomic DNA was amplified by polymerase chain reaction. DNA sequencing was performed on the purified PCR products.
Results: Two heterozygous missence mutations including AαArg16His and γAsp185Asn were discovered in the proband. Her son only harbored the former mutation. AαArg16His had been reported by other teams and γAsp185Asn was identified firstly in our study as a novel variant. Endonuclease restriction digestion was performed to exclude polymorphism. The homologous sequences alignment was compared among different species to identify this new mutation site was a kind of conservative one.
Summary/Conclusions: The heterozygous AαArg16His and γAsp185Asn mutations identified in the study probably underlies the dysfibrinogenemia in this pedigree. The novel fibrinogen variant (γAsp185Asn) was named as fibrinogen Nanjing.

PB1751

INHIBITOR TO FIBRINOGEN WITHOUT PROPHYLACTIC THERAPY IN A PATIENT WITH CONGENITAL AFIBRINOGENEMIA. A CASE REPORT
T Patiroglu*, E Yilmaz, E Unal, M Karakukcu, MA Ozdemir
Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Afibrinogenemia is a rare condition and has an estimated prevalance of 1:1000000. The more common manifestations of afibrinogenemia are umblical stump bleeding, and bleeding from mucosal surfaces, particularly menorrhagia, epistaxis, gastrointestinal bleeding and intracranial hemorrhage.
Aims: We report a case with congenital afibrinogenemia which had pulmonary and intracranial hemorrhage. Although the patient had not prophylactic therapy with fibrinogen concentrate nor cryoprespitate before admission to the hospital, laboratory investigation revealed mixed test positivity
Methods: A case of an 18 years-old girl with congenital afibrinogenemia admitted to our department because of dyspnea and tachipnea. Her chest X-ray and CT showed pulmonary hemorrhage. Therefore, she was administered with fibrinogen conscentrate in doses of 50 mg per kg and prednisolon in doses 1 mg per kg. Furthermore, she underwent a generalized convulsion on second day and neuroimaging tests revealed intracranial hemorrhage. Although she was treated with fibrinogen concentrate and cryoprespitate every day her laboratory investigation revealed prolonged PT, aPTT and TT tests and fibrinogen level in plasma lower than 0.5g /L. Hence, we performed mixed test and the result was positive. On follow up, she was given IVIG in doses of 2 g per kg once and plasma exchange was planned every day. Furthermore, she was treated with fibrinogen concentrate and cryoprespitate every day to raise fibrinogen level in plasma to 1 g/L. Unfortunately, she died at intensive care unite because of intracranial hemorrhage 17 days after admission to the hospital.
Results: Replacement therapy is generally effective in treating of bleeding episodes in congenital afibrinogenemia. Options for replacement include plasma-derived fibrinogen concentrate, cryoprespitate, and fresh frozen plasma; Antifibrinolytic agents may be used especially for dental procedures. Prophylactic therapy have been employed after life-threatening bleedings such as intrcranial hemorrhage. Acquired inhibitors have been rarely reported after replacement and prophylactic therapy.
Summary/Conclusions: We surprisingly revealed inhibitor to fibrinogen (mixed test positivity) although the patient did not have prophylactic therapy with fibrinogen concentrate nor cryoprespitate before admission to the hospital.

PB1752

ROLE OF HIGH DOSE ASCORBIC ACID IN TREATMENT OF METHAMOGLOBINEMIA
K Sahu*, D Dhibar , P Deo, S Jain , S Varma , S Kumari
Internal Medicine, PGIMER, Chandigarh, India

Background: Methaemoglobin (MetHb) is an oxidized form of haemoglobin. MetHb has high affinity for oxygen, resulting decrease delivery of oxygen to the tissue. It can be congenital but in clinical practice drugs induced acquired form is more common. Methylene blue is used as first line therapy but the role of vitamin C in the treatment of methaemoglobinemia is yet to be established. Here we are presenting our experience with high dose of vitamin C used successfully to treated methamoglobinemia.
Aims: To study the role of high dose of ascorbic acid for treatment of methamoglobinemia.
Methods: This study was conducted over the span of 3 months (Nov 2015-Jan 2016). All patients visiting emergency services with suspected methamoglobinemia were included. In total we found three cases of the proven methamoglobinemia. Patients were given the best supportive therapy including haemodialysis, PRBCs, oxygen supplementation etc. All three patients were given high dose of ascorbic acid (2000mg/day).
Results: Table 1 mentions in detail the demographic details of patients included in the study. Two out of three patients had history of accidental consumption of inciting agent, while the third was prescribed dapsone for immune thrombocytopenia. Case 2 developed massive intravascular haemolysis leading to acute kidney injury requiring haemodialysis (5 sessions). All our patients were normal G6PD activity. Due to unavailability of methylene blue, it was decided to give high dose of ascorbic acid as an anti-oxidant (2000mg/day for 5 days followed by gradual tapering) to all these patients. All patients responded dramatically to this medication and had reduction of Meth-Hb levels.

Table 1. Treatment of cases of methamoglobinemia with 2000mg/day of Ascorbic acid

Age/Sex	Precipitating factor	Baseline Meth-Hb	Baseline disease	Outcome
45/M	Dapsone (300mg/day) for ITP	25	Immune thrombocytopenia	Alive
15/M	Naphthalene ball poisoning	25.5%	None	Alive
25/M	Paint thinner poisoning	46.4	None	Alive

Summary/Conclusions: Higher doses of ascorbic acid (2000mg/day) has proven to be beneficial in cases of methamoglobinemia.

PB1753

PROPHYLAXIS FOR HEMOPHILIA PATIENT IN KOREA

K Lee[1], S Hyun[2,*], J Seo[1], J Kim[1]
[1]Pediatrics, Kyungpook National University School of Medicine, Daegu, [2]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: Prophylaxis compare to on-demand treatment for severe hemophilia patients has a great profit for not only life quality but also life itself.
Aims: We have started prophylaxis for 5 intracranial hemorrhage patients after recovery since 1996. Fifteen years later, prophylaxis for hemophilia A and B patients only under 15 y/o have been approved by National Health Insurance Review and Assessment from January, 2011.
Methods: Intracranial hemorrhage was observed in 16 episodes from 9 patients between 1996 and 2002 at our hospital. All patients received FVIII concentrates with initial loading dose of FVIII 50 U/kg and then the continuous infusion, 3 U/kg/hr for 3 days, and then gradually decreased the volume for 7-10 days. We persuaded the patient/parent for life long prophylaxis to prevent further life-threatening hemorrhage. Five among 8 patients followed the prophylaxis (30 U/kg, 3 days/week).
Results: Age distribution was 2 mo-26 yr (mean; 8.8 yr). Severity was severe (4), moderate (4) and mild (1). Trauma history was in only 1 case. Initial symptom was vomiting (8), headache (4), seizure (3), and irritability (1). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean; 1.7days). Intracranial bleeding site was variety. Inhibitor was in 1 case and 2 cases were transient type. Previous life threatening hemorrhage history was observed in 5 cases (ICH in 4 and GI bleeding in 1). Family history was observed in 7 cases. Eight patients received FVIII concentrates with initial loading dose of FVIII 50 U/kg and then the continuous infusion, 3 U/kg/hr for 3 days, and then gradually decrease the volume for 7-10 days. Inhibitor patient was treated with by-passing agent. Craniotomy was done in 4 cases and no operation was in 4 cases. All recovered except one (who died within 30 minutes after arrival, bleeding site was cerebellar vermis & 3rd ventricle) and are alive without any neurologic sequelae except one with mild limping gate for more than 10 years.
Summary/Conclusions: Prophylaxis for severe hemophilia has to expand to all age, to moderate hemophilia with previous life threatening bleeding history and to inhibitor patients in Korea.

PB1754

VON WILLEBRAND DISEASE AND ACQUIRED VON WILLEBRAND SYNDROME – A DIAGNOSTIC ALGORITHM

MM Campos[1,*], V Pishchanskyy[1], F Carriço[2], MJ Marques[1], ME Ribeiro[1], T Araújo[1]
[1]Department of Immunohemotherapy (Head: D. Espírito Santo), Hospital Curry Cabral - Centro Hospitalar Lisboa Central, EPE, [2]Laboratory of Hematology, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal

Background: Von Willebrand disease (VWD) is a common inherited bleeding disorder (prevalence of 1:10000) but acquired von Willebrand syndrome (AVWS) is a very rare bleeding state associated with lymphoproliferative, myeloproliferative, cardiovascular and autoimmune conditions, hypothyroidism, uremia, liver cirrhosis, pancreatitis and the use of ciprofloxacin, griseofulvin, valproic acid and tetracycline. More than 60% of the few reported cases of AVWS correspond to lymphoma, multiple myeloma, monoclonal gammopathy of undetermined significance, essential thrombocythemia, polycythemia vera, chronic myeloid leukemia and primary myelofibrosis.
Aims: To establish a diagnostic algorithm for VWD and AWVS, differential diagnosis must be done including other coagulopathies. Factor VIII:C (FVIII:C) and von Willebrand factor (VWF) are endothelium injury markers and their levels may increase in inflammatory diseases. Individuals with blood group O exhibit lower levels of VWF but there is a general raise of VWF with ageing.
Methods: The prothrombin time (PT) and the activated partial thromboplastin time (APTT) are not reliable tests in screening for diagnosis of VWD. Optional tests as thrombin time or fibrinogen are not relevant. So, a basic approach with PT, APTT, and an evaluation of platelet count, morphology and function, must be followed by WVF-specific tests, like a profile with VWF antigen (VWF:Ag), functional VWF (VWF:f) that corresponds to VWF activity (VWF:Act) or VWF ristocetin cofactor (VWF:RCo) and FVIII:C. For inhibitor screening the VWF:f is carried out with several dilutions of patient plasma with factor diluent (the parallelism loss suggests an inhibitor, which can be present in AWVS). Another procedure is the plasma mixing test with patient plasma and normal plasma. Low-dose ristocetin-induced platelet aggregation (RIPA), multimer analysis by agarose gel electrophoresis, molecular genetics, VWF binding to collagen (VWF:CB) and VWF propeptide (VWFpp) by enzyme-linked immunosorbent assay (ELISA) are other resources for specialized laboratories.
Results: The diagnostic algorithm (Figure 1) summarizes our methodology. The Table 1 shows our laboratory results of different types of VWD, AVWS and low VWF.

Table - Laboratory results of different types of VWD, AVWS and low VWF (levels in%)

	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7
VWF:Ag	35.0	34.0	30.2	9.0	49.1	53.4	13.4
VWF:RCo	33.0	8.0	<7.0 (4.8)	-	45.4	39.1	8.2
VWF:Act	36.0	<19.0 *(10.0)*	-	<19.0 *(1.0)*	40.9	-	<19.0 *(3.2)*
FVIII:C	64.0	53.0	37.7	4.0	54.8	53.5	18.1
VWF:CB	27.2	8.1	-	8.1	-	-	-
RIPA	-		-	Absent	-	-	-
Multimers	Normal	HIMWM	-	All absent	-	-	-
Genetics (mutations)	-	-	R1374H	-	-	-	-
VWF:f parallelism	-	-	-	-	-	-	Inhibitor
Defects	Type 1	Type 2A	Type 2M	Type 3	*Low VWF*	*Low VWF*	AWVS
Gender (M/F)	F	F	M	F	F	M	F
Age (years)	42	33	34	34	35	18	74

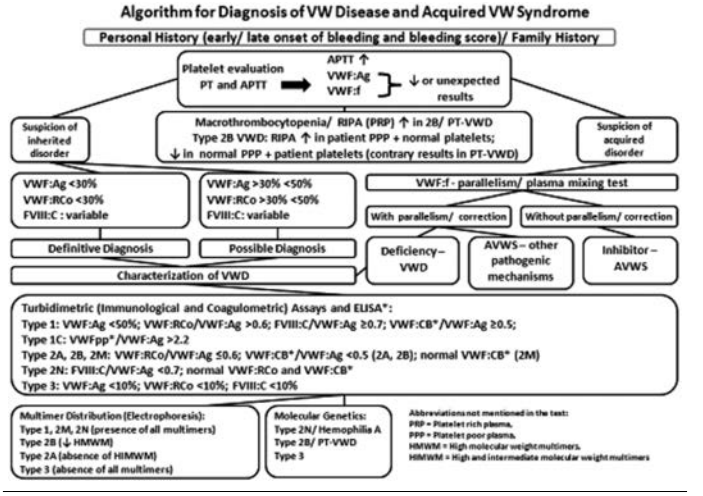

Figure 1.

Summary/Conclusions: 1) We propose an algorithm for the diagnostic approach of mucocutaneous bleeding with high clinical suspicion of VWD, platelet type pseudo-VWD (PT-VWD) and AVWS. 2) The main goal is to create a multistep screening based in threshold values. 3) The differentiation between type 2B VWD and PT-VWD is essential to avoid misdiagnoses and provide adequate therapy. 4) The clarification between type 1 VWD and low level of VWF:Ag and/or VWF:RCo (30-50%) is controversial: asymptomatic individuals don't need an extensive testing, only those with a past severe hemorrhages (a good predictor of recurrence) or presenting relatives with similar levels require an advanced assessment. 5) If VWFpp is available it may be helpful in the identification of type 1C VWD.

PB1755

DIAGNOSTIC CHALLENGES IN ACQUIRED VON WILLEBRAND DISEASE: A COMPLEX CASE OF PROSTATE CARCINOMA

PE Claus[1,*], E Moreau[1], D Deeren[2]
[1]Clinical Biology, [2]Hematology, AZ Delta, Roeselare, Belgium

Background: Acquired von Willebrand disease (AVWD) is a rare bleeding disorder associated with a variety of underlying diseases and with clinical manifestations similar to congenital von Willebrand disease.
Aims: We present a case of prostate carcinoma in which AVWD was diagnosed.
Methods: The patient was an 80-year-old man who suffered from ulcerative colitis. He was diagnosed with a Gleason 7 prostate adenocarcinoma for which he received radiotherapy in combination with hormonal therapy. Due to melena he underwent a coloscopy during which biopsies were taken. The procedure was complicated by diffuse bleeding and a cardiac infarction. Urgent coronary artery bypass surgery (CABG) was performed but was also complicated by postoperative bleeding. Laboratory studies showed a normal platelet count, a prolongation of the activated partial thromboplastin time (aPTT) and low factor VIII levels. His von Willebrand factor (VWF) antigen level and ristocetin cofactor activity were low.
Results: The diagnosis of AVWD in this patient challenged us to look for the different pathogenic mechanisms of the disease. Several disorders have been described to be associated with AVWD, the commonest being hematoproliferative, cardiovascular and autoimmune disorders. Neoplasms are rarely documented and their pathogenic mechanisms are not well known. The underlying mechanisms differ among these disorders and may even overlap. These include, among other things, mechanical destruction of VWF under high shear

stress and development of autoantibodies. Selective and/or non-selective absorption of VWF on or inside malignant cells is believed to be the main mechanism in hematoproliferative and non-hematologic malignancies.
Summary/Conclusions: In this report we give a concise overview of the mechanisms of the diseases that we encountered in this complex case.

PB1756

TAR SYNDROME - DIAGNOSTIC AND TREATMENT. CASE REPORT
V Grajqevci-Uka*, R Maxhuni, B Abrashi, F Selimi
Hemato-oncology, UCCK, Pediatric Clinic, Prishtina, Kosovo

Background: Thrombocytopenia absent radius syndrome (TAR) is a rare genetic disorder that is apparent at birth. TAR syndrome is inherited as an autosomal recessive trait. This disorder is characterized by low levels of platelets in blood (thrombocytopenia) resulting in potentially severe bleeding episodes primarily during infancy.
Aims: Presentation of the case with (TAR) syndrome which was admitted to Hematology Oncology Unit at Pediatric Clinic with petechia and hematomas skin.changes,
Methods: : A 2.5 month old male child, was admitted in our unit with petechial and hematoma's skin changes and epistaxis. Diagnosis of the patient was made with help of the clinical examinations, laboratory findings, radiological images and genetic reaserch.
Results: At the radiological imaging examination of the upper limbs, radius was absent in both shoulders.. Complete blood count: hemoglobin, 11 g/dL; mean corpuscular volume, 95 fl; mean corpuscular hemoglobin, 34 pg; reticulocytic count, platelet count, 20,000/uL; prothrombin time, 12.8 seconds; partial thromboplastin time, 28.0 seconds. Liver function tests had the following results: bilirubin (total), 6.20mg/dL; (direct), 0.25 mg/dL; glutamic pyruvic transaminase, 35 U/L; and glutamic oxaloacetic transaminase, 34 U/L. Electrolytes and kidney function were: Na, 146 mmol/L; K, 3.8 mmol/L; serum creatinine, 0.9 mg/dL. TORCH screens were normal Radiography of the forearm showed bilateral absence of radii. Abdominal and cranial ultrasonography were normal. The genetic analysis was positive.
Summary/Conclusions: TAR syndrome is a rare genetic disorder characterized by low platelet level and radial aplasia. The tranfusions with platelet concentrate is needed when patient is presented with low platelets count.

Background: Rare factor deficiencies (RFD) cover the deficiencies of fibrinogen, Factor II, Factor V, Factor V+VIII, Factor VII, Factor X, Factor XI, Factor XIII, and vitamin K associated factors. Many national and international study groups conducted studies regarding the diagnosis and treatment of rare factor deficiencies in 2000s. The existence a mortality and morbidity risk associated with severe bleedings has brought the search for prophylaxes related to these disorders into the agenda. In addition, the good results obtained with primary and secondary prophylaxes in haemophilia cases have attracted the attention to the possibility that the same consideration could also be applied to rare factor deficiencies. Prophylaxis is recommended in these patients if such severe bleedings as central nervous system bleedings, gastrointestinal bleedings, and articular hemorrhages recur.
Aims: Our prophylaxis application related to 13 congenital rare factor deficiency cases being followed at our clinic comprising of five patients with Factor VII deficiency, four patients with Factorxdeficiency, three patients with afibrinogenemia, and one patient with FV deficiency, were evaluated in our article.
Methods: Information concerning our patients was compiled from patient files and the data contained in the electronic information processing environment created after 2005.
Results: Presenting ages of our patients ranged between one week and 7 years of age. Seven of them were boys and 6 were girls. Prophylaxis was applied due to intracranial bleeding to three of our Factor VII deficiency patients, for gastrointestinal system bleeding to one of them, and for the development of chronic hemarthrosis and hemarthrosis that requires the application of radioisotope synovectomy to one patient. 20 mcg/kg active recombinant FVII was used once a week in the prophylaxis of our FVII deficiency cases. Transition to two doses a week was required for one patient. Prophylaxis is being applied with 20 IU/kg prothrombin complex concentrate two days a week to our patients with Factorxdeficiency for central nervous system bleedings and with 50 mg/kg fibrinogen every two weeks to our patients with afibrinogenemia for recurring intramuscular bleedings causing severe pain and difficulty of walking. Our patient with FV deficiency to whom prophylaxis is applied due to intracranial bleeding, on the other hand, receives 20 ml/kg fresh frozen plasma once a week. The prophylaxis periods of our patients range between 2 months and 9 years.
Summary/Conclusions: The observation as well as clinical and laboratory findings of our patients together with the details related to their prophylaxis processes were presented in our proceedings accompanied with the relevant literature.

TWO IMPORTANT FACTORS WHICH AFFECT HEMOSTASIS IN HEMOPHILIA PAITENT WITH SURGERY
K Lee[1], J Kim[1], J Seo[1], S Hyun[2,*]
[1]Pediatrics, Kyungpook National University School of Medicine, Daegu, [2]Internal Medicine, Yonsei University Wonju College of Medicine, Wounju, Korea, Republic Of

Background: The severity and hemostasis in hemophilia is based on one's factor level. In surgery of hemophilia patient appropriate hemostasis is very important for prognosis. Individual pharmacokinetic is quite different especially in recovery rate (RR).
Aims: We evaluate the prognosis of surgical cases according to different recovery rate recently. And we infused the concentrate in bolus followed by continuous infusion method during and after surgery. Also we checked *in vitro* factor activity as time goes on.
Methods: Twenty seven major surgeries were done in 20 patients (severe; 12, moderate; 4 and mild; 4). The mean age was 32 yr. The patient was divided into 3 groups. Group A (A) composed of 12 patients whose RR was above 0.8 with no further correction. Group B (B) composed of 10 patients whose RR are below 0.8 with further correction to make 1.0 before surgery. Group C (C) composed 5 patients whose RR was below 0.8 without further correction because of emergency operation. In continuous infusion we reconstitute the concentrate every 2-4 hours volume because *in vitro* factor activity will decrease as time goes on.
Results: The hospitalization periods of A, B and C were 14.5+/-12.1, 13.9+/-4.0, and 45.8+/-15.7 respectively (p=0,015 and 0.006 in A & C and B & C). The consumption of factor A concentrate of A, B and C were 481+/-195 U/kg, 1,311+/-283 U/kg and 3,502+/-1,529 respectively (p<0,001 in A & B and p=0.006 in B & C). Complications such as hematoma, sepsis CNS infection and hydrocephalus were observed in C. The mean *in vitro* factor activity at 2, 4, 6, 8 and 24 hours of reconstitution were gradually decreased to 97.7%, 95.3%, 92.9%, 90.6 and 73.0% respectively in all 3 drugs. Best activity at 24 hours was observed in light shield sample.
Summary/Conclusions: Although the recovery rate will be changed in different condition and time preliminary check is important for the emergency. In continuous infusion we recommend to reconstitute the concentrate every 2-4 hours to make a desired *in vivo* factor level.

INTERLEUKIN-27 RS153109 POLYMORPHISM AND THE RISK FOR ACQUIRED APLASTIC ANEMIA IN A CHINESE POPULATION

M Ge*, W Yu, Y Zheng
State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Acquired AA, characterized by pancytopenia in peripheral blood (PB) and bone marrow (BM) hypoplasia, is a BM failure syndrome attacked by autologous T cells on BM hematopoietic progenitors. Interleukin-27 (IL-27), as a novel heterodimeric cytokine of the IL-12 family, has been shown to play a vital role in the pathogenesis of aplastic anemia (AA) .The present studies demonstrated that IL-27 enhanced the production of TNF-α and IFN-γ in both $CD4^+$and $CD8^+$T lymphocytes from AA patients, and the elevated IL-27 and IL-27-induced TNF-α and IFN-γ overproduction might be involved in the pathogenesis of AA. Among the IL-27 polymorphisms identified, the SNP of IL-27 rs153109 polymorphism has been reported to be associated with the risk of asthma, chronic obstructive pulmonary disease and inflammatory bowel diseases. To our knowledge, little is known about the role of the SNP of IL-27 in individual susceptibility to AA. To address this question, we have detected the IL-27 rs153109 polymorphism with an aim of identifying site(s) of variation, which may be helpful for better understanding the genetic influences of this gene. We herein performed a case-control study to investigate whether the IL-27 rs153109 polymorphism is associated with AA in Chinese people.
Aims: The aim of the present study was to investigate the association of single nucleotide polymorphisms (SNP) of IL-27 gene with the risk for aplastic anemia (AA).
Methods: *Patients Studied* - The subjects comprised 205 AA patients (109 male and 96 female) with age range of (14–76 years) referred to our hospital, and 196 healthy controls from the employees of our hospital. The characteristics of the subjects are shown in Table 1A. *Extraction of Genomic DNA* - Genomic DNA was extracted using DNA Purification Kit (promega Cat. #A1125 Beijing, China) according to the manufacturer's protocols. *IL-27 rs153109 Genotyping by Polymerase Chain Reaction-restriction Fragment Length Polymorphism (PCR-RFLP)* - The genotyping of the TRAF1/C5 rs10818488 was performed by PCR-RFLP. The upstream primer 5´- ACCAAGAAACCCCATCCTCT -3´ and the downstream primer 5´- TCAGTCAGTGACCAGGATCG -3´ were used to generate a region of 224 bp of IL-27 gene. Genotyping for IL-27 rs153109 SNP was performed by restriction analysis using the PaeR7I restriction enzyme (New England Biolabs), which digests specifically DNA amplified from the G (but not the A) allele into 179-bp and 45-bp fragments. Both undigested and digested PCR products were visualized in 2% agarose gel stained with ethidium bromide. Genotypes were scored blindly, and analyses of all ambiguous samples were repeated. *Statistical Analysis* - SPSS16.0 (SPSS Inc., Chicago, IL) was used for statistics analysis. A *p* value <0.05 was considered to be statistically significant.

Table 1.

A The characteristics of AA patients and the controls.

	AA	Control
Number of patients(%)	205	196
Gender (male: female)	109:96	105:91

a NR compared with controls
b PR compared with controls
c CR compared with controls

Results: In our study, the IL-27 rs153109 polymorphism genotypes between AA patients and healthy controls were first determined and compared. The frequencies of AA, AG and GG genotypes, and A and G alleles were 39.5%, 48.3%, 12.2%, 63.7% and 36.3%, respectively, in AA patients. There was no significant differences in terms of genotype and alleles distributions between AA patients and healthy controls (*P*=0.653 and 0.908, respectively).(Table 1B). Furthermore, AA patients were further subdivided into three groups according to the disease serevity: vSAA, SAA, and NSAA. The distribution of this polymorphism genotype was compared between each of these three groups and the controls, respectively. No statistical differences were identified (Table 1C). We also investigated whether the IL-27 rs153109 polymorphism could influence response to treatment. Nine of 205 (4.4%) patients were lost to follow-up. Responders included complete and partial responders. No significant correlations between the genotype and allele frequencies and response of treatment in this cohort of AA patients were observed (Table 1D).
Summary/Conclusions: In conclusion, IL-27 rs153109 polymorphism may not play an important role as a genetic risk factor in the pathophysiology of AA in a Chinese population. More studies with larger sample are warranted to further confirm the role of IL-27 rs153109 polymorphism in determining the risk of AA.

PB1760

THE DYSFUNCTION OF PLATELETS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

R Fu*, Y Meng, H Liu, Y Wang, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Thrombosis is a dangerous complication of paroxysmal nocturnal hemoglobinuria (PNH), with a high mortality rate. However, the mechanism underlying the development of thrombosis in PNH remains unclear.
Aims: To explore the function of platelets in PNH.
Methods: Serum concentrations of the terminal complement complex (sC5b-9) were determined by ELISA and the levels of C5b-9, CD61 and CD62p on platelet membranes by flow cytometry. Clinical parameters were assessed, including D-dimer and platelet aggregation induced by adenosine diphosphate (ADP) and arachidonic acid (ARA).
Results: Serum sC5b-9 concentrations were significantly lower in the PNH/PNH-AA than in the control group ($p<0.01$). C5b-9 deposition was significantly higher on $CD59^-$ platelets than on $CD59^+$platelets in PNH/PNH-AA patients and healthy controls ($p<0.01$ each). D-dimer concentration was significantly higher in PNH/PNH-AA patients, especially those with lactate dehydrogenase concentrations >1000 U/L, than in controls ($p<0.05$). CD61 ($p<0.05$) expression was lower on $CD59^+$platelets in PNH than controls and $CD59^-$ platelets in PNH. CD62p($p<0.01$) expressions were lower on $CD59^-$ and $CD59^+$platelets ($p<0.01$) in PNH than controls. Platelet aggregation stimulated by the agonists ADP and ARA was lower in the PNH/PNH-AA than in the control group ($p<0.05$). Interestingly, CD61 expression on $CD59^+$platelets was higher in PNH patients than in patients with higher type II PNH clones.

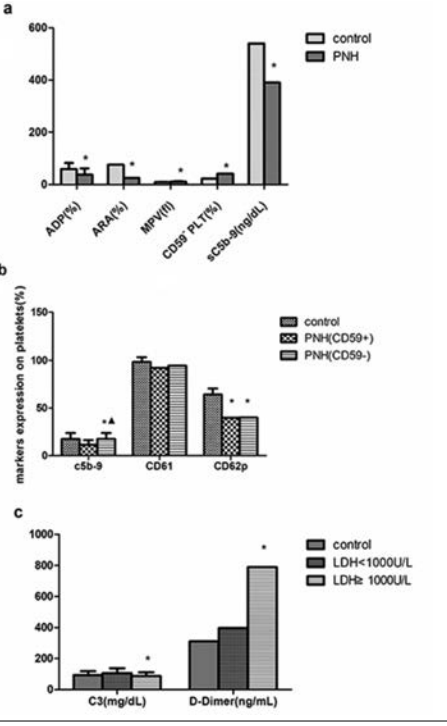

Figure 1.

Summary/Conclusions: Platelet function of platelets, especially of CD59+platelets, was inversely inhibited in PNH/PNH-AA even in the presence of continuous hypercoagulation.

PB1761

IDENTIFICATION OF HAEMOSTASIS SYSTEM PATIENTS, SUFFERING FROM APLASTIC ANEMIA

V Kobilyanskaya[1,*], S Bessmeltsev[1], E Shilova[2], T Morozova[1]
[1]Hematology department, [2]Russian research Institute of Hematology and Transfusiology of the FMBA of Russia, St-Petersburg, Russian Federation

Background: Since the first description by Paul Arliam acquired aplastic anemia (AA) over 100 years ago, but today this disease remains in the spotlight hematologists and physicians in adjacent fields. AA - a serious disease of the blood system, resulting from damage to the stem cells (precursors of all blood cells), resulting in a profound inhibition of normal hematopoiesis with the development of pancytopenia. One of the main clinical manifestations is hemorrhagic syndrome caused by thrombocytopenia and impaired activity of plasma coagulation factors: reduction factors of the prothrombin complex, decreased fibrinogen, lack of blood clot retraction. However, some patients with AA, there is a tendency to hypercoagulability, which is not as widely described in the scientific literature as hemorrhagic manifestations.
Aims: The search for diagnostic markers hypercoagulation status in patients with AA.
Methods: The research material was venous blood 25 patients (17 men and 8 women, mean age 38±0,5), with a diagnosis of «aplastic anemia». Patients received standard immunosuppressive therapy without platelet transfusions. Platelet count ranged from 8 to 30x10 9/l. Plasma level of hemostasis was evaluated in the following coagulation tests: activated partial thromboplastin time (APTT), prothrombin time Quick (PT), thrombin time (TT), the concentration of fibrinogen (Fg), the activity of the factor VIII, activity of antithrombin (AT). The control group consisted of 40 clinically healthy men and women of similar age.
Results: Compared to the normal performance of screening tests (APTT, PT, TT, FG) in 18 (72%) of 25 patients reported a significant increase in the activity of factor VIII, which is usually regarded as an indicator hypercoagulation state of hemostasis (189,8%±96,5% against normal value 119,0%±30.5%, p <0,001). In 8 (44%) of 18 patients with elevated factor VIII revealed reduced levels of antithrombin, which amounted to 68% (fluctuations from 74% to 62%). However, clinical manifestations hypercoagulation syndrome (thrombosis and thromboembolism) single patient not were observed.
Summary/Conclusions: Thus, in patients with AA showed increased activity of factor VIII and decreased levels of anti-thrombin. Whether these indicators markers hypercoagulation state, or is it a manifestation of compensatory functions, which prevent severe hemorrhagic complications in this category of patients. Research in this direction continues. Our further studies aimed at clarifying roles in the body of the identified changes

Bone marrow failure syndromes incl. PNH - Clinical

ACQUIRED HLA-B*40:02 MUTATION LEADING TO FRAME SHIFT IN DIOPATHIC APLASTIC ANEMIA

J Huh[1,*], YC Mun[2], HJ Huh[3]
[1]Laboratory Medicine, [2]Internal Medicine, Ewha Womans University College of Medicine, Seoul, [3]Laboratory Medicine, Dongguk University, Ilsan Medical Center, Ilsan, Korea, Republic Of

Background: Idiopathic aplastic anemia(AA) has been reported to be associated with autoimmunity to hematopoietic stem/progenitor cells (HSPCs). Specific human leukocyte antigen (HLA) alleles are the target antigens of autoreactive cytotoxic T cells (CTL). One study reported that Japanese patients with idiopathic AA typically inherited only those four HLA alleles such as HLA-A*02:01, HLA-A*02:06, HLA-A*31:01 and HLA-B*40:02. (Katagiri *et al.,* 2011). AA acquired copy number neutral loss of heterozygosity of the 6p arms (6p CN-LOH), leading to loss of one HLA haplotype. Moreover, the missing haplotype was concentrated in the same particular alleles : HLA-A*02:01, HLA-A*02:06, HLA-A*31:01 and HLA-B*40:02. Therefore, 6p CN-LOH may arise from selective pressure to escape from autoreactive CTL through loss of HLA alleles. In the other hand, nonsense mutation in HLA-B*40:02 (CAG to TAG) at codon 54 in exon 2 of HLA-B*40:02 with no involvement of 6p CN-LOH in a case with AA was first reported by Osumi T *et al.,* (Br J Haematol 2013:162:706).
Aims: In this study, we report a patient with idiopathic AA who acquired a mutation in HLA-B*40:02 allele (4 nucleotide deletion, leading frame shift). Our case is the second report of HLA-B*40:02 mutation, to our best knowledge.
Methods: HLA high resolution typing was performed by sequence based typing (Biowithus HLA PCR-SBT, Korea).
Results: A 54-year-old man was diagnosed with severe acquired AA with normal karyotype. Although he received immunosuppressive therapy (cyclosporine and anti-thymocyte globulin) for 8 months, he didn't achieve remission and regular blood transfusions and G-CSF had been required. Therefore, stem cell transplantation was scheduled. His HLA results identified by high resolution sequencing based typing in a peripheral blood sample was HLA-A*26:01, HLA-A*33:03, HLA-C*03:04, HLA-C*07:01, HLA-DRB1:07:01, HLA-DRB1:15:01, HLA-DQB1:02:02, HLA-DQB1:06:02. However, HLA-B could not be easily typed by sequencing based typing. To resolve the problem, we performed the low resolution HLA typing using SSP(sequence-specific primer) method and the result showed HLA-B*40 and HLA-B*44. Furthermore, HLA-B type of one sibling having HLA-A, HLA-C and HLA-DRB1 matching was HLA-B*40, HLA-B*44. We reanalyzed HLA-B high resolution typing using DNA from patient's buccal epithelial cells, patient's peripheral blood and the sibling's peripheral blood. The HLA-B typing of patient's buccal epithelial cells and the sibling's blood showed the same results : HLA-B*40:02, HLA-B*44:03. By a closer examination of sequence electropherogram of patient's peripheral blood, we identified that that 4 nucleotides (ACAC deletion) were deleted between codon 187 and 188 in exon 4 of HLA-B*40:02, leading to a frame shift. The mosaicism of wild type and mutant HLA-B*40:02 alleles was restricted to patient's blood cells, not buccal epithelial cells.
Summary/Conclusions: Acquisition of mutation could not be an accidental event, but is caused by immunological escape and selection, because HLA-B*40:02 is a possible target antigen of T cells in idiopathic AA. Activated CTLs might kill HSPCs that expressed HLA-B:40:02, whereas HSPCs carrying the mutation might survive with a growth advantage over other HSPCs expressing HLA-B:40:02. Our case suggests that mutation (ACAC deletion) of HLA-B:40:02 could be a possible mechanism to restore hematopoiesis via immune escape with no involvement of 6pLOH.

PB1763

HEMATOPOIESIS FEATURES OF APLASTIC ANEMIA PATIENTS WITH PNH CLONES

E Shilova[1], V Balashova[2], N Semenova[2,*], V Rugal[2]
[1]Department of Hematology, [2]Laboratory of leukosis studies, Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: One of the reasons for the development of aplastic anemia (AA) is considered immunopositive inhibition of hematopoiesis – cytotoxicity of antigen-specific T lymphocytes and over-production of inflammatory cytokines type I. In addition, AA may be associated with defective hematopoietic stem cells (HSC) and a violation of the regulatory effect of stromal microenvironment. It is known that colony-forming units (CFU) HSC of AA patients drastically reduced and may be absent at all. At the same time in AA patients often recorded the emergence of PNH clones. However, the functional potential of HSCs of the indicated category of patients is characterized by little

Aims: Study of CFU HSC bone marrow of AA patients depending on the presence of PNH clones.
Methods: The research is based on the bone marrow aspirates of 55 AA patients with no PNH clone and 25 patients with PNH clones. CFU HSC was studied using the method of culturing cells in complete nutrient medium Metho-Cult HYY35 on the basis of methyl cellulose. This environment contains all the necessary growth factors and is able to support the growth of erythroid, granulocyte-monocyte and multilinear colonies. The cultivation was carried out in CO2-incubator at t – 37° C for 14 days in Petri dishes with a diameter of 40 mm.
Results: Revealed a sharp decline CFU HSC of AA patients with primarily established diagnosis prior to treatment. The total number of colonies in patients without PNH clones amounted to 57,0 (0-252) 1x105 of myelokaryocytes. At the same time, the number of colonies in PNH patients amounted to 130,0 (8-293) for the same volume of myelokaryocytes. The results suggest that CFU bone marrow HSC in AA patients with PNH clones is significantly higher than in patients without PNH clones. On this basis we can conclude about the relative safety of the proliferative potential of HSC in AA patients with PNH clones.
Summary/Conclusions: Analysis of CFU HSC confirms a defect in the development of progenitor hematopoietic cells in AA. However, in patients with AA with PNH clones the level of violations of the proliferative activity of HSC is expressed to a lesser extent. It is known that the effectiveness of therapy significantly higher in AA patients with PNH clones. Given our data on the functional status of HSC, it is possible to conclude that higher efficiency of treatment of AA patients with PNH clones may be associated with relative preservation of proliferative potential of HSC in this category of patients.

PB1764

COMPREHENSIVE LONG-TERM FOLLOW-UP OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: A REPORT FROM A SINGLE CENTRE
A Sempere*, S Bonanad, A Moret, L Cordon, S Romero, A Regadera, I Jarque
Hematology and Hemotherapy Unit, Hospital Universitari i Politècnic La Fe, Valencia, Spain
Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare life-threatening acquired clonal hematopoietic stem cell disorder characterized by chronic complement activation associated with intravascular hemolysis, thrombosis, and bone marrow failure. Before the availability of anti-complement therapy with eculizumab, treatment remained largely supportive, since the only curative procedure available is allogeneic hematopoietic stem cell transplantation (HSCT), which is associated with substantial morbidity and mortality.
Aims: This study was planned to report on the management and clinical course in a series of PNH patients in a tertiary reference centre reflecting trends in diagnosis and management through the last four decades.
Methods: This descriptive, observational, single centre study evaluated patients diagnosed with PNH between January 1979 and January 2016. An electronic case report form was completed for each patient using clinical data collected from digital or paper medical records. Patients were divided into three groups according to the Parker classification: classic, associated with another bone marrow failure syndrome (BMFS) or subclinical.
Results: A total of 37 patients (mean age 37.2 years±20.6, 20 male (54%)] were included. A large number of diagnoses were made after 2008 (16 patients, 43%), related to improvements in flow cytometry (FC) analysis. The median follow-up time was 6.9 years [IQR: 3.4-15.2]. Nine patients (24%) were diagnosed with classic PNH, 26 (70%) with BMFS; and 2 (5%) with subclinical PNH. Median values for laboratory parameters at diagnosis were: serum lactate dehydrogenase (LDH) 489 UI/L [IQR: 404-1123]; hemoglobin 9.8 g/dL [IQR: 9.1-10.9]; haptoglobin 10 mg/dL [IQR: 7.8-57]; and serum creatinine 0.8 mg/dL [IQR: 0.6-1.1]. At diagnosis 68% of patients presented with pancytopenia. All 20 patients with FC data had GPI-deficient granulocytes (median 5.5% [IQR: 1-31]), as well as GPI-deficient monocytes (median 3% [IQR: 0.5-39.5]). Seven patients had type III erythrocytes (median 2.7% [IQR: 0.4-12]). As expected, FC analysis showed that the GPI-deficient cell clone size was higher in classic PNH than BMFS. A total of 15 patients (41%) required transfusion support. The most frequent therapy was immunosuppression (70%). Twelve (32%) patients, 3 of whom had classic PNH, underwent allogeneic hematopoietic stem cell transplantation (HSCT) at a mean age of 30 years (range 23–37 years). The stem cell source was peripheral blood in eight patients (67%), bone marrow in three (25%) and umbilical cord blood in one. Only two patients received eculizumab (5%). Two patients with classic PNH had a history of severe thrombotic complications (Budd-Chiari syndrome, pulmonary thromboembolism). At last follow-up, eight (22%) patients had died (3 with classic PNH, 5 with BMFS). The leading causes of death were hemorrhage and HSCT-related complications.
Summary/Conclusions: PNH is a rare disease with a highly variable clinical outcome. Improvements in FC techniques have contributed substantially to detect new cases in recent years. Long-term follow-up studies like ours facilitate a better understanding of the natural history of PNH and contribute to improve the management of our PNH patients.

PB1765

CLINICAL CHARACTERISTICS OF CHINESE PAROXYSMAL NOCTURNAL HEMOGLOBINURIA DIAGNOSED BY FLAER
J Li [1], S Wang[2], H Hua[1], W Shen [2], Y Wu [2], J Li [2], G He[2,*]
[1]Department of Hematology, The Third Affiliated Hospital of Nantong University, Wuxi, [2]Department of Hematology, JiangSu Province Hospital,The First Affilated Hospital of NanJing Medical University, Nanjing, China

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare bone marrow failure disorder caused by the absence of glycosylphosphatidylinositol (GPI) on the membranes of blood cells. It was claimed that FLAER gave a more accurate assessment of the GPI anchor deficit in PNH .It can detect as few as 1% PNH monocytes and neutrophils in aplastic anemia, that were otherwise undetectable using CD55 and CD59 on RBC's. Therefore, the clinical characteristics of PNH patients diagnosised by FLAER method might be different from previous CD55/CD59 and Ham test used before in China.
Aims: To find the clinical characteristics of Chinese paroxysmal nocturnal hemoglobinuria diagnosed by FLAER.
Methods: The clinical data of 98 cases diagnosed by FLAER methods from September 2011 to March 2014 were analyzed retrospectively, including demography, clinical features, laboratory examination results and complications.
Results: 48 were male and 50 were female, median age 30.5 years (1~74 years), the median follow-up time were 24 months (12 ~30 months). 11 patients with PNH less than 18 years of age belong to adolescents, 6 patients of them were male, median age was 13 years (1~16 years). There were 43 cases of classic PNH (43.9%), 45 of PNH combined with other specific bone marrow disorders (45.9%), 10 cases of subclinical PNH (10.2%).
The clinical features (Table 1) showed many patients with bone marrow failures. Fatigue (71.4%), hemoglobinuria (41.8%), headache/dizziness (38.8%), bleeding (22.4%), and dyspnea (19.4%) were commonly encountered symptoms. Thrombosis in 9 cases (9.18%), 3 cases of deep vein thrombosis, 1 case of pulmonary thromboembolism, 2 cases of mesenteric venous thrombosis, and 2 cases of hepatic portal thrombosis happened in group of classic PNH. Only one case of hepatic portal thrombosis was found in PNH with aplastic anemia. 17 cases cooccurrented with renal impairment respectively, there were 14 patients (14.5%), 16 patients (16.3%) and 1 patient (1%) at stage of CKD1, CKD2, and CKD3 respectively. Only 2 cases of PNH were suffered with pulmonary hypertension. The estimated OS at 3 years after diagnosis as 82.0%, 11 patients who died during follow-up period. Comparison of OS among the three subcategories was no statistical significance(P=0.978). Univariate analysis revealed that thrombocytopenia (P=0.048),abdominal pain(P<0.001), thrombotic events (P<0.001),and recurrent infections(P<.001) were of risk factors affecting survival. Multivariate analysis further confirmed that thrombotic events and recurrent infections remained to be statistically significant risk factors affecting survival (Table 2).

Table 1. Clinical features of patients with PNH.

Characteristic	Classic PNH	PNH SBMD	Subclinical PNH	Total
Hemoglobinuria	30(69.8%)	11(24.4%)	0 (0%)	41 (41.8%)
Abdominal pain	4 (9.3%)	2 (4.4%)	0 (0%)	6 (6.1%)
Dysphagia	4 (9.3%)	0 (0%)	0 (0%)	4 (4.1%)
Headache/ dizziness	13(30.2%)	25(55.6%)	0 (0%)	38 (38.8%)
Pectoralgia	0(0%)	1(2.2%)	0(0%)	1 (1.0%)
Back pain	3(7.0%)	0(0%)	0 (0%)	3 (3.1%)
Dyspnoea	9(20.9%)	10(22.2%)	0(0%)	19 (19.4%)
Bleeding	2 (4.7%)	19(42.2%)	1 (10.0%)	22(22.4%)
Fatigue	30 (69.8%)	34 (75.6%)	6 (60.0%)	70 (71.4%)
Infections	0 (0%)	9(20%)	1(10%)	10 (10.2%)

PNH with another specified bone marrow disorder PNH SBMD

Summary/Conclusions: Bone marrow failure is frequently found in the Chinese Patients with PNH. Renal, liver impairment and thrombosis in rare sites was relatively common. But pulmonary arterial hypertension happened seldom. Thrombotic events and recurrent infections influenced survival of patients with PNH.

PB1766

PREVALENCE AND PATTERNS OF TREATMENT OF APLASTIC ANEMIA IN KOREA
H Kim[1,*], JC Jo[1], Y Choi[1], SK Park[2], MH Chang[3]
[1]Division Of Hematology and Cellular Therapy, [2]Department of Pediatrics, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, [3]Division of Oncology-Hematology, National Health Insurance Service Ilsan Hospital, Ilsan, Korea, Republic Of

Background:
Aplastic anemia (AA) is a relatively rare bone marrow failure syndrome and

has the wide variety of cytopenia spectrum from transfusion-independent mild cytopenia to severe pancytopenia that needs for allogeneic hematopoietic cell transplantation (HCT). However, the exact incidence of AA in whole-nation-wide survey and the whole picture of treatment pattern is extremely rare.
Aims: We aimed to figure out the real incidence and treatment pattern of AA in Korea as a nation-wide database analysis. Also we wanted to know whether incidence and treatment had regional variation.
Methods: We collected AA patients from Korea National Health Insurance Service (KNHIS) database. The minimal requirements for the diagnosis of AA were registation to a rare/difficult to treat disease as AA and performance of bone marrow biopsy at the time of registration. Newly diagnosed patients were defined as a new entry to registration as AA. Treatment were collected from the each drug prescription. Region was categorized into 4 areas according to city size; capital city, metropolitan city, samll city and rural area.
Results: Data between year 2008 and 2012 were collected from KNHIS database. The annual prevalance of AA was 8.6, 15.3, 20.5, 22.9 and 23.6 (average 17.5) patients per million (PPM) in years 2008, 2009, 2010, 2011, 2012, respectively. Prevalence of male (average 17.5 PPM) and female (average 18.9 PPM) were similar. Prevalence increased as the age increased: average 12.9 PPM in younger than 10y old; average 25.5 PPM in older than 80y old. Reginal differences were found: average 17.3 PPM in capital city, 17.7 PPM in metropolitan cities, 12.9 PPM in small cities and 24.2 PPM in rural areas. The crude incidence rates (CIRs) were similar in recent 5 years: 6.8 PPM in 2008, 8.9 PPM in 2009, 9.5 PPM in 2010, 9.4 PPM in 2011 and 8.4 PPM in 2012. There were age differences in CIRs. CIR in elderly population was more than 2 times higher when comparing with younger population: average 5.4 PPM in population younger than 10y; average 13.2 PPM in elderly population older than 80y. Average CIRs in reginal categories were 8.6 PPM in capital city, 8.3 PPM in metropolitan cities, 6.1 PPM in small cities and 10.8 PPM in rural areas. Treatments of newly diagnosed AA patients were follows: transfusion in 74.1%, cyclosporin in 34%, thymoglobulin in 26.4%, G-CSF in 44.6% and HCT in 12.5% . Thymoglobulin and HCT were received 34.5% and 21.5% of newly diagnosed AA youger than 40y, but the rates were droped to 16.8% and 4.5%, respectively in older than 40y patients.
Summary/Conclusions: Korea has high CIR of AA than wetern countries. CIR increases as age increases. Rural areas has higher CIR than small cities. The treatment pattern was different between younger age group and older age group as expected.

PB1767

APLASTIC ANEMIA IN CENTER TUNISIA
A Bechir[1,*], R Haifa[1,2], B Emna[1], BS Nesrine[1], BY Yosra[1], K Abderrahmen[1]
[1]Hematology, Farhat Hached Hospital, Sousse, [2]Hematology, Farhat Hached Hospital,El Mansourah, Tunisia

Background: Aplastic anaemia is a rare but very serious blood disease, combining a central pancytopenia and bone marrow hypocellularity. Its etiology remains mostly unknown. Treatment is either allogeneic hematopoietic stem cell or on immunosuppressive therapy.
Aims: 1- To analyze the epidemiological, clinical and laboratory patients. 2-. Evaluate the terms and therapeutic results. 3- To study the different responses and survival depending on the treatment administered.
Methods: This is a retrospective study conducted over 14 years (January 2000 - December 2013) which included 95 patients with acquired aplastic anemia, diagnosed and treated at the hematology department of the University Hospital Farhat Hached hospital Sousse.
Results: The median age of patients was 32 years. The sex ratio was 1.26. At diagnosis, all patients were symptomatic. An anemic syndrome associated with hemorrhagic syndrome was the main factor of discovery (44.2%). At the initial blood count, pancytopenia was observed in 92.6% of patients. The myelogram showed a poor marrow in 85.2% of patients. A bone marrow biopsy, bone marrow was wealth 0-1 95.8% of patients. Myelosuppression was, moderate in 33 patients (34.7%), severe in 26 patients (27.4%) and severe in 36 patients (37.9%) by the score of Camitta. Fourteen patients underwent a bone marrow allograft. One patient received the anti-lymphocyte serum in combination with ciclosporin. Immunosuppressive treatment with cyclosporin alone was undertaken in 51 of our patients. Forty-two patients received androgen therapy, prescribed alone or in combination with ciclosporin or corticosteroids. At the end of our study: 35 patients (36.8%) were in CR, 6 patients (6.3%) in PR, 14 patients (14.7%) and RM 39 patients (41.1%) in Failure . One patient was lost to follow just after diagnosis. The factors that significantly influenced the response were the severity of myelosuppression, sex, hemoglobin, the rate of white blood cell, the neutrophil rate and allograft. The overall survival rate at 2 years was 47.3% at 5 years and 44.9%. The allograft is the most significant prognostic factor for survival.
Summary/Conclusions: Despite progress regarding treatment protocols, changes in the Aplastic anaemia is often fatal. The overall mortality rate in our series is due to the problem of access to specific therapies, namely the allogeneic hematopoietic stem cell and lymphocyte serum.

PB1768

MONITORING OF SMALL PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE IN PATIENTS AFFECTED BY SEVERE APLASTIC ANEMIA OR APLASTIC ANEMIA
R Milani[1,*], MT Lupo-Stanghellini[2], F Giglio[2], B Migliavacca[1], G Torriani[1], L Santoleri[3], F Ciceri[4]
[1]SIMT-Cytometry, [2]Hematology, [3]SIMT, IRCCS San Raffaele Hospital, [4]Hematology, IRCCS San Raffaele Hospital-UniSR, Milano, Italy

Background: Flow cytometry is the gold standard method for screening of paroxysmal nocturnal hemoglobinuria (PNH). The most reliable marker to detect and monitor small granulocyte or monocyte PNH clones is FLAER (fluorescent aerolysin), especially in conditions such as myelodysplastic syndromes or bone marrow failure, when traditional GPI-linked surface marker expression can be significantly altered. More than 50% of aplastic anemia patients have a PNH clone detectable by highly sensitive assays, although the underlying mechanism is yet to be unveiled.
Aims: Monitoring of small PNH clone in patients followed at our Institute for severe aplastic anemia or aplastic anemia.
Methods: Between May, 2011 and Feb, 2016, sixteen patients with severe aplastic anemia (sAA)/ aplastic anemia (AA) provided 52 blood samples for PNH flow cytometry at different time points in the course of their evaluation and treatment. We performed serial quantification of the PNH clone size by multiparameter flow cytometry using a Navios cytometer (Beckman Coulter) and Navios software. The immunophenotype evaluation is performed on EDTA whole blood samples. Granulocytes, monocytes and red blood cells (RBCs) were gated using forward and side scatter as well as lineage-specific markers. The GPI-linked markers FLAER and CD59 were comparatively evaluated. Neutrophils and monocytes were screened with FLAER/CD24/CD14/CD33/CD45 combination. The sensitivity of detection allowing identification of PNH clone sizes as small as 0.01% for RBCs and 0.03% for granulocytes.
Results: Eight of 16 sAA/AA patients were detected to have PNH clone positivity. All of them were treated with standard immunosuppressive therapy such as antithymocyte globulin and cyclosporine (ATG/CsA) or CsA alone and two non responder patients received allogeneic stem cell transplantation (alloSCT) after myeloablative conditioning. Granulocyte PNH clone was <1% in 4 patients, 1-5% in 3 patients and >30% in one patient. Lactate dehydrogenase (LDH) values were normal in all patients except the one with PNH clone >30%, who had clinical evidence of hemolysis. Haptoglobin level was normal in 5 patients. Two patients with PNH clone 1-5% had very low concentration of haptoglobin, without altered LDH values. These were patients who did not respond to ATG/CsA and received alloSCT. Direct Antiglobulin Test (DAT) were negative in all patients. PNH clone sizes were stable during immunosuppressive therapy courses with a median follow up of 42 months (3-60), while PNH clone became undetectable after alloSCT and haptoglobin levels returned to normal values (respectively 6 month and 36 month follow up).
Summary/Conclusions: Whether the presence of a small PNH clone in the setting of hypocellular marrow failure has clinical significance or predicts response to treatment and outcomes is still controversial, an accurate monitoring of PNH clone with high sensitive assays and hemolysis parameters might be useful to clarify the pathophysiology of these complex and rare diseases.

Background: Characteristic chromosomal abberations (*i.e.* 11q, 13q, 17p, and+12) play crucial role in chronic lymphocytic leukaemia (CLL) as important idenpendent prognostic factors. Combination of FISH and conventional chromosome banding (CBA) after stimulation with CpG oligonucleotides (CpG-ODN) and interleukin-2 (IL-2) allowed to capture increased number of chromosomal anormalities. We focused on rare recurrent chromosomal aberrations (RCA) that can provide new prognostic information in CLL.
Aims: Metaphase cytogenetic and molecular-cytogenetic analyses were performed in 766 CLL-patients from 2008 to 2015 (293 female, 473 male, median age at the time of analysis: 67 years) to evaluate the incidence of RCA.
Methods: CBA was performed on peripheral blood or bone marrow samples cultured in medium with stimulants. FISH was performed on unstimulated cells for detection of trisomy 12, del(11q), del(13q), del(17p). RCA were confirmed by interphase FISH (I-FISH), multicolor FISH or multicolor banding.
Results: A total of 714/766 (93,2%) cases were succesfully stimulated for metaphase analysis. Chromosomal aberrations were detected in 600/714 (84,0%) of patients by combining both methods. RCA were detected in 144 cases (144/714, 20,2%) and they were as follows: 3,5% rearrangement of *IGH* (translocations partners 2, 4, 8, 9, 11, 12, 13, 16 and 19), 3,4% gain of 2p, 3,4% del(6q), 2,5% del(14q), 1,7% gain of 8q (*MYC* gene), 1,3% del(8p), 1,3%+18, 1,1%+19, 0,6% del(5q), 0,6% t(18;22), 0,4% gain of 12q, 0,4%+21 and 0,1% t(2;18).
Summary/Conclusions: Cytogenetic results are highly relevant in defining the prognosis of CLL patients. I-FISH as gold standard for detection of important chromosomal aberrations and CBA after stimulation with cocktail of CpG-ODN and IL-2 are efficient tools (methods) in routine diagnostic (analysis) of chromosomal aberrations. The importance of RCA in CLL will be discussed in the poster.

OXIDATIVE STRESS IN CHRONIC LYMPHOCYTIC LEUKEMIA

G D'Arena[1,*], O Perbellini[2], M Coscia[3], C Vitale[3], A Patriarca[1], V Pizza[4], F La Rocca[5], V Ruggieri[5], V De Feo [6], G D'Arena Sr[7], G Pietrantuono[1], C Visco[2], P Musto[8], EL Iorio[9]

[1]Hematology and Stem Cell Transplantation Unit, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [2]Hematology Unit, "S. Bortolo" Hospital, Vicenza, [3]Hematology Department, University, Turin, [4]Neurophysiopathology Unit, "S. Luca" Hospital, Vallo della Lucania, [5]Laboratory of Pre-Clinical and Translational Research, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [6]Pharmacology Department, University, Salerno, [7]Clinical Pathology Laboratory, "D'Arena s.r.l.", Vallo della Lucania, [8]Scientific Direction, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [9]International Oxidation Observatory, Salerno, Italy

Background: Oxidative stress (OS) is an imbalance between production of free radicals and reactive metabolites, so-called oxidants or reactive oxygen species (ROS), and their elimination by protective mechanisms, referred to as antioxidants. Extensive evidence has shown that disturbances of oxidative metabolism are a common feature of transformed tumor cells. However, the effect of OS levels in chronic lymphocytic leukemia (CLL) is largely unknown.
Aims: To investigate the oxidative stress status in CLL and analyze the relationship with the disease status and prognostic factors evaluated at diagnosis.
Methods: We analyzed peripheral blood samples from 76 patients with untreated CLL evaluated at diagnosis (48 male and 28 female; mean age 67 years; range 36-90 years; 57 patients with A Binet stage, 15 patients with B stage, and 4 patients with C stage) and 20 healthy individuals as matched control group. Serum total antioxidant capacity was determined by performing the d-ROMs test, whose chemical principle is based on the ability of a biological sample to oxidize N,N-diethylparaphenilenediamine (normal range 250-300 U CARR, where 1 U CARR is equivalent to 0.8 mg/L H2O2), while serum OS was assessed by means of BAP test, which measures the ability of a serum sample to reduce iron from the ferric to the ferrous ionic form (optimal value >2.200 micromol/L reduced iron).
Results: A significant oxidative damage was showed in CLL patients (d-ROMs test: 407 U CARR±194; range 194 - 794; BAP-test: 2.033 micromol/L±310.6; range 1.024 – 3.300) with respect to normal controls (d-ROMs test: 259.6 U CARR±87.5; range 158 - 425; BAP-test: 2.505 micromol/L±306; range 1.876-3.045) (p 0.0014 and 0.0001, respectively). However, no correlations were found with absolute lymphocytosis, haemoglobin and platelet levels, Binet disease stage and cytogenetics abnormalities (evaluated only in 52 patients) detected by FISH (normal *vs* del17p *vs* del11q *vs* trisomy12 *vs* del13q14). Unmutated IgVH CLL patients displayed significantly higher d-ROMs test values than mutated IgVH patients (p 0.0057). On the contrary, no differences were found in BAP test according to mutational IgVH status. At a mean follow-up of 50 months (range 6-211 months), 16 patients progressed needing treatment. d-ROMS test was found significantly higher at diagnosis in this cohort of patients with respect to non progressed patients (501 U CARR±135 *vs* 385±149; p 0.006). No differences were also found with respect to BAP test. Finally, no correlations were found between time to treatment and both d-ROMS and BAP test levels.
Summary/Conclusions: CLL patients show oxidative stress features (increased oxidative damage, evaluated by d-ROMs test, and reduced antioxidant capacity, measured by means of BAP test) which are usually irrespective of clinical and biological characteristics detected at diagnosis, reflecting constitutive CLL findings, rather than disease burden and activity. In particular, differently from a previous observation (Collado R *et al.,* 2014), no correlations were found in our cohort of patients between increased oxidative damage and unfavourable cytogenetics subgroups. Our data support the investigational use of antioxidants in the clinical setting.

PB1771

THE ROLE OF CD38, CD23, CD200 AND CD43 EXPRESSION IN DISCRIMINATION OF CHRONIC LYMPHOCYTIC LEUKEMIA AND MANTLE CELL LYMPHOMA

M Falay[1], F Ceran[1], S Dagdas[1], K Gunes[1], G Ozet[1], D Avcı[2,*]

[1]Hematology, [2]Ankara Numune Education and Resarch Hospital, Ankara, Turkey

Background: Chronic lymphocytic leukemia (B-CLL) and mantle cell lymphoma (MCL) share many features and their differential diagnosis may be challenging, especially when a leukemic picture alone is present. Monoclonal antibody panels are often useful, with CD23 being the most reliable. In the CD5+/CD10- subgroup cases with CD23+cells are usually classified as CLL, whereas CD23 – cells are diagnosed as MCL. However, the immunphenotypic profile of MCL cells is a quite heterogeneous, and cases of CLL and MCL can frequently overlap to a significant degree. MCL diagnosis should be confirmed by immunohistochemical cyclin D1 detection, sometimes with equivocal or even negative results. Other cytofluorimetric, cytogenetics or molecular techniques are reliable but not widely available.
Aims: B-CLL leukemic cells express CD23, CD22, CD38, CD79b, CD200 and CD43 antigens may improve the distinction between CLL and MCL cases. Both CD200 and CD43 are used in clinical cytometry laboratories for a long time now,but need for harmonization
Methods: We investigated by 5 color multiparametric flow cytometry 357 patients (241 males and 116 females; median age of 68±10,6 years) diagnosed with B-cell LPD were studied. According to the WHO criteria (R), patients were grouped as follows: 308 cases CLL,31 cases MCL, 18 cases HCL . Median PB lymphocyte counts at diagnosis were of 19.8×10^9 lymphocytes/l (range: 0.8–274×10^9 lymphocytes/l). Diagnosis of all MCL was confirmed by immunohistochemisrty detection of cyclin D1 or detection of t (11:14) by FISH. The monoclonal antibodies (MoAbs) used for flow cytometry labeling were obtained from the Beckman Coulter Company (BC, Florida, USA). CD45, CD79b, CD3, CD5 FITC, CD10 PE, CD11c, CD19, CD20, CD22, CD23, CD25, CD38, CD103, FMC7, CD43 (clone DFT1), Kappa, Lambda, CD200 (clone OX2, Becton/Dickinson Biosciences-BD, USA) MoAbs were used for this purpose
Results: We found in one CLL case CD200 negative, and one case CD43 negative. However we have not observed any CD23 negative in all CLL cases. We observed 10 MCL cases CD23+, 3 cases CD200 positive and 2 cases CD43 positive. CD200 appeared a valuable marker in the differential diagnosis of CLL and MCL (p<0.001). As for CD43 expression in CLL, it was positive in 297 (96.4%) cases but negative in only 11 (3.6%) cases while it was negative in 20 (64.5%) and positive in 11 (38.5%) cases. CD43 was significantly different between CLL and MCL. In the MCL group, the proportion of the CD43 cases was significantly higher (p<0.001), CD38,CD22,CD79b are not significantly.

Summary/Conclusions: We concluded that although CD 23, CD22, CD79b, CD38 is not a useful marker in discrimination of CLL and MCL, CD43 and CD200 used together in routine panels could be of diagnostic utility in excluding MCL diagnosis. However, as with other markers, the use of these markers may also be flawed by heterogeneous distribution and variable expression. Therefore, standardized sampling and staining for flow cytometry and specific techniques should be primarily defined, and then followed by the evaluation of these markers and harmonization studies in larger and more diverse patient populations.

PB1772

CD38 AND INTERLEUKIN 6 GENE POLYMORPHISM IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA- CORRELATION WITH CLINICAL AND LABORATORY PARAMETARS

V Vukovic[1,*], D Antic[1,2], V Cokic[3], M Buac[3], M Diklic[3], M Todorovic- Balint[1,2], J Bila[1,2], B Andjelic[1,2], M Dencic- Fekete[4], V Djurasinovic[1], A Sretenovic[1], J Jelicic[1], B Mihaljevic[1,2]
[1]Lymphoma center, Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, [3]Institute for Medical Research, University of Belgrade, [4]Genetic Laboratory, Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: CD38 receptor and interleukin 6 (IL-6) level increases proliferation and survival of chronic lymphocytic leukemia (CLL) cells and increased CD38 expression as well as IL-6 level are a negative prognostic marker CLL patients. CD38 and IL-6 have a genetic polymorphism characterized by a C>G variation.
Aims: This study was designed to examine the influence of CD38 (184C/G; rs6449182) and IL-6 (-174 G/C; rs1800795) gene polymorphism on laboratory and clinical parameters in chronic lymphocytic leukemia (CLL) patients.
Methods: Genotyping polymorphism is performed using restriction fragment length polymorphism-polymerase chain reaction for CD38 (184C/G) and IL-6 (-174 G/C) in 44 CLL patients and 5 healthy subjects. We separated CLL patients in three groups: 1) the G allele for IL-6 and C allele for CD38; 2) the C allele for IL-6 and CD38; 3) the full fragment for either IL-6 or CD38. The plasma level of VEGF was measured using immunoassay. Kaplan-Meier method was used for estimating survival rates.
Results: A higher prevalence of the C allele was found both in CD38 (184C/G, 84%) and IL-6 (-174 G/C, 66%) gene polymorphism of CLL patients. Furthermore, we found a lower level of CD38-positive cells in group 1 of CLL patients. The group 3 has significantly higher level of thrombocytes and lactate dehydrogenase (425 U/l, p<0.05) than group 2. The group 1 has increased beta 2 microglobulin in comparison of group 3. According to previous reports for a strong correlation between CD38 and VEGF expression, we found increased levels of plasma VEGF (med 50, range 16 - 438 ng/mL) in CLL patients *vs* control subjects and in group 1 of CLL *vs* other two groups (med 79 *vs* 50 and 53 ng/mL in groups 2 and 3, respectively). According to the pattern of bone marrow infiltration, the diffuse type was the most present in group 1 (33%), while the nodular/interstitial was dominant in group 3 (91.7%). Furthermore, patients in the group 3 demonstrated the most favorable clinical stage according to Binet (A - 91.7%) and Rai (0 – 75%). Regarding CD38 expression, there was no significant difference between groups, although patients with C allele exhibited reduced CD38 expression (12% *vs* 25%). Mean overall survival was 97, 101 and 82 months in group 1, 2 and 3, respectively without statistical significance. Median survival in group 1 and 3 was 65 and 79 months, respectively, while in group 2 was not reached . No statistical significant difference in survival among three groups was noted (p=0.90).
Summary/Conclusions: Presented results revealed that CLL patients with the full fragment for either IL-6 or CD38 genes tend to have more favorable clinical and laboratory parameters at diagnosis, but do not exhibit survival advantage.

PB1773

THE EXPRESSION OF TOLL-LIKE RECEPTORS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA.

J Rybka[*], A Butrym, T Wróbel, A Bogucka-Fedorczuk, R Poręba, B Jaźwiec, E Frączak, K Kuliczkowski
Wroclaw Medical University, Wroclaw, Poland

Background: B-cell chronic lymphocytic leukemia (B-CLL) presents with progressive accumulation of monoclonal B-cells in the peripheral blood, bone marrow and lymphoid organs. B-CLL is characterized by heterogenous clinical outcome. Some patients have an indolent disease and the others have an aggressive clinical course of B-CLL. Toll-like receptors (TLRs) play an important role in B-cell activation and maturation and may be involved in the pathogenesis of B-cell lymphomas. TLRs are essential receptors of the innate immune system and key regulators of the acquired immune system. TLRs are mainly expressed in human immune related cells such as monocytes, neutrophils, macrophages, dendritic cells, T cells, B cells and NK cells. The expression of TLRs and their association with other prognostic factors in B-CLL patients remains unclear.
Aims: The aim of our study was to evaluate the expression of TLR2, TLR4 and TLR9 and their significance as biological markers in patients with B-cell chronic lymphocytic leukemia.
Methods: 60 patients with newly diagnosed B-CLL were evaluated (29 females and 31 males). The median age of patients was 68 years (range: 52-88 years). The diagnosis was performed according to the IWCLL/NCI criteria for CLL. 40 patients (67%) had early-stage CLL (Rai stage 0-II) and 20 patients (33%) had advanced-stage CLL (Rai stage III and IV). All patients were either untreated. The healthy control group included 14 age-matched individuals (7 females and 7 males). Using quantitative reverse transcriptase PCR, the mRNA expression of genes TLR2, TLR4 and TLR9 was measured. The relative quantitation was indicated by cycle threshold (Ct) values. The Ct value of the target genes was normalized (ΔCt) to the Ct value of the GUS gene of the samples. The results were statistically analysed using 'STATISTICA 8,0'. Statistical analysis was performed by means of Mann-Whitney's U-test and p<0,05 indicated a significant difference. Overall survival (OS) was determined using Kaplan-Meier method. The long-rank test was used to compare the curves.
Results: In comparison to control group TLR2 and TLR4 mRNA expression was higher in B-CLL patients than in healthy individuals (ΔCt TLR2 6.46±9.58 *vs* 0.98±0.43 and ΔCt TLR4 11.91±70.22 *vs* 2.21±0.32)(p<0.05). TLR9 mRNA expression was higher in control group than in patients with B-CLL (ΔCt TLR9 23.65±16.29 *vs* 3.35±1.93) (p<0.05). We found that patients with higher mRNA expression of TLR9 had significantly longer OS than patients with lower mRNA expression of TLR9 (p<0.05).TLR2 mRNA expression was higher in patients with advanced-stage CLL (Rai stages III and IV) than in patients with early-stage disease (Rai stages 0-II) (ΔCt TLR2 19.10±17.76 *vs* 7.94±6.25) (p<0.05). Moreover we observed that expression of TLR2 in patients with anemia was significant higher than in patients without anemia (ΔCt TLR2 17.18±14.29 *vs* 7.10±5.98) (p<0.05) (Figure 1).

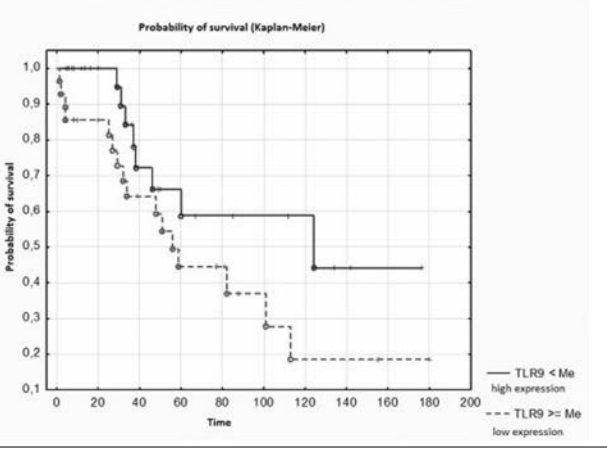

Figure 1.

Summary/Conclusions: In conclusion, our results suggest that TLRs could become new potential biological markers for the clinical outcome in patients with B-cell chronic lymphocytic leukemia. However, this observation should be validated by a larger study.

PB1774

AGING AND PD-1 & PD-L1 GENE EXPRESSION: MARKERS OF IMMUNOSENESCENCE?

L Dang[1], K Willard Gallo[2], S Garaud[2], H Duvillier[3], JN Lodewyckx[4], C Solinas[2], P Da Silvia[2], C Gu [2], C Sibille[5], D Bron[3,*]
[1]Dpt of Hematology and Molecular Immunology Unit, [2]Molecular Immunology Unit, [3]Dpt of Hematology, Institut Jules Bordet (ULB), [4]Molecular Immunology Unit, Institut Jules Bordet, [5]Anatomo-pathology Dpt, Institut Jules Bordet (ULB), Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favors infection and cancer development. Cancer cells can escape immune surveillance by upregulating inhibitory immune checkpoint such as PD-1 and PD-L1. High surface expression of PD-1 was reported in association with T-cell exhaustion. The PD-1/PD-L1 axis inhibits the immune response leading to anergy of lymphocytes.
Aims: In this study, we examined the expression of PD-1 and PD-L1 genes in lymphocytes subsets according to age.
Methods: Lymphocyte subsets (CD3+CD4+; CD3+CD8+, CD19+) were isolated using the MACS isolation system from PBMC of healthy donors (HD) and Chronic Lymphocytic Leukemia (CLL) patients. PD-1, PD-L1, IL4 and IFNɣ were quantified by qRT-PCR for each purified lymphocyte subset.
Results: PD-1, PD-L1, IL4 and IFNɣ gene expression was studied using qRT-PCR to evaluate 28 HDs [14 HDs under 50y (median-: 38) and 14 HDs above 50y (median: 62)] compared with 23 untreated CLL patients (median age: 69). The purity of each lymphocyte subset was 95%>99%. PD-1 was significantly

up-regulated in most lymphocyte subsets in the older group: CD4+, CD8+T cells and CD19+B cells (p=0.015; 0.02 and 0.01, respectively). Compared with a similar age group of HDs, PD-1 expression was strongly upregulated in CD4+, CD8+and CD19+subsets of CLL patients (p=0.001; 0.002 and <0.001). High PD-L1 expression was correlated with age in the normal B lymphocytes (p=0.046). The leukemic B cells also expressed higher levels of PD-L1 than circulating normal B cells as compared with the older group of healthy donors (p=0.001). In order to further investigate the PD-1/PD-L1 axis contribution to T cell dysfunction, we have checked for the expression of IL4 and IFNɣ genes in CD4+and CD8+lymphocytes subsets, respectively. A significant down-regulation of IL4 and IFNɣ (p=0.008 and 0.001) in CLL patients was also demonstrated.
Summary/Conclusions: 1) PD-1 and PD-L1 gene expression is correlated with aging 2) Upregulation PD-L1 is even more pronounced in leukemic B cells, suggesting a potential benefit of anti PD-1/PD-L1 drugs in CLL patients 3) In CLL patients, upregulation of PD1 and lower expression of IL4 and IFNɣ gene are observed in CD4+and CD8+T cells.

Martino-IST, Genova, [8]Unità di Ricerca Biotecnologica and Hematology Unit, Department of Onco-hematology, Azienda Sanitaria Provinciale, Aprigliano (CS) and A.O. of Cosenza, Cosenza, Italy, Cosenza, Italy

Background: NGS technology allows to study the molecular genetics of CLL through the comprehensive detection of genetic lesions.
Aims: We describe the application of a NGS panel based on Ion AmpliSeq™ technology to analyze the full coding region of *TP53* (ex 2–11) in a single workflow.
Methods: Purified B-cells, from 39 therapy-free CLL patients (pts) visiting our outpatient clinic. Library preparation and sequencing were performed on the Ion Torrent™-PGM platform (Thermofisher) according to the manufacturer's protocols. For each run, 10 pooled samples were loaded on a 316chip and sequenced (flow rate 500x). Data processing, filtering and base calling were performed using the Ion Torrent server v4.4.2. Based on Variant Caller Parameters we accepted all variants with an allele frequency (VAF)>5% with high quality, rejected variants had VAF<3% and low quality. Genomic sequences were compared to the IARC TP53 database and confirmed using Sanger sequencing.
Results: ION-PGM sequencing data showed a high coverage in 90% of sequenced amplicons with average coverage uniformity of 89%, average mean depth of 13130 (range 8812–17960), and 97% of mapped reads on target. We identified 84 variants in 39 pts (including synonymous [N=2/2 pts] and non-synonymous [NS] mutations [n=44/26 pts]) in TP53 regions. A total of 84 variants were identified in 30/39pts (77%). Overall, of the 39 pts analyzed, 9 pts were $TP53^{WT}$, while 30/39 76.9% presented variants along the entire TP53 sequence. 3/39 presented only intronic mutations and were considered $TP53^{WT}$; 1/39 pts with a 3'UTR mutation with VAF=4.5%. In the remaining 26 pts NGS identified 46 exonic mutations (range, 1-5 variants/patient): 6/26 with clonal mutations only, defined as VAF>10%, (23.1%); 16/26 (61.5%) clonal and subclonal; and in 4/26 (15.4%) only subclonal variations were identified. Exon mutation hotspots were located in ex-7 (domain IV), ex-11 (C-terminal) and the 3'UTR, with 13, 11, and 10 variants, respectively. Overall, a notable% of mutations were identified having a VAF between 3–5%(60/84 variants, 71.4%) and between 5–10% (6/84, 5.9%), which may be considered subclonal variants defined as below the detection limit of Sanger sequencing. Of the 46 exon variants (26 pts) identified, 44 were NS mutations with the following effects at the protein level: 28 deleterious, 3 frameshift, 12 neutral, 1 stop/loss and 2 unclassified mutations and were indicated as alterations likely producing nonfunctional protein according to *in silico* analysis. The mutations in the 3'UTR (10) and 5'UTR (1) could potentially affect regulation of TP53 gene expression by target miRNA and/or transcription factors. Correlation with FISH analysis showed that of the 4 pts with del17p, 3 pts presented a clonal TP53 mutation (with VAF range 22.5–94.7%) in the remaining allele, while the 4th presented a subclonal mutation with a VAF of 3.1%, of note this was the only del17p patient alive in this cohort.
Summary/Conclusions: The ION PGM-TP53 panel offers an easy to use platform for the evaluation of small clonal TP53 mutations. A total of 67/84mutations were detected as small TP53-mutant subclones having a VAF<10%, that would likely be considered WT by Sanger sequencing, demonstrating the high sensitivity of the technique. The presence of subclonal mutations could anticipate the development of a chemo-refractory phenotype among CLL pts requiring treatment. We are currently evaluating TP53 clonal alterations identified by NGS screening in these CLL pts prospectively. Special thanks to Celegene and AIRC-CARICALRegional Grant 16695.

GOLD NANOPARTICLES CONJUGATED WITH RITUXIMAB FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA
C Tomuleasa[*]
Research Center for Functional Genomics, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania

Background: Chronic lymphocytic leukemia (CLL) is a monoclonal disorder that is characterized by a continuous accumulation of malignant lymphocytes. Despite progress in targeted therapy options for CLL, relapse or progression to a Richter syndrome still appears. Thus, a more focused and targeted therapeutic option is required. This can be achieved by increasing the concentration of a cytostatic drug in the tumor while reducing its' systemic toxicity.
Aims: In the continuous effort toward the development of more efficient therapeutic approaches for the treatment of CLL, in the current study we report the conjugation of rituximab antibody drug onto spherical gold nanoparticles. Their effective trans-membrane delivery inside CLL cells and their validation as real-potential therapeutics with increased efficacy, in comparison with drug alone.
Methods: The internalization of Rituximab-nanocarriers was proved by the strongly scattered light from gold nanoparticles and was correlated with the results obtained by transmission electron microscopy and dark-field microscopy. The therapeutic effect of the newly designed drugs was investigated by several methods including cell counting assay as well as the MTT assay.
Results: The therapeutic effect of the newly-designed drugs was investigated by several methods including cell counting assay as well as the MTT assay and was found to be superior when compared with the drug alone, data confirmed by state-of-the-art analyses of internalization, cell biology (flow cytometry, apoptosis and autophagy assay), genomics (RT-PCR for MS4A1) and proteomics (confocal microscopy and western blotting for CD20).
Summary/Conclusions: The efficient formation of drug-nanocarriers was proved by spectroscopic characterization of the particles. The internalization of rituximab-nanocarriers was proved as a result of the strongly scattered light from gold nanoparticles and was correlated with the results obtained by TEM and dark field microscopy.

THE ROLE OF TUMOR NECROSIS FACTOR (TNF) AND IT'S SOLUBLE RECEPTORS, STNFRI AND STNFRII, IN MYELOSUPRESSION DEVELOPING IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)
V Barilka[1,*], V Matlan *[2], S Prymak[3], O Vygovska[4], O Shalay[5], V Loginsky[6]
[1]Immunocytology and genetics of blood neoplasms, SI Institute of Blood Pathology and Transfusion Medicine of the NAMS of Ukraine, [2]* Lviv National Medical University named Danylo Halytsky, Lviv, Ukraine, [3]SI Institute of Blood Pathology and Transfusion Medicine of the NAMS of Ukraine, Lviv, Ukraine, [4]department of hematology, SI Institute of Blood Pathology and Transfusion Medicine of the NAMS of Ukraine, [5]immunocytology and genetics of blood neoplasms, [6]immunocytology and genetics of neoplasms of blood, SI "Institute of Blood Pathology and Transfusion Medicine of the NAMS of Ukraine", Lviv, Ukraine, Lviv, Ukraine

Background: Myelosupression with severe anemia or thrombocytopenia refers to the adverse factors in clinical course of B-CLL. The production of TNF, a pleiotropic cytokine, and it's soluble receprors (sTNFRs), sTNFRI and sTNFRII, in B-CLL patients (pts) in blood are broken, but the final role of these proteins in development of myelosupression in B-CLL pts is studied poorly.
Aims: To determine the role of TNF, sTNFRs in myelosupression developing in B-CLL pts.
Methods: Determination of TNF, sTNFRs was performed using blood plasma of 74 pts with B-CLL at different stages of the disease before treatment. Determining the concentration of TNF was carried out by biological methods, using mouse fibroblasts cell culture line L929. The level of sTNFRI and sTNFRII was performed by immunological methods using the kits of BioSource Europe S.A., Belgium. These parameters were analyzed in relation with complete blod counts of the pts with B-CLL. The control group consisted of 15 healthy donors. Probability statistics was evalueted using Student's *t*-test. The reletionship between the concentration of TNF, sTNFRs and hemograms of pts at different stages (A,B,C by Binet) of B-CLL was established by correlation coefficient (*r*), which was calculated by Excel program.
Results: The significantly higher levels of TNF (0,938±0,124 ng/ml), sTNFRI (2,740±0,277 ng/ml) and sTNFRII (32,180±4,350 ng/ml) were established in plasma of B-CLL pts at all stages of the disease compared with healthy donors (0,089±0,017 ng/ml; 1,210±0,014 and 4,170±0,231 ng/ml, accordingly). On the other hand, appreciably lower levels (p<0,001) of TNF (0,482±0,184 ng/ml) and sTNFRII (17,080±1,294 ng/ml) were determined in plasma of B-CLL pts at early stages in comparision with more advanced stages, B-C (1,011±0,260 and

33,300±5,690 ng/ml, accordingly). An increased reticulocytosis (>10 $^{0}/_{00}$), as a sign of hemolytic syndrome, was accompanied by significantly higher levels of TNF in plasma comparing to pts with a normal number of reticulocytes (1,266±0,114 *vs* 0,752±0,188ng/ml). The concentrations of TNF and sTNFRII correlated negatively with hemoglobin level (r=-0,37) but positively with absolute lymphocytic count (r=0,42) at early stages of the disease. In addition, any changes in concentrations of these proteins were not detected in plasma of B-CLL pts with thrombocytopenia.
Summary/Conclusions: These studies suggest that increasing of the concentration of TNF and sTNFRs in B-CLL, possibly as a result of their production by leukemic cells, may adversely affect hematopoiesis, promote hemolysis and development of anemia of different origin in B-CLL pts. In advanced stages of B-CLL an augmented secretion both of TNF and sTNFRII comparing with early stages may contribute to the leukemic progression. Determination of TNF and sTNFRs in blood of B-CLL pts may be used to predict the development of anemia as well as to initiate treatment, especially at early stages of this disease.

PB1778

IS CD200 EXPRESSION A SIGNIFICANT MARKER FOR DIFFERENTIATION OF B- LYMPHOPROLIFERATIVE DISEASES? IN A SINGLE TUBE ANALYSIS
P Aytan*, I Kozanoglu, N Buyukkurt, M Yeral, M Kasar, S Solmaz, C Boga, H Ozdogu
Hematology, Baskent University Adana Medical and Research Hospital Bone Marrow and Transplantation Centre, ADANA, Turkey

Background: B cells have specific antigen patterns and flow cytometric techniques have been used for discrimination of chronic lymphoproliferative disorders (CLDs). Despite CD23 is considered a reliable marker, because of its positivity in chronic lymphocytic leukemia (CLL) and negativity in mantle cell lymphoma (MCL), there are some cases where CD23 does not discriminate. CD 200 is a trans-membrane glycoprotein belonging to the immunoglobulin super-family mostly expressed by B cells.
Aims: Our aim was to evaluate CD200 expression in the diagnosis and classifications of B-cell CLDs in a single tube by using flow cytometric techniques.
Methods: This is a retrospective study utilizing data on consecutive patients with B CLDs in a single center. The study was performed on erythrocyte-lysed whole peripheral blood samples, after staining with directly conjugated monoclonal antibodies. A single tube was designed to include CD45, CD19, CD5, CD23, CD22, CD10, CD20 and CD200. Samples were analyzed using 8-color MFC (FACS Canto II; BD, Bioscience), and FACS DIVA was used for data analysis. An antigen was considered positive when at least 20% of the cells expressed that antigen.
Results: A total of 59 B-CLD patients - 42 male (71.2%) and 17 female (28.8%) - were evaluated between January 2014 and January 2016. All patients expressed CD19 and while CD20 was found to be positive in all but one CLL case. 36 patients were diagnosed as CLL and 4 patients diagnosed as atypical CLL (aCLL). A total of 19 patients were diagnosed as lymphoma; 3 of them were mantle cell lymphoma (MCL), 2 of them were marginal zone lymphoma (MCL), 2 of them were follicular lymphoma (FL), 2 of them were diffuse large B cell lymphoma (DLBCL) and 2 of them were small lymphocytic lymphoma (SLL). Also 8 patients were unclassified and they were defined as other B lymphoproliferative diseases. While CD200 was positive in all CLL and aCLL patients, it was negative in MCL, MZL, DLBCL patients. CD200 was also positive in unclassified form of B lymphoproliferative diseases in 5 patients. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of CD200 for diagnosis of B-CLL are 100%, 52.2%, 76.6% and 100% respectively. These values were 100%, 47.8%, 75% and 100% respectively for CD5. CD 23 was positive in 32 of 36 B-CLL patients (88.9%), and weak positive in the remaining 4 B-CLL patients (11.1%). CD 23 was also found to be positive in 1 (4.3%), weak positive in 4 (17.4%) and negative in 18 (78.3%) patients without B-CLL.
Summary/Conclusions: Multiple reports have showed that CD 200 expression is moderate –high in CLL. However, it is dim to negative in mantle cell lymphoma and proposed as another marker to distinguish between CLL and MCL. CLL/ SLL demonstrates low intensity staining for surface immunoglobulin, low expression of CD 22, CD 79B, strong expression of CD 5 and CD 23 but leukemic phase of MCL can be misdiagnosed as CLL. Since MCL is a more aggressive disease and generally treated differently than B-CLL, it is important to differentiate them. In our study, it is showed CD200 expression has a great impact on accurate B-CLDs at diagnosis and it could be added to the routine panels and might be able to show in a single tube by using 8 colour flow cytometer . Also there is high expression of CD200 in B-CLL and it could be a good option for targeted immune therapy in the near future.

PB1779

STRUCTURAL AND FUNCTIONAL ALTERATIONS OF THE COMPLEMENT SYSTEM IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS
R Michelis[1,*], C Suriu[1,2], L Akria[1,2], M Barhoum[1,2], A Braester[1,2]
[1]Haematology, Galilee Medical Center, Nahariya, [2]Faculty of Medicine in Galilee, Safed, Israel

Background: Chronic lymphocytic leukemia (CLL) is the most common adult leukemia in the western world, accounting for 30% of all leukemias. The therapeutic approach in CLL includes chemotherapeutic regimens of purine analogues and therapeutic monoclonal antibodies. The immunotherapeutic approach triggers immune responses against the leukemic B-cells that synergize with cytotoxic chemotherapeutic agents. The therapeutic monoclonal antibodies mediate anti-tumor effects through complement-mediated cytotoxicity (CDC), antibody-dependent cell-mediated cytotoxicity (ADCC), and phagocytosis. The efficacy of the CDC thus depends on the expression level of the targeted antigen on B-cells, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement system.
Aims: To study structural and functional characteristics of key complement components in untreated CLL patients, in order to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment.
Methods: Blood samples were collected from 13 untreated CLL patients and 8 healthy controls (HC). Clinical biochemical and haematological parameters, as well as CLL staging were recorded. Three key complement components, C3, C4 and C5 were studied by Western blot analysis. The activity of the complement system before and after activation with Zymosan or aggregated IgG was followed by the levels of C5b-9, the terminal product of complement activation, using ELISA. The link between levels of complement activity and complement isoforms, as revealed by Western analysis, was studied.
Results: The Western analysis results indicate differences in the pattern of C5 and C4 in CLL patients compared to HC subjects. Specifically, the C5 complex, which exists as a single band in HC, appeared in CLL patients as a clear double-band. This alteration was observed in >50% of the patients. Western analysis did not indicate clear differences in C3 pattern in the patients. Activity analysis revealed higher basal levels of C5b-9 in the CLL patients (compared with HC), that were particularly high in the patients presenting altered pattern of C5. Maximal activation, achieved by Zymosan or aggregated IgG, appeared to be inversely correlated with basal activation levels.
Summary/Conclusions: These preliminary data demonstrate a possible link between the activation potential of the complement system in CLL patients and alterations in the complex structure of C5. The exact mechanism by which "modified" C5 distracts the complement activity needs further clarification. Yet, the appearance of "modified" C5 in CLL patients with disturbed complement activity bears the potential to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment due to compromised CDC. Development of such a marker may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.

BACH2 & PRDM1: PREDICTIVE MARKERS OF IMMUNOSENESCENCE IN AGING?
L Dang[1], K Willard Gallo[2], S Garaud [2], H Duvillier[3], JN Lodewyckx [2], C Solinas[2], P Da Sivia[2], C Gu [2], C Sibille [4], D Bron[3,*]
[1]Hematology and Molecular Immunology Unit, [2]Molecular Immunology Unit, [3]Dpt of Hematology, [4]Anatomo-Pathology Unit, Institut Jules Bordet (ULB), Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favours cancer development. This is illustrated by the high median age of most malignant hemopathies. There is currently a lack of information related to genetic or epigenetic modifications of tumor suppressor genes (TSGs) in ageing immune cells. Our previous studies investigated the 6q deletion in T-cell lymphoproliferative diseases and we reported that BACH2 gene is a candidate TSGs.
Aims: In this study, we examined whether BACH2 and PRDM1 could be predictive markers of immunosenescence in lymphocytes subsets according to age.
Methods: Lymphocytes subsets were analysed using multi-colour flow cytometry to assess expression of CD45, CD3, CD4, CD8, CD45RA, CD25, CD197, CD19, CD27, CD5, CD56 and CD16. Lymphocyte subsets were isolated using the MACS isolation system for subsequent molecular investigations. BACH2 and PRDM1 were quantified by qRT-PCR and western blotting for each purified lymphocytes subset.
Results: Peripheral blood samples were obtained from 35 healthy donors (HDs) of different ages (20y to 90y), including 18 HDs under 50y (median: 36) and 17 HDs above 50y (median: 61). Absolute lymphocyte counts did not vary between these two groups but alterations in lymphocyte subsets distribution were detected. The number of naïve T cells and CD8+cytotoxic T cells was significantly reduced in the older group (p=0.01 and 0.002). Our data confirmed that the CD4:CD8 ratio and effector T cells numbers are significantly increased (p<0.0001 and 0.01) with age. BACH2 and PRDM1 gene expression was studied by using qRT-PCR to evaluate 28 HDs [14 HDs under 50y (median: 38) and 14 HDs above 50y (median: 62)] compared with 23 untreated Chronic Lymphocytic Leukemia (CLL) patients (median age: 69). The purity of each lymphocytes subset was 95%>99%. BACH2 was significantly down-regulated in most lymphocytes subsets in the older group: CD4+, CD4+naïve, CD8+T cells and CD19+B cells (p=0.001; 0.005; 0.004 and 0.03, respectively). Com-

pared with a similar age group of HDs, BACH2 expression was even more severely reduced in CD19+, CD4+, CD8+subsets of CLL patients (p=0.004; 0.001 and <0.001). In contrast, PRDM1 was significantly up-regulated in the CD4+and CD8+T cells (p=0.003; 0.001) of CLL patients but not in leukemic B cells. There was inverse correlation between BACH2 and PRDM1 (Pearson r=0.82; p<0.0001) in T cells of CLL patients. In addition, by using western blot BACH2 and BLIMP1 protein expression in CD4+, CD8+and CD19+lymphocytes correlated significantly with their transcripts expression levels. These observations uncover the roles of BACH2 and PRDM1 in the survival of immune cells in HD and CLL patients.
Summary/Conclusions: Our investigations suggest that BACH2 and PRDM1 expression is correlated with immunosenescence. Moreover, in CLL patients, this down regulation of BACH2 is even more pronounced. Further investigation should be conducted to better understand the role of unbalanced expression of BACH2 and PRDM1 genes in lymphocytes functions and survival.

PB1781

ALTERED SETMAR EXPRESSION ASSOCIATES WITH CLINICAL CHARACTERISTICSIN CHRONIC LYMPHOCYTIC LEUKEMIA

F Piazera[1,*], R Lucena-Araujo[2], F Morato de Oliveira[2], E Magalhaes Rego[2], F Saldanha-Araujo[2], F Pittela Silva[1]
[1]Laboratory of Molecular Patology of Cancer, University of Brasilia, Brasilia, [2]Department of Internal Medicine, University of São Paulo, Ribeirão Preto, Brazil

Background: The Chronic lymphocytic leukemia (CLL) is the most common chronic lymphoid malignancy in the western population. To date, several studies have been developed to elucidate the genetic factors involved in the biology and progression of CLL. Epigenetic changes have been shown to be increasingly important in the genesis of various tumors and especially in chronic lymphoid neoplasms.Histone methylation is one of the leading and most studied epigenetic events. The gene *SETMAR*(or *METNASE*) was associated with carcinogenesis of acute myeloid leukemia by losing disjuntion checkpoint in cells treated with inhibitors of protein topo II alpha such as etoposide, doxorubicin and mitoxantrone. However, the role of *SETMAR* in CLL leukemogenesis remains unknown.
Aims: Determine relative expression of the gene in SETMAR CLL samples.
Methods: In this study, we evaluated the relative expression of *SETMAR*[FP1] between a group of 59 CLL patients and 10 samples from peripheral blood of healthy blood donors by real-time qPCR.Quantification of *SETMAR* was performed by Real Time PCR (qPCR) and normalized to endogenous *ACTIN* expression. Results were analyzed by the comparative 2 $^{-\Delta\Delta Ct}$ method. The amount of target gene, normalized to the endogenous control gene and relative to a reference sample, was converted into relative quantification. Based on the distribution of *SETMAR* expression in CLL samples, we adopted the median value as the cutoff to dichotomize CLL patients in "low expression group (LEG)" and "high expression group (HEG)". The expression of *SETMAR* was thencorrelated with clinical relevant prognostic factors such ascytogenetic, immunophenotypic and hematologic features in this disease.
Results: We found that *SETMAR* was significantly overexpressed in patients with CLL compared to controls (p <0.0014). After the dichotomy, the LEG showed high leukocyte count (p <0.0050), low platelet count (p <0.0489) and predominance of cytogenetic abnormalities (p <0.030). The clinical staging of BINET and expression of ZAP-70 did not show statistical significance between the LEG and the HEG. Our results shows that SETMAR expression is altered in CLL patients when compared to healthy controls, and revealed that a lower expression of *SETMAR* in patients is clinically associated with chromosomal instability and progression of the tumor mass though increased leukocytosis.
Summary/Conclusions: These findings are immediate in CLL samples, and further studies are necessary for evaluation as a prognostic factor in this disease.

PB1782

P-GLYCOPROTEIN TRANSPORT ACTIVITY UNDER REDOX BALANCE CHANGES IN LYMPHOCYTES OF PATIENTS WITH B-CHRONIC LYMPHOCYTIC LEUKEMIA

Y Harmaza[1,*], A Tamashevski[1], N Goncharova[2], E Slobozhanina[1], A Svirnovski[2]
[1]Laboratory of Medical Biophysics, Institute of Biophysics and Cell Engineering of National Academy of Sciences of Belarus, [2]Laboratory of the cellular drug resistance mechanisms, Republican Scientific and Practical Center for Transfusiology and Medical Biotechnologies, Minsk, Belarus

Background: The experimental data about the close relationship between tumor progression and cellular redox balance are published lately. It is shown that the redox balance alterations play a key role in the cell response to the anticancer agents influence, and it is an important regulator of the protein-transporters associated with the phenomenon of multidrug resistance (MDR) expression. However, the impact of the redox imbalance in human tumor cells on the functional activity of MDR proteins has not been studied yet. Such investigations necessary for explanation of the conventional chemotherapy possible failure and their protocols modification, taking into account the features of MDR transporters functioning under the cellular redox balance changing.
Aims: To study the influence of chemotherapeutic agents on the redox status of lymphocytes of patients with B-chronic lymphocytic leukemia (CLL) and to assess the P-glycoprotein (P-gp) transport activity in these cells.
Methods: Lymphocytes were separated from the CLL patients peripheral blood by density gradient centrifugation on histopaque. Monoclonal antibody UIC2-PE (Immunotech) was used to evaluate P-gp expression and functional activity, anti-CD5-FITC (Immunotech) and anti-CD19-PC5 (Beckman Coulter) were used to determinate $CD19^+CD5^+$B-CLL cells. Reactive oxygen species (ROS) level and low-molecular antioxidants content were assessed using CM-H_2DCF-DA (Molecular Probes) and Antioxidant assay kit (Sigma), respectevly. Cells viability was assessed using Calcein-AM test and propidium iodide (Sigma). All investigations were carried out on the FACScan and FACScanto II (BD).
Results: The effect of drugs applied in the treatment of CLL (purine nucleosides - fludarabine and cladribine analogs: fludarabel (Flu), 17,5 μM and leucladine (Leu), 7,0μM (Belmeddrugs, Belarus); anthracyclines – doxorubicin (Dox), 1,72 μM (Sigma); vinca-alkaloids – vincristine (Vincr), 47,2 nM (Lens-Farm, Russia)) on the functional activity of membrane transporter P-gp associated with MDR in lymphocytes of patients with B-CLL is studied. Also the ROS level and low-molecular antioxidants content are evaluated in leukemic cells during the chemotherapeutic drugs metabolism. A degree of low-molecular antioxidants involvement in maintaining of the redox balance in lymphocytes of patients with B-CLL under exposure to drugs was determined. It is found that change of the ROS level in the leukemic B-lymphocytes comparative to values in intact cells, as well as its further recovery leads to increase of P-gp transport activity. The viability of leukemic B-cells under exposure to the antitumor drugs decreases and depends on the redox balance changes but to a lesser degree than in donor's B-cells, as had been established previously. Nevertheless, the statistically significant relationship between the functional activity of the membrane protein P-gp and viability of lymphocytes of patients with B-CLL wasn't detected.
Summary/Conclusions: The received results has allowed to characterize the functioning of the main MDR transporter under redox balance changing caused by the metabolism of the investigated anticancer drugs.

PB1783

IDENTIFICATION AND ROLE OF HUMAN REGULATORY B LYMPHOCYTES IN CHRONIC LYMPHOCYTIC LEUKEMIA

A Mohr*, A Bordron, JO Pers, C Jamin
Laboratoire d'Immunothérapies et Pathologies Lymphocytaires B EA2216, INSERM ESPRI, ERI29, BREST, Brest, France

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Europe. There is no curative treatment. CLL is characterized by expansion of CD19+CD5+B cells in blood, lymph nodes and bones marrow. In this pathology, immune responses are disrupted, at least due to dysfunctions of T cells, contributing to the immunodeficiency and the disease progression. Generally speaking, B lymphocytes play an intricate role in the immune system and are able to slowdown the anti-tumor responses favoring tumor escape. They are called regulatory B cells.
Aims: The main focus of this project is to evaluate the regulatory function of CLL B cells, aiming to estimate their influence on the lack of anti-tumor responses mediated by T cells.
Methods: *In vitro* models of co-cultures between T and B cells are used to appraise the regulatory capacity of CLL B cells on T cell proliferation evaluated by flow cytometry. Regulatory activity of CLL B cells, stimulated or not with CpG-ODN, is estimated as their ability to inhibit the T cell proliferation. Concurrently, phenotypic characteristics of regulatory B cells and T cells are evaluated.
Results: Two groups of patients have been identified following CpG-ODN stimulation. The first group presents defective regulatory B cell functions compared with control B cells. In the second group, no inhibitory activity is detected, leading even to T cell proliferation in some cases. Compared with unstimulated cells, stimulation with CpG-ODN do not induce any regulation, suggesting insensitivity of the second group. Surprisingly, the level of TLR9 expression is similar in both groups. Furthermore, no correlation is found between functional and phenotypic signature of T and B cells. However longitudinal study suggests a switch of group with a strong clinical course.
Summary/Conclusions: These results suggest functional TLR9 pathway but alteration of the regulatory-induced function of CLL B cells in the first group, while the TLR9 pathway seems to be totally defective in the second group of patients, explaining the lack of regulation. To go further, it will be of interest to identify the molecular mechanisms damaging the TLR9 pathway. These results would contribute to clarify the lack of anti-tumor immune response found in the CLL patients.

PB1784

PRAME PROTEIN IS LOCATED IN EXTRACELLULAR SIDE OF MEMBRANE AND MIGHT BE A GOOD TARGET FOR ANTIBODY THERAPY OF HEMATOLOGICAL MALIGNANCIES

N Lyzhko[1,2,*], Y Finashutina[1], V Misyurin[1,2], O Solopova[1], A Misyurin[1,2], L Kesaeva[1,2], N Kasatkina[1], E Misyurina[3], O Burova[1], M Baryshnikova[1]
[1]FSBI "N.N. Blokhin Russian Cancer Research Center", [2]«GeneTechnology» LLC, [3]City Clinical Hospital No52, Moscow, Russian Federation

Background: PRAME protein is not expressed in normal cells, but is active in large number of tumor cells. Thus PRAME protein might be a promising target for cancer immunotherapy. It is known that PRAME located in nucleus and cytoplasm of tumor cells. Tajeddine *et al.,* (2005) and Wadelin *et al.,* (2010) reported that this protein was located in nucleus and cytoplasm of tumor cells. On the other hand, Proto-Siqueira *et al.,* (2006) and Quintarelli *et al.,* (2008) found this protein on cell membrane.
Aims: To prove that PRAME protein is located on tumor cell surface and can bind with a specific monoclonal antibody.
Methods: We used 11 samples of B-CLL patients blood and cell lines K562, THP-1 and NOMO-1. 5 samples of healthy blood donors were used as negative controls. PRAME expression level was determined by RQ-PCR in blood of 8 B-CLL patients and in cell lines. PRAME epitops in surface of cell from patients and cell lines was determined by flow cytometry and immunocytochemistry experiments. Cell lines were incubated with anty-PRAME monoclonal antibodies (mAbs) 5D3F2 and 6H8F12, together and separately, at concentrations 111 and 112 ug/ml, 11 and 12 ug/ml, respectively. Cell count was carried out after incubation with mAbs. The number of dead cells was evaluated during MTT assay.
Results: PRAME expression level in K562 THP-1 and NOMO-1 cells lines was 104%, 1,6% and 0,5%, respectively. 6 patients were PRAME-negative and 2/8 had PRAME expression median lewel 4,43%. According to flow cytometric data K562, THP-1 and NOMO-1 cell lines had PRAME-positive cells 14%, 3% and 0,9%, respectively. One patient had 0% PRAME-positive cells (flow cytometric data) and none mRNA of PRAME gene expression (RQ-PCR data), one another patient had 100% PRAME-positive cells whith mRNA expression level 8,84%). Immunocytochemistry data showed, that protein PRAME was located in cell's surface of 11,5% cells in blood of 2/4 patients with B-CLL (we hadn't RQ-PCR data in this cases). K562 and THP-1 cells decreased growth rate by 15-20% and about 15-20% of died cells was observed after incubation with mAbs 5D3F2 and 6H8F12, together and separately, at concentrations 11 and 12 ug/ml, respectively. K562 and THP-1 cells decreased growth rate by 50% and about 4% of cells died after incubation with mAbs 5D3F2 and 6H8F12, together and separately, at concentrations 111 and 112 ug/ml, respectively. NOMO-1 cells decreased growth rate by 30% and around 10% of cells died after incubation with mAbs 5D3F2 and 6H8F12 together at concentrations 11 and 12 ug/ml. NOMO-1 cells decreased growth rate by 30% during incubation with mAb 6H8F12 at concentration 112 ug/ml, but this cells didn't die. NOMO-1 cell did not demonstrate slowing of cell growth or dying after incubation with mAb 5D3F2 at concentration 111 ug/ml.
Summary/Conclusions: We confirmed evidence that PRAME protein is located on surface of cancer cells. The protein is expressed only in cases when mRNA of PRAME is expressed. Cytostatic and cytotoxic effect of mAbs 5D3F2 and 6H8F12 were detected. This mAbs are effective against cell lines K562, THP-1 and NOMO-1. Interestingly, at a lower concentration mAbs have a more pronounced effect. In cases with higher expression level of PRAME gene in cells, we obserwed a greater number of cells with PRAME epitopes on cell surface and more powerful MAbs-depended cytostatic and cytotoxic effect. Our data suggest that PRAME might be a promising target for immunotherapy of PRAME-positive patients with B-CLL.

PB1785

CD49D AND CD26 ARE INDEPENDENT PROGNOSTIC MARKERS FOR DISEASE PROGRESSION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

L Ibrahim*
Clinical Pathology And Haematology, Mansoura Faculty of Medicine- Egypt, Abu Dhabi, United Arab Emirates

Background: CLL is characterized by extremely variable clinical course. Several prognostic factors can predict disease progression and therapeutic outcomes in those patients.
Aims: The aim was to evaluate the use of CD49d and CD26 as independent prognostic markers in CLL patients. The present study measured surface expression of CD49d and CD26 by three-color flow cytometry in a series of 103 untreated CLL patients.
Methods: The present study measured surface expression of CD49d and CD26 by three-color flow cytometry in a series of 103 untreated CLL patients. We evaluated the prognostic role of CD49d and CD26 to predict the risk of lymphocyte doubling, disease progression and overall survival.
Results: We evaluated the prognostic role of CD49d and CD26 to predict the risk of lymphocyte doubling, disease progression and overall survival.We confirmed that CD49d and CD26 were significant predictors of lymphocyte doubling(P b 0.001 for both markers) and disease progression (P b 0.001 for both markers) but insignificant for overall survival(P=0.303 and 0.519 respectively. Multivariate analysis between clinical parameters and flow cytometry markers revealed that CD49d and CD26 are independent prognostic markers for lymphocyte doubling (HR=1.487 P=007 and HR=2.248, P=0.014 respectively) and progression to a more advanced stage (HR=3.191, P=0.049 and HR=7.887, P=0.003) (Figure 1).
Summary/Conclusions: Also, concordant expression of both markers was found to improve their predictive power. Many studies reported that CD49d and CD26 combined analysis was found to improve their power to predict the risk of lymphocyte doubling and disease progression. CD49d and CD26 have independent prognostic value and we suggest its use as a part of routine panel for prognostic stratification of CLL.

PB1786

IMPORTANCE OF CD38 MARKER IN PROGNOSIS OF B CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL) IN THE NEW ERA

D Dukovski*, S Trajkova, I Panovska, L Cevreska
Hematology, Clinic for Hematology - Skopje, Skopje, Macedonia

Background: Several published studies suggested that transmembrane glycoprotein- CD38 on the surface of leukemic cells. CD38 is accepted as a dependable marker of unfavorable prognosis and as an indicator of activation and proliferation of CLL cells.
Aims: The aims of the present study were to establish the predictive value of the CD38 expression and to examine the corelation between CD38 positivity and other established prognostic markers in our CLL patients in the new era.
Methods: Peripheral blood samples from 180 consecutive treatment naïve CLL patients were analyzed by flow cytometry for CD38 expression on CD5/CD19 leukemic cells. Various patients established prognostic characteristics and molecular markers were studied in correlation to time to treatment (TTT). The Kaplan-Meier method was used to construct survival curves, and the log-rank statistic was used to compare these curves.
Results: CD38 was expressed in 63% of the patients. Patients with high CD38 expression (30% or more) with high value of B2M and advance disease according to Binet had significantly shorter survival times (p=0 .00001) and (p=0.00033) respectively.
Multivariate analyses showed that CD38 expression is an important prognostic factor for shorter TTT associated high B2M level (P .000002), age(P.00000), gender(P.00000), lower hemoglobin level (P.00008),hepatomegaly (P.00086)
Summary/Conclusions: CD38 expression identified a group of patients with aggressive disease that was considered by traditional staging to be early-stage disease (Rai stages 0-II or Binet A). Patients with CD38 samples have significantly aggressive disease regardless of their clinical stage. But today in era of molecular and genetics markers when CD38 is loosing it prognostic value in CLL patients prognosis, we propose serial analyses of the percentage of CD38+cells to be done, resembling indicators of leukemiccell proliferation and may signal clone evolution to a more aggressive state.

IMPACT OF IGVH MUTATIONAL STATUS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA WITH ISOLATED GOOD AND INTERMEDIATE RISK GENETIC ABERRATIONS

J Sandoval-Sus[1], LM Juárez Salcedo[2,*], C Talati[1], S Dalia[3], BD Shah[1], C Bello[1], J Lancet[1], KL Sweet[1], R Komrokji[1], EM Sotomayor[4], F Locke[1], MA Kharfan-Dabaja[1], L Sokol[1], JC Chavez[1], J Pinilla-Ibarz[1]
[1]Department of malignant hematology, Moffitt Cancer Center, Tampa, United States, [2]Haematology Department, Principe de Asturias University Hospital, Alcalá de Henares, Spain, [3]Hematology/Oncology, Mercy Clinic, Joplin, [4]Hematology/Oncology, George Washington University, Washington D.C., United States

Background: Genetic abnormalities in chronic lymphocytic leukemia (CLL) have prognostic impact. The presence of trisomy 12 (T12) and normal karyotype (NK), and 13q deletion (del13q) are associated with an intermediate and good risk profile in CLL, respectively (Dohner *et al.* NEJM, 2000). The unmutated status of the immunoglobulin variable heavy chain gene (IgVH) correlates with survival in sole del13q CLL (Gladstone *et al.,* Leukemia 2011). The prognostic relevance of IgVH mutational status in isolated intermediate risk genetic variants (T12 and NK) has not been described. We investigated the impact of the IgVH mutational status in CLL patients with isolated del13q, T12 or NK in a large single institution cohort.
Aims: To assess the prognostic impact of the IGVH mutational status in CLL patients with isolated del13q, T12 and NK.
Methods: From January 2000 to January 2013 we identified 1267 CLL patients using the Moffitt Cancer Center and Total Cancer Care databases. Descriptive data was reported in patients with both unmutated (<2% from the germline sequence) and mutated IgVH (>2% from the germline sequence). Time to first treatment (TFT) and overall survival (OS) were estimated using the Kaplan-Meier method and the log-rank test. A significant difference was considered at p≤0.05. All analyses were done using SPSS version 19.0.
Results: We identified 145 CLL patients (median age: 59 years) with isolated del13q (mutated IgHV=96, 66.2%; unmutated IgVH=49, 33.8%), 49 patients (median age: 64 years) with isolated T12 (mutated IgVH=17, 34.7%; unmutated IgVH=32, 65.3%), and 79 patients (median age: 57 years) with NK (mutated IgVH=41, 51.9%; unmutated IgVH=38, 48.1%), respectively. Unmutated IgVH was associated with shorter TFT in patients with sole del13q (unmutated 2.1 years *vs* mutated 6.0 years, p <0.001) and isolated NK (unmutated 1.9 years *vs* mutated 3.3 year, p=0.05). IgVH mutational status had no impact in the TFT of patients with sole T12. Patients with isolated del13q and mutated IgVH had a longer median OS compared to unmutated patients (not reached *vs* 10.5 years, p=0.03). Nonetheless, the IgVH mutational status did not significantly impact the OS of sole T12 patients (p=0.29) and NK (p=0.14) (Figure 1).

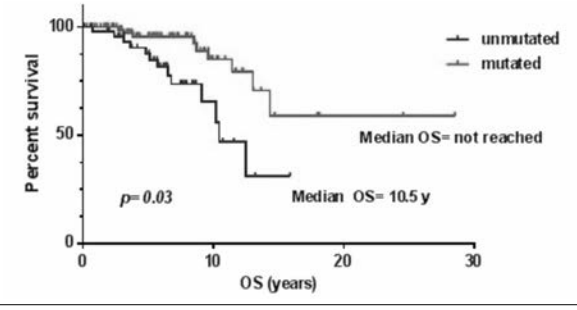

Figure 1. Overal survival per IGVH mutational status.

Summary/Conclusions: Our results confirm the negative impact of the unmutated IgVH status in CLL patients with isolated del13q. The mutational IgVH status did not impact the OS of T12 and NK CLL patients.

PB1788

REDISTRIBUTION PATTERN AND ASSESSMENT OF EARLY RESPONSE TO IBRUTINIB IN CLL BY TOTAL TUMOR MASS SCORE (TTM) - KROHEM CLL2 STUDY

O Jaksic[1,*], S Basic Kinda[2], I Aurer[2], D Carzavec[3], I Mandac Rogulj[4], V Haris[1], J Sincic Petricevic[5], G Rincic[3], V Pejsa[1], S Ostojic Kolonic[4], B Jaksic[4], D Nemet[2]
[1]University Hospital Dubrava, [2]University Hospital Centre Zagreb, [3]University Hospital Centre Sisters of Mercy, [4]University Hospital Merkur, Zagreb, [5]University Hospital Centre Osijek, Osijek, Croatia

Background: Ibrutinib is Bruton's tyrosine kinase inhibitor with significant efficacy in CLL. Ibrutinib monotherapy usually leads to redistribution of tumor mass from lymphoid organs to peripheral blood before eventual response in all compartments. This leads to certain problems in response assessment by iwCLL criteria requiring several modifications. Total Tumor Mass score (TTM) (Jaksic, BJH 1980) is a simple quantitative clinical parameter for evaluation of tumor mass in all relevant lymphoid compartments in CLL (PB+BM, LN and spleen) that was successfully used in CLL trials by several international cooperative groups (EORTC, IGCI) in alkylator and purine analog era. It is helpful in routine clinical practice for monitoring of total tumor load, progression and/or response to treatment. Due to its characteristics TTM may overcome problems caused by significant redistribution during TKI treatment (Jaksic, BJH 2014).
Aims: To evaluate usefulness of TTM in evaluation of response and redistribution during ibrutinib treatment in CLL patients in a real life setting.
Methods: This is an observational study from Croatian cooperative group for hematological malignancies (KROHEM) were data from patients included in ibrutinib NPP (420 mg daily) were collected on national level. Thirty patients with relapsed/refractory B-CLL were included, 24 males and 6 females, median age 65.5 years (50-83) and median 2 prior lines of therapy (1-6). There were 4 pts with del 17p and 6 with del 11q (out of 24 with data). Baseline routine evaluation was done before ibrutinib treatment. Clinical and laboratory assessments of tumor mass were collected at start and on months 1, 3, 6, 9 and 12. Bone marrow assessment, US and MSCT scans were performed when clinically indicated. Response was assessed by modified iwCLL criteria (Hallek, Blood 2008, 2012, 2013) and by TTM criteria (Jaksic, BJH 2014). TTM scoring system: TM_1=√Lymphocytes ($\times 10^9$/l), TM_2=largest palpable lymph node (cm), TM_3=spleen below left costal margin (cm). TTM=TM_1+TM_2+TM_3, TTM-D=TM_1/TTM (percentage of tumor mass in leukemic compartment). ΔTTM – response/progression, ΔTTM-D - redistribution
Results: At 6th month 81% of patients responded with tumor mass (TTM) reduction >25%; 67% of patients responded with tumor mass reduction >50% and 43% of patients responded with tumor mass reduction >75%. Modified iwCLL response correlated well with TTM response criteria on months 3, 6 and 9 (Spearman correlation 0.538, p<0.001; 0.762, p<0.001; 0.739, p<0,009 respectively), but not in month 1 (Spearman correlation 0.175, p=0.356). At month 6, there were 13/21 patients in PR and PR+PR-Ly 19/21 (iwCLL) compared to 14/21 (TTM reduced >50%) and 17/21 (TTM reduced >25%) respectively. Lymphocytosis changed from baseline=1.0 to months 1, 3, 6 and 9 (median 2.60; 1.95; 0.67 and 0.51 respectively) taking into account all cases. However, while this describes a typical increase, actually no increase of lymphocytosis at month 1 was observed in 30% of patients. Neither multiple stepwise regression found any statistically significant correlation with baseline predictors, nor were patients with increase of lymphocytosis at month 1 significantly different from typical responders in distribution of baseline predictors according to Mann Whitney U test. Tumor distribution (TTM-D, median) rose from 0.47 (baseline) to 0.84 in month 1, and to 1.0 from months 3 on. Multiple stepwise regression with response at month 6 as dependent variable and 10 predictor variables at baseline: age, disease duration, previous lines of therapy, lymphocytosis, lymph node size, spleen size, TTM, TTM-D, hemoglobin and platelets identified in the model only TTM at baseline as significant negative predictor of response (p=0.001) (Figure 1).

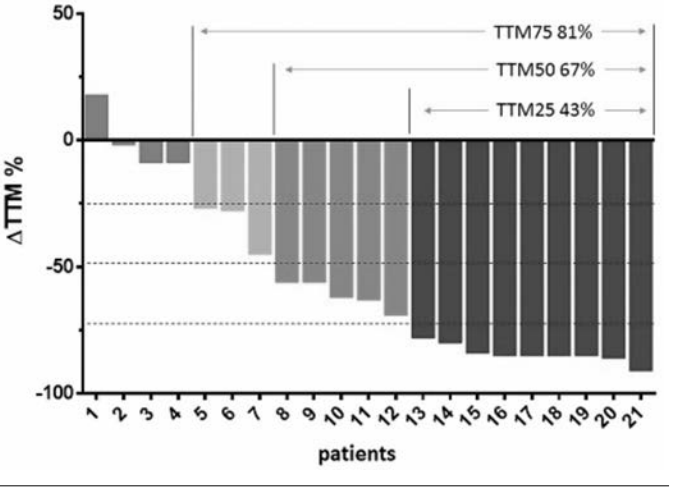

Figure 1. TTM response at 6 months.

Summary/Conclusions: TTM is a simple and useful parameter successfully applied in ibrutinib treated patients in routine clinical practice for response assessment and follow-up. It is highly correlated with modified iwCLL criteria after 3rd month. It is more robust then iwCLL criteria because it incorporates and quantify tumor redistribution and therefore can be applied regardless of therapy used without specific modifications.

PB1789

A NEW PROGNOSTIC SCORING SYSTEM FOR TTFT FOR PATIENTS WITH CLL IN CHINA

H Li*, W Xiong, Z Li, L Qiu
State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China

Background: The established clinical staging systems (Rai/Binet) can not accurately discriminate among prognostic groups, especially for patients in early stages. Several prognostic factors have been identified to predict the outcome of patients with chronic lymphocytic leukemia (CLL), but only a few studies analyzed more markers together.
Aims: In this study, we identified the biologic prognostic markers and combined them in a new prognostic scoring system, the CLL prognostic index (CLL-PI) for predicting time to first treatment (TTFT) in patients with CLL in China.
Methods: Taking advantage of a population of 402 untreated Chinese patients with CLL at early and advanced stage of disease, we identified the strongest prognostic markers of TTFT and, subsequently, in a cohort of 173 patients we integrated data of traditional staging system, cytogenetic lesions and immunoglobulin heavy chain variable region (*IGHV*) mutational status in CLL-PI. The median follow-up time was 45 months (ms). Methods of multivariable statistics were applied, and the end point was TTFT.
Results: Based on multivariate Cox regression analysis, three independent factors for TTFT were identified: clinical stage (Rai risk group), del17p and *IGHV* mutation status. Applying weighted grading of these three independent factors based on regression parameters, a CLL-PI was constructed, which could categorize four different risk groups [low (score 1), intermediate (score 2), high (score 3) and extremely high risk (score 4-6)] with significantly different TTFT (median TTFT of NR, 65.0 ms, 24.0 ms and 12.5 ms, respectively, p<0.001). Further, this index provided accurate estimation regarding overall survival (OS) (median OS of NR, 210.0 ms, 97.0 ms and 43.0 ms, respectively, p<0.001] (Tables 1 and 2, Figure 1).

Table 1. Scores assignment to three independent factors of PI

Rai risk group	Scores	*IGHV* status	Scores	17p-	Scores
Low (Rai 0)	1	M-*IGHV*	0	Negative	0
Intermediate (Rai I-II)	2	U-*IGHV*	1	Positive	2
High (Rai III-IV)	3				

Abbreviation: IGHV*, mutated immunoglobulin heavy chain variable region; M, mutated; U, unmutated.*

Table 2. Survival data in each subgroup according to the scoring system

Groups (PI scores)	N	Median TTFT (months)	95% CI (months)	p-value
Low risk (=1)	21	NR	NE-NE	0.000
Intermediate risk (=2)	56	65.0	40.9-89.1	
High risk (=3)	67	24.0	6.2-41.8	
Extremely high risk (4-6)	27	12.5	7.6-17.4	

Abbreviation: CI, confidence interval; TTFT, time to first therapy; NR, not reached; NE, not evaluated.

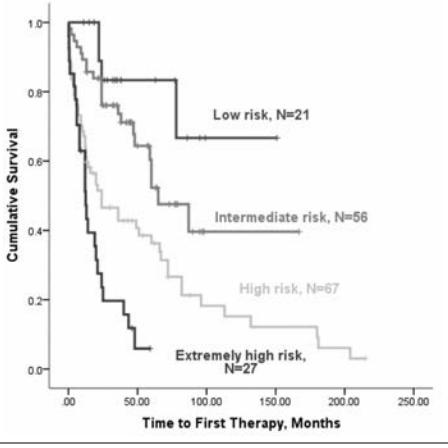

Figure 1.

Summary/Conclusions: This study developed a weighted, integrated CLL-PI which combines the most important genetic prognostic markers (*IGHV* mutation status, 17p deletion) with traditional clinical stage. This newly modified PI could be used to discriminate among groups and may help predict the TTFT and prognosis of patients with CLL.

PB1790

AN ASSESSMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WHO ARE ELIGIBLE FOR FIRST-LINE THERAPY BUT UNSUITABLE FOR FULL-DOSE FLUDARABINE

D Jeyakumaran[1,*], S Cote[1], A Kempel-Waibel[2]
[1]HEOR, Janssen EU HEMAR, High Wycombe, United Kingdom, [2]HEOR, Pharmametrics GmbH, Freiburg, Germany

Background: Chronic Lymphocytic Leukemia (CLL) is a rare disease which has been granted orphan designation by the EMA. Treatment of CLL is only initiated in patients with symptomatic, active disease and treatment options are dependent on patient characteristics. The European Society for Medical Oncology (ESMO) identifies three subgroups of symptomatic CLL patients who are eligible for front-line treatment; physically fit patients, elderly patients or those with major comorbidities, and patients with del17p/TP53 mutation. Older patients and those with severe comorbidities are less able to tolerate the full-dose fludarabine treatments prescribed to physically fit patients. Fludarabine-based therapies are also considered unsuitable for patients with the del17p/TP53 mutation. These patient subgroups may thus benefit from the introduction of newer, less aggressive therapies.
Aims: The aim of this analysis is to estimate the number of CLL patients who require treatment initiation but who are unsuitable for treatment with full-dose fludarabine, namely those who are elderly (≥70 years), or those who are younger but have comorbidities (aged between 65 and 69 with comorbidities). It also identifies the number of patients with the del17p/TP53 mutation. To our knowledge this is the first study to stratify the total symptomatic, treatment naïve CLL patient population by these patient characteristics which influence treatment decisions.
Methods: A targeted literature review was conducted in Medline and Embase, as well as in cancer-related statistical sources in nine European countries (Belgium, France, Germany, Italy, Spain, UK, Netherlands, Poland and Sweden), applying all relevant keywords related to the disease and to the parameters to be assessed (incidence, prevalence, mortality, survival, asymptomatic, symptomatic, age, fitness, comorbidities). Based on relevant articles extracted and reviewed, the annual number of patients unsuitable for full-dose fludarabine is estimated.
Results: Patients eligible for first-line therapy comprise all newly diagnosed symptomatic CLL patients as well as patients who have transitioned from an asymptomatic disease state to an active disease state. The crude incidence rate of CLL was found to range from 3.88 per 100,000 in Germany to 6.9 per 100,000 in the UK. Of these newly diagnosed patients, between 51.9% and 75.6% are asymptomatic. Approximately 5.0% to 7.8% of previously diagnosed patients transition from an asymptomatic state to a symptomatic state every year. Assuming a mean CLL incidence rate of 4.94 per 100,000 and a mean yearly transition rate of 6.4%, the total estimated number of patients eligible for front-line treatment in 2015, across the nine European countries considered, was 12,370. Of these symptomatic patients, 986 (8.0%) had the del17p/TP53 mutation. Among symptomatic patients without the del17p/TP53 mutation, 56.5% were aged ≥70, and 6.7% were aged between 65 and 69 with major comorbidities. Thus in 2015, across the nine European countries considered, there were an estimated 7,191 symptomatic CLL patients aged ≥70 or aged between 65 and 69 with major comorbidities, who were eligible for first-line treatment but not suitable for full-dose fludarabine.
Summary/Conclusions: This study provides an in-depth overview of the treatment-naïve CLL patient population across nine European countries and provides an estimate of the number of patients unsuitable for full-dose fludarabine and fludarabine-based therapies, and who could potentially benefit from newer, more tolerable therapies.

PB1791

INSULIN-LIKE GROWTH FACTOR SYSTEM AS A PROGNOSTIC BIOMARKER IN CHRONIC LYMPHOCYTIC LEUKEMIA: A CROSS-S ECTIONAL STUDY

M Dalamaga[1], GS Christodoulatos[2], M Triantafilli[3], K Karmaniolas[4], G Sotiropoulos[5], A Lekka[3,*]
[1]Biological Chemistry, University of Athens, School of Medicine, [2]Laboratory of Hematology, KAT Hospital, [3]Laboratory of Hematology, [4]Internal Medicine, [5]NIMTS General Hospital, Athens, Greece

Background: B-cell chronic lymphocytic leukemia (B-CLL) is characterized by the accumulation of long-survived B lymphocytes arrested in $G_{0/1}$ phase by impaired apoptosis. Growth factors may contribute to paracrine or autocrine loops affecting CLL cell survival via the induction of apoptosis-related genes. Insulin-like growth factor I (IGF-I), which is mainly produced by hepatocytes, constitutes an important anti-apoptotic factor for several malignant cells. Furthermore, IGF-I and its main binding protein IGFBP3 are related to the development and pathogenesis of insulin resistance, diabetes as well as in obesity-associated malignancies.
Aims: The goal of the present study was to evaluate circulating levels of IGF-I and IGFBP3 in patients suffering from B-CLL and control participants. We also

explored the ratio of IGF-I/IGFBP3, which gives a mechanistic insight into IGF-I bioavailability, as well as IGF-I and IGFBP3 as prognostic parameters of B-CLL.
Methods: Blood samples were collected from ninety five cases with incident B-CLL and an equal number of hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Informed consent was obtained from all study participants. Serum IGF-I and IGFBP3 were determined using commercially available ELISA assays (DIAsource ImmunoAssays S.A, Louvain-la-Neuve, Belgium). Moreover, serum lactate dehydrogenase (LDH), β2-microglobulin (BMG), lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocytes were assessed. Statistical analysis of the data was performed using univariate and multivariate analyses with IBM-SPSS® version 23 for Windows.
Results: Overall, B-CLL patients had a significantly elevated body mass index (BMI) as compared to control participants (27.8 *vs* 26.7 kg/m^2; p<0.01). In univariate analysis, circulating levels of IGF-I were similar in cases compared to controls (126.75±21.41 *versus* 125.10±25.50 ng/mL, respectively, p=0.63). However, serum IGFBP3 was significantly lower in cases than controls (3.16±0.96 *versus* 4.22±1.03 µg/mL, respectively, p<0.001) while the IGF-I/IGFBP3 ratio was significantly elevated in cases compared to controls (0.049±0.07 *versus* 0.030±0.05, respectively, p=0.01). Lower serum IGFBP3 levels were associated with B-CLL risk in multivariable analyses adjusting for age, gender, date of diagnosis, family history of lymphohemopoietic cancer, BMI, serum IGF-I and insulin (<0.001). In B-CLL patients, serum IGF-I was significantly and positively associated with Binet stage, IGFBP3, LDH and BMG (p<0.001), and negatively associated with age (p<0.001).
Summary/Conclusions: The observed results highlight the potential involvement of IGF-I bioavailability in the B-CLL pathogenetic process. Circulating IGF-I might be a potential biomarker for B-CLL prognosis. Further prospective and longitudinal studies are needed in order to confirm these observations as well as to elucidate the contribution of the IGF-I system in B-CLL progression.

PB1792

SECONDARY MALIGNANCIES IN CHRONIC LYMPHOCYTIC LEUKEMIA: A SINGLE CENTRE RETROSPECTIVE ANALYSIS

G Reda[1,*], B Fattizzo[1], R Cassin[1], N Orofino[1], E Flospergher[1], D Consonni[2], W Barcellini[3], A Cortelezzi[1]
[1]Oncohematology Division, [2]Epidemiology Division, IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milan, [3]Oncohematology Division, IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milano, Italy

Background: Chronic lymphocytic leukemia (CLL) is characterized by progressive immunodeficiency with high prevalence of infections, autoimmune phenomena and secondary malignancies. The immune deregulation may be due to the disease itself or it may be a consequence of the treatment performed.
Aims: To evaluate the occurrence of second cancers in CLL patients and their relationship with clinical and laboratory features as well as with therapy lines.
Methods: Clinical history of 514 CLL patients diagnosed and followed from 1983 until 2014 at our Institution were retrospectively evaluated and the diagnosis of a second cancer was collected. History of neoplasia preceding CLL diagnosis was also registered. Student t test for continuous variables, chi-square test for categorical ones and Log rank test for survival analysis were performed.
Results: Clinical, hematological and biological characteristics are listed in Table 1. Secondary cancers were categorized according originating organ/tissue; skin cancers were divided into melanoma and non-melanoma. During the follow up 88 patients (17%) developed secondary cancers, with a mean time from diagnosis to secondary neoplasia of 9 years. Considering tumor histology, we observed 9 blood, 9 lung, 5 breast, 19 uro-genital tract (5 kidney, 10 prostate, 4 bladder, 2 uterus, and 2 ovarian), 15 gastro-enteric tract (12 colon, 2 gastric and 1 tongue), 4 pancreas, 3 melanoma and 15 skin cancers other than melanoma. No significant differences were observed according to age, gender, Rai/Binet stage and hematologic parameters in patients with or without secondary tumors (Table 1). Considering CLL prognostic features, the development of second cancers was associated with higher age (p<0.001) at diagnosis, increased beta2microglobuline levels (p=0.03) and un-mutated VHIG status (p<0.005; Figure 1). At variance, no association was found with 13q, 11q or 17p deletion, chromosome 12 trisomy, nor with ZAP-70 and CD-38 positivity (Table1). Past history was positive for malignancies in 70 patients (13%): 2 blood, 3 airways (2 lower and 1 upper), 3 breast, 6 uro-genital tract (3 bladder, 3 prostate, 2 uterus and 1 ovarian), 3 gastro-enteric tract, 3 skin cancers other than melanoma, and 3 melanoma. On the whole, 46/88 (52.3%) and 219/426 (51.4%) patients with or without secondary cancers, underwent at least one therapy line. More specifically, 86 patients were treated with fludarabine containing regimens, of whom 11 developed a secondary cancer; 180 with chlorambucil, of whom 34 developed a secondary tumor and 65 with alemtuzumab, of whom 10 were later diagnosed with a second cancer. During the follow up, 121 patients died, of whom 8 directly from secondary malignancies, 41 from CLL progression, 2 from thrombotic events, and 11 from infections.

Table 1.

Clinical and laboratory features of 514 CLL patients with or without secondary malignancies. Data are expressed as median (range) or absolute number (%).

	Secondary malignancies	
	Yes (N=88)	No (N=426)
Age years	64 (39-80)	63 (31-90)
Gender M/F	57/31	250/176
Follow-up years	12 (0-30)	12 (1-25)
Rai/Binet		
<C/III	85 (97)	401 (94)
≥ C/III	3 (3)	25 (6)
WBC x10e3/mmc	18.74 (3.6-138)	17.3 (3-384)
ALC x10e3/mmc	12.63 (1.8-91.8)	11.9 (1.4-381)
Hb g/dL	14 (9-17)	14 (8-18)
PLT x10e3/mmc	198 (77-608)	184 (58-472)
LDH U/L	325 (144-838)	334 (142-795)
Beta2microglobulin mg/L	2 (1-23)	2 (0-10)
FISH*		
Del11q	6 (13)	23 (9)
Del13q	19 (40)	101 (40)
Del17p	4 (8)	15 (6)
+12	6 (13)	38 (15)
VHIG unmutated**	15 (42)	80 (39)
ZAP-70 positive***	14 (39)	73 (36)
CD-38 positive****	15 (42)	76 (37)

*Tested in 48 and 252 patients respectively. **Tested in 36 and 205 patients respectively. ***Tested in 33 and 182 patients respectively. ****Tested in 56 and 291 patients respectively.

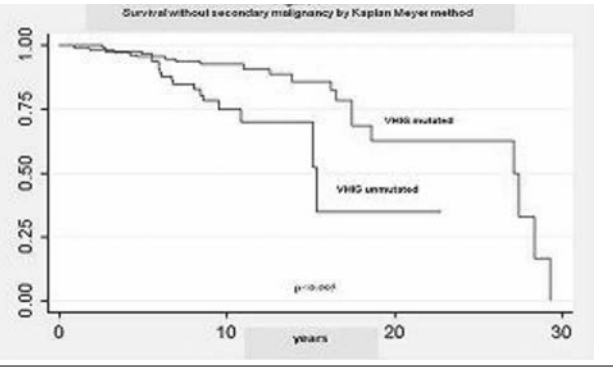

Figure 1.

Summary/Conclusions: Secondary malignancies are not infrequent in patients with CLL and patients with un-mutated VHIG status are at higher risk of developing a second cancer. As secondary neoplasia are not clearly related to biologic markers or to the treatment performed, a careful clinical follow up, encompassing sex and age adjusted tumors screening is advised.

PB1793

COMPLEX ACTIVATION OF ANGIOGENIC SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA: EVIDENCE FROM CIRCULATING ANGIOGENIC CYTOKINES

L Smolej[1,*], C Andrys[2], P Vodarek[1], M Motyckova[1], M Simkovic[1], D Belada[1], P Zak[1]
[1]4th Department of Internal Medicine - Hematology, [2]Institute of Clinical Immunology and Allergology, University Hospital and Charles University Faculty of Medicine, Hradec Kralove, Czech Republic

Background: Angiogenesis is an important and well-known player in the biology of chronic lymphocytic leukemia. Elevated plasma/serum concentrations of various angiogenic cytokines have been reported in CLL; however, their exact prognostic role, association with modern prognostic factors and impact on clinical course (especially overall survival) is largely unknown.
Aims: To evaluate prognostic significance of vascular endothelial growth factor (VEGF), fibroblast growth factor-2 (FGF-2), soluble endoglin (sCD105), angiopoietin-2 (Ang-2), transforming growth factor-1 (TGF-β1) and inhibitors endostatin and thrombospondin-1 (TSP-1) in patients with untreated CLL followed at a single tertiary center.
Methods: Plasma levels of VEGF, FGF-2, sCD105, Ang-2, TGF-β1, endostatin and TSP-1 were quantified using enzyme-linked immunosorbent assay (ELISA Quantikine kits, RD Systems) in 206 patients with CLL (median age, 64 year; males, 69%; Rai modified risk: low/intermediate/high in 38/46/16%; unmutated IGVH genes, 58%; del 11q/del 17p by FISH, 19 and 4%) and 80 healthy controls. Plasma concentrations ≥median of the CLL cohort were considered elevated.
Results: VEGF, FGF-2, sCD105 and Ang-2 were significatly elevated in comparison to the control group; differences in TGF-β1, endostatin and TSP-1 were on the border of statistical significance (Table 1). There was a positive association of high Ang-2 with unmutated IGHV genes (p=0.027); patients with high sCD105 and lowTGF-β1 had more advanced Rai stages (p=0.0004 and p=0.052). High levels of Ang-2, endostatin, sCD105 and low TGF-β1 correlated

with shorter time to first-line therapy (p=0.0001, p=0.0001, p=0.0021 and p=0.027); in addition, patients with high Ang-2 and endostatin had significantly shorter overall survival (p=0.0006 and p=0.015).

Table 1.

Group	n	Median	95% CI	Units	p
VEGF CLL	206	70	60-90	ng/l	0.0092
VEGF controls	80	46	26-56		
FGF-2 CLL	206	115	78-144	ng/l	< 0.001
FGF-2 controls	80	9	5-10		
sCD105 CLL	200	6,2	5.6-6.5	µg/l	< 0.0001
sCD105 controls	69	4,2	4.1-4.5		
Ang-2 CLL	158	2030	1903-2457	ng/l	0.0016
Ang-2 controls	30	1631	1453-1856		
TGF-β1 CLL	97	3700	3098-4471	ng/l	0.066
TGF-β1 controls	13	4960	4550-6140		
TSP-1 CLL	97	704	391-1097	µg/l	0.088
TSP-1 controls	13	324	288-372		
Endostatin CLL	165	165	152-182	µg/l	0.073
Endostatin controls	34	150	135-170		

Summary/Conclusions: Our results indicate that a complex network of angiogenic signaling is active in CLL and has an impact on clinical course; Ang-2 and endostatin appear to possess the best prognostic value and deserve further evaluation.

Supported by DRO (Univ Hospital Hradec Králové, 00179906).

FINAL RESULTS OF THE NCRI CLL210 TRIAL OF ALEMTUZUMAB, DEXAMETHASONE AND LENALIDOMIDE IN PATIENTS WITH HIGH-RISK CLL (ORIGINAL PROTOCOL)

AR Pettitt[1,*], F Polydoros[2], J Dodd[2], M Oates[1], K Lin[3], N Kalakonda[1], H McCarthy[4], A Bloor[5], A Schuh[6], A Duncombe[7], C Dearden[8], C Fegan[9], B Kennedy[10], C Yap[11], SE Coupland[1], P Hillmen[12]

[1]Department of Molecular and Clinical Cancer Medicine, [2]CR-UK Liverpool Cancer Trials Unit, The University of Liverpool, [3]Department of Blood Sciences, Royal Liverpool University Hospital, Liverpool, [4]The Royal Bournemouth Hospital, Bournemouth, [5]Department of Haematology, The Christie NHS Foundation Trust, Manchester, [6]Department of Oncology, Churchill Hospital, Oxford, [7]Southampton General Hospital, Southampton, [8]Haemato-Oncology Trials Unit, Royal Marsden NHS Foundation Trust, Sutton, [9]University Hospital of Wales, Cardiff, [10]Leicester Royal Infirmary, Leicester, [11]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, [12]Faculty of Medicine and Health, University of Leeds, Leeds, United Kingdom

Background: 17p- chronic lymphocytic leukaemia (CLL) is notorious for its resistance to chemotherapy. The Phase II NCRI CLL206 trial showed that alemtuzumab plus high-dose methylprednisolone was safe and effective in this setting, although the median progression-free survival (PFS) was only 11.8 months (J Clin Oncol 2012;30:1647-55).

Aims: In an attempt to improve on these results, the NCRI CLL210 trial was developed to examine the safety and efficacy of alemtuzumab, dexamethasone and lenalidomide which has activity in 17p- CLL.

Methods: Patients with previously untreated 17p- CLL or CLL progressing within 12 months of FCR received dexamethasone (40 mg po day 1-4 of weeks 1,3,5,7,9,11,13,15), lenalidomide (5 mg od weeks 3-4 and 10 mg od weeks 5-24) and alemtuzumab (30 mg sc days 1,3,5 of weeks 7-22). Patients who achieved a complete response (CR) or partial response (PR) were allowed to proceed to allogeneic stem-cell transplantation if considered appropriate, or were randomised to lenalidomide maintenance (10 mg od until disease progression) *versus* no further treatment. Supportive medication consisted of allopurinol, G-CSF, co-trimoxazole, aciclovir, itraconazole, lansoprazole, alendronic acid, aspirin, plus immunoglobulin replacement therapy where appropriate. Written informed consent was obtained from all patients prior to entering the study. The primary endpoints were post-induction CR/CRi rate and progression-free rate after 2 years of maintenance therapy. Response data were assessed by an independent endpoint review committee using the 2008 NCI/IWCLL criteria.

Results: Sixteen patients out of the planned 85 were recruited from 7 UK sites during the first 7 months of recruitment before accrual was halted in September 2012 due to withdrawal of marketing authorisation for alemtuzumab. The protocol was subsequently amended to replace alemtuzumab with ofatumumab. This report describes the outcome of the initial cohort of alemtuzumab-treated patients (8 untreated and 8 FCR failures; 17p- in 13). Ten patients (62%) completed induction, whereas 6 (38%) stopped induction prematurely due to toxicity (3), disease progression (1), change in diagnosis (1) or death (1). Three patients (19%) proceeded to allogeneic stem-cell transplantation, 5 (31%) were randomised to lenalidomide maintenance (3) or no further treatment (2) and 2 (12%) withdrew from the randomised part of the trial despite completing induction successfully. The post-induction OR and CR/CRi rate among evaluable patients (11) was 91% and 18% respectively. The progression-free rate after 2 years of maintenance phase among evaluable patients (4) was 50% in both treatment arms. With a maximum follow-up period of 46 months, the median PFS for all 15 eligible patients was 29.3 months. The median OS was not reached since there were only 4 deaths. Grade ≥3 toxicity occurred in 93% of patients and the treatment-related mortality was 6%.

Summary/Conclusions: Although the small sample size prevents definitive conclusions from being drawn, the results of this prematurely terminated study suggest that alemtuzumab, dexamethasone and lenalidomide is feasible to deliver in most patients with high-risk CLL and has an acceptable safety profile. The regimen also appears to be effective, with a high overall response rate and a median PFS somewhat longer than the 11.8 months that was observed with alemtuzumab plus methylprednisolone. We conclude that the efficacy of glucocorticoid/alemtuzumab in this setting may be enhanced by the addition of lenalidomide without incurring significant additional toxicity.

PB1795

SERUM RESISTIN IN RELATION TO B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA RISK AND ITS CORRELATIONS WITH PROGNOSTIC BIOMARKERS

M Dalamaga[1], GS Christodoulatos[2], M Triantafilli[3], K Karmaniolas[4], G Sotiropoulos[3], A Lekka[3,*]

[1]Biological Chemistry, University of Athens, School of Medicine, [2]Laboratory of Hematology, KAT Hospital, [3]Laboratory of Hematology, [4]Internal Medicine, NIMTS Hospital, Athens, Greece

Background: Excess weight and insulin resistance are now considered risk factors for many types of malignancies, including leukemia and lymphoma. Potential mechanisms that may link obesity and insulin resistance to B-cell chronic lymphocytic leukemia (B-CLL) include also the abnormal secretion of adipocytokines. Resistin, an adipocytokine belonging to the family of resistin-like molecules, was originally discovered as a molecule enhancing insulin resistance or impaired hepatic sensitivity to insulin and provoking hyperglycemia without affecting peripheral insulin sensitivity. However, data in humans are controversial.

Aims: In this cross-sectional study, we attempted to investigate the contribution of resistinemia to B-CLL risk taking into account potential important confounders including the family history of lymphohematopoietic cancer (LHC), body mass index (BMI), serum insulin and other adipocytokines. We also attempted to ascertain whether a relationship between serum resistin and prognostic markers exists amongst patients with B-CLL diagnosis.

Methods: Blood samples were collected from 95 cases with incident B-CLL and 95 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Informed consent was obtained from all study participants. Serum resistin was determined using a commercially available ELISA assay (Phoenix, CA, USA). Furthermore, serum lactate dehydrogenase (LDH), β_2-microglobulin (BMG), lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocytes were assessed. The statistical analysis of the data was performed using IBM-SPSS® version 23 for Windows.

Results: Patients with B-CLL had on average a higher BMI as compared to control participants (27.8 *vs* 26.7 kg/m^2; p<0.01). Significantly, more patients than controls presented a positive family history of LHC (13 *vs* 3 controls; p<0.01). In univariate analysis, circulating levels of resistin were statistically significantly elevated in cases as compared with controls (10.43±5.42 *versus* 8.12±4.88 ng/mL respectively, p=0.002). However, although serum higher resistin was associated with B-CLL risk in unadjusted analyses, in multivariable analyses controlling for age, gender, date of diagnosis, family history of LHC, BMI, serum insulin, leptin and adiponectin levels, serum resistin presented a borderline statistical significance with B-CLL occurrence (OR: 1.08, 95% CI: 0.99-1.16, p=0.06). Amid patients, serum resistin was not associated with Binet stage (p=0.85) and absolute lymphocyte count (p=0.55). Nevertheless, circulating resistin presented a borderline negative correlation with BMG (p=0.07) and CD38 (p=0.07).

Summary/Conclusions: Circulating resistin was found to be elevated among cases as compared to controls in univariate analysis. It has been recently shown that hyperesistinemia is linked to the risk for many malignancies. These results need to be confirmed in larger study populations using a prospective study design; but if reproduced in adjusted analyses they may suggest that resistin may be upregulated and/or upregulate the synthesis of other inflammatory factors etiologically linked to B-CLL etiopathogenetic process.

PB1796

CALRETICULIN GENE MUTATION IN HAIRY CELL LEUKEMIA AND RELATIONSHIP WITH PROGNOSIS

S Subari[1,2,*], A Kizikli[1], S Kul[3], S Oztuzcu[4], G Nacarkahya[4], I Sari[5], M Turker[1], M Pehlivan[2], V Okan[2], M Yilmaz[2]

[1]Internal Medicine, [2]Hematology, [3]Biostatistics, [4]Medical Biology, [5]Pathology, Gaziantep University, Gaziantep, Turkey

Background: Hairy cell leukemia (HCL) is a malignant hematologic neoplasm characterized by peripheral blood and bone marrow hairy cells. Etiology of disease is not clear. Calreticulin (CRT) is a protein located on endoplasmic reticulum which plays role on protein folding, calcium homeostasis, regulation and loading antigenic peptides into major histocompatibility class-I in the cells. As of today, CRT gene mutations were determined in JAK2 and MPL negative myeloproliferative neoplasms. However, the effect of this gene mutation on hairy cell leukemia which is a lymphoproliferative disease is unknown.
Aims: To study the presence of CRT mutations in hairy cell leukemia and effects.
Methods: A retrospective single institution study chart review of cases with HCL at Gaziantep University between 2005- 2015 was performed. Patients with precise hairy cell leukemia were included. Bone marrow tissue biopsy samples were used. Following the isolation of genetic material and gene sequence analysis by PCR, mutations were investigated for CRT. Complete blood count, peripheral blood smear, bone marrow aspiration and biopsy, flow cytometry were used to diagnose HCL patients. Laboratory counts were determined as anemia <12g/dL, thrombocytopenia <100x10^9/L, neutropenia <1 x10^9/L and monocytopenia <0.2 x10^9/L. We used French Society of Hematology remission criteria for treated hairy cell leukemia. Appropriate ethics approval approval was obtained in accordance with the Helsinki declaration. Comparison between group medians was done using Mann Whitney U, while survival estimates were calculated using Kaplan-Meier curves SPSS V22.
Results: Out of 33 HCL samples, 21 (63.6%) CRT exon-9 sequencing analyses could be performed and CRT gene mutation was not detected in any. In the clinical analysis of these patients median age was 54 years, with 26 (78.8%) patients were males. Labs at diagnose included median white blood cell was 2.7 x10^9, Hemoglobin 9.5 g/dL, platelet 58 x10^9, monocytes 0.28x10^9, lymphocyte 1.3 x10^9, neutrophil 1 x10^9. Laboratory count were found anemia in 22 (%73.3), trombocytopenia in 21 (70%), neutropenia in 14 (48.3%) and monocytopenia in 12 (41.4%) of patients. Out of 33 patients, 27 (90%) had splenomegaly documented at the time of diagnosis. When evaluated pretreatment splenic size by ultrasound, median spleen size was 20.3 centimeter (median%25-75, 16.5-24). Cladribine was used in the treatment of 23 (69.7%) patients. Among these patients' complete response was 13 (56,5%), partial response was 3 (13%) and overall response was 69.5%. Splenomegaly was significantly high in patients without monocytopenia (p=0.05). There were survival differences between treated (n=23) and untreated (n=10) patient groups (85.6±3 and 17.7±7.8 median months, respectively p=0.001). The patients who treated had significantly longer overall survival compared to those untreated. Furthermore, pretreatment median hemoglobin level was higher in remission group compared to no remission group as 10.1 g/dL *vs* 8.5 g/dL respectively and there was a statistically significant difference between them (p=0.047).
Summary/Conclusions: This is the first study carried out regarding CRT gene mutation in HCL in the literature. We consider that CRT gene mutations are not effective on disease pathogenesis. As a result, spleen size was larger in patients with who had no monocytopenia and initial hemoglobin levels were higher in remission group. This result may be an important finding in terms of timing of treatment in patients with HCL. In this respect, it may be appropriate approach to start to the treatment before anemia develops. Additional larger studies are needed to confirm our results.

PB1797

FACTORS ASSOCIATED WITH TREATMENT CHOICE AND RESPONSE IN RELAPSED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS RE-TREATED WITH RITUXIMAB: THE OBSERVATIONAL PERLE STUDY

D Chaoui[1,*], L Sanhes[2], B Mahé[3], M Hacini[4], O Fitoussi[5], Y Arkam[6], H Orfeuvre[7], MS Dilhuydy[8], M Barry[9], E Jourdan[10], B Dreyfus[11], A Tempescul[12], S Leprêtre[13], A Bardet[14], R Guillier[15], M Maynadié[16], S Choquet[17], A Delmer[18]
[1]Centre Hospitalier Victor Dupouy, Argenteuil, [2]Hôpital Saint-Jean, Perpignan, [3]CHU de Nantes, Nantes, [4]Centre hospitalier de Chambéry, Chambéry, [5]Polyclinique Bordeaux Nord, Bordeaux, [6]Hôpital Emile Muller, Mulhouse, [7]Centre hospitalier de Fleyriat, Bourg en Bresse, [8]Hôpital Haut Levêque, Bordeaux, [9]Centre hospitalier du Dr Duchenne, Boulogne sur Mer, [10]CHU de Nîmes, Nîmes, [11]Pôle Régional de Cancérologie, Poitiers, [12]Hôpital Auguste Morvan, Brest, [13]Centre Henri Becquerel, Rouen, [14]Roche France, [15]Lincoln, Boulogne-Billancourt, [16]CHU du Bocage, Dijon, [17]Hôpital La Pitié Salpêtrière, Paris, [18]CHU Robert Debré, Reims, France

Background: The treatment of patients with relapsed and refractory chronic lymphocytic leukemia (r/rCLL) previously treated with rituximab-based regimen (R) and re-treated with rituximab is relatively complex.
Aims: Exploratory analyses were conducted to identify factors leading to the choice of a specific combined chemoimmunotherapy: R-Bendamustine (RB), R-purine analogs (RP), R-alkylating agents (RA) or others regimens (Oth) and factors associated with the quality of response.
Methods: PERLE is a prospective non-interventional cohort study (main results presented at EHA 2014 - P876) conducted in r/rCLL patients. Two sets of exploratory analyses using data-mining methods were performed on baseline characteristics: decision trees to find patterns of factors defining subgroups of patients and random forests to provide a robust predictor model with a ranking between all available information. To confirm these outputs, standard logistic models, univariate and multivariate were implemented. Among baseline characteristics (clinical, demographics, disease and patients' management) analysed with data mining, some were identified as candidate factors. The most impacting factors associated either with choice of chemotherapy or with response were confirmed by multivariate analyses.
Results: Overall, 310 patients were included. Their median age was 72 years [35 - 93] and 68% were men. The majority (187, 60%) was in first relapse. Rituximab was administered during first (69%), second (94%), or both (16%) previous treatment lines. More than half of the patients received RB, 16% received RP and 18% received RA (including 40% with chlorambucil). RB was favored in patients with a previous purine based-treatment (OR=2.36 [1.4; 3.9]) which is the opposite of RP (OR=0.39 [0.2; 0.8]). RA was preferentially prescribed in elderly patients (≥70 y.o., OR=4.29 [2.0; 8.9]). Overall response rate (ORR) at the end of induction was 84%. A significantly better response was observed with the use of 500mg/m^2 rituximab dose *versus* 375mg/m^2 (84.5% *versus* 53.4%), when neutrophils count was ≥1.10^9/L *versus* <1.10^9/L, (76.3% *versus* 47.4%) and when response duration was ≥12 months *versus* <12 months (80.1% *versus* 62.5%). The number of previous rituximab-based treatment lines also impacts the quality of the response: ORR 76.2% with 1 treatment line *versus* ORR 45.0% with 2 previous treatment lines. Imbalance between responders and non-responders according to 17p deletion was also observed (patients with deletions: 49% responders; without deletion: 80%). Furthermore, ORR differences were observed between treatment groups: 85% with RB, 89% with RP, and 78% with RA. In this observational study, adverse events (all grades) were hematological (26.9%, including neutropenia (11.9%)) and infectious (14.4%). Grade ≥3AEs occurred in 28.4% of patients and were mainly hematological (19.7%); 22 patients (6.9%) died during induction treatment (15 deaths related to progression; 7 for AEs).
Summary/Conclusions: In real-life setting, treatment choice for r/r CLL is multifactorial. Overall, whatever the patient's profile and the treatment strategy, the dose of rituximab (500mg/m²), as well as a single previous rituximab-based treatment line, are associated with a significantly better quality of response.

PB1798

PLATELET DYSFUNCTION CAUSED BY IBRUTINIB TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. MONOCENTRIC EXPERIENCE: CLINICAL AND LABORATORY CHARACTERIZATION

I Innocenti[1,*], MA Alberelli[2], F Autore[1], S Sica[1], E De Candia[2], L Laurenti[1]
[1]Department of Hematology, [2]Department of Oncology and Hematology, Institute of Internal Medicine, Catholic University of Sacre Heart,Rome, Rome, Italy

Background: Ibrutinib (IBR) is a potent and irreversible inhibitor of Bruton's tyrosine kinase (Btk), approved for treatment naïve of chronic lymphocytic leukemia (CLL) with del 17p or TP 53 mutation or for patients (pts) with relapsed/refractory (R/R) disease. IBR treatment is associated with bleeding events, mostly mild to moderate (I-II grade of severity), rarely severe (III-IV grade of severity). The mechanism causing these bleeding events remains unknown. A defect of platelet function has been hypothesized and inhibition of signaling by glycoprotein VI (GP-VI) has been previously described. IBR associated bleedings and platelet dysfunction may be relevant in CLL pts who are elderly and with comorbidities.
Aims: To investigate and characterize the effect of IBR on platelet function *in vitro* and *in vivo* in pts with CLL.
Methods: Nine pts with CLL were treated with oral IBR at dose of 420 mg/day; 7 received IBR in monotherapy for relapsed/refractory CLL and 2 in association with monoclonal antibody anti-CD20 for treatment-naïve CLL. Median age was 68 years (57-75); 5 pts had unmutated IgVH and 2 had 17p deletion on FISH. The median number of prior therapies in R/R CLL pts was 3 (range 2-7). After a median follow up of 14 months (range 6-20) all pts achieved a partial response. Thereafter 2 pts discontinued IBR therapy: 1 for Richter's transformation, 1 underwent allogeneic HSCT. All pts before and after initiation of treatment with IBR were studied with light transmission aggregometry (LTA) using platelet-rich-plasma and the following agonists : ADP 2-4 uM, PAR1-AP 25 uM, Collagen 10 ug /mL, arachidonic acid 1 mM, ristocetin 0.6-1.2 mg/mL; measurement of von Willebrand factor(vWF) antigen and ristocetin cofactor activities by chemiluminescent immunoassay.
Results: We recorded only grade I or II bleeding events (bruising, petechiae, conjunctival hemorrhage, rectal bleeding) in 7 pts at a median time of 3 months after IBR treatment (range 1-9); no patient needed treatment interruption or dose reduction. Eight pts displayed abnormalities of the aggregation induced by 10 ug/ml collagen after initiation of IBR treatment. At these collagen concentration, only significant prolongation of the lag phase was measured (74.6+/- 23.7 sec *vs* basal 40.4+/- 17.2 sec), whereas the maximal aggregation was not impaired (67.9+/- 21.4% *vs* basal 85.5+/-5.8%). Interestingly, in 5 pts a significant improvement of the aggregation by 2 uM ADP (91.2+/- 5.1% *vs* basal 39.3+/- 24.6%) and 4 uM ADP (91.6+/- 2.9% *vs* basal 65.4+/- 19.4%) during IBR treatment was reported. On the contrary the aggregation by PAR1-AP, ristocetin and arachidonic acid was not affected under IBR. Finally, in 3/3 pts the vWF antigen and ristocetin cofactor activity were higher at the onset of the disease (169+/- 38%) and returned to normal values under IBR treatment (111.4+/- 47%).

Summary/Conclusions: Our study showed that collagen induced platelet aggregation resulted impaired while ADP induced aggregation improved upon IBR treatment. Finally the levels of vWF were significantly higher in CLL pts before treatment and normalized during IBR. In conclusion, IBR treatment in CLL pts causes a mild bleeding phenotype most probably due to platelet dysfunction. The bleeding risk was unrelated to platelets count. The assessment of platelet aggregation in IBR treated CLL pts could help to predict and monitor bleeding risk, and to guide pts through invasive procedures.

PB1799

EFFICACY OF IBRUTINIB-BASED THERAPY IN THE TREATMENT OF RECURRENT AND REFRACTORY FORMS OF CHRONIC LYMPHOCYTIC LEUKEMIA

A Kuvshinov*, S Voloshin, I Martynkevich, L Martynenko, A Garifullin, E Kleina, K Abdulkadyrov
Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Several studies in chronic lymphocytic leukemia (CLL) have determined the achievement of minimal residual disease (MRD) negativity as an independent favorable prognostic factor, leading to prolonged disease-free and overall survival, regardless of the treatment protocol or the presence of other pre-existing prognostic indicators. Novel therapies that incorporate purine analogs, monoclonal antibodies and new agents targeting the B-cell receptor signalling pathway recently improved response rates in relapsed/refractory CLL. The number of patients achieved MRD negative remission increased.
Aims: To estimate of response rate and MRD after ibrutinib therapy in the treatment patients with relapsed/refractory CLL.
Methods: 47 pts were included in the analysis. Stratification of patients into prognostic groups based on identified chromosomal abnormalities by standard GTG-method and interphase FISH analyses with use of DNA probes: LSI *RB1* (13q14), LSI *ATM* (11q22), CEP12, LSI *TP53* (17p13.1) (Abbott). Group 1 (n=26): 1st line rituximab-based chemotherapy (RB-12, FCR-14); Group 2 (n=17): 2nd and subsequent lines of rituximab-based chemotherapy (RB-12, FCR-4, R-CHOP-1) and Group 3 (n=9): ibrutinib-based therapy (420 mg daily oral Ibrutinib±Rituximab). Median age in Group 1 was 57 years (35-67), in Group 2-62 years (49-83), in Group 3-65 years (51-82). Patients received, regardless of the programs of therapy. We have used NCI-IWCLL revised guidelines for treatment initiation and assessment of response. MRD was detected by multicolor flow cytometry of bone marrow in patients achieved a complete or partial remission: Group 1-26 pts, Group 2-7 pts, Group 3-4 pts.
Results: Patients with unfavorable chromosomal abnormalities were detected in each group: Group 1-4 pts (del(11q)-3, complex karyotype-1); Group 2-2 pts (combination del(11q) with del(13q)); Group 3-1 pts (del(17p)). Overall response rate (ORR) in Group 1 was 100%: complete remission (CR)-10 pts (unfavorable prognosis (UP)-2), partial remission (PR)-16 pts. Group 2: ORR 82% (CR-1 pts, PR-13 pts (UP-2)); stable disease (SD)-1 pts, progression disease-2 pts. Group 3: ORR 89% (CR-3 pts, PR-5 pts (UP-1); SD-1 pts). MRD-negative remission was achieved in 46% pts in Group 1 (12/26: CR-6 pts (UP-1), PR-6 pts (UP-2)), in Group 2-14% (1/7, CR), in Group 3-25% (1/4, CR).
Summary/Conclusions: Evaluation of response and MRD after ibrutinib-containing programs therapy in the treatment patients with relapsed/refractory chronic lymphocytic leukemia require further research. The influence of genetic abnormalities on the treatment efficacy and MRD status has yet to be defined.

PB1800

USE OF IBRUTINIB IN PATIENTS WITH B CELL LYMPHOID MALIGNANCIES: ADVERSE EVENTS AND MANAGEMENT IN COMMUNITY SETTING

W Alexander, R Ramakrishna*, P Reddy
Southern Haematology and Cancer Research Institute, Wollongong, Australia

Background: Bruton's tyrosine kinase (BTK) is expressed in B-cell malignancies, playing an important role in B-cell receptor (BCR) signaling and offering a promising new strategy for the development of targeted drugs. Malignant B cells in mantle cell lymphoma (MCL) and chronic lymphocytic leukemia (CLL) rely on BCR signaling pathways for cell survival, proliferation, adhesion, and migration. Ibrutinib is a BTK inhibitor which has been found to be an effective therapy option in patients with relapsed/refractory mantle cell lymphoma, relapsed/refractory chronic lymphocytic leukemia/small cell lymphoma (SLL) or newly diagnosed patients with CLL and a chromosome 17 deletion (del 17p)[1]. Most responses tend to be partial, but nearly two thirds of MCL and CLL patients treated have had a durable response, despite many being refractory, having high risk cytogenetic abnormality and/or heavily pre-treated[2]. The medication is tolerable with <10% of trial patients discontinuing use due to side effects[3]. Published trial data highlight side effects including nausea, diarrhoea, fatigue, bleeding, decrease in blood cell counts, renal impairment[2]. Our analysis of data on side effects from this drug in our cohort differs from those side effects highlighted in drug trials.
Aims: To better understand the side effect profile of ibrutinib and management of these patients in real life.
Methods: A cohort of 36 patients all refractory to at least two lines of therapy or with del 17p were entered into this study; with a mix of 25 patients with CLL, 7 with SLL, 4 with MCL. All were treated with ibrutinib at either 560mg/day (MCL) or 420mg/day (all others) until disease progression or death with a median treatment time of 9 months.
Response and adverse event data has been recorded for these patients and subsequently analysed.
Results: In our cohort the most common side effects were dermatologic complications, affecting nearly one third of patients to some degree. As well, one sixth of patients in our cohort experienced symptomatic gastro-oesophageal reflux requiring treatment with proton pump inhibitors. We had one patient who experienced transaminitis related to ibrutinib requiring cessation of therapy. No patient in our cohort experienced cytopenias or renal impairment or significant diarrhoea or nausea related to therapy. Bruising and platelet dysfunction was noted in 20% of patients, especially if already on antiplatelet therapy (APA) or anticoagulants (OAC). None of these patients required cessation of either therapies, but dose or frequency reduction of APA or OAC.
Most of the patients in our cohort have achieved at least very good partial response, with only six patients with progressive disease (all with CLL or SLL).
Summary/Conclusions: Our real life experience of using ibrutinib in patients with refractory CLL or MCL has shown very good response with most patients tolerating the therapy very well. In our cohort the side effects were different from those recorded in clinical trials. Cutaneous reactions and acne like lesions as well as staphylococcal infections appear to be more common than appreciated and GIT side effects were less common in our experience. We have found topical treatment of acne lesions with antibiotics to be mostly effective and oral or intravenous antibiotics required for extreme cases. Ibrutinib therapy is a well tolerated and effective therapy option for patients with high-risk CLL or MCL. Therapy can be managed in the community without requiring hospitalisation.

PB1801

APPLYING PROBED CAPILLARY ISOELECTRIC FOCUSING (PROBED CIEF) FOR RESPONSE MONITORING OF SIGNAL INHIBITOR THERAPY DIRECTED AGAINST BRUTONS TYROSINE KINASE (BTK) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

K Rees-Unwin[1], C Hutchinson[2], S Gordon[1], J Adams[3], J Burthem[1,*]
[1]Institute of Cancer Studies, University of Manchester, Manchester, [2]Haematology, University of Plymouth, Plymouth, [3]Haematology, Central Manchester Foundation Trust, Manchester, United Kingdom

Background: Signals mediated through the B cell receptor (BCR) of chronic lymphocytic leukemia (CLL) are central to disease pathobiology. Bruton's Tyrosine Kinase (BTK) is a key regulator of BCR signalling. Small molecule inhibitors of BTK (BTKi) have therefore emerged as effective therapeutic agents. BTKi treatment is particularly successful in CLL; however responses may not be complete or durable. It is therefore important that we have tools to monitor disease response and direct therapy. Probed capillary isoelectric focussing (probed cIEF) uses fine capillaries that contain an ampholyte pH-gradient to separate protein within cell-lysates according to their charge. Many post-translational modifications induce significant changes to charge, and modified proteins are readily separated. Antibodies that recognise specific signal-molecules are then used to probe the samples and to generate profiles that demonstrate the presence and relative abundance of different charge-forms of the target molecule. These charge-forms reflect structural alteration, lipid modification or different phosphorylation states, modifications that reflect differential activation of the signalling molecule. The technique offers the capability to detect and evaluate the full range of changes to BTK, and therefore can be used to support clinical monitoring of drug effectiveness.
Aims: To evaluate the use of probed cIEF in signal response monitoring for patients treated with BTK inhibitors.
Methods: CLL cells were cultured *in-vitro* in the presence or absence of BCR activation (anti-IgM cross-linkage) with and without BTKi (ibrutinib). Cells lysates were separated according to charge using an ampholyte pH-gradient (nested 5-8). To assess BTK response, separated protein was probed with total BTK antibody to generate profiles of the presence and relative abundance (area under curve for peak volumes (Compass software)) of different charge-forms of the molecule. *Ex-vivo* cells of CLL pre and post *in-vivo* BTK signal inhibitor therapy were analysed to compare with *in-vitro* profiles.
Results: Phosphoprotein traces were reliably obtained yielding reproducible dose-response profiles. A significant complexity of charge-forms was identified for BTK, with a range of peaks differing substantially between resting and activated cell states. Ibrutinib greatly changed the profile of BTK, both through new peak formation and peak shifts that were not attributable to recognised effects of the drug against standard regulatory motifs. The peak changes we observe are therefore complex, they combine the expected prevention of BTK activation, but also new and unexpected changes not simply a return to the "resting state profile" of the molecule. We suggest these form a molecular signature representing a biomarker of drug response. Studies of inhibitor action in clinically treated and clinically responsive CLL cells mirrored that of our profile

of BTKi treated cells *in-vitro* indicating our profile to represent biochemical modification of BTK signalling after clinically relevant therapy.
Summary/Conclusions: Probed cIEF offers the capability to monitor complex signal-interactions, and to identify important signalling changes in a simple, objective and reproducible manner. Future work will aim to precisely identify the biochemical changes that underlie the specific peaks of the BTK profile that may represent clinically useful biomarkers of treatment response.

PB1802

IS C-REACTIVE PROTEIN A RELIABLE SURROGATE MARKER FOR INFECTION TO HELP FACILITATE DISCHARGE IN PATIENTS ON IBRUTINIB? (A SINGLE CENTRE EXPERIENCE

D Sparksman*, KZ Maw, S Sadullah, C Gomez, M Mangi
Haematology, James Paget University Hospital, Gorleston, United Kingdom

Background: C-Reactive Protein (CRP) is an acute phase protein made by the Liver in response to interleukin-6 (IL-6). It is produced from cells including macrophages, T and B Cells in response to inflammation. It is a poor marker of sepsis at day zero, rising at 4-6 hours and peaking at 36 hours. Ibrutinib is a covalent Bruton's tyrosine kinase (BTK) inhibitor. BTK is an essential part of the B-cell receptor signalling pathway. It mediates both the microenvironment system and promotes survival and proliferation of B-cells. Anecdotally, since Ibrutinib's introduction as a treatment for Chronic lymphocytic Leukaemia (CLL), Mantle Cell Lymphoma (MCL) and Waldenstrom's Macroglobulinaemia (WM) we have noticed some patients admitted with confirmed infections whose CRP response was lower than expected.
Aims: To analyse the correlation between CRP and confirmed infections in all patients on Ibrutinib at a small single centre in the UK.
Methods: We retrospectively reviewed the notes of all 46 patients who had been started on Ibrutinib since its approval, and collected data including sequential CRP's (significant if >60 mg/L) for all episodes requiring admission with confirmed infection, defined as a positive culture result (blood, sputum, skin swab, mid stream urine), or imaging changes consistent with an infection (as reported by Radiology).
Results: Of the 46 patients (29 CLL, 17 MCL) to have received treatment, only 16 (10 CLL, 6 MCL) were admitted to hospital with infection. 5 of these 16 patients had multiple admissions resulting in 25 admission episodes. Of these 25 episodes only 15 met the criteria for confirmed infection. On analysis of the data, the mean length of stay was 10.1 days with a mean admission CRP of 73 mg/L which rose to 85 mg/L at 48 hours. The majority of the episodes (10/15, 67%) appear to have had an appropriate CRP response in the first 48 hours. Of interest one of these 10 was diagnosed with *Listeria monocytogenes* on multiple blood cultures, the admission CRP (58 mg/L) did not rise significantly at 24 hours (68 mg/L) and fell thereafter. The patient never mounted an appropriate response for the clinical picture and by the time she died at day 15 her CRP was 3 mg/L. Of the 5 remaining episodes who's CRP remained low in the first 48 hours (mean CRP 25 mg/L) 4 had imaging and symptoms consistent with a chest infection and 1 was blood culture positive for *Pseudomonas aeruginosa* sepsis (mean length of admission in this group 10.2 days). The data shows 33% of admission episodes with confirmed infection did not have a significant rise in CRP in the first 48 hours.
Summary/Conclusions: In clinical trials Ibrutinib has shown excellent results and the number of patients taking it stand to rise considerably over the coming years. Our single centre study is relatively small and did not obtain enough data to say whether CRP is a reliable surrogate marker for infection in this group. However the 5 cases with low CRP and to a certain extent the 6th (*Listeria monocytogenes* case) mentioned above raise the possibility that Ibrutinib could have an effect on CRP that has yet to be identified. The proposed possible mechanism would be IL-6 reduction. For this reason we have changed departmental policy, stopping Ibrutinib on admission, relying on clinical picture in the first 48 hours before re-checking CRP to assess response to treatment and therefore likelihood for discharge. Possible areas for further investigation include a multicentre study looking for correlation, comparing alternative inflammatory markers and evaluating IL-6 release in patients with infections on Ibrutinib.

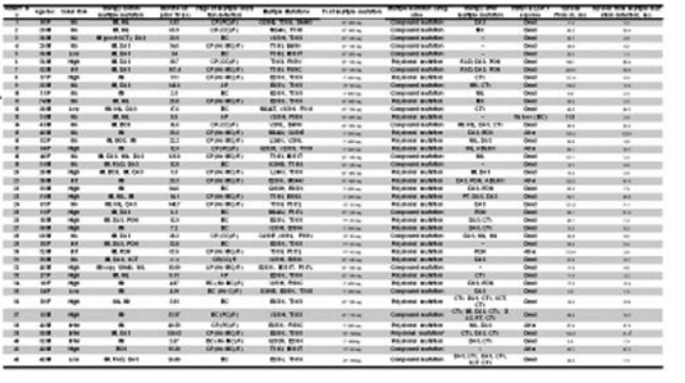
DYNAMICS OF BCR-ABL1 MULTIPLE MUTATION DETECTED BY SUBCLONING AND SEQUENCING IN TYROSINE KINASE INHIBITOR RESISTANT CML

KH Kang[1,*], SH Kim[1], SY Choi[1], SE Lee[1,2], HL Yoo[1], MY Lee[1], HY Song[1], HJ Hwang[1], KM Kee[1], EJ Jang[1], DW Kim[1,2]
[1]The Catholic Leukemia Research Institute, [2]Department Hematology, Seoul St. Mary's Hospital. The Catholic University of, seoul, Korea, Republic Of

Background: BCR-ABL1 kinase domain (KD) point mutation causes resistance to tyrosine kinase inhibitors (TKI) in CML patients through impaired binding of TKI to the target site. One of the characteristics of patients with BCR-ABL1 kinase domain point mutations is the fact that some patients have multiple mutations. However there have not been many studies showing that data about clinical relevance or dynamics of multiple mutation during CML treatment.
Aims: The aim of this study to was to evaluate dynamics and characteristics of multiple mutations in the serial samples from the patients carrying multiple mutations using subcloning and sequencing.
Methods: Since 2002, 735 CML patients were screened for mutation analysis due to sign of resistance to TKI including imatinib, nilotinib, dasatinib, bosutinib, radotinib or ponatinib at Seoul St Mary's Hospital using direct sequencing and ASO-PCR. Among them, 42 patients showed multiple mutations. We analyzed serial samples from the 42 patients using subcloning and sequencing to investigate whether the multiple mutations are on same clone (defined as compound mutation), separated clones (defined as polyclonal mutation) and characterize its clinical relevance and dynamics.
Results: Details on response and survival outcome of 42 patients with multiple mutations is shown in Table 1. In order to investigate whether the multiple mutations are on same clone or on separated clone, we cloned serial samples from the 42 patients. Cloning of cDNA region corresponding to BCR-ABL1 KD into plasmid was performed and followed by transformation into competent cells, colony formation, plasmid preparation of 20 colonies from each sample, and then direct sequencing. Distribution of disease phase at first multiple mutation detection, advanced phase or blast phase was 48% and chronic phase was 52%. With a median follow-up of 35.6 months (range, 4.8-224), 20 different mutations were detected by direct sequencing in 42 patients. 36 patients harbored 2 mutations and 6 patients harbored 3 mutations. Among 42 patients with Multiple mutation, 19 (45%) and 23 (55%) patients had compound mutation and polyclonal mutation, respectively. of 19 patients with compound mutation, 18 patients (95%) were dead. 26 of 42 patients (62%) developed multiple mutations including T315I. Among them, 16 patients (62%) also had P-loop mutation.

Table 1.



Summary/Conclusions: Analysis of serial samples from a same patient provided evidence of dynamic change of portion of compound mutation. In most case, portion of the containing compound mutation was increased as treatment went on, indicating the clone harboring compound mutation can take survival advantage over TKI treatment in comparison of the clone containing individual type of mutation. In addition, some patients showed change in individual mutation type comprising multiple mutations as treatment went on. Patients with compound mutation showed poor outcomes compared with polyclonal mutation in our cohort, further investigation on a large patient cohort will be needed. Updated data about dynamics and characteristic of multiple mutations with longer follow-up duration will be presented in the meeting.
**Even though E255k detected by direct sequencing, it was not detected by subcloning and sequencing.*

PB1804

PPARΓ IS A NOVEL THERAPEUTIC TARGETS IN PH-POSITIVE LEUKEMIA CELLS

S Okabe*, T Tauchi, Y Tanaka, J Sakuta, K Ohyashiki
Department of Hematology, Tokyo Medical University, Shinjuku-Ku, Japan

Background: ABL tyrosine kinase inhibitors (TKIs) such as imatinib, nilotinib and dasatinib have demonstrated the potency against Philadelphia chromosome (Ph)-positive leukemia patients. However, resistance to ABL TKI can develop in chronic myeloid leukemia (CML) patients due to BCR-ABL point mutations and leukemia stem cells, because ABL TKIs cannot eradicate leukemia stem cells. Therefore, new approach against BCR-ABL mutant cells and LSCs may improve the outcome of Ph-positive leukemia patients. Peroxisome proliferator-activated receptors (PPARs) compose a superfamily of nuclear hormone receptors and regulate the transcription of target genes. Three subtypes of PPARs (α, γ and δ/β) have been identified. PPARγ is expressed not only adipose tissue but also cancer cells. The PPARγ agonist, pioglitazone was used for the treatment of diabetes patients. Recently, it has been reported that PPARγ agonist eradicate leukemia stem cells of CML patients (Prost S *et al.* Nature. 2015;525:380-3).
Aims: We hypothesized that targeting PPARγ, in combination with ABL TKI, would result in enhanced therapeutic activity in Ph-positive leukemia cells including T315I mutation and primary samples.
Methods: In this study, we investigated the effect of PPARγ agonist, pioglitazone on Ph-positive leukemia cell lines (K562, NCO2, Ba/F3 BCR-ABL, Ba/F3 T315I) and primary samples.
Results: 72 h treatment of pioglitazone did not exhibit cell growth inhibition against K562 cells.
We found that mRNA of PPAR subunit, PPARα and PPARγ was increased after pioglitazone treatment. We examined the intracellular signaling after treatment of pioglitazone. We found phosphorylation of BCR-ABL and Crk-L was not reduced after pioglitazone treatment. In contrast, phospohorylation of AMP-activated protein kinase (AMPK) was increased and S6 ribosomal protein was reduced. We investigated the pioglitazone activity against T315I positive cells. Pioglitazone did not induce cell growth inhibition of Ba/F3 T315I cells. However, combined treatment of Ba/F3 T315I cells with ponatinib and high concentration of pioglitazone caused more cytotoxicity than each drug alone. Phosphorylation of BCR-ABL and Crk-L was not reduced. However, phosphorylation of S6 ribosomal protein was reduced and AMPK phosphorylation and cleaved poly (ADP-ribose) polymerase (PARP) was increased after ponatinib and pioglitazone treatment. We also found that the treatment of ponatinib and pioglitazone exhibits cell growth inhibition against Ph-positive primary samples with T315I mutation. Phosphorylation of S6 ribosomal protein was reduced and AMPK phosphorylation and cleaved poly (ADP-ribose) polymerase (PARP) was increased after ponatinib and pioglitazone treatment. We next investigated the anti-angiogenic effects of PPARγ agonist on human umbilical vein endothelial cells (HUVEC). Pioglitazone inhibited tube formation of HUVEC (size, length and junction) in matrigel assay. Pioglitazone also inhibited chemotaxis of HUVEC.
Summary/Conclusions: Our study indicated that administration of the PPARγ agonist, pioglitazone enhances the effects of ABL TKI and is effective in suppression of angiogenesis, suggests that PPARγ agonist may possess promising clinical relevance as a candidate for treatment of Ph-positive leukemia patients.

PB1805

PLASMA PROTEOMICS IN CHRONIC MYELOID LEUKEMIA PATIENTS BEFORE AND AFTER INITIATION OF TYROSINE KINASE INHIBITOR THERAPY REVEALS INDUCED TH1 IMMUNITY AND LOSS OF ANGIOGENIC STIMULI

S Söderlund[1,*], L Christiansson[2], I Persson[3], H Hjorth-Hansen[4], J Richter[5], B Simonsson[1], S Mustjoki[6], U Olsson-Strömberg[1], A Loskog[2]
[1]Department of medical sciences, [2]Department of immunology, genetics and pathology, [3]Department of statistics, Uppsala University, Uppsala, Sweden, [4]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [5]Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden, [6]Hematology Research Unit, Department of Hematology, University of Helsinki, Helsinki, Finland

Background: Chronic myeloid leukemia (CML) treated with tyrosine kinase inhibitors (TKIs) in most cases have an excellent long-term prognosis. However, there are still problematic issues in a smaller proportion of CML patients related to TKI resistance and long-term treatment side effects and costs. Much is still unknown about why patients respond differently to TKI treatment and why some patients are even able to stop TKI treatment without disease relapse while others relapse quickly despite seemingly good, durable treatment responses. Proteomics is an area of growing interest and the simultaneous measurement of many proteins is now possible using multiplex assays. Multiplexing is used for several purposes, such as surveys of changes in protein abundance, biomarker validation and clinical diagnostics and to our knowledge, the usefulness of plasma proteomics has not been evaluated in CML patients.
Aims: In this pilot study we investigated a total of 124 proteins in plasma from CML patients with the purpose of identifying proteins that are differently expressed at diagnosis and after TKI treatment initiation, either as a result of the decreased disease burden or as an effect of the TKI treatment itself.
Methods: Samples were taken from 14 CML patients at diagnosis and after three months of TKI treatment (imatinib or dasatinib). Samples were analyzed by three different multiplex platforms: Human proinflammatory 9-plex Ultra-Sensitive kit by MesoScale Discovery, Multi-analyte profiling (MAP) technology by Myriad RBM and Proseek Oncology 1 by Olink. Results were correlated to disease activity (Sokal score, presence of Ph+stem and progenitor cells at diagnosis) and treatment response.
Results: Many protein markers were significantly altered after three months of TKI treatment. Some proteins were analyzed on more than one platform and results for markers present in low concentration in plasma were sometimes contradicting between platforms, which may reflect the specificity and sensitivity variation of the platforms used. It is also highlighting possible difficulties analyzing multiple markers of different concentration ranges in a single sample at one dilution. The protein patterns demonstrated a decrease of pro-tumorigenic analytes (VEGF, TGFβ, IL10, CD31, MICA) while some analytes known to be of importance to T-helper 1 (Th1) immune responses and anti-cancer immunity were increased after TKI initiation (IL12, CXCL9/MIG, IFNγ) (Figure 1), likely reflecting a restoration of normal immune functions after treatment initiation. Interestingly, the level of TGFβ, which has been connected to the maintenance of leukemic stem cells, was correlated to the leukemic stem cell burden ($Ph^+CD34^+CD38^-$ cells) at baseline. We also found reduced angiogenic stimuli which could reflect normalization of bone marrow angiogenesis after treatment initiation since increased bone marrow vascularity and elevated angiogenic factors have been described in untreated CML patients. Further, some single plasma proteins were identified that can be of potential interest to study further for biologic, prognostic or therapeutic significance such as E-selectin, uPAR, growth hormone and carbonic anhydrase IX.

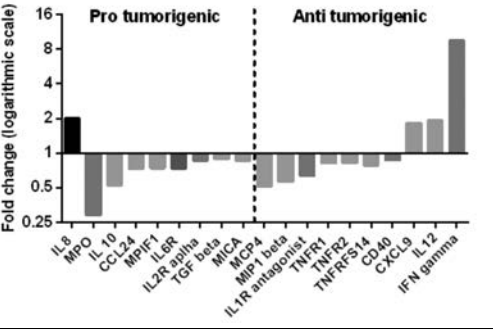


Figure 1.

Summary/Conclusions: Plasma proteomics seems feasible and useful in CML patients, both for studying patterns of protein expression and for identifying single proteins differentially expressed before and after treatment. Hence, plasma proteomics can be used to gain better understanding of drug mechanisms and treatment responses in CML. Some of the significantly altered proteins indicate novel disease or treatment mechanisms and further studies may give novel insights in CML and TKI therapy.

PB1806

LEUKEMIC STEM CELLS DEFINED BY DIPEPTIDIL-PEPTIDASE IV (CD26) EXPRESSION IN CD34+CD38- STEM CELLS AND TYROSINE KINASE INHIBITOR THERAPY IN CHRONIC MYELOID LEUKEMIA

P Rodrigues Santos[1,2,*], J Almeida[2], P Couceiro[2], V Alves[1], L Ruzickova[3], P Freitas-Tavares[3], M Santos-Rosa[1]
[1]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [2]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, Universidade de Coimbra, [3]Serv Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Recently, dipeptidil-peptidase IV (DPP IV; CD26) has been described as a specific marker of leukemic stem cells (LSC) within the $CD34^+CD38^-Lin^-$ compartment present in chronic myeloid leukemia (CML) patients. These cells seem to be difficult to eradicate by tyrosine kinase inhibitors (TKI), although the efficacy of different generations of TKI remains unknown. In addition, the negative influence of these LSC on optimal therapy responses (time to achieve major molecular response) is under investigation in CML.
Aims: In this study, we aimed at the evaluation of the presence of LSC in chronic phase CML patients to establish the additional parameters to better define the efficacy of different therapeutic strategies.
Methods: Peripheral blood samples from chronic phase CML patients (n=45) under Interferon-alpha 2b (IFN-α 2b), imatinib, dasatinb, nilotinib, bosutinib and ponatinib therapy were analyzed by multi-parametric flow cytometry for the characterization of LSC. Buffy coats (n=3) from healthy blood donors were

used as control. Cytokines and chemokines were evaluated in a 34-plex panel by xMAP technology (Luminex®).
Results: Circulating CD34 positive cells were increased in chronic phase CML patients when compared to controls (0.15±0.05% *vs* 0.06±0.05%). CD26 was found expressed in CML $CD34^+CD38^-Lin^-$ stem cells (12.07±4.14%) and absent in controls. CD26 expression was higher in LSC compared to progenitor cells (MFI 704.6±200.8 *vs* 270.4±34.8). We also found SDF-1 significantly overexpressed in CML patients undergoing TKI treatment when compared to IFN-α 2b. An impairment of LSC to respond to SDF-1, associated with less migration to stem cells niche, has been observed, although they express high levels of CXCR4. All of our chronic phase CML patients with detectable LSC in peripheral blood samples needed to change therapy and/or increase TKI dose and the majority of these patients present high or intermediate clinical prognostic risk score (Sokal) on initial evaluation.
Summary/Conclusions: Detection of LSC defined by CD26 in CD34+CD38-Lin- stem cells might be an important tool to improve CML treatment strategy in the near future.

PB1807

MODULATION OF LEUKOTRIENE SIGNALING INHIBITING CELL GROWTH IN CHRONIC MYELOID LEUKEMIA
E Yektaei-Karin[1,*], A Zovko[1], A Nilsson[1], L Kanter[1], O Rådmark[2], M Ekblom[3], H Qian[4], J Wallvik[5], L Stenke[6]
[1]Oncology Pathology, [2]Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, [3]Dept of Laboratory Medicine, Lund University, Lund, [4]Hematology and Regenerative Medicine, Karolinska Institutet and University Hospital, Stockholm, [5]Public Health and Clinical Medicine, Umeå University, Umeå, [6]Hematology, Karolinska Institutet and University Hospital, Stockholm, Sweden

Background: The introduction of tyrosine kinase inhibitors (TKI) has dramatically improved the outcome in chronic myeloid leukemia (CML). However, for most patients cure remains unlikely due to residual, detectable leukemic stem cells. This may be due to aberrant regulation of BCR-ABL-independent signaling pathways. One such suggested pathway leads to the formation of leukotrienes (LT), inflammatory mediators indicated to play a role also in the tumorigenicity of several malignancies (*e.g.* in the colon, prostate, breast, lung). We have previously shown that CML patient-derived myeloid cells have an elevated capacity to synthesize LT, paired by an increased expression of the enzyme LTC_4 synthase (LTC4S). Recently an up-regulation of the arachidonate 5-lipoxygenase (5-LO) gene was observed in BCR-ABL-positive CML mice, together with an improved animal survival when this enzyme was pharmacologically inhibited.
Aims: To examine the effect of leukotriene-signaling-modulating compounds on the growth of human CML cells.
Methods: Human CML cells were grown in 3-day *in vitro* cultures (MTT), with and without addition of different specific blockers of LT-signaling and tyrosine kinase inhibitors (TKI). Protein expression was determined by Western blot.
Results: The cysteinyl-LT1-receptor (CysLT1rec) antagonist montelukast significantly reduced the growth of K562, KCL22 and KU812 CML cells in culture in a dose-dependent manner (IC50 1.1-1.7 μM, *i.e.* clinically achievable concentrations). Montelukast also inhibited the growth of the CysLT1rec-expressing colon cancer cell line HCT116, but not of normal fibroblasts. As expected, several TKIs, including imatinib, also clearly suppressed the growth of the CML cells. When combining montelukast with imatinib an additive inhibition occurred. Similarly, inhibition of CML cell growth was also evident after addition of the 5-LO-inhibitor BWA4C, the 5-LO-activating protein (FLAP) inhibitor licofelone and the LTB4(BLT)1-receptor antagonist LY293111. All three CML cell lines where shown to express 5-lipoxygenase, LTA4hydrolase and LTC4S, key enzymes in the formation of bioactive leukotrienes.
Summary/Conclusions: Our data indicate that blocking of LT-signaling selectively suppresses expansion of human CML cells and may thus provide an additional therapeutic possibility targeting residual disease in this leukemia. Some of the tested pharmaceuticals are already in clinical practice for non-hematological disorders, facilitating the initiation of prospective CML intervention trials.

ISODERIVATIVE PHILADELPHIA CHROMOSOME IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA
A Lukianova[1,*], K Kotlyarchuk[1], O Zotova[1], I Vanko[1], A Pastwinska[2], J Rygier[3], B Pienkowska-Grela[3]
[1]Institute of Blood Pathology and Transfusion Medicine UAMS, Lviv, Ukraine, [2]Medical University of Warsaw, [3]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland

Background: The key point in pathogenesis of chronic myeloid leukemia (CML) is occurrence of Philadelphia chromosome as a result of reciprocal translocation of chromosomes 9 and 22 leading to formation of the *BCR-ABL* fusion gene. Increasing number of copies of this oncogene may be one of the reasons for disease progression and lack of response to treatment with tyrosine kinase inhibitors. Usually, this process develops due to occurrence of additional copies of the Ph-chromosome without alteration of its structure. This report however describes 5 cases of changed morphology of derivative chromosome 22 (particularly isochromosome 22), leading to increased number of *BCR-ABL* gene copies. Despite the fact that occurrence of an isochromosome can be quite frequent in various malignancies reports concerning isoderivative chromosome 22 are quite rare.
Aims: The aim of this study was an attempt to establish the mechanisms leading to modifications of derivative 22 structure; and to investigate the number of *BCR-ABL* gene copies and its localization.
Methods: Methods of conventional cytogenetics (karyotyping of bone marrow cells) and FISH using BCR-ABL DC DF probe (Vysis) were applied.
Results: Cytogenetic aberrations involving increased numbers of copies of Ph-chromosome and *BCR-ABL* gene were detected in 30 patients overall. Occurrence of 1 or more additional Ph-chromosomes without structural changes was found in 25 of the cases. Structural modifications of derivative chromosome 22 were revealed in 5 patients. Evidences of isoderivative chromosome 22 were found in 4 of them in amount of 1-2 copies per metaphase plate, whereas in 1 case dicentric isoderivative chromosome 22 was detected in amount of 1-5 copies per metaphase plate (Figure 1). Presence of two copies of *BCR-ABL* on both arms of isoderivative 22 in all cases was confirmed by FISH on metaphase plates. It was hence proved that the detected isoderivative 22 in these 4 patients was composed of the long arms of Ph-chromosome with fragments of chromosome 22 and 9 linked by centromere of chromosome 22. Presence of two copies of *BCR-ABL* was also confirmed by FISH for the patient with dicentric isoderivative chromosome 22. However, in this case the isoderivative comprised two cetromeres of chromosome 22 and the long arms were connected by telomeric areas of the translocated fragments of chromosome 9. Total number of *BCR-ABL* copies in cells with isoderivative was 2-10. The described abnormalities were detected in 4 patients treated with imatinib. Therapy was subsequently changed to nilotinib in 3 of them and to dasatinib in 1 patient. After switching to nilotinib cytogenetic response was not achieved in 2 patients who subsequently died of disease progression. In case of dasatinib the patient also failed to reach cytogenetic response. Only in one patient after 2 years of nilotinib complete cytogenetic response (CCyR) was obtained. In remaining 5th patient who failed after 1 year of imatinib without any clonal evolution treatment was changed to nilotinib. After 6 months of this treatment CCyR was achieved, however after 12 months occurrence of isoderivative 22 was for the first time detected in 50% of the cells. The patient currently continues being followed.

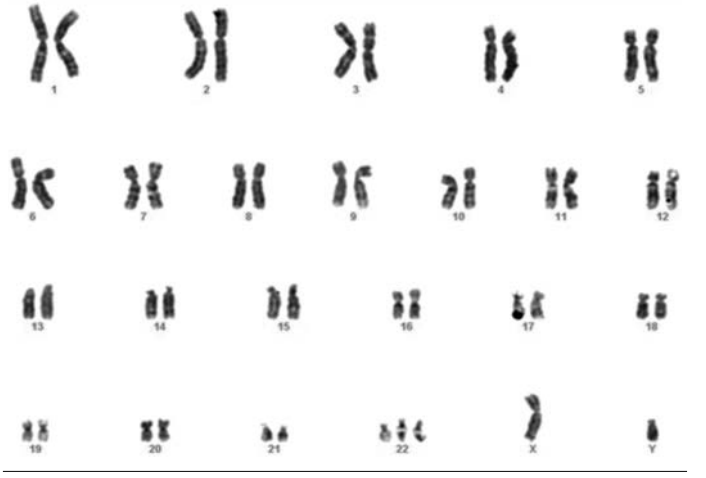

Figure 1.

Summary/Conclusions: The paper describes 5 cases of rare structural modifications of derivative chromosome 22, leading to increased numbers of copies of *BCR-ABL* gene. In majority of these cases patients were resistant to treatment with tyrosine kinase inhibitors. Detected aberrations most probably represent one of the mechanisms of the secondary resistance and disease progression in CML.

PB1809

MOLECULAR AND FUNCTIONAL INTEGRITY OF CRYOPRESERVED CHRONIC MYELOID LEUKAEMIA CD34-POSITIVE HAEMATOPOIETIC STEM CELLS
C Hodkinson[1,*], D Sewell[1], J Downes[1], K Jestice[2], J Baxter[1]
[1]Cambridge Blood and Stem Cell Biobank, Dept. of Haematology, University of Cambridge, [2]Stem Cell Laboratory, Clinical Haematology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Biopreservation is a billion dollar industry, despite this, access to large numbers of high quality biospecimens remains a challenge for many researchers. Chronic myeloid leukaemia (CML) is a rare condition of approx-

imately 1 new case per 100,000 in the UK per year. CML is a clonal disorder originating from a CD34-positive haematopoietic stem cell. Studies of molecular targets and functional processes in tumour-initiating stem cells have greatly enhanced the understanding of oncogenesis and disease progression, but the impact of freezing, thawing and long-term storage on tumour-initiating cells is under reported. Knowledge of these bioprocesses is critical to the development of high-quality biobank collections.
Aims: To investigate the effect of cryopreservation on CML CD34-positive cells and the utility of such material for downstream molecular and functional analyses.
Methods: Mononuclear cells (MNCs) and CD34-positive cells were isolated from excess cryopreserved autologous peripheral blood stem cell (PBSC) harvests, collected between 1990 and 2006, fresh whole blood from untreated CML patients, and healthy NHS blood donors. Cells were cryopreserved by controlled-rate freezing, stored in gas-phase liquid nitrogen and underwent three cycles of freeze-thaw (FT). Molecular and functional assays were performed at each cycle. RNA integrity number (RIN), as a measure of total RNA quality, were assessed on an Agilent Bioanalyzer, and semi-quantitative PCR, using GUSB as a reference gene, was performed to evaluate BCR-ABL gene expression. CD34-positive cell frequency was determined by two-colour flow cytometry using CD34 PE-Cy5.5 and the vital dye Calcein. Analysis of CD34-positive cell clonogenic potential was conducted using a colony-forming unit (CFU) assay, whereby cells were incubated in complete CFU media, supplemented with 3U/ml erythropoietin, for 16 days.
Results: Mean RIN values for normal and CML cell subsets were ≥7. RIN values for normal MNCs and CD34-positive cells were significantly higher ($p<.01$) compared to CML cellular subsets; there was no significant effect of repeat FT on total RNA derived from either normal or diseased cell subsets. GUSB and BCR-ABL expression were significantly higher ($p<.05$) in freshly isolated CML cell subsets compared to FT cycles 2 and 3, but not cycle 1. A downward trend in the ratio of BCR-ABL:GUSB expression was observed with repeat FT cycles but this did not reach statistical significance. The frequency of live CD34-positive cells remained stable with successive FT cycles. No difference in CFU potential was observed for CD34-positive cells in healthy donors between fresh and FT cycle 1, but significantly fewer ($p<.05$) colonies were observed for successive FT cycles. Cryopreservation of CML CD34-positive cells resulted in a significant reduction ($p<0.5$) in CFU potential compared to fresh material.
Summary/Conclusions: Long-term storage and cryopreservation has minimal impact on the quality of genetic material for use in downstream molecular analysis. However, gene expression data indicates a potential global down-regulation of gene regulation post freeze-thaw and functional studies suggest that while CD34-positive cells are sufficiently robust to withstand cryopreservation they experience a loss in proliferative potential, to which CML derived cells are more sensitive. This implies that there are different handling and storage requirements for cell subsets derived from healthy and diseased individuals, highlighting the need to standardise biospecimen preparation and storage for meaningful analyses where access to fresh material is limited.

PB1810

COMBINED ANTICANCER ACTIVITY AND SIRNA DELIVERY BY DENGUE VIRUS CAPSID PROTEIN PEPTIDES PEPR AND PEPM AGAINST CHRONIC MYELOID LEUKEMIA

I Figueiredo[1,*], JM Freire[1], BG de la Torre[2], AS Veiga[1], D Andreu[2], FJ Enguita[1], MA Castanho[1]
[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal, [2]Department of Experimental and Health Sciences, Pompeu Fabra University, Barcelona Biomedical Research Park, Barcelona, Spain

Background: Cancer remains a major cause of morbidity and mortality worldwide. Although progress has been made regarding chemotherapeutic agents, new therapies that combine increased selectivity and efficacy with low resistance are still needed. In the search for new anticancer agents, therapies based on biologically active peptides, in particular, antimicrobial peptides (AMPs), have attracted attention for their decreased resistance development and low cytotoxicity. AMPs, which have been essentially studied and developed as potential alternatives for fighting infectious diseases, have been tested as anticancer peptides (ACPs) in cancer therapy either alone or in combination with other conventional drugs. Moreover, the usage of cell-penetrating peptides (CPP) to deliver anticancer drugs, such as siRNA targeting molecular causes of cancer are currently being developed.
Aims: Chronic Myeloid Leukemia (CML) is a myeloproliferative disorder caused by a single genetic mutation, a reciprocal translocation that originates the BCR-ABL gene with constitutive tyrosine kinase activity. Because there is a specific gene associated to this pathology it is an optimum therapeutic target for RNA silencing therapy (siRNA). Thus we developed a siRNA-based therapeutic approach in which the siRNA is delivered by Dengue Virus Capsid Protein-derived peptides, pepM and pepR. These peptides were used with the intention of having have dual role, to deliver siRNA into cells and act as Anticancer molecules by targeting intracellular cancer signaling events.
Methods: Dengue virus-peptides ability to transfect the positive BCR-ABL$^+$Cell Line (BV-173) was evaluated by confocal microscopy following GFP fluorescence emission after plasmid expression. Anti-BCR-ABL siRNA design was performed using a siRNA design web-tool and the BCR-ABL downregulation kinetics (48h to 168h) after transfection by Dengue virus-peptides was evaluated by RT-PCR. The Anticancer action of either pepR or pepM was assessed by genome-wide analysis microarray and further validated by testing BV 173 cell cycle and cell proliferation analysis by RT-PCR.
Results: siRNA design for BCR-ABL retrieved 148 potential siRNA sequences, which were reduced to 5 BCR-ABL siRNA for *in vitro* analysis after thorough screening. Positive efficacy of siRNA targeting BCR-ABL was tested using a commercial transfection agent. Significant BCR-ABL gene knockdown were observed for siRNA #3 when delivered by pepM with maximum decrease at 120h. Both pepM and pepR showed downregulation effects on proliferative CML cancer-related signaling pathways having direct impact on BV 173 cell cycle and proliferation at the G2/M phase.
Summary/Conclusions: With this work we showed the potential therapeutic technology of combining a drug delivery system (CPP) with anticancer properties to deliver functional siRNA into CML cell model. Acting together, these conjugates significantly decreased BCR-ABL gene expression levels, and perturbed leukemogenic cells homeostasis, revealing a potential scaffold to develop an alternative CML therapy. The development of a selective ACP is still a current challenge. It is not straightforward the prediction and design peptides with antitumor activity and we believe that these results will enrich ACP-structure based prediction.

PB1811

ASSOCIATION OF 3'BCR GENE DELETION WITH LACK OF MOLECULAR RESPONSE IN CML PATIENTS WITH PH-VARIANTS TREATED WITH TYROSINE KINASE INHIBITORS

S Angelova[1], B Spassov[1,*], G Tsvetkova[2], G Balatzenko[1], V Hrischev[1], K Batschvarov[3], E Hadjiev[2], G Mihaylov[4]
[1]National Specialized Hospital for Active Treatment of Hematological Diseases, [2]Department of Internal diseases, UMHAT "Alexandrovska"- Clinic of hematology, [3]Specialized Children's Oncohaematology Hospital, [4]National Specialized Hospital for Active Therapy of Hematological Diseases, Sofia, Bulgaria

Background: Chronic myeloid leukemia (CML) is a disease of the clonal hematopoietic stem cells caused by a balanced translocation t(9,22)(q34;q11) forming derivate 22 or Philadelphia chromosome (Ph), and molecularly BCR/ABL gene fusion. The standard for treatment of CML patients (pts) is therapy with tyrosine-kinase inhibitors (TKIs). About 8-10% of Ph+CML pts have more composite rearrangements involving additional chromosomes (Ph-variants) or cryptic translocations. Ph-variants are accompanied more frequently by microdeletions in the regions of chromosome breakpoints than by standard t(9,22)(q34;q11). Although the proportion of CML pts with Ph-variants resistant to TKI therapy is the same as in the group with standard translocation, the specific mechanisms involving Ph-variants in TKI resistance are still unclear.
Aims: Evaluating the molecular-cytogenetic impact to resistance of TKIs treated CML pts with Ph-variants.
Methods: We have analyzed 13 CML cases, 12 of which were with Ph-variants and 1 of the patients was with cryptic translocation detected via G-banding cytogenetic analysis (CyG) and metaphase fluorescence *in situ* hybridization (met-FISH). The pts are aged 16 to 78 years and were treated with TKIs and followed for at least 18 months in hematology clinics in Sofia, Bulgaria. No less than 20 metaphases with CyG and no less than 10 with met-FISH were examined in each patient. Hematologic, cytogenetic and molecular responses were evaluated regularly.
Results: Our data showed that the following breakpoints were included in three- or four-way translocations: 1q42, 2q37, 3p25, 4p14, 4q33, 6q21, 7q34, 8q24, 11q11, 17q21, 19p13 (in 2 cases), 22q13 and Xq26. At diagnosis, two of the 13 pts had additional aberrations in the karyotype besides Ph-variants. The met-FISH technique allowed us to detect that the rearrangements in 10 of the cases are more complex than registered by CyG: additional chromosomes or additional regions in the visibly rearranged chromosomes were involved in 2 of the cases; loss of the 5' portion of *ABL* gene (*5' ABL*) was observed in 3 of the cases, deletions in *3'BCR* and *3'ABL* genes were detected in 4 and 1 cases, respectively. Complete cytogenetic (CCgR) and major molecular response (MMR) were achieved in 61.5% (8/13) of the pts. The *3'BCR* gene deletions were observed in 80% (4/5) of the pts without MMR. Two out of 5 resistant pts have the same t(9;19;22)(q34;p13;q11), but only one of them has a *3'BCR* deletion with no achievement of CCgR and MMR. The the latter patient (without the *3'BCR* deletion) has achieved CCgR and suboptimal molecular response on the 18 month after the start of the therapy.
Summary/Conclusions: We suggest that the lost of material in the chromosome 22 region including *3'BCR* gene in CML pts with Ph-variants may be associated with TKIs resistance. Further research is necessary to confirm these results.

PB1812

PROTEOMIC PROFILE CORRELATES TO MOLECULAR RESPONSE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

N Sgherza[1,*], VM Garrisi[2], A Iacobazzi[3], G De Tullio[3], E Savino[2], I Abbate[2], N Cascavilla[1], A Guarini[3]
[1]Hematology Unit-IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, [2]Clinical & Experimental Pathology Laboratory-National Cancer Research Centre "Istituto Tumori Giovanni Paolo II", [3]Hematology Unit-National Cancer Research Centre "Istituto Tumori Giovanni Paolo II", Bari, Italy

Background: Recent advances in the proteomic field have allowed us to better understand the biology of several cancer types and/or discover new candidate biomarkers. Very few data are available about the serum protein expression of patients with Chronic Myeloid Leukemia (CML).
Aims: The aim of our pilot study was to evaluate a correlation between depth of molecular response (MR) and proteomic profile of CML patients, and if possible to find novel potential biomarkers complementary to currently existing proven tools to monitor therapy response.
Methods: Thirty sera from peripheral blood (PB) were sampled from 8 patients in MR1 response, 6 in MR2, 11 in MR3, and 5 in MR4. For 11 patients serum from bone marrow (BM) was also available. In particular 3 were sampled from patients in MR1, 3 in MR2, 4 in MR3, 1 in MR4. The one patient at diagnosis was included in MR1 group. Samples were divided into 2 groups according to the achievement of MR3: Group A, which comprised 14 samples from patients with a MR lower than MR3, and Group B, including 16 samples from patients who experienced a MR greater than or equal to MR3.The association of proteomic profile with MR was investigated using the SELDI ToF Mass Spectrometry platform. Each specimen was analyzed in duplicate. Expression Differences Mapping analysis was applied in order to generate a cluster peaks list, which describes how a singular peak is expressed in the specimen spectrum. Finally, with the aim to give a preliminary identity to the most differentially expressed peaks, an in silico identification was attempted using the Mascot database search available at www.matrixscience.com.
Results: Comparing PB sera from group A and group B, only a peak at 5075 Da had a p-value=0.05. Comparing sera from patients with different MR (MR1 *vs* MR2 *vs* MR3 *vs* MR4), statistical analysis found two features at 11092 Da and once again that at 5075 Da as differentially expressed and statistically significant (P-value=0.0034 and 0.0084 respectively) between MR1 and MR4. In particular the peptide at 11092 Da was overexpressed in MR4 patients. Also the peak at 5075 Da was highlighted as statistically significant, but its significance was less important than that of 11092 Da due to a slightly worse sensitivity (80%). Sera from PB were compared with those extracted from BM. Interestingly, no difference was highlighted. Regarding the two peaks (5075 Da and 11072 Da) we hypothesized that they were closely related, probably as a fragmentation product. With the aim to quickly give a preliminary identity to the peptide, we attempted an "in silico" mass peptide finger print using the open-source tool available at www.matrixscience.com. The bioinformatic tool identified the peptide with a high probability score, as a truncated part of a larger nuclear protein ZMIZ2. It would interact with the Wnt/β-catenin pathway participating in its activation. As suggested by data from literature, we can try to hypothesize that, unlike non responders, in the serum of responsive patients a part of ZMIZ2 is present, as a consequence of the degradation of the entire protein; this finding results in an under-regulation of the Wnt/β-catenin pathway with consequently a better response.
Summary/Conclusions: These preliminary data suggest that the peptide at 11092 Da is very closely related to a good response. Our efforts are now oriented to definitively confirming the identity of the peptide and to clarify its role.

PB1813

EVALUATION OF BECLIN-1 PROTEIN EXPRESSION IN CHRONIC MYELOID LEUKEMIA PATIENTS ON IMATINIB THERAPY

Z Emarah[1,2,*], L Mahmoud[3], A Mansour[3], M Elzaafarany[1,2], R Elsaied[3], A EL-Sebaie[3]
[1]Medical Oncology, Oncology Center, Mansoura University, [2]Internal Medicine, [3]Hematology Unit, Clinical Pathology Department, Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background: Imatinib is a tyrosine kinase inhibitors that used for the treatment of chronic myeloid leukemia (CML). Recent studies showed imatinib-induced cell death in many types of cancers. Autophagy is the physiological process in which cellular components are broken down by the lysosomal activation. Beclin-1 is a protein that encoded by the BECLN1 gene which sits at the core of autophagy regulation.
Aims: the aim of this study is to evaluate the role of Beclin-1 in regulation of BCR-ABL1 fusion gene in patients with chronic myeloid leukemia.
Methods: Peripheral blood samples collected from 30 patients (16 males and 14 females) diagnosed with CML at Oncology Center Mansoura University. Ages ranged from 18 to 50 (44.7±10.2) years. Diagnosis was based on typical finding in the peripheral blood smear and bone marrow aspiration then confirmed by detection of Philadelphia chromosome by cytogenetics or BCR/ABL1 fusion gene using Quantitative RT-PCR. Further samples collected form 30 apparently healthy individuals (16 males and 14 females) subjected as matched controls. Beclin-1 protein was measured by ELISA technique in serum of controls and patients before starting treatment (Time point A) and after 6 months of Imatinib therapy (Time point B).
Results: there was a significant increase in mean Beclin-1 protein level in CML patients either at initial diagnosis (32.6 ng/dl, p ≤0.001) or after 6 month of imatinib therapy (44.3, p ≤0.001) compared to matched control (9.5 ng/dl). Although its mean level increased after 6 month of imatinib therapy, this increase was not statistically significant. There was a strong negative correlation between mean Beclin-1 protein and hemoglobin level (r=-0.56, p=0.001), white blood cells count (r=-0.62, p=0.008), BCR/ABL1 fusion gene level (r=-0.43, p=0.03).
Summary/Conclusions: there was a statistically significant negative correlation between Beclin-1 protein expression and BCR/ABL1 fusion gene level. Beclin-1 protein expression may be used as a dynamic biomarker to predict response to imatinib therapy. However, larger studies are needed to validate these results.

PB1814

REVERSINE TRIGGERS MITOTIC CATASTROPHE AND APOPTOSIS IN BCR-ABL POSITIVE CELLS

APNR Alves[*], JA Machado-Neto, PS Scheucher, HH Paiva, EM Rego, F Traina
Internal Medicine, University of Sao Paulo at Ribeirao Preto Medical School, Ribeirao Preto, Brazil

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative neoplasm of the hematopoietic stem cell characterized by the presence of the oncoprotein BCR-ABL1, which have a constitutive tyrosine kinase activity. The tyrosine kinase inhibitors for BCR-ABL1 (*e.g.* imatinib, dasatinib and nilotinib) can lead towards the elimination of the BCR-ABL1 clone and increase survival of CML patients. However, acquisition of resistance to tyrosine kinase inhibitors has emerged as a challenge for CML patients and the identification of novel targets is necessary. BCR-ABL1 activation induces aurora kinase A (AURKA) and aurora kinase B (AURKB) expression, which are serine-threonine kinases that play an important function in chromosome alignment, segregation and cytokinesis during mitosis. Aurora kinase inhibition has proven to be an attractive anticancer approach. In the present study, we explored the cellular effects of reversine, an AURKA and AURKB inhibitor, in the BCR-ABL1positive K562 cell line.
Aims: Based on the evidence of participation of aurora kinases in the BCR-ABL1 signaling pathway and CML malignant phenotype, we explored the cellular effects of reversine in BCR-ABL1 positive cells.
Methods: K562 cell line was treated or not with the AURKA and AURKB pharmacological inhibitor, reversine, at 1, 10, 20 and 50μM for 24, 48 and 72 hours. After drug exposure, cells were evaluated for cell viability (MTT assay) and apoptosis (Annexin V/PI and cleavage caspase 3). For DNA content distribution analysis (Cycletest™ Plus DNA Reagent Kit) and Confocal immunofluorescence microscopy, K562 cells were treated or not with reversine at 1 and 10μM for 48 hours. Comparisons between the control and treated groups were performed by the ANOVA test and Bonferroni post-test. A p value <0.05 was considered statistically significant. At least three independent experiments for each method were tested.
Results: In K562 cells, reversine treatment significantly reduced cell viability in a dose- and time-dependent manner (all p<0.05). Using a nonlinear regression analysis, IC50 citotoxicity for K562 was 44.6 μM for 24 hours, 12.9 μM for 48 hours and 9.4 μM for 72 hours. We evaluate the DNA content distribution of K562 cells, since aurora kinases are known to be an important protein family for cell cycle progression and success of mitosis. We observed an increased percentage of K562 cells with tetraploidization (4N) or endopolyploidization (>4N) upon reversine treatment. These findings were confirmed by confocal microscopy analysis, which reveals large cells with several nucleus. Taken together, these data indicate that reversine is a potent inductor of mitotic catastrophe. Reversine significantly induced apoptosis in dose- and time-dependent manner (all p<0.05). In order to confirm our results regarding reversine-induced apoptosis, we also evaluated the caspase 3 cleavage in K562 cells and increased levels of cleaved-caspase 3 were observed in a dose-dependent manner.
Summary/Conclusions: Our preclinical study establishes that reversine presents an effective antileukemia activity against K562 cells and provide new insights on anti-cancer opportunities for CML.

PB1815

COMPARISON BETWEEN AUTOMATED AND MANUAL INTERPHASE FLUORESCENT *IN SITU* HYBRIDIZATION (FISH) ANALYSIS OF T(9;22) (Q43;Q11.2)

H Chaker[*], J Lavoie
Cytogenetics Laboratory, Children's Hospital, Montreal, Canada

Background: Metafer 4 or Metacyte is an automatic interphase FISH scoring system offered by MetaSystems. The scanning system contains a motorized microscope and a computer that achieves microscope control and real time image analysis.
Aims: Around the world, many laboratories have adopted Automated FISH

scoring for interphase FISH analysis, however few have reported their experience. In our laboratory, we have validated automated FISH analysis for a number of probes, including BCR/ABL ES Dual Color Translocation (Abbott). Detection of t(9;22)(q34;q22) generating the *BCR-ABL* gene fusion by FISH is a tool available for clinical diagnosis and treatment monitoring of Chronic Myeloid Leukemia (CML).
Methods: Six different pools of leukemic blood cell suspensions were used as negative controls and 55 CML patient samples were analyzed by automatic FISH and manual analysis.
Results: A Cut off value of 0.8µm was set as maximum distance between signals for fusion count and 1.2µm as minimum spot distance for red and green spot count. Compared to manual read, the scored nuclei are categorized in a higher number of signal patterns with automated FISH analysis. In addition, the number of nuclei per category is different between the two methods. However, there was a strong correlation between automated and manual interpretation results. Only one case out of the 55 cases analyzed was discordant (1.8%), with results above normal reference range by Automated analysis, but within the normal range by Manual analysis.
Summary/Conclusions: Our scoring and interpretation criteria, as well as the advantages of the automated approach will be discussed.

Chronic myeloid leukemia - Clinical

PB1816

HALVING TIME AND LOG REDUCTION ARE GOOD PREDICTORS OF OPTIMAL MOLECULAR RESPONSE IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH SUB-OPTIMAL RESPONSE AT 3 MONTHS

MJ Mendes*, M Coucelo, AT Simões, A Pereira, JC Almeida, M Duarte, LF Araújo, ML Ribeiro
Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: In Chronic Myeloid Leukemia (CML) the 3-month molecular evaluation defines suboptimal responders with BCR-ABL1>10%. This group shows worse prognosis and is thought to benefit from treatment change to 2nd-line TKIs in an early onset. Nonetheless, some patients respond favorably long-term without treatment change. The decline rate of the BCR-ABL1, measured at 3M of treatment, may distinguish patients with suboptimal response that will achieve good responses from those who will need therapy switch.
Aims: In a group of CML patients, analyze clinical and laboratorial differences between patients with optimal/sub-optimal response, after 3M of Imatinib. To determine the predictive value of halving time and log reduction for optimal molecular response at 6 and 12M in patients with suboptimal response.
Methods: Single center retrospective analysis of 24 CP-CML patients treated with Imatinib 1st-line. Halving time at 3M of treatment calculated according to the formula proposed by Branford *et al.,* (2014), $c=-ln(2)/k$, c is the halving time, k ($k=[ln(b)-ln(a)]/d$) the reduction in BCR-ABL1 transcript between initial (a) and 3M quantification (b), divided by the number of days (d) between the two evaluations. Log reduction ($log(a/b)$) calculated at 3M of treatment, a is the 3M QPCR value and b the baseline value. Descriptive statistic analysis performed using the SPSS (v.21). The predictive value was calculated through the area under the curve (AUC), using *MedCal* statistical program. The optimal cut-offs were calculated using the Younden (J) Index.
Results: Between January 2006 and August 2014, 24 patients were diagnosed with CP-CML and started on Imatinib 400mg id; 16 male (66,7%) and 8 female (33,3%), median age=57,71 years(±15,75). Clinical-laboratory findings at diagnosis: mean Hb=12,42g/dL (±1,81;), Plts=452,92x10^3/uL (±299,51), median Leuc=75,1x10^3/uL (141), mean peripheral basophil percentage=2,43%(±1,8) and peripheral blasts=2,3% (±2,07); mean LDH=1302,79U/L (±852,41); mean palpable spleen size=13cm (±5,97). Sokal and EUTOS scores were obtained for 21/24 patients (Sokal score: 3 (14,3%) low-risk; 9 (42,9%) intermediate-risk; 9 (42,9%) high-risk. EUTOS score: 19 (90,5%) low-risk; 2 (9,5%) high-risk). The mean time between initial and 3M QPCR evaluation was 93,25 days (±18,43). At 3M, 14 patients (48,3%) had optimal and 10 (41,7%) suboptimal response. Transcript level at baseline was significantly higher in the suboptimal group (127,3±70,62 *vs* 73,53±25,5;p=0,04). In the suboptimal group, the halving time was highly predictive of optimal molecular response at 6M (AUC=0,93;p<0,0001), as well as response failure (AUC=0,83;p=0,02). The log reduction was highly predictive of optimal molecular response at 6M (AUC=0,96; p<0,0001), at 12M (AUC=0,83;p=0,03) and for response failure at 12M (AUC=0,85;p=0,01). The most predictive cut-off values (J) for halving time and log reduction were obtained for the 6M optimal response (J=0,87). A halving time of 22,59 days and a -1,1 log reduction were predictors of optimal molecular response at 6M.
Summary/Conclusions: In this group, patients with suboptimal response at 3M had a significantly higher BCR-ABL1 transcript at baseline. A halving time of 22,59 days and a -1,1 log reduction predicted optimal molecular response at 6M. In an early time-point of molecular evaluation, the use of parameters evaluating kinetics of the transcript decline will contribute to discriminate patients outcome and guide treatment options.

EVALUATION OF CLINICAL EFFICACY AND SAFETY OF GENERIC IMATINIB IN THE TREATMENT OF CHRONIC MYELOID LEUKEMIA

I Cojbasic[1,*], L Macukanovic-Golubovic[1,2], M Vucic[1,2], N Govedarovic[1,2]
[1]Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, [2]Medical Faculty, University of Nis, Nis, Serbia

Background: Application of generic imatinib (GI) should allow to lower price of cancer drug making it available to a larger number of patients, that way improving health care of the population. Serbia was one of the first countries in Europe to adopt generic imatinib which has been used since 2012. Thereafter, all patients with CML have been switched from the original imatinib (OI) to GI, while newly diagnosed CML patients have been frontline treated with GI.
Aims: The aim of this study was to evaluate the clinical efficacy and safety of GI in the treatment of patients with CML both as frontline therapy and continued therapy after switching from the OI.
Methods: Our study included 70 adult patients with chronic phase CML that were treated with OI and/or GI in the period from August 2006 until February 2016. Patients were divided into two study groups: the first one had 34 patients

switched from the OI to GI, second had 36 newly diagnosed patients who were treated with GI as frontline therapy. All patients underwent hematological, cytogenetic and molecular monitoring and had been treated in accordance with the applicable national guidelines and ELN recommendations.
Results: The median follow-up was 74.7 months (range 46-115) for the patients who started treatment with OI and 20.3 months (range 6-43) for those receiving frontline GI. In the both analysed groups a slight predominance of female subjects was found. In the first group, at the time of the switch from OI to GI, all patients achieved complete cytogenetic response (CCgR) while major molecular response (MMoR) achieved 25/34 (73.5%) of analysed patients. During 41 months of follow-up, 6 patients lost CCgR, but after switching to the 2nd line therapy nilotinib, all have achieved secondary CCgR. The overall rate of MMoR for the group of patients that switched from OI to GI was 22/28 (78.6%). Among newly diagnosed patients receiving frontline GI, the overall rate of CCgR was 29/36 (80.6%), while overall rate of MMoR was 17/36 (47.2%). During the study follow-up, 10 patients were switched to 2nd line therapy nilotinib due to cytogenetic refractoriness or relapse and 7 of them achieved secondary CCgR. When the two study groups were compared regarding the most common non-hematologic adverse events (AEs) of any grade, in the group that started with OI therapy, there were peripheral edema (n=8), skin reactions (n=4) and myalgia (n=3), while in group with frontline GI there were nausea (n=10), peripheral edema (n=6) and fatigue (n=4). In both groups most common hematological AEs were neutropenia (n=5 *vs* n=4) and thrombocytopenia (n=2 *vs* n=3). There were no dose reductions due to toxicities in both groups.
Summary/Conclusions: The results of our study have shown that generic imatinib is not inferior in efficacy and safety compared to the original imatinib. Despite these encouraging results, the need remains for the large prospective randomized studies that would allow for the definitive confirmation of the generic imatinib efficiency in the treatment of patients with CP-CML.

Background: Front-line treatment of newly diagnosed Chronic Myeloid Leukemia (CML) patients with 2nd generation tyrosine kinase inhibitors (2G-TKIs) dasatinib (DAS) or nilotinib (NIL) resulted in higher rates of deep molecular response (MR) as compared to imatinib. Very little is known about rates and stability of deep MR when 2G-TKIs are used after imatinib failure.
Aims: To assess the probability and predictors of stable deep MR in ≥2nd line of treatment.
Methods: We restrospectively analyzed 127 chronic phase CML patients treated with imatinib 400 mg daily as first-line therapy and then switched to 2G-TKIs for resistance or intolerance. Patients progressing to advanced phases before switch were excluded. Deep molecular response (MR^4) was defined as $BCL\text{-}ABR^{IS}$ ratio ≤0.01% or undetectable disease with ≥10,000 ABL copies. Patients with MR^4 lasting ≥2 years, ongoing at the last contact, and with at least a Q-PCR test every 6 months were defined as stable MR^4. Patients with any sample >0.01% $BCR\text{-}ABL^{IS}$ after the achievement of MR^4 were defined as unstable MR^4. Age, sex, Sokal and EUTOS risk score, type of BCR-ABL transcript, duration of imatinib, reason for switch to 2G-TKIs and early molecular response to 2G-TKIs have been examined for the association with stable MR^4. Frequencies were compared by Fisher's exact test. Univariate and multivariate regression analysis were performed using the competing risk model of Fine and Gray.
Results: Median age at diagnosis was 55 years (range 20-88) and median duration of imatinib treatment was 19 months (range 1-115). Patients resistant (n=89; 70%) or intolerant (n=38; 30%) to imatinib were switched to DAS (n=82; 64.5%) or NIL (n=45; 35.5%). Thirty-six patients were resistant or intolerant to their first 2G-TKI and were switched to 3rd-line NIL (n=20), DAS (n=12), bosutinib (n=2), or ponatinib (n=2). At a median follow-up of 52 months after switch to 2G-TKI (range 6-126), best deep MR to 2G-TKI was: no MR^4 in 57 patients (45%), unstable MR^4 in 28 patients (22%; 24 with 2nd line and 4 with 3rd line treatment), and stable MR^4 in 42 patients (33%; 37 with 2nd line and 5 with 3rd line treatment). Five-year cumulative incidence of stable MR^4 was 28.7% (95%CI: 18.9-37.3%). Age, sex, risk scores at diagnosis, type of BCR-ABL transcript, duration of imatinib and type of 2G-TKI were similar between patients with or without stable MR^4 (Table 1). Predictors of stable MR^4 were reason for switch to 2G-TKI (intolerance *vs* resistance HR 0.41, 95%CI: 0.22-0.79; p=0.007) and 3-month BCR-ABL level after 2G-TKI start (≤10%^{IS} *vs* >10%^{IS} HR 0.08, 95%CI: 0.01-0.59; p=0.01). Three stable MR^4 patients attempted discontinuation and are presently in treatment-free remission phase at 2, 22 and 27 months after 2G-TKI stop, respectively.

Table 1. Characteristics of patients and frequency or MR^4 (unstable or stable).

Characteristics	No MR^4 (n=57)	Unstable MR^4 (n=28)	Stable (≥2 yrs) MR^4 (n=42)	p
Sex (male / female)	34 / 23	19 / 9	22 / 20	0.43
Age, median (range)	59 (22-88)	55 (20-80)	55 (23-78)	0.77
Sokal risk				
- low	21 (37)	12 (44)	16 (38)	0.56
- intermediate	22 (39)	14 (50)	18 (43)	
- high	11 (19)	1 (3)	7 (17)	
- not evaluable	3 (5)	1 (3)	1 (2)	
EUTOS risk				
- low	50 (88)	22 (79)	39 (93)	0.33
- high	2 (3)	2 (7)	2 (5)	
- not evaluable	5 (9)	4 (14)	1 (2)	
BCR-ABL transcript				
- b2a2	26 (46)	15 (54)	19 (45)	0.74
- b3a2	18 (31)	10 (36)	18 (43)	
- b2a2/b3a2	7 (12)	1 (3)	3 (7)	
- other	6 (11)	2 (7)	2 (5)	
Duration of imatinib				
- <12 months	24 (42)	7 (25)	13 (31)	0.27
- ≥12 months	33 (58)	21 (75)	29 (69)	
Reason for switch				
- intolerance	10 (17)	11 (39)	17 (41)	**0.019**
- resistance	47 (83)	17 (61)	25 (59)	
Type of 2G-TKI				
- dasatinib	39 (68)	14 (50)	29 (69)	0.20
- nilotinib	18 (32)	14 (50)	13 (31)	

Summary/Conclusions: In this retrospective, real-life experience, long-term use of 2G-TKIs in ≥2nd line of treatment after imatinib failure resulted in more than half of patients achieving the "safe haven" of deep MR, with around 60% of them in stable MR^4, a prerequisite for discontinuing treatment.

PB1819

MTOR INHIBITION IN CML: A NEW THERAPEUTIC OPTION

RS Alves[1,2,3], AC Gonçalves[1,2,3], P Couceiro[2,4], P Rodrigues-Santos[2,4], P Freitas-Tavares[5], L Ribeiro[5], A Almeida[6], AB Sarmento-Ribeiro[1,2,3,5,*]
[1]Laboratory of Oncobiology and Hematology, Faculty of Medicine, University of Coimbra (FMUC), Portugal, [2]Center of Neurosciences and Cell Biology/Biomedical Institute of Investigation of Light and Image (CNC.IBILI), University of Coimbra, [3]Center of Investigation in Environment, Genetic and Oncobiology (CIMAGO), [4]Immunology, Faculty of Medicine, University of Coimbra (FMUC), Portugal, [5]Clinical hematology department, Centro Hospitalar Universitário de Coimbra (CHUC), Coimbra, [6]Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E., Lisboa, Portugal

Background: *BCR-ABL1* fusion gene, which encodes an oncoprotein with a deregulated tyrosine kinase activity, is the hallmark of chronic myeloid leukemia (CML) – a myeloproliferative disorder. Despite the high rate of response to treatment with Imatinib and other tyrosine kinase inhibitors (TKI), the number of patients with suboptimal response or resistance to TKI has been increased. The BCR-ABL oncoprotein activates multiples signaling pathways responsible for tumor cells characteristic, namely the high cellular proliferation rate and resistance to apoptosis. One of these pathways is the PI3K/AKT/mTOR pathway, which is correlated with the increase in cell survival and resistance to apoptosis. Leukemic stem cells use these pathways as a mechanism of defense against treatment and as tumor maintenance.
Aims: The aim of this study was to evaluate the therapeutic potential of the mTOR inhibitor, Everolimus, in CML cell lines sensitive and resistant to TKI and in primary cultures of CML patients.
Methods: For this purpose, we used a CML cell line sensitive to Imatinib, the K562 cells, and established two sub-cell lines resistant to Imatinib, the K562-RC and K562-RD cells. Cell lines were treated in the absence and presence of different concentrations of Everolimus and the effect in cell viability was analyzed by the resazurin assay. Cell death was determined by flow cytometry (FC) using the Annexin V/Propidium Iodide staining. The cell cycle analysis was accessed using Propidium Iodide incorporation by FC. *Ex-vivo* studies were performed in peripheral blood samples of 56 patients under TKI treatment. In our cohort, 52 (93%) patients presented molecular response and 4 (7%) cytogenetic response. Moreover, 39 (74%) patients were treated with Imatinib, and 14 (26%) with 2nd or 3rd generation TKI. Patients' samples were culture with increasing concentrations of Everolimus during 48h. Cytotoxic effect was evaluated by FC in different cell populations using Annexin V staining.

Results: Our results show that Everolimus induced a reduction in cell lines viability, with an IC50 of 20μM for sensitive cells and 25μM for Imatinib resistant cell lines. The cell death was induced by apoptosis and this drug has also an antiproliferative effect through an arrest in cell cycle progression in G_0/G_1.
In *ex-vivo* studies, Everolimus reduced cell viability by increasing apoptosis of hematopoietic stem cells ($CD34^+$cells) without cytotoxicity to lymphocytes. In the the dose of 25 μM this mTOR inhibitor induced in CD34 cells an increase of 19% of these cells positive to annexin V compared with control, and only 8% of lymphocytes are in apoptosis. Comparing the response to TKI treatment with sensibility to Everolimus, we observed a tendency to higher efficacy in patients with cytogenetic response (CR) comparing with patients under molecular response (MR) (24,5% *vs* 18,7% of CD34 cells positive to annexin V). When compared patients under Imatinib treatment *versus* patients treated with 2nd or 3rd generation TKI, we observed a better response to Everolimus in the second group, also associated with lower toxicity to lymphocytes.
Summary/Conclusions: Our results reveal the efficacy of Everolimus in inducing cell death in CML cells, without cytotoxicity to normal cells, suggesting that Everolimus could be an alternative targeted therapeutic approach in CML patients. However, it is important to increase the number of patients in the study to confirm our results.
This work was support by CIMAGO (Project 18/12) and R.A. was supported by FCT with a PhD grant (SFRH/BD/51994/2012).

Background: Even though they were approved last June 2011 to be used on first line, it is not a common procedure to begin treatment of CML-CP with 2G-TKI, despite it has been demonstrated its efficacy and safety against imatinib on ENESTnd and Dasision clinical trials.
Aims: To describe the RALMC experience in terms of efficacy and safety of 2G-TKI on first line of treatment in CML-CP in real life evidence.
Methods: Descriptive analysis of 73 RALMC patients, treated from the outset in 18 hospitals of Andalusia (Spain) with nilotinib and dasatinib from June 2011 out of clinical trials. Results of BCR ABL are expressed in IS by means of GenXpert system. Responses are cataloged according to the 2013 ELN group guidelines. Toxicity of each treatment, overall survival (OS), failure free survival (FFS), event free survival (EFS) and progression free survival (PFS) were evaluated. Event was defined as death from any cause, progression to accelerated phase (AP) or blast crisis (BC), loss of CCgR or MMR and change of treatment for any reason.
Results: Median of 49 years of age (18-78) and median of follow-up of 38 months (3-56). 59% male, 41% female. 54% low, 26% intermediate, 20% high Sokal index. 79% low, 21% high Eutos score (n 63). Treatment of first line: nilotinib 46 (63%), dasatinib 27 (37%). Probability of achieving CCgR at 6 months was 100% (54 of 54 evaluated patients). Probability of achieving MMR at 12 months was 85,7% (54 of 63 evaluated patients) and MMR at 18 months 93,4% (57 of 61 evaluated patients). Depth of the responses are detailed in the Table 1. No statistically significant differences are found between both treatments as they achieve MMR in months 12 and 18. In our patients treated with 2G-TKI in first line, probability to obtain BCR ABL ≤10% in month 3 (65 evaluated patients) was 100% and ≤1% of 77% (50 of 65 evaluated patients). In both branches of treatment, 77% of patients obtained rates of BCR ABL ≤1% (30 patients of 39 evaluated with nilotinib and 20 of 26 with dasatinib). Overall median value of BCR-ABL at 3 months was 0.16% (0.22% nilotinib, 0.15% dasatinib). Probability to achieve MMR in month 12 if BCR ABL in month 3 was <1.5% is of 94% as opposed to BCR ABL ≥1.5% which is 55% (p-value 0.001). Only one death is reported on the dasatinib branch (death related with CML). EFS with nilotinib was 85.5%, and 74.4% with dasatinib. FFS with nilotinib was 89.9% and 86.1% with dasatinib; there is no statistically significant differences between both treatments in terms of EFS and FFS (p-value 0.28 and 0.73 respectively). No patient of the series progresses to AP or BC. 12 treatment changes are carried out; 5 due to toxicity (7%): 2 with nilotinib (1 neutropenia, 1 dermatological toxicity) and 3 with dasatinib (1 pleural effusion, 1 thrombocytopenia, 1 ocular thrombosis). 7 treatment changes due to lack of efficacy (9.5%): 4 failures due to CCgR loss, 2 dasatinib and 2 nilotinib (mutational study was positive with nilotinib: 1 E308V and 1 T315I mutation), 2 fails due to MMR loss (1 dasatinib, 1 nilotinib) and 1 change from nilotinib to dasatinib in month 9 due to warning.

Table 1.

Evaluated responses at 12 month (n 63)					
TKI	**CCgR**	**MMR**	**MR 4.0**	**MR 4.5**	**MR 5.0**
Nilotinib	7 (18.4%)	8 (21.1%)	7 (18.4%)	11 (28.9%)	5 (13.2%)
Dasatinib	2 (8%)	6 (24%)	6 (24%)	7 (28%)	4 (16%)
MR at 12 month according BCR ABL at month 3, n 59 (p-value 0.001)					
BCR ABL ratio		**No MR**		**MMR**	
< 1.5%		3 (6.25%)		45 (93.75%)	
≥ 1.5%		5 (45.455)		6 (54.54%)	

Summary/Conclusions: The use of nilotinib and dasatinib as first-line treatment is consolidated as an excellent therapeutic alternative to CML-CP. Showing with our series the efficacy and safety of 2G-TKI, with high rates of cytogenetic and molecular responses, deep and early, and low rates of toxicity carrying over treatment changes. The cutoff point of BCR ABL in month 3 of 1.5% could determines the optimal response in month 12 as soon as they achieve MMR.

PB1821

OPTIMIZATION OF RADOTINIB DOSES BASED ON DOSE-EFFICACY AS WELL AS DOSE-SAFETY RELATIONSHIP ANALYSES FOR NEWLY DIAGNOSED PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA

H Noh[1,*], SY Jung[2,3], JY Kwak[4], SH Kim[5], SJ Oh[6], DY Zang[7], HL Park[8], DJ Cho[8], DW Kim[9], J Lee[2,3]
[1]Department of Pharmacy, College of Pharmacy, Yonsei University, Incheon, [2]Department of Pharmacy, College of Pharmacy, Seoul National University, [3]Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, [4]Chonbuk National University Medical School & Hospital, Jeonju, [5]Department of Internal Medicine, Dong-A University College of Medicine, Busan, [6]Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, [7]Department of Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, [8]Central Research Institute, IL-YANG Pharm. Co., Ltd., Yongin, [9]Seoul St. Mary's Hospital, Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Radotinib is a selective second generation BCR-ABL1 tyrosine kinase inhibitor approved for the treatment of chronic myeloid leukemia (CML). In the previous dose-safety relationship analyses (Leuk Lymphoma. DOI 10.3109/10428194.2015.1113278), a positive association was found between the radotinib dose adjusted for the patient's body weight (Dose/BW) and the risk of dose-limiting toxicity (DLT). Hence, a weight-based dosing method was suggested to improve the safety outcomes of radotinib.
Aims: To explore an optimal radotinib dosing regimen for the treatment of chronic phase (CP) CML based on the dose-efficacy as well as dose-safety relationship analyses of Phase 3 study data
Methods: The Phase 3 data were derived from a total of 160 newly diagnosed patients with CP CML treated with radotinib 300 mg BID or 400 mg BID (fixed dose regardless of BW). A logistic regression analysis was conducted to assess the impact of Dose/BW of radotinib on the achievement of major molecular response (MMR) (dose-efficacy relationship) or occurrence of DLT (dose-safety relationship) within 48 weeks of treatment. Subsequently, an optimal Dose/BW cut-off was selected based on chi-square tests and Kaplan-Meier analyses with log-rank test.
Results: *Efficacy.* A statistically significant inverse relationship was found between Dose/BW and the probability of achieving MMR when gender was controlled for (p=0.033). A significantly higher rate of MMR was achieved in patients who received <6.5 mg/kg than ≥6.5 mg/kg (56% *vs* 34%; chi-square test, p=0.045). *Safety.* A statistically significant positive relationship was found between Dose/BW and the probability of DLT occurrence (p=0.003). Among various Dose/BW cut-offs, the greatest difference in the rate of DLT occurrence was observed between patients who received <6.5 mg/kg and ≥6.5 mg/kg (57% *vs* 91%; chi-square test, p <0.001) with the median time to first DLT being 194 days and 83 days, respectively (log-rank test, p <0.001). Therefore, Dose/BW of 6.5 mg/kg BID appears to be a threshold dose of radotinib below which the efficacy is improved as well as the risk of toxicity is reduced.
Summary/Conclusions: The results indicate the need for dose adjustment of radotinib according to the patients' individual BW. Based on the proposed cut-off of Dose/BW 6.5 mg/kg BID, the radotinib doses for patients weighing ≤60 kg and >60 kg are suggested to be 300 mg BID and 400 mg BID, respectively. A randomized well-controlled clinical trial would be needed to confirm the efficacy and safety of this weight-based dosing strategy.

REAL-WORLD DATA FROM 54 BELGIAN PATIENTS FROM THE PONATINIB NAMED PATIENT PROGRAMME (NPP)

L Knoops[1], G Verhoef[2], Z Berneman[3], D Selleslag[4], N Straetmans[5], L Noens[6], P Lewalle[7], M André[8], D Pranger[9], P Zachee[10], E Strobbe[11], LJ McGarry[11], T Devos[2,*]
[1]Cliniques Universitaires Saint-Luc, UCL, Brussels, [2]University Hospitals Leuven, Leuven, [3]University Hospital of Antwerp, Antwerp, [4]AZ Sint-Jan Brugge-Oostende, Brugge, [5]Jolimont, Haine St. Paul, [6]Ghent University Hospital, Ghent, [7]Institut Jules Bordet ULB, Bruxelles, [8]UCL Mont Godinne, Yvoir, [9]GHdC, Charleroi, [10]Ziekenhuis Netwerk Antwerpen Stuivenberg, Antwerp, Belgium, [11]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: Ponatinib is a tyrosine kinase inhibitor (TKI) indicated for adult patients with refractory chronic- (CP), accelerated- (AP), or blast-phase (BP) chronic myeloid leukemia (CML) and Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ALL), or those with the T315I mutation. Fifty-four patients from 17 Belgian centres entered the ponatinib Named Patient Programme (NPP) from August 2012 through September 2015.
Aims: To provide evidence of the efficacy and safety of ponatinib in real-world Belgian patients.
Methods: Limited patient data were collected prospectively for patients enrolled in the NPP, based on a questionnaire approved by the Ethics Committee of the Cliniques Universitaires Saint-Luc. Demographic data are presented for all patients, and efficacy and safety data for patients recruited from August 2012 through June 2015 with at least 3 months of follow-up. All patients provided informed consent.
Results: Patients with CP-CML (N=35), AP/BP CML (N=5) or Ph+ALL (N=14) had a median age of 62 years; 89% were in ≥3rd-line of TKI therapy. Mutation analysis revealed baseline mutations in 43% of CP-CML and 83% of Ph+ALL patients; 42% and 40% of mutations were T315I. Of CP-CML patients 63% received a starting dose of 45mg/day, 29% 30mg/day and 8% 15mg/day. Dose reductions occurred in 42% of CP-CML patients: 29% due to adverse events and 13% to prevent cardiovascular complications after achieving response. For Ph+ALL patients, starting doses were 45 mg/day (69%), 30 mg/day (23%), and 15 mg/day (8%). Among 27 CP-CML patients with outcome data, 10 patients stopped ponatinib within 3 months due to: disease progression (n=2), thrombocytopenia (n=2), gastrointestinal complaints (n=2), cutaneous lesions, uncontrolled hypertension, ischemic CVA and planned allotransplant (n=1 each). Best responses in CP-CML patients treated beyond 3 months were: major molecular response (MMR; n=10), complete cytogenetic response (CCyR; n=3), partial cytogenetic response (PCyR; n=2), and complete hematologic response (CHR; n=2). Four of 17 CP-CML patients discontinued due to disease progression (n=2) and vascular occlusive events (toe necrosis after 19 months [n=1]; cardiac death after 14 months [n=1]). Thirteen CP-CML patients remain on treatment (median: 17 months; Figure 1). Among 10 evaluable Ph+ALL patients, 4 achieved MMR, 3 of whom remain in remission after 15, 24 and 33 months.

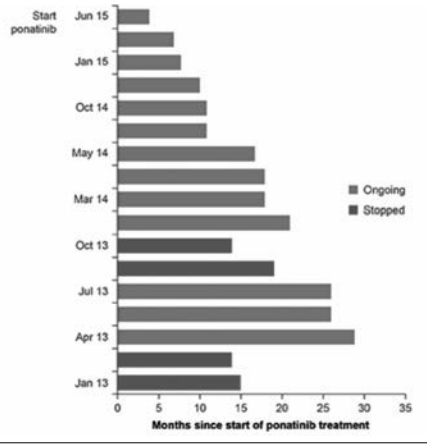

Figure 1. Treatment duration for 17 patients with CP-CML that continued ponatinib treatment beyond 3 months.

Summary/Conclusions: Despite limited data, ponatinib appears efficacious in the Belgian NPP; results appear comparable to the PACE clinical trial, which included resistant or intolerant CML and Ph+ALL patients.

PB1823

PREDICTORS FOR 12-MONTH MAJOR MOLECULAR RESPONSE IN CP CML PATIENTS WHO FAILED 3-MONTH EARLY MOLECULAR RESPONSE WITH IMATINIB THERAPY

SE Lee[1,*], SY Choi[2], SH Kim[2], HY Song[2], HL Yoo[2], MY Lee[2], HJ Hwang[2], KH Kang[2], KM Kee[2], EJ Jang[2], DW Kim[1,2]
[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Catholic Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Recent studies have demonstrated that measurements of BCR-ABL1 transcript levels at 3 months were able to identify high-risk patients treated with imatinib (IM). However, the value of early molecular response (EMR) has not been fully defined. Until now, whether no achievement of BCR-ABL1 transcripts ≤10% after 3 months of treatment is sufficient to define failure necessitating a change of treatment remains obscure.
Aims: The aim of this study was to identify predictive factors for an achievement of 12-month major molecular response (MMR) in the patients who failed 3-month EMR, as additional information to guide clinical decisions on selecting high-risk patients.
Methods: Among 413 newly diagnosed CP CML patients who received IM with no prior treatment and had available molecular data at 3 months, 120 (29.1%) patients failed to achieve 3-month EMR. Finally, to identify predictive factors for an achievement of 12-month MMR, 94 patients with available decision for 12-month MMR were included in this study. All qRT-PCR were tested with at least 4.5-log sensitivity in a single laboratory (Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea).
Results: Ninety-four newly diagnosed CP CML patients (including 69 men and 25 women) were analyzed. With a median age of 36 years (range, 14-73 years), the distribution of low, intermediate, and high Sokal risk scores were 30%, 42% and 25%, respectively, with 4% unknown risk. 16 (17%) patients of the patients who did not achieve a 3-month EMR had MMR at 12 months, while 78 (83%) patients failed to achieve MMR at 12 months. Univariate analyses revealed that female sex, transcript type of b3a2, >0.65 of log reduction of BCR-ABL1 from individual baselines to 3 months, and smaller spleen size were potential predictive factors for an achievement of 12-month MMR. After adjusting for factors affecting achievement of 12-month MMR on univariate analyses, multivariate analyses showed that transcript type of b3a2, compared to b2a2 (RR of 0.09, *P*=0.022) and >0.65 of log reduction of BCR-ABL1 from individual baselines to 3 months (RR of 5.75, *P*=0.031) were independent factors for the achievement of 12-month MMR. The patients with larger spleen size showed a trend for no 12-month MMR (RR of 0.82, *P*=0.057).
Summary/Conclusions: This study analyzed various predictive factors for an achievement of 12-month MMR in the patients group who failed 3-month EMR. It provides additional information on selecting high-risk patients necessitating a change of treatment. Base on our findings, the patients with transcript type of b2a2, larger spleen size, and ≤0.65 of log reduction of BCR-ABL1 from individual baselines to 3 months need a clinical decision of changing therapy according to the results of qRT-PCR at 3 months. Further clinical investigations in a larger patient population with longer follow-up are needed.

PB1824

REAL-WORLD TREATMENT OF CHRONIC MYELOID LEUKEMIA (CML) IN PATIENTS WHO FAILED ≥2 PRIOR TYROSINE KINASE INHIBITORS (TKIS) AMONG US COMMUNITY ONCOLOGISTS

B Feinberg[1], J Kish[1], J Laney[1], U Mujumdar[1], L McGarry[2], H Huang[2,*]
[1]Cardinal Health, Dublin, [2]Ariad Pharmaceuticals, Cambridge, United States

Background: In the era of tyrosine kinase inhibitors (TKIs) most (chronic phase) CP-CML patients can expect to achieve excellent response with 1st-line (1L) therapy. However, in those who relapse, as many as one-third will not achieve a major molecular response in 2nd line (2L), and over time, up to one-half relapse. Lipton *et al.* (*Leuk Res, 2015)* reported that for CP-CML patients receiving a 3rd line (3L) TKI, sequential treatment with a 2nd-generation (2G) TKI after a prior 2G TKI failure is effective in only 22-26% of patients. Understanding real-world patterns of care and outcomes in this poor prognosis subset of CML patients is critical to developing new treatment strategies.
Aims: To document treatment patterns and measure real-world duration of treatment (DOT) across therapy lines in CML patients who were treated with ≥2 prior TKI lines.
Methods: In a retrospective study, the Navigating Cancer® electronic medical record (EMR) database was used to examine treatment patterns and estimate the benefit of TKI therapy in real-world practice. This database is comprised of community oncologists across the US. Patients with an ICD-9 code for diagnosis of CML, between August 2001-August 2015, who were treated with ≥2 prior lines of TKIs from pharmacy records were included. Patients included were ≥18 years of age at index date (initiation of 3L treatment), with no prior history of concomitant treatment for secondary cancers. Disease phase was reported in clinical progress notes. Line of therapy (LOT) was assigned for each specific regimen. Treatment discontinuation was defined as a gap in therapy of >90 days. As a surrogate for treatment benefit, DOT was calculated from prescription dates and days of therapy dispensed.
Results: One-hundred and fifty two CML patients met all inclusion criteria: 51% were female, and 67% Caucasian (16% unknown), with a mean age at index date of 58.7 years (23-88 years). Disease phase was available for 85 patients, among whom 64 were in CP-CML at most recent follow-up. For all 152 patients, the median DOT was 2.98 months in 1L, 1.01 months in 2L, and 5.45 months in 3L. For the 64 CP-CML, 3L DOT was 7.89 months. The most common treat-

ment sequence for the first 3 lines was imatinib/dasatinib/nilotinib (observed in 20% of patients). 61% of 3L therapy received 2G agents (24% dasatinib, 28% nilotinib, 9% bosutinib), 30% received imatinib, and 9% received ponatinib. Among 3L patients, 35% discontinued treatment and 38% progressed to 4-6 total lines. Most common 4L treatment was dasatinib (33%) followed by imatinib (24%), ponatinib (16%) and nilotinib and bosutinib (both 14%). 52% of all 4L TKI use was in patients who had received the same drug in an earlier LOT.
Summary/Conclusions: Our analysis affirms the limited effectiveness of current therapies in patients who relapse after 2LTKI for CP-CML. Use of 2G TKI and imatinib in 3L remains common among community oncologists. Our analysis identifies a subset of CML patients who not only fail quickly after TKI initiation, but subsequent 2G TKI treatment has short DOT. A variety of treatment sequences were observed across patients in ≥3L, and early switching of therapy appears common, suggesting an absent standard of care. In addition, the observed 52% repeat use of TKI in 4L suggests significant unmet need. More research into understanding the optimal treatment of these poor prognosis patients is needed to address the unmet clinical need.

PB1825

STEPWISE DOSE ESCALATION METHOD FOR NILOTINIB STOP TRIAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (STEP STOP TRIAL): A MULTICENTER PHASE 2 TRIAL

K Ota[1,*], T Akagi[1], K Yamagata[2], K Mayama[2], T Fujii[1], K Kamata[3], S Fukuda[2], K Kubo[1]
[1]Hematology, Aomori Prefectural Central Hospital, Aomori City, [2]Gastoroenterology and Hematology, Hirosaki University Graduate School of Medicine, [3]Gastoroenterology and Hematology, Hirosaki National Hospital, Hirosaki City, Japan

Background: The STIM trial, stood in innovative point of view, indicate that imatinib may be successfully stopped in patients with deep molecular responses. Subsequently, the feasibility of various TKIs discontinuation trials have been investigated. The most important factor in TKIs discontinuation trials is the molecular response of BCR-ABL. The molecular response affected by many factors, such as Sokal score, percentage of basophil, additional chromosome anomaly and so on. Another important factor for the success of TKIs stop study is adverse events of TKIs itself. Several patients are not able to continue the TKIs by the adverse events.
Aims: Stepwise dose escalation method of NIL improved the proportion of patients who had treatment free Remission or not. A prospective, multicenter, single-arm phase 2 trial was conducted.
Methods: The Stepwise Dose Escalation Method for Nilotinib Stop trial in Patients with Chronic Myeloid Leukemia (Step Stop trial) was a prospective, multicenter, single-arm phase 2 trial. Adult CML-CP patients with newly diagnosed or experienced TKIs (imatinib, dasatinib or nilotinib) was enrolled. The first half of this study was "stepwised induction (achieve CMR) and consolidation (for 2 years) phase", stepwise dose escalation of NIL was conducted to avoid discontinuation of NIL by the adverse events. And the second half was "stop and monitoring phase".Eligible patients were administered nilotinib with stepwise dose escalation method, *i.e.* 150 mg per day for 2 weeks, 300mg per day for 2 weeks, 450mg per day for 2 weeks, and a final dose, 600 mg per day was continued. After achieve MR4.5, patients was received nilotinib consolidation therapy for 2 years. The primary end point was the proportion of patients who had treatment free remission at 12 months from the final day of the administration. The trough levels of NIL were examined and relapse was defined as a loss of MMR.
Results: Between November 2013 and August 2015, 26 patients was enrolled. 22 patients were previous treated and 4 patients were newly diagnosed. 16 patients were male and 10 patients were female. A median age was 55.2 years old (range 30-79). 21 patients were PS0, and 5 patients were PS 1. No patients were dropped out of stepwise Dose Escalation phase and consolidation phase. A total of 21 pts were found adverse events (81%), and 14 pts were found cutis such as itching and rash (54%). No severe adverse event was found and tolerability for NIL administration was 100%.No significant changes were found in the peripheral Lymphocytes count (CD3+, CD19+, and CD16+56+), but NK activities were significantly increased between before and after treatment by NIL (n=25, Before:6.184(%), After 9.48(%),. %: +53%, p-value 0.004).
Summary/Conclusions: The sustainable rate of the chemotherapy by NIL for CML-CP was 100% by the stepwise dose escalation method. These method may improve CML treatment. NK activities might be induced by NIL. Primary endpoint of this study,the proportion of patients who had treatment free remission at 12 months, would be presentated at EHA after day.

PB1826

IMMUNOMODULATORY EFFECT OF DASATINIB THERAPY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

M Cioch*, P Jarosz, D Jawniak, A Goracy, M Wach, E Wasik-Szczepanek, M Hus
Department of Haematooncology and Bone Marrow Transplantation, Medical University in Lublin, Lublin, Poland

Background: Dasatinib is a second generation tyrosine kinase inhibitor (TKI), widely used in patients (pts) with chronic myeloid leukemia (CML), especially in failure after imatinib. The quite often side effect of dastinib is lymphocytosis and pleural effusion (PE). These phenomenons are probably connected with immunological mechanisms.
Aims: The aim of our study was analysis of the influence of three presently used TKIs: imatinib, nilotinib and dasatinib on different populations of lymphocytes: B cells (Bc), T helper (Th), T suppressor (Ts), T regulatory (Treg), NK cells (NKc) and NKT cells (NKTc).
Methods: A total 37 pts with CML from Department of Haematology and Bone Marrow Transplantation in Lublin were recruited to this study. There were 17 pts on imatinib therapy (imatinib group; IG), 10 pts on nilotinib therapy (nilotinib group; NG) and 10 pts on dasatinib therapy (dasatinib group; DG). As control group there were 23 healthy volunteers. Material for the analysis was vein blood collected from CML pts after minimum 3 months of TKIs therapy. Blood samples were used for the evaluation of lymphocyte count and its immunophenotype to distinguish such subpopulataions as: Bc, Th, Ts, Treg, NKc and NKTc.
Results: Patients treated with dasatinib had significantly higher median number of lymphocytes in blood (3.59 G/L) compared with pts treated with nilotinib (2.31 G/L; p<0.01) and imatinib (1.93 G/L; p<0.001). The median CD19+expression (Bc) in comparison with control group was significantly lower in DG than in IG and NG (p=0.00039). There was no significant difference in Th, Ts and NKTc antigens expression. The analysis showed that in DG there was significantly higher expression of NKc antigens (CD3-CD16+CD56+) compared with control group than in IG and NG (p<0.05). The expression of Treg antigens (Foxp3+CD4+CD25high) was significantly lower in DG compared with control group than in IG and NG (p<0.001).
Summary/Conclusions: The results of our study showed immunomodulatory effect of dasatinib therapy in pts with CML manifested by increase of lymphocyte count and NK cells and decrease of Treg and B cells. This action of dasatinib is associated with such immunological phenomenon as PE and may be considered as additional factor influencing on better clinical response.

Background: 2013 ELN recommendations defined endpoints in the treatment of chronic myeloid leukemia patients, introducing the concept of early molecular and warning response, but did not provide precise indications on timing of possible early switch to overcome negative prognosis.
Aims: Aim of our study is to evaluate how Italian physicians are adherent to ELN recommendations and how the different use of available TKIs would have changed therapeutic strategies.
Methods: We collected 218 patients treated consecutively, outside clinical trials, in 13 different Italian centers.
Results: There were 124 males and 94 females, median age 58 years (range 18-90), 20 patients with a previous neoplasia. Ten patients had at baseline ACA (6 major routes). According to Sokal risk, 50% of patients were low, 35% were intermediate and 16% were high risk. According to Eutos risk, 87% were low and 13% were high risk. As frontline treatment 55 patients received dasatinib (52 patients started with 100 mg, 3 at reduced dose), 82 patients received nilotinib 300 mg BID and 81 patients started imatinib (67 patients at 400 mg, 14 at <400 mg). Median age and comorbidities at baseline strongly influenced choice of TKI at baseline. At 3 months, in the dasatinib-treated cohort, 81% of patients were classified as optimal responders and 7% were warning but none of them changed therapy, due to concomitant comorbidities or toxicity experienced that allowed modification of dose. At 6 months, 84% of patients were in the optimal response category, 6% in the warning response (none of them changed) and 4% in failure category (1 patient increased the dose to 140 mg/day). At 12 months, 72% were in the optimal category, 25% in the warning category (none of them changed due to BCR-ABL/ABL ratio slightly above 0.1%) and 6% were in failure category (1 patient switched to nilotinib). At 3 months, in the nilotinib-treated cohort, 90% of patients were classified as opti-

mal responders and 4.8% as failure (1 patient switched to dasatinib). At 6 months, 87% of patients were optimal, 6% warning (none of them changed) and 3% were failure (only 1 patient switched to dasatinib). At 12 months, 80% were in the optimal category, 16% in the warning category (none of them changed due to a ratio BCR-ABL/ABL slightly above 0.1%) and 9% in the failure category (1 patient switched to dasatinib and 1 patient switched to ponatinib). In the imatinib-treated cohort, at 3 months, 74% of patients were classified as optimal responders, 16% patients were warning (5 switched to second-generation TKIs), 3.7% were failure (2 switched to other TKIs). At 6 months, 72% of patients were in the optimal category, 27% were in the warning category (1 patient only changed therapy) and 3% were failure (only 1 patient switched to dasatinib). At 12 months, 52% were in the optimal category, 32% were warning category (none of them changed due to comorbidities) and 15% were in failure category (3 patients switched to nilotinib or dasatinib, 1 patient to high dose imatinib). Cytogenetic analysis at 6 and 12 months was not performed in 40% of patients already in MR3.

Summary/Conclusions: The results of this retrospective analysis indicated that with frontline second-generation TKIs, warning and failure category were reduced at 3 and 6 months and that with this approach, Italian physicians were less likely to perform an early switch.

PB1828

COMBINATION OF HEMOGLOBIN LEVEL AT PRESENTATION WITH MOLECULAR RESPONSE AT 3 MONTHS BETTER PREDICTS SURVIVALS AND DEEP MOLECULAR RESPONSE TO IMATINIB IN CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA PATIENTS

PS Ko[1,2,*], YB Yu[1,2], CY Liu[2,3], CJ Liu[1,2], LT Hsiao[1,2], YC Liu[1,2], CH Tzeng[1,2], TJ Chiou[2,4], JP Gau[1,2], PM Chen[1,2], JH Liu[1,2]

[1]Division of Hematology, Taipei Veterans General Hospital, [2]Faculty of Medicine, National Yang-Ming University, [3]Department of Oncology, [4]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, ROC

Background: Anemia at presentation is not uncommon in newly diagnosed chronic-phase chronic myeloid leukemia(CP-CML). However, hemoglobin level at diagnosis of CP-CML is not included in the formulas for calculating three scoring systems, namely Sokal, Hasford and EUTOS scores, for predicting survival outcomes. To our best knowledge, studies on the prognostic values of hemogobin levels at diagnosis of CP-CML were scarce, especially in association with survial outcomes and treatment responses.

Aims: We retrospetively collected data from consecutively newly diagnosed CP-CML patients treated with Imatinib to explore the value of hemoglobin level at presentaiton in predicting survival outcomes and treamtment responses as compared with current scoring systems.

Methods: A cohort of 154 newly diagnosed CML-CP patients treated with frontline Imatinib was surveyed retrospectively from January 2001 to April 2014. The cut-off value of baseline hemoglobin (Hb) level at diagnosis was defined as 10.0 g/dl arbitrarily. The influence of severe anemia (Hb<10.0 g/dl) and three CML scoring systems (Sokal, Hasford, and EUTOS) at diagnosis on treatment response landmarks, progression-free survival (PFS), event-free survival (EFS) and overall survival (OS), were examined by univariate and multivariate analyses. The discriminatory abilities of three prognostic models and baseline characteristics were examined by using the Cox proportional hazards model, and the consequences of the Cox model were expressed with the Akaike information criterion (AIC), which revealed how the EFS, PFS and OS were affected. The model with lower AIC is more explanatory and informative.

Results: Severe anemia with Hb<10.0 g/dl was identified in 43 (27.9%) of 154 newly diagnosed CP-CML patients treated with Imatinib. Patients with Hb<10.0 g/dl was associated with splenomegaly (76.7% *vs* 52.3%, *p*=0.006), high EUTOS risk (37.2% *vs* 16.2%, *p*=0.005), high Sokal score (48.8% *vs* 22.5%, *p*=0.001), high Hasford score (27.9% *vs* 7.2%, *p*=0.001), additional chromosomal abnormalities (25.6% *vs* 12.6%, *p*=0.049) but not associated with gender. Hb<10.0 g/dl was associated with higher white blood cell count (median=177.4 *vs* 88.6, *p*<0.001), blast percentage in peripheral blood (PB)(median=2.0% *vs* 1.0%, *p*=0.002), and eosinophil percentage in PB (3.0% *vs* 2.0%, *p*=0.038), but not assciated with MCV, basophil percentage in PB or platelet counts. Patients with Hb<10.0 g/dl had less favorable treatment responses including *BCR-ABL*≦10% at 3 months (51.2% *vs* 68.5% in Hb≧10.0 g/dl, *p*=0.045), complete cytogenetic response at 6 months (19.0% *vs* 50.5% in Hb≧10.0 g/dl, *p*<0.001), and major molecular response at 12 months (22.5% *vs* 45.2%in Hb≧10.0 g/dl, *p*=0.009). Furthermore, Hb at 10.0 g/dl could significantly distinguish EFS, PFS and OS with lower AIC value as compared with EUTOS, Hasford and Sokal scores. Moreover, combination of *BCR-ABL*≦10% at 3 months with Hb≧10.0 g/dl at presentation, it could predict the patients with better EFS, PFS, and OS and deeper molercular responses (MR4.5) (Figure 1).

Summary/Conclusions: Severe anemia (Hb<10.0 g/dl) at presentation was associated with less favorable treatment responses, poor EFS, PFS and OS in newly diagnosed CP-CML patients treated with frontline Imatinib. Combination of Hb≧ 10.0 g/dl at presentation with early molecular resposne (BCR-ABL≦10%) a 3 months, it could better predict survival outcomes and cumulative incidence of deep molecular response (MR4.5) as compared with current three scoring systems. Our study highlights the need for revisiting traditional CML scoring systems in the TKI era and suggests that CP-CML patients with Hb level≧ 10.0 g/dl at presentation and with early molecular response at 3 months might respond to Imatinib well thereafter.

Background: Elderly patients are a substantial proportion of chronic myeloid leukemia (CML) patients (22% in a population-based registry study performed in Europe) (Hoffman V *et al.,* Leukemia 2015;29:1336-43) but are under-represented and selected in academic and commercial studies. Their treatment and their outcome are poorly known.

Aims: To investigate the treatment, response and outcome in an unselected cohort of elderly patients with newly diagnosed chronic phase (CP) CML.

Methods: In a cohort of 337 newly diagnosed, adult, CP, Ph+,BCR-ABL1+, CML patients who were registered according to the population-based criteria in two Italian Regions (Emilia-Romagna and Sicily) between 2008 and 2012, we identified 85 patients (25%) who were ≥70 years old. Five of them were treated only with hydroxyurea (HU); 17 of them were treated in first-line with nilotinib. We report here on the 63 patients who were treated in first-line with imatinib, 400 mg once daily.

Results: Males were 54%. Median age at diagnosis was 77 years (range 70-95). Median follow-up was 48 months (range 30-65), so that median patients age at data analysis was 81 years. Sokal risk distribution was 3% low, 56% intermediate, and 41% high. 41 patients (65%) received only imatinib. 14 patients (22%) were switched to a 2nd generation TKI for failure. 8 patients

were switched to a 2nd generaion TKI (n=5) or to HU (n=3) for toxicity. Responses and outcomes are shown in the Table 1. Molecular responses (early molecular response, major molecular response, and deeper molecular response) were in the range reported for younger patients in prospective studies of treatment. Overall survival was poorer, because 19% of patients died in MMR or in CP without any evidence of progression, due to age-related complications, mainly cardiovascular and cerebrovascular.

Table 1.

No. of patients	63
Early molecular response (BCR-ABL1 ≤ 10%) at 3 months	76%
MMR or better (BCR-ABL1 ≤ 0.1%) by 1 year	53%
MMR or better (BCR-ABL1 ≤ 0.1%) by 4 years	74%
MR 4.0 or better (BCR-ABL1 ≤ 0.01%) by 4 years	53%
Failure@ (including progression to blast phase@)	27%
Progression to blast phase/death in blast phase	9%
Death in remission or in chronic phase@	19%
Deaths, total	28%
@As defined by European LeukemiaNet, 2009	

Summary/Conclusions: These data reinforce the concept that in CML age is not a barrier to the success of a targeted therapy.

PB1830

THYROID DYSFUNCTION CAUSED BY SECOND-GENERATION TYROSINE KINASE INHIBITORS IN PHILADELPHIA CHROMOSOME-POSITIVE CHRONIC MYELOID LEUKEMIA

E Tothova[1,*], A Kafkova[2], L Stejskal[3], R Hajek[4]
[1]Dpt of Clinical and Medical Biophysics, University UPJS, Kosice, Slovakia, [2]Dpt. Oncohematology, HEMKO I.t.d, Kosice, Slovakia, [3]Hematooncology, University of Ostrava, [4]Hematooncology, Universtity of Ostrava, Ostrava, Czech Republic

Background: Protein tyrosine kinase inhibitors (TKI) are currently an important drug class in the treatment of leukemia. They represent targeted cancer therapy and have become the treatment of choice in chronic myeloid leukemia (CML). Many studies clearly have demonstrated that they were able to induce thyroid abnormalities including hypothyroidism and less often hyperthyroidism. Increased awareness and monitoring of thyroid function tests are important in patients maintained on TKIs. Thyroid dysfunction is a well-known adverse effect of first-generation tyrosine kinase inhibitors (TKIs), like sunitinib.
Aims: The aim of this study was to investigate the effect of second-generation TKIs on thyroid function in chronic myeloid leukemia (CML) patients treated in 2 centres.
Methods: We retrospectively assessed the effect of the first-generation TKI imatinib and the second-generation TKI nilotinib and dasatinib on thyroid function tests in 73 Philadelphia chromosome-positive (Ph-positive) chronic myeloid leukemia patients.
Results: Overall, 11 of 73 (15%) had one or more thyroid function test abnormalities during follow-up. Hypothyroidism or hyperthyroidism were found in 6 of 73 (8,2%) and 3 of 73 (4.1%) cases after a median of 6 and 22 weeks, respectively. In most patients thyroid dysfunction was transient without clinical symptoms. Therapy of hypo-/hyperthyroidism was required in three patients. Thyroid dysfunction never resulted in the discontinuation of TKI therapy. Under treatment with imatinib, nilotinib, and dasatinib, thyroid abnormalities were detected in 25%, 35%, and 40%, respectively. Three of 45 patients treated with nilotinib had evidence for an autoimmune thyroiditis (antibody positive in 2 of 3 patients) with an episode of hyperthyroidism preceding hypothyroidism.
Summary/Conclusions: Thyroid dysfunction is a common adverse event with second-generation TKI therapy in patients with Ph-positive chronic myeloid leukemia. Although the mechanism is still unclear, the higher frequency of thyroid abnormalities, including autoimmune thyroiditis, warrants regular and long-term monitoring of thyroid function in these patients.

ASSESSMENT OF THE MOLECULAR DISEASE LEVEL IN PATIENTS WITH BCR-ABL1 POSITIVE CML IN DENMARK AND ICELAND

N Pallisgaard[1,*], L Udby[2], IH Dufva[3], MT Severinsen[4], OW Bjerrum[5], OJ Bergmann[6], J Starklint[7], D Ronnov-Jessen[8], S Reykdal[9], J Stentoft[10]
[1]Pathology, [2]Hematology, Roskilde University Hospital, Roskilde, [3]Hematology, Herlev Hospital, Herlev, [4]Hematology, Aalborg University Hospital, Aalborg, [5]Hematology, Copenhagen University Hospital, Copenhagen, [6]Hematology, Esbjerg Hospital, Esbjerg, [7]Hematology, Holstebro Hospital, Holstebro, [8]Hematology, Vejle Hospital, Vejle, Denmark, [9]Hematology, National University Hospital of Iceland, Reykjavík, Iceland, [10]Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: Since the introduction of TKI treatment in CML in the beginning of this century, the expected survival of CML patients has increased substantially and is now close to the survival of the background population. Thus, the prevalence of CML has increased dramatically, and the number of patients in therapy, needing molecular monitoring increases accordingly. Whereas a large number of studies analyze the outcome of CML in cohorts, no population-based studies to our knowledge have focused on the distribution among the various TKIs and the molecular response.
Aims: The aim of this multicenter study was to measure the cross sectional molecular *BCR-ABL1* response in CML patients in a demographic area and to analyze the molecular response across the different treatments available along with the distribution of treatment duration.
Methods: All hematological centers in Denmark and Iceland were invited to participate. One blood sample was taken in two Paxgene tubes per CML patient after informed consent as part of a routine visit and shipped to central *BCR-ABL1* analysis in the EUTOS MR4.5 certified laboratory in Vejle along with information on date of birth, gender, current treatment, dose, start date and line of treatment.
Results: Eight out of ten hematological centers I Denmark participated in the study as well as the Icelandic center. Five of the centers included more than 95% of their CML patients and in total 360 samples were included. One blood sample was lost during preparation, and of the remaining 359 samples 354 samples fulfilled the EUTOS quality criteria for Molecular Response (MR) scoring (>24,000 *GUSB* copies per qPCR well). In the MR scoring system the patients were found to be 6.5% >MR2.0, 7.3% in MR2.0, 19% in MR3.0 (=MMR), 17% in MR4.0 (of which 55/59 were *BCR-ABL1* positive) and 50% in MR4.5 (of which 26/176 were *BCR-ABL1* positive). Thus 150 pt (42%) were *BCR-ABL1* negative and in MR4.5, indicating that the potential for TKI interruption was high in this population, predominantly treated with imatinib. The average and median age of the patient group at sampling time was 58.7 years and 61.0 years, respectively with a gender distribution of 57% males and 42% females. Of the 360 patients, 214 pt (59%) were in 1st line treatment, average duration 10.4 years (197/Imatinib, 4/Dasatinib, 12/Nilotinib and 1/NA); 97 pt (27%) were in 2nd line treatment, average duration 3.3 years (16/Imatinib, 47/Dasatinib, 28/Nilotinib, 5/TKI and/or interferon combinations and 1/Pause (*BCR-ABL1* negative); 33 pt (9%) were in 3rd line treatment, average duration 2.6 years (3/Imatinib, 8/Dasatinib, 18/Nilotinib, 3/Bosutinib and 1/Pause (*BCR-ABL1* negative); 10 pt (3%) were >3rd line treatment, average duration 1.1 year (1/Imatinib, 5/Dasatinib, 3/Bosutinib, 1/Ponatinib); 3 pt were transplanted; 1 *BCR-ABL1* positive pt had been in treatment free remission for 12 years; and 2 pt lacked information on treatment line.
Summary/Conclusions: This study describes in the Danish and Icelandic CML patient population the present distribution of treatment, treatment line and duration combined with molecular response.

PB1832

SAFETY AND EFFICACY OF PONATINIB IN REAL WORLD CLINICAL PRACTICE. RESULTS FROM THE SPANISH COMPASSIONATE USE PROGRAM. A GELMC STUDY

Background: In clinical trials, ponatinib has demonstrated excellent efficacy in heavily pretreated chronic myeloid leukemia (CML) patients. However, a high rate of vascular complications has been reported with the standard dose of 45 mg per day, and seems to be associated with previous cardiovascular (CV) risks. Hence, close safety monitoring and tapering of the dose have been recommended, although there are limited data supporting their benefit. Since patients included in clinical trials are a selected population, there is a need of real world data to properly assess the results of ponatinib treatment.

Aims: The purpose of this study is to provide safety and efficacy information from patients treated with ponatinib in real world clinical practice.
Methods: We have retrospectively collected data from 23 patients treated with ponatinib after resistance to previous treatment with tyrosine kinase inhibitors (TKIs). Molecular biology tests were done according to ELN guidelines and BCR-ABL/ABL is expressed as% IS. Clinical and comorbidities information (including CV risk factors were collected before and during ponatinib treatment.
Results: Median age at diagnosis was 56 years (34-83). Most (70%) had CV risk factors and 20% had suffered a previous CV event. The percentage of low, intermediate and high-risk Sokal groups were 25%, 45% and 15%, respectively. Median time of TKIs exposure before ponatinib was 43 months. One patient was treated in accelerated phase (AP), while the rest were in first or second chronic phase (CP). Thirty seven (%) of the patients had previously received 2 TKIs (imatinib, dasatinib, nilotinib, or bosutinib), and N (62%) had received ≥3 . At ponatinib start, 69% of patients had not achieved complete cytogenetic response (CCyR) while the rest were in CCyR (including 17% with major molecular response (MMR)). Sixty percent of the patients had one or more *BCR-ABL1* kinase domain mutations at the time of ponatinib start (45% had T315I mutation). Median follow-up was 29 months (3-53). Initial daily dose was 45, 30, and 15 mg in 85%, 5%, and 10% of patients, respectively. The initial dose was reduced in half of the patients, either due to side effects or to minimize the CV toxicity. In the last control, ponatinib daily dose was 45 mg, 30 mg and 15 mg in 65%, 10%, and 25% of the patients, respectively. Probabilities to obtain or maintain previous CCyR or MMR were 65% and 25%, respectively. Fifty eight percent of patients without CCyR at baseline achieved CCyR (17% achieving MMR), while 60% of patients with CCyR at baseline improved their molecular response. No differences in the response rates were observed depending on the mutational status or the initial ponatinib dose. By 43 months, event free survival, and progression free survival were 50% and 80%, respectively. At time of analysis, 40% of the patients had discontinued ponatinib due to toxicity (25%), lack of efficacy (25%), hematopoietic stem cell transplantation (37%) or death (13%). Most common non-hematological toxicities were liver toxicity (20%), lipase increase (10%), and hypertension 15%. No CV events were reported during treatment.
Summary/Conclusions: Ponatinib was shown to rescue a significant proportion of patients failing prior TKI treatment. It is worth noting that, with of a median follow-up of more than 2 years, no CV events appeared, suggesting that early dose modification could be protective against the occurrence of vascular complications.

PB1833

EARLY GOOD LATER BETTER. RELATIONSHIP OF BCR-ABL LEVEL AT 12 MONTHS OF TARGET THERAPY WITH INDIVIDUAL CHARACTERISTICS OF MOLECULAR RESPONSE IN EARLY TREATMENT PERIOD IN CHRONIC MYELOID LEUKEMIA

M Fominykh[1,*], K Abdulkadyrov[1], A Turkina[2], V Shuvaev[1], I Martynkevich[1], G Tsaur[3,4], N Bederak[5], E Chelysheva[2], O Shukhov[2], A Abdullaev[2], V Udaleva[1], I Zotova[1], D Shikhbabaeva[1], L Polushkina[1], M Ivanova[1], E Petrova[1], L Martynenko[1], E Kleina [1], N Tsybakova[1]
[1]Clinical department, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]Hematology Research Center, Moscow, [3]Regional Children's Hospital No. 1, [4]Research Institute of Medical Cell Technologies, [5]Municipal Central Hospital No. 7, Ekaterinburg, Russian Federation

Background: The search of surrogate prognostic markers for early detection of high risk disease progression still is actual problem in chronic myeloid leukemia (CML) management. The existing prognostic scales consider characteristics only at moment of diagnosis, whereas individual *BCR-ABL* level trend remains out of its vision.
Aims: The aim of this study was to evaluate the relationship between individual characteristics of early response to treatment and *BCR-ABL*^{IS} level at 12 months.

Table 1. The frequency of the optimal response (MMR) achievement at 12 months of TKI therapy in the relationship with type of first line therapy.

Groups of patients	TKI1 (*n* = 41)			Switching from TKI1 to TKI2 (n = 14)			TKI2 (*n* = 13)		
	n	MMR at 12 months:		n	MMR at 12 months:		n	MMR at 12 months:	
		abs.	%		abs.	%		abs.	%
BCR-ABL at 3 months of therapy:									
≤10%	33	23	69,7	6	4	66,7	13	10	76,9
> 10%	8	2	25	8	2	25	0	0	0
Ratio *BCR-ABL* 3 months to baseline:									
< 0,1	23	17	73,9	1	1	100	11	9	81,8
> 0,1	18	8	44,4	13	5	38,5	2	1	50

Methods: Fifty-four patients with chronic phase CML were included in the study. Forty-one patients started treatment with the first generation of tyrosine kinase inhibitors (TKI1) - Imatinib 400 mg QD. Twelve patients were treated with the second generation of tyrosine kinase inhibitors (TKI2) as first-line: Nilotinib 300 mg BID and 1 patient with Dasatinib 100 mg QD. Fourteen patients initially treated with TKI1 were subsequently switched to TKI2 (Table 1). We have conducted multivariate analysis of relationship between *BCR-ABL*^{IS} levels at 12 months and early molecular response (EMR, *BCR-ABL*^{IS} level ≤10% at 3 months) achievement, individual rates of *BCR-ABL* decline, type of first line therapy, fact of switching therapy from TKI1 to TKI2.
Results: The parameters that have statistical significance influence on *BCR-ABL*^{IS} level at 12 months of therapy were as follows: individual rate of *BCR-ABL* decline from 3 months to baseline (<0,1/>0,1) – p=0.044, type of first-line therapy (TKI1/TKI2) – p=0.0002, switching of therapy from TKI1 to TKI2 (yes/no) – p<0.0001. Achievement of EMR did not reach statistical significance – p=0,51. In addition, we have revealed the fact, that timely switch to TKI2 for resistant CML patients led to the rates of MMR achievement at 1 year of therapy similar to the MMR rate in the remaining TKI1 treated patients, eliminating resistance to TKI1.
Summary/Conclusions: Individual characteristics of the early response to treatment, for example individual rate of *BCR-ABL* decline, might be used as predictors of achievement optimal treatment result in CML treatment. The adequate treatment switching from first to second generations can restore treatment efficacy in resistant patients.

PB1834

EFFICACY OF GENERIC IMATINIB IN NEWLY DIAGNOSED CP-CML PATIENTS IN ESTONIAN POPULATION

E Laane[1,*], K Raudsepp[2], H Everaus[3], M Punab[3]
[1]Department of Hematology, North Estonia Medical Center, Tallinn, [2]United Laboratories, [3]Hematology and Bone Marrow Transplantation, Tartu University Hospital, Tartu, Estonia

Background: Tyrosin kinase inhibiitor (TKI) imatinib is the gold standard 1st line therapy of chronic phase chronic myeloid leukemia (CP-CML). Imatinib was implemented in Estonia for the 1st line therapy of CML in July 1, 2006. However in 2012 generic version of imatinib was approved in European Union and since January 1, 2014 only generic imatinib has been available in Estonia.
Aims: The aim of the study was to evaluate the clinical efficacy of generic imatinib in the treatment of CP-CML in Estonia and to compare results with historical group of patients treated brand name imatinib.
Methods: 25 patients in CP-CML have been diagnosed during 2014-2015 and have started 1st line treatment with generic imatinib. Optimal response was assessed at 3, 6 and 12 months after the start of treatment according to European LeukemiaNet 2013 guidelines: BCR/ABL ≤10%, <1% and ≤0,1% at 3, 6, 12 months respectively. For comparison historical group of 72 patients in CP-CML who received brand name imatinib for 1st line treatment during 2006-2013 were used. In this group pre-treatment with hydroxyurea for maximum 3 months but not interferon-alfa was allowed, OR was assessed at 6, 12 and 18 months after the start of imatinib and defined according to European LeukemiaNet 2010 recommendations.
Results: OR with generic imatinib was achieved in 16/21 (76.2%) evaluable patients at 3 months, 11/14 (78.6%) patients at 6 months and 7/11 (63.6%) at 12 months. At 18 months there were only 3 evaluable patients who all obtained OR. None of the patients not having OR at 3 months and continuing with imatinib, obtained OR later. One patient without OR at 3 and 6 months, progressed to lymphoid blastic crisis in 9 months after diagnosis. Two patients had failure to generic imatinib - one patient having BCR/ABL level at 6 months over 10% and one patient over 1% at 12 months; both patients were switched to the 2nd generation TKIs. Three patients having OR at 3 and 6 months lost it by 12th month, but 2 of them had treatment interruption periods due to poor tolerability. No new safety signal emerged. The most common adverse effects to generic imatinib occurring more than 10% of patients were nausea/vomiting, diarrhea/constipation, muscle pain in legs, periorbital oedema and allergic skin reactions. Due to adverse events 6 patients were switched to different generic imatinib and one patient not tolerating two different generic imatinibs was switched to the 2nd generation TKI. In the historical group OR was achieved in 33/45 (73%) evaluable patients at 6 months and 33/50 (66%) patients at 12 months. At 18 months OR was obtained in 22/51 (43%) evaluable patients. None of 11 patients not in OR at 6m obtained OR at 12m or 18 months.
Summary/Conclusions: Generic imatinib appears to have the same efficacy as brand name imatinib. Despite differences in group size and OR definition by European LeukemiaNet 2010 *vs* 2013 recommendations the treatment results with generic and brand name imatinib were quite comparable with 78.6-66% of OR rate at 6 months and 63.6-66% at 12 months. To improve treatment results, for patients not achieving early OR at 3 months or 6 months should be offered treatment with 2nd generation TKI.

PB1835

ROLE OF CHR AS A SURROGATE FOR MMR AT 12 AND 18 MONTHS IN RESOURCE CONSTRAINT SETTINGS: PATIENTS UNABLE TO AFFORD FREQUENT MOLECULAR MONITORING

K Sahu[1,*], U Yanamandra[2], N Parashar[1], S Naseem[3], A Khadwal[2], G Prakash[2], S Varma[2], N Varma[2], P Malhotra[2]
[1]Internal Medicine, [2]PGIMER, Chandigarh, India, [3]PGIMER, PGIMER, Chandigarh, India

Background: Studies on CML in last decade have correlated early molecular response (EMR) both at 3/ 6 months and velocity of BCR-ABL reduction with MMR at 18 months. But, this requires molecular monitoring at 3 monthly interval to the least till the achievement of MMR as per NCCN/ELN guidelines. For studying velocity of fall, the molecular monitoring is required at further greater frequency. In resource constraint settings, it is very difficult to monitor patient with qPCR for BCR-ABL transcripts at regular interval owing to the poor educational status, financial constraints, logistic issues (non-availability of testing facilities at all places) and lack of standardization at various labs. Considering these limitations, it is very essential to identify surrogate markers which are universally available for predicting MMR at 18 months.
Aims: To study the role of CHR as a surrogate for MMR at 12 and 18 months in resource constraint settings in patients unable to afford frequent molecular monitoring.
Methods: *Study Design:* It's a prospective single center observational study from northern India. This is part of PRICE study (PGIMER Real world Indian CML Experience) registered vide UTN U1111-1177-8918 and under registration in CTRI. *Patients:* As part of this study a total of 230 CML patients were screened prospectively attending Adult Hematology Clinic of the host institution. All patients (age>12 years) who were fulfilling the diagnostic criteria of CML-CP before initiation of imatinib therapy were included in the study. Exclusion criteria were either (a) patients in accelerated phase and blast crisis or (b) patients in whom Imatinib was discontinued due to hypersensitivity/ intolerant. *Protocol:* As part of this study protocol, all newly diagnosed cases of CML-CP were managed with TKI therapy with regular molecular monitoring (3, 6, 12, 18 and 24 months). Patients were initially evaluated with complete hemogram, bone marrow analysis and diagnosis was then confirmed with qualitative molecular test to detect the presence of BCR-ABL translocation. Sokal, Hasford and EUTOS scores were calculated at baseline. Imatinib, was started and Clinical examination and hemogram was done at weekly intervals to assess for complete hematological remission. Molecular responses at 3, 6 months for EMR and 12, 18 months for MMR was monitored in all these patients.
Results: 85.1% patients achieved CHR within 12 weeks with median time to achieve CHR being 40 days. Median time to achieve CHR was longer in female patients (42 days) as compared to male patients(36 days), difference was not statistically significant (p=0.636). Patients who achieved MMR at 12 months had a mean CHR duration of 42 days (SD-437.79, n=73) and the patients who didn't achieve MMR at 12 months the mean duration of CHR was 62.81 days (SD-55.8, n=69). The difference was statistically significant (p=0.01). We also compared the duration of CHR with MMR at 18 months. The patients who achieved MMR at 18 months had a mean CHR duration of 35.45 days (SD-25.41 n=56) and among the patients who didn't achieve MMR at 18 months the mean duration of CHR was 56.71 days (SD-59.6, n=28). The difference was again significant with p value of 0.024 (Table 1).

Table 1.

Categories of MR	Groups	n	Days to achieve CHR	P value
EMR at 3 months	BCR/ABL <10%	159	46.79	
<0.001				
	BCR/ABL >10%	32	81.34	
OMR at 6 months	BCR/ABL <1%	113	46.11	0.02
	BCR/ABL >1%	77	64.16	
MMR at 12 months	BCR/ABL <0.1%	69	39.16	0.001
	BCR/ABL >0.1%	69	62.81	
MMR at 18 months	BCR/ABL <0.1%	56	35.45	0.024
	BCR/ABL >0.1%	28	56.71	

Summary/Conclusions: CHR is a good marker to predict the disease response in patients with CML on therapy.

PB1836

DEVELOPMENT OF INTERNATIONAL SCALE SECONDARY STANDARDS FOR BCR-ABL1 TRANSCRIPT QUANTITATIVE ASSAY

J Keierleber[1], C Rundell[1], J Gordon[1], GJ Day[2,*], K Shridhar[2], W Wong[2]
[1]Maine Molecular Quality Controls, Scarborough, [2]Oncology Research and Development, Cepheid, Sunnyvale, United States

Background: Presence of fusion gene BCR-ABL1 is indicative of chronic myelogenous leukemia. Quantitative assay of BCR-ABL1 transcript in patient blood can measure response to therapy. Harmonization of BCR-ABL1 transcript assay results among laboratories is needed in order to standardize clinical reporting. In 2009 the World Health Organization (WHO) developed a panel of four BCR-ABL1 primary standards to calibrate secondary standards and to establish an international scale (*IS*) for reporting assay results as a ratio of fusion transcript to control gene transcript (%*IS*). Reliable secondary standards are essential for monitoring performance of BCR-ABL1 quantitative assays.
Aims: This study creates a panel of BCR-ABL1 secondary standards, based on the WHO primary standards, for use with Xpert BCR-ABL Monitor assay (Cepheid).
Methods: Maine Molecular Quality Controls, Inc. (MMQCI) manufactured a panel of four secondary standards consisting of BCR-ABL1 b3a2 fusion transcript and ABL1 control gene transcript in a proprietary stabilizing matrix. Transcript ratios were calibrated to yield the same%*IS* results as the four WHO primary standards: approximately 0.01%*IS*, 0.1%*IS*, 1%*IS*, and 10%*IS*. Three lots of MMQCI panels were tested on one lot of Xpert BCR-ABL Monitor contemporaneous with testing WHO primary standards.
Results: Three unique lots of MMQCI secondary standards panels yielded quantitative results in good agreement with one another and with the WHO primary standards panel at each of the four%*IS* levels. MMQCI secondary standards panels demonstrated linearity across the range of%*IS* levels, comparable to linearity of WHO primary standards.
Summary/Conclusions: MMQCI's BCR-ABL1 secondary standards panel shows potential for verifying performance of Xpert BCR-ABL Monitor, thereby contributing to harmonization of minimal residual disease (MRD) measurements to the International Scale. This approach to creating standards secondary to WHO primary standards serves as a model for creation of secondary standards for Xpert BCR-ABL Ultra (Cepheid).

PB1837

LOW DOSE DASATINIB TREATMENT IN ELDERLY CML PATIENTS

H Sano[1,*], H Itamura[1], T Shindo[1], Y Kubota[1], T Ando[1], E Sueoka[2], K Kojima[1], S Kimura[1]
[1]Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, [2]Department of Clinical Laboratory Medicine, Faculty of Medicine, saga university, saga, Japan

Background: Clinical outcomes and survival of chronic myeloid leukemia (CML) patients treated with ABL tyrosine kinase inhibitors (TKIs) have significantly improved. To achieve a good prognosis, including cessation of TKI treatment, a rapid and deep response to TKIs is important. Elderly patients usually cannot receive the standard dose (100mg QD) of dasatinib because of its adverse effects (AE). Nevertheless, several elderly patients achieve a deep response to very low doses of ABL TKIs.
Aims: We retrospectively analyzed the efficiency of low dose dasatinib in elderly patients with CML.
Methods: We retrospectively evaluated imatinib-resistant and -intolerant CML-CP patients aged 65 or over who had been administrated less than 100mg QD dasatinib between 2010 and 2015 at Saga University Hospital. We estimated therapeutic efficiencies based on bcr-abl mRNA levels measured by RQ-PCR compensated according to international scale (IS) and/or TMA (transcription mediated amplification) method for peripheral blood. In the TMA method, undetectable is considered to be the same as a 4-log reduction (MR^4) of RQ-PCR on the IS. In addition to efficacy, adverse effects at lower doses of dasatinib were also investigated.
Results: Twenty-one elderly CML-CP patients were investigated. Sixteen patients (76.2%) were newly diagnosed. The median age at diagnosis was 72 years old (range, 65–83). Thirty-three per cent were male, and the median follow up time was 20.5 months (range, 4–56). The mean dose of dasatinib was 24.6 mg. The numbers of patients receiving a mean dasatinib dose of 50mg or less and 20mg or less were 19 (90.4%) and 15 (71.4%), respectively. Twenty patients (95.2%) and 16 patients (76.2%) achieved a major molecular response (MMR) and a MR^4, respectively. In addition, 10 patients (47.6%) achieved a $MR^{4.5}$. The median durations of dasatinib treatment to achieve a MMR and an MR^4 were 6 months (range; 2–11) and 12 months (range; 3–50), respectively. All cases achieved a complete cytogenetic response (CCyR) within 12 months. In the case of the 15 patients receiving a mean dose of 20 mg or less, 14 patients (93.3%) achieved a MMR and 11 patients (73.3%) achieved a MR^4. The median durations of MMR and MR^4 were 6 months (range, 3–10) and 9.5 months (range, 3–38), respectively. Additionally, 13 patients treated with a dose of 20mg or less as first line therapy. MMR and MR^4 were achieved in 84.6% and 69.2%, respectively. 53.8% achieved a $MR^{4.5}$. The median durations of MMR and MR^4 were 6 months (range, 3–11) and 10 months (range; 4–38), respectively, in this cohort. The main AE was plural effusion (6 patients; 28.5%). Surprisingly, HBV reactivation occurred in 2 patients treated with 20 mg QD. Except for 1 patient who changed to another TKI because of gastrointestinal bleeding, most AEs became tolerable after dose reduction. Seven patients administered 50 mg or less had increased large granular lymphocyte counts.
Summary/Conclusions: Treatment with dasatinib at lower than standard doses was well tolerated and resulted in an adequate molecular response in elderly CML patients without causing severe AEs. Thus, prospective studies should be performed to determine the effects of administering lower doses of dasatinib to elderly CML-CP patients.

PB1838

A NATIONWIDE OBSERVATIONAL STUDY OF THE ISRAELI EXPERIENCE WITH PONATINIB OUTSIDE CLINICAL TRIALS IN CHRONIC MYELOID LEUKEMIA

A Shacham Abulafia[1,2,*], P Raanani[1,2], D Lavie[3], Y Volchek[4], R Ram[2,5], I Hellmann[6], L Shargian[1], A Gourevietch[7], E Chubar[8], R Ratzon[2], U Rozovski[1,2]
[1]Institute of Hematology, Davidoff Cancer Center, Beilinson Hospital, Rabin

Medical Center, Petah-Tikva, [2]Sackler School of Medicine, Tel Aviv University, Ramat-Aviv, [3]Department of Hematology, Hadassah-Hebrew University Medical Center, Jerusalem, [4]Hematology Division, Chaim Sheba Medical Center, Tel-Hashomer, [5]Bone Marrow Transplantation Unit, Sourasky Medical Center, Tel Aviv, [6]Department of Hematology, Meir Medical Center, Kfar Saba, [7]Hematology institute, Soroka University Medical Center, Beer-Sheva, [8]Hematology Institute, Haemek medical center, Afula, Israel

Background: Ponatinib is an oral tyrosine kinase inhibitor (TKI) that has been designed to be effective also in patients who harbor the TKI-refractory threonine to isoleucine mutation at position 315 (T315I). In December 2014 the drug was granted an accelerated approval by the FDA, based on the promising results from the phase II PACE trial. Nevertheless, the wide use of the drug has been limited due to safety matters, in particular arterial thrombotic complications, reported in up to 17% of patients. Currently, there is little real-life information regarding the use of ponatinib outside of clinical trials.
Aims: 1) To characterize patients with chronic myeloid leukemia (CML) who received ponatinib. 2) To determine safety profile of ponatinib outside clinical trials. 3) To assess the efficacy of ponatinib outside clinical trials.
Methods: Between 4.2011 and 7.2015 (51 months) 24 patients in 7 medicals with CML received ponatinib. We reviewed the medical records of these patients and asked their physicians to rank the quality of life of their patients on a 1 to 5 scale.
Results: The median age was 44 years (rang: 23 to 79) and most were in accelerated (21%, N=5) or blast crisis (41%, N=10) phases at time ponatinib was initiated. Prior to ponatinib, the patients were treated for a median of 55 months (range: 1 to 215) with 1 to 3 different TKIs (median: 3). Thirteen received at least one course of chemotherapy or interferon-α, and two underwent allogeneic bone marrow transplantation. Mutations at the bcr-abl DNA binding domain were detected in 11 patients (69%) and T315I mutation in 8 of those. Based on the medical history, 48% were at-risk for vascular complications either because of prior cerebrovascular event or myocardial infarction (18%) or because of vascular risk factors (30%). Baseline ECG and cardiac ECHO studies were available in 11 patients and none had significant structural or functional pathology. Patients were followed between1 to 34 months at time of analysis (median: 6 months) and during this time 4 patients died and 14 were still receiving ponatinib. Patients discontinued the treatment either because of major cardiovascular events (N=3), severe pancytopenia (N=1), planned bone-marrow transplantation (N=1) or because they were lost to follow-up (N=1). Seventeen patients were available for response assessment at time of analysis and the overall response rate was 77% (N=13). Five of six patients at chronic phase achieved either complete or major molecular response. Eight patients at accelerated phase or at blast crisis (8/11, 72%) achieved either hematological (5/11, 45%) or molecular response (3/11, 27%). Two of those, with hematological response, underwent allogeneic bone marrow transplantation. The median subjective scoring of ponatinib contribution to the quality of life of patients was 2.4 (range 1 to 5). Physicians that gave low scoring mentioned Severe weakness, myalgia and cytopenias were mentioned as a major concern.
Summary/Conclusions: In real- life setting ponatinib is generally used as a last resort. In our cohort, it was almost exclusively given to patients who experienced failure to previous TKIs. Only one third of patients tolerated the recommended dose of 45mg. Yet, response rate was still relatively high, suggesting that a daily dose of 30mg might be appropriate. With only 6 months of follow-up we documented 3 cardiovascular events (12%) that prompted discontinuation of the drug. The high response rate and overall contribution to quality of life in patients, who already experienced failure of other TKIs, support the use of ponatinib in this setting.

PB1839

ASSESSMENT OF PLATELET FUNCTIONS IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

Y Sener[1], F Akbiyik[1,*], S Aydın[2], Y Buyukasik[2], ZG Dikmen[1]
[1]Medical Biochemistry, [2]Hematology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Bleeding is observed time to time in chronic myeloid leukemia (CML) patients using tyrosine kinase inhibitors (TKI). It has been suggested that tyrosine kinase inhibitors can disrupt platelet functions and cause beeding without thrombocytopenia in CML patients.
Aims: In this study, we aimed to evaluate platelet functions of CML patients using tyrosine kinase inhibitors and examine in conjunction with beeding symptoms to find out whether there is a correlation between them.
Methods: In this study, bleeding surveys were performed for 68 CML patients in cronic phase receiving imatinib (n=47), dasatinib (n=15) and nilotinib (n=6). Hematology analyzer LH780 (Beckman Coulter) was used for measurement of complete blood counts. BCS XP coagulation analyzer (Siemens) was used for measurement of PT, aPTT, TT, fibrinogen and factor assays. In our coagulation laboratory, platelet rich plasma pool was prepared and light transmittance agregometry (Chrono-Log) was used for the evaluation of platelet functions. Platelet agregation was induced in *in vitro* conditions by different agonists (ADP, epinephrine, collagen, ristocetin) and the agregation percentage/time graph was analyzed to evaluate platelet functions.
Results: The median age was found as 47 years (range, 18-78 years) in CML patients. Complete blood counts and coagulation test results were in normal range; white blood cell count 6.72,5 $\times 10^3/\mu L$, hemoglobin 13.0±1,7 g/dL, platelets 234.7±74,5 $\times 10^3/\mu L$, PT 12,8±1,4 sn, INR 1,0±0,1, aPTT 27.6±2,8 sec, TT 16.5±2,0 sec, fibrinojen 325.7 mg/dL and Factor VIII levels were 120,8±11,2%. When the bleeding survey results were analysed, the patients who have bleeding score below 3 were accepted as *minor bleeding*. When the relation between bleeding scores and TKI treatment were evaluated; we observed that 25,6% of the patients who use imatinib and 20% of the patients who use dasatinib have minor bleeding symptoms. In Nilotinib treatment group, no bleeding symptom was observed. In total, 22% of CML patients under TKI treatment have bleeding symptoms; 17,6% with bleeding score 1 and 4,4% with bleeding score 2. In platelet function tests, when aggregation was induced by ADP, epinephrine, collagen and ristosetin, *secretion type defect* was observed in 26% of the patients. No correlation was observed between platelet function defects and minor bleeding symptoms in these patients.
Summary/Conclusions: As a result, platelet agregation disorders can be observed in CML patients treated with tyrosine kinase inhibitors. However, platelet dysfunction is not associated with bleeding disorder. Furthermore, the effect mechanism of tyrosine kinase inhibitors on platelet homeostasis warrants further investigation.

PB1840

ELEVEN-YEAR RESULTS OF THE THERAPY OF CML TYROSINE KINASE INHIBITOR IN A LARGE INDUSTRIAL CENTER OF SIBERIA

A Lyamkina[1,*], T Pospelova[1]
[1]Therapy, hematology and transfusiology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Modern method of therapy inhibitors tyrosine kinase (ITK) of chronic myeloid leukemia (CML) allows patients have long-term remission and life expectancy comparable to the general population. The effectiveness of treatment depends on the sensitivity of the malignant clone to a medicine, and from of patient compliance of treatment.
Aims: To evaluate eleven-year results of therapy of chronic myelogenous leukemia treatment with tyrosine kinase inhibitors.
Methods: For the period of January 2004 and up until now the 103 CML patients have been observed at the municipal hematology center of Novosibirsk – capital of Siberia: 39 men (37.9%) and 64 women (62.1%), with age ranging from 16 to 78 years, and the mean value being 43.4±14.15 years, 71.8% patients was included in the analysis (74 patients): 71 people in the chronic phase, 3 - in the acceleration phase. All patients in the chronic phase started taking the TKI in the first 6 months after diagnosis of CML. Patients in accelerated phase and blast crisis were diagnosed before 2003, these patients were significantly pre-treated with various cytotoxic medications and interferons. All patients are receiving treatment by various tyrosine kinase inhibitors (imatinib at a dose of 400-800 mg per day, nilotinib at 800 mg per day, dasatinib 80-100 mg per day). In Russia, imatinib therapy became available only in 2004, as part of the charity program GIPAP (on treatment 10% of patients). All the patients treatment became available in 2005. Today in Russia are using generic medications Philachromin® and Genfatinib®, instead of using original medication Glivec®, their effectiveness requires further observation. New patients - 10 people (9.7%), they are treated by the TKI less than 6 months and have not got the analysis. Also excluded from the analysis of 19 people (18.4%) with low compliance to therapy, they have not received an adequate response to treatment. 22 patients have died: 9 patients in chronic phase, for reasons not related to hematological malignancies, 13 patients with low compliance due to the progression of CML.
Results: Administration of a TKI as a first and second line was followed by a complete clinical and hematological response in 98.5% patients, complete cytogenetic response (CCyR) – in 83,1%, major molecular response (MMO) – in 63,1%. In 3 patients AP - clinical and hematological response. Survival was analyzed in patients administered TKI, as compared to patients not administered TKI (data based on the retrospective review of medical records of CML patients observed at Novosibirsk municipal hematology center for the period of 1999 – 2004). A statistical method of calculating the cumulative fraction of survivals (Kaplan-Meier) was used to evaluate survival, with $p<0,05$ established as the reliability criterion. No medial survival was established in the group administered TKI, the 11-year survival - 84.8%, the estimated 15-year survival was 71,2%. Overall event-free survival rate was 57.8%, in the chronic phase - 69.7%. In the group treated with other cytotoxic agents median survival was 4.1 years, the estimated 15-year survival rate - 3%, $p <0,000001$.
Summary/Conclusions: TKI (original medicine and branded generics) are considered an effective and safe method of treatment for CML in CP, if the patient in compliance with all recommendations of the doctor, associated with a high MMO rate in the chronic phase, which leads to a significant increase in the overall and event-free survival.

PB1841

CML AS PART OF DUAL MALIGNANCIES: POSSIBLE MECHANISMS AND REVIEW OF LITERATURE

K Sahu[*], U Yanamandra, A Khadwal, G Prakash, P Malhotra, S Varma, N Varma

Internal Medicine, PGIMER, Chandigarh, India
Background: Since the time Imatinib Mesylate has been recommended as standard of care for chronic myeloid leukaemia, the overall survival of CML patients is almost equivalent to general population. Improved survival in CML patients have provided an opportunity to study disease behaviour and its associations in long term basis.
Aims: To study the incidence of secondary malignancies in CML and their outcome.
Methods: We reviewed the medical records of all the CML patients treated with Imatinib at PGIMER, Chandigarh, India from 2001-2014**.**
Results: During a 15 year period (Jan 2001 to Dec 2014), a total of 2183 patients of CML were registered with the adult haematology clinic of PGIMER, Chandigarh of which 1677 patients were included where complete patient details were available. A total of 15 patients were found to have co-existent second malignancy with CML. Four patients had CML as the secondary malignancy. Among 15 patients, three patients had synchronous and 12 had metachronous malignancy. The median age of the patients was 50y (25-66) at the time of diagnosis in this series. Of the 15 patients five were male and rest 10 were female. None of our patients were on 2nd line TKI (Nilotinib and Dasatinib). Two of these 15 patients were in accelerated phase and none in blast phase at the time of diagnosis. History of smoking was present in only one patient who developed bladder cancer and one patient was consumed alcohol in non cirrhogenic doses. None of our patients had history of any carcinogenic exposure. Median duration of imatinib therapy in patients with secondary malignancy is 45.5 months (5 to 130 months). Median duration of follow up was in patients with dual malignancies. Two patients with dual malignancies succumbed to their illness because of blast crisis and one among them was lost to follow up for last 1.5year. None of the patients of CML succumbed to the co-existing malignancy. In patients with CML presenting as primary malignancy (patient no 1-8) the median interval until development of secondary malignancy was 62.3 months (ranged from 8 to 240 months). Whereas, in patients with CML presenting as secondary malignancy the median interval of development of CML was 118.5 months (range 60 to 144 months). None of our patients of co-existent malignancy with CML underwent bone marrow transplantation. Cumulative incidence of second cancer (all categories) in our CML patient cohort is 0.0089. Accordingly, within the limitations of the number of patients which are enrolled in this retrospective analysis, the total number of cases of cancer could be in accordance with the incidence of cancer in the Indian population.
Summary/Conclusions: None of our patients of co-existent malignancy with CML underwent bone marrow transplantation. Cumulative incidence of second cancer (all categories) in our CML patient cohort is 0.0089. Accordingly, within the limitations of the number of patients which are enrolled in this retrospective analysis, the total number of cases of cancer could be in accordance with the incidence of cancer in the Indian population.

PB1842

THE RESULTS OF TYROSINE-KINASE INHIBITORS TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS ACCORDING TO 2013 EUROPEAN LEUKEMIANET RESPONSE CRITERIA: RUSSIAN SINGLE-CENTER STUDY

O Shukhov[1,*], A Turkina[1], E Chelysheva[1], G Gusarova[1], I Nemchenko[1], A Bykova[1], A Abdullaev[2]
[1]Scientific and Advisory Department of Chemotherapy of Myeloproliferative Neoplasms, [2]Laboratory of molecular hematology, Federal State Budgetary Institution Hematology Research Center of Health Ministry of Russian Federation, Moscow, Russian Federation

Background: The 2013 European LeukemiaNet (ELN) response criteria define when to change therapy in the case of treatment failure, when the treatment with tyrosine-kinase inhibitors (TKIs) of CML patients should be continued (optimal response) and when a careful monitoring is required (warning). To date, no data presented that show the results of the treatment approach according to ELN2013 response criteria.
Aims: The aim of the study was to evaluate the results of TKIs treatment in CML patients according to ELN2013 recommendations.
Methods: The prospective study included 71 adult patients with newly diagnosed CML in chronic phase. Baseline demographics characteristics: median age: 44 years (interquartile range (IQR) 31-57 years); male sex: 51% (n=36); Sokal score: high 23%, intermediate 27%, low 50%. Baseline treatment: imatinib (IM) 400 mg (n=63), nilotinib (NIL) 600 mg (n=7), dasatinib (DAS) 100 mg (n=1). The switching to another TKI or increasing doses was performed at 3,6,12 months or late in case of failure according to ELN2013 recommendations. Therapy was also changed in cases with no early molecular response (EMR) (BCR-ABL ≤10% at 3 months). Overall survival (OS), cumulative incidence of complete cytogenetic response (CCyR), major molecular response (MMR) and deep molecular response (MR4 or deeper) were evaluated (Intention-to-treat analysis).
Results: The failure was recorded in 14 (20%) cases (at 3 months n=6, at 6 months n=3, at 12 months n=2, after 12 months n=2, 1 patient died before 3 month assessment due to progression). Imatinib was a baseline treatment in all failures. Therapeutic options for failures: increasing dose of IM (600 mg) n=2, switching to DAS n=5, switching to NIL n=4, 2 patients are currently being examined before switching. In 6 cases switching or IM dose escalation was performed because of no EMR (out of failure) (NIL n=3, DAS n=1, IM600 mg n=2), other reasons (toxicity, late warning): n=4 (NIL n=2, DAS n=2). Median time to switching after failure detection was 67 days (IQR 36-103 days). Median follow-up: 19 months (IQR 12-31 months). Still alive: n=69; on IM treatment: n=44 (64%), on 2nd TKI: n=25 (36%). The 3-yars OS was 96%. Cumulative incidence of CCyR, MMR and MR4 was 98%, 86% and 73% respectively. Independent of switching, cumulative incidence of MR4 was higher in group with EMR than no EMR: 73% and 22%, respectively (p=0,03) (3 months landmark) (Figure 1).

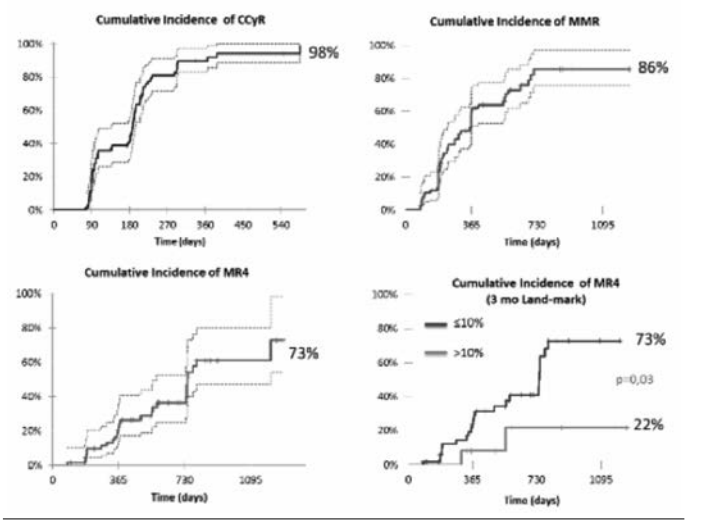

Figure 1.

Summary/Conclusions: The principle of early therapy modification in patients with no optimal response according to ELN2013 response criteria allows to reach CCyR (the main surrogate endpoint for survival) in almost all cases. Early molecular response is a predictor of achieving deeper molecular response not depending on early switching approach.

Gene therapy, cellular immunotherapy and vaccination

OUT OF THE BAG – FUNCTIONAL CHARACTERIZATION OF *EX VIVO* EXPANDED MSC

S M Lopes*, A Pinho, F Amado, S Ferreira, F Bordalo, S Roncon
Cellular Therapy, IPO PORTO, Porto, Portugal

Background: Bone marrow (BM) derived mononuclear cells (MNC) are the starting point of numerous protocols, such as *ex vivo* expansion of HPC, neuro and mesenchymal stem cells (MSC). We have previously established that the BM collection bag and filter system (which are usually discarded) are an alternative source of MNC, yielding viable and sterile cells equivalent to 50ml of filtered BM, and should not be considered clinical waste. The viability and functionality of the recovered MNC were evaluated by trypan blue exclusion and *in vitro* differentiation into MSC, respectively.
Aims: In order to further validate the applicability of these cells, MSC obtained were tested for morphology, immunophenotype, ability to hamper alloreactivity and to differentiate into adipocytes. tyle='mso-ansi-language:EN-GB'>We have previously established that the BM collection bag and filter system (which are usually discarded) are an alternative source of MNC, yielding viable and sterile cells equivalent to 50ml of filtered BM, and should not be considered clinical waste. The viability and functionality of the recovered MNC were evaluated by trypan blue exclusion and *in vitro* differentiation into MSC, respectively.
Methods: The collection bag and filter system were back-washed and rinsed with RPMI under aseptic conditions and MNC isolated by density gradient centrifugation. To obtain long term MSC cultures, MNC were cultured in DMEM media supplemented with foetal bovine serum, at 37ºC and 5% CO_2. Cultures were replated when confluence was reached. MSC morphology was confirmed with a reverse microscope, and immunophenotype by flow cytometry. To assess adipogenic differentiation capacity, MSC were cultured in the presence of dexamethasone and diclofenac, with adipocytes generation tested by Oil Red staining of lipid deposits. To evaluate their imunossupressive role a one way MLR was performed. Briefly, irradiated MNC (stimulator) and CFSE-dyed MNC (responder) were co-cultured in the presence or absence (control) of MSC. After 7 days of incubation, proliferation of responder cells was measured by flow cytometry.
Results: In all cases, filter recovered MNC viability was superior to 90%, and long term MSC cultures were established, as shown by morphology and immunophenotype (CD105+, CD44+, CD90+, CD73+, CD45-, CD14-, and CD34-). To further characterize our MSC lineage differentiation, a hallmark of MSC, was shown by Oil Red staining of MSC-derived adipocytes. Another characteristic of MSC, down regulation of alloreactivity, was demonstrated *in vitro*, with a consistent 20% reduction of proliferating cells. -family:Calibri;mso-bidi-font-family:"Times New Roman"; mso-ansi-language:EN-GB;mso-fareast-language:EN-US;mso-bidi-language:AR-SA'>MSC morphology was confirmed with a reverse microscope, and immunophenotype by flow cytometry. To assess adipogenic differentiation capacity, MSC were cultured in the presence of dexamethasone and diclofenac, with adipocytes generation tested by Oil Red staining of lipid deposits. To evaluate their imunossupressive role a one way MLR was performed. Briefly, irradiated MNC (stimulator) and CFSE-dyed MNC (responder) were co-cultured in the presence or absence (control) of MSC. After 7 days of incubation, proliferation of responder cells was measured by flow cytometry.
Summary/Conclusions: With this study we demonstrated that, from the usually discarted BM collection bag and filter system, long term MSC cultures can be established. These cells can be expanded *ex vivo,* maintaining an appropriate phenotype and functional capabilities, being suitable for both investigation and clinical settings.

PB1844

FUNCTIONAL CAPACITY OF TUMOR LYSATE-PULSED MONOCYTE-DERIVED DENDRITIC CELLS INDUCING *IN VITRO* IMMUNE RESPONSES

C Pinho[1,*], S Lopes[1], F Amado[1], A Verdelho[2], J Abreu de Sousa[3], S Roncon[1]
[1]Cellular Therapy, [2]Neurosurgery, [3]Oncology Surgery, IPO PORTO, Porto, Portugal

Background: Dendritic cells (DC) have been shown to be a promising adjuvant to initiate antitumor immune responses. Over the last years, several methods have been developed to isolate DC from cancer patients, *ex vivo* expand and pulse them, aiming to generate highly immunogenic clinical grade infusion products.
Aims: In order to validate our previously established *in vitro* methodology for DC generation, the present study aims to assess the functional capacity of the DC final product inducing immune responses. usion products.
Methods: As part of an authorized pre-clinical study with solid tumors, four experiments were performed using tumor lysates (2 glioblastomas, 1 sarcoma and 1 breast cancer) for DC stimulation. DC were differentiated from monocytes obtained from peripheral blood (PB) and subsequently matured and pulsed with previously prepared tumor lysate, during 8 days of culture in cytokines-supplemented medium. Loaded mature DC (mDC) were evaluated for cell counting, viability, morphology and immunophenotype. DC functionality was evaluated via one-way MLR using peripheral blood mononuclear cells (PBMC) which were isolated from PB by density gradient centrifugation and pre-labeled with the 'green' fluorescent dye CFSE. The $CFSE^+$PBMC (responder cells) were co-cultured with mDC (stimulating cells) in a 96-well plate. PBMC without DC stimulation was used as negative control. In both MLR and negative control, the same tumor lysate used in DC stimulation was added or not. After 7 days of incubation at 37°C, 5% CO_2, proliferation of responder cells was measured by flow cytometry.
Results: The single-cell suspension obtained at the end of culture showed: numerous cells presenting extended and multiple dendrites; up-regulation of the characteristic maturation markers CD83/CD86; and down-regulation of CD14, marker of the precursor cells. Taken together these results prove the achievement of the DC maturation state. These final loaded mDC were assessed for the antigen presentation skills by their *in vitro* allostimulatory capacity of PBMC. The average percentage of proliferating PBMC obtained when co-cultured with mDC was greater than that verified without DC stimulation (47.7±3.0% *vs* 19.3±8.4% and 47.0±5.0% *vs* 8.8±3.5%, with and without tumor lysate, respectively). Despite the small sample size, DC stimulation consistently induced more than double the PBMC proliferation.
Summary/Conclusions: This study demonstrated the functionality of the mDC final product to induce *in vitro* immune responses. With our mDC manufacturing protocol validated, we are motivated to obtain the legal authorization for the implementation of this Advanced-Therapy Medicinal Product in clinical grade. It may be beneficial for the patients to have cell collection, production and administration available in the same hospital setting.

PB1845

CELLULAR IMMUNOTHERAPY: A STORY OF HOPE

A Van De Velde[1,2,*], H Daenens[3]
[1]Haematology, University Hospital Antwerp, Edegem, [2]BIOMAB, University of Antwerp, [3]DigitalStories, Antwerp, Belgium

Background: Narrative medicine is a medical approach that recognises the value of people's narratives in clinical practice, research and education. Narrative medicine aims not only to validate the experience of the patient, but also to encourage creativity and self-reflection in the health care provider and researcher.
Aims: Rupert Suply, a young adult diagnosed with Ewing Sarcoma, was included in a study with dendritic cell vaccination to prolong his second remission period. This new therapy slowed down the aggressive tumor growth. Because he is convinced that cellular immunotherapy gave him many extra quality years and he believes in its future possibilities he knows that his story of HOPE is his way of contributing to clinical practice and research.

Figure 1.

Methods: In a documentary short film, directed by Hedwige Daenens, we use narrative medicine to describe our progress of adoptive cellular therapy in diseases where relapse remains a major problem and has an important impact on survival. Rupert tells us his moving story and guides the audience through the different steps in making a cancer vaccine. We filmed at the Center for Cell Therapy and Regenerative Medicine CCRG of the University Hospital Antwerp. This project was made possible by a collaboration with Biological and Medical Art in Belgium BIOMAB, based at the University of Antwerp, and the country's leading organisation to promote interdisciplinary research between scientists and those with an interest in the synergy between Art, Science and Technology.
Results: Leukapheresis, DC generation, antigen loading of DCs by electroporation of WT1-encoding mRNA, cryopreservation of WT1 mRNA-electroporated

DCs, timing of first vaccination, thawing of the DC vaccine, immunisation schedule, route of administration and vaccine dose are described by using documentary methods in a hospital and research setting. Each procedure is explained in detail by a qualified member of staff understandable for a general audience. This movie shows a series of various interactive scenes at different departments, mostly restricted areas, during Rupert's path creating his personal cancer vaccine.
Summary/Conclusions: Narrative medicine is a valuable tool to describe cell collection, processing and therapy. It promotes understanding between researcher, clinician, nurse and patient, encourages additional therapeutic options and generates new hypotheses. The documentary A STORY OF HOPE was presented for the first time at this year's EBMT meeting (Figure 1).

Hematopoiesis, stem cells and microenvironment

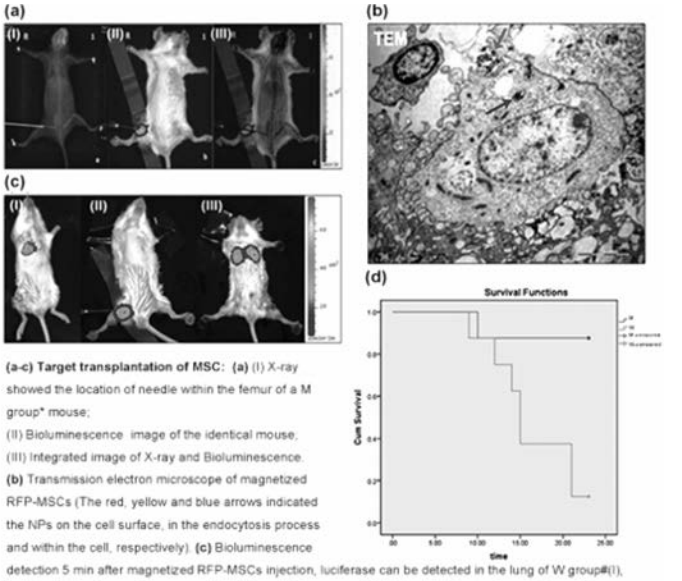
MAGIC-TT-MEDIATED CELLS TARGET TRANSPLANTATION INTO BONE MARROW WHICH INCLUDES THE STUDY OF CELL DISTRIBUTION *IN VIVO* AND THE EFFECTS OF HEMATOPOIETIC RECONSTRUCTION

H Huang[1,*], Q Jiang[1], Y Zhou[1], Q Zhang[1],xSun[2], M Zhang[2], J Sun[1], Q Mai[2], Z Zheng[2], Y Lu[2], L Liu[2], J Majaw[2], N Gan[3], S Jiang[2]
[1]Nanfang Hospital, [2]Southern Medical University, Guangzhou, [3]Ningbo University, Ningbo, China

Background: Target cell transplantation to bone marrow (BM) is possible by Magnetism-induced cell target transplantation (MagiC-TT) (EHA2015posterP701).
Aims: RFP-MSC were used to observe the cell's distribution and the following effect, additionally $CD45^+$GFP cells were used to evaluate the promotion of hematopoietic reconstitution of MagiC-TT.
Methods: 1) *Target transplantation of MSC:* Fe_3O_4@PDA@Au nanoparticles (NPs) were synthesized and introduced into Luciferase gene modified RFP-MSC (Luc-RFP-MSCs). Magnetized and wt Luc-RFP-MSCs were compared on the biological feature and their ability of migration *ex vivo*. Then magnetized RFP-MSCs were micro-injected into the femur cavity of the mice with the help of X-ray (Figure 1a), under magnet in M group or without in W group. Bioluminescence, FACS, PCR and histopathological analysis were ued after transplantation. 20 eGFP transgenic mice and another 20 C57 mice were used. 2) *$CD45^+$cells transplantation:* 34 C57 mice were randomly divided into 2 groups evenly. 7.5Gy myeloablative irradiation were given 1d before, then $CD45^+$cells were isolated by MACS from eGFP transgenic mice and freshly micro-injected into right femur, 1×10^6 cells/20uL per mouse, with or without magnet for 24hrs (M or W group). At 0h, 24h, 72h after injection, every 3 mice in both groups were sacrificed at each time point for detection, then remaining 8 mice in both groups were compared with the general conditions, hematopoietic recovery, GFP^+cells in different organs *etc.*
Results: 1) *Target transplantation of MSCs:* NPs exist within or on the surface of magnetized RFP-MSCs (Figure 1b), no obvious change was found. The magnetized RFP-MSCs were capable of target migration under magnetism *ex vivo*. Bioluminescence assay showed that the magnetized Luc-RFP-MSCs appeared in the lung of W group 5 min after cell injection, while fixed in the femur of M group mice. However, on withdrawal of magnet 1h after cell injection, strong fluorescence was observed in the lung of M group gradually (Figure 1c). By pathological examinations, FACS and PCR, large number of RFP-MSCs were observed to reside within the BM in M group while few in W group, thereby demonstrating the specific BM target transplantation of magnetized RFP-MSCs. Those RFP-MSCs were found to survive more than 3m in different organs. 2) *$CD45^+$cells transplantation:* The mice that survived were 7/8 *vs* 1/8 in M or W group respectively (Figure 1d). The GFP% in femurs of both groups (Table 1) also proved the specific BM target transplantation in M group. Platelet recovery in M group is faster than that in W group (12.33d±2.42d *vs* 16.38d±2.39d, P=0.009); and the lowest value of decreased hemoglobin in M group was higher than that of W group (43.75±13.02 *vs* 13.75±5.18, P<0.001).



(a-c) Target transplantation of MSC: **(a)** (I) X-ray showed the location of needle within the femur of a M group* mouse; (II) Bioluminescence image of the identical mouse; (III) Integrated image of X-ray and Bioluminescence. **(b)** Transmission electron microscope of magnetized RFP-MSCs (The red, yellow and blue arrows indicated the NPs on the cell surface, in the endocytosis process and within the cell, respectively). **(c)** Bioluminescence detection 5 min after magnetized RFP-MSCs injection, luciferase can be detected in the lung of W group#(I), but fixed in the femur of M group until withdrawal of the magnet 1 h after (II), 15 min after withdrawal of magnet, fluorescence displayed in the lung of M group gradually (III). **(d) CD45+ cells transplantation:** Survival curves of mice in M group and W group (P<0.05).
* the experimental group with magnetic field. #: the control group without magnetic field.

IMPLICATION OF THE PERCENTAGE OF MACROPHAGES WITH HAEMOPHAGOCYTOSIS IN THE DIAGNOSIS AND PROGNOSIS OF PATIENTS WITH HAEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

T Knight Asorey[1,*], C Prats Martín[1], RM Morales Camacho[1], F Márquez-Malaver[1], O Pérez López[1], E Arbelo[1], MT Vargas[1], T Caballero Velázquez[1], MA Herrera[1], J Borrero[2], R Bernal[1], JA Pérez Simón[1]
[1]Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio- Virgen del Macarena, [2]Department of Pathology, Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Haemophagocytic lymphohistiocytosis (HLH) is a serious condition whose diagnosis is based on clinical,analytical and histopathological criteria established by "The International Histiocyte Society"(IHS) in 2004. Haemophagocytosis is one of the diagnostic criteria. However,haemophagocytosis can also be observed in other disorders in absence of HLH.
Aims: To review a series of patients with HLH and determine the percentage of macrophages and macrophages with haemophagocytosis observed in bone marrow aspirate (BMA). To compare the haemophagocytosis in this group with that observed in patients without HLH. To evaluate the possible impact of both parameters in diagnosis and survival of HLH patients.
Methods: A retrospective study of 31 patients diagnosed with HLH between 2008-2015.Cytomorphological review was carried out by 2 experienced cytohaematologists. The percentage of macrophages was established from a minimum sample of 500 nucleated cells and the percentage of haemophagocytosis from number of macrophages (minimum 30 macrophages).Clinical and analytical data were gathered concerning diagnosis, treatment and follow-up. A control group consisting of patients with haemophagocytosis without HLH criteria was formed. SPSS v19.0 was used for the statistical analysis. Survival analyses were performed using Kaplan-Meier method.
Results: 31 patients were included:median age 41 (range 6 months-80 years),17 male and 14 female. Underlying diseases were:lymphomas 11/31 (36%); infections 10/31 (32%): 3 EBV, 3 leishmanosis, 2 CMV and 2 leishmanosis associated to EBV; autoimmune diseases 5/31 (16%); other causes (solid neoplasm and surgery) 2/31 (6%); idiopathic 3/31 (10%). At diagnosis 30/31 (97%) had fever and 27/31 (87%) had splenomegaly. One cytopenia was observed in 5/31 (16%), bicytopenia 12/31 (39%) and pancytopenia 14/31 (45%). Biochemical parameters:hyperferritinemia in 20/31 (64%),hypertriglyceridemia in 13/31 (42%),high levels of LDH 17/31 (55%), and hypofybrinogenemia in 9/31 (29%).From the total, 12 patients (39%) were treated according to IHS protocol; 10 (32%) with chemotherapy aimed at lymphoma; 3 (10%) steroides; 5 (16%) with antibiotics and 1 was not treated. At median of follow up of 8.2 months,overall survival was 50%. 15 of 31 patients died, 10 of them (32%) within the first 90 days. 40 patients with haemophagocytosis not attributed to HLH were used as control group. Underlying diseases were:lymphomas 11/40 (27.5%);cytopenias 8/40 (20%);leukaemias 4/40 (10%);plasma cell neoplasms 3/40 (7.5%);bone marrow failure 3/40 (7.5%);myelodysplastic or myeloproliferative syndromes 3/40 (7.5%);infections 2/40 (5%);other causes 6/40 (15%).The average of macrophages in patients with HLH was 1.5% (range 0.5-90%) compared to 1% (0.2- 35%) in the control group (p=0.25). The average percentage of macrophages with haemophagocytosis in patients with HLH was 25% (range 0.5-75%) compared to 3.5% (0.5- 60%) in control group (p<0.001). In the group of patients with HLH, those who had a percentage of macrophages >1.5% had a median survival of 99 days compared to 243 days for those with lower percentage (p=0.76). Patients with percentage of macrophages with haemophagocytosis >25% had a survival rate of 107 days compared to 190 days for those who had a percentage lower than 25% (p=0.45).
Summary/Conclusions: The percentage of macrophages observed in BMA in patients fulfilling criteria of HLH is similar to that of patients without HLH. However, there are significant differences in the percentage of macrophages with features of haemophagocytosis. This information could be useful in the differential diagnosis. Among patients with HLH, a trend towards a lower median survival was observed in those with the highest percentage of macrophages as well as in those with a higher percentage of haemophagocytosis.

PB1848

BIOSIMILARS OF FILGRASTIM – ZARZIO® - ASSOCIATED TO PLERIXAFOR ARE EFFECTIVE FOR MOBILIZATION IN LYMPHOMA PATIENTS DEFINED AS HARD TO MOBILIZE

A Tempescul[1,*], V Rebiere[1], M Zdrenghea[2], C Tripogney[3], JC Ianotto[1]
[1]Clinical Hematology, Teaching Hospital Brest, Brest, France, [2]Clinical Hematology, UMF Cluj, Cluj-Napoca, Romania, [3]EFS site de Brest, EFS Bretagne, Brest, France

Background: he biosimilars of G-CSF are the object of debates on their efficiency and their harmlessness princeps medicine. Their use and efficiency for mobilization of the peripheral stem cells (CSP) were less studied. Even less informations are available on the association of biosimilars and Plerixafor in view of the peripheral stem cells harvest in patients defined as hard to mobilize.
Aims: We present our experience on the association of Zarzio ®-Plerixafor for mobilization of lymphoma patients, define as hard to mobilize, with the aim of obtaining of a sufficient graft for an autologous stem cell transplantation.
Methods: Between January, 2012 and December, 2014, we identified 18 patients, 9 mens and 9 women with an average age of 53 years (22-69 years) which benefited from a harvest of the peripheral stem cells at University hospital Brest, France. The patients underwent stimulation by Zarzio ® 30MUI two injections a day, during 5 days (D-4 has D0) and Plerixafor 0.24mg/kg starting at day 0 J0. The stimulation was pursued until the obtaining of a sufficient graft (defined as more than 2.5 millions CD34+/ kg) or for a maximum of 3 consecutive days. We collected for the patients the number of aphaeresis per patient and the number of the CD34+cells harvested by aphaeresis and by patient.
Results: All in all we have made 39 aphaeresis in 18 patients that underwent a double stimulation. The average number of aphaeresis per patient was of 2.16 sessions (1-3/patient). Two patients benefited from a single session of aphaeresis, eleven patients benefited from two sessions of aphaeresis and five patients of three sessions of aphaeresis. For twelve of eighteen patients (66.7%) we achieved the target of a sufficient graft according to the local consensus ($2.5x10^6$ CD34+/ kg). For 14 of 18 patients (77.8%) there was a sufficient according to the recommendations EBMT ($2x10^6$ CD34+cells/kg) on the minimum necessity has the autograft.The average number of CD34+taken by aphaeresis was $1.58x10^6$ cells/kg ($0.22\text{-}6.31x10^6$ CD34+cells/kg). The total average number of the CD34+cells harvested per patient was $3.41x10^6$/kg ($1.5\text{-}6.77x10^6$ CD34+cells/kg).
Summary/Conclusions: We analyzed in a cohort of 18 lymphoma patients defined as hard to mobilize the results of the peripheral stem cell harvest obtained after stimulation by plerixafor associate to a biosimilar of filgrastim - Zarzio ®. We obtained a sufficient graft in 77% according to international recommendation with a limited number of aphaeresis procedure – 2.1 aphaeresis per patient. The results obtained by associating Zarzio® and Plerixafor for peripheral stem cell harvest in lymphoma patients defined as hard to mobilize are comparable with those obtained with products princeps and publish in the literature.

PB1849

THE ROLE OF ENDOTHELIAL CELL-EXPRESSED ALPHA HEMOGLOBIN AND ITS MOLECULAR CHAPERONE AHSP IN BLOOD PRESSURE REGULATION

C Lechauve[1,*], L Biwer[2], A Freiwan[1], S Frase[3], H Tillman[4], B Isakson[5], M Weiss[1]
[1]Hematology, St. Jude Children's Research Hospital, Memphis, [2]University of Virginia, Charlootesville, [3]Cellular Imaging, [4]Veterinary Pathology, St. Jude Children's Research Hospital, Memphis, [5]Molecular Physiology and Biophysics, University of Virginia, Charlootesville, United States

Background: Because hypertention is the leading indicator of cardiovascular disease, understanding the blood pressure regulation and regional blood flow to specific vascular beds is of great medical importance. We have recently hypothesized a new mechanism for blood pressure regulation mediated specifically by the alpha subunit of hemoglobin (αHb) [1].
Aims: The α subunit (but not the β subunit of Hb) is expressed in endothelial cells (ECs) within the myoendothelial junction (MEJ), a structure in resistance arteries where ECs and smooth muscle cells (SMCs) cross-communicate to regulate vascular tone. In the MEJ, αHb is proposed to degrade NO via the dioxygenase reaction and thereby increase vascular tone. Moreover, aHb forms a complex with endothelial nitric oxide synthase (eNOS, the major local source of NO production) and cytochrome B5 reductase (CYB5R3) an enzyme that reduces ferric αHb to favor dioxygenase activity [1-3]. Alpha hemoglobin stabilizing protein (AHSP) is a molecular chaperone that binds free αHb, stabilizes its structure and also regulates its redox state, at least in the context of red blood cells [4,5]. Free αHb is extremely unstable and would not be expected to exist without a binding partner in cells. Moreover, we showed previously that AHSP converts bound ferrous αHb into a stable hexacoordinate ferric form that lacks ability to degrade NO [6,7]. Based on this data, we hypothesized that AHSP both stabilizes αHb and regulates its redox state and dioxygenase activity in vascular ECs.
Methods: We investigated this hypothesis by using vascular cell co-culture model composed of human coronary ECs and SMCs, and Ahsp-/- and alpha thalassemic mice strains.
Results: Our studies demonstrate that αHb interaction with AHSP and eNOS

is mutually exclusive and αHb protein expression is disrupted in Ahsp-/- and alpha thalassemic ECs, resulting in reduced arterial tone, lowered blood pressure and abnormal arterial structure.
Summary/Conclusions: Through these mechanisms, AHSP-bound αHb may regulate blood vessel tone dynamically according to ambient conditions and CYB5R3 availability.

THE "NORMOBARIC OXYGEN PARADOX": INFLUENCE OF NEW MODELS ON THE EVOLUTION OF ERYTHROPOIETIN, RETICULOCYTE COUNT AND HEMOGLOBIN CONCENTRATION IN PATIENTS UNDERGOING BREAST RECONSTRUCTION SURGERY

R Calabrese[1,*], M Khalife[1], J Valsamis[2], C Balestra[3], F Urbain[4], M Sosnowski[1]
[1]Anesthesiology, Institut Jules Bordet, [2]Clinical Biology, CHU-Brugmann, [3]Divert Alert Network (DAN), Europe Research Division, [4]Plastic and Reconstructive Surgery, Institut Jules Bordet, Brussels, Belgium

Background: The "Normobaric Oxygen Paradox" (NOP) is a physiologic mechanism that induces an increase of endogenous erythropoietin (EPO) production by creating a state of relative hypoxia in subjects previously exposed to a period of normobaric hyperoxia, followed by a rapid return to normoxia. To date, the oxygen exposure duration and the inspired oxygen fraction required to observe a significant increase in hemoglobin or EPO production are not clearly defined.
Aims: This study sought to observe the effect of two models of relative hypoxia compared to a control group on EPO, reticulocytes and hemoglobin stimulation through the NOP theory in patients undergoing breast reconstruction surgery.

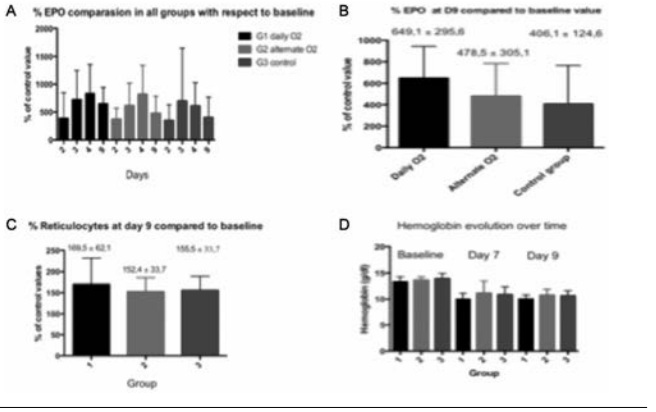

Figure 1.

Methods: After local ethic committee approval and obtaining written informed consent, thirty patients undergoing deep inferior epigastric perforator (DIEP) flap breast reconstruction were prospectively randomized into 3 groups. Nine patients were excluded from analysis for lack of results and/or patient withdrawal. The first group (G1; n=7) was exposed to 5 L O_2/m for 60 minutes per day through a nasal cannula from day one to day nine postoperatively. The second group (G2; n=6) was similarly exposed to O_2, but on alternate days, while the third group (G3; n=8) served as control. All groups recived FiO_2=50% during surgery. Serum EPO was measured on day 0 and postoperatively on days 2, 3, 4 and 9. Serum hemoglobin level and reticulocyte count were measured on day 0 and postoperatively on days 7 and 9. Taking the initial value as 100%, percentage changes in EPO and reticulocytes were calculated, thereby allowing an appreciation of the magnitude on change rather than the absolute values. We used a two-way analysis of variance (ANOVA) for repeated measures to test the variation between groups and over time.
Results: We noticed a pic% EPO elevation at days 3 and 4 with no significant difference between the groups (Figure 1A). At day 9,% EPO in G1, G2 and G3 was 649,1±295,6; 478,5±305,1 and 406,1±124,6 mIU/mL respectively (p>0,05) (Figure 1B). However, the% EPO at day 9 in G1 tended to be more elevated compared to G2 and G3. At day 9, reticulocyte count was more elevated in G1 compared to G2 and G3 (Figure 1C). Hemoglobin level in G1, G2 and G3 was 10,04±0,77; 10,73±1,14 and 10,64±0,96 g/dL respectively (Figure 1D).
Summary/Conclusions: Relative hypoxia seems to be a stimulus for EPO production in all our groups. However, further studies are needed in non-surgical patients with larger sample size and longer follow-up to determine its real impact on hemoglobin.

PB1851

THE RELATIONSHIP BETWEEN BONE MARROW STROMAL FIBROBLASTS, MYELOGRAM PERFORMANCE AND EFFICIENCY OF CHEMOTHERAPY IN CHILDREN WITH ACUTE LEUKEMIA

K Bruslova[1,*], N Tsvietkova[1], L Panchenko[2], L Lyashenko[3], T Pushkareva[1], S Yatsemyrskyy[1], O Kuznetsova[1]
[1]Radiation Hematology for Children, SI "National Research Center for Radiation Medicine of NAMS of Ukraine, [2]SI"Institute of Traumatology and Orthopedics NAMS Ukraine", [3]SI "National Research Center for Radiation Medicine of NAMS of Ukraine, Kiev, Ukraine

Background: Tumor microenvironment plays an important role in cancer initiation and progression. The cancer associated fibroblasts impact on resistance development to chemotherapeutic agents in the treatment of acute leukemia (AL) discussed.
Aims: The aim of the study was to determine the relation between colony-forming efficiency of bone marrow stromal fibroblasts, myelogram parameters and effectiveness of chemotherapy (CT) in children with lympho- and myelovariants of acute leukemia (ALL, AML).
Methods: The study involved 38 children: ALL - 24, AML - 14. Age of children ranged from 6 to 18 years. Treatment was performed by standard protocols. Investigation of patients executed in complete remission phase after full chemotherapy course of primary diagnosis leukemia. Retrospective surveillance was conducted for 15 years. The effectiveness of chemotherapy evaluated by presence/absence of AL relapse. Among patients with ALL the relapse stated in 8 persons, among AML - in 7 children. Efficiency of bone marrow stromal fibroblast colony-forming units (E -CFUf) *in vitro*, myelogram performance were studied. Spearman correlation coefficient, U- test were used.
Results: E-CFUf not depend on the variant of acute leukemia (Uemp.=61.5). In patients with AL we found the inverse correlation between the E-CFUf index and the percentage of erythroblasts (Rs=- 0,52) and monocytes (Rs=- 0,45) in the bone marrow. The direct connection between the number of monocytes and erythroblasts in myelogram defined (Rs=+0,59), probably because of their joint operation in the development of erythroid elements of hematopoiesis. The inverse correlation(Rs=-0,44) between the percentage of monocytes in patients myelogram and AL relapse occurence was found.
Summary/Conclusions: The inverse correlation between stromal fibroblasts and erythroblasts as monocytes in the bone marrow of AL children indicates the regulatory role of stromal microenvironment elements in the functioning of hematopoiesis in the development of malignancy. Discovered correlation between relapse development and the number of monocytes in the AL patients bone marrow after end of protocol treatment opens up further possibilities to determine the mechanisms of chemoresistance formation at AL and review the ways to prognose the effectiveness of treatment of such patients.

APHERESIS COLLECTION OF MOBILIZED HEMATOPOIETIC STEM CELLS FROM PERIPHERAL BLOOD IN HEALTY DONORS – 15 YEARS OF EXPERIENCE

R M Grubovic[1,*], L Cevreska[2], B Georgievski[2], S Genadieva-Stavric[2], A Stojanovic[2], S Useini[3], A Pivkova[2], Z Stojanoski[2], E Petkovic[3], L Cadievski[2], M Grubovic[3]
[1]Head of Stem Cell Collection, Institute for Transfusion Medicine of RM, Medical Faculty - Skopje, [2]University Hematology Hospital, [3]Institute for Transfusion Medicine of RM, Medical Faculty - Skopje, Skopje, Macedonia

Background: Mobilized hematopoietic peripheral blood stem cell (PBSC) has been widely used for allogeneic transplantation in different hematologic malignancies. Optimal donor and recipient outcomes require maximized stem cell collection efficiency.
Aims: The aim of our study is to present our experience of 15 years in collecting of PBSC in healthy donors.
Methods: This is a retrospective study performed in the Institute for Transfusion Medicine of Republic of Macedonia and University Hematology Hospital for period from January 2001 till December 2015. All donors were HLA typed and

matched; they were fully informed on the donation procedure and signed an informed consent for donation. Minimum dose required to ensure successful and sustained engraftment was 2x10^6/kg CD34+cells and 2x10^8/kg mononucleated cells (MNC). PBSC harvesting was performed with continuous flow cell separator Baxter C53000 and COBE Spectra using conventional-volume apheresis processing the 2 – 2.5 total blood volumes per apheresis. A femoral catheter was used for harvesting and Acid Citrate Dextrose formula A is used for anticoagulation. Recombinant human granulocyte colony-stimulating factor (G-CSF) is used to mobilize PBPC for collection. Harvesting of PBSC is usually performed after 4 to 5 days of G-CSF subcutaneous administration at a dose of 10 µg/kg body weight.
Results: All the donors were siblings of the patients treated at the University Hematology Hospital. There were 126 apheresis procedures performed in 74 healthy sibling donors. There were 48 males and 26 females, aged 19-55. The single procedure usually took 3-4 hours and the volume of collected stem cells was 50-220 ml. The needed number of MNC and CD34+cells was successfully collected by 1.7 apheresis (range 1-2). There were 9 ABO incompatible donors. Procedures for mobilization and collection of PBPC from healthy donors are generally well tolerated. The only adverse effects of the apheresis procedure were bone pain as reaction of G-CSF and numbness of the extremities as reaction of ACD-A (hypocalcemia), which occur rarely and were very mild. The collected PBSC were used in allogeneic stem cell transplantation in patients with: acute myeloid leukemia – 61.3%, acute lymphoblastic leukemia – 17.7%, chronic myeloid leukemia – 9%, myeloproliferative disorders – 4.1%, severe aplastic anemia – 2.7%, non-Hodgkin lymphoma – 2.7%, chronic lymphoblastic leukemia - 1.3%, Hodgkin disease – 1.3% and multiple myeloma – 1.3%.
Summary/Conclusions: The apheresis collection of PBSC in healthy donors is an effective and safe procedure. We are developing a National Stem Cell Donors Registry as a part of Bone Marrow Donors Worldwide. In that way we hope we will help widen the world network of stem cell donors and enlarge the possibility for each patient to find the right match.

PB1853

PERFORMANCE EVALUATION OF Q-FLAG OF HEMATOLOGY ANALYZER, SYSMEX XN-20
HR Kim*, OJ Kweon
Chung-Ang University College of Medicine, Seoul, Korea, Republic Of

Background: The Sysmex XN modular analyzer (Sysmex, Kobe, Japan), which were introduced in 2011, applied several new analysis channels compared to previous analyzer, XE series. White cell precursor channel (WPC), one of the new channels, adopted fluorescence flow cytometry technology and developed especially for detecting myeloblasts or lymphoblasts more accurately than any other channels applied in previous modules.
Aims: Our study aim to investigate the flagging performance of Sysmex XN-20 modular analyzer focusing on the Q values.
Methods: We investigated the performance of Q values flagging according to interinstrumental agreement, intrainstrumental precision, and diagnostic accuracy. Tested suspect flags are “blasts/abnormal lymphocytes”, “atypical lymphocytes” from white cell differential channel, and “blasts” from white cell precursor channel.
Results: In interinstrumental agreement evaluation, two XN modules showed significant Q value correlation for each suspect flags although Pearson’s correlation coefficient for “blasts/abnormal lymphocytes” and “blasts” flags were too low; they were 0.28 and 0.29. However, from Pearson’s chi-square tests, there were significant difference in flagging performance between two analyzers for all of each flags (P<0.01 for all of tested flags). Absolute agreement rates were ranged from 65.0% to 83.5%, and kappa values were ranged from 0.305 to 0.501. In intrainstrumental precision evaluation, for the specimens with Q value of 50-150, standard deviations were ranged from 4.8 to 23.9 for “blasts/abnormal lymphocytes” flag, from 18.7 to 59.1 for “blasts” flag, and from 11.0 to 23.0 for “atypical lymphocytes” flag during 10 replicates. For diagnostic accuracy, in the default Q value cutoff setting (Q value of 100), sensitivities and specificities for “blasts/abnormal lymphocytes” flag were 90.1% and 73.8%, the values for “blasts” flag were 92.1% and 86.3%, and the values for “atypical lymphocytes” flag were 70.0% and 89.9%, respectively.
Summary/Conclusions: We recommend to adjust the Q value threshold setting for “blast/abnormal lymphocyte”, “blast” and “atypical lymphocytes” because of their inadequate diagnostic accuracy of default threshold setting. However, their poor intrainstrumental precision and interinstrumental agreement weaken the reliability of Q value flags.

SURVIVORSHIP PROGRAM: SECOND MALIGNANCIES IN LYMPHOMA SURVIVORS
MP Simula[1,*], AM Mamusa[1], S Usai[1], E Montaldo[2], E Angelucci[1]
[1]Struttura Complessa di Ematologia e Centro Trapianti. Ospedale Oncologico di Riferimento Regionale. Cagliari, Italia, AOB Cagliari, [2]ASL 8, Cagliari, Italy

Background: Improvements in the treatment of both Hodgkin’s (HL) and non Hodgkin’s Lymphomas (nHL) have resulted in an increasing number of long term survivors. However this patient’s population is at high risk of developing late therapy related complications that can negatively affect long term survival and quality of life.
Aims: In our institution the HL and aggressive NHL long term survivors are followed up in a dedicated clinic since September 2014. Here we report preliminary data on second malignancies.
Methods: We have collected retrospective data on second tumours in 469 consecutive lymphoma survivors.
Results: We have analyzed data regarding 469 patients coming in our clinic from 15 September 2014 to 18 February 2016, 247 have been successfully treated for HL and 222 for nHL. Two hundred thirty three were females, 236 males; median of age at lymphoma diagnosis was 29 years for HL (range 13-84) and 48 years for nHL (range 12-83). Median age at last observation in the follow up clinic was 50 years for HL (range 21-89) and 62 years for nHL (range 24-88).The median of duration of follow up was 18 years for HL (range 5-40) and 13 years for nHL (range 5-37).Sixty two patients (13%) experienced a second cancer, 4 of them had 2 neoplasms, so we documented 66 second tumours (Table 1). They were: 23 skin (35%) and 43 non cutaneous cancers (65%). The non skin neoplasms were: 10 breast, 9 gastroenteric, 8 thyroid, 6 prostatic, 1 lung, 4 bladder, 1 renal, 1 tongue, 1 testis 1 gynecological metastatic, and 1 cutaneous appendages malignant cancers (Table 2). Four of these tumours (2 colon, 1 thyroid and the metastatic gynecological one) have been diagnosed with our program of early diagnosis of second cancers and thyroid dysfunctions. The median of time between diagnosis of lymphoma and diagnosis of second malignancy was 18 years (range 1-41). Regarding the previous therapies: mediastinal radiotherapy has been administered to 7 out of 10 of the females with breast cancer (70%), mantel or neck radiotherapy to 6 out of 8 (75%) with thyroid cancer; no one of the intestinal and prostatic cancers have received abdominal radiotherapy; one out of 4 of the patients with urinary cancer (25%) had abdominal radiotherapy and MOPP/ABVD regimen; the one with lung cancer had MOPP chemotherapy and mantle radiotherapy. Chemotherapy has been administered for the treatment of lymphoma to 6 with breast (60%), to 7 with thyroid (88%), to all with gastroenteric (100%), and to 4 with bladder cancers (67%). Median of age of breast cancer in our setting was 50 years (range 38-70), of thyroid cancer was 40.5 years (range 24-55), and of gastroenteric cancer was 66 years (range 42-83). Moreover we have documented relapse of their original lymphoma in 3 patients (2 HL and 1 nHL) respectively at 9, 22 and 28 years after initial diagnosis.

Table 1. Features of patients with second neoplasms.

Sex	32 female	30 male
Lymphoma type	40 HL	22NHL

Table 2. Type of second malignancies in our lymphoma survivor patients.

Type of neoplasm	number
Skin	
Basocellular carcinoma	20
Spinocellular carcinoma	3
Breast carcinoma	10
Gastroenteric tract carcinoma:	
Colon-sigma-rectum	7
Gastric	1
Esophagus	1
Thyroid carcinoma	8
Prostatic malignancies	
Adenocarcinoma	5
Sarcoma	1
Bladder	4
Lung carcinoma	1
Tongue carcinoma	1
Cutaneous appendages	1
Testis carcinoma	1
Renal carcinoma	1
Gynecological metastatic neoplasm (histology ongoing)	1

Summary/Conclusions: In our Department we described a significant number of cases of second neoplasms in the lymphoma survivors population: 4 of these (9% of non cutaneous cancers) were detected by tests done for early diagnosis of late complications. These results outlne the importance of a risk adapted plan for early diagnosis of cancers in this setting of patients that would be encouraged by both hematologist and general practitioners.

PB1855

GEMCITABIN, VINORELBINE AND PREDNISOLONE (GVP)±RITUXIMAB COMBINATION IN RELAPSED/REFRACTORY LYMPHOMA CASES: RETROSPECTIVE ANALYSIS

S Paydaş[1,*], E Bagir[2], M Ergin[2]
[1]Medical oncology, [2]pathology, Çukurova University, Adana, Turkey

Background: Lymphomas are heterogenous group of disorders and relapse is not infrequent after standard chemotherapy regimens. Salvage regimens are used to determine the chemosensitivity before stem cell transplantation. GVP combination is one of the salvage regimens used as in cases with relapsed /refractory Hodgkin Lymphoma (HL) or non- Hodgkin Lymphoma (NHL).
Aims: The aim of this study is to evaluate the results of Gemcitabin, vinorelbine and prednisolone GVP plus minus Rituximab regimen in cases with lymphoma treated by GVP.
Methods: Thirty seven cases with lymphoma were included in this analysis. Age range was between 18-77, male female ratio was 20/17. Twenty one of the cases had HL and 16 had NHL. Among NHL, 8 had diffuse large B cell lymphoma (DLBCL), 3 had peripheral T cell lymphoma (PTCL), 3 had indolent NHL (iNHL), 2 had transformed NHL and one had anaplastic large cell lymphoma. All the cases had been treated by standard first line chemotherapy regimens. Results were analyzed retrospectively.
Results: The most commonly used 1st line salvage regimen was DHAP±Rituximab. GVP±Rituximab was used as 1st line, 2nd line and after than 4th line setting in 7, 28 and 2 cases, respectively. Response to 1st line GVP±Rituximab: complete response (CR) was detected in 1 case, partial response (PR) in four cases, minimal response (MR) in one case and progressive disease (PD) in one case. Response to 2nd line GVP±Rituximab: CR, PR and PD were detected in 5, 9 and 14 cases, respectively. Responses according to lymphoma subtypes: 1st line GVP setting CR, PR and PD were detected in 1, 1, 1 cases with HL and PR and MR in 3 and 1 cases with NHL. In 2nd line GVP setting CR, PR and PD were detected in 5, 6 and 7 cases with HL and 1, 2 and 8 cases with NHL, respectively.
Summary/Conclusions: GVP as salvage regimen in second line setting, although the number of the cases treated in 1st line setting is limited, is a reasonable choice with 50% overall response rate in cases with HL but not in NHL.

PB1856

LYMPHADENOPATHY WITH ELEVATED IGG4 PLASMA CELLS IN CHILDHOOD: A POSSIBLE ASSOCIATION WITH MALIGNANCIES OR IMMUNE MEDIATED DISEASES

MP Boaro[1,*], A Marzollo[2], E Carraro[2], ESG d'Amore[3], R Alaggio[4], E Varotto[2], M Gabelli[2], P Dall'Igna[5], M Zuliani[6], M Pillon[2], MC Putti[2], G Basso[2]
[1]Clinica di Oncoematologia Pediatrica, Dipartimento della Salute della Donna e del Bambino, Azienda Ospedaliera-Universita' di Padova, [2]Clinica di Oncoematologia Pediatrica, Dipartimento della Salute della Donna e del Bambino, Azienda Ospedaliera-Università di Padova, Padova, [3]Dipartimento di Patologia, Ospedale San Bortolo, Vicenza, Vicenza, [4]Dipartimento di Patologia, Università degli Studi di Padova, [5]Unità di Chirurgia Pediatrica, Dipartimento della Salute della Donna e del Bambino, Azienda Ospedaliera di Padova, [6]Dipartimento di Radiologia, Università degli Studi di Padova, Padova, Italy

Background: IgG4 related disease (RD) is a fibroinflammatory condition, identified in 2003, that can involve every organ and apparatus. The diagnostic criteria for IgG4 (RD) are based on three characteristics of the disease: organ enlargement or nodular lesions in different organs, increase of serum IgG4 and infiltration of IgG4 plasma cells. The most frequent disease manifestations are autoimmune pancreatitis, sialadenitis, dacryoadenitis and retro-peritoneal fibrosis; IgG4 related lymphadenopathy is rare. Differential diagnosis of IgG4 RD are malignancies and autoinflammatory diseases. It is usually diagnosed in middle and senile aged men; only few pediatric cases in literature are described, and the organs involved are orbits, lungs, mediastinum and abdomen. Lymphadenopathy of IgG4 (RD) is often the first manifestation of the disease, that could progress and involve any organ; a disease localized only in lymph nodes is rare and poorely characterized. No pediatric cases of IgG4 related lymphadenopathy or association with malignancies or other immune-mediated disorder are described in literature.
Aims: To describe for the first time two pediatric cases of lymph node histological pattern of IgG4 (RD) with association with lymphoma and immune-mediated disease.
Methods: Data of the two pediatric patients were retrospectively reviewed. The specimens for the histological analysis were centrally reviewed.
Results: Data of two patients with a histological pattern of IgG4 lymphadenopathy were analyzed. Both of them had a history of persistent lymphoadenopathy. Patient #1, a 11 years old male, with normal serum IgG4 concentration, had a first cervical lymph node biopsy with the evidence of progressive transformation of germinal centers and a high number of IgG4 plasma cells; two months later, for increasing of lymph nodes dimension, he had a second biopsy and the diagnosis of nodular lymphocyte predominant Hodgkin Lymphoma (HL) was made. He was treated with three cycles of prednison, vinblastine and cyclophosphamide, obtaining a complete remission (follow-up: 18 months). Patient #2, a 18 years old male, with a personal history of asthma and atopic dermatitis, had a persistent neck lymphadenopathy after 8 years from an infectious mononucleosis. He had high serum IgG4 concentration. Histology showed follicular hyperplasia and increased IgG4 plasma cells in germinal centers. Following analysis evidenced elevated (10%) double negative TCR alpha-beta positive T cells, suggesting the diagnosis of Autoimmune Lymphoproliferative Syndrome (ALPS). Fas-mediated apoptosis assay is currently ongoing.
Summary/Conclusions: We described for the first time 2 pediatric cases with with histological lymph node characteristics usually found in IgG4 (RD); in particular in one patient this finding was associated with a nodular lymphocyte predominant HL, in another patient with clinical and hematological features suggestive of ALPS. The significance of this histological finding in adult patients with isolated lymphadenopathy is still unclear and rare correlations with lymphomas and with autoimmune diseases are reported. Our data suggest that also in childhood this pattern is not specific for IgG4 RD but may be present in different malignant and non malignant disorders. A careful throughout examination and follow-up should be carried out in patients affected by IgG4 RD or with lymph node biopsy showing the IgG4 features, to monitor the possible development of lymphoma and other immune mediated diseases.

PB1857

LATE RELAPSE OF HODGKIN LYMPHOMA – IS IT DIFFERENT IN CLINICAL CHARACTERISTICS AND OUTCOME?

O Markovic[1,*], B Andjelic[2], O Tarabar[3], M Todorović[2], B Filipović[1], J Bila[2], D Antić[2], D Marisavljevic[1], B Mihaljević[2]
[1]Hematology, Clinical Hospital Center "Bezanijska kosa" Medical Faculty Belgrade, [2]Hematology, Clinic of Hematology, KCS, [3]Hematology, Military Medical Academy, Beograd, Serbia

Background: Relapse of Hodgkin lymphoma usually occur in 20-30% patients. The disease relapse usually occur within the first 5 years after the diagnosis, with the trend of the diminishing after three years ans subsequently, only minority relapses after 5 years.
Aims: The aim of this study was to evaluate the clinical characteristics, prognostic factors, therapy and outcomes of patients with late relapse (>5 years).
Methods: We retrospectively analyzed clinical presentation, the prognostic significance of clinical parameters, therapy and outcome in the group of patients with very late relapse of Hodgkin lymphoma and compare them with patients who relapse earlier.
Results: In group of 102 patients with relapsed Hodgkin disease 16(15.68%) patients had very late relapse of disease. Median time to very late relapse was 86 months (range 61 to 199 months). Most of these patients (11, 68.5%) were in advanced clinical stage (III, IV). 11(68.75%) patients with very late relapse were treated with high dose chemotherapy and autologous bone marrow transplantation. Second complete response was achieved in 13(81.25%) patients. At a median of 4,5 years after therapy for very late relapse, 13(81.25%) patients are still alive and free of disease and 3 patients died: 2 patients from Hodgkin lymphoma, and one patient from brain tumor. There was not noticed significant difference between initial clinical parameters between of patients with very late relapse and patients who relapse earlier. Median survival of patients with very late relapse of disease was significantly longer (p=0.001). However, survival calculated from the moment of relapse of disease was not significantly different between these two group of patients (p=0.83).
Summary/Conclusions: The late relapse is relatively rare event in our group of patients with Hodgkin lymphoma. Patients with very late relapse have longer OS, than the patients who relapse earlier, but survival calculated from relapse was not significantly different. Remains an open question is it necessary to apply high dose therapy and autologous transplantation in all patients with very late relapse of disease. Further clinical trials are needed to characterize best therapy option in patients with very late relapse tailored to disease risk and comorbidities.

PB1858

LYMPHOMA SURVIVORSHIP AND CARDIOVASCULAR DISEASES SURVEILLANCE

MP Simula[1,*], AM Mamusa[1], S Usai[1], G Locci[2], E Angelucci[1]
[1]Struttura Complessa di Ematologia e Centro Trapianti. Ospedale Oncologico di Riferimento Regionale. Cagliari, Italia, [2]Struttura Complessa di Cardiologia, AOB Cagliari, Cagliari, Italy

Background: Improvements in the treatment of Lymphomas have resulted in

an increasing number of long term survivors. This patient's population is at risk of developing late therapy related complications that can negatively affect their survival and quality of life.
Aims: In our institution since September 2014 the Hodgkin's (HL) and aggressive non Hodgkin's Lymphomas (nHL) long term survivors are followed up in a dedicated clinic aimed to detect long term clinical problems that can affect people undergone previous radiation therapy and/or chemotherapy.
Methods: We had planned electrocardiographic and echocardiografic evaluation in patients without known cardiological problems.
Results: We have analyzed data regarding consecutive 469 patients coming in our clinic from 15 September 2014 to 18 February 2016, 247 have been treated for HL and 222 for nHL. Two hundred thirty three were females, 236 males; median of age at diagnosis was 29 years for HL (13-84), 48 years for nHL (12-83); median of age at last observation in the follow up clinic was 50 years for HL (range 21-89) and 62 years for nHL (range 24-88). The median of duration of follow up was 18 years for HL (range 5-40) and 13 years for nHL (range 5-37). Thirty seven of our patients had cardiovascular disorders before the diagnosis of lymphoma. The cardiac function has been studied in three hundred sixty one of our patients. Two hundred twenty five out of 361 (62%) developed cardiac abnormalities of different type and severity in the period following treatment for their lymphoma (Table 1 and Table 2). They were 124 females (55%) and 101 males; 126 had previous HL (56%) and 99 nHL.The median age at cardiovascular disease detection was 54 years (range 20-83). The median time between diagnosis of lymphoma and diagnosis of cardiovascular diseases was 14 years (range 0-43).The most common cardiac disturbances described were valvulopathies of different type and grade (95), arterial hypertension (76) and ischemic cardiopathy (32); some patients had more than one alteration. Moreover 77 out patients showed a diastolic relaxation abnormality without ventricular dysfunction which whose the only alteration detected in 33 cases.
In 114 patient abnormalities were first detected during screening in asymptomatic condition: in fact we had planned electrocardiographic and echocardiografic evaluation in 206 patients without known cardiological problems. One hundred fourteen out of 206 screened (55%) showed previous unknown cardiac disturbance. Regarding the previous therapies: mediastinal radiotherapy had been administered in 64 of patients with valvulopathies (and in all with only calcification) (67%), in 13 with ischemic cardiopathies (41%) and in 33 with diastolic relaxation abnormality (43%); chemotherapy antracycline-based had been receveid by 77 with valvulopathies (81%), by 19 with ischemic cardiopathies (60%) and by 73 with diastolic relaxation abnormality (95%).

Table 1. Feature of survivors patients.

Sex	233 females	236 males
Lymphoma	247 HL	222 nHL
Median age at diagnosis	29 years for HL (13-84)	48 years for nHL (12-83)
median of age at last observation in the follow up clinic	50 years for HL (range 21-89)	62 years for nHL (range 24-88)
The median of duration of follow up	18 years for HL (range 5-40)	13 years for nHL (range 5-37)

Table 2. Type of cardiovascular disorders in the lymphoma survivors (225 patients).

Type	Patients
Diastolic relaxation abnormality	77
Valvulopathies	
Insufficiency	78
Sclerosis	10
Calcification without dysfunction	5
Mitral prolapsed	2
myocardic thickness	2
arterial hypertension	76
pulmonary hypertension	6
Cerebrovascular disease	
Chronic	1
Acute	5
Atherosclerosis SAT	3
Arrhythmias	
Ventricular fibrillation	2
Atrial Fibrillation	8
Other	10
Ischemic cardiopathy	32
Dilatative cardiomyopathy	2

Summary/Conclusions: Our analysis confirms that a high percentage of patient survived to lymphomas can develop cardiovascular diseases and outline the importance of cardiac surveillance.Their monitoring would be promote because can detect asymptomatic structural and functional anomalies as diastolic relaxation abnormality considered an early sign of cardiomyopathies.

PB1859

OSTEONECROSIS DETECTED BY WHOLE BODY MAGNETIC RESONANCE IN PATIENTS WITH HODGKIN LYMPHOMA TREATED BY BEACOPP

C Patti[1,*], A Mulè[1], B Scalici[2], GD Albano[2], A Costa[1], C Ortolano[1], M Galia[2], D Albano[2]
[1]Hematology Unit, AOOR Villa Sofia-Cervello, [2]radiology unit, university of palermo, Palermo, Italy

Background: The treatment of Hodgkin Lymphoma (HL) has led to the progressive achievement of high survival rates over the last years . ABVD regimen has been considered for a long time the standard treatment for advanced-stage HL patients, due to well documented efficacy and a favourable toxicity profile. Several studies demonstrated the increase of progression-free survival rates by using BEACOPP regimen compared to ABVD, especially in advanced-stage disease, at the cost of increased toxicity. Osteonecrosis (ON) is a complication of chemotherapy that may compromise the patient's quality of life and it is often identified in advanced stages when the only available treatment is joint replacement. The use of corticosteroids is one of the most common risk factors, responsible for 10-30% of cases of ON.
Aims: The purpose of this retrospective study was to assess the frequency of ON with the Whole Body MRI (WB-MRI) scans performed on patients with HL treated by different chemotherapy regimens, including protocols with high doses of corticosteroids.
Methods: We evaluated the WB-MRI scans performed on 42 patients with HL treated by three chemotherapy regimens (6 ABVD, 2 ABVD+4 escalated BEACOPP, 2 ABVD+4 escalated BEACOPP+4 standard BEACOPP), excluding those patients with main risk factors for ON. All the patients underwent WB-MRI without contrast agent administration and FDG-PET/CT before treatment, after two cycles of ABVD, after four cycles of escalated BEACOPP and a month after the end of chemotherapy.
Results: Six out of 7 patients (85.7%) who received 2 ABVD followed by 4 cycles of escalated BEACOPP+4 standard BEACOPP and 1 out of 5 patients (20%) who received 2ABVD followed by 4 BEACOPP escalated presented ON, with a statistically significant difference of frequency between the two groups of patients ($p<0.05$); whereas no injury has been reported in patients treated by only ABVD. The ON lesions identified in those patients treated with eight BEACOPP were all absent on the WB-MRI scans performed after four escalated BEACOPP, so they developed ON during the last four cycles of chemotherapy. Among a total of 48 ON lesions observed, 23 (48%) were detected in the knee; multifocal ON were detected in six out of seven patients (86%).
Summary/Conclusions: The development of ON seems to be strictly related to the chemotherapy protocol adopted and the number of cycles received, strengthening the hypothesis of a correlation between the dose of corticosteroids included in the BEACOPP scheme and this complication. WB-MRI can be considered as a helpful tool that allows, not only for staging and follow patients with lymphoma, but also to detect ON in patients treated with corticosteroids, avoiding radiation exposure or contrast administration.

PB1860

MORPHOLOGIC PATTERN AND PROGNOSTIC SIGNIFICANCE OF CD30 DISTRIBUTION WITHIN NEOPLASTIC CELLS IN HODGKIN LYMPHOMA

F Gaudio[1,*], FE Laddaga[1], T Perrone[1], A Franco[1], G Ingravallo[2], P Pedote[3], G Specchia[1]
[1]Hematology, [2]Pathology, [3]Radiology, University of Bari, Bari, Italy

Background:
Hodgkin's lymphoma (HL) is a highly curable disease and 5-year survival is improving, being currently 86%. Cure rates of more than 90% for early HL and more than 70% for those with advanced HL are expected. CD30 protein is expressed on Hodgkin and Reed-Sternberg (HRS) cells in nearly all cases of classical Hodgkin lymphoma (HL). CD30 is present on a cell membrane and on the Golgi complex of the endomembrane cell system. Given the growing clinical application of CD30 targeting we were interested to see if there is variability in distribution of CD30 protein between the cell surface and the cytoplasm and the impact on outcome.
Aims: Given the growing clinical application of CD30 targeting we were interested to see if there is variability in distribution of CD30 protein between the cell surface and the cytoplasm and the impact on outcome.
Methods: To further assess the presenting features and the prognostic significance of CD30 expression in HL we performed a retrospective single institution study of 179 cases with a median follow-up of 5 years. The median ages were 40 years (range, 14–83 years) for men and 34 years (range, 16–77 years) for women; Histological subtypes of HL were nodular sclerosis in 155 (87%), mixed cellularity in 19 (11%), lymphocyte rich in 5 (3%) of cases. Stages III-IV were present in 116 pts (65%), bulky disease in 68 pts (38%), extranodal disease in 21 (12%) and 73 (41%) had a score >2 (intermediate-high-risk). Combined radio-chemotherapy was administered in 116 pts (65%) and chemotherapy alone in 63 (35%).The CD30 protein was evaluated in formalin-fixed paraffinembedded (FFPE) tissue sections by immunohistochemistry (IHC) with monoclonal mouse antihuman antibody CD30 (clone Ber-H2) (Dako). Morphological pattern (localization of CD30) of CD30 expression was evaluated in each case under a microscope examination.
Results: FFPE tissue specimens from 179 HL patients were examined. Immunophenotype was typical of classical HL, and HRS cells were positive for CD30 in all cases. Immunostaining for CD30 was present only on the Golgi body in 147 (82%) of cases, and it was demonstrated on the Golgi body and

on the cell membrane in 32 (18%) of cases. The 32 patients with golgi and surface CD30 expression had poor prognosis compared with the patients with CD30 surface alone (5 year progression-free survival [PFS], 20% *versus* 86%; p<0.001).
Summary/Conclusions: In our series of 179 patients with classical HL, predominant pattern of CD30 expression was cytoplasmic (Golgi body), and only 18% of cases demonstrated cell surface and cytoplasmic expression, with the evidence of poor prognosis.

PB1861

EFFICACY AND SAFETY OF APREPITANT FOR PREVENTION OF CHEMOTHERAPY INDUCED NAUSEA AND VOMITING IN PEDIATRIC PATIENTS

G Giagnuolo, S Buffardi, L Marchese, R Parasole*, F Petruzziello, A De Matteo, R Cuccurullo, V Poggi
Pediatric Hemato-Oncology, Santobono Pausilipon Hospital, Naples, Italy

Background: Chemotherapy-induced nausea and vomiting (CINV) are common side effects for cancer patients with a considerable impact on quality of life. Traditional regimens to prevent CINV commonly contain a combination of corticosteroid plus ondansetron, a 5-hydroxytryptamine receptor antagonist. Nevertheless, CINV persist in 20-30% of patients and in 40% remains even after of chemotherapy (delayed nausea and vomiting). The NK-1 receptor inhibitor aprepitant, in addition to usual anti-emetic therapy, seems to improve both acute and delayed nausea and vomiting in adults. Preliminary studies have shown good efficacy and tolerability also in adolescents; however, trials of using aprepitant in pediatric hemato-oncologic disease are limited.
Aims: Here, we report our experience about the safety and the efficacy of aprepitant in children and adolescents with Hodgkin Lymphoma (HL), treated with highly emetogenic chemotherapy.
Methods: Pediatric patients aged >10 years and with diagnosis of HL received aprepitant as part of triple antiemetic prophylaxis during a cycle of chemotherapy. Aprepitant was administered orally at a dose of 125 mg on Day 1 and 80 mg on Days 2 and 3; at the same time, patients received ondansetron at a dosage of 4 mg/mq and dexamethasone (0.5-2 mg/kg). The efficacy of the drug was evaluated through a questionnaire given to the patient in the next cycle, after obtaining informed consent. Toxicity was evaluated according to CTCAE criteria (*v 4.02: Sept. 15, 2009)*.
Results: Ten patients were enrolled between January 2015 and January 2016; nine received a first line chemotherapies (COPP/ABV, ABVD), while only one of them underwent a fourth-line therapy (Bendamustine); mean age was 13.6 (range 11-16 yrs) and mean number of cycle administered was 3.8 (range 1-6). Five of ten patients reported nausea with a variable intensity from 2 to 6, measured with a scale from 1 to 10; only two patients reported vomiting (2 and 4 episodes). All patients experienced a grade III-IV neutropenia and a a slight increase in transaminases, effects likely related to chemotherapy; no other side effects were registered.
Summary/Conclusions: In our experience, aprepitant, in combination with ondansetron and dexamethasone, significantly decreased the incidence of CINV in children receiving highly emetogenic chemotherapy. We obtained a complete response rate of 50% with a good toxicity profile. This results make us continue to use aprepitant in our patients, since the reduction of nausea and vomiting sensation represents a considerable advantage on quality of life and therapeutic efficacy.

Indolent Non-Hodgkin lymphoma – Clinical

TCL1A EXPRESSION IN SPLENIC MARGINAL ZONE LYMPHOMAS (SMZL) AND CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): CORELLATION WITH IMMUNOPHENOTYPE, MYD88L265P EXPRESSION AND CLINICAL DATA

G Pangalis[1], C Kalpadakis[2,*], S Sachanas[1], M Angelopoulou[3], P Korkolopoulou[4], A Dimitrakopoulou[5], E Koulieris[1], P Konstantinou[6], M Moschogiannis[1], MC Kyrtsonis[7],xYiakoumis[1], I Mavroudi[2], P Tsirkinidis[1], H Papadaki[2], T Vassilakopoulos[3], D Rondogianni[6]
[1]Haematology, Athens Medical Center-Psychikon branch, Athens, [2]Haematology, University of Crete, Heraklion, [3]Haematology, [4]Pathology, University of Athens, [5]Immunology Laboratory, Laikon General Hospital, [6]Anatomic Pathology, Evangelismos Hospital, [7]1st Department of Propedeutics, University of Athens, Athens, Greece

Background: SMZL and CBL-MZ display significant similarities. TCL1A expression may be a valuable tool for the diagnosis of SMZL. TCL1A has been recently shown to be highly expressed in Waldenstrom macroglobulinemia, although data is limited.
Aims: The aim of the present study was to evaluate TCL1A expression in a series of bone marrow samples involved by SMZL and CBL-MZ and correlate the findings with other immunophenotypical, morphological, and clinical data, as well as with the presence of MYD88 L265P mutation.
Methods: 45 patients were retrospectively analyzed: 20 with SMZL and 25 with CBL-MZ. Immunohistochemical staining was performed using the following antibodies: CD5, CD20, Ki67, cyclin D1, TCL1, T-bet, DBA44, CD23, CD27, IRTA1. MYD88 L265P mutation was detected by allele specific PCR.
Results: The main clinical characteristics as well as immunohistochemical and molecular findings are summarized in the Table 1.TCL1A staining was negative in 17/20 cases of SMZL (85%) and 22/25 (88%) cases of CBL-MZ.DNA-44 was positive in 17/24 (71%) of cases in both groups. None case expressed IRTA1. T-bet was positive in 55% and 36% of SMZL and CBL-MZ cases, respectively. No correlation was found between TCL1A and DBA44 expression. Regarding SMZL cases, all TCL1A-positive cases were also positive for CD27. 8/25 (28%)CBL-MZ cases were positive for the presence of MYDL265P mutation. In SMZL cases only 1/11 patient was positive for the presence of MYD88. No correlation was found between TCL1A expression and the presence of MYD88 mutation. None of the mutated cases were TCL1A positive. Among TCL1A-positive SMZL cases, 1/3 presented disease progression with histologic transformation to double-hit lymphoma. All TCL1A-negative SMZL cases were treated with rituximab-monotherapy and are alive without disease.2/3 TCL1A-positive CBL-MZ cases progressed and required therapy due to the presence of cytopenias and one of them died of the disease. None of the TCL1A-negative CBL-MZ cases presented disease progression.

Table 1. Characteristics of SMZL and CBL-MZ cases.

Feature	SMZL # (%)	CBL-MZ # (%)
Male sex	11/20 (55)	5/25 (20)
Age	65 (49-85)	71 (46-81)
Splenomegaly	20 (100)	0
Lymphadenopathy	7/20 (35)	0
ALCs (median)	5200 (690-32100)	2800 (1000-10010)
Hb<10gr/dl	4/20 (20)	0
PLTs<100.000/μL	2/20 (10)	0
HCV (+)	0	0
LDH elevated	9/20 (45)	0
Paraproteinemia	5/20 (25)	16/25 (64)
%BM infiltration	40 (5-85)	30 (15-80)
Pattern		
Mixed	11 (55)	15 (60)
Nodular	14 (70)	10 (40)
Intrasinusoidal	10 (50)	12 (48)
TCL1A (+)	3/20 (15)	3/25 (12)
MYD88 L265P (+)	1/20 (5)	7/25 (28)
DBA44 (+)	9/12 (75)	8/12 (67)
IRTA 1	0/20	0/25
T-bet	11/20 (55)	9/25 (36)
CD27	6/7 (86)	2/2 (100)

Summary/Conclusions: Both SMZL and CBL-MZ display similar pattern of TCL1A, DBA44, IRTA1 and T-bet expression. TCL1A is rarely expressed in SMZL and CBL-MZ cases. No correlation was found between TCL1A and DBA44 expression. No correlation was found between TCL1A and MYDL265P mutate. CD27 and TCL1A were not mutually exclusive. TCL1A expression may be associated with worse outcome, although the number of TCL1A positive cases are small in order to reach safe conclusions.

PB1863

DESCRIPTION OF LATE ONSET NEUTROPENIA IN PATIENTS TREATED WITH BENDAMUSTINE PLUS RITUXIMAB

B Verriere[1,*], L Gastaud[2], F Peyrade[2], A Thyss[2], D Re[2]
[1]Pharmacy, Antibes General Hospital, Antibes, [2]Oncology, Anticancer Center Antoine Lacassagne, Nice, France

Background: Bendamustine (B) is an alkylating drug indicated for the treatment of patients with chronic lymphoid leukemia (CLL) who are not eligible to Fludarabine. In addition, Rummel *et al.* (Lancet 2013) described B associated with Rituximab (R) as a therapeutic alternative to R-CHOP in follicular and other indolent lymphomas. Although hematoxicity of B is largely described in the literature, both late onset neutropenia and lymphopenia occurring after the last cycle of immunochemotherapy are not described.
Aims: We report a cohort of patients treated with B+R showing late onset neutropenia after the end of lymphoma treatment.
Methods: This is an observational retrospective study (Anticancer Center Antoine-Lacassagne, Nice and General Hospital, Antibes, France) including patients treated from January 2009 to June 2015. The study included patients with CLL and indolent NHL (follicular, mantle cell and marginal zone) having received at least one cycle of the association of R (375mg/m²) and B (70 or 90mg/m²x 2 D) as part of their first or second line treatment. Assessment of hematotoxicity was performed according to CTCAE v4.0. We excluded patients with neutropenia preexisting to immunochemotherapy or relapsing within 3 months after the end of induction treatment.
Results: 287 patients received one to six cycles of B+R. We noted a total of 83 episodes of late onset of neutropenia (51 grade I/II, 32 grade III/IV) in 36 patients (follow-up 12 months). The characteristics of those 36 patients are the following: sex ratio (M/F) 0.61; median age 73 years (48 to 93); 94% PS 0/1; 36% CLL, 42% follicular lymphomas (FL), 14% mantle cells lymphomas (MCL) and 8% other indolent lymphomas (including marginal lymphoma). Dose intensity is 100% for B and R with an average of 5 cycles (92% of patients received more than 4 cycles of R+B). Among 15 patients with FL, 13 received a maintenance treatment after B+R, with R monotherapy (mean number of cycles: 5.9) that was interrupted in 8 for at least grade II neutropenia. Grade III/IV neutropenia occurred in 9 patients (including 2 patients with FL treated with R maintenance). There was no event of febrile neutropenia within the study period. Four patients had ongoing grade I/II neutropenia one year after the last cycle of immunochemotherapy. Bone marrow smears weren't performed systematically in our patients (n=13).
Summary/Conclusions: In our retrospective study we describe late onset neutropenia in lymphoma patients treated with R+B. The incidence reported is 12,5% (11% for grade ≥3). Although we did not observe febrile neutropenia in those patients, late onset neutropenia directly impacts on the strategy of lymphoma treatment especially in FL patients receiving R maintenance. We cannot determine separately the impact of R or B for late onset neutropenia but it is hypothesized that the association of R+B increases late onset neutropenia when compared to each treatment alone. Exploratory sub-group analysis is under way. Considering those results, we suggest a close hematologic follow-up of patients treated with R+B immunochemotherapy in order to identify and treat late onset neutropenia.

PB1864

IS THERE A REAL INCRESED PREVALENCE OF HEPATITIS B REACTIVATION IN PATIENTS WITH CD20+INDOLENT NON HODGKIN LYMPHOMA DURING MAINTENANCE WITH RITUXIMAB?

O Vitagliano[1,*], F Trastulli[1], L Simeone[1], V Russo[1], L Marano[1], M Raimondo[1], C Cimmino[1], R Della Pepa[1], G Giagnuolo[1], S Luponio[1], G Beneduce[1], C Cerchione[1], M Masarone[2], M Persico[2], A De Renzo[1], F Pane[1]
[1]Division of Hematology, University Federico II, Naples, [2]Internal Medicine and Hepatology Unit, University of Salerno, Salerno, Italy

Background: Hepatitis B reactivation is a potentially serious complication of anti CD20 antibody (Rituximab) based chemotherapy regimens although sporadic HBV reactivation cases are reported in patients on maintenance with single therapy Rituximab.
Aims: The aim of this study is to assess the prevalence of HBV reactivation among patients HBsAg-/HBcAb+undergoing maintenance chemotherapy with Rituximab.
Methods: We have analyzed 148 patients treated for non Hodgkin's lymphoma according to standard maintenance therapy with Rituximab (375 mg/mq every 2 months for 2 years) from January 2007 to February 2016. Patients received different chemotherapy regimens during induction: 15.5% (23/148) with RCHOP, 27% (40/148) with R-FN, 22% (23/148) R-Bendamustine, 4% (6/148) with R-Fludarabine, 4% (6/148) with R-Leukeran, 19% (28/148)with R-CEOP, 2% (3/148) with R-CVP, 0.6% (1/148) with R-FC, 0.6% (1/148) with R-C, 1.2% (2/148) with R-FN and Bendamustine and 3% (5/148) with Rituximab monotherapy. We performed blood tests for HBV (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb) and liver function tests in all patients at diagnosis and before each administration of maintence with Rituximab. Patients HBsAg-/HBcAb+with increased level of transaminases perfmormed HBV-DNA test. Six patients with HBsAg+received prophylactic therapy with antiviral drugs during induction and maintenance therapy.
Results: 69.6% of the patients (103/148) completed therapy with Rituximab and 30.4% of the patients (45/148) are still in maintenance therapy : 32% of the all patients (47/148) were HBcAb+positive. Only 4.2% (2/47) of these patients occurred HBV reactivation.
Summary/Conclusions: In clinical practice patients HBsAg-/HBcAB+treated with Rituximab in single therapy are normally considered for prophylaxis with lamivudine. In our experience HBsAg-/HBcAB+patients don't received therapy with antiviral drugs during maintenance therapy with Rituximab. Only two of our patients experienced HBV reactivation during maintence therapy. In terms of cost benefit analysis there is an advantage in the monitoring approach that was used in our patients in respect to universal prophylaxis, with a savings of about € 3.400,00 for each patient and a total cost of 159.000€ for all our patients. This study is the first study which analyzes HBV reactivation among HBcAb positive patients which underwent to maintenance therapy with Rituximab for indolent NHL.

PB1865

THE ABSOLUTE LYMPHOCYTE COUNT AS INDEPENDENT PARAMETER MAY PREDICT PROGNOSIS OF FOLLICULAR LYMPHOMA PATIENTS

J Jelicic[1,*], M Todorovic[1], B Andjelic[1], D Antic[1], O Markovic[2], I Petkovic[3], A Sretenovic[1], J Bila[1], V Vukovic[1], V Djurasinovic[1], M Smiljanic[1], I Pejicic[3], B Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [2]Clinical Hospital Center "Bezanijska Kosa", Belgrade, [3]Clinic of Oncology, University Clinical Centre Nis, Nis, Serbia

Background: The role of absolute lymphocyte count (ALC), absolute monocyte count (AMC) and lymphocyte to monocyte ratio (LMR) in follicular lymphoma (FL) as potential surrogate markers of gene expression profiling analysis has been investigated with consequently reported contradictory data.
Aims: The aim of this study was to evaluate the role of clinical and laboratory parameters, including ALC, AMC and LMR, on the overall survival (OS) and event free survival (EFS).
Methods: A total of 185 patients (106 females/79 males) with median age of 55 years (range 30-88 years) were analyzed. Majority of patients (87.6%) were in advanced Ann Arbor clinical stage (III-V), while 8.1% had leukemic phase of the disease. Bone marrow infiltration had 61.1% patients and histopathological grade 3 of disease had 25.4% of them. Low FLIPI (Follicular Lymphoma International Prognostic Index) had 22.2% of patients, intermediate 28.1% and high 44.3%. Pre-therapy median ALC was $1.83x10^9$/L (range 0.10-$123.9x10^9$/l), AMC $0.52x10^9$/l (range 0.06-$12.39x10^9$/l) and LMR 4.0 (range 0.04-$97.0x10^9$/l). Cut off values were set on $1.1x10^9$/l, $0.63x10^9$/l and $4.7x10^9$/l for ALC, AMC and LMR, respectively, according to the previously published data. All patients were treated with immunochemotherapy.
Results: Complete remission (CR) was achieved in 64.9% of patients, partial remission (PR) in 27.0% and 8.1% of patients had primary resistant disease. The disease relapse was verified in 39.5%. The following variables didn't influence neither OS nor EFS: gender, Ann Arbor disease stage, presence of B symptoms, bulky disease, and leukemic phase of disease. However, the FLIPI had significant impact on the OS (Log Rank=11.75, p=0.003) and EFS (Log Rank=9.14, p=0.01). Furthermore, the patients with lymphoma grade 1-3 had superior OS (Log Rank=10.70, p=0.001) and EFS (Log Rank=6.89, p=0.009) compared to the patients with grade 3. The patients with ALC≥$1.1x10^9$/l had better OS (Log Rank=4.135, p=0.042) and EFS (Log Rank=3.9, p=0.049) compared to those with lower ALC values. However, AMC and LMR were not in correlation with the outcome. Multivariate Cox regression analysis among FLIPI, lymphoma grade and ALC, has sorted over lymphoma grade as the most important parameter that influenced OS (HR=6.57, 95% CI 1.49-6.58, p=0.003) and EFS (HR=2.56, 95% CI 1.24-5.32, p=0.011) along with the FLIPI (OS, HR=1.50, 95% CI 1.09-2.05, p=0.012; EFS, HR=1.4, 95% CI 1.03-1.92, p=0.03).
Summary/Conclusions: In FL patients ALC, as individual parameter, markedly influenced survival. Moreover, in the rituximab era FLIPI still retains prognostic significance along with the histological grade of FL illustrating biologically different course of disease.

PB1866

PEGFILGRASTIM IN PRIMARY PROPHYLAXIS OF FEBRILE NEUTROPENIA DURING RITUXIMAB-BENDAMUSTINE TREATMENT IN INDOLENT NON HODGKIN LYMPHOMA : A REAL-LIFE EXPERIENCE

C Cerchione[*], A De Renzo, C Cimmino, M Raimondo, M Di Perna, M Picardi, F Pane
Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: Febrile neutropenia (FN) is a serious side effect of chemotherapy, and even when it does not result in significant morbidity, mortality and costs, it normally leads to a delay in chemotherapy treatments.
Aims: Pegfilgrastim is a pegylated long-acting recombinant form of G-CSF which extends the half-life, requiring less frequent dosing. The objective was to evaluate the efficacy and safety of pegfilgrastim in newly diagnosed patients

with indolent NHL, in treatment with R-Bendamustine (RB), in order to determine whether a single injection of pegfilgrastim is as effective as daily injections of filgrastim, in terms of toxicity, febrile neutropenic episodes, antibiotic usage, and hospitalization duration.
Methods: 59 patients (31 M/28 F), median age 48.7 years (range 33-87), since first course of treatment performed blood counts twice weekly and received, d8-d19, prophylactic oral quinolones and anti-fungal drugs. During neutropenia, filgrastim (5 µg/kg/d for at least 3 days) was given "on demand" if neutrophils count was <1000x10^9 cells/L. Median number of filgrastim administrations was 3.4 (r.3-5); nadir neutropenia was registered after a median of 9.1 d. (r.8-15); median of nadir neutrophil count was 1.27x10^9 cells/L (range 0.3-1.7x10^9 cells/L), with maximum duration of 11 days. From the second course, all patients switched to pegfilgrastim (6 mg) prophylaxis, injected subcutaneously with a single administration on day+4.
Results: During pegfilgrastim, neutropenia was never longer than 7 days, with a consequent reduction of risk of infections. Median nadir neutrophil count, evaluated for at least 3 courses of therapy (r.3-6) registered at d+11, was 1.626 (range 0.88-2.11x10^9 cells/L); only 9 patients (15.2%) needed, after pegfilgrastim, a supplement of 3 administrations of filgrastim. During pegfilgrastim, neutropenia, when present, was shorter than during filgrastim treatment (median of 3.3 d, range 3-8). Pegfilgrastim was well tolerated: main side effects were mild fever and bone pain (8/59 : 13.5%). Moreover, no hospitalization was needed during pegfilgrastim, while two hospitalization for pneumonia were needed during filgrastim. During observation, no patient died during filgrastim or pegfilgrastim.
Summary/Conclusions: In patients affected by newly diagnosed patients indolent NHL, in treatment with RB, pegfilgrastim seems to reduce the incidence of neutropenia, is better tolerated and may increase the possibility to maintain the schedule of treatment.

PB1867

RISK OF HISTOLOGIC TRANSFORMATION (HT) IN SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) PATIENTS TREATED WITH RITUXIMAB

C Kalpadakis[1,*], G Pangalis[2], S Sachanas[2], T Vassilakopoulos[3], D Rondogianni[4], A Dimitrakopoulou[5], E Koulieris[2], M Moschogiannis[2],xYiakoumis[2], M Psyllaki[1], P Tsirkinidis[2], H Papadaki[1], P Panayiotidis[6], M Angelopoulou[3]
[1]Haematology, University of Crete, Heraklion, [2]Haematology, Athens Medical Center-Psychikon branch, [3]Haematology, University of Athens, [4]Anatomic Pathology, Evangelismos Hospital, [5]Immunology Laboratory, Laikon General Hospital, [6]1st Department of Propedeutics, University of Athens, Athens, Greece

Background: SMZL is an indolent lymphoma with long survival. The risk of HT is not well defined, ranging between <5% to >20% in various reports. Rituximab has shown significant activity in the treatment of SMZL. In the rituximab era there is no study assessing the incidence of HT in SMZL patients.
Aims: To analyze the incidence and risk factors for HT in a large series of SMZL patients homogeneously treated with rituximab.
Methods: The studied cohort included 89 SMZL patients diagnosed and treated between 2003 and 2015 exclusively with rituximab monotherapy as first line treatment. 41% were males with a median age of 65 years (range, 41-95). 6/89 (7%) presented with B-symptoms and 43% with elevated LDH. According to IPI, 31% were classified as intermediate high and high risk. No patient was HCV(+). The response rate to rituximab was 95%. HT was confirmed by detailed immunomorphologic study and defined by a biopsy-proven transformation of previous SMZL into an aggressive entity. Overall survival (OS) and progression free survival (PFS) were estimated by the Kaplan-Meier method.
Results: 7-year PFS and OS of the whole population were 69% and 87%, respectively. After a median follow-up of ….years, HT was observed in 4(4%) patients. HT occurred at a median interval of 40 months (range: 32-114) after diagnosis. The main features at diagnosis of the patients who experienced HT are summarized in the Table 1. Transformation into diffuse large B cell lymphoma (DLBCL) was documented in all patients. In one of them a "double hit lymphoma" was reported due to the presence of the rearrangement of c-MYC, and BCL2. In one case a coexisting low-grade component was present in the context of the same specimen.Risk of HT was ?% at 5 and 10 years after diagnosis. At the time of HT 2 patients had high LDH and one B-symptoms. No patient had splenomegaly, while BM was infiltrated by HT in one patient (Table 1). The site of transformation was the lymph nodes in all cases, and additionally BM in one case (the one with the double hit lymphoma). Immunohistochemistry showed positivity of CD30 in 3/4 cases. Treatment at the time of HT included RCHOP in 3 and R-Bendamustine in one case. Two patients achieved CR, one PR, while the fourth did not respond and is alive with progressive disease. At a median follow-up of 10 months (range, 5-13) after HT, 3 patients are alive, 2 in CR, 1 in PR and one with PD.
Summary/Conclusions: To our knowledge, this is one of the largest series of consecutive SMZL patients treated homogeneously with rituximab monotherapy, evaluating the incidence and risk factors for HT. HT occurred in 4% of the cases as a relatively early event during disease course. Post-transformation survival cannot be safely assessed due to short follow up after HT.

Table 1. Main features at diagnosis and at the time of HT in the four patients who were transformed in DLBCL.

Features	Case #1	Case #2	Case #3	Case #4

OUTCOMES OF INDOLENT LYMPHOMAS (INHL) IN THE ELDERLY - AN OBSERVATIONAL STUDY OF KROHEM, THE CROATIAN COOPERATIVE GROUP FOR HEMATOLOGICAL DISEASES

D Dujmovic[1,*], S Bašić Kinda[1], B Dreta[1], A Duletić-Nančinović[2], I Radman[1], D Radić-Krišto[3], G Rinčić[4], V Pejša[5], J Sinčić-Petričević[6], J Jakelić-Piteša[7], H Holik[8], I Aurer[1], D Nemet[1]
[1]Department of Hematology, UHC Zagreb, Zagreb, [2]Department of Hematology, UHC Rijeka, Rijeka, [3]Department of Hematology, CH Merkur, Zagreb, [4]Department of Hematology, UHC Sestre Milosrdnice, Rijeka, [5]Department of Hematology, CH Dubrava, Zagreb, [6]Department of Internal medicine, UHC Osijek, Osijek, [7]Department of Internal Medicine, UHC Split, Split, [8]Department of Internal medicine, CH Slavonski Brod, Slavonski Brod, Croatia

Background: New treatment approaches have improved outcomes in patients with indolent NHL. However, only limited data exist on outcomes of elderly patients.
Aims: We performed this observational study to analyse disease characteristics, treatment patterns, outcomes and prognosis of elderly patients with indolent B-NHL.
Methods: Data were generated from a country-wide observational study of patients treated with rituximab in 2007 and 2008 and from the KroHem Lymphoma registry. Only those receiving front-line treatment were included; watch-and-wait patients were excluded.
Results: We identified 172 patients older than 60 years. Median age was 72, the oldest treated patient was 95 years old; 58% were women. 82 patients had follicular lymphoma (FL), 59 marginal zone lymphomas (MZL), 16 small lymphocytic lymphoma (SLL) and 15 lymphoplasmacytic lymphoma (LPL). Median follow-up of the whole cohort was 44 months. Most patients received R-CHOP (45%) or R-CVP (39%). Selected patients with stage 1 disease were treated with radiotherapy only and those with splenic lymphomas with surgery. Only 22 received rituximab maintenance. 5-year overall survival (OS) was 61% and progression-free survival (PFS) 46%. Extranodal MZL had best OS and PFS (72% and 66% at 5y respectively). FL had better OS but not PFS (64% and 42% at 5y respectively) than non-FL iNHL. Nodal MZL, SLL and LPL had similar outcomes (OS at 5y 53%, 48% and 47%; PFS at 5y 44%, 38% and 33%, respectively). Best outcomes were seen in the group of patients amenable to local therapy: surgery or irradiation. R-CHOP did not improve OS in comparison

to R-CVP but there was a trend to better PFS, especially in patients with FL (p=0.07). When compared to younger patients registered in the observational study, patients older than 60 had somewhat inferior OS and PFS, but the difference in outcomes between those younger and older than 75 was striking (p<0.0001) (Figure 1). All types of deaths were more frequent in the very elderly, but deaths during treatment especially so; 22% of deaths in the group between 60 and 75 occurred during front-line treatment in comparison to 37% in those above 75. In contrast, 58% of deaths in those between 60 and 75 occurred after relapse in comparison to only 37% in the older group.

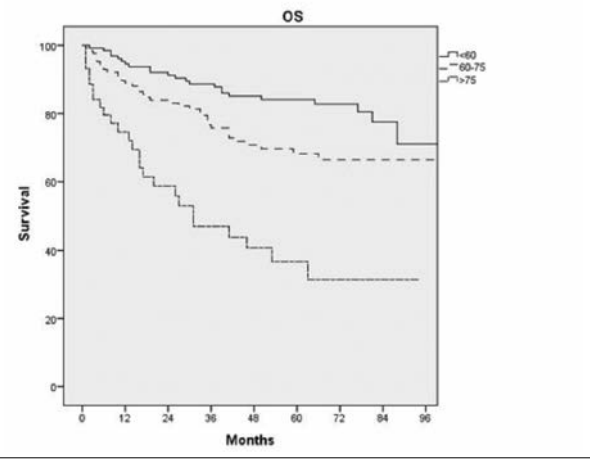

Figure 1.

Summary/Conclusions: It seems that the prognostic influence of iNHL types has remained unchanged from the pre-rituximab era with extranodal MZL having the best prognosis, followed by FL. Patients with stage one disease have an excellent outcome. The impact of anthracyclines seems limited. Currently used regimens are too toxic or not effective enough in patients older than 75. In this group of patients new treatment approaches are needed that would reduce mortality during front-line treatment without compromising efficacy.

PB1869

RESPONSE ASSESSMENT USING IWG2007 AND DEAUVILLE CRITERIA IN B-CELL NON-HODGKIN LYMPHOMA PATIENTS TREATED WITH 90Y-IT

M Andrade-Campos[1,*], P Lievano[2], T Baringo[2], P Giraldo[1]
[1]Translational Research Unit, IIS-Aragon. CIBERER., [2]Nuclear Medicine, Miguel Servet University Hospital, Zaragoza, Spain

Background: 90Y-Ibritumomab-tiuxetan (90Y-IT) has become an efficient alternative therapy in non-Hodgkin Lymphoma (NHL). The staging and response assessment have changed and PET/CT scan with Deauville/Lugano criteria have become the recommended tool.
Aims: To analyse our updated information of patients treated with 90YIbritumomab/tiuxetan in our institution comparing the IWG2007 Chenson and Lugano/Deauville criteria to analyse treatment outcome.
Methods: 120 NHL patients were included in a clinical protocol conducted by a multidisciplinary team and treated in the same centre. For this sub study 54 patients have been included, all of them followed by more than 12 months and the response assessed with PET/CT scan after 12 weeks out therapy using the same machine, the images were available for re-assessment retrospectively according Deauville/Lugano criteria. Endpoints: objective response rate (ORR), time to relapse (PFS) overall survival (OS).
Results: Until August 2015, 56 patients had receive therapy with 90Y-IT and completed at least 1 year of follow-up were considered to analysis; M/F 29/27 mean age 59.7 years (31-86); ECOG 0-1 94.4%. According WHO classification: follicular-NHL 44 (78.6%), mantle cell-NHL 2 (3.6%), DLCB-NHL 7 (12.5%) and MALT-NHL 3 (5.4%). Score risk distribution: low 19 (33.9%), intermediate 24 (42.9%) and advanced 13 (23.2%). 54.5% of patients were stage IV. The majority of patients received ≤2 (90.7%) previous therapy schedules and >2 (9.3%). The mean follow-up time: 53.1 months (95% CI: 12; 145). 31 (57.4%) patients received 90Y-IT as consolidation of first line therapy and 23 relapsed/refractory (42.6%). According IWG2007 criteria: ORR was 98.2% CR: 50 (92.6%); PR 3 (5.4%) and 1 failure (1.9%) in relapsed/refractory disease. According Lugano following the recommendation of Deauville criteria about the presence of residual mass and the scale of 5 points, the response were: CR (1-2 scores or 3 scores with a reduction respect the baseline and no presence of residual disease) 46 (85.2%), presence of residual disease (scores 4-5 or mass with score 3 without a reduction respect baseline): 8 (14.8%). During follow-up 13 patients (24.1%) had relapsed, 10 were categorized as CR by IWG2007, 9 CR by Lugano and 7 CR by Deauville with a higher negative predictive value. The mean PFS: 109.6 months (95% CI: 94.8; 124.4) median NR. However for patients classified as CR by Deauville, the mean PFS was 117.1 month (102.2-132.0), median NR, and 40.7 (16.4-65.2), median 16 (6.2-25.7) months for the rest, (Figure 1). During follow up eight patients have dead, 5 of them after 55 or more months after 90Y-IT therapy. Dead were related to disease in 7 patients.

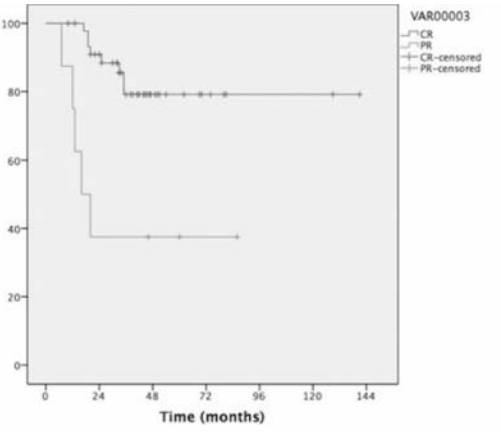

Figure 1. PFS according deauville classification after 90Y-IT therapy.

Summary/Conclusions: In our series of NHL patients treated with 90Y Ibritumomab tiuxetan, the re-assessment of response by PET/CT scan according Deauville criteria at the end of therapy shows more restrictive for CR when scale 3 combining with residual mass is considering as residual disease, improving the accuracy of CR in 7.4% and prolonged PFS in 7.5 months, respect IWG2007.

PB1870

SHOULD STAGE I AND II FOLLICULAR LYMPHOMA BE TREATED EVEN IN THE RITUXIMAB ERA?

DS Toral Ibarra[*], AM Gonzalez Salinas, MM Ibarra Molares, A Bobes Fernandez, WM Torres Jimenez, FA Gonzalez Fernandez, M Polo Zarzuela, R Martinez Martinez
Hemathology and Hemotherapy, Hospital Clínico San Carlos, Madrid, Spain

Background: The optimal management of stage I and II follicular lymphoma (FL), according to consensus guidelines, is not well defined, there are heterogeneous criteria to choose the option of treatment and the decision used to be based on uncontrolled experiences. Diverse treatment approaches are used because the most of guidelines recommended a broad spectrum of alternatives that includes from observation to radiotherapy or chemotherapy, without clear indications to choose one. It is still widely accepted to observe advanced stage FL in case of asymptomatic and stable disease, nevertheless, this watch-and-wait policy is not too well established in early stages. The clinical outcome of patients with follicular lymphoma has been improved since the introduction of rituximab, nevertheless the guidelines still recommend the radiotherapy as a first option.

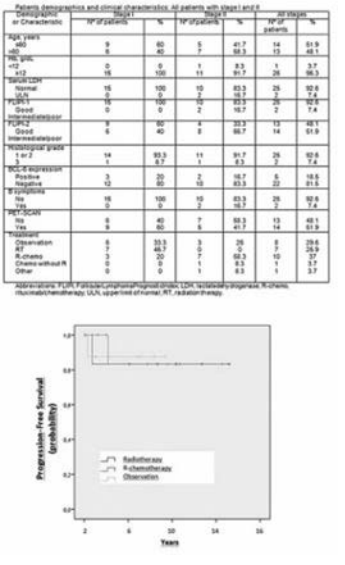

Figure 1.

Aims: This study was launched to evaluate the time to relapse with the three more common approaches in the Rituximab era.
Methods: All patients with histologically confirmed diagnosis of follicular lymphomas grade I-II were selected from our data base starting from January 2000 to June 2015.
Results: From January 2000 to June 2015, 179 patients were diagnosed of follicular lymphoma in our Institution. 35 patients were staged as I and II, 5 patients were excluded from the analysis because of not rigorous staging as defined by bone marrow biopsy and an imaging study either with computed tomography [CT] scan of the whole body or a positron emission tomography [PET]/CT scan, and 3 patients were excluded because of bulky stage II. The median age at diagnosis was 58 years (range 29-78). PET/CT was done in 52% patients. Treatments given to staged patients were rituximab/chemotherapy (R-chemo; 37%) that includes regimes such as R-CHOP (cyclophosphamide [C], doxorubicin, vincristine [V] and prednisone [P]) R-CVP, R-FC (fludarabine [F], cyclophosphamide), chemotherapy without immunotherapy (3.7%), RT (25.9%), observation (29.6%), and other (3.7%). With a median follow-up of 70 months for PFS, there were 3 progression events (11,11% of patients). PFS was statistically significant improved with observation compared with patients treated either receiving R-QT or RT (p=0.042). There were nostatistical differences in PFS according to FLIPI 1 or 2 score, histological grade or BCL-6 expression in univariate analysis. There were not differences in overall survival (Figure 1).
Summary/Conclusions: This retrospective monocentric study suggest that observation could be a valid approach for patients of FL stage I and not bulky II, not only for stage III or IV. PFS did not improve with treatment, even with rituximab-containing chemotherapy regimens. It is necessary prospective and randomized studies in these cases to get stronger conclusions.

PB1871

18FDG-PET ROLE OF IN THE EVALUATION OF BONE MARROW INFILTRATION IN PATIENTS WITH NHL

F Trastulli[1,*], L Marano[1], A De Renzo[1], S Pellegrino[2], T Mannarino[2], N Frega[2], L Simeone[1], O Vitagliano[1], V Russo[1], M Raimondo[1], I Peluso[1], M Notarangelo[1], L Catalano[1], CG Mainolfi[2], F Pane[1]
[1]Division of Hematology, [2]Department of Radiology, University Federico II, Naples, Italy

Background: ^{18}FDG PET/CT is now the standard procedure to evaluate indolent and non indolent non-Hodgkin lymphoma (NHL). It plays an important role in staging, restaging, prognosis and planning treatment. On the other hand bone marrow infiltration affects stage, prognosis and therapeutic approach
Aims: To compare three basal ^{18}FDG PET/CT parameters to detect bone marrow infiltration in patients with newly diagnosed non Hodgkin lymphoma (NHL).
Methods: 25 patients with newly diagnosed NHL from February 2012 to February 2016 were retrospectively analyzed. All patients received diagnosis both ^{18}FDG PET/CT contrast enhanced scan and bone marrow biopsy in the posterior iliac crest. There were three evaluation parameters of ^{18}FDG PET/CT to detect bone marrow infiltration: visual analysis, maximal standardized uptake values (SUVmax) in bone marrow of iliac crest (>2.5) and ratio of maximal standardized uptake values of iliac crest bone marrow to liver intensity (Deauville score positive when ratio >1). All results were compared with the bone marrow biopsy. Twelve patients (48%) had an aggressive NHL (9 DLBCL, 1 Burkitt Lymphoma, 1 T cell lymphoma, 1 mantle cell lymphoma,); 13 (52%) had indolent NHL (7 follicular lymphoma, 2 marginal zone lymphoma, 4 small lymphocytic lymphoma)
Results: We divided patients in two different groups: indolent and aggressive NHL. For each group we analyzed the accuracy, sensitivity and specificity of the three parameters (visual analysis, SUVmax and Deauville score). Aggressive NHL: Accuracy, sensitivity and specificity accord to visual analysis were 60%, 75% and 25%, respectively. Accuracy, sensitivity and specificity accord to SUVmax were 50%, 71% and 20%, respectively. Accuracy, sensitivity and specificity according to Deauville score were75%, 89% and 33%, respectively Indolent NHL. Accuracy, sensitivity and specificity accord to visual analysis were 53%, 14% and 100%, respectively. Accuracy, sensitivity and specificity accord to SUV max were 46%, 43% and 50%, respectively. Accuracy, sensitivity and specificity according to Deauville score were77%, 57% and 100%, respectively. Taking into consideration the aggressive NHL group the three parameters compared to standard bone marrow biopsy point to high sensitivity and low specificity. In indolent group the three parameters point to low sensitivity and high specificity. In particular, in this later group, the presence of 4 CLL patients (31%) commonly not FDG avid could have reduced the sensitivity of the imaging procedure compared to bone marrow. According to preliminary observation Deauville score seems to be more accurate in evaluation of bone marrow infiltration both in indolent and in aggressive NHL patients.
Summary/Conclusions: Although obtained in a small group of patients, our results show a significant correlation between bone marrow infiltration verified by biopsy procedures and peculiar aspects of bone marrow FDG uptake, in particular when they are analyzed by the Deauville score.

PB1872

SUCCESSFUL SWITCH FROM INTRAVENOUS TO SUBCUTANEOUS RITUXIMAB AT THE ULSTER HOSPITAL, BELFAST, NORTHERN IRELAND

R Dillon[1,*], Y Ong[1], M Bowers[1], J Hamilton[1], P Carlin[2], M El-Agnaf[1]
[1]Haematology Dept, [2]Research Dept, Ulster Hospital, Belfast, United Kingdom

Background: Chemo-Immunotherapy is currently widely used in treating lymphoproliferative disease. There is ever increasing indications for the monoclonal antibody, rituximab, with varied chemotherapy regimens. In our chemotherapy day unit there has been a significant increase in patients requiring chemo-immunotherapy. This increase has led to increasing waiting times for patients to start their chemotherapy. In 2005, a group at the Ulster Hospital completed a project examining the use of rapid intravenous (IV) rituximab infusion over 90 minutes as opposed to standard 4 ½ hours administration at this time, for continuing therapy as long as the first infusion had been tolerated without any reaction (El-Agnaf, *et al.*, 2007). With the availability of subcutaneous (SC) rituximab, the group decided to switch to this product for patients with DLBCL and Follicular Lymphoma being treated with a combination of rituximab and chemotherapy.
Aims: - Investigate the safety profile of SC Rituximab in treatment of DLBCL/Follicular lymphoma. - Impact of SC Rituximab on the resource utilisation within our department. - Convenience of adminstration of SC Rituximab for both patients and nursing staff.
Methods: We examined the notes of all patients who received subcutaneous Rituximab either in combination with CHOP, CVP or alone as maintenance treatment. The first dose of rituximab was given IV as per the product monograph. The second and subsequent doses for eligible patients were given over 5-6 minutes SC at a fixed dose of 1400 mg. All eligible patients received standard oral premedication of prednisolone, chlorphenamine and paracetamol. Patients were monitored closely and any adverse events recorded using National Cancer Institute (NCI) common terminology criteria for adverse events. Vital signs (Blood Pressure (BP), temperature, pulse, digital O2 saturation and respiratory rate) were checked before the first Rituximab infusion and 15 minutes after the infusion commenced. If normal at these time points, they were then checked 30 minutes later and at infusion end. For SC rituximab, vital signs were measured prior to first injection, and one hour post administration. If the patient had no adverse reaction to the first SC injection, subsequent SC therapy was given with vital signs monitored prior to injection only. A sample of patients were contacted by telephone and asked about their treatment preference. The nursing staff were also asked about their preference.
Results: There were no reported adverse reactions to the first infusion in all patients. SC rituximab was well tolerated apart from mild local skin reactions. None of these reactions requires specific therapy and did not preclude further SC treatments. The service change from IV to SC was smooth with no issues noted by staff involved. In total 29 patients (7DLBCL and 22 Follicular lymphoma) received 135 vials of 1400mg SC rituximab from 1st January 2015 until 31st December 2015. If all 29 patients had rapid IV infusion over 90mins, they would have taken 202hours 30mins (if each infusion went smoothly). Our SC rituximab patient sample took 37hours 30mins to infuse (allowing 10mins for injecting the SC rituximab and 1hour observation post 1st SC rituximab). This equated to a minimum saving of 165 nursing hours. Our pharmacy takes 31mins to manufacture IV rituximab as opposed to 7mins for SC rituximab. In 2015 we saved our pharmacy a minimum of 55hours. Patients uniformly preferred SC Rituximab over IV, as did the nursing staff.
Summary/Conclusions: A number of studies (Salar, *et al.*, 2014) (Davies, *et al.*, 2014) showed that there was non inferiority of SC rituximab (1400 mg) compared with IV rituximab (375 mg/m^2) for treatment outcomes and that the only safety considerations relates to a higher incidence of administration related reactions. Overall response rate and complete response rate indicate that switching to SC rituximab has no effect on anti-lymphoma activity, but decreases overall administration time to 5-6 minutes without significantly affecting patient safety, and is acceptable to patients. Switching from IV to SC Rituximab has had a significant impact on the time spent for the patient in the unit, the time pharmacy saved in Rituximab preparation and storage of the product and the time saved by nursing staff administering the drug.

PB1873

THERAPY AND LONG-TERM RESULTS OF HEPATITIS C-ASSOCIATED INDOLENT NON-HODGKIN LYMPHOMA

S Lepkov[1,*], I Subortseva[2], G Tumyn[3], O Kolomiytsev[3], P Zeynalova[3], A Kovrigina[2], N Kokosadze[3], O Ettinger[1], J Riabuhina[3], I Iliasova[3], I Komarov[3]
[1]Therapy, Russian National Research Medical University Named by N.I Pirogov, [2]Hematology, Hematology Research Center, [3]Oncology, Cancer Research Center by N.N. Blochina, Moscow, Russian Federation

Background: The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin's lymphoma (IL) is approximately 15%. In those cases where the tumor cell NHL patients were in the presence of hepatitis C virus protein by immunohistochemistry (IHC), we define diagnosis of hepatitis C associated indolent lymphoma (IL+C).

Aims: Since 2004 to 2014 81 patients were observed with IL+C. The median age 50 years, the disease is equally common in men and women. Almost all patients (97%) were determined III-IV st of the disease. In 25% of patients were primary extranodal variants IL+C . Most often determined by the follicular lymphoma, 74%, 32% - cell lymphoma marginal zone. HCV RNA was determined in 82% of patients in the blood, the median viral load was $2.3x10^5$ copies/mL. Increased ALT and LDH was diagnosed in 71% and 82%, respectively.
Methods: As a first-line therapy of 52 patients was only antiviral treatment by interferon and ribaverin . If tumor remission was achieved, the antiviral therapy lasted for 2 years. 29 patients as a first line therapy was immunochemotherapy (R-CHOP, R-CVP).
Results: Complete and partial remission of antiviral therapy were obtained in 88% of patients, on immunochemotherapy - in 64% of patients. Median progression-free survival in patients with IL+C treated with antiviral treatment was 42 months, during immunochemotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). After immunohimoterapy in 19 patients was the relapse of the disease . All this patients was treated by antiviral therapy as second-line therapy . Complete and partial remission was achieved in 92% of patients. Median progression-free survival in these patients was 31 months.
Summary/Conclusions: Antiviral therapy in first-line and relapse of disease better then immunochemotherapy in the overall effectiveness, of the disease-free survival and overall survival in patients of NHL associated with hepatitis C. Antiviral therapy is a priority for patients with hepatitis C-associated lymphoma.

PB1874

DURABLE RESPONSES WITH IDELALISIB MONOTHERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA (SLL)

AJ Davies[1,*], AK Gopal[2], IW Flinn[3], P Ghia[4], A Goy[5], E Abella-Dominicis[6], B Philip[6], B Sorenson[6], GA Salles[7], ND Wagner-Johnston[8]
[1]Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, [3]Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, United States, [4]Universita' Vita-Salute San Raffaele and IRCCS Instituto Scientifico San Raffaele, Milan, Italy, [5]John Theurer Cancer Center/Hackensack University Medical Center, Hackensack, NJ, [6]Gilead Sciences, Inc., Foster City, CA, United States, [7]Hospices Civils de Lyon, University Claude Bernard, Pierre Benite, France, [8]Department of Medicine, Washington University School of Medicine, St Louis, MO, United States

Background: SLL, an indolent non-Hodgkin lymphoma (iNHL), is often diagnosed at an advanced stage, and patients (pts) with relapsed or refractory (R/R) disease have a poor prognosis.Idelalisib (IDELA), is a selective, oral PI3Kδ inhibitor which as monotherapy (IDELA-mono) showed considerable anti-tumor activity in pts with R/R iNHL in phase 1 (Study 02; NCT00710528) and phase 2 studies (Study 09; NCT01282424; Gopal *et al. NEJM*. 2014;370:1008-18).
Aims: The objective of this post hoc analysis was to describe the efficacy and safety of IDELA-mono specifically in pts with R/R SLL enrolled in Study 02 or Study 09.
Methods: Eligible pts with previously-treated SLL were those with R/R disease (disease status defined by response to last prior regimen) treated with IDELA-mono across 7 dose cohorts (minimum dose 50 mg BID; maximum dose 350 mg BID) in Study 02, and those with double-refractory disease (to both rituximab and an alkylating agent) treated with IDELA-mono (150 mg BID) in Study 09. In both studies, IDELA was continued until progressive disease (PD) or unacceptable toxicity. Radiographic and pertinent clinical data were reviewed by an independent review committee (IRC) to determine response based on standard criteria for lymphomas (Cheson *et al.* J *Clin Oncol*. 2007;25:579-86).
Results: A total of 39 pts with R/R SLL participated in the 2 trials, 11 in Study 02, (5 on IDELA doses <100 mg BID; 6 on IDELA doses >100 mg BID), and 28 in Study 09 (IDELA 150 mg BID). The median age of pts was 69 and 65 yrs [range 34-87], and 73% and 75% were male, in Studies 02 and 09, respectively. In both studies, 82% of pts had Ann Arbor Stage IV disease at baseline and had received a median of 4 prior regimens [range 1-9]. In Study 02, 9 of the 11 pts (82%) had refractory disease; all 11 pts had received prior regimens containing fludarabine. In Study 09, 27/28 pts (96%) were refractory to both rituximab and an alkylating agent (1/28 pts had received insufficient cycles of bendamustine). Common prior therapies included: rituximab (n=28), cyclophosphamide (n=25), bendamustine (n=21), vincristine (n=19), and fludarabine (n=18). The overall response rate (ORR) was 6/11(55%) in Study 02, with all 6 responders achieving a partial response (PR) and 3/11 pts (27%) having stable disease (SD). In Study 09, the ORR was 17/28 (61%), with a complete response (CR) reported in 1/28 pts (4%), a PR in 16/28 pts (57%) and SD in 10/28 pts (36%); 1 pt (3.6%) was not evaluable. Among responders, median time to response was 0.9 mo and 1.9 mo, respectively; median duration of response (DOR) was 2.3 mo and 12.5 mo. Median progression-free survival (PFS) was 3.7 mo (Study 02) and 11.4 mo (Study 09). Median (KM-estimated OS was not reached for Study 02; OS was 88.9% at 12 mo, 88.9% at 24 mo and 59.3% at 36 mo. Median KM-estimated OS was 22.5 mo in Study 09; OS was 89.1% at 6 mo, 74.3% at 9 mo and 70.4% at 48 mo. In Study 02, grade ≥3 AEs and laboratory abnormalities occurring in ≥20% of pts included pneumonia (n=5), febrile neutropenia (n=3), and neutropenia (n=4). In Study 09, these AEs and laboratory abnormalities included pneumonia (n=7) and neutropenia (n=8).
Summary/Conclusions: IDELA-monotherapy provides clinical evidence of efficacy in pts with R/R SLL, with a safety profile similar to that described in other larger clinical trials.

PB1875

INITIAL TREATMENT RESPONSE PREDICTS THE OUTCOME OF ELDERLY FOLLICULAR LYMPHOMA PATIENTS TREATED WITH IMMUNOCHEMOTHERAPY

B Andjelic[1,2,*], J Jelicic[1], M Todorovic[1,2], J Bila[1,2], D Antic[1,2], V Djurasinovic[1], A Sretenovic[1], V Vukovic[1], M Smiljanic[1], B Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Advanced age is considered as an unfavorable prognostic factor for follicular lymphoma (FL). The optimal treatment approach for elderly FL patients is still not clearly defined.
Aims: The aim of this study was to compare the outcome of FL patients between by age (50-60 years and more than 60 years) two adjacent patients groups treated with immunochemotherapy. The second aim was to identify high risk patients for poor outcome.
Methods: A retrospective study was performed on 101 FL patients older than 50 years who had to be treated, including the patients who were previously on watch and wait. Forty-eight patients were older than 60 years. All the patients were treated with immunochemotherapy R-CHOP or R-CVP in the period 2002-2014. Totally 10 patients received R-CVP, of whom 5 were older than 60 years. The examined parameters in statistical analysis were gender, FLIPI score, the presence of B symptoms, bulky disease, bone marrow involvement, ECOG PS, FL grade and response (complete remission or not) on initial treatment.
Results: The median age of the patients was 58 (range 51-82). Complete remission (CR) was achieved in 65 (65.3%) patients. None of the examined parameters was more often present on diagnosis in elderly patients compared to patients 50-60 years old. Patients older than 60 yrs had significantly shorter overall survival (OS) compared to patients 50-60 years old (log rank=4.855, $p<0.05$), while there was no difference in event free survival (log rank=0.015, $p>0.05$). Elderly patients with ECOG PS >1, as well as the patients who didn't achieve CR had significantly worse OS (log rank=4.892, $p<0.05$; log rank=33.980, $p<0.01$; respectively), while none of the examined parameters had an influence on EFS. In patients 50-60 years old, the patients who didn't achieve CR had significantly worse EFS (log rank 13.977, $p<0.01$), while none of the examined parameters had an influence on OS. The multivariate Cox regression analysis identified treatment response as an independent prognostic factor for OS in elderly patients and for EFS in patients 50-60 years old.
Summary/Conclusions: The patients older than 60 years with FL had worse outcome when compared to 50-60 years old patients. According to our results, achieving CR on initial treatment should be one of the goals in treating elderly FL patients.

DURABLE RESPONSES WITH IDELALISIB MONOTHERAPY IN PATIENTS (PTS) WITH RELAPSED OR REFRACTORY MARGINAL ZONE LYMPHOMA (MZL)

E Gyan[1,*], P Martin[2], A Armas[3], AK Gopal[4], ND Wagner-Johnston[5], E Abella-Dominicis[6], W Ye[6], B Philip[6], B Sorenson[6], J Walewski[7], S de Vos[8]
[1]Service d'Hématologie et thérapie cellulaire, Centre Hospitalier Universitaire, TOURS CEDEX 1, France, [2]Division of Hematology/Oncology, Weill Cornell Medical College, New York, NY, [3]Calaway Young Cancer Center, Glenwood Springs, CO, [4]Medical Oncology Division, University of Washington School of Medicine, Seattle, WA, [5]Dept. of Medicine, Washington University School of Medicine, St. Louis, MO, [6]Gilead Sciences, Inc., Foster City, CA, United States, [7]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland, [8]Division of Hematology/Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States

Background: MZL is a group of indolent non-Hodgkin lymphomas (iNHL) arising from marginal zone B cells in lymph nodes and/or extranodal tissues, is classified per the World Health Organization as splenic MZL (SMZL), nodal MZL (NMZL) and extranodal marginal zone B-cell lymphoma (mucosa-associated lymphoid tissue; MALT). Given the rarity of MZL, few randomized trials have directly compared treatment options. Thus, there is a lack of consensus about best practices. Idelalisib (IDELA) showed considerable anti-tumor activity in pts with relapsed/refractory (R/R) iNHL in a phase 1 (P1) dose-escalation study (NCT00710528; Flinn, 2014) and in pts with refractory iNHL in a phase 2 (P2) study (NCT01282424; Gopal, 2014).

Aims: The objective of this post hoc analysis was to describe the safety and efficacy of IDELA in a subset of pts with MZL.
Methods: The P1 and P2 studies were single-arm monotherapy trials that assessed safety and efficacy of idelalisib in R/R hematologic malignancies (P1) or iNHL (P2). Eligible pts with MALT, NMZL or SMZL were those with R/R disease (disease status defined by response to last prior regimen) in the P1 study and those with double-refractory disease (to both rituximab and an alkylating agent) in the P2 study. IDELA was given as monotherapy (P1: minimum dose 50 mg BID, maximum dose 350 mg BID; P2: 150 mg BID) until progressive disease (PD), death or unacceptable toxicity. Radiographic and pertinent clinical data were reviewed by an independent review committee (IRC) to determine the response based on standard criteria for lymphomas (Cheson *et al. J Clin Oncol.* 2007;25;579-586).
Results: In all, 21 pts with MZL were enrolled, 6 in the P1 and 15 in the P2 study: 12 with MALT, 7 with NMZL and 2 with SMZL. Median age was 74 and 72 yrs [range 50-91], and 50% and 80% were male, in the P1 and P2 studies, respectively. Pts had received a median of 4.5 prior regimens in the P1 study [range 1-10] and a median of 2 prior regimens in the P2 study [range 2-9]. The median (range) IDELA exposure was 5 mo (0.4-16.4) and 6.4 mo (1.8-21.6) in the P1 and P2 studies, respectively. In the P1 study, Gr≥3 adverse events (AEs) occurring in ≥20% of pts included diarrhea (3/6), and chills, fatigue, pyrexia, urinary tract infection and dizziness (each 2/6); key Gr ≥3 laboratory abnormalities occurring in ≥20% of pts included thrombocytopenia (4/6), and anemia, neutropenia, and ALT and AST increases (each 2/6). In the P2 study, Gr≥3 diarrhea and Gr≥3 neutropenia laboratory abnormalities each occurred in 3/15 pts. Of the 21 pts, 9 (43%) achieved a response. Outcomes by MZL subtype are shown in the Table 1. Median times to first response were 1 mo and 3.5 mo in the P1 and P2 studies, respectively. In the P1 study, the median duration of response (DOR) was 8.2 mo, and in the P2 study 18.4 mo. In the P1 study, with median follow-up time of 5 mo, median progression free survival (PFS) was 7.4 mo; in the P2 study, with median follow-up time of 20 mo, median PFS was 6.6 mo. Overall Survival (OS) was 100% at 1 yr in the P1 study, and in the P2 study was 86% at 6 mo, 79% at 9 mo, and 72% at 1 yr.

Table 1.

Best Overall Response, n	CR	PR	SD	PD
MALT	1	4	6	1
NMZL	0	2	4	1
SMZL	0	2	0	0

Summary/Conclusions: Although the sample size was small, IDELA showed promising activity in pts with R/R MZL. IDELA was well tolerated with no apparent disease-specific safety signals.

PB1877

THE STRUCTURE AND EFFICACY OF B-CELL LYMPHOMA'S REAL LIFE TREATMENT ACCORDING DATA OF THE REGIONAL SEGMENT OF THE RUSSIAN FEDERATION'S FEDERAL REGISTER

S Volkova*
Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation

Background: The Russian federal program of "7 nosology" since 2008 has given the chance of stable treatment CD20+B cell lymphoma patients with rituximab, B cell chronic lymphoid leukemia patients with rituximab and fludarabin and multiple myeloma (MM) patients with bortezomib in combination with conventional chemotherapy. The obtaining medications provide patient's inclusion in the federal register and exception from the register in case of death and other actions.
Aims: To analyze the federal register's regional segment of the of patients with B-cell mature lymphomas, residents of the Nizhny Novgorod Region of RF (Population of the Nizhny Novgorod Region in 2008 of-3359,8 thousand and in 2015 – 3164,2 thousand people) for receiving demographic data and efficacy of real life treatment with using rituximab without or with fludarabin and conventional chemotherapy on the basis of overall survival (OS) by Kaplana-Meyer's method.
Methods: Materials and methods: from Jan 2008 to Dec 2015 2094 patients are allocated, the analysis has included 2051(98%) with diagnoses: C82 Follicular lymphoma – 103 (5%), C83.0 – Lymphoma from small lymphocytes, Nodal marginal zone lymphoma, Lymphoplasmacytic lymphoma (excepting Waldenstrom macroglobulinemia) – 183 (9%), C83.1 – Mantle cell lymphoma -46 (2%), C83.3 – Diffuse large B-cell lymphoma (all variants) – 532 (26%), C91.1 – Chronic lymphocytic leukemia – 578 (28%), C90 – multiple myeloma - 609 (30%). Date of death is determined in 713 (35%) cases, other censored for date of the last data in the register. The OS of patients is defined from the date of inclusion in the program of 7 nosology. In the groups the OS is defined depending on a sex, age group with the step in 10 years, of a year of inclusion in the program of 7 nosology. To analyze the Excel and Statistica 9 software are used.
Results: The probability of OS from the moment of inclusion in the register within 12 months for patients with C82 was 87%, C83.0 - 84%, C83.1 - 67%, C83.3 - 77%, C91.1 - 86%. The probability of OS for patients with C82 till 96 months is 72%, C 83.0 till 93 months – 29%, C 83.1 till 34 months – 59%, C 83.3 till 96 months - 61%, C 91.1 till 96 months - 45%, (Chi-square=23,2, p=0,0001). In groups except C91.1 women prevailed, distinctions of OS according sex aren't received. Only in the group C 91.1 men (315) prevailed (women 154), the median of OS for women isn't reached, for men – 62 months (p <0,003). Depending on age with a step in 10 years in all groups distinctions in OS aren't received. The maximum number of patients with the diagnosis C82, C83.1, C83.3, C91.1 were in age 60-69 years, with the diagnosis C83.0 – in age 50-59 years. Only patients with the diagnosis C83.3 are registered in all age groups. During 2009-2015 the number of the patients included in the register in a year with diagnoses of C82 has made from 7 to 24, on average 13; C83.3 – from 32 to 96, on average 68, C91.1 – from 30 to 83, on average 63; C83.0 – from 16 to 27, on average 21, C 83.1 from 1 to 15, on average 9. In each group of distinctions of survival depending on a year of inclusion in the program of 7 nosology it isn't received (Figure 1).

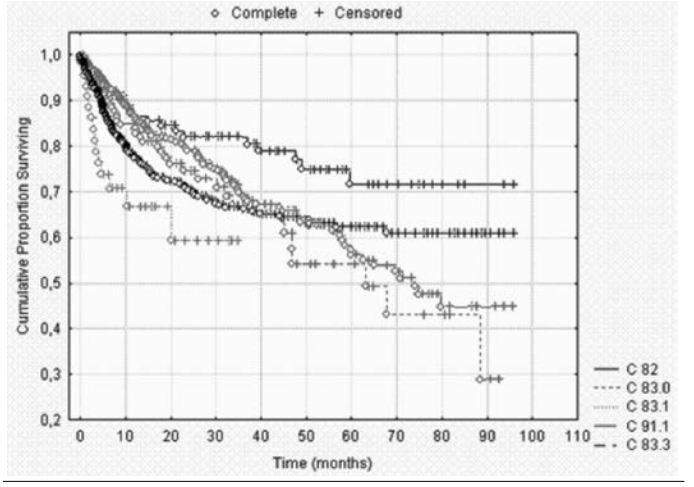

Figure 1. Overall surviving patients with mature B-cell lymphomas (Kaplan-Meier).

Summary/Conclusions: The rituximab for all CD20+lymphomas and fludarabin+rituximab for BCLL improve the outcome patients in real life clinical practice. The register interacted to the mechanism of the provision of medication is the effective resource allowing to have demographic data and data on efficacy treatment in real life medical practice.

PB1878

DETECTION OF MYD88 (L265P) SOMATIC MUTATION IN SPLENIC MARGINAL ZONE LYMPHOMA (SMZL)

C Kalpadakis[1,*], G Pangalis[2], M Angelopoulou[3], M Roumelioti[4], S Sachanas[2], F Kontopidou[5], A Dimitrakopoulou[6], E Koulieris[2], M Moschogiannis[2], MC Kyrtsonis[4], T Tzenou[4], S Kokoris[7],xYiakoumis[2], P Tsirkinidis[2], C Pontikoglou[1], H Papadaki[1], P Panayiotidis[4], T Vassilakopoulos[3]
[1]Haematology, University of Crete, Heraklion, [2]Haematology, Athens Medical Center-Psychikon branch, [3]Haematology, [4]1st Department of Propedeutics, [5]2nd Department of Internal Medicine, University of Athens, [6]Immunology Laboratory, Laikon General Hospital, [7]Haematology Laboratory, Attikon University Hospital, Athens, Greece

Background: MYD88 L265P is a somatic mutation that has been identified in about 90% of Waldenstrom macroglobulinemia (WM)/ lymphoplasmacytic lymphomas (LPLs). Several reports demonstrated the presence of the mutation in other lymphomas mainly DLBCL of activated type and SMZL. In SMZL, the frequency of MYD-88 mutation ranges between 0-21% in various studies.
Aims: The aim of the present study was to determine the presence of L265P MYD-88 mutation in a well characterized series of SMZL cases along with an extended analysis of the clinical, morphologic, immunophenotypic and histologic features.
Methods: We retrospectively evaluated 37 SMZL cases. The identification of MYD 88 L265P mutation was performed in blood or BM mononuclear cells with allele specific PCR. The sensitivity of the method was 10^{-3}.
Results: The main clinical and laboratory characteristics are shown in the Table 1. 11/37 (30%) were males with a median age of 62 years. All cases presented with splenomegaly and one with B-symptoms. Lymphadenopathy was evident in 7 cases (19%). Bone marrow (BM) was infiltrated in all cases, with a mixed (nodular and intrasinusoidal) pattern of infiltration in most cases. Paraproteinemia was present in 9/29 (31%), 6 of the IgG and 3 of the IgM type.None of the studied cases had positive serology for the hepatitis C virus. Anemia and thrombocytopenia were found in 28% and 8%, respectively. MYD-88 L265P mutation was detected in one case (1/37, 3%). This was a case of a 62-year old man with IgMκ paraproteinemia of low level (550mg/dl), lymphocytosis

(8000/μL), no anemia, mild to moderate splenomegaly (max 15.6 cm), small hilar lymphadenopathy and 60% BM infiltration with a nodular and intrasinusoidal pattern. At the time of CR documentation, disease was not detectable including the disappearance of the IgMκ monoclonal fraction in the blood, except the presence of the MYD-88 mutation in the BM mononuclear cells which in the same specimen was IgVH negative. The other two patients with an IgM monoclonal band were negative for the MYD-88 mutation, as were those with IgG monoclonal gammopathy.

Table 1. Characteristics of the SMZL cases studied for the presence of MYD-88 L265P mutation.

Feature	# (%)
Total #	37
Male sex	11 (30)
Age (median)	62
(range)	(49-85)
B-symptoms	1 (3)
Splenomegaly	37 (100)
Lymphadenopathy	7 (19)
IPI	
Low	11/33 (33)
Low/intermediate	13/33 (39)
High/intermediate	9/33 (27)
HB<10gr/dl	10/35 (28)
PLTs<100.000/μL	3/35 (8)
ALC>5000/μL	18/35 (51)
%BM infiltration	40
(median) (range)	(0-85)
Paraproteinemia	9/29 (31)
IgG	6/9 (67)
IgM	3/9 (33)
HVC (+)	0
MYD-L265P (+)	1/37 (3)

Summary/Conclusions: Based on our findings, MYD88 L265P mutation is very rare in SMZL. In our series of 37 SMZL cases, MYD88 L265P mutation was detected in only one case (3%), which a monoclonal IgMκ was present. Our findings support the view that the presence of an IgM monoclonal gammopathy in the serum, with a lymphocytic – lymphoplasmacytic infiltration of the BM by no means document the diagnosis of WM/LPL.

PB1879

SIGNIFICANT ROLE OF FLOW CYTOMETRY IN THE DIAGNOSIS AND FOLLOW UP OF GASTRIC LNH

S Luponio[1,*], A De Renzo[1], M Romano[2], A Miranda[2], D Sgambato[2], M Raia[3], G Scalia[3], R Della Pepa[1], M Raimondo[1], L Marano[1], F Pane[1], L Del Vecchio[3]
[1]Hematology, university Federico II, [2]Clinical and Experimental Internal Medicin, AOU SUN, [3]Biotecnologie Avanzate, CEINGE, Naples, Italy

Background: The diagnosis of lymphoma is mainly based on morphology, but the diagnostic accuracy is greatly increased by the use of ancillary techniques like immunophenotyping, cytogenetic and molecular tests. This multiparametric approach is recommended by WHO classification.
Aims: To evaluate the role of flow cytometry in the study of gastric biopsies with suspect of NHL. We have assessed the validity of integration of histological and cytometric assays to optimize diagnosis of lymphoproliferative diseases and to lower the number of inconclusive cases at histological exam. The aim of flow cytometry was to define lineage and clonality of lymphoid proliferation, thus giving a support to final diagnostic assessment.
Methods: 33 patients with primary gastric lymphoma underwent, from January 2007 to December 2015, to double gastric biopsy at diagnosis or during follow up. Diagnosis was MALT in 19/33 (58%), DLBCL in 9/33 (27%) and other histological type in 5/33 (15%). Every patient underwent complete staging and the stage was I/E in 18/33 and II/E in 15/33. Therapy was antibiotic eradication of HP in 8/33 pz and chemo-immunotherapy in accordance with guidelines. Samples for histology were fixed with formalin and stained with HE, then tested by antibodies for CD3, CD5, CD10, CD20, CD21, CD23, CD30, CD38, CD43, CD45RO, CD79a, CiclinaD1, BCL-2, BCL-6, Ki67, EMA, k e l. Samples for flow cytometry were put in saline, sent to laboratory within thirty minutes and processed with standard methods. A cytometric pattern was defined as pathological if there was an evident atypical assembly of B or T lymphoid antigens along with clonal restriction for Ig light chains or TCRVb repertoire.
Results: We have carried out 44 biopsies in a population of 33 patients and we obtained a final diagnosis in all cases. Diagnosis was: NHL in 11/42 (9 MALT,1 follicular lymphoma,1 DLBCL), plasmacytoma in 1/42, and benign conditions in the remaining 32/44. There was strict concordance between the two methods, but in one case flow cytometry was negative and histology was positive for lymphoma, in other one positivity of flow cytometry led to histological revision and, finally, to full concordance.
Summary/Conclusions: This study demonstrated that flow cytometry is an easy and reliable diagnostic tool for gastric lymphoma: assumed that its goal is to assess lineage and clonality, it is fast, sensitive and specific. It is synergistic to histology, especially in difficult cases like biopsy performed during a revaluation after chemotherapy or antibiotic therapy, or reactive conditions where lymphoid infiltrates can mimic lymphoma. Histological diagnosis certainly remains the gold standard for lymphoma diagnosis but flow cytometric typing can usefully support histology to reach a correct diagnosis in 100% of cases.

PB1880

RESULTS OF LAPAROSCOPIC SPLENECTOMY IN SPLENOMEGALY

O Soboleva[*], K Ntanisian, S Karagyulyan
Hematologic surgery, Hematology Research Center for Hematology, Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: Surgical approach to splenectomy depends on clinician's experience and laparoscopic technique. However, splenectomy in patients with splenomegaly remains a challenge. Due to the lack of randomized controlled studies the main sources of data to evaluate surgical approach to splenomegaly are case-control series.
Aims: Our goal was to determine criteria for laparoscopic approach to splenomegaly
Methods: Since 1999 1027 patients underwent laparoscopic splenectomy (LS) at our department. Spleen size was considered to determine surgical approach in connection with other factors such as abdominal cavity volume. Splenomegaly was detected in 506 cases of 1027 LS performed. In this group the mean spleen size was 21.25 sm (range 14-34 sm), mean spleen weight was 1016 g (range 300-2650 g). The mean age was 37 years (range 14-72 years). Indications were same as for the open procedure. Mean operative time was 137 min *versus* 115 min in open procedure. Mean blood loss was 54 ml *versus* 664 ml in open procedure. Conversion rate was 19.7% (100 cases). Spleen hilum infiltration and perisplenitis were the factors most commonly leading to conversion. There were no severe complications and no deaths.
Results: Splenomegaly is not considered a crucial factor to determine surgical approach. We've separately analyzed 250 LS performed before 2003. Conversion rate in this group was 22%, and it was as high as 31% in cases of splenomegaly. Since 2003 gaining experience resulted in conversion rate decrease to 18.7% in patients with splenomegaly. The conversion rate decreased with the increasing surgical experience. Apparently excessive spleen size is relevant if analyzed in proportion to limited working space in abdominal cavity. Conversion rate in lymphoproliferative disorders was 28% and for benign disorders – 13%. LS has proved to have advantages over open procedure such as minimal tissue injury, improving exposure to the superior pole and splenic pedicle and minimization of pancreatic injury. Even if excessive spleen size leads to conversion, laparoscopic approach facilitates dissection as the first operative step.
Summary/Conclusions: LS is being increasingly used in patients with splenomegaly. Spleen size is not the most important factor to determine approach to splenectomy. There is a decrease in conversion rate with the increasing surgical experience. Laparoscopic approach to splenomegaly is preferable considering sufficient knowledge and skill of the operating surgeon.

PB1881

BRAF GENE MUTATIONS AND PROGNOSTIC SIGNIFICANCE OF CLINICAL FINDINGS IN CASTLEMAN DISEASE

M Türker[1,*], S Subari[1], M Keklik[2], MS Dal[3], N Sahin[4], M Comert[5], G Alanoglu[6], E Kara[7], S Kocarslan[8], E Gundogan[9], H Buyukbayram[10], O Ayyildiz[3], A Unal[2], S Oztuzcu[11], N Akpolat[4], G Saydam[5], S Bircan[6], C Demir[7], I Sari[12], M Yilmaz[9]
[1]Internal Medicine, Gaziantep University School of Medicine, Gaziantep, [2]Hematology, Erciyes University School of Medicine, Kayseri, [3]Hematology, Dicle University School of Medicine, Diyarbakir, [4]Hematology, Inonu University School of Medicine, Malatya, [5]Hematology, Ege University School of Medicine, Izmir, [6]Hematology, Suleyman Demirel University School of Medicine, Isparta, [7]Hematology, Van Yuzuncu Yıl University School of Medicine, Van, [8]Pathology, Harran University School of Medicine, Sanliurfa, [9]Hematology, Gaziantep University School of Medicine, Gaziantep, [10]Pathology, Dicle University School of Medicine, Diyarbakir, [11]Medical Genetics, [12]Pathology, Gaziantep University School of Medicine, Gaziantep, Turkey

Background: Castleman's Disease is a quite rare lymphoproliferative disorder. The association with IL-6 secretion, HIV/HHV-8 is well described, but the pathogenesis is not fully understood. BRAF is a serine/threonine kinase that has an important role in the mitogen activated protein kinase (MAPK) pathway. Dysregulation of this pathway and gene mutations lead to development of malignancy. BRAF mutations are present in malignant melanoma, colorectal cancer, ovarian carcinoma, papillary thyroid carcinoma and hairy cell leukemia.
Aims: We aimed to determine the presence of BRAF gene mutation in Castle-

man's Disease and to assess clinical data of disease and the relationship with prognosis.
Methods: This retrospective study included 34 patients who were diagnosed as Castleman's Disease between 2007-2014 from 8 different medical centers in Turkey. Clinical and laboratory findings of the patients have been evaluated from medical records. All tissue samples were characterized for the presence of the BRAF mutation by pyrosequencing. Statistical analysis was performed to determine any associations among histological variants,clinical type and clinical features of the patients including age, gender, survival, and laboratory findings.
Results: There were 17 men and 17 women. Hyaline vascular variant was the most common subtype (75.6%). The study included 21 (61.8%) cases with unicentric Castleman's Disease (UCD) and 13 (38.2%) cases with multicentric Castleman's Disease (MCD). Hyaline vascular variant was more common in the UCD group ($p<0.05$). Cases were divided in 3 sites according to involvement; thoracic, abdominal and cervical. The majority of patients (61.7%) had cervical involvement. 10 of patients (29.4%) had more than one region involvement. The plasma cell variant was significantly higher in men ($p=0.006$). The mean age was significantly higher in the plasma cell group and MCD ($p<0.05$). CRP levels were found significantly higher in plasma cell variant compared to hyaline vascular variant ($p<0.05$). The BRAF gene mutation was not detected in all tissue samples. Hepatomegaly and/or splenomegaly were presented significantly common in patients with multiple site involvement ($p<0.05$). Splenomegaly was presented significantly common in MCD ($p=0.001$). 3-year overall survival was significantly higher in patients treated with only radiotherapy or chemotherapy in addition to radiotherapy when compared to only chemotherapy ($p=0.001$). Mean survival was significantly higher in patients with hyaline vascular variant and UCD ($p <0.05$).
Summary/Conclusions: This study is the most comprehensive study in our country about Castleman's Disease and we obtained important information about clinical, histopathological and prognostic features of the disease. We suggest combined therapy with radiotherapy is superior to chemotherapy alone, but as we know the efficiency of radiotherapy in the treatment of unicentric Castleman's Disease and we may have got this outcome due to some of the unicentric patients in our study were treated by radiotherapy alone.

PB1882

OCULAR ADNEXAL LYMPHOMAS: A CASE SERIES
S Dhawan[1,*], MA Khan[1], N Barrett[1], R Kapoor[1], M Mulhern[2], S Kumar[1], E Elhassadi[1], F Jackson[1], S Kennedy[3], B Hennessy[1]
[1]Haematology Department, University Hospital Waterford, [2]Ophthalmology Department, Whitfield Clinic, Waterford, [3]Pathology Department, Royal Victoria Eye and Ear Hospital, Dublin, Ireland

Background: Ocular lymphomas comprise only 1% of all non-Hodgkin lymphomas (NHL)[1]. However, it is a common extranodal site (5-15% of the extranodal cases)[2]. Lymphoma arises from the localized lymphoid tissue affecting the orbit, the eyelids, the conjunctiva and the lacrimal gland. The high curative potential of the local disease makes prompt diagnosis clinically important.
Aims: Case series involving 16 patients with ocular adnexal lymphoma and study of their treatment outcomes.
Methods: Retrospective review of 16 patients' records from Royal Victoria Eye and Ear Hospital Dublin and University Hospital Waterford with a diagnosis of ocular adnexal lymphomas (OAL).
Results: In our case series, we found that follicular lymphomas were the most common subtype (50%), followed by extranodal marginal zone B-cell lymphoma or mucosa-associated lymphoid tissue (MALT) lymphoma (37.5%) and diffuse large B-cell lymphoma (12.5%). Majority of the patients were between the ages of 70-80 years. Male to female ratio was 1:1.3. Nine patients (56.2%) had primary OAL, 6(37.5%) had concurrent systemic involvement and one (6.25%) presented with ocular relapse of systemic disease. The most common presenting complaint was swelling of the eye or visible lump (62.5%) and the most common site was the orbit (37.5%) followed by conjunctiva (25%) and eyelid (25%).
Summary/Conclusions: Ocular site of the tumor does not influence the natural history of NHL. Localized disease was controlled in all cases. 10 patients (62.5%) had localized disease; radiotherapy remained the standard of treatment. Patients with localized disease who were treated with 4 cycles of monoclonal antiCD20 antibody (Rituximab) alone responded well to the treatment and sustained remission. Treatment with Rituximab alone averts potential toxicity of radiotherapy (*e.g.* cataract formation). Systemic disease accounted for 37.5% of the cases and were treated with systemic chemotherapy.

RISK FACTORS AND MICROBIOLOGICAL FEATURES OF BLOODSTREAM NONTYPHOIDAL SALMONELLA INFECTION IN ADULT PATIENTS RECEIVING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
PS Ko[1,2,*], HY Wang[1,2], CY Wu[1,2], NW Fan[,2,3], YC Liu[1,2], CJ Liu[1,2], YB Yu[1,2], LT Hsiao[1,2], TJ Chiou[2,4], CH Tzeng[1,2], PM Chen[1,2], JP Gau[1,2], JH Liu[1,2]
[1]Division of Hematology, Taipei Veterans General Hospital, [2]Faculty of Medicine, National Yang-Ming University, [3]Department of Ophthalmolgy, [4]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, ROC

Background: In patients receiving allogeniec hematopoietic stem cell transplantation (allo-HSCT), it is not uncommon to encounter post-transplant infection and/or acute or chronic graft-versus-host disease (aGVHD or cGVHD) which commonly involve gastrointestinal tract and liver. Thus, post allo-HSCT patients might be vulnerable to foodborne pathogens, such as nontyphoidal salmonella (NTS) infection. To the best of our knowledge, very few reports discuss this issue of post allo-HSCT bloodstream NTS infection. We retrospectively analyzed the clinical risk factors and microbiological features of bloodstream NTS infection among adult allo-HSCT recipients during a 12-year period in our institution.
Aims: To determine the survival outcomes, the risk factors and microbiological features of bloodstream nontyphoiidal salmonella infection in adult allo-HSCT recipients.
Methods: We retrospectively reviewed adult (age ≥18 years) allo-HSCT recipients between 2003 and 2014 with regular follow-up till October 2015. Pretransplant and transplant-related clinical data were collected. Myeloablative conditioning included busulfan (4mg/kg/day for 4 days) and cyclophosphamide (60mg/kg/day for 2 days), or total body irradiation (TBI) of 12 Gy combined with cyclophosphamide (60 mg/kg/day for 2 days). Fludarabine-based conditioning were administered to elderly patients or with comorbidities. Standard protocol with cyclosporin (i.v 3.0 mg/kg/day in 2 split doses with dose being adjusted to maintain trough plasma level at 100-250 ug/L) and short-term low dose methotrexate were adopted for GVHD prophylaxis. Recipients of unrelated donor transplants also recieved anti-thymocyte globulin (2mg/kg/day for 3 days). The overall survival (OS) in patients with or without bloodstream NTS infection was analyzed by Kaplan-Meier method. A log-rank test was used to compare survival curves for statistical significance. Odds ratios (ORs) and the 95% confidence interval (CI) were calculated using logistic regression models. We used multivariate logistic regression models to calculate odds ratios while adjusting for possible independent confounding factors. All risk factors with $p<0.1$ in the univariate model further entered into the multivariate analysis. All statistical testing was performed using 2-tailed tests; $p<0.05$ was considered statistically significant.

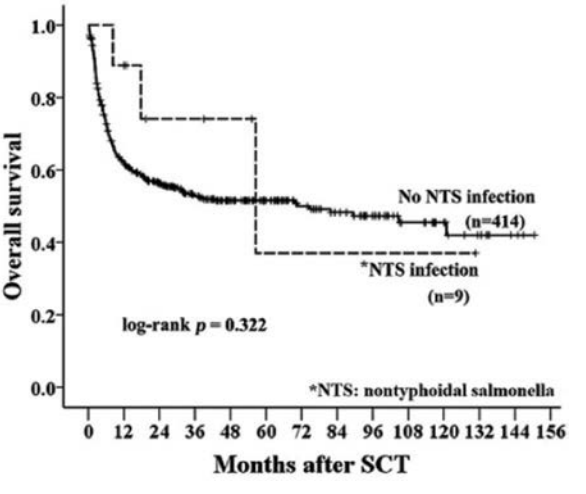

Figure 1.

Results: Total nine patients (2.13%) of 423 patients recieving allo-HSCT experienced post-tansplant bloodstream NTS infection in a median onset of 315 days after HSCT. As for the nine with NTS infection, fever was a majorly presenitng symptom. Metastatic infection of knee joint occurred in 2 patients. One suffered from concurrent bloodstream NTS infection and spetic arthritis and the other one had subsequent septic arthritis after 42 days of bloodstream NTS infection. *Salmonella* group *D* was cultured in eight out of nine patients (89%). Of note, among the 9 bloodstream NTS infection, 7 patients had cGVHD, 5 of whom suffered from extensive cGVHD. Fortunately, all patients recovered with

antibiotic therapy, which comprised of a at least third-generation cephalosporin or a quinolone or both. In addition, in patients with or without bloodstream NTS infection, there was no statistical difference of post-transplant survival (p=0.322; Figure 1). After multivariate analysis, there were statistical significances in patients receiving non-myeloablative conditioning (OR: 4.604; 95% CI: 1.098-19.308; p=0.037) and post-transplant extensive cGVHD (OR: 8.054; 95% CI: 2.048-31.674; p=0.003).
Summary/Conclusions: In a cohort of 423 adult patients recieving allogeneic hematopoietic SCT, 9 patients (2.13%) developed post-transplant NTS infection, including two patients had subsequent or combined metastatic infection. Multivariate analysis revealed that extensive chronic graft-versus-host disease (GVHD) (OR 8.054, p=0.003) and non-myeloablative transplant conditioning (OR 4.604, p=0.037) were significant risk factors for NTS infection. Our study determined the risk factors and microbiological features for this infection.

PB1884

THE REAL WORLD USE OF BISPHOSPHONATES IN MULTIPLE MYELOMA AT UNIVERSITY COLLEGE HOSPITAL (UCH), LONDON: A COMPARISON WITH LATEST GUIDANCE

O Cohen*, N Rabin, S D'Sa, R Popat, A Rismani, K Yong
Haematology, University College London Hospital, London, United Kingdom

Background: The use of intravenous bisphosphonates in patients diagnosed with myeloma is regarded as standard of care, irrespective of the presence of bone lesions. The only exceptions may be patients in advanced renal failure, or those with osteonecrosis of the jaw (ONJ). Zoledronic acid is the bisphosphonate of choice given evidence of an anti-myeloma effect, including survival. Optimal duration of bisphosphonate usage is less clear but the recommendation from the International Myeloma Working Group (IMWG) is to continue for a minimum of 1-2 years after which discontinuation can be considered if complete response (CR) or very good partial response (VGPR) is achieved. This guidance is recommended but not always followed. We review clinical practice surrounding bisphosphonate usage at a tertiary centre.
Aims: To describe the real world use of bisphosphonates in patients attending a specialist myeloma clinic and how it compares with published guidance.
Methods: A sample of 60 patients with symptomatic myeloma was taken sequentially from clinic lists in December 2015. Data was collected for these patients from clinical case record (CDR) and electronic prescribing system (Chemocare) in regards to current disease status, chemotherapy, bisphosphonate use and complications and renal function. A literature search was performed using Pubmed in order to collate the latest guidance.
Results: 60 patients with myeloma attending the myeloma clinic were identified. Of these, 55% were male. 10% patients were <50 years old, 72% patients were aged 50-70 and 18% were >70 years old. 27% were diagnosed with myeloma within the last 2 years. Disease isotypes were: 52% IgG, 12% IgA, 17% kappa light chain, 13% lambda light chain and 6% other disease type. 52% were on active treatment; 17% on Bortezomib regimens, 25% on Lenalidomide, 8% on Pomalidomide and 2% on other regimens. 58% of patients had abnormal renal function (GFR<90ml/min). 57/60 were commenced on a bisphosphonate at diagnosis, which was Zoledronic acid in 77% of all cases but just 46% in patients with eGFR <60ml/min. In all other cases, it was Pamidronate. All patients had renal function monitored via a blood test prior to each bisphosphonate infusion but urine albumin was not measured. DEXA scans were not routinely done to assess bone density. 88% of patients diagnosed within 2 years were still on 4-weekly bisphosphonates. After 2 years, 12% had the bisphosphonate stopped whilst 48% had the frequency reduced to 2-3 monthly. The remaining 40% remained on monthly treatment. Of the 40% on monthly bisphosphonate treatment more than 2 years from diagnosis, most (88%) were being actively treated for their myeloma. Of the 31 patients on active treatment, 71% were still on 4 weekly bisphosphonates. Of patients with an eGFR of <60ml/minute, 64% had their bisphosphonate dose reduced. One patient had a reduction in treatment frequency as a consequence of ONJ. A further 4 patients had dental intervention documented during bisphosphonate treatment, one of whom had their bisphosphonate treatment held for 2 months as a result.
Summary/Conclusions: Compliance with IMWG guidance on initiation of bisphosphonates occurred in 95% of cases. Zoledronic acid is used less frequently in patients with abnormal renal function. Whilst frequency of bisphosphonate use often reduces after 2 years (61%), there is marked variability in the time point and disease status at which this occurs. Further work is required to clarify optimal duration of bisphosphonate use and scheduling, and the adjustments for osteonecrosis and dental intervention.

PB1885

ANTIFUNGAL PROPHYLAXIS WITH MICAFUNGIN IN PATIENTS UNDERGOING AUTOLOGOUS AND ALLOGENIC STEM CELL TRANSPLANTATION. A SINGLE CENTRE EXPERIENCE

A Alba Sosa*, P González Sierra, A Cruz Díaz, E López Fernández, L Morataila López, Z Mesa Morales, A Romero Aguilar, M Jurado Chacón
Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Micafungin is an echinocandin antifungal approved for prophylaxis in patients undergoing allogenic hematopoietic stem cell transplantation. It has a broad spectrum against yeasts and filamentous fungi. In our institution, we employ Posaconazole as antifungal primary prophilaxis for allogenic transplantation and Fluconazole for autologous procedures but there are different situations that require us to change the protocol such as tolerance or toxicity to azoles or interactions with other drugs such as rapamycin.
Aims: Analyze the efficacy and safety of the use of Micafungin for antifungal prophylaxis in patients undergoing autologous and allogenic hematopoietic stem cell transplantation.
Methods: Between January 2013 and December 2015, 77 patients have received Micafungin at doses 50 mg daily. 51 (66.2%) of them were male. The mean age at transplantation was 43.7 years-old (20-61). Diagnoses were 23 acute leukemias (29.8%) twenty-two (28.5%) Non-Hodgkin Lymphoma, twelve (15.5%) Hodgkin Disease, six (7.7%) myelodisplastic síndrome, five (6.4%%) Multiple Myeloma, five (6.4%) philadelphia-negative chronic myeloproliferative neoplasms, three (3.8%) aplastic anemia and one case of Chronic Myeloid Leukemia. Most of the stem cell transplantation were allogenic (85%). Only seven (8.8%) and five (6.5%) were autologous and haploidentical procedures respectively. Major of Conditioning regimen was myeloablative (71.3%), 17.5% undergoing reduced intensity conditioning regimen and only 11.3% no myeloblative regimen. 46.3% of the patients presented absolut neutrophils count (ANC) less than 1000/mm^3. The average duration of treatment with micafungin was 20.7 days (5-150) and the median duration was 14 days. The reason to start micafungin treatment was primary prophylaxis in ten cases (10%), bad gastrointestinal tolerance to azoles in fifty-four cases (70.1%), farmacological interactions with azoles in seven patients (9%) and toxicity to azoles in only five patients (6.4%).
Results: Reason to finish prophilaxys with micafungin was the improve of the gastrointestinal syntoms and, consequently, the end of prophilaxys period in fifty-two cases (67.5%). Six patients (7.8%) presented breakthrough fungal infection. Other causes were positive antigen galactomannan (2 patient), persistent fever (5 patient), exitus not attributable to IFI (5 patient), toxicity to micafungin (2 patients) and unknown cause in four patients. Six patients (7.8%) presented breakthrough fungal infection (all probably invasive fungal infection according to the EORTC criteria). Isolated fungi were Geosmithia argillaceae, Aspergillus Fumigatus, Aspergillus Flavus and Aspergillus spp. Mortality due to Fungal infection was 3.8% (three patients). With regards to tolerance, there were no reports about any infusional reaction. Only 2 patient referred micafungin liver toxicity grade II without any problem when the micafungin was suspended.
Summary/Conclusions: 1. Micafungin at doses of 50 mg/24 hours, is an effective and safe option for yeast prophylaxis in patients undergoing autologous and allogenic stem cell transplantation. 2. In our series, although they have identified six breakthrough infections (7.8%), it must be noted that these were patients with active refractory GVHD to several lines of immunosuppressive therapy, including, of course, high-dose steroids. Maybe, we have to use prophylaxis protocol based on liposomal anfotericin, with a better anti-mold spectrum, in this group of high risk patients. 3. The safety of the treatment was excellent, without tolerance problems. The kidney and liver function was not altered by treatment with micafungin.

PB1886

THE POSITIVE IMPACT OF ANTIMICROBIAL STEWARDSHIP IN THE BIGGEST PEDIATRIC HAEMATOLOGY ONCOLOGY CENTRE, RUSSIA

V Pirumova, G Solopova*
Infection Prevention and Control, Dmitry Rogachev Research Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Multidrug resistant organisms (MDRO) are the emerging problem across the world, and one of the most effective and mandatory steps in solving it is optimization of antibiotics use. Here we present the first results of the fight against MDRO at the Dmitry Rogachev Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russia (Center).
Aims: The Infection Prevention and Control Department (IPCD) has made a number of steps to rationalize the use of anti-infectives.
Methods: On January 1st, 2014, the algorithm for empirical anti-infective therapy in febrile neutropenia was implemented. It included recommendations for first line (empiric) antibacterial therapy (in accordance with the patient's risk group), spectrum of recommended evaluation tests and rules for treatment modification. For example, fluoroquinolones and ceftazidime were excluded from empiric therapy and reserved for the targeted one only. The same recommendations were made regarding tigecycline and ertapenem. Another step was the implementation of guidelines for perioperative antibiotic therapy, with cephalosporins I-II regarded as the drugs of choice in most of cases. Along with those measures, precise control of antibiotics and antifungals discontinuation was established. For the evaluation of the effectiveness of the results we have calculated the use of the most common classes of antibiotics and antifungals (per 100 bed-days) before the intervention and a year after it. Microorganisms'-wise drug resistance index (DRI) was also calculated.
Results: Having compared the respective rates before and after the intervention, we detected the overall decrease of use in vancomycin (64%), piperacillin/

tazobactam (15%), aminoglycosides (15%) and fluoroquinolones (7%) in all the Center's departments. Calculated separately, the rates were significantly higher for the intensive care unit, where interaction compliance with the IPCD was the highest: reduction of aminoglycosides use -58%, fluoroquinolones -66%, cephalosporins III-IV-8%, vancomycin-82,5%, piperacillin/tazobactam -52%, carbapenems-20%, linezolid-47%. The use of colistin remained on the same level, while the use of tigecycline raised 35%. As for antifungals, the analysis showed a 75% reduction of use in amphotericin B and an 18% reduction in case of voriconazole. Posaconazole raised 25%. Although echinocandins were used as the drugs of choice in empiric antifungal therapy in febrile neutropenia algorithm (in accordance with the ECIL recommendations), their use remained on the same level. During the surveillance period DRI levels for *P.aeruginosa* and *E. coli* dropped down (graph 1). In terms of money, the reduction of anti-infectives use have saved the Center around €500,000 in 12 months. It is important to mention that the rates of infections-related mortality has not increased since the intervention (26 in 2013 compared to 16 in 2014).

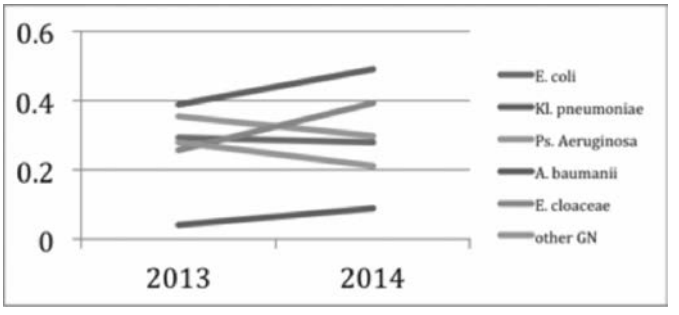

Figure 1.

Summary/Conclusions: The reduction of antibiotics and antifungals use and as a result - the decrease of microbial resistance and money savings in hematology/oncology hospital is an achievable goal. Every hospital should make the effort to initiate and sustain an effective Antimicrobial Stewardship Program.

PB1887

INVESTIGATION OF RELATIONSHIP BETWEEN NEUTROPENIA AND SERUM CHITOTRIOSIDASE AND NEUTROPHIL GELATINASE RELATED LIPOCALIN ENZYME ACTIVITY IN CHILDREN UNDERGOING CHEMOTHERAPY

O Gursel[1,*], I Eker[1], O Babacan[1], S Kılıc[2], E Kurekci[1]
[1]Department of Pediatric Hematology, [2]Department of Pediatrics, Gulhane Military Medical Academy and Medical Faculty, Ankara, Turkey

Background: Human chitotriosidase (ChT) is a member of the chitinase family and it is synthesized and secreted by activated macrophages and neutrophilic granulocyte progenitors. Neutrophil gelatinase related lipocalin (NGAL) is situated in secondary granules of granulocytes and is specific to neutrophils.
Aims: The aim of this study was to investigate the relationship between neutropenia and serum ChT and NGAL levels in patients with hematologic malignancy and hospitalized because of febrile neutropenia.
Methods: This study included 27 children between 1-15 years old, who have hematologic malignancies and whose chemotherapies were still ongoing and were known not having a disease that leads to macrophage activation. Complete blood count (CBC),serum levels of c-reactive protein (CRP), lactate dehydrogenase (LDH), ChT and NGAL were determined before the initiation of chemotherapy while the patients were not neutropenic. The same tests were studied also in the severe neutropenic period and after the recovery of neutropenia. Serum ChT and NGAL levels of the patients during these periods were compared. Whether there is a correlation between the number of neutrophils and these enzyme levels were also investigated.
Results: Total granulocyte count (TGC), CRP, LDH, NGAL and ChT levels were statistically significant different between the periods of severe neutropenia, improving neutropenia and recovered neutropenia (p:0,0001). There was a statistically significant positive correlation between ChT and TGC levels during the period of severe neutropenia (p:0.034, Pearson's r: 0,418). There was not a statistically significant relationship between NGAL and TGC levels during the period of severe neutropenia.
Summary/Conclusions: The results of our study exhibiting a statistically significant difference, between serum ChT and NGAL levels, during the periods of severe neutropenia, improving neutropenia and recovered neutropenia, supports the data suggesting that these enzymes are secreted by neutrophils. Especially, statistically significant positive correlation between ChT and TGC levels suggests that levels of this enzyme can be used as a marker to determine the period of recovery from neutropenia. Further studies are needed to investigate the relationship between febrile neutropenia prognosis and NGAL and Cht levels.

PB1888

EPIDEMIOLOGY OF FEBRILE EVENTS (FE) IN NEUTROPENIC PATIENTS (PTS) WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) TREATED BY «ALL-2009» PROTOCOL

V Okhmat*, G Klyasova, V Troitskaya, E Gribanova, S Kravchenko, E Parovichnikova
National Research Center for Hematology, Moscow, Russian Federation

Background: Hematological patients with acute leukemia undergoing intensive myelosupressive treatment are at high risk for severe, life-threatening infections.
Aims: To evaluate the epidemiology of FE in neutropenic pts with ALL on different chemotherapy phases (CP).
Methods: Single-center, prospective observational study in adults with newly diagnosed ALL treated by «ALL-2009» protocol (NCT01193933) was performed from Jan 2013 till Jan 2016. Pts were followed up for 180 days.
Results: Total of 44 pts were enrolled (22 - male, 22 - female; median age 26 (17-61). On admission hyperleukocytosis was in 25% (11/44) of pts, ECOG score ≥3 had 61% (27/44). These pts had 271 CP (induction I-43, induction II-42, consolidation I-42, consolidation II - 41, consolidation III-40, consolidation IV - 33, consolidation V - 30). Neutropenia was in 33% of CP, median duration 9 (2 - 45) days, more frequent and prolonged in induction then in consolidation (58% *vs* 22%, p<0.0001; 19 *vs* 6 days, p<0.000001). FE occurred in 18% (48/271) of CP, more often in induction than in consolidation (36% *vs* 9%, p<0.0001). FE (48) reasons were: fever of unknown origin (FUO) in 29% (14), clinically documented infection (CDI) in 48% (pneumonia - 17, cellulitis - 6) and bloodstream infection (BSI) in 23% (11). Among BSI pathogens Gram-negative bacteria were in 77% (*E. coli*-3, *Salmonella* spp.-3, *K. pneumonia*-2, *E. asburae*-1, *C. youngae* - 1), Gram-positive bacteria were in 23% (*B. cereus*-1, *S. aureus*-2). BSI was polymicrobial in 18% (2/11). Rate of invasive mycoses (IM) was 14% (6/44): 2 - invasive aspergillosis, probable (IA), 1 - mixed IA, probable plus mucormycosis, 3 - hepatosplenic candidiasis. All IM occurred in induction. Nobody had IM in consolidation (p=0.0002). Overall 180 days mortality was 5% (2/44), 1 patient died in induction (1-IA plus mucormycosis) and 1 in follow-up period (BSI due to *Salmonella* spp.).
Summary/Conclusions: Our study showed moderate rate of infections (18%) in ALL pts treated by «ALL-2009» protocol. FE were more frequent in induction than in consolidation (36% *vs* 9%). Most pts (71%) had CMI and BSI. IM occurred only in induction. Overall 180 days mortality was relatively low (5%).

PB1889

THE CLINICAL SIGNIFICANCE OF PROCALCITONIN MONITORING IN INFECTED PATIENTS WITH HEMATOPATHY

J Zheng, A Sun*, T Zhang, W Chang, S Chen, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Due to the application of the drugs such as high doses of chemotherapy, immune inhibitors and hormone, hematopathy patients are becoming more likely to get granulocyte lack and the resistence to infection. For those patients with the application of the peripheral venipuncture in granulocyte lack period, infection incidence can be as high as 53% ~ 80%. Accordingly, infection is one of the most common life-threatening complications, and therefore the early diagnosis and treatment of infection is very important to better prognosis. But now there is no sufficient sensitive markers to reflect the level of inflection in hematopathy patients. Traditional markers such as the number of white blood cells, C - reactive protein have no obvious specificity in the diagnosis of hematologic malignancies with infection. Positive bacteriology of blood culture is the only gold standard in the diagnosis of patients with bloodstream infections.However, it can't meet the requirements for early and rapid diagnosis, because the blood culture positive rate is only 10% ~ 20%, and pathogen isolation and culture time is long; Calcitonin original protein (PCT) is the precursor of calcitonin,which has been proven to be high in a variety of disease infection since it was found in 1993. Furthermore, it is a sensitive and specific indicator in early granulocyte lack with severe bacterial infections.
Aims: To evaluate the clinical value of procalcitonin (PCT) measurement and its dynamic monitoring in hematopathy patients undergoing chemotherapy or transplant-related infections.
Methods: The clinical data were collected and analyzed retrospectivey in 497 hematopathy patients with serum PCT above 0.5μg/L. The procalcitonin were compared between the patients with septic shock and those without. The procalcitonin were also compared between the patients with positive blood culture and those with negative blood culture. Further, theprocalcitonin were compared between the patients with gram-positive bloodstream infection and those with gram-negative bloodstream infection. Receiver operating characteristic (ROC) curve was used to evaluate the diagnostic value of procalcitonin in predicting sepsis. PCT values were collected at the onset of fever and 3, 7, 14, 21, 28 days after antimicrobial therapy. The dynamic change of PCT after operation

was compared between the patients whose infection was successfully controlled and those without adequate control.
Results: There were totally 497 hematopathy patients with serum PCT value >0.5μg/L, 421 (84.7%,421/497) cases among whom were diagnosed with infection based on clinical symptoms and microbiological assays. Out of these 421 patients, we found that 296 (70.3%, 296/421) cases' PCT values increased (>0.50μg/L) within 24 hours after having a fever. The median (range) procalcitonin level [6.29 (0.505-100) μg/L]was significantly higher in 59 (14.0%, 59/421) patients with septic shock than in those (86.0%, 362/421) without [1.16 (0.502-100) μg/L,Z=-7.726,P<0.01].408 patients received blood culture examination. The median (range) procalcitoninlevel [2.47 (0.508-100) μg/L]was significantly higher than in 167 patients with positive blood culture than in 240 patients with negative blood culture [1.15 (0.501-100) μg/L, Z=-5.762, P<0.01]. Additionally the median (range) procalcitoninlevel [4.315 (0.508-100) μg/L] was significantly, higher in 108(64.7%, 108/167) patients with gram-negative sepsis than in 37 (22.2%, 37/167) patients with Gram-positive sepsis [1.39 (0.521-55.44) μg/L, Z=-2.024, P<0.01]. The area under the curve (AUC) for PCT was 0.670, whereas a cut-off value of 2.05μg/L, provided the best sensitivity and specificity with a value of 54.3, and 70%, respectively. The dynamic changes of 289 monitoring PCT patients reflected the infection course. No significant difference was found between the patients with deteriorate and persistent infection and those whose infection was successfully eradicated properly within 72 hours (*P*>0.05). However,the PCT after 72 hours were significantly different among the three group (All *P*<0.01).
Summary/Conclusions: Procalcitonin monitoring could be used as a rapid and supplementary diagnostic marker of infection,especially in blood culture-negative infected patients.Additionally,its dynamic change could also reflect the infection course,which provides a better guide for the use of antibiotics.

PB1890

PREVALENCE OF CYTOPENIAS IN PATIENTS LIVING WITH THE HUMAN IMMUNODEFICIENCY VIRUS. AN OBSERVATIONAL COHORT STUDY
DL Teofilo[1,*], A Enrico[1], F Otermin[2], M Szelagowski[1], MV Prates[1], H Dick[1], S Yantorno[1], JJ Napal[3], S Ramirez Borga[2], J Milone[1]
[1]Hematologia, [2]Infectologia, [3]Medicina interna, Hospital Italiano La Plata, La Plata, Argentina

Background: HIV-induced immunosuppression was an important reason for the increased morbidity and mortality. Disorders in haematopoiesis are encountered far less frequently in the current era of highly active antiretroviral therapy (*HAART*). The expected survival of people living with HIV who are diagnosed early in the course of infection and who have access to modern antivirals now almost equals that of the general population. Ineffective haematopoiesis from direct suppression of bone marrow progenitor cells by HIV infection or indirectly through excessive secretion of inflammatory cytokines induced by HIV, can blunt haematopoiesis. So too can nutritional deficiencies, infiltrative bone marrow disease of infectious or neoplastic origin, and adverse drug effects. Cytopenias play a significant role in the morbidity associated with HIV. Although cytopenias may be poorly documented, they can also impact negatively on quality of life.
Aims: To analyze the prevalence of cytopenias in patients with HIV infection and evaluate the impact of HAART in our patients.
Methods: This is a retrospective study of 108 patients older than 16 years, HIV infected, diagnosed between 2002-2014. Their medical histories were analyzed. Data was collected from laboratory at the moment of diagnosis, one year later and two years of follow-up. 98 patients were included in this analysis. We did not include patients with pediatric HIV infection or a history of vertical transmission and patients with loss of follow-up (follow-up less than 2 years).

Table 1.

Table 1: Cytopenias in patients with and without AIDS at the diagnosis, at 0 (dx), 12 (12m) and 24 months (24m) of follow up.

n(%)	No AIDS	AIDS	Total
N	67	31	98
Sex F/M	15/52	10/21	25/73
Anemia (dx)	20 (28%)	23 (61%)	43 (44%)
Thrombocytopenia (dx)	21 (29%)	18 (54%)	39 (40%)
Leukopenia (dx)	1 (2%)	4 (16%)	5 (5%)
Anemia (12m)	17 (20%)	11 (30%)	28 (25%)
Thrombocytopenia (12m)	4 (7%)	-	4 (5%)
Leukopenia (12m)	-	-	-
Anemia (24m)	17 (19%)	3 (8%)	20 (17%)
Thrombocytopenia (24m)	6 (8%)	-	6 (7%)

Results: The selected 98 patients showed a median age of 37.7 years (r16-65), 74% were male. At the time of diagnosis, 44% had anemia, 40% thrombocytopenia and 5% leukopenia (table 1). Only 8% of the patients had neutropenia. At the beginning, anemia was present in 48% of female and 36% of male patients. At the time of diagnosis, 31.6% (n31) were diagnosed with AIDS (according to WHO criteria). Out of these 31 patients, 61% had anemia basal *vs* 28% in those without AIDS at the start (p:0.001). At 12 months, only 29% of the patients showed anemia, with improvement in both male and female patients compared to the time of diagnosis as well as in the group of patients with initial AIDS. The presence of thrombocytopenia was observed in 5% of the patients. At 24 months of follow-up, 21% had anemia, and only 7% of those who initially had a diagnosis of AIDS. The thrombocytopenia appeared in 7%. None of the patients presented leukopenia at 12 or 24 months. As regards HAART, out of the 98 patients, 64.2% (n:63) received treatment since the diagnosis. Within this group, the emergence of anemia at 1 and at 2 years was 22% and 15% respectively, compared to 24% and 16% in patients who received no treatment at the beginning. Twenty-three of the patients who received zidovudine (AZT) developed anemia after one year of treatment. Those who did not receive AZT, the 27% presented anemia at 12 months. None of the patients who received AZT treatment showed leukopenia at one year of follow-up.
Summary/Conclusions: In our experience, the most frequent hematological alteration was anemia, mainly at the time of diagnosis and in patients with AIDS. The haemoglobin level evolved favorably in all patients, regardless of the presence or absence of antiretroviral therapy at the beginning. The thrombocytopenia was more frequent at the time of diagnosis, but it decreased with time. The less frequent cytopenia was the leukopenia, showing no association with HAART. HIV associated cytopenias are very frequent and its appearance occurs mainly at the time of the diagnosis. When faced with this type of cytopenias, it is mandatory to have this infectious disease in mind within the diagnosis algorithm.

PB1891

IMMUNOGLOBULIN SUPPLEMENTATION IN ACUTE LYMPHOBLASTIC LEUKEMIA TREATMENT IN A SINGLE PEDIATRIC INSTITUTION: COMPARISON BETWEEN TWO CONSECUTIVE AIEOP CLINICAL TRIALS
F Petruzziello, G Giagnuolo, A De Matteo, R Parasole[*], G Sepe, E Ruberto, G Menna, S Buffardi, V Poggi
Pediatric Hemato-Oncology, Santobono-Pausilipon Hospital, Naples, Italy

Background: The intensification of chemotherapy in childhood acute lymphoblastic leukemia (ALL) has dramatically improved the 5-years overall survival but, at the same time, has increased the site effects therapy related. The most common complication remains the immunosuppression that causes increased risk of infections. The recent introduction of a pegylated formulation of L-Asparaginase (Peg-L-Asp), with more prolonged half-life and immunosuppressive effect than *native* E. Coli L-Asp, could result in a greater injury on ALL patients' humoral immunity.
Aims: We compared the rate of supportive Immunoglobulin (Ig) infusion during two consecutive therapeutic protocol of the Italian Association of Hematology and Pediatric Oncology (AIEOP) in a single pediatric center. The first trial, ALL 2009, contained Peg-L-Asp and the second, ALL 2006, *native* L-Asp; the remaining chemotherapy was similar.
Methods: Seventy-three patients, stratified in high-risk (HR; n=19), medium-risk (MR; n=32) and standard risk (SR; n=22), enrolled in ALL 2009 protocol, were compared with 68 patients (15 HR, 30 MR and 23 SR), of ALL 2006 trial. Patients submitted to a bone marrow transplantation or early relapsed were excluded by the analysis. Number of Immunoglobulin infusions, type and number of L-Asp administrations, risk stratification, IgG levels at diagnosis and episode of infections were collected by clinical records of both protocols. Possible correlations between Ig supplementation rate and the other parameters were analyzed using t-Student test and linear regression. Immunoglobulins were supplemented for Ig levels beyond 5.0 g/L at the standard dose of 0.5 g/kg.
Results: In ALL 2009 protocol**,** mean of Ig infusions were 6.2±2.9 SD (range 1-12) in HR, 2.8±2.0 SD in MR (range 0-8), and 2.2±2.1 SD in SR (range 0-4), while in ALL 2006, mean of Ig administrations were 2.9±1.7 in HR (range 0-6), 1.2±1.3 in MR (range 0-6) and 1.5±1.6 in SR (range 0-7), respectively. A higher rate of Ig infusions was observed in ALL2009 trial but this cumulative rate is not statistically significant. However, the difference between HR and MR risk stratification for the average of Ig infusions was significant (p <0.05) comparing ALL2009 and ALL 2006 trials. No correlation was found between Ig supplementations and risk of infections, number of L-Asp administrations, and IgG level at diagnosis.
Summary/Conclusions: In our experience, an higher Ig supplementation was observed in the very intensive protocol (HR and MR), mostly in ALL2009 trial. Further studies, with more extensive series of patients, need to understand the reason to the increased demand of immunoglobulin support in HR and MR patients treated with Peg-L-Asp.

PB1892

CANDIDAEMIA SPECTRUM: RESULTS OF A THREE-YEAR ANALYSIS AT THE PEDIATRIC HAEMATOLOGY ONCOLOGY CENTRE, RUSSIA
V Pirumova[*], G Solopova
Infection prevention and control, Dmitry Rogachev Research Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Invasive infections due to Candida spp. are among the leading

causes of morbidity and mortality of immunocompromised pediatric patients. Candidemia levels are still high, despite the ongoing improvements in diagnostics, prophylaxis and treatment possibilities. It not only affects the outcomes of cancer treatment, but also shifts the treatment costs. As for now, there are no data available on the epidemiology of invasive candida infections for pediatric hematology/oncology in Russia.
Aims: The study's aim was to determine the rate and spectrum of candidemia in Russia's largest pediatric hematology/oncology center.
Methods: We present a retrospective analysis of candidemias occurred at the Dmitry Rogachev Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russia. All blood cultures positive for Candida spp. taken from 22 March 2013 to 22 November 2015 have been identified, and all first patient-episode pairs have been included. Spectrum of species, patient's characteristics, treatment strategies and outcomes have been analyzed.
Results: During surveillance period 34 episodes in 32 patients occurred. 36 Candida spp. were identified. 2 patients had 2 separate candidemia episodes, and in 2 cases more than one Candida spp. was cultured. Age distribution was 0-21 years (58% 0-3 years, 16% 5-10 y., 26% 11-21 y.). The majority of patients had some sort of hematological malignancy (39%), 29% had primary immunodeficiency, 26% had solid tumors and 3% had severe congenital neutropenia. 6 patients among all those with candidemia were after hematopoietic stem cells transplantation (18.7%). *C. parapsilosis* was responsible for the majority of episodes (53%) (graph 1). In 11 of 18 isolates the ecchinocandines susceptibility testing was performed: 10 (90.9%) were susceptible, 1 had intermediate susceptibility. As the first line therapy, 19 patients (59%) received echinocandins, 6 - amphotericin B, 3 - voriconazole, and 3 - fluconazole. In all cases antifungals were given within 24 hours from the time of execution of the blood cultures. One patient did not receive any therapy (although the central line was removed immediately). Central line was removed in 29 (88%) cases. Speaking of the outcomes, 72% patients were alive at the end of the episode. Mortality attributed to Candidemia was 12.5% (4 cases), with the time median of 21 day (3-37 days).

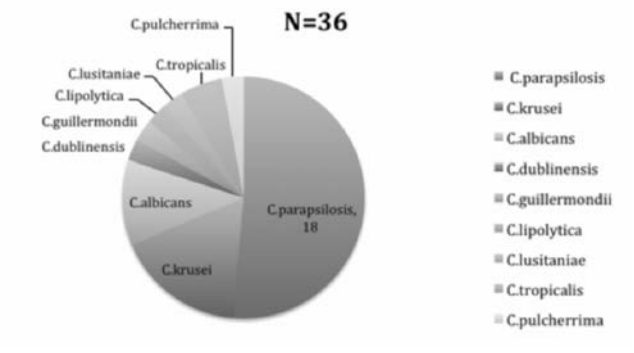

Figure 1.

Summary/Conclusions: Invasive candidiasis is a common complication in pediatric hematology/oncology patients. In our hospital in 2013-2015 candidemia accounted 8.6% of all bloodstream infections. *C. parapsilosis* was responsible for the majority of the cases, while mixed infections were rare. The attributive mortality was as high as 12.5%.

PB1893

RISK FACTORS FOR INFECTION AND HIGH MORTALITY RATE AMONG PATIENTS WITH KPC PRODUCING KLEBSIELLA PNEUMONIAE BACTERAEMIAS IN A HAEMATOLOGY UNIT

A Galanopoulos[1,*], P Bakarakos[1], D Tsokanas[1], G Drakos[1], M Orfanidou[2], G Ganteris[2], H Vagiakou[2], P Giakkoupi[3], A Vatopoulos[4], H Malamou-Lada[2], N Anagnostopoulos[1]
[1]Hematology Department, [2]Medical Microbiology, GNA "G.Gennimatas", [3]Microbiology, [4]Microbiology, National School of Public Health, Athens, Greece

Background: Emergence of carbapenem resistant enterobacteriae, especially Klebsiella spp, causing nosocomial infections is growing worldwide and has become a great challenge especially for clinicians and the Public Health System. Klebsiella pneumoniae carbapenemase (KPC)-producing Klebsiella pneumoniae (KPC-Kp) infections in Haematology Unit patients are associated with increased mortality.
Aims: This study was carried out to determine risk factors for KPC-Kp infections and predictors of mortality in Haematology Unit patients with KPC-Kp bacteraemias.
Methods: In this retrospective study of a 3-year period, all patients with hospital-acquired KPC-Kp isolation were included and were compared with other non bacteraemic patients. K. pneumoniae were identified by Vitek 2 technology, antibiotic susceptibility was determined by agar disk diffusion method and minimum inhibitory concentrations were determined by Etest. The presence of the *bla*KPC gene was confirmed by PCR. Molecular typing was performed by pulsed field gel electrophoresis (PFGE) of XbaI-restricted genomic DNA.
Results: Eighteen episodes of infections were identified and KPC-Kp strains were isolated from 16 patients. Acute myeloid leukaemia was the underlying disease in 10 patients, non-Hodgkin lymphoma in two and acute lymphoblastic leukaemia, chronic lymphoblastic leukaemia, aplastic anaemia and multiple myeloma, one each. Seven of them were males and nine were females and their median age was 70 years (range: 25-83). The medical records of patients were retrospectively collected for demographic, clinical, and microbiological data. Clinical infections *versus* hospitalization and the outcome of infected patients were defined. The median duration between admission and the isolation of KPC-Kp strains was 24 days. Twelve patients were neutropenic during the bacteraemias. Colonization or bacteraemia from multiple pathogens, including multidrug resistant P. aeruginosa, K. pneumoniae (ESBL), vancomycin resistant Enterococcus and various fungi were concurrently identified in 12 patients with bacteraemia from K. pneumoniae. All patients had either multiple or prolonged hospitalizations and all of them had received antibiotics for prophylaxis or treatment prior to the isolation of the pathogen. Infection due to KPC- Kp was the leading cause to death in 11/16 patients (68,8%). One patient died of brain hemorrhage (not attributed to his infection), three died of infections caused by other bacteria, after having survived the KPC infection, and three remained alive. Risk factors for KPC-Kp bacteraemia were the number of intravenous catheters or ports, prior prolonged administration of high spectrum of cephalosporins and prolonged hospitalization. In multivariate analysis the age, performance status, prolonged severe neutropenia, resistance to gentamicin and septic shock were independent predictors of mortality.
Summary/Conclusions: We found many risk factors involved in KPC-Kp infections among Haematology Unit patients. The high mortality rate in these patients reinforces the urgent implementation of appropriate infection control measures to prevent the spread of carbapenemases producing Enterobacteriaceae.

PB1894

PLASMA POSACONAZOLE CONCENTRATION DURING CONCOMITANT TREATMENT WITH PROTON PUMP INHIBITHOR OMEPRAZOLE IN ADOLESCENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANT

M Ribersani[1,*], K Paciaroni[1], C Alfieri[1], G De Angelis[1], C Gallucci[1], J Gaziev[1], A Isgrò[1], M Marziali[1], P Sodani[1], L Dori[2], S Fallani[3], A Novelli[3], C Girmenia[4], G Lucarelli[1]
[1]Istituto Mediterraneo di Ematologia-Policlinico Tor Vergata, [2]U.O.C. Malattie Infettive, Policlinico Tor Vergata, Rome, [3]Dipartimento di Scienze della Salute, Sezione di Farmacologia Clinica e Oncologia, University of Florence, Florence, [4]Dipartimento di Ematologia, Oncologia, Anatomia Patologica e Medicina Rigenerativa, La Sapienza University, Rome, Italy

Background: Posaconazole (PCZ) is a broad-spectrum triazole approved for primary antifungal prophylaxis in patients (pts) with acute myeloid leukaemia or myelodisplastic syndrome during chemotherapy, in pts who develop a graft *versus* host disease (GVHD) after allogeneic stem cell transplant (allo-SCT) and for salvage therapy of pts with invasive fungal diseases (IFD). Concomitant use of PCZ suspension (PCZ-susp) and proton pump inhibitors (PPIs) has been associated with a significant reduction in the bioavailability of the antifungal drug, however, whether and in what extent this reduction affects the probability in reaching the target levels should be defined. Furthermore, few data are available in the paediatric population.
Aims: Omeprazole is a PPI often prescribed to allo-SCT recipients who receive steroids for prophylaxis or treatment of GVHD, therefore concomitant PPI and PCZ-susp are commonly administered. In this study the impact of omeprazole on plasma PCZ concentration (PPC) in 4 adolescents who received PCZ-susp after allo-SCT was evaluated.
Methods: This study represents a sub-analysis of a large, prospective, multicenter trial which included adult and paediatric allo-SCT pts. The trial was approved by Ethic Committee, written informed consent was obtained from each parent prior to any study-related activity. They were 3 males and 1 female (aged 11-13-16 and 17 years) and they were affected by sickle cells disease and β-thalassemia (2 pts each) and underwent allo-SCT from related donors. Two pts received PCZ-susp for second line therapy of proven *Aspergillus Terreus* infection and possible IFD respectively, and other 2 pts received PCZ-susp for primary prophylaxis during GVHD. PCZ-susp was administered at standard dose (600 mg/die or 12 mg/Kg regard to the weight). Plasma samples were stored at -80°C. The PPC was measured by high-pressure liquid chromatography at a reference pharmacology laboratory in Florence. All pts received concomitant treatment with omeprazole during the entire PCZ-susp therapy. At steady state (after 5 days of treatment) 0.7 mcg/ml was considered the therapeutic cut-off value.
Results: Overall, 2, 2, 3 and 6 samples were obtained, respectively. In two pts PPC was always above the cut-off value (mean 2.34 and 1.19 mcg/ml respectively), while in two pts the first PPC was inadequate (0,27 and 0,49 mcg/ml respectively) but reached higher values at a second evaluation (0,50 and 2,05 mcg/ml respectively), without changing the dosage of the drug. The patient with persistent sub-therapeutic PPC suffered of gastro-intestinal GVHD with diarrhoea.

Summary/Conclusions: PPC monitoring is considered a standard good practice in pts treated with PCZ-susp. However, considering that a timely PPC monitoring is difficult to perform in several centers, clinical conditions which may impact on the bioavailability of the drug can be considered for the safe use of PCZ-susp without PPC monitoring. This small experience in adolescent SCT pts doesn't seem to show a significant impact of omeprazole in the bioavailability of PCZ-susp. In the only patient with inadequate PPC, diarrhoea, and not concomitant PPI, presumably was the cause of reduced absorption. While diarrhoea has been associated to impaired intestinal absorption in several experiences, concomitant use of PPI doesn't seem to significantly impact on PPC and doesn't seem to be considered an absolute indication to PPC monitoring.

PB1895

A NOVEL MARKER FOR DIFFERENTIAL DIAGNOSIS BETWEEN HEPATITIS B AND HEPATITIS C USING ROUTINE COMPLETE BLOOD COUNT AND CELL POPULATION DATA

J Kahng[1,*], K Han[2]
[1]Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Bucheon, [2]Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Final diagnosis of hepatitis B or hepatitis C requires various immunologic and molecular diagnostic tests, and accordingly takes a significant amount of time prior to initiation of treatment. There is a high incidence of hepatitis in Korea, incurring high medical costs for hepatitis B (HBV) and hepatitis C (HCV). Reports have recently come that propose screening markers using CBC with cell population data (CPD) for infectious diseases such as sepsis and tuberculosis. If such screening markers for hepatitis are developed, it will contribute to the reduction of time prior to treatment and medical costs.
Aims: The study aims to find any possible screening marker or a combination of parameters detecting HCV from HBV among hepatitis patients using CBC with CPD.
Methods: We analyzed 3787 CBC data from 3721 individuals including patients with hepatitis (325 HBV and 84 HCV), anemia, malignancy, infection other than hepatitis, and health check-up at Seoul St. Mary's Hospital, Korea, between December 2012 and July 2014. We used an automatic hematology analyzer (DxH 800, Beckman Coulter Inc., Miami, FL, USA) to obtain data including CBC-diff and CPD from using direct current impedance to measure cell volume (V) for accurate size of all cell types, ratio frequency opacity to characterize conductivity (C) for internal composition of each cell, and a laser beam to measure light scatter (S) for cytoplasmic granularity and nuclear structure. Each CPD parameter value for WBC, neutrophils, lymphocytes, eosinophils, monocytes, NN RBCs (non-nucleated RBCs) is first stored in Excel, and the values are divided by the mean value from the normal health check-up individuals. HBV and HCV cases are colored red and blue, respectively, and sorted in ascending order in Excel. After sorting, we identify grouping of HBV or HCV cases for each parameter. If grouping is found, the parameter is taken as a marker; otherwise, e.g., even distribution, the parameter is of no value as a marker. The cutoff value for each candidate marker is set when the combination of them yields over 75% both of sensitivity and specificity.
Results: A combination marker composed of four parameters with cutoff values for detecting HCV in the mixture of HBV and HCV is as follows: SD C NNRBC >0.93; MN NNRBC C/AL2 >0.55; MN AL2 EO (Eosinophils) >0.97; SD V Ly >1. The new combination marker detected 142 cases which consist of 64 from 84 HCV cases (76.2%) and 78 from 325 HBV cases (24.0%).
Summary/Conclusions: A new set of CPD marker is proposed with 76.2% sensitivity and 76.0% specificity to differentiate hepatitis C from hepatitis B within less than 1 hour by simple CBC test, reducing time and costs as a screening measure.

PB1896

PREVENTION AND TREATMENT OF INVASIVE FUNGAL INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES - RESULTS FROM A SINGLE HEMATOLOGICAL CENTRE

JL Iványi[1,*], M Plander[1], T Szendrei[1], C Tóth[2]
[1]Department of Hematology, [2]Department of Pathology, University Teaching Hospital Markusovszky, Szombathely, Hungary

Background: Invasive fungal diseases could influence morbidity and early treatment-related mortality in patients of malignant hematological disorders treated with aggressive chemotherapy,especially in acute leukemias or after hematopoietic stem cell transplantation.
Aims: In an observational survey during 2010-2015 we investigated in our hematological department occurence of invasive systemic fungal infections (aspergillosis, systemic candidiasis, other species), methods of antifungal primary and secondary preventions and therapy of patients with acute myelogenous and lymphoblastic leukemias, lymphomas and transplant recipients according tot the criteria of EORTC/MSG, as well.
Methods: During suspect mycotic infection identification of pathogenic fungi specimens taken from blood and/or stool, bronchoalveolar lavage and histological analysis by autopsy, moreover chest/abdominal CT were performed (proven, probable and possible infections). Within period of survey 61 patients (pts) with acute myelogenous leukemia (AML), 32 ones with acute lymphoblastic leukemia (ALL) treated with aggressive cytostatic regimens, in small number other patients of hematological malignancies with systemic fungal infections were also analysed. During prolonged neutropenia patiens were getting antimycotic prevention (in myelogenous leukemia rather posaconazol, in lymphoblastic leukemia mainly fluconazol) in probable or proven mycotic infections such as in Candida infections first line liposomal AmphotercinB, echinocandins, or other second-line drugs (caspofungin), in suspect or manifest Aspergillus infection mostly voriconasol was given (empiric, pre-emptive or targeted treatment strategy).
Results: Systemic Candida infection proven by autopsy in four pts with AML (4/61), in three with ALL(3/32), Mucormyces in one with AML were diagnosed post mortem, probable candidiasis in five others (myeloma, lymphomas, chronic lymphocytic leukemia). Mold infection (Aspergillosis) proven by autopsy in 14/61 pts with AML, in 2 pts with ALL,and in two posttransplanted one, they survived after voriconazol therapy. In invasive Candida sepsis from 10 pts five expired, 5 recovered,out of 25 pts with Aspergillosis 13 ones (chiefly pts with AML) died despite antimycotic treatment, mortality in both fungal infections was equal (50-50%). In remaining pts getting antimycotic prophylaxis during neutropenic episodes invasive fungal infections did not occured.
Summary/Conclusions: Incidence of Candida infections was higher in ALL, whilst of Aspergillosis in AML, however mortality rate was high and same in both groups.but recently due to the early introduction of pre-emptive antifungal therapy fatal outcome could be diminished. Antifungal prophylaxis in prolonged neutropenia reduced frequency and severity of systemic fungal manifestation resulted in better survival data in our leukemic patients.

PB1897

EPIDEMIOLOGY AND CLINICAL CHARACTERISTICS OF BLOODSTREAM INFECTIONS IN HEMATOLOGICAL CANCER PATIENTS

V Chebotkevich[*], E Kiseleva, N Stizhak, E Kaytandzhan, V Burylev, A Garifullin, S Bessmeltsev
Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Bloodstream infections (BSI) are life-threatening illness for immunocompromised patients with hematological malignancies.
Aims: To compare epidemiology, causative pathogens and outcome of hospital-acquired BSI.
Methods: During the period 2007-2014 239 blood samples obtained from patients (pts) with hematological malignancies were studied. All blood cultures were incubated in the continuous monitoring system for 7 days before discard. The real-time PCR was used for indication DNA of human herpesviruses: Herpesvirus 6 (HHV-6), Cytomegalovirus (CMV) and Epstein-Barr virus (EBV). All patients, who showed fever or signs/symptoms of infection underwent at least two sets of blood culture. In this study 65 pts (with 79 episodes of BSI) who fulfilled criteria of systemic inflammatory response syndrome with positive peripheral blood cultures were investigated. All pts received empirical anti-infectious therapy with subsequent correction based on the bacteriological, virological and mycological analyses results.
Results: A total Gram-positive (G+) accounted for 62.7% of BSI, Gram-negative (G-) for 33.3% and mixed (G+ and G-) for 4,0%. Among G+ BSI Coagulase Negative Staphylococci and Staphylococcus aureus were the most frequent pathogens (92.0%), among G- BSI Escherichia coli (42.9%) was predominant. Fungi (Candida spp (5), Rhodotorula spp. (1), Aspergillus fumigatus (3)), including mixed infections, were responsible in 11.4% of BSI. It is shown that the incidences of BSI were significantly more frequent at the background of detectable CMV and EBV specific DNA in blood (38.1% and 51.1% respectively *vs* 4.8 and 24.9% in pts without BSI, $p<0.05$) With regard to the outcome 30 days mortality was 15/79 (19.0%) (7/47 (14.9%) in G+ *vs* 6/25 (24.0%) in G- BSI).
Summary/Conclusions: The empirical anti-infectious therapy showed high efficacy. Further epidemiological surveillance is warranted in order emerging resistant strains and related mortality. Reactivation of CMV and EBV is significantly associated with higher incidence of bacterial BSI.

PB1898

SIMULTANEOUSLY MONITORING OF SERUM AND URINE CYTOMEGALOVIRUS DNA IN PATIENTS UNDERWENT HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y Lu[*],xZhang, S Liao, F Li, Y Chen
The third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Hemorrhagic cystitis (HC) is one of the most common complications after hematopoietic stem cell transplantation (HSCT). Early diagnosis of HC is very important to improve the disease prognosis.
Aims: The aim of this work is to explore the significance of simultaneously monitoring serum and urine cytomegalovirus(CMV) DNA on diagnosing HC after HSCT.
Methods: 57 patients were included in this study and median age was 32 years

(range 10-54). 40 patients were diagnosed of acute leukemias, 6 were lymphoma, 5 were severe aplastic anemia, 4 were chronic myelocytic leukemias, 1 was myelodysplatic syndrome and 1 was multiple myeloma. Among the 57 patients, 30 patients received graft from HLA-identical relative donors, 10 patients received graft from HLA- identical unrelated donors, 10 underwent auto-HSCT and 7 underwent unrelated cord blood transplantation. Serum CMV DNA was tested weekly by real-time PCR from one week before conditioning to 100 days after HSCT. For patients with CMV viremia or lower urinary tract symptoms, urine CMV DNA was also tested.
Results: Within 100 days after transplant, 23/57 (40.35%) patients developed CMV viremia. Among the 23 patientsa, 8 developed CMV uremia. Only 2 (5.88%) patients presented CMV uremia in the 34 patients with normal serum CMV DNA. All of the 10 patients with CMV uremia had complaints of lower urinary tract symptoms and were found abnormal urine routine result and CMV related HC was considered. 10 patients received anti-virus treatment and all of them obtained complete remission.
Summary/Conclusions: The incidence of CMV infection is still high during HSCT. For patients with CMV viremia, urine CMV-DNA surveillance is necessary in order to diagnose HC early and improve the disease prognosis.

PB1899

MORTALITY PREDICTORS IN PATIENTS WITH BLOOD MALIGNANCIES IN INTENSIVE CARE UNIT AFTER CHEMOTHERAPY
B Bakirov*, A Baybulatova
The Clinic of Bashkir state medical university, N.Mostovaya str. 8-38, Ufa, Russian Federation

Background: The leading role in the treatment of malignant blood diseases belongs to high-dose chemotherapy. However, despite the high rates of successful treatment of hemoblastosis, the complications such as suppression of the immune system, septic neutropenia, DIC, multiple organ failure threaten the patient's life. The patients are transferred to the intensive care unit (ICU) for the treatment of such complications. The practical application of new treatment regimens and medications can successfully treat and stabilize patients in critical conditions. Despite this, currently there are groups of patients (especially those who have the extended lung ventilation and multiple organ failure) with poor prognosis of therapy outcome.
Aims: The identification of adverse outcome predictors allows to determine in time the treatment approach, which significantly reduces the risk of developing complications, the cost of treatment, significantly improving survival.
Methods: There was made a retrospective analysis of 138 adult patients in State Financed State Institution "Republican Clinical Hospital named after GG Kuvatova of Ufa" with malignant blood diseases, who received different chemotherapy protocols. However the complications developed, which required treatment of these patients in the intensive care unit. Critical analysis was made using the scales SOFA, LODS, ODIN, SAPS II, APACHE II, ICNARC model. Predisposing causes of hospital mortality for all patients were calculated according to the method of Knaus *et al.* Statistical analysis was made using Statistica package, 9.2. (StataCorp. LP, College Station, TX). The average age of patients - 28.7 years, AML (acute myeloid leukemia) - 88 patients (63.8%), ALL (acute lymphocytic leukemia) - 34 patients (24.6%) and 16 patients (11.6%) with other blood system diseases.
Results: The average time of a patient's staying in the unit before being transferred to the intensive care unit: 7 days. At average, duration of stay in the ICU was 15.5 days. According to the results of staying in ICU the patients were divided into two groups. The first group included patients with fatal case - 47 patients. In this group 6 patients got artificial pulmonary ventilation (12.8%), 11 patients had neutropenia (23.4%), 14 patients had inotropic support (29.8%), 8 patients had a fungal infection (17.0%), 13 patients had a confirmed sepsis (27.7%) and 35 patients had trombocytes less 50x109/ l (74.5%). 35 patients had more than 2 of target affected organs (25.4%). The second group included patients who were transferred from ICU with physical condition improvement - 91 patients, 17 patients have neutropenia (18.7%), 4 patients have fungal infection (4.4%), 26 patients have thrombocytes less 50x109/L (28.6%), and 18 patients have sepsis (19.8%). 31 patients have more than 2 of target affected organs (22.5%). According to the analysis of the first and second groups, the average score on APACHE II - 32 and 12, respectively, on-scale SAPS II - 76 and 34, SOFA - 20 and 5, LODS -4.05 and 6.4, ODIN -1.1 and 1.49.
Summary/Conclusions: The mortality predictors of patients in intensive care unit after chemotherapy are multiple organ failure (loss of 2 or more organ systems), as well as prolonged mechanical ventilation. Many other proposed criteria (eg, age, neutropenia, and data of physiological disturbance rating scales) should not be considered as an absolute outcome predictors of ongoing intensive care.

INVASIVE FUNGAL INFECTIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA: SINGLE CENTER EXPERIENCE IN TURKEY
T Patiroglu*, E Yilmaz, A Ozcan, E Unal, M Karakukcu, MA Ozdemir
Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients with hematological malignancies. The risk of IFI increase in prolonged febrile neutropenia and stem cell transplantation.
Aims: We aim to present the data of patients with acute lymphoblastic leukemia (ALL), who developed IFI between the years of 2010 and 2015 at the pediatric hematology department of Erciyes University's Medical Faculty.
Methods: We assessed 166 patients with ALL, aged between 2 and 18 years (mean age of 5 years) in this retrospective study. There were 73 female and 93 male patients. They were grouped as IFI and oral candidiasis. Serum galactomannan, computerized tomography scanning and cultures of tissue, blood or fluids were used to make a definitive diagnosis of IFI.
Results: Among 166 patients with ALL, 21 (12.6%) developed IFI. Furthermore, 110 patients (66.2%) had oral candidiasis. Ten patients (47.6%) with IFI had relapsed/ refractory ALL and three of them underwent haploidentical stem cell transplantation. Five patients (23.8%) also had high-risk ALL. We found Candida spp in 7 patients (33.3%) with IFI, 10 Aspergillus spp (47.6%), 1 Zygomycetes (4.76%), 1 G. capitatum (4.76%), 1 A. strictum (4.76%) respectively. One patient (4.76%) had candidiasis and aspergillosis. All patients received fluconazole as proflactic antifungal therapy during chemotherapy. Effective antifungal drugs were started after diagnosis of IFI. Nine patients received granulocyte suspensions in addition to antifungal therapy. Eleven patients (52.8%) died because of IFI despite all the therapy efforts.
Summary/Conclusions: Since invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients with ALL, further studies are needed to investigate new diagnostic and therapeutic strategies to identify and prevent IFI.

PB1901

EPIDEMIOLOGY AND PROGNOSIS OF PATIENTS WITH HEMATOLOGIC MALIGNANCIES ADMITTED TO INTENSIVE CARE
R haifa*, A Bechir, B emna, B rania, BY yosra, K abderrahim
Hematology, farhat hached hospital, sousse, Tunisia

Background: The hospitalisation in intensive care unit of a patient with malignant haematology constitutes a difficult problem for haematology and intensive care teams.
Aims: -carry out an assessment of activity of the medical intensive care unit of Farhat HACHED hospital in Sousse. -studying demographic and haematological characteristics of these patients and their specific care in the ICU, mostly in terms of organ failure -study the short-term survival of the population -Finally, this study will attempt to identify prognostic factors for ICU mortality.
Methods: Single retrospective study, in the medical intensive care unit of Farhat Hached hospital Sousse on 20 years (1994-2014).this study included 105 patients with haematological malignancies.
Results: During the study period, 6000 patients were hospitalized in the intensive care unit of which 105 (1.75%) had hematologic malignancies. the median age of the study population was 49 years (15-86 years). the sex ratio was 1.56. the 2 most frequent haematological diseases were non-Hodgkin lymphoma and acute myeloid leukaemia. 33,3% of patients were in the diagnosis stage; 51.4% were in relapse or progression stage and 18.1% were in complete remission. the median scores of APACHE and SAPSII scores were respectively 48 and 32. The reason for admission of patients was acute respiratory failure in nearly half the cases. The cause of acute respiratory failure was pneumonia in 54% and an acute oedema of the lungs in 35% of cases. 45% of patients were intubated and ventilated; the median duration of invasive mechanical ventilation was 2 days. 27 patients had received non-invasive ventilation therapy (25.5%) at admission. forty two (40%) patients needed treatment with catecholamine's. the median length of ICU stay was 4 days and the mortality rate in ICU was therefore 73.3%. Independent predictors factors of mortality in intensive care were severity at admission (score SAPSII) (p=10-3), the use of invasive mechanical ventilation (p=0.015), and the use of catecholamine's (p=0.038).
Summary/Conclusions: The short-term prognosis, according to this study, is exclusively predicted severity at admission, the use of invasive mechanical ventilation, and the use of catecholamines. According to recent data, discussion between haematologist and intensive care, the very early admitted patients and non invasive ventilation seem to improve survival.

PB1902

USEFUL CLINICAL FEATURES AND HEMATOLOGICAL PARAMETER FOR THE DIAGNOSIS OF DENGUE INFECTION IN ACUTE FEBRILE ILLNESS PATIENTS
A Tantiworawit*, J Chaloemwong, T Rattanathammethee, S Hantrakool, C Chai-Adisaksopha, E Rattarittamrong, L Norasetthada
Internal medicine, division of Hematology, Chiang Mai university, Maung Chiang Mai, Thailand

Background: Dengue infected patients are presented with acute febrile illness without localizing signs and symptoms. Clinical presentations may mimic other

infections. The serology (Dengue nonstructural protein 1 (NS1) antigen or Dengue IgM antibody) for definite diagnosis is costly and inaccessible in many hospitals. There was no study to identify these daily changes to distinguish dengue infection from the other causes in acute febrile illness patients.
Aims: The aim of the study was to identify the clinical features and hematologic parameters from complete blood count (CBC) to distinguish dengue infection from the other causes in acute febrile illness patients.
Methods: This was a retrospective study. All patients who presented with acute fever between September 2013 and July 2015 were included. The diagnosis with dengue infection must be confirmed by serology (Dengue NS1 antigen or IgM antibody). The control group included rickettsia, leptospirosis, malaria, and primary bacteremia patients who also presented with acute febrile illness without localizing signs. The sample size by calculation was 300 and divided in to 2 groups. Clinical data and CBC results from diagnosis until recovery were reviewed and compared between two groups.
Results: One hundred fifty-four dengue patients and 146 control patients were included. Headache, nausea, loss of appetite and bleeding diathesis were significantly presented in dengue patients compared to control group 47.4 *vs* 34.2, 33.8 *vs* 15.1, 34.4 *vs* 15.8, 5.8 *vs* 0% respectively (p=0.05). There were several hematologic parameters from CBC which were diverse in dengue patients compared to control group. Moreover, this study also identified the day of fever which these parameters were statistically significant. The dengue group had higher hemoglobin and hematocrit from day 3 to day 10 (highest on day 7; 14.3 *vs* 12.9 g/dl, 43.3 *vs* 39.2%, p <0.001), lower white blood cell (WBC) count from day 1 to day 10 (lowest on day 4; 3,333 *vs* 8,561 per cu.mm., p <0.001) and lower platelet count from day 3 to day 10 (lowest on day 6; 68,910 *vs* 196,137 per cu.mm., p <0.001). For the differential count of WBC, dengue infection showed higher monocytes on day 1-4 (highest on day 2; 11.7 *vs* 5.4%, p <0.001), higher atypical lymphocytes on day 5-9 (highest on day 7; 13 *vs* 0.4%, p <0.001) and higher eosinophils on day 9-10 (highest on day 9; 2.2 *vs* 0.7%, p 0.001). Furthermore, the neutrophil to lymphocyte ratio of dengue group was >1 on the first 5 days then reversed on day 6 to Day 9 (0.69, 0.89, 0.83, and 0.80 respectively) but in non-dengue group, the ratio was always >1.
Summary/Conclusions: We identified important clinical features and useful CBC parameters to differentiate dengue patients from other causes of acute febrile illness patients. This could be done in local hospital to give diagnosis, tailor to further investigation and early treatment.

DIFFERENT WHO SUBTYPES OF CHROMOSOMALLY NORMAL MDS SHARE COMMON AMPLIFIED AREAS ON ACGH/SNPA

P Bernasconi*, I Dambruoso, M Boni, PM Cavigliano, B Rocca, R Zappatore, I Giardini, C Calvello, M Caresana, A Orlando
SC Ematologia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Various studies have reported that aCGH and SNPa can reveal hidden prognostically relevant karyotype alterations in chromosomally normal MDS patients as compared to conventional cytogenetics: aCGH offers a superior resolution of unbalanced chromosomal defects and SNPa identifies areas of copy neutral loss of heterozygosity (LOH).
Aims: Thus, the principal aims of the present study were to test the power of aCGH/SNPa in chromosomally normal MDS patients, to establish whether the extension and the number of cryptic gains/losses and LOH areas correlated with the WHO MDS subtype and to check whether patients with the same WHO subtype shared common abnormal areas.
Methods: aCGH/SNPa were carried out on the DNA of mononuclear cells from fifteen patients examined between January 2013 and December 2015. There were four females and eleven males, whose median age was 66 years (range 24-78). According to WHO classification, 9 patients were diagnose as RA, one as RA with ringed sideroblasts, one as refractory cytopenia with multilineage dysplasia (RCMD), one as RAEB-1 and 3 as RAEB-2. According to R-IPSS, 11 patients were considered low-risk, 2 intermediate-1 risk and 2 intermediate-2 risk. Median follow-up was eight months (range 1-23). At the time of the analyses one patient who progressed to AML and was submitted to two allogeneic HSCT (allo-HSCT) has relapsed and died; the RAEB-1 patient progressed to RAEB-2 and is alive nine months after an allo-HSCT. Molecular karyotyping was performed using the SurePrint G3 Human Cancer CGH+SNP Microarray Kit 4X180 (Agilent Technologies, Santa Clara, CA, USA) according to the manufacturer's enzimatic labeling protocol. The array was scanned through the Agilent scanner G26000DA and analysed with CytoGenomics software (v3.0.6). FISH was carried out to confirm aCGH/SNPa results; commercial probes were obtained from Abbot Molecular Inc. (Chicago, Il, USA) and Kreatech (Amsterdam, NL) and applied according to manufacturer's guidelines.
Results: aCGH/SNPa revealed an abnormal pattern in all MDS patients. In the three RAEB-2 patients aCGH showed the highest number of cryptic chromosomal lesions and many areas of LOH. Unexpectedly, two RAEB-2 patients presented a monosomy 7 together with additional defects including a p53 loss and a 5q deletion. The clinical value of these aCGH/SNPa results was strengthened by the fact that one patient progressed to AML that never achieved complete remission despite two allo-HSCT, whereas the other two patients experienced a quick AML progression. In the other twelve patients aCGH/SNPa detected small chromosomal lesions which size varied between 5kb and 1.8Mb and LOH areas of much longer size (range 1Mb-5.7Mb). Interestingly, by comparing the various chromosomal lesions, it was observed that different patients with different WHO MDS subtypes shared common amplified areas that included the NOTCH1 gene in five patients and the FGFR3 gene in three.
Summary/Conclusions: i) aCGH/SNPa can truly reveal cryptic chromosomal lesions in chromosomally normal MDS patients, a finding that determines a change in patients' R-IPSS score; ii) advanced MDS presented the highest number of lesions which size was longer than that of lesions present in early MDS; iii) patients with different WHO MDS subtypes shared common amplified areas that contained cell cycle genes with a potential role in MDS pathogenesis.

PB1904

THE ASXL1 GENE ALTERATIONS IN BONE MARROW CELLS OF PATIENTS WITH DELETION 20Q AND MYELOID DISORDERS

J Brezinova[1,*], I Sarova[1], H Lhotska[2], S Ransdorfova[1], S Izakova[2], K Svobodova[2], L Podskalska[2], J Markova[1], Z Zemanova[2], J Cermak[1], A Jonasova[3], K Michalova[2]
[1]Institute of Hematology and Blood Transfusion, [2]Center of Oncocytogenetics, [3]1st Medical Department, General University Hospital, Prague, Czech Republic

Background: In recent years, identification of gene mutations together with chromosomal aberrations allows the better characterization and treatment stratification of patients with myeloid disorders. Deletion of 20q - del(20q) - is a recurrent abnormality observed in myelodysplastic syndromes (MDSs), myeloproliferative neoplasms (MPNs), or acute myeloid leukemia (AML). As a sole aberration this finding gives a good prognosis. In our previous study we proved a fusion of the *ASXL1* and *TSHZ2* genes resulting in an isodicentric chromosome of a deleted 20q in a patient with MDS. The *ASXL1* gene maps to chromosome region 20q11.21 and in contrast with del(20q) recurrent mutations in this gene are generally associated with poor prognosis.
Aims: The aim of this study was to determine the frequency of *ASXL1* gene alterations in bone marrow cells of patients with del(20q) and/or with ider(20q) as a sole aberration and to characterize the breakpoints with molecular cytogenetic techniques.

Methods: Fluorescence *in situ* hybridizations (FISH) with locus specific probes for 20q11 and 20q12 regions (Abbott, Kreatech) confirmed the cytogenetically observed deletions of 20q in a cohort of 21 patients (15 male, 6 female, median age 69 years) with myeloid disorders (MDS 14x, MPN 3x, myelofibrosis 2x, thrombocytopenia 2x). In nineteen patients deletion of 20q was a sole aberration, in two patients an isodicentric chromosome of deleted 20q was detected by FISH with a subtelomeric probe 20p/20q (Abbott). Metaphase FISH mapping with a set of four bacterial artificial chromosome (BAC) probes (BlueGnome) localized in 20q11.21 and 20q13.2 was used to determine the breakpoints. Array comparative genomic hybridization (aCGH, CytoChip Cancer 4x180K v2.0, BlueGnome/Illumina) was performed on DNA samples of bone marrow cells of 11 patients with suspected *ASXL1* gene deletion to find out the gene copy number variation.
Results: A weak signal of RP11-358N2 BAC probe (30.93-31.12 Mb from telomere on the short arm, 20q11.21) was observed in six patients (29%), suggesting the proximal breakpoint of the deletion in the *ASXL1* gene (30.95-31.03 Mb, 20q11.21). However, the distal breakpoint in the *TSHZ2* gene (51.80-52.11 Mb; 20q13.2) was found in one patient only. In seven patients (33%) the signal of RP11-358N2 BAC probe was not present on the derivative chromosome confirming the *ASXL1* gene deletion. In the remaining eight patients the proximal breakpoint of the deletion was determined distally to the *ASXL1* gene. In the group of six patients with proximal breakpoint in *ASXL1* gene aCGH determined the breakpoint: in one patient in exon 1, in one patient in exon 4, in three patients behind the exon 4, in one patient in exon 5-8 and in one patient in exon 12. Five patients died in a group of thirteen patients with *ASXL1* gene alteration.
Summary/Conclusions: Deletion 20q is assumed to play a key role in pathogenesis of myeloid malignancies. FISH with BAC probes used is a reliable fast technique that can point out patients with *ASXL1* alterations and therefore potentially worse prognosis than expected. In our cohort, the *ASXL1* gene was altered in thirteen out of twenty-one patients (62%). We suppose that the determination of the *ASXL1* gene alterations in del(20q) cases may have the prognostic impact, but the relations with clinical data should be studied in a larger cohort of patients.
Supported by MHCR project for conceptual development of research organization 00023736, RVO-VFN64165 and GACR P302/12/G157.

ASSOCIATION BETWEEN POLYMORPHISM OF FOLATE AND METHIONINE METABOLISM RELATED GENES AND ABERRANT DNA METHYLATION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME
Z Sidorova[1,*], S Kapustin[1], I Kostroma[2], S Gritsaev[2]
[1]Laboratory of biochemestry, [2]Hematological Clinic, FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", Saint-Petersburg, Russian Federation

Background: Abnormal DNA methylation is often seen in patients with myelodysplastic syndrome (MDS). Polymorphism of folate and methionine metabolism (FMM) related genes can influence the methylation process and, therefore, modify the risk of MDS development.
Aims: The aim of this study was to assess the association between polymorphism of FMM related genes and aberrant methylation of promoter regions of several tumor supressor genes in MDS patients.
Methods: Fifty-one patients with MDS (24 men and 27 women, mean age 62.4 yrs) were genotyped for the MTHFR C677T, MTHFR A1298C, MTR A2756G, MTRR A66G and MTHFD G1958A polymorphisms by PCR-RFLP technique. The differences in allele and genotype frequencies were assessed by Fisher's exact test with computation of odds ratios (OR), their 95% confidence intervals (CI) and p-values. Methylation-specific PCR was used to study the methylation status of promoter regions of *SOX7*, *p15^{INK4b}*, SFRP1, SFRP4 and SFRP5 genes.
Results: Twenty-one patients (9 men and 12 women) had aberrant methylation of 0-2 genes (0-2 MG) and 30 patients (15 men and 15 women) had aberrant methylation of 3-5 genes (3-5 MG). The MTRR 66 GG genotype was more frequently seen in the group 0-2 MG than in the group 3-5 MG (47.6% *vs* 13.3%, respectively, OR=5.9, 95%CI: 1.5-22.9, p=0.011). The MTHFR 1298 CC variant was present in 6 patients from the 3-5 MG and in 1 patient from the group 0-2 MG and (20.8% *vs* 4.8%, respectively, OR=5.0, 95%CI: 0.6-45.1, p=0.2). The presence of the MTHFR 677T allele was increased in male patients from the group 0-2 MG when compared to male patients in the 3-5 MG group (100% *vs* 46.7%, respectively, OR=21.5, 95%CI: 1.2-437, p=0.01), and female patients from the 0-2 MG group (100% *vs* 33.4%, respectively, OR=35.9, 95%CI: 1.7-770, p=0.005). At the same time, positivity for the MTHFR 677T allele was not different between women from 0-2 MG and 3-5 MG groups (33.4% *vs* 46.7%, respectively, OR=1.8, 95%CI: 0.4-8.4, p=0.7). The simultaneous presence of the MTHFR 677T allele and MTRR 66GG genotype was more often detected in the 0-2 MG group than in the 3-5 MG group (33.3% *vs* 10.0%, OR=4.5, 95%CI: 1.0-20.1, p=0.07).
Summary/Conclusions: We conclude that polymorphism of the FMM related genes could have an important role in mechanism of epigenetic disturbances in MDS associated with aberrant methylation of CpG islands of tumor-supressor genes.

PB1906

DEPLETION OF PROINFLAMMATORY MONOCYTES AND INCREASED LEVELS OF CD56 EXPRESSION ON CLASSICAL MONOCYTES IN THE PERIPHERAL FROM PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES
A Aires[1], C Moreira[2], R Cabral[2,*], M Gonçalves[2], AS Jorge[2], V Mesquita[2], ML Queirós[2], A Mota[2], C Gonçalves[2], L Pinho[2], L Xavier[2], J Coutinho[2], I Freitas[3], C Lau[2], MDA Teixeira[2], M Lima[4]
[1]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto (ICBAS/UP), [2]Hematology, [3]Laboratory Hematology, Hospital de Santo António (HSA), Centro Hospitalar do Porto (CHP), [4]Hematology, Hospital de Santo António (HSA), Centro Hospitalar do Porto (CHP); Multidisciplinary Unit for Biomedical Sciences (UMIB/ICBAS/UP), Porto, Portugal

Background: Myelodysplastic syndromes (MDS) are hematologic neoplasms characterized by morphologic dysplasia and peripheral blood (PB) cytopenias. Flow cytometry (FC) studies have revealed that bone marrow monocytes (Mon) from MDS patients have abnormal maturation patterns and aberrant antigen expression. However, the immunophenotypic alterations in PB monocytes (PB-Mon) have been much less explored.
Aims: To evaluate the levels of CD11b, CD11c, CD13, CD14, CD15, CD16, CD64 and HLA-DR expression in PB-Mon from patients with lower risk MDS (LR-MDS), as compared to normal individuals (NI). To quantify the proinflammatory (CD14+loCD16+) and classical (CD14+hiCD16-) PB-Mon subsets, and to search for abnormal CD56 expression on PB-Mon from LR-MDS patients.
Methods: Fourteen patients with LR-MDS (8 males, median age 76 years), and an equal number of NI (blood donors, 8 males, median age 55 years) were studied. Patients who were being treated with myeloid growth factors were excluded, as did patients with active infections and other concomitant neoplasms. The median time from the diagnosis was 7.6 years, ranging from 0.5 to 12.6 years. Seven patients had refractory anemia with ringed sideroblasts (RARS), 4 patients had refractory cytopenias with unilineage dysplasia (RCUD), and 3 patients had refractory cytopenias with multilineage dysplasia (RCMD). Eight patients had low IPSS risk and 6 patients had intermediate 1 IPSS risk. The median PB-Mon count was of 426/mm3 (17 to 1132), in LR-MDS (>1000/mm3 in 1 case) and 482/mm3 (294 to 937), in NI (no cases with >1000/mm3). PB samples were collected into EDTA-K3 containing tubes. Cell immunophenotyping was performed by 8-color FC using fluorochrome conjugated monoclonal antibodies with different specificities (T1: CD15-FITC, CD13-PE, CD34-PerCPCy5.5, CD10-PC7, CD11b-APC, CD14-APC-H7, CD16-V450, CD45-KO; T2: HLA-DR-FITC, CD64-PE, CD34-PerCPCy5.5, CD56-PC7, CD11c-APC, CD14-APC-H7, CD16-V450, CD45-KO), and a whole blood stain-lyse-and-then wash method (FACSLysing, Becton Dickinson–BD). A normal PB sample was run in parallel with each patient. Sample acquisition was performed in a FACSCanto II flow cytometer (BD), calibrated according to the Euroflow SOP. Data analysis was done with Infinicyt (Cytognos). Results are expressed as median, minimum and maximum values of the median fluorescence intensity observed for each marker. P values <0.05 were considered statistically significant (Mann-Whitney U test).
Results: PB-Mon from patients with LR-MDS had FSC and SSC similar to the PB-Mon from NI (p>0.05). In the same way, the overall levels of CD13, CD14, CD15, CD45 and CD64 expression on PB-Mon from patients with LR-MDS did not differ significantly from those observed in NI (p>0.05). In contrast, PB-Mon from LR-MDS patients had significantly higher levels of CD56 (p=0.006), and lower levels of CD11c (p=0.004), CD16 (p=0.005) and HLA-DR (p=0.042), and showed a tendency for a lower CD11b expression (p=0.089), as compared to NI. Additionally, PB-Mon from LR-MDS patients had a marked decrease in the fraction of CD14+loCD16+ subset (3.1% ranging from 0.1 to 8.1% and 11.5% ranging from 4.1 to 27.7%, respectively; p<0.001). Moreover, CD14+hiCD16- PB-Mon from LR-MDS patients had a significantly higher% of CD56+ cells, as compared to NI (14.8% ranging from 0.1 to 98.7% and 7.1% ranging from 0.1 to 14.9%, respectively; p=0.026).
Summary/Conclusions: PB-Mon from patients with LR-MDS have abnormal levels of CD11b, CD11c, CD16 and CD56 expression and a high classical/proinflammatory Mon subset ratio.

PRIMARY RESISTANCE TO AZACYTIDINE IN MDS: PRELIMINARY DATA ON THE POTENTIAL ROLE OF HIF-1A EXPRESSION
V Bakou[1], A Spathis[2], F Kontsioti[1], D Vasilatou[1], C Economopoulou[1], A Bouhla[1], K Gontopoulos[1], C Roubakis[1], G Stavroulaki[1], I Glezou[1], S Papageorgiou[1], E Bazani[1], P Karakitsos[2], E Kontandreopoulou[3], N Viniou[3], A Galanopoulos[4], K Zafeiropoulou[5], A Symeonidis[5], G Dimitriadis[1], V Pappa[1,*]
[1]Second Department of Internal Medicine and Research Institute, [2]Department of Cytopathology, Attikon University General Hospital, [3]Department of Hematology, Laiko General Hospital of Athens, [4]Department of Clinical Hematology, General Hospital of Athens 'G. Gennimatas', Athens, [5]Hematology Unit, General University Hospital of Patras, Patras, Greece

Background: The hypomethylating agent azacytidine is the standard of care

for patients with high-risk myelodysplastic syndromes (MDS) (IPSS intermediate-2 or high) and patients with AML with 20-30% bone marrow blasts. Nevertheless, approximately 40% of patients fail to respond, whereas even responders will inevitably relapse. Currently, the exact mechanisms of azacytidine failure are largely unknown and there is no approach to circumvent azacytidine resistance. Hematopoietic and leukemia stem cells (HSCs and LSCs, respectively) reside in a particularly hypoxic niche and several reports have demonstrated the significance of hypoxia in the regulation of both physiological and malignant hematopoiesis. In addition, Hif-1α regulates the expression of human equilibrative nucleoside transporters (ENTs) and ribonucleotide reductase (RR), both of which are involved in the transport and intracellular metabolism of hypomethylating agents.
Aims: The scope of this study is to investigate the potential role of Hif-1α in azacytidine resistance in MDS patients.
Methods: Bone marrow samples from 26 *de novo* MDS patients and 2 CMML patients (21 males and 7 females) with a median age of 75 (60-89) and 10 healthy donors were collected. MDS patients were classified according to WHO as RCMD (1/28), RAEB I (6/28) and RAEB II (19/28) and received treatment with azacytidine at the dose of 75mg/m^2 x7 days SC. Before treatment, bone marrow mononuclear cells were isolated using the Ficol-paque method, followed by RNA extraction using TRIzol reagent and cDNA preparation using Superscript II reverse transcriptase. Hif-1α expression was estimated by real time PCR TaqMan gene expression assay, using the appropriate primers and probes. Relative gene expression was calculated by comparative threshold cycle (ΔΔCt) method. β-actin was used as a housekeeping gene.
Results: Out of the 28 patients used in our study, 17 responded to azacytidine-treatment (including CR, PR and HI) while 11 failed to respond. We found by real time PCR that the ΔΔCt ratio of Hif-1α/β-Actin expression for control samples was 0,72±0,13, for MDS patients who responded to azacytidine- treatment was 1,564±0,439, while for non-responders 0,839±0,17.
Summary/Conclusions: Our data suggest that increased pretreatment expression of Hif-1α might be associated with better response to azacytidine, indicating a potential role of hypoxia signaling in azacytidine resistance. These encouraging initial results need to be further confirmed in a larger number of patients. The identification of hypoxia related mechanisms in azacytidine resistance will provide novel insights regarding the links of hypoxia signaling with the epigenetic derangement in the pathobiology of MDS and can serve as a platform for the therapeutic targeting of the Hif-1α pathway.

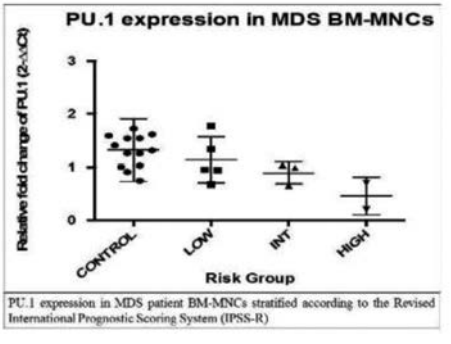
PU.1 EXPRESSION CORRELATES WITH PATIENT DISEASE STATUS IN THE MYELODYSPLASTIC SYNDROMES, A NEW PROGNOSTIC MARKER?
R Simpson[1], A Goddard[1], J Lally[1], C Graham[2], CR Rinaldi[1,*]
[1]School of Life Science, University of Lincoln, Lincoln, [2]School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom

Background: Myelodysplastic syndromes (MDS) are a group of clonal hematopoietic stem cell disorders characterised by ineffective haematopoiesis and dysplasia, manifesting as variable degrees and combinations of peripheral blood cytopenia. The result is often transfusion-dependent anaemia, increased risk of infection, bleeding complications, and an increased potential of progression to acute myelogenous leukaemia (AML). In recent years treatment with 5-azacytidine (AZA) has seen an increase in patient survival for intermediate and high-risk group MDS patients, although the precise mechanism of action is not yet fully understood. Previous studies have demonstrated down regulation of the PU.1 transcription factor in high-risk MDS patients, which can be reversed by administration of AZA. However, it is not currently known if PU.1 levels correlate with MDS disease severity and/or prognosis.
Aims: Assess if PU.1 expression levels in MDS patients correlate with disease prognosis as determined by risk group stratification using the Revised International Prognostic Scoring System (IPSS-R). In addition, we will use commercially available cell lines (SKM-1, MOLM-13, K562, HL60) to explore the potential of AZA in correcting down-regulated PU.1 expression that is seen in high-risk MDS.
Methods: BM specimens were collected from 10 patients diagnosed with MDS who were stratified according to IPSS-R guidelines (5-low, 3-int, 2-high risk) and from 13 haematological normal controls. Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for PU.1 expression relative to the housekeeping gene GAPDH using the $2^{-\Delta\Delta CT}$ method. *In vitro* models of MDS, SKM-1 and MOLM-13 were treated with 1 μM AZA for 24, 48, or 72hr followed by analysis of PU.1 expression analysis by RT-qPCR.
Results: Analysis of patient samples revealed that PU.1 expression is significantly lower in high-risk patients compared controls. In addition, preliminary data suggests that PU.1 expression also correlates with disease severity and could provide insight as a prognostic marker. PU.1 expression was significantly increased upon treatment with 1 μM AZA in commercially available cell lines.
Summary/Conclusions: PU.1 is found to be down regulated in high-risk MDS and it appears that expression correlates well with the IPSS-R classification of prognosis group. As such, PU.1 provides a potential biomarker for MDS diagnosis and progression. In addition, PU.1 expression in MDS *in vitro* models is increased by treatment with AZA providing a potential mechanism for AZA function *in vivo*.



PU.1 expression in MDS patient BM-MNCs stratified according to the Revised International Prognostic Scoring System (IPSS-R)

MLPA® (MULTIPLEX LIGATION-DEPENDENTPROBEAMPLIFICATION) IS A FEASIBLE, COST-EFFECTIVE, TECHNIQUE FOR GENETIC CLASSIFICATION OF MYELODYSPLASTIC SYNDROME
E Anguita Mandly[1], DS Toral Ibarra[1,*], WM Torres Jiménez[1], R Oancea Ionescu[2], A Chaparro[1], A Campaña[1], C Cotarelo[2], R Martínez Martínez[1]
[1]Hemathology and Hemotherapy, [2]Cytogenetics, Hospital Clínico San Carlos, Madrid, Spain

Background: Since their inclusion in IPSS-R in 2012, cytogenetic alterations play a decisive role in the prognosis of patients with myelodysplastic syndrome (MDS). These alterations may be identified through several methods; cytogenetic study, including karyotype and FISH, is the most widely used and proved. However, new molecular techniques for the detection of these alterations have appeared which may be equally effective and far less expensive.
Aims: This study evaluates the MLPA cost-effectiveness in detecting cytogenetic alterations comparing it directly to FISH as gold standard test and karyotype.
Methods: We prospectively collected 131 bone morrow mononuclear cells samples from 118 MDS patients from September 2011 to June 2015. DNA was isolated by salting out and Multiplex Ligation-dependent Probe Amplification (MLPA), MRC Holland, following manufacturer recommendations. We did cytogenetic studies (karyotype and FISH) by conventional techniques. Human material and clinical information was obtained with informed consent and approval of institutional ethics committee.
Results: We obtained MLPA data from 131 bone marrow samples from 118 patients with morphological diagnosis of MDS, examined in our Institution. Karyotype was performed in 104 samples, the technique failed in six and 21 were not sent. FISH was only performed in cases with with abnormal or dubious karyotype; MLPA was performed in 125 samples, in 6 cases we did not receive sample. Alterations were detected in 39.4%, 71.4% and 52% by kariotype, FISH and MLPA, respectively. Specificity of MLPA could be assessed by comparing it with karyotype. Instead we could analyze the sensitivity of MLPA comparing with the most sensitive standard technique, FISH. Forty results were included for sensibility analysis, 31 studies corresponded to new diagnosis and 9 to follow-up samples. Comparing MLPA with karyotype, MLPA showed a high specificity 95% ($p<0.05$) (S: 71% E 95%). We could compare fISH and MLPA in 40 cases (Figure 1), MLPA analysis showed sensitivity of 75% and specificity of 85.7% ($p<0.05$). The results were correlated in 74.2%. We observed a increase of sensitivity (85% and 82% ($p<0.05$) in the subgroup of new diagnosis. Moreover, MLPA detected several alterations which had gone unobserved by FISH, such as: –Y, SMAD4+ y 8pq+. MLPA also proved less expensive in both reagents and staff time.

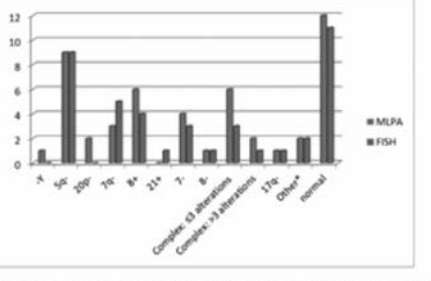

Figure. Detection comparison of the most frequent and clinically relevant abnormalities between MLPA and FISH.

Figure 1.

Summary/Conclusions: Our data indicate that MLPA is a useful tool, as valid as FISH and with a better cost-effectiveness. Although it has sensitivity limitations (in cases of follow-up), it can be used as first-line screening and also as a complementary test for the cytogenetic study. Furthermore, MLPA allows the simultaneous assessment of many loci and the detail study of the most important ones, adding more information to the analysis of copy number variations, which are the most frequent and relevant abnormalities in MDS.

PB1910

CHARACTERIZATION OF THE ERYTHROPOIETIC RESPONSE OF THE DYSPLASTIC MARROW

M Pereira[1,*], M Santos[1], R Tenreiro[1], E Cortesão[1], M Fortuna[2], AB Sarmento-Ribeiro[1], L Ribeiro[1], A Paiva[2]
[1]Clinical Hematology Department, [2]Flow Cytometry Operational Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Myelodysplastic syndromes (MDS) are characterized by peripheral citopenias within the context of a dysplastic, and frequently hypercellular bone marrow. Anemia is one of the most frequent findings, with 20 to 40% of patients responding to exogenous erythropoietin (Epo), with or without the addition of G-CSF, despite normal to elevated levels of serum endogenous Epo, reflecting the complexity of erythropoietic control in these syndromes. Nevertheless, a different likelihood of response to exogenous Epo has been identified between patients with Normal (<=20 IU/L), Mildly Elevated (20-100 IU/L), Moderately Elevated (100-500 IU/L) and Markedly Elevated (>500 IU/L) endogenous Epo levels.
Aims: To further characterize the early erythropoietic response in MDS and its relation to serum Epo levels, and thereby analyze the medullary response to anemia, focusing on the percentage of erythroblasts in maturation stages I to IV, the expression of surface transferrin receptor (TfR, CD71) and the levels of hemoglobin (Hb) and ferritin.
Methods: We prospectively analyzed 57 newly-diagnosed MDS patients, focusing on MDS subtype; bone marrow morphology; and endogenous Epo levels, serum ferritin levels and Hb concentration at diagnosis. Flow cytometry was performed on all patients (CD45, CD34, CD117, HLA-DR, CD71, CD36, CD35, CD44 and CD105) and on 16 normal controls (samples collected during orthopedic surgery).
Results: Patients (63.2% female) had a mean age of 71.2±11.3 years (range: 22-89) and controls (68.8% female) had a mean age of 63±15; 70.2% of patients had RCMD, 8.8% had RCUD, 8.8% had RCRS, 7.0% had RAEB-1, 3.5% had RAEB-2 and 1.8% had 5q- syndrome; 35% of patients had Normal Epo, 53% had Mild elevations, 8% had Moderate and 4% had Marked elevations. There was no association between the percentage of erythroblasts (by flow or morphology) and the MDS subtype (p=NS), degree of dysplasia (p=NS), Epo levels (p=NS), ferritin levels (p=NS) or Hb levels (p=NS), nor between Epo levels and the MDS subtype (p=NS), although, as expected, there was an inverse correlation between Hb and Epo levels (r= -0.35, p=0.0014). There were no differences in the percentages of erythroblasts in stages I to IV between the normal marrow and MDS patients with Normal-to-Mildly elevated Epo levels (p=NS); however, there was a significant threefold increase in Stage I (2.2±1.0% *vs* 0.7±0.1%, p<0.001) and Stage II (4.8±2.9% *vs* 1.8±0.2%, p=0.02) erythroblasts in patients with Epo levels over 100 IU/L compared to patients with Epo<100 IU/L. There was a decrease in the expression of TfR in patients with MDS with Epo<100 IU/L compared to Epo>100 IU/L, for Stages I (p<0.001), II (p=0.019) and III (p<0.001), but not IV (p=NS), with patients with Epo>100 IU/L reaching a similar expression of transferrin receptor as normal marrows, across all stages (p=NS for I to IV).
Summary/Conclusions: There was an expected inverse correlation between Hb and Epo levels that, however, was not reflected in the percentage of erythroblasts in the bone marrow. The distribution of erythroblasts by maturation stage was identical in normal marrows and patients with MDS with normal to mildly elevated (<100 IU/L) Epo, as observed in the clinical model of response to exogenous Epo. The percentage of early stage erythroblasts increased in patients with Epo levels >100 IU/L, likely reflecting an increase in the commitment of CD34+ cells to the erythroid lineage. The expression of surface transferrin receptor decreased in all stages with Epo<100 IU/L compared to the normal marrow, with levels over 100 IU/L being necessary to obtain similar levels of expression of TfR to the normal marrow, possibly explaining the clinical model of increased likelihood of response to exogenous Epo in patients with levels <100 IU/L, and the fact that the expression of surface transferrin receptor is Epo-dependent both through transcriptional and post-transcriptional mechanisms.

USEFULNESS OF MUTATIONAL ANALYSIS FOR DIAGNOSIS OF IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE AND MYELODYSPLASTIC SYNDROME

DS Lee[1,*], B Hwang[2], K Im[1], SN Park[3], D Bang[4], SY kim[1], JA Kim[1]
[1]Dept of Laboratory Medicine, Seoul National University College of Medicine, [2]Department of Chemistry, Yonsei University College of Natural Science, [3]3Cancer Research Institute, Seoul National University College of Medicine, [4]Department of Chemistry, Yonsei University College of Natural Science, Seoul, Korea, Republic Of

Background: Myelodysplastic syndrome (MDS) is a heterogeneous group of myeloid neoplasms characterized by cytopenias that are associated with impaired hematopoietic differentiation, and have a risk of progression to acute myeloid leukemia (AML).
Aims: Aim of this study is to identify the frequency of clonality revealed by next generation targeted sequencing in patients with idiopathic cytopenia of unknown significance.
Methods: A total of 36 patients with idiopathic cytopenia of undetermined significance (ICUS), were enrolled in this study. Targeted sequencing of 87 selected genes was performed.
Results: The putative mutations were analyzed compared to a normal reference control population. 25. /36 (69.4%) ICUS patients harbored at least one mutation.

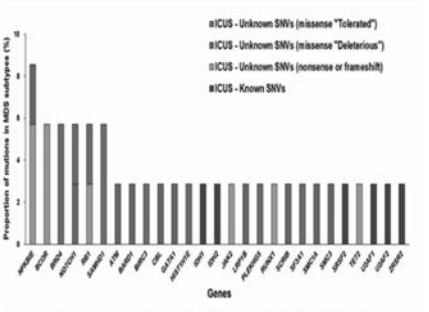

Figure. Frequencies of mutated genes in 36 ICUS patients

Figure 1.

Summary/Conclusions: The molecular profiling of target genes can improve diagnostic accuracy for ICUS and MDS and can assist better subclassification of prognostic groups of MDS patients.

PB1912

THE USAGE OF NEUT-X AND NEUT-Y PARAMETRES IN A ROUTINE HEMATOLOGY LABORATORY AS DIAGNOSTIC MARKERS OF MYELODYSPLASTIC SYNDROMES (MDS)

P Tsiatsiou[*], A Tsocha, F Netsika, K Kouirouxis, D Lazaridou, L Skoura, A Nikolaidou
Clinical Microbiology, AHEPA University Hospital, THESSALONIKI, Greece

Background: NEUT-X and NEUT-Y are structural parameters provided by a hematological analyzer, SYSMEX XE-5000. Notably, NEUT-X evaluates the neutrophil granularity and NEUT-Y the nuclear maturity, which are the average value side scatter diffraction and fluorence, respectively.
Aims: The aim of this study is to investigate the values of NEUT-X and NEUT-Y as diagnostic markers in a routine hematology laboratory in patients with Myelodysplastic Syndromes (MDS)
Methods: The investigation was conducted in AHEPA University hospital. A total of 134 whole-blood samples were collected in tubes with K3-EDTA and were analysed in approximately 3 h of collection, from outpatients and inpatients from different hospital units. 67 of them were from patients with MDS defined from clinical and laboratory findings. Also, 67 randomly selected samples from patients without MDS were included in this study, as a control group. These patients didn't have, perforce, normal values for the complete blood count (CBC). Some of them had anemia due to various causes. Patients with MDS revealed in their majority microscopically hypogranulation or agranulation (N=45) and patients in the other group showed in their blood films neutrophils with normal granulation. The two groups were similar in regard to sex (67 males - 67 females) and age (52 - 90 years avg=78 years). The values of the NEUT-X and NEUT-Y parameters were measured by SYSMEX XE-5000. Mean value comparison independent samples tests was used in order to examine the statistical significance between patients with MDS and control group. The significance level was defined as p <0.05 All statistical analysis was performed using SPSS 22 and Mc Excel 2010.
Results: The values of NEUT-X and NEUT-Y (mean+/-SD) for the control group were (137,49+/-3.17) and (41,02+/-2,70) respectively. The MDS group revealed lower mean values for NEUT-X and NEUT-Y (131,44+/-9,01) and (38,40+/-8,21). The values of NEYT-X and NEYT-Y of MDS were statistically significant lower than the NEYT-X and NEYT-Y values of control (p-values were less than 0,05).
Summary/Conclusions: There is a proportion between low NEUT-X and NEUT-Y values and neutrophil dysplasia. These structural parameters can contribute as auxiliary indicators to the differential diagnosis MDS from other

diseases especially in elderly people with anemia. Also, they can be used as an important part of the daily routine complete blood count.

PB1913

LOW LEVELS OF CD10, CD11B, CD13, AND CD16 EXPRESSION IN THE PERIPHERAL BLOOD NEUTROPHILS FROM PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES

C Moreira[1], A Aires[2], R Cabral[1,*], M Gonçalves[1], AS Jorge[1], V Mesquita[1], L Oliveira[1], M Santos[1], A Mota[1], C Gonçalves[1], L Pinho[1], L Xavier[1], J Coutinho[1], I Freitas[3], C Lau[1], MDA Teixeira[1], M Lima[4]
[1]Hematology, Hospital de Santo António (HSA), Centro Hospitalar do Porto (CHP), [2]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto (ICBAS/UP), [3]Laboratory Hematology, Hospital de Santo António (HSA), Centro Hospitalar do Porto (CHP), [4]Hematology, Hospital de Santo António (HSA), Centro Hospitalar do Porto (CHP); Multidisciplinary Unit for Biomedical Sciences (UMIB/ICBAS/UP), Porto, Portugal

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic neoplasms characterized by morphologic dysplasia, aberrant hematopoiesis and peripheral blood (PB) cytopenias, and an increased probability of transformation to acute leukemia. Diagnosis of MDS relies on well-defined cytological and cytogenetic criteria but is challenging in a significant number of patients. The detection of abnormal maturation patterns and aberrant antigen expression in the bone marrow (BM) cells has been extensively studied by flow cytometry (FC) and is now considered a promising tool to improve MDS diagnostics. However, the value of immunophenotyping the PB cells from patients with MDS has been largely ignored. Having regard to accessibility of PB samples, it would be useful to establish FC criteria for the diagnosis of MDS in the PB.
Aims: To evaluate the levels of CD10, CD11b, CD13, CD15, CD16 and CD45 expression in PB neutrophils (PB-Neut) from patients with lower risk MDS (LR-MDS), as compared to normal individuals (NI).
Methods: Fourteen patients with previously diagnosed LR-MDS (8 males, median age 76 years), and an equal number of NI (blood donors, 8 males, median age 55 years) were studied. Patients who were being treated with myeloid growth factors were excluded, as did patients with active infections and other concomitant neoplasms. The median time from the diagnosis was 7.6 years, ranging from 0.5 to 12.6 years. Seven patients had refractory anemia with ringed sideroblasts (RARS), 4 patients had refractory cytopenias with unilineage dysplasia (RCUD), and 3 patients had refractory cytopenias with multilineage dysplasia (RCMD). Eight patients had low IPSS risk and 6 patients had intermediate 1 IPSS risk. The median PB-Neut count was of 2590/mm3 (365 to 6945), in LR-MDS (<1500/mm3 in 4 cases) and 4181/mm3 (3083 to 8633), in NI (no cases with <1500/mm3). PB samples were collected into EDTA-K3 containing tubes. Cell immunophenotyping was performed by 8-color FC using fluorochrome conjugated monoclonal antibodies with different specificities (CD15-FITC, CD13-PE, CD34-PerCPCy5.5, CD10-PC7, CD11b-APC, CD14-APC-H7, CD16-V450, CD45-KO), and a whole blood stain-lyse-and-then wash method (FACSLysing, Becton Dickinson–BD). A normal PB sample was run in parallel with each patient PB sample. Sample acquisition was performed in a FACSCanto II flow cytometer (BD), calibrated according to the Euroflow SOP. Data analysis was done with Infinicyt (Cytognos). Results are expressed as median, minimum and maximum values of the median fluorescence intensity observed for each marker. P values <0.05 were considered statistically significant (Mann-Whitney U test).
Results: PB-Neut from patients with LR-MDS had significantly lower FSC (p=0.008) and SSC (p<0.001), as compared to those of NI. In addition, the levels of CD10 and CD11b (p<0.001 in both cases), CD16 (p=0.002) and CD13 (p=0.022) expression in PB-Neut from patients with LR-MDS were significantly decreased in patients with LR-MDS, as compared with NI. No significant differences were observed for CD15 and CD45 expression (p>0.05).
Summary/Conclusions: PB-Neut immunophenotyping may provide useful information for the diagnosis of MDS, as a complement to cytomorphology. Each center should establish its own normal reference values, on the basis of monoclonal antibodies (clones, fluorochromes) and experimental conditions used. In addition, should be given special attention to the conditions of calibration and stability of the cytometer.

MULTIDISCIPLINARY EVALUATION AT BASELINE AND DURING TREATMENT IMPROVES THE RATE OF COMPLIANCE AND EFFICACY OF DEFERASIROX IN ELDERLY MYELODYSPLASTIC PATIENTS

L Del Corso[1,*], E Parodi[2], N Bardi[1], A Bellodi[1], G Berisso[3], M Brunofranco[4], T Calzamiglia[5], C Di Grazia[6], R Filiberti[7], R Ghio[1], S Galimberti[8], E Molinari[1], R Russo[2], M Rousseau[8], M Scudelletti[9], R Tassara[10], MT Van Lint[6], E Arboscello[1]
[1]Internal Medicine, Departement of hemato-oncology, [2]Nephrology Unit, irccs-auo san martino-ist, Genova, [3]Internal Medicine, San Bartolomeo Hospital, Sarzana, [4]Transfusional Centre, Imperia Hospital, Imperia, [5]Internal Medicine, Sanremo Hospital, Sanremo, [6]Hematology and Bone Marrow Transplantion, [7]Epidemiology, Biostatistics and Clinical Trials and b Department of Laboratory Medicine, irccs-auo san martino-ist, Genova, [8]Hematology and Bone Marrow Transplantion, Irccs AOU Pisana, Pisa, [9]Internal Medicine, Sestri Levante Hospital, Sestri Levante, [10]Internal Medicine, San Paolo hospital, Savona, Italy

Background: Myelodysplastic syndromes (MDS) are one of the most common hematologic malignancies, the median age at diagnosis is 75 years in most of the series; therefore it can be considered a disease of the elderly patients (pts). Red blood cell transfusion (RBCT) is the main stone of supportive care and a cardinal option to keep patients alive while waiting for effects of specific therapeutic strategies. Transfusion dependency and the consequence iron overload (IOL) has been identified as an independent factor associated with decreased survival. The most important guidelines recommend to start iron chelation therapy (ICT) in all MDS pts with low- and INT1 risk disease with life expectancy >1 year, who have elevated serum ferritin (SF) up to 1000 mcg/L or evidence of iron overload and/or received at least 20 RBCT.
Aims: The aim of the study was to assess the effectiveness of (ICT) in relation of dosing and right management of adverse events (AE) particularly the renal injury. We also evaluate hematological response.
Methods: The safety and the efficacy of DFX were examined in a retrospective multicenter observational study of transfusion MDS patients with International Prognostic Score System (IPSS) low- or INT-1 risk. We included all pts treated with DFX up to 12 months, divided into two groups: the first one (group A) not under multidisciplinary assessment and the second group (group B) with pts under multidisciplinary control by hematologist, Internist, Nephrologist and Immune-hematologist. All pts received DFX at starting dose of 10 mg/kg/day increased up to 30mg/kg/day according to transfusion regimen, SF, IOL, and tolerance.
Results: We evaluated 44 MDS pts (13 female, 31 male); 26 belonging to the first group and 18 to the second group. The mean age was respectively 74.3±9.0 and 77.9±5.5. The ECOG 0-1 was 84.6% and 83.3%, respectively. The median of RBCT prior starting DFX was 20 (range 3-60) in the first group and 13 (4-150) in second group. The median serum ferritin level at baseline was 1125.5 ng/mL (388-2099) and 1317.0 ng/mL (160-3018), respectively. Serum ferritin level decreased at least of 20% as follows: in 29% of pts of first group and in 31% of second group at 3 months, in 17% and 36%, respectively, at 6 months. At 12 months percentages were 22% and 58%, respectively (p=0.06). The drug related AE was evaluated by the Common Terminology Criteria for Adverse Events (CTCAE version 4.02). The SAE occurred in 11% at 3 months, 29% at 6 months and 16% at 12 months. The most Common AE were diarrhea and serum creatinine increase. The rate of drop out after renal AE was respectively 0% and 10%. The positive hematological response in overall pts was observed in 16% at 6 months and 20% at 6 months.
Summary/Conclusions: Un appropriate multidisciplinary assessment of the pre-existing or concomitant comorbidities, the evaluation of the home therapy and of the possible interaction with DFX, a vigilance in co-administration with nephrotoxic drugs may represent strategies to improve the safety and the adherence to ICT and thus the effectiveness. Early starting therapy with DFX at lower doses, maintaining the same dose for the first months avoiding rapid iron depletion, regular clinical and laboratory monitoring appears essential to identify early treatable renal and potentially renal injury avoiding serious adverse effects without necessarily interrupting DFX therapy.

PB1915

PEPTIDE VACCINATION AGAINST CANCER TESTIS ANTIGENS IN COMBINATION WITH AZACITIDINE FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKEMIA: AN ONGOING PHASE I STUDY

S Holmberg[1,*], A Ortved Gang[1], IM Svane[2], I Høgh Dufva[1], S Reker Hadrup[3]
[1]Dept. of Hematology, [2]Center for Cancer Immune Therapy, Herlev Hospital, Herlev, [3]Section for Vaccinology and Immunology, Technical University of Denmark, Copenhagen, Denmark

Background: Myelodysplastic Syndrome (MDS) is a clonal disorder and characterized by increasing bone marrow failure due to accumulation of genetic and epigenetic changes in hematopoietic stem cells. Patients with high-risk

disease have a poor prognosis and a high risk of progression to Acute Myeloid Leukemia (AML). The dysplastic cells harbor chromosomal breakage, point mutations and promoter hyper-methylation of tumor suppressor genes. For most patients, who are not eligible for bone marrow transplantation, hypomethylating agents, such as azacitidine (AZA), are currently the only treatment option. The demand for more effective therapies in this patient group is huge. Though the mechanism of AZA is not fully elucidated re-expression of tumor suppressor genes can serve as a mechanism for growth arrest. In addition, there is accumulating evidence for an up-regulation of cancer testis antigens (CTA), which could lead to increased immune recognition of tumor cells and immune-mediated tumor cell killing. CTA's are known to be immunogenic and are only expressed at immunoprivileged sites and on malignant cells, making them attractive as targets for therapeutic cancer vaccination.

Aims: We have set up a phase I trial where we combine the treatment of hypomethylating agents with a peptide vaccine, to boost an immune response against four selected tumor associated antigens which are known to be regulated by methylation, in patients with high-risk MDS and AML.

Methods: For this vaccine specifically three CTA's were chosen where abundant re-expression has been shown following AZA treatment, including NY-ESO-1, MAGE-A3 and PRAME. WT-1 is additionally included as this protein has proven to be an important antigen in hematological malignancies and is likewise upregulated in response to AZA treatment. The peptides are between 25-29 mer and include a broad selection of HLA class I and II epitopes. Each vaccine contains ~50 µg of each peptide and is mixed as a suspension with Montanide ISA-51. The use of synthetic long peptides has shown superior effect in contrast to minimal peptide sequences. They contain several CD4 and CD8 T- cell epitopes for a broad range of HLA types, and thus allowing inclusion of participants without prior selection based on HLA expression. Inclusion commence after six courses of AZA and following a treatment evaluation. If there is continued indication of AZA treatment, a set of three vaccinations is given together with the following three courses of AZA. An additional vaccination is then given every six months for two years or until there is unfavorable disease progression.

Results: At the time of writing we are planning for the inclusion of our first patient which is expected to take place in late March 2016. Preliminary results from the first vaccinations will be available to show at the conference.

Summary/Conclusions: 15 patients from the department of Hematology at Herlev Hospital, Copenhagen, Denmark, will be included starting March 2016. The primary endpoint is to elucidate whether the combination of AZA and peptide vaccination is a safe and tolerable treatment, but specific immune responses and clinical efficacy will also be evaluated.

Background: Chronic myelomonocytic leukemia (CMML) is a clonal hematologicdisorder sharing features of myelodysplastic syndromes (MDS)and chronic myeloproliferative (MP) disorders.The International ScoringPrognostic System (IPSS) for MDS and its recent revision (IPSS-R)excluded CMML-MP cases. Thus, the CPSS (CMML Prognostic Scoring System) was designed specifically for patients with CMML in 2013. Also, the German Group proposed to divide CMML-1 into: CMML-0 and CMML-1 according to the limit of <5% bone marrow blasts in 2014.However, both proposalshave not been widely reproduced.

Aims: To evaluate different prognostic factors for survival and evolution to AML, to validate the CPSS and to test the new proposed cut-point for BM blast in South American population with CMML *de novo.*

Methods: This is a multicenter analysis of 234 patients with *de novo* CMML from Argentina (152) and Brazil (82) diagnosed between March 1985 to December 2015. Clinical and hematologic data of patients was retrospectively collected and diagnosis of *de novo* CMML wasperformed according to WHO 2008 criteria.

Results: The CMML population showed a median age of 71 (range 15-95) years being 83% older than 60 years old, with a sex ratio M/F: 2.1. With a median overall survival of 31 months, 56 (24%) evolved to AML and 122 (52%) died. Table 1 shows the distribution of patients according to CMML-MD and CMML-MP subtypes; to WHO classification and to German proposal, karyotypes according to CPSS. Also, the different variants for the CPSS were calculated, including transfusion requirement, hemoglobin level limit of 10g/dL and the adjusted by gender. As it is shown, most of the prognostic parameters and all CPSS proposals were useful to predict outcome in our population (Kaplan Meier and log-rank, p<0.05). Since transfusion data was not available for most patients, only models including both hemoglobin cut-points were analyzed in multivariate analysis (Cox Regression, Backward-Stepwise method). The CPSS (hemoglobin threshold of 10 g/dL) sustained its independence both for survival [p<0.001, exp(B) 1.912] and evolution to AML [p<0.001, exp(B) 2.352]. Also LDH level and the German Proposal, not included in the original CPSS system, were analyzed in a multivariate model. This last cut-off for BM blast showed an additive value to predict survival and evolution to LMA [p=0.053 and p=0.003, exp(B) 1.335 and 2.057] when compared with the CPSS-Hb variant [p<0.001 and p=0.052, exp(B) 1.654 and 1.537]. Our results showed that the new proposed classification for CMML dividing them into CMML-0, -1 and -2 may add prognostic value to the CPSS.

Table 1.

Variable		N (%)	OS (50%, months)	*P*	Evolution to AML (months, 25%)	*p*
Age	<60 yrs	38 (17)	28		12	
	≥60 yrs	191 (83)	35		31

SERUM ERYTHROPOIETIN (SEPO) TESTING, LEVELS, AND SUBSEQUENT TREATMENT PATTERNS FOR TRANSFUSION-DEPENDENT PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

A Gerds[1,*], G Binder[2], A Fliss[2], M McGuire[2], S Hawthorne[3], K King-Concialdi[3], M DiBonaventura[3]
[1]Cleveland Clinic, Cleveland, OH, [2]Celgene Corporation, Summit, NJ, [3]Kantar Health, New York, NY, United States

Background: The European Society for Medical Oncology and the National Comprehensive Cancer Network have developed guidelines for the treatment of MDS, describing sEPO level as a useful measure at initial evaluation and for supporting decisions about whether to treat with erythropoietin-stimulating agents (ESAs). A high pre-treatment sEPO level is associated with a lack of response to ESAs, and therefore patients with high sEPO levels should be considered for other therapies.

Aims: To evaluate rates of sEPO testing and sEPO levels, and the subsequent use of ESAs among patients who became transfusion-dependent (TD) at or after MDS diagnosis.

Methods: A retrospective chart review of patients with MDS was conducted in the US. 26 oncologists and hematologists provided data from sequential patient charts. Patient inclusion criteria were: age ≥18 years, diagnosis of International Prognostic Scoring System Low/Intermediate-risk MDS within the last 1–5 years, and TD onset ≥12 months previously. Patients who had high-risk disease prior to TD onset, had a concurrent malignancy, or were in an MDS clinical trial were excluded. Demographics, disease history, treatment history, and lab values were collected and reported descriptively. Results were compared using chi-square tests.

Results: Information was collected on 133 TD MDS patients. 57.9% were male and median age was 67 years (range 37–89), with a median of 25 months since diagnosis (range 12–58). 66 (49.6%) patients had an sEPO test at diagnosis; of these, 39.4% had levels ≥200 mU/mL, including 13.6% ≥500 mU/mL. For patients without sEPO testing, reasons included practice dynamics (28.4%), testing not considered worthwhile (28.4%), and no intent for ESA use (17.9%). Excluding this latter group, 21.8% of untested patients were treated with ESA *vs* 36.4% of those tested (*P*=0.08).

Summary/Conclusions: Of US patients with TD MDS, only half had undergone sEPO testing at diagnosis. Many had sEPO ≥200mU/mL, including a proportion with ≥500 mU/mL; alternative treatments to ESAs should be considered for these patients. Nevertheless, ESA use occurred in nearly a fifth of patients not tested at diagnosis, suggesting that expanded sEPO testing may identify additional patients not appropriate for ESAs.

PB1918

IS A 1ST LINE ERYTHROPOIETIN APPROACH IN MYELODYSPLASTIC PATIENTS WITH DEL 5Q- USEFUL?

P Volpicelli*, M Mancini, A Ferretti, I Carmosino, ML De Luca, F Vozella, S Trasarti, E Sangiorgi, C Lisi[1], M Breccia, R Latagliata, G Alimena
Cellular Biotechnologies and Hematology, Policlinico Umberto I, Rome, Italy

Background: Efficacy and safety of Erythropoietin (EPO) in patients with myelodysplastic syndromes (MDS) have been demonstrated by various studies, with response rates ≥60%. On the other hand, MDS patients with 5q deletion (del5q) and transfusion requirement can achieve high response rates with Lenalidomide, but this drug has shown severe hematologic and extra-hematologic toxicities.
Aims: Thus, it could be advisable to evaluate the efficacy of EPO treatment as 1st therapeutic choice in this subset of patients.
Methods: To address this issue, 65 consecutive patients with MDS and del5q- [M/F 18/47, median age at onset 72.9 yrs, interquartile range (IR) 65.2-81.1] who received EPO treatment at our Institution from 6/2000 to 7/2015 were retrospectively evaluated.
Results: According to WHO 2008, 30 patients (46.2%) were classified as del5q- syndrome, 1 (1.5%) as refractory anemia, 20 (30.8%) as refractory citopenia with multilineage dysplasia, 9 (13.8%) as refractory anemia with excess of blasts-1 and 3 (4.6%) as refractory anemia with excess of blasts-2: according to IPSS risk assessment, 30 patients (46.2%) were low-risk, 23 (35.4%) intermediate-1, 9 (13.8%) intermediate-2 and 3 (4.6%) high-risk. As to karyotype, 42 patients (64.6%) had an isolate del5q-, while in the remaining 23 patients (35.4%) there were other co-existing cytogenetic abnormalities. Median age at EPO start was 73.3 yrs (IR 65.9 - 81.7), with a median interval from diagnosis of 6.2 months (IR 1.5-14.3). Median Hb level at baseline was 9.0 g/dl (IR 8.2-9.5) and 25 patients (38.5%) were transfusion dependent. Median EPO level at baseline was 120 mU/ml (IR 68.8-270). Thirty-one patients (47.7%) received standard dose EPO (30,000 - 40,000 UI weekly) and 34 (52.3%) high-dose (60,000 - 80,000 UI weekly). On the whole, 22/65 patients (33.8%) [5/25 (20%) with transfusional requirement and 17/40 (42.5%) without transfusional requirement at baseline] achieved an erythroid response according to IWG 2006 criteria, after a median EPO treatment period of 1.9 months (IR 1.0-2.7): among these 22 responding patients, 14 (63.6%) lost the response after a median response period of 14.6 months (IR 7.6-29.6), while 8 patients (36.4%) are still in response continuing EPO treatment. In the remaining 43 non responding patients, EPO treatment was discontinued after a median period of 4.0 months (IR 2.0-5.9) due to resistance. The median overall survival of the entire cohort from EPO initiation was 47.5 months (95% CI 33.7-61.2), without differences between responding and non responding patients (p=0.1).
Summary/Conclusions: This retrospective evaluation showed a substantial reduced efficacy of EPO treatment in patients with del5q- compared to other MDS low-risk subgroups, thus supporting the choice of lenalidomide as 1st line approach in such subset of MDS, particularly in patients with del5q- and transfusional requirement.

PB1919

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) SCREENING IN PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) IN CLINICAL PRACTICE: FREQUENCY AND INDICATIONS

S Wong[1,*], B Dalal[2], H Leitch[3]
[1]Medicine, Royal College of Surgeons, Dublin, Ireland, [2]Division of Laboratory Hematology, Vancouver General Hospital, [3]Hematology, St. Paul's Hospital and the University of British Columbia, Vancouver, Canada

Background: MDS is a group of bone marrow disorders characterized by ineffective hematopoiesis leading to peripheral blood cytopenias. Most MDS patients (pts) develop significant anemia and red blood cell (RBC) transfusion dependence (TD). In PNH, mutations in the phosphatidyl inositol glycan (PIGA) gene lead to lack of the glycosylphosphatidyl inositol (GPI) anchor on the cell surface allowing complement-mediated lysis to occur. The PNH phenotype includes direct antiglobulin test (DAT) negative hemolysis and cytopenias including TD anemia, hemoglobinuria (resulting in iron deficiency in some pts), and thrombosis. PNH clones are detected in up to 50% of MDS pts, might confound the reason for RBC TD and PNH+ MDS pts may have better response to immunosuppressive therapy (IST). Eculizumab is the first specific treatment for PNH approved in Canada (2009). It reduces hemolysis and RBC transfusion requirements, prevents thrombosis, improves renal function, quality of life and overall survival (OS).We wanted to determine whether PNH as a contributor to anemia is considered in MDS pts.
Aims: We wanted to determine whether PNH as a contributor to anemia is considered in MDS pts.
Methods: All pts with MDS seen at St. Paul's Hospital were reviewed. Only pts with a bone marrow biopsy confirmed MDS diagnosis (dx) since 2009 were included. Data extracted were baseline clinical and laboratory features, clinical course, treatment and outcome. Indicators of hemolysis including increased levels of lactate dehydrogenase (LDH), bilirubin (BILI) andreticulocyte count (RETICS), decreased haptogobin (HAPTO), and results of DAT testing were recorded. High resolution PNH testing was done by flow cytometry for expression of FLAER, CD24, CD14, and CD59 on neutrophils, monocytes and RBC.
Results: Of 395 MDS pts, 152 were diagnosed in 2009 or later. Median age at MDS dx was 73.5 (range 38-91) years and 66% were male. MDS dx was: RA, n=7; RARS, n=17; RCMD±RS, n=40; RAEB, n=23; hypoplastic, n=4; other, n=61. IPSS scores were: low, n=53; int-1, n=59; int-2, n=32; and high, n=8. MDS treatment was supportive care only in 53 pts. The erythropoietin (EPO) level was ≥500mIU/mL in 4 pts. LDH, BILI and RETICS were measured (and elevated) in 96 (23), 109 (10) and 142 (14) pts, respectively and HAPTO was decreased in 2 of 7 measured. DAT was negative in 9 of 13 pts and serum ferritin level <100ng/mL in 14 of 116. No pts had hemoglobinuria or thrombosis. The hemoglobin was <100G/L in 86 at MDS dx. 79 (52%) pts were RBC TD, with a median transfusion requirement of 4 (1-8) units/8 weeks. PNH testing was positive in 1 of 11 pts tested. Reasons for PNH testing were: anemia, n=3 (with abdominal symptoms and pre-MDS dx, n=1 each); new MDS dx, n=2;hypoplastic MDS, n=2; decreased HAPTO; increased RBC transfusion requirements; and iron deficiency, n=1 each; see Figure and Table. Of patients with an RBC transfusion requirement >4 units/8 weeks none underwent PNH testing. At a median follow up of 21.1 (0.7-69.9) months for all patients, 113 were alive and the median OS was not reached.

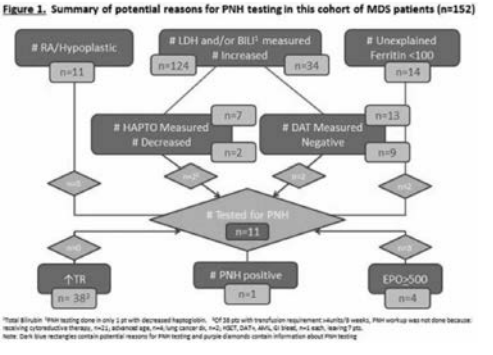

Figure 1.

Summary/Conclusions: PNH was tested for infrequently in MDS patients in clinical practice. Only 11 (7%) of MDS pts since 2009 had PNH testing done despite potential indicators of hemolysis in 27%. Clinical rather than laboratory indicators prompted PNH testing in 6 of 11 pts. Although the clinical significance of PNH clones in MDS is not yet fully defined, complement mediated hemolysis could exacerbate anemia. As there is now an effective treatment available, and PNH+ MDS pts may respond to IST, screening for PNH in MDS should be considered.

PB1920

COMPASIVE USE OF 5-AZACITIDINE IN PATIENTS WITH LOW/INT-1 RISK MYELODYSPLASTIC SYNDROMES

DM Dunia*, G Nuria, D Miguel, A Jaime, G Helga, S Dolores, M Dolores, P Blanca, F Cristina, V Alejandro, H Sonia
Hematologia, Hospital universitario de Guadalajara, Guadalajara, Spain

Background: 5-azacitidine (AZA) significantly prolonged overall survival in higher-risk patients with myelodysplastic syndromes (MDS) in international phase III trial (AZA-001). However, data about efficacy of AZA in lower risk MDS are less consistent and only few studies have addressed this topic.
Aims: Evaluate efficacy and security of AZA in low/int-1 risk MDS patients.
Methods: we evaluate the efficacy and safety in low and intermediate-1 risk MDS patients.
Results: In our institution, a total of 59 MDS patients were treated with AZA between 2006 to September 2015. We evaluated 40 patients diagnosed according to WHO criteria as low/intermediate-1 International Prognostic Scoring System (IPSS) risk MDS. At baseline, median age was 75 year old (range 46-90), male/female ratio 26/14. Median time from diagnosis to Aza treatment was 19,8 months (range 1-185). 80,9% patients were transfusion-dependent, 85,7% had received a prior treatment (rhu-EPO+G-CSF 44,4%, only rhu-EPO 55,5%). Low/Int-1 risk patients received AZA dose of 75mg/sqm/d subcutaneously during days 1-7 in a 28-day cycle. The median number of monthly cycles was 11 (range 1-50), and 58% completed at least 6 treatment cycles, respectively.86% patients had a overall response (53% transfusional independence, 23% PR, 10% CR). OS was 44 months. Overall adverse events documented in these

patients were neutropenia (33%), anaemia (22%) and thrombocytopenia (17%). Non-hematological adverse events: injection site reaction 39%, 50% constipation, 22% diarrhea and 10% fever. Response duration ranged from 4 to 43 months (median 12 months). 25% patients lost response. There were no significant differences in response rate according to age, previous treatment, transfusion requirements, basal EPO and Hb pre-AZA. 8 patients (13%) were transformed to AML after median 23 months (7-36), Time since AZA treatment 14 months (1-24m).
Summary/Conclusions: 1.- 86% patients achieved a overall response. 2.- Time to response is early (3 months), although some patients response later (5 cycles or more). 3.- Efficacy and safety of AZA treatment is a valid alternative in low/int-1 risk MDS patients.

PB1921

A REAPPRAISAL OF THE AZA TREATMENT OUTCOME: ASSESSING THE VALUE OF DISEASE STABILISATION AND EFFECT OF TREATMENT SCHEDULE MODIFICATION
EM Casartelli[1,*], L Borin[1], C Gambacorti Passerini[1], L Antolini[2], P Pioltelli[1], EM Elli[1], M Fedele[1], M Fumagalli[1], M Parma[1]
[1]Ematologia, Ospedale San Gerardo Monza, [2]University of Milano Bicocca, Monza, Italy

Background: 5-Azacytidine is a chemical analog of cytidine used in the treatment of myelodysplastic syndrome. We considered two unanswered questions in the treatment of myelodisplastic syndrome: the significance of stable disease and the impact of dose reduction or treatment delay on the outcome of patients.
Aims: In this study we considered a population of patients affected by myelodysplastic syndrome with IPPS intermediate 2 or high risk treated with 5-Azacytidine. We analysed the prognostic impact of stable disease and treatment schedule modification.
Methods: We retrospectively analysed 57 patients treated with 5-Azacytidine from 2008 to 2015 at San Gerardo Hospital, Hematological Unit (Monza, Italy). We defined the response to treatment according to International Working Group 2006. All patients continued the treatment until loss of response, even if they obtained stable disease. The median number of cycles of drug was 7, from a minimum of 1 to a maximum of 27.
Results: The median time between the start of treatment and the loss of response is 24 months. In the subgroup of patients who did not receive bone marrow transplantation the median time is 20 months. The median survival after loss of response is 4,8 months. We established 3 classes: 20 patients obtained a response to treatment, defined as complete response, partial response, marrow CR, cytogenetical response, hematologic improvement; 15 patients obtained stable disease; 22 patients failed the treatment. The median survival from the diagnosis in responding patients, patients with stable disease, or treatment failure is respectively 27 months, 30 months and 10 months. Similarly the median survival from start of treatment of these 3 classes is respectively 23 months, 27 months and 3,7 months. Fourteen out of 57 patients required, during the treatment, a dose reduction of 5-Azacytidine or treatment delay because of toxicity. Considering the treatment efficacy we deduced that 53% of patients who did not need a treatment schedule modification obtained a response or stable disease (23 of 43). Indeed 85% of patients who required a dose reduction or a treatment delay obtained a response or stable disease (12 of 14). This difference, despite the few cases, appears statistically significant with p value 0,02. In the subgroup of patients who required a dose reduction the median survival from diagnosis is 31 months *versus* 25 months in patients who do not have dose reduction. Similarly the median survival from start of treatment is respectively 23 months and 16,7 months. The median survival of all patients who required a treatment schedule modification, as dose reduction or treatment delay, is 31 months from the diagnosis and 23 months from the start of treatment, *versus* 21 months and 16 months in patients who respected the schedule.
Summary/Conclusions: This study shows that in patients affected by myelodysplastic syndrome with IPSS intermediate 2 or high risk treated with 5-Azacytidine, the stable disease should be considered response to treatment. The only patients who have low median survival are treatment failures, in fact outcome is similar in responders and in patients with stable disease. Furthermore dose reduction or treatment delay does not seem to adversely affect the therapy efficacy and survival, but they reduce the treatment toxicity.

PB1922

DIAGNOSTIC VALUE OF PERIODIC ACID-SCHIFF POSITIVITY OF BONE MARROW ERYTHROBLASTS IN MYELODYSPLASTIC SYNDROMES
R Invernizzi[*], E Travaglino, F Quaglia, R Bastia, I Ambaglio, C Milanesi, E Boveri, MG Della Porta, L Malcovati, M Cazzola
IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: The revised 2008 WHO classification confirmed minimal morphological criteria of myelodysplastic syndrome (MDS) diagnosis: at least 10% of bone marrow (BM) cells of at least one hematopoietic cell lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid-Schiff (PAS) positivity, but the PAS positivity diagnostic power is not yet fully clear. Neither was this morphological aspect taken into account by the "Rete Ematologica Lombarda (REL)" clinical network that proposed a structured and reproducible approach for the precise recognition of BM dysplasia (Della Porta *et al*. Leukemia 2015; 29:66-75).
Aims: Since dysplastic alterations of BM precursors and of peripheral blood cells are still fundamental for diagnostic classifications, the aims of our study were to evaluate the diagnostic value of erythroblast PAS positivity in MDS and to investigate a possible correlation between PAS positivity levels and other morphological and clinical features.
Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 120 MDS patients, 105 patients with non-clonal cytopenia and 49 healthy subjects. By counting 100 nucleated cells for the erythroid lineage and classifying them for their degree of PAS reactivity, we developed a PAS score for MDS identification on the basis of a ROC curve analysis.
Results: PAS positive erythroblasts were observed in 74 (62%) MDS patients, 43 (41%) patients with non-clonal cytopenia and 12 (24%) healthy subjects ($p<0.0001$). In MDS, both positivity rates (mean 3.9%, range 0-31%) and scores (mean 5.8, range 0-49) were significantly higher than those in normal and pathologic controls ($p=0.0001$ and $p<0.0001$, respectively). Positive erythroblasts showed diffuse or granular cytoplasmic reactivity. In MDS, no significant relationship was detected between erythroblast PAS positivity rate or score and dyserythropoiesis grading, multilineage dysplasia or excess blasts, whereas there was a significant inverse correlation between PAS score values and percentages of BM erythroblasts ($p=0.041$) and between PAS score values and percentages of ring sideroblasts ($p=0.012$). Anemic patients showed higher score values than non-anemic subjects ($p=0.016$). PAS positivity was unrelated to karyotype abnormalities. A ROC curve analysis allowed us to identify a PAS score value >0 (AUC=0.642, $p=0.0001$) and a PAS positive erythroblast percentage >0 (AUC=0.629, $p=0.0002$) as optimal cut-off to discriminate MDS patients from controls with sensitivity and specificity ranging from 62% to 66%. Positive and negative predictive values of PAS positivity were 74% and 58%, respectively. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the recognition of BM dysplasia was lower than that of ring sideroblasts and megaloblastosis, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and internuclear bridges.
Summary/Conclusions: The evaluation of BM erythroblast PAS positivity may be useful in the work-up of patients with suspected MDS, especially if there is only unilineage dysplasia without excess blasts or ring sideroblasts. This parameter should be included in the diagnostic morphological panel to be used for a correct application of the WHO classification.

NFE2L2,KEAP1AND NQO1GENE EXPRESSION IN MYELODYSPLASTIC SYNDROME AND MONOCLONAL GAMMOPATHIES-CLINICAL IMPLICATIONS
J Jorge[1,2], AC Gonçalves[1,2,3], E Cortesão[1,2,4], C Geraldes[1,2,4], B Gomes[1], A Pires[1,2], S Fernandes[1], R Alves[1,2,3], L Ribeiro[4], AB Sarmento-Ribeiro[1,2,3,4,*]
[1]Laboratory of Oncobiology and Hematology (LOH),University Clinic of Hematology and Applied Molecular Biology, Faculty of Medicine, [2]Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine, [3]Center for Neuroscience and Cell Biology (CNC.IBILI), University of Coimbra, [4]Clinical Hematology Service, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Oxidative stress (OS) deregulation has been associated with almost all neoplastic diseases, including leukemia, where it contributes to disease development and progression. NRF2 (*Nuclear factor erythroid-2-related factor 2*) is a transcription factor codified by *NFE2L2* gene (*Nuclear factor erythroid2-like 2*) that activate many antioxidant and detoxification genes, like the NQO1 (NAD(P)H:quinone oxidoreductase 1) gene, through its binding to antioxidant response element (ARE) and regulate ARE-mediated gene expression and induction. Moreover, NRF2 is strongly regulated by KEAP1 (*Kelch-like ECH-associated protein 1*). NRF2-KEAP1 system seems to have an extremely important role in OS regulation, contributing for disease development and/or influence therapy response.
Aims: Our aim was to evaluate the expression levels of *NFE2L2*, *KEAP1* and *NQO1* genes in Myelodysplastic Syndrome (MDS) and Monoclonal Gammopathies (MG) patients, and its correlation with clinical and laboratorial data, in order to identify potential biomarkers of diagnosis and/or prognosis.
Methods: We evaluated 135 samples, 53 MDS (26 refractory cytopenia with multilineage dysplasia; 8 chronic myelomonocytic leukemia; 7 refractory cytopenia with unilineage dysplasia; 5 refractory anemia with excess blasts-1; 4 refractory anemia with ringed sideroblasts; 2 refractory anemia with excess blasts-2; 1 5q-), 40 MG (15 monoclonal gammopathies of undetermined significance; 25 multiple myeloma) and 42 controls (Ctl). Samples were collected after informed consent obtained in accordance with the Helsinki Declaration. Real-time PCR was used to evaluate the gene expression level of *NFE2L2*, *KEAP1*,

NQO1 and *GUS* (control gene). Results were considered statistically significant when $p<0,05$.
Results: Our results showed that patient's group presents higher *KEAP1* expression levels comparing to controls (Patients: 0,175; CTL: 0,097; $p=0,04$), while *NFE2L2*did not presented differences between any groups. When we analyzed by pathology, it was observed that *KEAP1* gene expression levels was higher in GM patients compared with controls (GM:0,2059; CTL: 0,09717; $p=0,009$). No association was observed between MDS and CTL; however RCDM patients have lower levels of *NFE2L2* (RCMD: 1,754; CTL: 5,033; $p<0,05$) and higher levels of *KEAP1* (RCMD: 0,185; CTL: 0,097; $p=0,005$). Furthermore, our preliminary results for *NQO1* gene expression showed that MDS patients present lower levels than controls (MDS: 0,1884; CTL: 01969; $p=0,0058$). No associations were found between clinical and laboratory data (erythropoietin and ferritin levels) and the analyzed genes. Through ROC analysis we observed that *NFE2L2* (cut off <2,044; sensitivity: 75%; specificity: 83,3%) and *KEAP1* levels (cut off >0,1627; sensitivity: 54,17%; specificity: 86,67%) might be diagnostic biomarkers for RCMD patients, as well as, *NQO1* levels for MDS patients (cut off >0,00654; sensitivity: 74,29%; specificity: 78,26%). Also, *KEAP1* levels might be biomarkers for MM patients (cut off >0,1645; sensitivity: 52,38%; specificity: 86,67%). Survival analysis showed that RCMD patients with *NFE2L2* expression levels over 2,044 and *KEAP1* levels under 0,1645 present a tendency for lower survival. The same is observed in MM patients with *KEAP1* levels under 0,1645.
Summary/Conclusions: Our results suggest that the expression pattern of *NFE2L2*, *KEAP1* and *NQO1* genes might be associated with the development of hematological malignancies, and may have a great potential as diagnostic and prognostic biomarkers for Myelodysplastic Syndrome and Multiple Myeloma.

PB1924

BIOSIMILAR ERYTHROPOIETIN ALFA FOR THE THERAPY OF ANEMIA IN "LOWER RISK" MYELODYSPLASTIC SYNDROMES. INTERIM RESULTS FROM A PROSPECTIVE OBSERVATIONAL STUDY OF THE "RETE EMATOLOGICA LOMBARDA" (EPOREL)

AM Pelizzari[1,*], E Borlenghi[1], J Mariotti[2], M Riva[3], A Molteni[4], D Lambertenghi[5,6], A Passi[1], V Orlando[1], C Lamorgese[1], E Morra[3]
[1]Hematology, Asst Spedali Civili Brescia, Brescia, [2]Hematology and Transfusion Unit, Asst Treviglio-Caravaggio, Bergamo, [3]Hematology, O.Niguarda Ca' Granda, [4]Hematology, Ospedale Niguarda Ca' Granda, [5]Medicine III, Asst SS Paolo e Carlo, [6]University of Milan, Milan, Italy

Background: Biosimilar EPO use for the treatment of anemia of MDS is based on therapeutic equivalence extrapolated from originator drug employed in other clinical settings; specific prospective evaluation of their activity in MDS are scarce. From November 2014 "lower risk" pts with newly-diagnosed MDS referred to the haematologic centres of REL and symptomatic anaemia participate to an observational multicenter prospective study on efficacy and safety of biosimilar EPO (EPOREL1 protocol).
Aims: 1) *Primary endpoint*: to prospectively assess the response rate of "lower risk" MDS anaemic pts treated with biosimilar EPO alfa; 2) *Secondary endpoint*: to validate the prognostic power of Scandinavian Myelodysplasia Group score (SMG) (Hellstrom-Lindberg E et al, Br J Haematol 1997; 99:344) in this setting.
Methods: The study was in accordance with the ethical standards of the Committee of Human Experimentation of the coordinating center. MDS were diagnosed according to WHO 2008 criteria and classified according to IPSS and IPSS-R. EPO alfa was administered subcutaneously at the starting dose of 40.000 U/w. EPO was doubled in not responsive pts after 2 ms, reduced at mainteinance dose if hgb ≥12 g/dl and stopped in case of refractoriness, relapse, AML evolution, death or major toxicity. Responses were defined by IWG criteria 2006.

Table 1.

"LOWER RISK" MDS 21 pts			
WHO 2008	N (%)	IPSS	N (%)
RCUD-RA +/- RS	9 (43)	LOW	12 (57)
RCMD +/- RS	9 (43)	INTERMEDIATE 1	9(43)
RAEB I	2(9.5)		
MDS/MPN	1(4.7)	IPSS-R	N (%)
		VERY LOW	2 (9.5)
		LOW	8(38)
		INTERMEDIATE	11 (35)

Results: Data were collected from the charts of 26 consecutive pts treated with biosimilar EPO alfa; 21 were evaluable (five too early). Median age was 79 yrs (71-90); F/M 0,3. Their diagnostic and prognostic characteristics are described in Table 1. Twelve (57%) pts were transfusion dependent with median transfusion need of 2 units/ms (1-3). Median haemoglobin was 8,7 (7,5-9,8) and median endogeneous serum EPO, evaluable in 19 pts (90%), was 50 U/L (11-1410). Fifteen pts (71%) responded after a median time of 1 mo (1-10; D.S. 4,1, C.I.95%), 5/12 (42%) transfusion dependent pts reached transfusion independency. EPO dose was incremented to 80.000U/w in 13 pts (62%) after a median of 2 ms (1-8). After a median f.up of 6 ms (2-15), all responsive pts maintained the response and are still on treatment. Ten of 11 (91%) pts with SMG score good and 1/6 (17%) pts with SMG score intermediate achieved an erythroid response (p=0.005). No adverse events were reported up to now. AML evolution was documented in three non responsive cases after a median follow-up of 3 ms (2-6): two pts were off therapy; one case IPSS int1, IPSS-R int, normal karyotype, evolved during treatment. Two pts died: one off-therapy after AML transformation for septic shock, one responsive with previous cardiopathy for congestive hearth failure.
Summary/Conclusions: To our knowledge this is the first prospective study on MDS pts treatment with biosimilar EPO alfa (HX575). The response rate and safety profile of biosimilar EPO alfa is comparable with published data on originator EPO, even in this older MDS cohort. The study confirms the prognostic power of SMG score in this setting. Further evaluation after prolonged follow-up on larger series of pts is warranted.

PB1925

PROGNOSTIC FACTORS IN MYELODYSPLASTIC SYNDROMES AND THEIR INFLUENCE ON OVERALL SURVIVAL

T Sotirova[1,*], O Karanfilski[1], B Georgievski[1], A Stojanovic[1], S Stankovic[1], S Genadieva-Stavric[1], M Pavkovic[1], A Eftimov[2], A Dimovski[2]
[1]Hematology, University Clinic of Hematology, [2]Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, Skopje, Macedonia

Background: Prognostic factors have been evaluated so far in different combinations in order to detect those that would influence overall survival (OS) in patients with MDS and would be incorporated in future revisions of prognostic scoring systems.
Aims: 1.Analysis of chromosomal abnormalities with 'Multiplex ligation-dependent probe amplification' (MLPA), 2.Evaluation of the prognostic significance of age, sex, bone marrow (BM) blast percentage, cytopenias, MCV, transfusion dependency, serum ferritin, LDH, serum albumin, comorbidities and chromosomal abnormalities and 3.Their implication on OS and transformation in acute myeloid leukemia (AML).
Methods: 215 adult patients with 'de novo' and t-MDS were included in the study, diagnosed at the University Clinic of Hematology in Skopje, from January 2011 till April 2015, with follow-up period of 52 months. Patients were divided into two groups: 70 patients as an investigational group (IG) and 145 patients as a control group (CG). Detection of the chromosomal abnormalities was performed with the method MLPA. Informed consent was obtained.
Results: Patients were classified according to the FAB and WHO classifications. Risk stratification was made in accordance with IPSS and R-IPSS. OS and transformation in AML were followed. We evaluated the association among 17 factors and OS in the IG. The univariate analysis revealed only 4 from 17 factors associated with OS: platelet number, blast percentage in the BM, IPSS and R-IPSS. Multivariate analysis revealed that predictors of the event were platelets <100x109/L, IPSS - low risk and R-IPSS-intermediate risk. We also evaluated the association among 14 factors and OS in the CG. The univariate analysis revealed only 5 from 14 factors associated with OS. The OS was associated only with age, platelet number, blast percentage in the BM, WHO subtypes and comorbidities. Multivariate analysis revealed that predictors of the event were age <50 years and platelets <100x109/L. Transformation in AML was detected in 26 (12.1%) patients.
Summary/Conclusions: MLPA proved to be a reliable method for detection of chromosomal abnormalities in MDS. Platelets <100x109/L, IPSS - low risk and R-IPSS-intermediate risk in the IG and age <50 years and platelets <100x109/L in the CG influenced OS in our cohort. Only age was not incorporated in the IPSS and R-IPSS. Probably, it should be taken in consideration in further refinement of the prognostic scoring systems.

PB1926

CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF MYELODYSPLASTIC SYNDROMES (MDS) IN ADULTS ACCORDING TO THE DATA OF MUNICIPAL HEMATOLOGY DEPARTMENTS IN MOSCOW, RUSSIA

S Semochkin[1,2,*], T Tolstykh[2], G Dudina[3], O Fink[4], E Misyurina[2]
[1]Oncology, Hematology and Radiotherapy, Pirogov Russian National Research Medical University, [2]Hematology, City Clinical Hospital #52, [3]Hematology, Moscow Clinical Research Center, [4]Bone marrow transplantation, Russian Children's Clinical Hospital, Moscow, Russian Federation

Background: The myelodysplastic syndromes (MDS) are a distinct group of clonal disorders of hematopoietic stem or progenitor cells characterized by ineffective hematopoiesis, peripheral cytopenias, abnormal dysplastic cell mor-

phology, and potential for clonal evolution to secondary acute myeloid leukemia (AML). AML is eventually diagnosed in up to 30-40% of MDS cases. Population-based registry data in the USA and Europe indicate an incidence of MDS in western countries of around 3-5 cases per 100.000 person-years with male predominance. The epidemiology of MDS has been carefully investigated in western countries while exact data on the epidemiology of MDS in Russia are absent.

Aims: To study the registered incidence of MDS in adults in the city of Moscow, to evaluate methods of diagnosis confirmation and choice of therapy in the system of Health Care.

Methods: The observational study included adult patients with newly diagnosed MDS in 2010, who were residents of Moscow. Evaluation of overall survival (OS) conducted as of September 2014.

Results: A total of 201 (male-110, female-118) adult patients were reported to the system of Moscow Health Care with newly diagnosed MDS in 2010. Median age at diagnosis was 71.5 years (range, 23.9-93.7). The incidence rate of MDS was 2.0 cases per 100.000 persons per year in the general adult population. Incidence accurately increased with age (Fig. 1). The maximum incidence 18.1 cases per 100.000 men was registered in the age over ≥85 years and 9.8 cases per 100.000 women in age 75-79 years. Most frequent morphological types of MDS distributed as follows: refractory anemia (RA)-33.8%, refractory anemia with ring sideroblasts (RARS)-8.4%, refractory cytopenia with multilineage dysplasia (RCMD)-12.0%, refractory anemia with excess blasts-1 (RAEB-1)-12.9% и RAEB-2-21.9%. Cytogenetic variants of MDS assessed only in 36 (17.9%) patients. All patients divided into 5 groups depending on the type of first-line therapy: 69 patients treated with epoetin alfa or beta (rHuEpo) as monotherapy; 20-low-dose ara-C (LDAC); 12-hypomethylating agents (azacitidine, decitabine); 60-symptomatic (red cell transfusion for low-risk MDS) and 38 - palliative care (elderly and weakened high-risk patients). Two patients with 5q- syndrome treated with lenalidomide. With a median follow-up for survivors 46 months 4-year overall survival (OS) for all patients was 34.8±13.4% (median 24.3 months). Early mortality over the first 60 days was 5.0%. rHuEpo used primarily in low-risk patients: 4-year OS 60.7±5.9%. Hypomethylation agents and LDAC applied in advanced MDS morphological variants: 4-year OS 25.0±12.5% (median 21.1 months) and 15.0±8.0% (15.3 months) respectively. Depending on the morphological variant of the 4-year OS was the following: 5q- syndrome-57.1±18.7% (median › 46 months); RA-50.8±6.1% (35.7); RARS-35.3±11.6% (32.8); RAEB-1 - 32.8±9.4% (24.7) and RAEB-2-5.7±3.7% (15.3).

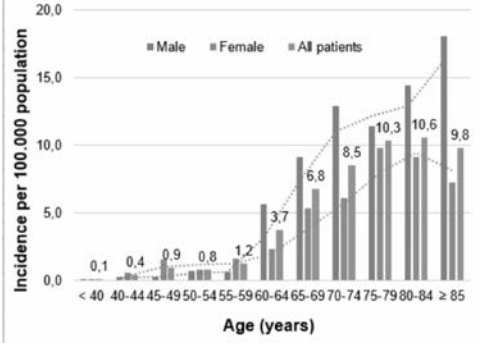

Figure 1.

Summary/Conclusions: The incidence of MDS in Moscow, Russia is 1.5-2 times lower than in Europe and the United States. Current diagnostic standards under the mandatory health insurance does not include genetic and molecular studies. Implementation a cytogenetic study and FISH in MDS typical chromosomal abnormalities in all patients with unexplained cytopenias will improve the diagnostic level.

PB1927

HIPERFERRITINEMIA IN MYELODISPLASTIC SYNDROME (MSD) PATIENTS CORELATION WITH EVOLUTION AND SURVIVAL

M Ionita[1], I Ionita[2], D Calamar[2], C Ionita[3], D Oros[2], O Potre Oncu[2], H Ionita[2,*]
[1]Internal Medicine, [2]Hematology, [3]Surgery, University of Medicine and Farmacy Victor Babes Timisoara, Timisoara, Romania

Background: Most myelodysplastic (MDS) patients have anemia and many of them require red blood cells (RBC) transfusions leading to iron overload. Hematological improvement during iron chelation therapy was first pointed out more than twenty years ago. This phenomenon seems to be more frequent after introduction of Deferasirox. The most simple test assessing iron overload is serum ferritin concentration.

Aims: Assessment of hyperferritinemia incidence in MDS patients at the moment of MDS diagnosis, and correlation between ferritin level and evolution an survival in patients diagnosed with MDS.

Methods: The retrospective data collection from a single center experience (Department of Hematology County Hospital, Timisoara, Romania) between January 2005 and December 2014 included 121 patients (73men and 48 women) with MDS. All the patients had complete blood count and serum ferritin level, and complete follow-up data.

Results: Ferritin level above1000 ng/mL was found in 45 patients (31%) (Group 1) and ferritin level ≤1000ng/mL in 76 patients (69%) (Group 2). Most patients with significant hiperferritinemia, were RBC transfusion dependent (78% of patients). Among patients with ferritin level ≤1000 ng/mL, 48% were RBC transfusion dependent. Serum hemoglobin concentration was lower in Group 1 patients in comparison with Group 2 patients (6.2 g/dL *vs* 9,3 g/dL, p<0,001). The most frequent MDS subtype in Group 1, were patients with refractory anemia (RA) (32%), compared with patients with ferritin ≤1000 ng/mL - 15% (p<0,04). According to IPSS score, there were no differences between studied groups. Median follow up was 15 months. There was an improved overall survival (OS) in RBC transfusion independent patients compared to RBC transfusion dependent patients, but mean OS was not significantly statistically different in studied groups. No correlation was found between ferritin level and time to acute myeloid leukemia (AML) transformation.

Summary/Conclusions: Hiperferritinemia >1000 ng/mL does not influence survival and time to AML transformation in MDS patients. The most frequent MDS subtype in patients with ferritin level >1000 ng/mL was MDS RA. Among patients with ferritin level >1000 ng/mL 76% were RBC dependent.

PB1928

EFFICACY AND SAFETY OF XIAOAIPING TABLETS IN THE TREATMENT OF ELDERLY PATIENTS WITH INTERMEDIATE-RISK/HIGH-RISK MYELODYSPLASTIC SYNDROME: A PILOT TRIAL

X Sun[1,*],xDai[1], Z Xu[1], D li[2],xZhu[1], L li[1]
[1]Hematology, Jiangsu province hospital of TCM, [2]Hematology, Nanjign Benq Hospital, Nanjing, China

Background: Myelodysplastic syndromes (MDS) represent a group of biologically and clinically heterogeneous clonal hematopoietic neoplasms with very poor treatment efficacy and clinical outcomes and patients have been recommended enrolled in clinical trials. Traditional Chinese medicine has also made some progress in the treatment of MDS in resent years. Xiaoaiping tablet, an herbal medicine widely used as an anticancer wonder drug, is the extract of *Marsdenia tenacissima* (*Tong-guan-teng* in Chinese folk medicine),which is officially recorded in the Chinese Pharmacopoeia *Marsdenia tenacissima.* Since 1990s,Xiaoaiping preparations including tablet,injection and syrup which are all extractions of the plants, demonstrate anti-tumor effect on gastric, hepatic carcinoma and leukemia.

Aims: To observe the efficacy and safety of Xiaoaiping tablets in the treatment of elderly patients(over 60 years-old) with intermediate-risk/high-risk myelodysplastic syndrome.

Methods: Twenty-four patients were enrolled in the study. They received Xiaoaiping tablets (2.4-3.0g,oral,3 times daily) combined with supportive care therapy. The primary endpoint of efficacy was measured by the number of days between blood transfusions as well as haematolgical indicies. The changes in ECOG performance status were observed as well as adverse events.

Results: Twenty-one patients of the twenty-four completed therapy. Two patients (9.5%) had a complete remission (CR) 3 patients (14.3%) had a partial response (PR), the overall response rate was 23.8%. Eleven patients had haematological improvement (HI), with the HI rate being 52.4%. Haematologic indices of hemoglobin, total neutrophil count and platelet post Xiaoaiping-treatment were significantly higher than those before treatment (P<0.05).After treatment, the average interval of transfusion of red blood cells (RBC) and platelets was extended (P<0.05). The ECOG scores post-treatment was lower than those before treatment (P<0.05). Toxicities were limited. There were no grade 3 or 4 adverse events.

Summary/Conclusions: Xiaoaiping tablet was an efficacious intervention as measured by hematological indices, the number and frequency transfusions and patients performance status. It was an effective and safe agent in the treatment of elderly patients with intermediate-risk/high-risk MDS, and th**e** tablets might be a promising therapy for this group of patients.

PB1929

MYELOTOXICITY OF PEPTIDE RECEPTOR RADIONUCLIDE THERAPY OF NEUROENDOCRINE TUMORS: A DECADE OF EXPERIENCE

M Kesavan[*], JH Turner
School of Medicine and Pharmacology, University of Western Australia, Perth, Australia

Background: Myelodysplastic syndrome (MDS) and acute leukemia (AL) have been associated with peptide receptor radionuclide therapy (PRRT) in heavily pre-treated patients with a prior history of exposure to alkylating agents. Commenced 15 years ago PRRT is now becoming established as first and second line therapy for gastrointestinal and pancreatic neuroendocrine tumors (GEP-

NETS). Current therapies gain only marginal, albeit statistically significant, increase in progression free survival (PFS) without meaningful objective responses and are accompanied by significant toxicity. With the incidence of GEPNETS rising in the Western world, myelotoxicity is now the most significant potential adverse event following PRRT.
Aims: This review of the literature, and our own decade of experience with lutetium-177-octreotate-capecitabine +/- temozolamide PRRT-chemotherapy of GEPNETS analyses the risk of both short and long-term hematotoxicity.
Methods: All of the literature on myelotoxicity in associated with PRRT of NETS reported in papers published over the past 15 years has been reviewed and compared with our own experience of lutetium-177 PRRT combined with octreotate-capecitabine-temozolomide radiosensitising chemotherapy. Relevant primary research concerning myelotoxicity and PRRT was identified using medical databases. Key articles published from 2000 onwards were obtained primarily from PubMed, Ovid and Cochrane databases. Specific focus was given to articles published in *Cancer Biotherapy and Radiopharmaceuticals, European Journal of Nuclear Medicine and Molecular imaging, Neuroendocrinology, Journal of Clinical Oncology* and *Endocrine Related Cancer*.
Results: Sixteen key articles involving primary research were identified; 12 articles relating to PRRT as monotherapy and 4 articles relating to PRRT in combination with chemotherapy and/or novel agents. A total of 2225 patients were treated (2104 treated with PRRT monotherapy and 121 with PRRT combination) all of whom had been exposed to prior therapies, including somatostatin analogs, alkylating agents, radiotherapy, prior PRRT and surgery with the majority having had exposure to greater than two prior lines of treatment. The average age of patients in these studies ranged from 53 to 64 years with median duration of follow up ranging from 6 to 62 months. Short-term myelotoxicity was observed in 221 patients (10%), occuring in 213 of 2104 patients treated with PRRT monotherapy and 8 of 121 patients treated with PRRT combination. Acute toxicity manifested as modest self-limited grade 3/4 toxicity (CTCAE or WHO) most often affecting platelets then WBC and lastly hemoglobin, and was commonly observed during the first cycle of treatment, with the lowest nadir predictive of time taken for recovery. Toxicity manifesting early was easily managed with dose modification or therapy cessation, and was ameliorated by appropriate patient selection based on age, prior therapies, comorbidities and adequate baseline myeloid function. Long-term toxicity in the form of MDS and AL was a rare stochastic event occurring in only 32 (1.4%) of all the patients treated with PRRT (24 cases of MDS, 6 cases of MDS with subsequent transformation to AL and 2 cases of AL alone). Where bone marrow biopsy was performed the majority of cases of MDS displayed complex cytogenetic abnormalities, consistent with secondary MDS following exposure to chemotherapy with alkylating agents or irradiation. The development of MDS was a risk factor for AL. No significant difference in relative risk of MDS/AL was noted between patients salvaged with PRRT monotherapy or PRRT combination (1.4% and 1.6% respectively). Factors associated with development of significant short and long-term myelotoxicity included age >70 years, impaired renal function, baseline cytopenias, prior number of therapies, prior chemotherapy (especially alkylating agents) and prior radiation therapy. The latter two factors were associated with a significant of development of MDS and AL.
Summary/Conclusions: Early therapy with PRRT-containing regimens improves outcomes, minimizes myelotoxicity and renders the risk of MDS and AL negligible.

PB1930

ASSESSMENT OF B AND T LYMPHOCYTES FUNCTION IN PATIENTS WITHMYELODYSPLASTIC SYNDROMES
M M Moussa*, W Elsalakawy
Internal Medicine, Hematology and BMT unit, Ain Shams University, Cairo, Egypt

Background: An activated immune system has been observed in patients with myelodysplastic syndrome but its exact contribution to disease development and control is not fully clarified. The successful use of immunosuppressive therapies, the potentially curative role of allogeneic stem cell transplant, and the more recent data showing improved peripheral cytopenias and elimination of certain common cytogenetic abnormalities with immunomodulatory agents; highlight the role immune dysregulation in the development of MDS.
Aims: The aim of this study is to assess B and T cell function in patients with MDS and correlate them to the risk status of MDS.
Methods: The study included 30 adult Egyptian patients diagnosed with MDS based on blood picture, bone marrow examination and cytogenetic studies. Patients were classified according to IPSS risk scoring system. Immune system assessment was done by performing: antinuclear antibodies, coombs' test, serum protein electrophoresis and CD4/CD8 ratio in peripheral blood.
Results: We've found an association between inverted CD4/CD8 ratio and higher risk strata, presence of neutropenia and transfusion dependence. Regarding Humoral immune system involvement, positive coombs test was related significantly to younger age, higher bone marrow blasts count. Polyclonal gammopathy-as well-was found to be associated with higher bone marrow blasts count and presence of cytogenetic abnormalities.
Summary/Conclusions: Immune dysregulation-in the form of inverted CD4/CD8 ratio, positive ANA, positive coombs' test and polyclonal gammopathy-is well documented in myelodysplastic syndrome, and it is probably related to younger age, higher IPPS risk, higher bone marrow blasts count and the presence of cytogenetic abnormalities.

PB1931

DOMICILIARY AZACITIDINE: A NEW EXPERIENCE IN OUR CENTER
I Herráez Balanzat[1,*], MA Duran Pastor[1], E Delgado Mejía[2], MDC Ballester Ruiz[1], A Pérez Montaña[1], A Novo García[1], C Martorell Puigserver[3], E Torres del Pliego[2], A Sampol Mayol[1]
[1]Hematology, [2]Internal Medicine, [3]Pharmacy, Hospital Son Espases, Palma de Mallorca, Spain

Background: Azacitidine is an antineoplastic agent used in adults with no indication of bone marrow transplantation and with a diagnosis of intermediated-2 or high risk myelodisplastic syndrome (MDS), high risk chronic myelomonocytic leukemia (CMML) or myeloid acute leukemia (AML).
Aims: Show the experience of using domiciliary Azacitidine and to evaluate its effectiveness in a third level hospital. Evaluate the patient's satisfaction. Estimate the efficiency of the treatment.
Methods: Retrospective observational study including patients who have received treatment with domiciliary Azacitidine from June 2015 to January 2016. The following variables were chosen: gender, age, base pathology, treatment cycles, secondary effects, readmissions, *Exitus* and satisfaction. Domiciliary hospitalization unit (DH), trains patients and their families and monitors vital signs during the treatment. We have revised the official cost for one-day stay in an adult day hospital (ADH) *versus* domiciliary administration according to the July 2014 issue of "BOIB". Telephone surveys were conducted (table 1), asking patients and their families (with a score from 0 to 10), to evaluate the quality of the service.
Results: We have nine patients, six male and three female, between the ages 54-84. The treatment cycles at home vary between 1 and 8. We had no readmissions during the treatment. Three adverse effects appeared: itching, cutaneous reaction and asthenia. Of the nine patients, two died due to disease progression. We compared the costs for one treatment cycle: at the ADH the cost was 3,850 Euros (550 Euros a day for seven days) with the costs of the same treatment at home, which was 2,037 Euros (291 Euros a day for 7 days). If we calculate all the 34 cycles received, the costs would be 130,900 Euros for receiving the drug at the hospital, *versus* 69,258 Euros at home. In 7 months that we conducted the domiciliary program, the hospital saved 61,642 Euros. The telephone survey showed that 100% of the questions were answered with the maximum score.

Table 1.

1. Did you receive a more personalised medical care with the DH in comparison to ADH?
2. Did you perceive the treatment at home as more comfortable and did it have less interferences in your daily routines?
3. Did you notice any different secondary effects at home compared to the ADH?
Questions for the family:
4. Did you have less interferences in your daily routine?
5. Do you think that your family member (patient) has more privacy and feels more comfortable receiving the treatment at home?

Summary/Conclusions: There were no readmissions during the treatment and the secondary effects were minor, so we conclude that home administration is safe. All patients had a high level of satisfaction and experienced an improvement in their quality of life. The treatment with Azacitidine in DH has the same effectiveness and more efficiency than in ADH.

PB1932

A RETROSPECTIVE REVIEW OF AZACITIDINE THERAPY IN AN IRISH UNIVERSITY HOSPITAL SETTING
J M Nolan[1,*], M Leahy[1], D O'Keeffe[1], J Nally[2], H O'Leary[1]
[1]Haematology, [2]Pharmacy, University Hospital Limerick, Limerick, Ireland

Background: Azacitidine (AZA) is a a hypomethylating agent and nucleoside analogue of cytidine. Hypomethylating agents have revolutionised the therapy of intermediate-2 and high-risk myelodysplastic syndrome (MDS), chronic myelomonocytic leukaemia (CMML) and acute myeloid leukaemia (AML) in patients fit for neither intensive therapy nor haematopoietic stem cell transplantation (HSCT).
Aims: This retrospective review aimed to examine the usage of AZA commenced for any indication during a three year period in a university teaching hospital in Ireland. Data collected pertained to patient and disease characteristics, safety, efficacy, overall and progression free survival and the effect of therapy on transfusion dependence.

Methods: A retrospective analysis of patients receiving AZA at University Hospital Limerick in a three year period from October 2012 until October 2015 was conducted. Data was collected from patients' paper and electronic records and the electronic laboratory system. Included patients received at least one cycle of AZA. The World Health Organization Classification was used to classify disease status. Overall (OS) and progression-free survival (PFS) were calculated from the date of commencement of AZA therapy and were calculated using Kaplan-Meier estimates.
Results: Twenty-eight (28) patients commenced AZA between October 2012 and October 2015. 64% of patients were male and the cohort had a median age of 70 years (range 42-80 years). These patients comprised 3 patients with IPSS intermediate risk (level 2) MDS, 5 patients with IPSS high-risk MDS, 6 patients with CMML, 2 patients with MDS/MPN overlap, 1 patient with hypoplastic MDS, 1 patient with refractory anaemia with ring sideroblasts (RARS-MDS) and 10 patients with AML. Of the 10 patients with AML, 4 patients had 20-30% bone marrow myeloblasts confirmed morphologically and by flow cytometry and 6 patients had >30% blasts. 26 patients (93%) were transplant-ineligible due to age or comorbidity and 2 had received previous reduced intensity haemopoietic stem cell transplantation. An additional 2 patients had received prior intensive induction chemotherapy for AML. 55% of patients responded to therapy including achievement of stable disease. 66% of patients required red cell support initially, of whom 37% achieved red cell independence. CTCAE grade 3 or 4 toxicities were mostly haematological, with 66% of patients experiencing same. 52% of patients required at least one admission during AZA therapy, predominantly for severe infections (88%). Median OS and PFS were as follows: AML 9.4 months and 8.7 months, high-risk MDS 3 months and 2.6 months and CMML 8 months and 4.5 months.
Summary/Conclusions: AZA improved OS for patients with AML who were ineligible for intensive therapy or HSCT in our institution. AZA was well tolerated in general and brought about transfusion independence in 37% of transfusion-dependent patients. The most significant toxicities were haematological and relating to severe infection, often requiring hospital admission. Hypomethylating agents continue to provide an excellent therapeutic option for these difficult-to-treat patients.

Myeloma and other monoclonal gammopathies - Biology

CLINICAL CHARACTERISTICS, OUTCOME AND PROGNOSTIC FACTORS OF SURVIVAL OF MULTIPLE MYELOMA PATIENTS ACHIEVING AT LEAST VERY GOOD PARTIAL RESPONSE AFTER FIRST LINE TREATMENT IN THE ERA OF NOVEL AGENTS

E Giannopoulou[1,*], E Terpos[2], P Konstantinidou[1], A Gerofotis[1], E Verrou[1], S Papadaki[1], V Palaska[1], N Karampatzakis[1], D Stamati[1], K Keramidioti[1], A Ananiadis[1], K Kokoviadou[3], D Markala[3], D Mallouri[3], E Kastritis[2], I Batsis[3], I Sakellari[3], E Katodritou[1,3]
[1]Hematology, Theagenion Cancer Center, Thessaloniki, [2]Greek Myeloma Study Group, Athens, [3]Greek Myeloma Study Group, Thessaloniki, Greece

Background: Depth of response defined by conventional methods *i.e.* the achievement of at least very good partial response (≥vgPR) or complete response is correlated with OS in both eligible and non eligible for transplantation Multiple Myeloma (MM) patients. However, there are limited data regarding the prognostic factors for OS in patients who manage to achieve ≥vgPR.
Aims: Our aim was to study the clinical characteristics and outcome of MM patients who achieve ≥vgPR after first line treatment and seek for prognostic factors for OS.
Methods: We reviewed the records of 464 consecutive symptomatic MM patients diagnosed and treated in a single center between 2000-2015 (median age: 68 years, range: 29-90 years; M/F: 247/217; IgG: 261, IgA: 118, light chain: 65, non-secretory: 15, IgD: 4, IgM:1; ISS1: 142, ISS2: 146, ISS3: 176).
Results: Two hundred and sixty-eight patients (58%) achieved ≥vgPR after first line treatment (group A) and 196 (42%) had <vgPR (group B). With regard to clinical characteristics, patients in group A were younger, they had lower β2-microglobulin levels and higher levels of serum calcium (p<0.05 for all parameters). Molecular cytogenetics revealed that high-risk features *i.e.* del17p and/or t(4;14) and/or t(14;16) were present in 33% of patients. Revised International Staging System (R-ISS) was evaluated in 404/464 patients (87%). The number of patients with high risk features or the distribution of R-ISS did not differ between the two groups. Overall, the number of patients treated with novel agents (NA) in first line did not differ between groups; however, in group A, the number of patients who received thalidomide-based regimens was marginally higher (p=0.01). High dose therapy and autologous transplantation (ASCT) was offered in 20% of patients in group A *vs* 7% in group B (p<0.001). The median progression-free survival (PFS) of patients in group A *vs* group B was 26 months (95% CI: 23-29) *vs* 11 (95% CI: 8-13) (p<0.001). The median PFS2 did not differ between groups. After a median follow up of 8 years (95% CI: 80-114), 69/268 patients of group A are alive (26%) *vs* 61/196 patients of group B (31%). The median OS for patients in group A *vs* those in group B was 44 months (95% CI: 39-48) *vs* 27 months (95% CI: 18-36) (p<0.001). With regard to group A, in the univariate analysis, age, creatinine, LDH, ISS, R-ISS, the presence or not of high-risk molecular cytogenetics, the type of 2nd line treatment and ASCT predicted for overall survival (OS). In the multivariate analysis, the presence of high risk molecular cytogenetics was the only independent negative predictor for OS (p=0.01, HzR: 0.57 95% CI: 0.37-0.8). Median OS for patients with high risk cytogenetics *vs* standard risk patients, was 68 months (95% CI: 45-91) *vs* 46 months (95% CI: 40-52) (p=0.01); 5-year OS was 60% in group A *vs* 37% in group B. In addition, the presence of high risk molecular cytogenetics strongly predicted for PFS (HzR: 0.57 95% CI: 0.4-0.8, p=0.01).
Summary/Conclusions: Despite the established prognostic significance of the achievement of ≥ vgPR, OS within this group is not uniform. High-risk molecular cytogenetics independently predict for PFS and OS suggesting that high-risk patients display gene instability, which compromises sustained response and eventually patients' survival. Despite depth of response, close monitoring, including minimal residual disease is warranted in patients with high-risk molecular cytogenetics in order to optimize treatment strategy, after first line therapy.

IDENTIFICATION OF PROGNOSTIC RELEVANT GENETIC ABNORMALITIES IN MULTIPLE MYELOMA USING MICROARRAY-BASED GENOMIC PROFILING IN ROUTINE DIAGNOSTICS

PJ Poddighe[1,*], D Olde Weghuis[2], H Wessels[1], S Wezenberg[2], M van der Mespel[1], S Bhola[1], S Zweegman[3], M Stevens-Kroef[2]
[1]Dept of Clinical Genetics, VU University Medical Center, Amsterdam, [2]Dept of Human Genetics, Radboud University Medical Center, Nijmegen, [3]Dept of Haematology, VU University Medical Center, Amsterdam, Netherlands

Background: Multiple myeloma (MM) is a neoplasm that exhibits a broad

heterogeneity in both biological behavior and clinical presentation. Specific copy number abnormalities (CNAs) such as hyperdiploidy, 1p loss, 1q gain, 13q loss and 17p (*TP53*) loss, and IGH translocations, such as t(4;14)(p16;q32) and t(14;16)(q32;q23), play key roles in the pathogenesis of MM and, in addition, provide important information on its prognosis and treatment response. In routine diagnostics such prognostic relevant chromosomal abnormalities are detected by interphase fluorescence *in situ* hybridization (iFISH) on enriched plasma cells. However, iFISH analysis of multiple loci is laborious and provides only genetic information of the probe targets. Microarray-based whole genome profiling, on the other hand, will provide genome-wide genetic information, allowing the detection of small (cryptic) copy number alterations (CNAs) and copy neutral loss of heterozygosity (CNLOH), that are nor identified by targeted iFISH.
Aims: In this study we wanted to validate the detection of prognostic relevant copy number aberrations in MM by micro-array based genomic profiling.
Methods: We subjected 37 MM samples to iFISH with the diagnostic probe for the detection of prognostic relevant CNA, *i.e.* D5S23/D5S721/CEP9/CEP15 for ploidy assessment, LSI 13 (13q14) for the identification of loss of 13q, LSI TP53 (17p13.1) for the identification of loss of 17p, and CDKN2C/CKS1B for the identification of loss of 1p32 and gain of 1q21. Next, we performed microarray-based genomic profiling using the high density SNP-based CytoScan HD array platform.
Results: All prognostic relevant CNAs as detected by iFISH were also observed by microarray-based whole genome profiling. Micro-array was able to detect small clones with CNA, present in only 15% of the cells, which was lower than the EMN-proposed detection limit of 20% for CNA. In addition, in four cases micro-array revealed a copy neutral loss of heterozygosity (CNLOH), and in four other cases a 1p21 or 1p16 loss, which was outside the 1p32 iFISH target region.
Summary/Conclusions: In routine diagnostics the micro-array approach is a good and fast alternative for iFISH for the detection of prognostic relevant CNAs in multiple myeloma.

PB1936

CYR61/CCN1 STIMULATED THE PROLIFERATION AND DIFFERENTIATION OF OSTEOBLASTS IN MYELOMA BONE DISEASE IN VITRO
R Fu*, H Liu, F Peng, Z Liu, G Wang, L Li, J Song, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Myeloma bone disease (MBD) is a most common complication of multiple myeloma, which can cause high mortality. Cysteine-rich 61 (Cyr61 or CCN1), one secreted protein in bone marrow(BM) microenvironment, has diverse effects on many cellular activities like growth and differentiation. However, the effect of CCN1 on osteoblasts (OBs) in MBD is unclear.
Aims: To explore the effect of CCN1 on osteroblasts in MBD.
Methods: The levels of CCN1 in MBD patients were detected by ELISA and RT-PCR. The OBs from MBD patients were cultured with CCN1 in vitro, and proliferation and differentiation of OBs were observed. The transcription factors, runt-related transcription factor 2 (Runx2), β-Catenin and bone morphogenetic protein-2 (BMP2), were investigated by RT-PCR.
Results: The results showed that CCN1 level elevated in BM supernatant and CYR61 overexpressed in OBs in newly diagnosed MBD patients. After 30ng/L CCN1 stimulation for 24 hours in vitro, the OBs quantity increased to (3.39±1.21) × 10^5/mL, significantly higher than the blank (*P*=0.046). Meanwhile, the amount of mineralized nodules (14.33± 5.72/HPF) was also significantly increased than the blank group (9.11±0.97/HPF) (*P*=0.048). Futhermore, Runx2 and β-Catenin upregulated in OBs after CCN1 stimulation.

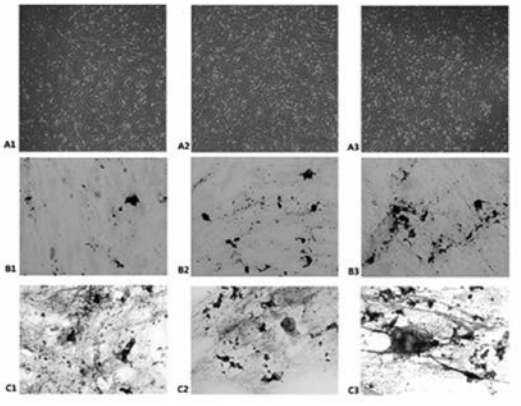

Figure 1.

Summary/Conclusions: In conclusion, CCN1 can stimulate the proliferation and differentiation of OBs via Wnt pathway in MBD.

PB1937

STABLE IN VITRO BORTEZOMIB RESISTANCE OF MYELOMA CELLS IS CHARACTERIZED BY CHROMOSOME 1Q21 COPY NUMBER GAIN
X Papanikolaou[1,*], R Edmonson[2], E Tian[2], S Johnson[2], J Sawyer[2], V McLeod[2], R Tytarenko[2], B Barlogie[3], J Epstein[2], C Heuck[2]
[1]Athens Medical School, Marousi, Athens, Greece, [2]University of Arkansas for Medical Sciences, Myeloma Institute, Little Rock, [3]Mount Sinai Medical School, New York, United States

Background: Bortezomib (Bz), the first agent of a new class of drugs in Multiple Myeloma (MM) -proteasome inhibitors (PI)-, has shown remarkable activity in MM and forms an important part of modern MM treatment. Nevertheless in the clinical setting refractoriness to the agent eventually develops in most cases with detrimental effects in their subsequent survival. Numerous publications have addressed this issue through *in vitro* developed models of acquired Bz resistance (BzR), however the results were quite different in each one and no common factor between them could be identified.
Aims: In order to address these issues a native effort was made for the development of an *in vitro* model of BzR that would resemble the clinical reality in the most accurate way.
Methods: Two MM cell lines were used, one resembling a multisensitive (JJN3) and the other a multiresistant (U266) drug behavior, that were both sensitive to Bz.Instead of a continuous increasing exposure to the agent, an intermittent one was chosen to resemble in a more accurate way the clinical pattern of drug exposure and subsequently the mechanisms of BzR.
Results: As a result of this method a 20 fold increase in the 48h Bortezomib IC50 was noted for both cell lines. The Bz resistant cell lines proved to be stable in the phenotype of resistance. The increase in the IC50 was able to be verified a year after the cell lines were cultured in normal medium. Bz resistant cell lines were cross-resistant with other PI, even with the PI Carfilzomib which belongs to a different drug category. A stable ratio of 3 fold increase in carfilzomib IC50 for every 10 fold increase in Bz IC50 was found in various different levels of BzR. Both basal activity and IC50 for the Bz specific β5-subunit of the proteasome was not statistical different in both Bz resistant and naive cell lines implying that the proteasome was not directly implemented in BzR and no pump flow mechanism was implicated. Interestingly enough the two MM cell lines through the various stages of their acquired BzR followed different phenotypical pathways. JJN3 through their evolution of their BzR and in accordance with various publications developed a more immature phenotype with loss of percentage and intensity of CD138 by flow cytometry, decreasing levels of the plasma cell differentiation factor XBP-1 and decreased immunoglobulin production both in terms of cell line specific immunoglobulin gene probe expression and cytoplasmic immunoglobulin content. On the contrary U266 retained percentage and intensity of CD138, while exhibiting increasing levels of XBP-1 and increased immunoglobulin production both in terms of cell line specific immunoglobulin gene probe expression and cytoplasmic immunoglobulin content. Driven from the stable nature of BzR of the cell lines, we applied metaphase cytogenetics, spectral karyotyping (SKY) and Fluoresence *in situ* Hybridization (FISH) to detect any structural genetic abnormalities. Both metaphase cytogenetics and SKY did not reveal any differences, while FISH was able to detect an increase in chromosome 1q21 copy number evident in both Bz resistant cell lines all in the form of jumping translocations.
Summary/Conclusions: In conclusion this work provides the *in vitro* verification of the linkage of 1q21 amplification and BzR. The fact that 1q21 amplification has been found to correlate with prognosis and a relapsed/refractory phenotype not only in MM but also in a multitude of solid tumors implies that at least part of BzR is linked with universal drug resistance mechanisms in cancer.

PB1938

ROLE OF EPO IN THE ANGIOGENIC ACTIVITY OF BONE MARROW ENDOTHELIAL CELLS OF MGUS AND MULTIPLE MYELOMA PATIENTS
D Ribatti*, B Nico
Department of Basic Sciences, Neurosciences and Sensory Organs, University of Bari Medical School, BARI, Italy

Background: Increasing evidences suggest several biological roles for erythropoietin and its receptor (Epo and EpoR), unrelated to erythropoiesis, including angiogenesis.
Aims: Here, we detected the expression of EpoR in bone marrow-derived endothelial cells from monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM) patients (MGECs and MMECs, respectively) and assessed whether Epo plays a role in MGECs- and MMECs-mediated angiogenesis.
Methods: This study was designed to determine the effects of Epo on ECs from monoclonal gammopathy of undetermined significance [MGUS, (MGECs)] and MMECs in *in vitro* and *in vivo* experimental assays.
Results: We show that EpoR is expressed by both MGECs and MMECs even though at a higher level in the first ones. Both EC types respond to rHuEpo in terms of cell proliferation, whereas other responses, including activation of JAK2/STAT5 and PI3K/Akt pathways, cell migration and capillarogenesis are enhanced by Epo in MGECs, but not in MMECs. In addition, the conditioned

media of both Epo-treated cells induce a strong angiogenic response *in vivo* in the chorioallantoic membrane assay, comparable to that of vascular endothelial growth factor (VEGF).
Summary/Conclusions: Overall, these data highlight the effect of Epo on MGECs- and MMECs-mediated angiogenesis: MGECs are more responsive to Epo treatment than MMECs, probably because over-angiogenic phenotype of MMECs is already activated by their autocrine/paracrine loops occurring in the "angiogenic switch" from MGUS.
Acknowledgments. This work was supported by European Union Seventh Framework Programme (FP7/2007-2013) under grant agreement n.278570 to DR.

POLYMORPHISM OF IL-10 RECEPTOR B AFFECTS THE PROGNOSIS OF MULTIPLE MYELOMA PATIENTS TREATED WITH THALIDOMIDE AND/OR BORTEZOMIB

T Kasamatsu[1,*], T Saitoh[1], R Ino[1], Y Kitamura[1], K Honma[1], N Gotoh[1], H Handa[2], M Matsumoto[3], M Sawamura[3], A Yokohama[4], N Tsukamoto[5], H Murakami[1]
[1]Graduate School of Health Sciences, [2]Department of Medicine and Clinical Science, Gunma University, Maebashi, Gunma, [3]Nishigunma National Hospital, Shibukawa, Gunma, [4]Blood Transfusion Service, [5]Oncology Center, Gunma University Hospital, Maebashi, Gunma, Japan

Background: Interleukin-10 (IL-10) and IL-10 receptor (IL-10R) single nucleotide polymorphisms (SNPs) have been implicated in the pathogenesis of many cancers, including hematologic malignancy. However, no previous studies have examined the possible association between IL-10/IL-10R SNPs and MM, especially prognosis in MM patients.
Aims: We investigated the influence of IL-10 -592C/A, IL-10RA I224V and IL-10RB K47E on the risk to develop multiple myeloma (MM) and clinical features of MM.
Methods: We extracted the genomic DNA from 128 MM patients and 202 healthy controls, and determined IL-10 promoter-592C/A (rs1800872), IL-10RA (rs2228055) and IL-10RB K47E (rs2834167) genotypes by using the PCR-restriction fragment length polymorphism method. Overall survival (OS) was defined as the interval from the date of diagnosis to the date of death or last clinical appointment.
Results: No statistically significant differences were observed in the genotype and allele frequencies of IL-10 -592C/A, IL-10RA I224V and IL-10RB K47E between MM patients and healthy control. IL-10RA II genotype was significantly associated with lower hemoglobin level than IV and VV genotypes (mean±standard deviation, 9.21±2.46 *vs* 10.3±2.33 g/dl, P=0.021). IL-10 -592 AA genotype was significantly associated with better OS than CA and CC genotypes (median OS, 74.5 *vs* 46.3 months, P=0.047). We observed significant differences in survival between patients treated with thalidomide and/or bortezomib and with conventional treatment (median OS, 74.5 *vs* 38.2 months, P=0.021). Therefore, we also examined the effect of IL-10 and IL-10R polymorphisms on clinical variables and OS in patients treated with thalidomide and/or bortezomib. IL-10-592 AA genotype was significantly associated with low albumin level than CA and CC genotypes (mean±standard deviation, 9.21±2.46 *vs* 10.3±2 .33 g/dl, P=0.021). In addition, IL-10RB EE genotype was significantly associated with poor survival than KK and KE genotypes (median OS, 46.3 *vs* 78.8 months, P=0.015) (Figure 1).

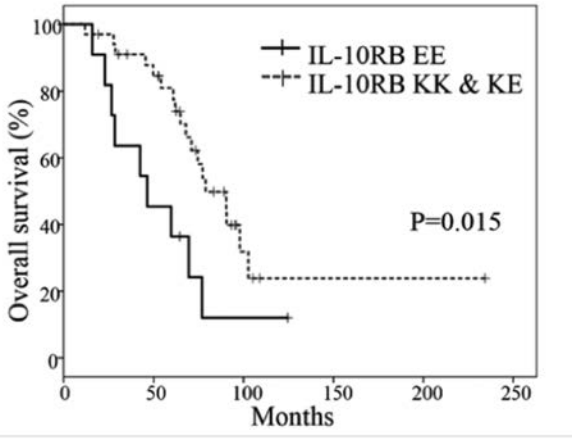

Figure 1. OS of patients treated with thalidomide and/or bortezomib according to the IL-10RB K74E genotype.

Summary/Conclusions: Our findings indicate that IL-10 and IL-10R gene polymorphisms may not contribute to susceptibility to MM, but they may be associated with the severity and prognosis of MM. Especially, IL-10RB K47E polymorphism influence the poor prognosis of patients treated with thalidomide and/or bortezomib.

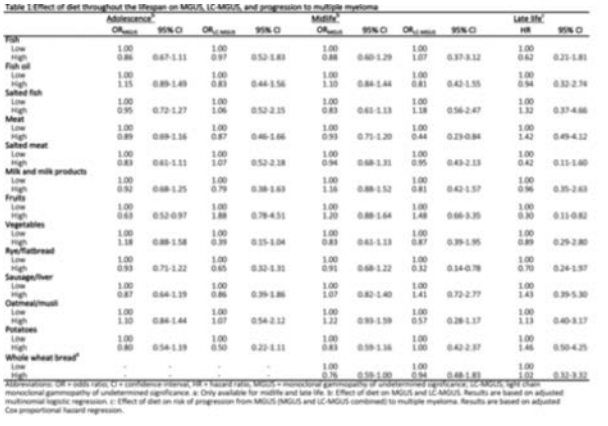
DIETARY HABITS ACROSS THE LIFESPAN AND RISK OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: A POPULATION BASED SCREENING STUDY

M Thordardottir[1,*], E Lindqvist[2], S Lund[1], R Costello[3], J Torfadottir[4], D Burton[3], L Steingrimsdottir[4], N Korde[5], S Mailankody[5], G Eiriksdottir[6], L Launer[7], T Harris[7], O Landgren[5], V Gudnason[6], S Kristinsson[1,2]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [2]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Multiple Myeloma Section, National Cancer Institute, National Institute of Health, Bethesda, United States, [4]Unit for Nutrition Research, University of Iceland, Reykjavik, Iceland, [5]Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, [6]Icelandic Heart Association, Kopavogur, Iceland, [7]National Institute on Aging, National Institute of Health, Bethesda, United States

Background: All multiple myeloma (MM) cases are preceded by the premalignant state, monoclonal gammopathy of undetermined significance (MGUS). The etiology of MGUS and MM is to a large extent unknown. However, researchers have found an elevated risk of MM to be associated with low occupation-based socioeconomic status, income, education, and high body mass index (BMI), indicating that lifestyle related factors, such as diet, may be important risk factors. Few studies on the effect of diet on MM have been conducted and the results have been inconclusive. No studies have been conducted on the effect of diet on MGUS.
Aims: The aim of this study was to explore the effect of high *vs* low intake of fish, salted/smoked fish, fish oil, meat, salted/smoked meat, milk and milk products, fruits, vegetables, potatoes, rye bread, whole wheat bread, and oatmeal/muesli on MGUS and progression to MM.
Methods: This study was based on participants from the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-RS; N=5,764; mean age=77 years [range=66-98]; 58% females), which is a continuation of the population-based Reykjavik Study (N=30,795). AGES-RS was initiated in 2002 and ended in 2006. Participants in the AGES-RS provided retrospective information on dietary habits in adolescence (14-19 years), midlife (40-50 years), as well as at study baseline using a short food frequency questionnaire. Serum protein electrophoresis and free light chain analyses was performed on all subjects to identify MGUS and light chain-MGUS (LC-MGUS). They were followed prospectively until 2014 and information on MM diagnosis was collected through the Icelandic Cancer Registry. Logistic regression and Cox regression models were used to analyze risk of MGUS and MM, adjustments were made for age and sex.
Results: A total of 300 MGUS (5.2%) and 52 LC-MGUS (0.9%) cases were identified. We found that high consumption of fruits in adolescence and high consumption of whole wheat bread in midlife were inversely associated with MGUS (odds ratio (OR)=0.63, 95% confidence interval (CI) 0.52-0.97 and OR=0.76, 95% CI 0.59-1.00, respectively), and that high consumption of meat and rye bread in midlife were inversely associated with LC-MGUS (OR=0.44, 95% CI 0.23-0.84 and OR=0.32, 95% CI 0.14-0.78, respectively). Other food items did not have an effect on MGUS or LC-MGUS risk (Table 1). Additionally, in an analysis were MGUS and LC-MGUS were combined (cMGUS) we found that high consumption of rye bread and potatoes in both adolescence and midlife were inversely associated with cMGUS (OR=0.70, 95% CI 0.55-0.95 and OR=0.63, 95% CI 0.45-0.96, respectively) when compared to individuals with low intake at both time points. A total of 18 individuals were diagnosed with MM during a mean follow-up of 8.2 years. We found an inverse association between high fruit intake in late life and progression to MM (hazard ratio (HR)=0.30, 95% CI 0.11-0.82). Other food items did not have an effect on progression (Table 1).

Table 1.



Summary/Conclusions: Our findings suggest that certain dietary factors during adolescence and/or midlife might reduce risk of MGUS and LC-MGUS.

Results regarding LC-MGUS should be interpreted with caution due to low statistical power. The findings also suggest that high late life intake of fruits might reduce the risk of progression to MM. The exact biological mechanism for these associations is not clear and more studies are needed to clarify the underlying mechanism for this finding.

PB1941

HEAVY-LIGHT CHAIN IMMUNOASSAYS FOR DIAGNOSIS AND MONITORING IGA MULTIPLE MYELOMA: SAVING PITFALLS ON PROTEIN QUANTIFICATION

M Andrade-Campos[1,*], N Espinosa-Lara[2], E Colorado-Ledesma[2], J Grasa[2], P Giraldo[3]
[1]Translational Research Unit, IIS-Aragon. CIBERER., [2]Hematology and Hemotherapy, Miguel Servet University Hospital, [3]Translational Research Unit, IIS-Aragon. CIBERER. FEHHA, Zaragoza, Spain

Background: Diagnosis and follow-up of Multiple Myeloma (MM) include the assessment of the involved protein named monoclonal component (MC) by serum protein electrophoresis (SPEP) with M-spike densitometry as the gold standard. MC quantification is usually not problematic for patients with IgG MM due to protein characteristics (molar weight, protein charge and migration); however, for IgA MM there are often some difficulties to impossibility their quantification. About 25% of monoclonal gammopathies are IgA subtype; due to the co-migration in alpha or beta area and the presence of IgA dimers, the diagnosis and follow-up is difficult based in the quantification of M-spike using conventional SPEP. The separate determination of intact immunoproteins of monoclonal and polyclonal isotype (heavy/light IgAk/IgAL, HLC) allows quantifying the monoclonal IgA and also assesses immunoparesis status.
Aims: To evaluate the correlation between M-spike concentration by SPE and the quantification by HLC and ratio, and their usefulness as biomarker for early biological relapse detection in IgA MM.
Methods: Every patient with an IgA monoclonal gammopathy, diagnosed of secretory MM according to the criteria for MM diagnosis by the IMWG, and treated in our hospital, was taken in account. The diagnosis and follow-up of monoclonal gammopathies were performed in our Hematology-immunoproteins lab. A chart review was performed collecting: demographic data, clinical stage at diagnosis and protein data: (SPEP, UPE of 24h), quantification of total immunoproteins, inmunofixation (IFX), quantification of FLC, HLC and their ratios (Freelite™, Hevylite™, The Binding Site, Birmingham, UK). Time of study: May 2008-Agosto 2015.
Results: Forty-seven patients were included. Females/males: 23/24; mean age: 67.43 (32-88 years); IgAk: 26 (55.3%); IgAL: 21 (44.7%); 34% of patients had free light chains detectable in urine. A total of 182 protein assessments were registered, 51 present a value of M-spike below 10 g/L, in 62 (34.0%) there were no M-spike by SPEP, but in 39 an abnormal HLCr demonstrated monoclonality confirmed by IFX in 30 samples. The isotype analysis at diagnosis for IgAk patients reveals: mean M-spike concentration 9.61 g/L (0-37.2), HLC-IgAk 24.71 g/L (0.02-63.94), HLC-IgAk minus HLC-IgAL: 24.52 g/L (0-63.94); for IgAL patients shows: mean M-spike concentration 11.4 g/L (0-25.6), HLC-IgAL concentration 17.61 g/L (0.6-41.1), and HLC-IgAL minus HLC-IgAk 16.95 g/L (0.06-41.08). Immunoparesis at diagnosis (abnormal HLC ratio) was present in all patients. In 144 samples with positive MC by SPEP, the mean concentration of M-spike for IgAk samples was 18.43 g/L (1-64.22), HLC-IgAk 22.54 g/L (0.2-109.20), and HLC-IgAk minus HLC-IgAL: 22.51 g/L (0-109.19); and for IgAL samples: 16.2 g/L (1-49.50), HLC-IgAL 20.87 g/L (0.56-55.65), and HLC-IgAL minus HLC-IgAk 20.35 g/L (0.10-55.27). The correlation between both techniques for patients with measurable M-spike for SPEP was excellent, remarking the sensitivity of the HLC (p=0.003 for IgA-k and p<0.001 for IgA-L); the HLCr is a good biomarker for monitoring response.
Summary/Conclusions: In this study, 34.0% of SPEP studies in IgA MM do not identify MC, nevertheless more than 50% of them showed monoclonality quantify by HLC-IgA, improving the quantification in cases with low concentrations. The incorporation of this tool for diagnosis and monitoring in IgA MM patients improve the accuracy of follow up. An updated analysis including the value of HLCr in relapse detection will be included in case of acceptance.

PB1942

IL-1R AND IL-1RA IN THE DEVELOPMENT OF MULTIPLE MYELOMA

A Pavlova[1,*], I Pavlova[1], L Bubnova[1], S Bessmeltsev[2]
[1]Immunohaematology laboratory, [2]Deputy Director for Research, Russian Institute of Haematology and Transfusion, Saint-Petersburg, Russian Federation

Background: Various cytokines are involved in the pathogenesis of Multiple myeloma (MM). They play a significant role in the development of tumor clone. It is known that single nucleotide polymorphisms (SNP) in the gene regulatory regions can influence on cytokines production which can effect on the development of the disease.
Aims: The aim of this study was to identify SNP genes of IL-1R (pst11970C/T) and IL-1RA (mspa111100T/C) associated with the development of MM among the residents of the North-West region of Russia as well as determining the severity of bone tissue damage.
Methods: We analyzed 50 MM patients which were divided into two groups depending on the detected changes in the bones (median age: 69.7±8.6): 1st group (22 patients) - with severe osteolytic bone lesions (III stage of the *Durie-Salmon staging* system); 2nd group (28 patients)-with manifestations of osteoporosis and isolated pockets of lysis (II stage of of the *Durie-Salmon staging* system). The diagnosis of symptomatic MM was verified based on the criteria of the International Working Group on myeloma. The most frequent type of myeloma that was observed in patients was G type (80%). The frequencies of myeloma A, as well as disease of light chains were about 20%. The control group consisted of 50 healthy unrelated Caucasoid blood donors (median age: 51.2±6.9). All analyzed people were from St.-Petersburg, Russia. Genomic DNA was extracted from the peripheral blood and gene genotyping was performed by use of PCR-SSP (Cytokine genotyping Kit, Invitrogen). Allele frequencies and expected Hardy Weinberg equilibrium (HWE) for each SNP were determined. P values less than 0.05 were considered statistically significant.
Results: Based on the SNP analyses we found that in general cohort of patients with MM some genotype frequencies differed from the control group. For instance, genotypes of IL-1RTT and IL-1RATT were varied in control group and group of patients 0.33 *vs* 0.16 and 0.28 *vs* 0.46 respectively (p≥0.05). However, genotype IL-1RTT in MM patients with severe bone lesions (1st gr.) occurs more often than in group of patients with symptoms of osteoporosis (2nd gr.): 0.33 *vs* 0.06 respectively (p≤0.05). Although, genotype IL-1RCT in the 2nd gr. was registered frequently compare to 1st gr. and control group- 0.50 *vs* 0.33 and 0.33 respectively (p≥0.05). However, IL-1RATT genotype frequency was less common in healthy people (0.28) compare to patients with MM (0.45 in 1st gr., 0.47 in 2nd gr.; p≤0.05). Finally, IL-1RACT was higher in control group (0.50) compare to patients with severe osteolytic bone lesions (0.33) and patients with symptoms of osteoporosis (0.40), p≥0.05.
Summary/Conclusions: Thus, our results allow to describe some genotypes as markers associated with the development of MM (IL-1RATT). In addition, it can be assumed that the genotype IL-1RTT associated with the development of severe osteolytic bone lesions in multiple myeloma in turn genotype IL-1RCT as an immunogenetic marker of a lighter form of bone disease manifested with osteoporosis and isolated pockets of lysis.

PB1943

ZOLEDRONIC ACID INHIBITS CELL GROWTH OF MULTIPLE MYELOMA CELLS AND SHOWS SYNERGISTIC ANTIMYELOMA EFFECTS WITH BORTEZOMIB VIA DOWNREGULATION OF PIM-2 THROUGH NF-KB PATHWAY

R Fu*, Z Liu, H Liu, F Peng, L Li, K Ding, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Recent studies showed that the third-generation biphosphonate Zoledronic acid (ZOL) can exhibit direct antitumour activity. However, its possible machnism remains unknown.
Aims: To explore the mechanism of Zol's antitumor activity.
Methods: In this study, RPMI-8226 cell line were treated with ZOL alone at various concentrations and combined with Bortezomib in vitro, then Cell proliferation, cell apoptosis, downsteam signaling pathway were detected by qRT-PCR and Western blot.

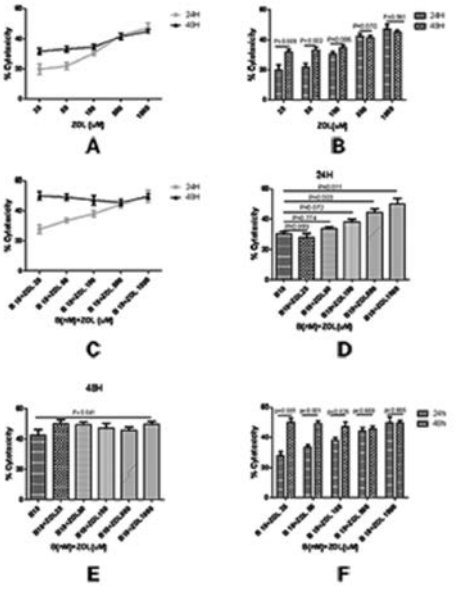


Figure 1.

Results: We found that ZOL alone strongly inhibited proliferation of myeloma cells *in vitro* and induced their apoptosis. The same results were obtained in ZOL combined with Bortezomib after 24h. Futhermore, we found that Ras, pAKT and NF-kB were suppressed by ZOL alone and combined with Bortezomib at 24h. We demonstrated NF-Kb/pim-2 pathway which were also inhibited at 24h. However, it did not show the same results at 48h. additionally,NF-kB plays a pivotal role in regulating of pim-2 which proved by the result of downregulation of pim-2 was appered when the NF-kB inhibitor(Ro 106-9920) was used in RPMI-8226 cell line.
Summary/Conclusions: In conclusion, ZOL and the combination of ZOL with Bortezomib inhibited proliferation of myeloma cell via inhibiting NF-Kb/pim-2 pathway. Ras and pAkt were also inhibited. Combination of Zol with Bortezomib within 24 hours maybe more benefitial to alleviate tumour load in MM patients.

VALIDATION OF REVISED INTERNATIONAL STAGING SYSTEM (R-ISS) IN THE ERA OF NOVEL AGENTS: REAL-WORLD DATA ON 481 MYELOMA PATIENTS FROM A GREEK MYELOMA CENTER

E Giannopoulou[1,*], E Terpos[2], P Konstantinidou[1], E Verrou[1], S Papadaki[1], V Palaska[1], A Gerofotis[1], N karampatzakis[1], K Kokoviadou[3], D Markala[3], E Gagkos[3], I Batsis[3], IS[3], A Anagnostopoulos[3], E Katodritou[1,3]
[1]Hematology, Theagenion Cancer Center, Thessaloniki, [2]Greek Myeloma Study Group, Athens, [3]Greek Myeloma Study Group, Thessaloniki, Greece

Background: Risk stratification has a crucial role in the management of Multiple Myeloma (MM). International staging system (ISS) has been a powerful tool for risk stratification and prognosis in MM for many years. Recently, a revised ISS (R-ISS) has been validated in a large study that included patients enrolled in international randomized studies. This staging system combined ISS with two additional prognostic factors of overall survival (OS), that is abnormal lactate dehydrogenase (LDH) and high risk molecular cytogenetics *i.e.* del17p and/or t(4;14) and/or t(14;16). According to the aforementioned study, R-ISS represents a single powerful prognostic system that stratifies MM patients more effectively than conventional ISS with respect to the relative risk of their survival. Data regarding the prognostic value of R-ISS outside clinical trials, are limited.
Aims: Herein, we have presented real-world data regarding the prognostic value of R-ISS, in a large number of MM patients from a single Greek Myeloma Center.
Methods: We have reviewed the records of 481 consecutive symptomatic MM patients diagnosed and treated in our center between 2000-2015 (median age: 68 years, range: 29-90 years; M/F: 258/:223; IgG: 271, IgA: 124 Light chain: 66, non-secretory: 15, IgD: 4, IgM:1 ISS1: 153, ISS2: 148, ISS3: 180).
Results: R-ISS was available in 411 patients (M/F: 221/190; median age: 68 years, range: 29-90 years; IgG: 237, IgA: 103 Light chain: 53, non-secretory: 13, IgD: 4, IgM: 1; ISS1: 101, ISS2: 144 and ISS3: 165). Fifty-seven (13.8%) patients had R-ISS1, 286 patients had R-ISS2 (69.5%) and 68 patients had R-ISS3 (16%). High-risk molecular cytogenetics were present in 27% of patients while high LDH was present in 27% of patients. Overall, 280/481 patients (58%) were treated with novel agents (NA) combinations in first line (IMiD-based: 168, Vel-based: 110, conventional therapy: 194, missing data: 9). Second line therapy was administered in 230/481 patients; 78% was treated with NA (Lenalidomide-dexamethasone: 67, Vel-based: 44, Thal-based: 70, chemotherapy: 49). Autologous transplantation was offered in 68/190 (36%) eligible patients. After 1st line therapy, the objective response rate was 82%, while at least very good partial response (≥vgPR) was achieved by 58% of patients. After a median follow up of 8 years (95% CI: 80-114), 135/481 (28%) patients are alive. In the univariate analysis, age, creatinine, ISS, R-ISS, molecular cytogenetics, type of 1st and 2nd line treatment, achievement of ≥vgPR and autologous transplantation (ASCT) predicted for overall survival (OS). In the multivariate analysis, R-ISS and ≥vgPR were independent predictors for survival (p<0.001, HzR:0.4, 95% CI: 0.2-0.6 and p=0.03, HzR: 0.6, 95% CI: 0.4-0.9, respectively). Median OS for patients with R-ISS1, R-ISS2 and R-ISS3, was 92 months (95% CI: 55-129), 36 months (95% CI: 32-40) and 20 months (95% CI: 13-27), respectively (p<0.001). A subgroup analysis confirmed the prognostic role of R-ISS irrespective of age (<65 or ≥65), period of diagnosis (<2006 or ≥2006), type of treatment (bortezomib-based, IMiD-based or chemotherapy) and administration or not of ASCT.
Summary/Conclusions: Our results confirm that R-ISS is the most powerful prognostic factor for OS in an unselected MM population. Its predictive value is maintained across different groups of patients providing a simple and available tool for risk stratification of MM patients, which is essential for therapeutic decisions.

PB1945

THE EFFECT OF HYPOXIA ON NOTCH PATHWAY IN MULTIPLE MYELOMA NICHE

S Garavelli[1,*], M Colombo[1], N Platonova[2], MT Palano[1], F Baccianti[1], A Neri[2], C Raffaella[1]
[1]Department of Health Sciences, [2]Department of Oncology and Hemato-oncology, University of Milano, Milano, Italy

Background: Multiple myeloma (MM) is an incurable hematological tumor representing 13% of all hematological malignancies and tumor cells accumulate in the bone marrow (BM) of patients. Several evidences demonstrate that Notch signaling mediates critical events in MM progression. The Notch pathway is highly conserved and consists of 4 receptors and two different ligand families (Delta and Serrate). Recently Notch receptors and ligands have been shown to be upregulated during MM progression and their signaling positively regulates cell proliferation, drug resistance and BM infiltration. Hypoxia is defined as a low oxygen condition and can induce angiogenesis; HIF-1α is the key mediator of hypoxic response and a transcription factor that can switch on different types of genes, which, in turn, regulate angiogenesis (VEGF) and proliferation of various stem cell populations. Recent reports indicate that HIF-1α may positively regulate Notch signaling and enhance the expression of Notch downstream genes. In MM, hypoxia can sustain stem cell-like population in MM and HIF-1α derived from bone marrow endothelial cells can have a role in promoting drug resistance in patients with MM.
Aims: The aim of this work is to evaluate if and how hypoxia can affect the activation of Notch signaling in MM microenvironment and the underlying mechanism.
Methods: OPM2, U266, H929 and RPMI8226 cell lines were cultured in complete RPMI-1640 medium. To induce an hypoxic-like condition, cells were treated with Cobalt Chloride ($CoCl_2$) 100 μM for 24 h. To analyze the modulation of the expression of HIF-1α, the MM cells were treated with $CoCl_2$ 100 μM for 2h, 6h, 12h and 24h. We evaluated the effect of hypoxia on cells proliferation, apoptosis and cell cycle; Western Blot and qPCR were used to analyze how hypoxia can affect the activation of the Notch pathway. Cell proliferation: absolute cell counts were determined using the volumetric count tool of the BD FACSVerse™ System (BD Biosciences, USA). Apoptosis: MM cell lines were treated with $CoCl_2$ 100 μM for 24h and stained with Annexin V-FITC and Propidium Iodide, then processed using the BD FACSVerse™ System (BD Biosciences). Western Blot: 100 μg of proteins were loaded on a 8% polyacrilamide gel and transfer onto a nitrocellulose membrane. The membrane was incubated with the following antibodies: Actin (Santa Cruz Biotechnology), HIF-1α (Santa Cruz Biotechnology) and Notch2-cleaved (Abcam). Quantitative PCR reactions were carried out on a 7500 Fast Real-time PCR system (Applied Biosystems) using the MaximaTM SYBR Green/ROX qPCR Master Mix (ThermoScientific).
Results: The MM cell lines OPM2, U266, H929 were treated with $CoCl_2$ 100 μM for 24 to mimic hypoxic condition and we evaluated the effect on cell proliferation and apoptosis: hypoxia inhibits proliferation in all MM cell lines used (H929, U266 and OPM2) and induces apoptosis only in H929 cell lines. To analyze the molecular effects of hypoxia, we treated MM cell lines with $CoCl_2$ 100 μM for 2h, 6h, 12h and 24h and performed a Western Blot. HIF-1α is highly expressed in treated cells if compared to normal controls; the hypoxic condition induced the expression of pro-angiogenic factors *i.e.* VEGF and SDF-1α. Interestingly these have been reported to be controlled by Notch. Consistently, hypoxia induced the activation of Notch2 receptor.
Summary/Conclusions: Our results, although still preliminary, indicate that hypoxia can affect MM cell lines survival and proliferation and finally and that it is able to induce the activation of the oncogenic Notch pathway.

PB1946

A NOVEL TOOL TO MONITOR ANGIOGENESIS IN BONE MARROW SMEARS: DETECTION AND QUANTIFICATION OF ENDOTHELIAL PROGENITOR CELLS BY MULTIPLE-LABELING IMMUNOFLUORESCENCE ANALYSIS

MM Tenreiro[1,*], R Malhó[2], M Silveira[3], ML Correia[4], MA Brito[1]
[1]Department of Biochemistry and Human Biology, Faculty of Pharmacy, Universidade de Lisboa, [2]BioISI, Instituto de Biossistemas e Ciências Integrativas, Faculty of Sciences, Universidade de Lisboa, [3]Instituto Português de Oncologia Dr. Francisco Gentil, [4]Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal

Background: Angiogenesis is a crucial event in cancer, as it is present in tumor growth, invasion and metastasis. It is considered to have a key role in several haematological malignancies that affect the bone marrow, such as multiple myeloma. Tumor neovascularization and angiogenesis involve the recruitment of endothelial progenitor cells (EPCs), which are bone-marrow derived circulating progenitors with the potential to differentiate into cells of the endothelial lineage. Two types of EPCs have been described: early EPCs, which can also be called angiogenic cells, and mature EPCs or endothelial outgrowth cells. These two types of cells differ in markers expression, morphology, proliferative potential and *in vitro* function, like vascular tube formation. Identification of EPCs is still a challenging task, since these cells display no specific cell-surface antigen. Even so, it is widely accepted that early EPCs are positive for the following markers: cluster of differentiation (CD)133, which is expressed by haematopoietic and progenitor cells; CD34, characteristic of hematopoietic stem cells and activated endothelium of small vessels; and vascular endothelial growth factor receptor (VEGFR)-2, present in endothelial lineage. Regarding mature EPCs, they are considered $CD133^-/CD34^+/VEGFR\text{-}2^+$.
Aims: To overcome the difficulty in the assessment of EPCs, usually by flow

cytometry and cell culture, we decided to develop a new triple-labelling immunofluorescence analysis protocol to assess EPCs in bone marrow smears as a tool to monitor the angiogenesis process and disease progression in pathologies like multiple myeloma.
Methods: Bone marrow smears archived at the Hematology Service of Instituto Português de Oncologia Dr. Francisco Gentil, Lisbon, from multiple myeloma patients were used. Smears were fixed and permeabilized with a 75% methanol/25% acetone/0.01% Triton X-100 solution and blocked with 10% goat serum/1% bovine serum albumin in PBS or 10% rabbit serum serum/1% bovine serum albumin in PBS, according to the host species of the secondary antibodies. Triple labelling was performed using antibodies against CD133, CD34 and VEGFR-2, followed by species-specific secondary antibodies, and nuclei labelling with DAPI. Smears were analysed under a confocal laser microscope and/or a widefield epifluorescence microscope with appropriate excitation and emission filters.
Results: With this protocol, it was possible to identify cells that were triple ($CD133^+$, $CD34^+$ and $VEGFR\text{-}2^+$) and double labelled ($CD133^-$, $CD34^+$ and $VEGFR\text{-}2^+$), which correspond to early EPCs and mature EPCs, respectively. Furthermore, quantification of the total number of labelled nuclei allowed the establishment of the percentage of early EPCs and mature EPCs relatively to the cellular population of the bone marrow smear. Moreover, analysis of samples of the same patient collected at different time points allowed the establishment of differences in EPCs subsets along the course of the disease.
Summary/Conclusions: Our protocol is an easy and accessible method to monitor angiogenesis based on analysis of EPCs, which can be implemented in any laboratory equipped with a suitable microscope. This protocol may be used to study multiple myeloma, as well as other pathologies involving enhanced angiogenesis in the bone marrow, therefore constituting a novel tool for early detection of angiogenesis and efficient monitoring of neovascularization along disease progression and treatment.

PB1947

THE EFFECT OF MIR-146A OVEREXPRESSION ON THE PROLIFERATION AND APOPTOSIS OF MULTIPLE MYELOMA CELL LINE

S Kazemzadeh[1,*], S Kaviani[1], J Sabour Takanlu[1], T Akbari Saeed[2]
[1]Department of Laboratory Hematology & Blood Banking, Tarbiat Modares University, Tehran, [2]Department of Laboratory Hematology & Blood Banking, Kerman University of Medical Sciences, Kerman, Iran

Background: After lymphoma, multiple myeloma (MM) is the second most common hematological malignancy worldwide contributing 1% of all cancers and nearly 2% of cancer mortalities. Deregulation of microRNAs has been implicated in the pathogenesis of multiple myeloma. miR-146a is one of the most important microRNAs in tumor initiation and progression which has a dual effect and act as a tumor promoter or a tumor suppressor.
Aims: The present study aimed to evaluate the functional effect of miR-146a in multiple myeloma cells.
Methods: The expression of miR-146a was examined in myeloma cell line, L363 by qRT-PCR. The effect of overexpression of miR-146a on proliferation and apoptosis of myeloma cells was further evaluated by lentiviral-based delivery method.
Results: According to our results, the expression of miR-146a significantly increased in cells transducted with transfer vector compered to non-transducted cells (P-value=0.001). Transfection of miR-146a resulted in significant decrease in tumor cell proliferation (P-value=0.001) and significant increase in apoptosis of multiple myeloma cells (P-value=0.004).
Summary/Conclusions: According to previous studies, miR-146a has a dual effect in cancers. Our result suggested that miR-146a acts as a tumor suppressor in MM. It seems that miR-146a regulates an miR-146-NF-κB negative feedback regulation loop in myeloma cells by inhibiting the expression of IRAK1 and TRAF6 and consequently prevents tumor cell proliferation and enhanced apoptosis.

PB1948

MAST CELLS INDUCE MYELOMA PLASMA CELLS' PROLIFERATION

G Tsirakis[1,*], M Devetzoglou[2], A Kolovou[1], K Pappa[3], E Stavroulaki[4], R Vyzoukaki[5], M Alexandrakis[2]
[1]Hematology, General Hospital of Chania "St George", Chania, [2]Hematology, University Hospital of Heraklion, [3]Internal Medicine, [4]Hematology, Venizelion Hospital of Heraklion, [5]Microbiology, University Hospital of Heraklion, Heraklion, Greece

Background: Mast cells (MCs) are inflammatory cells that participate actively in multiple myeloma (MM) progression. They mainly enhance angiogenesis through production of various pro-angiogenic molecules, whereas they may also participate per se in the vascular plexus.
Aims: The aim of the study is to explore whether MCs participate in other aspects of MM progression, such as proliferation of plasma cells.
Methods: We studied 57 newly diagnosed patients with active MM, 26 of them in at least partial remission after receiving bortezomib-containing regimens, and 20 age and sex-matched healthy controls. We studied in bone marrow MCs density (MCD) and plasma cells' proliferation rate (using immunohistochemical expression of tryptase and PCNA, respectively) and in sera levels of angiopoietin-2 (Ang-2) end endoglin (sCD105) (using ELISA).
Results: All variables were higher in active MM patients compared to both healthy subjects and responders to conventional treatment ($p<0.001$ in all cases). Moreover, in active MM patients, MCD correlated positively with PCNA expression ($r=0.490$), Ang-2 ($r=0.554$) and sCD105 ($r=0.566$) levels ($p<0.001$ for all cases).
Summary/Conclusions: MCs enhance angiogenesis and probably through this procedure they also induce proliferation of plasma cells. Although the correlation seems to be rather indirect, MCs are major participants in MM progression and therefore could be considered possible targets for therapeutic interventions.

PB1949

EARLY DETECTION OF PLASMA CELL DYSCRASIA IN SERUM PROTEIN ELECTROPHORESIS

M Rebordao[*], S Francisco, M Silva, L Costa
Laboratório Patologia Clinica, Hospital Forças Armadas, Lisboa, Portugal

Background: Monoclonal gammopathies are characterized by an excessive production of a single, or rarely more, types of immunoglobulins. They arise from the proliferation of one specific B cells malignant clone (plasma cell dyscrasia), which in turn generates an homogeneous population of monoclonal immunoglobulins. Early detection of these clones can be made by serum protein electrophoresis, which shows a different plot curve or a small narrow peak.
Aims: To early identify plasma cell dyscrasias by small changes in the electrophoretic curve profile, enabling a sooner diagnosis, effective follow-up and treatment.
Methods: A retrospective analysis was made. A total of 7265 electrophoretic curves from 4987 patients (no replicates) were analyzed - 3568 men and 1419 women with average ages of 51.0 and 57.8 years respectively. Patients with an electrophoretic changed pattern were divided into 2 groups. Group-I: alterations of the curve pattern between beta and gamma regions, including distortions and small peaks; Group-II: evident monoclonal peak. Electrophoresis was performed in agar gel and the chains were identified by immunofixation. Blood cells counts were studied in both groups. Statistical analysis was performed by SPSS and the critical level of significance was set at $p\leq0.05$.
Results: Monoclonal gammopathy was identified in 3.5% of the patients (n=176). The average age of this group was 70.0 years old and they were mostly male. To characterize these monoclonal gammopathies by immunofixation, a second harvest was performed in 34 of these patients-54.8% was associated with heavy chain IgG (n=17), 22.6% associated with IgA (n=7) and 19.4% with IgM (n=6) - kappa light chains 58% and lambda light chains 42%. 1 patient had biclonal gammopathy IgG and IgM (lambda light chain) and 3 patients did not have any band alteration. In Group-I (18 patients -58.1%) the average age was 69.6 years. The mean quantification of beta region was 15.4g/L (reference range 7-13 g/L). The mean quantification of gamma region was 13.3 g/L (reference range 6-16 g/L). The mean quantification of distortions and small peaks from this group by densitometry was 4.7g/L. This population had an average of $4.4x10^{12}$/L red blood cells and 13.6 g/L of hemoglobin. Monoclonal gammopathy of undetermined significance (MGUS) was the most common diagnosis (6 patients- 33.3%). This population of patients contrasts and differs significantly from Group-II (13 patients - 41.9%). Group II average age was 74 years old. Electrophoretic curve displayed a well-defined monoclonal peak of 14.7g/L ($p<0.001$), with an average of $3.83x10^{12}$/L red blood cells ($p=0.048$) and 11.2g/L of hemoglobin ($p=0.010$). Multiple myeloma (4 patients-33.3%) and Waldenström macroglobulinemia (2 patients-15.4%) were the most common diagnosis.
Summary/Conclusions: The characterization of monoclonal gammopathies by immunofixation allowed an early detection of situations that can lead to a plama cell dyscrasia. Initially, the protein levels in electrophoresis can be normal or slightly higher so, to detect these diseases in a timely effective manner is extremely important to analyse the electrophoretic curve pattern.

PB1950

SERUM LEVELS OF E-SELECTIN AND VCAM-1 IN ACTIVE MYELOMA

S Kyriakaki[1], A Kolovou[2], G Tsirakis[2,*], R Vyzoukaki[3], A Papadopoulou[3], A Antonakis[4], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, Heraklion, [2]Hematology, General Hospital of Chania "St George", Chania, [3]Microbiology, University Hospital of Heraklion, [4]School of Medicine, University of Crete, Heraklion, Greece

Background: Adhesion of myeloma plasma cells in bone marrow is an important hallmark for their homing. Various adhesion molecules participate in this process, such as E-selectin and VCAM-1. These molecules seem to participate in both cancer and inflammation.
Aims: The study, for the first time, of serum levels of E-selectin and VCAM-1 in active myeloma patients and correlation with bone marrow mast cell's density (MCD), serum levels of soluble endoglin (sCD105) (marker of endothelial activation) and disease progression.

Methods: We studied 54 newly diagnosed active myeloma patients and 20 healthy controls. We estimated bone marrow MCD using the immunohistochemical expression of tryptase and measured serum levels of E-selectin, VCAM-1 and sCD105 with ELISA.
Results: All parameters were higher in active myeloma patients compared to controls ($p<0.001$ for all cases) and were also increasing in parallel with ISS stages ($p<0.001$ for all cases). Significant positive correlations between MCD and levels of E-selectin ($r=0.448$), VCAM-1 ($r=0.597$) and sCD105 ($r=0.667$) ($p<0.001$ for all cases) were noted.
Summary/Conclusions: We found increased serum levels of the adhesion molecules, correlating with MCD, sCD105 and mainly with disease progression. These increased levels may represent increased bone marrow expression, which in turn may be the result of both enhanced angiogenesis and inflammation. By these means, E-selectin and VCAM-1 may be regarded as markers of disease activity.

PB1951

RISK FACTORS ASSOCIATED WITH EARLY MORTALITY IN PATIENTS WITH MULTIPLE MYELOMA IN THE NOVEL-AGENTS ERA
SH Jung[1,*], SS Lee[1], HK Kim[2], K Kim[2], SJ Kim[2], JW Cheong[3], SJ Kim[3], JS Kim[3], JS Ahn[1], DH Yang[1], HJ Kim[1], JJ Lee[1]
[1]Department of Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun-Eup, [2]Devision of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, [3]Devision of Hematology, Department of Internal Medicine, Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic Of

Background: Although the introduction of novel agents improved the survival outcomes in patients with multiple myeloma (MM), some patients died within less than one year (early mortality, EM) following the diagnosis.
Aims: In this study, we evaluated the EM rate, and investigated the risk factors associated with EM in MM patients.
Methods: Retrospective data from 542 patients who were initially treated with a novel agent-containing regimen were analyzed.
Results: The median overall survival (OS) for the entire cohort was 56.5 months. The median OS in the 2010-2014 group was longer than in the 2002-2009 group (59.2 months *vs* 49.1 months, P=0.054). The rate of EM was 13.8%, and the most common cause of EM was infection and comorbidity. In multivariate analysis, the age-adjusted Charlson comorbidity index (ACCI ≥4), low body mass index (BMI <20 kg/m^2), thrombocytopenia, and renal failure were significantly associated with EM. The presence of none, 1, or ≥2 factors was associated with a 4.1%, 14.3%, or 27.4% risk of EM (P <0.001), respectively. The median OS times was significantly different depending on the presence of factors associated with EM (P <0.001).
Summary/Conclusions: In conclusion, the ACCI (≥4), low BMI, thrombocytopenia and renal failure were strong predictors for EM in the novel agent era. These data may help manage MM patients and improve survival.

Myeloma and other monoclonal gammopathies - Clinical

PB1952

EXPECTANCY OF LIFE AND INCIDENCE RATE OF NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) PATIENTS. 15 YEARS RETROSPECTIVE ANALYSIS
B Ballina, S Cerdá, V Martínez-Robles, JA Rodriguez-Garcia, F Escalante*
Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: In the last decade we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Past decade also shows us a new demographic data in our society: the increment of expectancy of life and an excellent performance status. New expensive but very effective antimyeloma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems.
Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antimyeloma agents.
Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. Then we divide the cohort in several groups: sex and age at diagnosis (3 groups) and three 5-year period of time (1998-2002, 2003-07 and 2008-12). Characteristics of patients: n= 273. Male/female: 170/103. Median age at diagnosis: 74 years (Range: 39-100). We don't see differences in median age between that three 5-years periods. We have calculated the incidence per 100000 inhab/year using census data of our Local Registry of Tumours of our Public Health Area. *(Table 1)*
Results: There were a constant increase of Annual Average Incidence of more than 10% in the 3 periods: 4.57 *vs* 5,12 (+12%) *vs* 6,15 (+34,6%). This increment was due to older patients more than younger one. This young group accounts for a constantly near one quarter of all NDMM. There were a constant incidence of about 16-18 per 100000/year NDMM in population over 65 y. We don't observe large differences between groups over and under 75 years.
Summary/Conclusions: We have observed a more than expected incidence of NDMM in our Public Health Area. Demographics of other Public Health Areas Average Annual Incidence were quite different to ours, because of ageing of population in our Area. A preliminary analysis of incidence of period of 2013-14 are similar to last 2008-2012 period.

PB1953

IMPACT OF TIME SPENT WAITING FOR AUTOLOGOUS TRANSPLANTATION ON THE OUTCOME OF PATIENTS WITH MULTIPLE MYELOMA
F Ripamonti[1,*], M Da Vià[2], F Cocito[2], S Mangiacavalli[1], P Bernasconi[1], AA Colombo[1], D Caldera[1], CS Cartia[2], M Ubezio[1], I Casetti[2], C Klersy[3], M Cazzola[2], A Corso[2], EP Alessandrino[1]
[1]Hematology- Bone Marrow Transplantation, [2]Hematology, [3]Servizio di Biometria e Statistica, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: Autologous stem cell transplantation (Tx) is still the standard of care for symptomatic myeloma patients (pts) eligible for high-dose procedure. Whether time lasting between stem cell collection and Tx (Wait-Tx) has an impact on Tx outcome itself is matter of debate.
Aims: The aim of this study is to evaluate whether Wait-Tx impacts on the outcome of transplanted myeloma pts.
Methods: We reviewed data of 233 myeloma pts treated with HD Melphalan between January 2000 and December 2013; 20 pts with primary refractory disease and 26 pts treated with a double transplant program were excluded. One hundred eighty seven (187) pts entered the analysis: Male/Female 99(53%)/88(47%), median age 55 years (28-69), Myeloma Type IgG/IgA/light chain/non secretory 111(59%)/38(20%)/33(18%)/5(3%), Durie&Salmon stage II/III 26(14%)/161(86%). Induction therapy consisted of 4 VAD cycles in 83 pts (44%) treated from 2000 to 2005 or 4 Bortezomib-based cycles in 104 pts (56%) treated from 2006 to 2013. Stem cell collection was primed with a single course of DCEP or HD-EDX followed by G-CSF at 10 mcg/kg until completing stem cell collection (PBSC). Tx conditioning regimen consisted of single HD-Melphalan infusion 200 mg/m^2 in 137 pts (73%); HD Melphalan was given at the reduced dose of 160 mg/m2 in 50 pts (27%) due to comorbidity. Response was defined according to International Myeloma Working Group criteria.
Results: Median time between stem cell collection and transplantation (Wait-Tx) was 4 months (range 0.9-13.8 months). After a median follow up after Tx of 49 months (range 24-75 months), 140 patients (74%) relapsed or progressed, median progression free survival (PFS) after Tx was 23 months (range 12-54 months), with a median OS after Tx of 70 months (range 34 months -not reached). PFS was not different between tertiles of Wait-Tx (T1= 0.9-3.2 months, T2= 3.3- 4.6 months, T3=4.7-13.8 months; logrank test p=0.45, cfr Figure 1). When multivariate analysis was performed including Wait-Tx, age at Tx, disease status at Tx (≥VGPR *vs* PR *vs* <PR), type of induction (bortezomib based *vs* VAD) as covariates, disease status at transplant ≥PR (HR 2.88, CI

1.65-5.03, p<0.05) and bortezomib based induction (HR 0.63, CI 0.42-0.94, p=0.024) significantly correlated with longer PFS, while Wait-Tx was not associated with an increased risk of progression (HR 0.98, 95%CI 0.86-1.12, p=0.76). Similar results were found as far as OS was concerned (Wait-Tx HR 1.12, 95% CI 0.94-1.32, p=0.180; bortezomib based induction *vs* VAD, HR 0.7, 95% CI 0.4-1.2, p=0.223; ≥PR, HR 2.04, 95% CI 1.05-3.9, p=0.034).

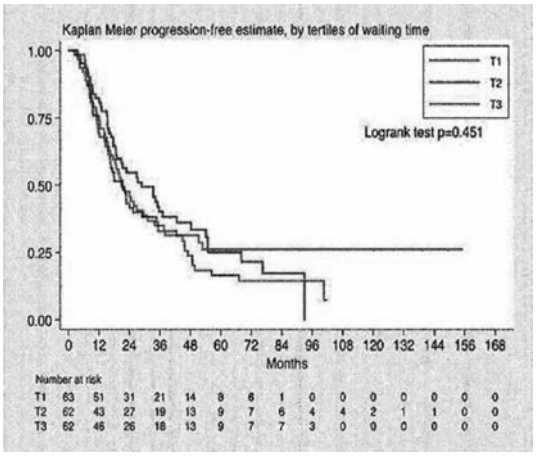

Figure 1.

Summary/Conclusions: Time frame between PBSC collection and stem cell infusion had no significant impact on the outcome of transplanted myeloma patients. Response to induction treatment and bortezomib based induction therapy are both predictive of better outcome ensuring a longer PFS after transplantation.

PB1954

SINGLE CENTRE OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA

T Rider*, R Benjamin, M Streetly, A Pagliuca, S Schey, M Kazmi, K Smith, J Jegard, S Omar, L Floro, J O'Sullivan
Haematology, Kings College Hospital, London, United Kingdom

Background: The introduction of novel drugs and autologous stem-cell transplantation (SCT) have improved outcomes in multiple myeloma (MM) but most patients relapse and remain uncured. Allogeneic SCT is a potentially curative therapy but high transplant-related mortality (TRM) limits use of this strategy. Reduced-intensity transplants have reduced TRM but consequently higher relapse rates occur.
Aims: Our primary aim was to evaluate progression free survival (PFS) and overall survival (OS) in patients with MM who underwent allogeneic SCT at our centre. We also examined the effect of several factors on PFS and OS; pre-allogenic SCT disease status, prior autologous SCT and number of lines of treatment, in addition to conditioning regimen, age, and 6 month chimerism levels.
Methods: A retrospective analysis of medical records for all consecutive MM patients that underwent allogeneic transplantation at our centre between May 1999 and December 2015.
Results: 29 MM patients underwent allogeneic SCT at a median age of 51 with the median year of transplant being 2005. Prior to allogeneic SCT a median of 3.6 treatment lines (range 2-9) were administered, including an autologous SCT which 79.3% of the cohort received. The subtype of MM was; IgG 48.3%, IgA 20.7%, plasma cell leukaemia 17.2%, kappa light chain myeloma 10.4% and lambda light chain disease 3.4%. Prior to allogeneic SCT 41.2% were in complete remission, 14.8% in very good partial remission (VGPR), 29.2% in partial remission and 14.8% had stable disease. A sibling was the stem cell donor in 57.1% of cases, the remainder had matched unrelated donors. 51.7% of patients received fludarabine, melphalan and alemtuzumab conditioning, 13.8% received fludarabine, busulfan and alemtuzumab, other regimens used included those utilising anti-thymocyte globulin ATG or total body irradiation. PFS and OS were 35 and 56 months respectively. The 10 year PFS was 23% and OS was 49%. 14 deaths occurred during a median follow-up of 58.1 months. Age, pre-allogeneic SCT disease status, 6 month chimerisms and type of conditioning regimen had no significant effect on PFS or OS. Those with fewer than 4 lines of treatment prior to allogeneic SCT had longer OS (P=0.4) and PFS (P=0.015). IMiD therapy was given to 51.7% of patients pre-allogeneic SCT and 27.6% received velcade. Those that received 1 autologous SCT (n=16) had longer OS (P=0.026) compared to those that received 2 (n=7) or no autologous SCT (n=6), but PFS was not affected. Neutrophil engraftment occurred after a median of 13 days. Graft *versus* host disease in the first 100 days occurred in 4 patients and in 5 patients after 100 days. 4 patients had pre-planned maintenance therapy post allogeneic SCT. Donor lymphocyte infusion was given to 9 patients post allogeneic SCT at a median of 9 months post allogenic SCT, a median of 3 infusions were administered. 2 patients subsequently received an autologous SCT post allogeneic SCT at a median of 36.5 months. A median of 1 line of treatment (range 0-5) were given to the 13 patients who relapsed following allogeneic SCT.
Summary/Conclusions: Our data indicates that performing an allogeneic SCT after less than 4 lines of treatment and after 1 autologous SCT yields better outcomes. Low disease burden as demonstrated by achieving at least a VGPR is also optimal, although not significant in our data. The role of immunomodulation including maintenance therapy post allogeneic SCT needs to be fully examined in prospective clinical trials to optimise the chance of allogeneic SCT being curative.

PB1955

OUTPATIENT STEM CELL MOBILIZATION WITH INTERMEDIATE-DOSE CYCLOPHOSPHAMIDE IS A SAFE AND EFFECTIVE PROCEDURE

A Pompa*, F Guidotti, G Mometto, M Goldaniga, F Rossi, R Marcolin, L Baldini, A Cortelezzi
UOC Oncoematologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, Milano, Italy

Background: Autologous stem cell transplantation (ASCT), even in the era of new drugs, is the treatment of choice in younger and fit Multiple Myeloma (MM) patients. Cyclophosphamide (CY) at different doses has been shown to be an effective regimen for collecting peripheral blood stem cells (PBSC) in MM. Clinical trials have demonstrated that intermediate dose CY (3 and 4 g/m2, ID-CY) combined with G-CSF, is an efficient mobilizing regimen with less toxicity compared with high dose CY (7 g/m2, HD-CY) in term of neutrophil recovery, thrombocytopenia, need of transfusions and IV antibiotics. (Goldschmidt, BMT 1996; Fitoussi, BMT 2001). The method used for PBSC mobilization has not been shown to affect overall transplantation outcomes (Kumar, Blood 2009). Mobilization therapy is usually administered in an inpatient regimen, for the concern of toxicity.
Aims: Our purpose is to evaluate the safety of mobilization therapy administered in an outpatient regimen, with the prospect to lower costs and minimize patient inconvenience, maintaining an optimal yield.
Methods: One hundred patients with newly diagnosed MM underwent outpatient stem cell mobilization with CY 3 g/m2 (80%) or 4 g/m2 (20%) + G-CSF after induction therapy with VEL-based (81%) or VAD (19%) regimens. G-CSF 10 mcg/Kg was started by day +5 and continued until completion of apheresis. No antibiotics prophylaxis was routinely used. Day 0 was defined as the CY infusion day. CY was administered in 2-4 consecutive 1h infusions (depending on total dose). Hyper-hydration (3.5/4 l), antiemetics and the uroprotectant Uromitexan were began IV 1 hour before CY infusion. Subsequently, Uromitexan was continued at home orally in the next 12h. Furthermore, the patient was advised to drink 2.5/3 l of water in the next 24h. Blood count was monitored at day + 4 and daily from day +7. CD34+ cells were counted on peripheral blood by day 7; apheresis was started at leukocyte rise and with a value of at least 20 CD34+/µl. Number of apheresis depended on the number of CD34+ cells collected to obtain al least $4x10^6$ CD34+/Kg. Stem cells were then manipulated and cryopreserved with standard techniques.
Results: Results are actually available for 88 of these patients. Median age at mobilization therapy was 57y (range 34-68). Response prior of mobilization was CR/sCR in 18%, VGPR in 52%, PR in 27%, and PD in 3%. Chemotherapy was very well tolerated. Most frequently observed adverse events (AEs) were nausea and vomiting of grade 1-2. Two patients experienced cystitis (one grade 1, one grade 2), 2 patients fever and infections. Only one patient required hospitalization for AEs for fever without microbiological findings, rapidly regressed with IV antibiotics. There were no other significant AEs related to chemotherapy. All patients proceeded to stem cell harvest and reached CD34+ target, but 7 patients required administration of Plerixafor on demand. After mobilization, 85 patients proceeded to ASCT.
Summary/Conclusions: In conclusion, outpatient mobilization with ID-CY appears to be an efficient and safe procedure, with minimal and manageable side effects and low rate of hospitalization. Outpatient mobilization could ameliorate the quality of life of patients and reduce costs, avoiding or minimizing the hospitalization rate, without compromising the safety profile and the success of PBSC collect.

[1]Hematology, [2]Hospital Dr. Peset, [3]Hospital La Fe, [4]Hospital Arnau Vilanova, [5]Hospital General, [6]IVO, [7]Hospital De Sagunto, Valencia, [8]Hospital De La

Plana, [9]Hospital Provincial, [10]Hospital General, [11]Hospital Vinaroz, Castellón, [12]Hospital Clinico, [13]Hospital La Ribera, [14]Hospital Manises, [15]Hospital Francesc Borja, [16]Hospital Requena, Valencia, [17]Hospital General, [18]Hospital San Juan, [19]Hospital De Denia, [20]Hospital Vinalopo, Alicante, [21]Hospital De Elda, Alilcante, [22]Hospital Virgen De Los Liros, [23]Hospital General De Elche, Alicante, Spain

Background: Multiple myeloma (MM) is the second most common malignant B-cell disorder. It accounts for 1% of all malignant diseases and for slightly more than 10% of all hematological malignancies. Based on international data, the incidence of MM in Spain has been estimated to be 0.056/1000 of population. However, most of this information is collected from secondary sources as press releases, industry, associations, analyst reports and others but real life epidemiological data based on national or local registries is lacking.
Aims: In order to have a better knowledge of the clinical characteristics at diagnosis of MM patients and to know the real incidence and prevalence of patients with newly diagnosed MM in our environment, the Grupo de Estudios de Mieloma (GREMI) developed in 2013 a prospective, multicenter registry including every patient undergoing a first diagnosis of MM in every public or private sanitary center of the Comunidad Valenciana, Spain.
Methods: The CV involves three regions in Spain (Alicante, Castellón, and Valencia) with a global population of 5,034,665 habitants. A total of 2,578,719 people live in Valencia, 1,868,438 in Alicante and 587,508 in Castellón. Diagnosis of MM is done according to the International Myeloma Working Group criteria. Primary data collection for the registry is done in every center by the local investigators. Immediately after a new diagnosis of MM is performed, the patient is registered on-line by means of an electronic database. Clinical and epidemiological data at presentation, the type of therapy administered, and survival status are included. We present the preliminary epidemiological, clinical, and laboratory results of the patients included in the registry in the period 2013-2014.
Results: From January 2013 to December 2014, a total of 332 patients have been registered in 23 centers. The overall incidence of patients with newly diagnosed MM (NDMM) in the Comunidad Valenciana in the study period was 0.066/1000 of population (0.046 in Alicante, 0.082 in Castellón, and 0.077 in Valencia). Three hundred and twenty-seven (98.5%) patients were of Caucasian descent. Median (range) age of the series was 70.76 (43.07-92.15) years and 95 (28.61%) of the patients were younger than 65 years. One hundred and seventy-seven (53.3%) patients were male. Overall, IgG myeloma was the most commonly observed type of myeloma (174 patients, 52.4%). Eighty-eight (26.5%), 52 (15.7%), and 82 (24.7%) patients presented with an International Staging System of I, II, and III, respectively. Clinical and laboratory data at time of diagnosis are shown in the Table 1.

Median	

Summary/Conclusions: This is the first epidemiological registry for NDMM patients available in Spain. Our preliminary results indicate that the incidence of MM in the Comunidad Valenciana is similar to that generally reported. Cytogenetic data were routinely collected in the great majority of patients 248 (74.7%). Survival data during the study period will be presented.

Background: Panobinostat (PAN), in combination with bortezomib (BTZ) and dexamethasone (DEX), is approved in the EU for the treatment of adult patients with relapsed and/or refractory multiple myeloma (MM) who have received ≥2 prior regimens, including BTZ and an immunomodulatory drug, based on significant clinical benefit of PAN+BTZ+DEX PANORAMA-1.
Aims: This analysis focuses on the impact of PAN+BTZ+DEX on patient experience, including measures of symptoms, function, and health-related quality of life (HRQoL), measured by FACT/GOG-Ntx, QLQ-MY20, and EORTC-QLQ-30.
Methods: In PANORAMA-1, patients who had received between 1 and 3 previous treatment regimens were randomized 1:1 to receive up to 12 cycles of PAN or placebo (PBO), in combination with BTZ+DEX. PRO measures were administered at screening, cycle 1 day 1, and every 6 weeks thereafter until end of treatment. We present here the results at the end of 24 weeks, after completion of the first 8 cycles of the study treatment (treatment phase 1).
Results: In the approved EU population, PRO baseline data were available for 71 and 69 PAN+BTZ+DEX and PBO+BTZ+DEX treated patients, respectively, for the EORTC QLQ-C30, Global Health Status/QoL scale and for 70 patients in each treatment arm for the QLQMY20, Disease Symptoms (DS) subscale and the FACT/GOG-Ntx Neurotoxicity subscale. At Week 24, FACT-GOG-Ntx scores were similar across treatment arms, suggesting no difference in neurotoxicity symptoms (31.75 *vs* 33.57 for PAN+BTZ+DEX *vs* PBO+BTZ+DEX treated patients, respectively). In both treatment arms, symptoms scores were generally low on the scale of 0-100, with lower scores in the QLQ-MY20 DS subscale observed following treatment initiation and no difference between arms observed at Week 24 (23.84 *vs* 16.55 for PAN+BTZ+DEX *vs* PBO+BTZ+DEX treated patients, respectively). EORTC QLQ-C30 Global Health Status/QoL scores were generally stable after treatment initiation, and comparable in the 2 arms at Week 24 (53.82 *vs* 58.05 for PAN+BTZ+DEX *vs* PBO+BTZ+DEX treated patients, respectively).
Summary/Conclusions: These findings support the addition of panobinostat to the well-established BTZ+DEX regimen as an efficacious treatment option with limited symptomatology and impact on patients' HRQoL. With the increasing importance of patient-relevant humanistic benefits in determining the overall value of oncology products findings such as these are important for treatment decision making.

PB1958

RETROSPECTIVE COHORT ANALYSIS EXAMINING THE EFFICACY AND SAFETY OF (V)DTPACE IN NEWLY DIAGNOSED AND RELAPSED/ REFRACTORY MYELOMA PATIENTS-THE UK EXPERIENCE

P Sriskandarajah[1,2,*], H Jolly[2], P Idaikkadar[2], C Pawlyn[2,3], K Mohammed[2], C Dearden[2], M Potter[2], F Davies[4], G Morgan[4], K Boyd[2], M Kaiser[2,3]
[1]Division of Cancer Therapeutics, Institute of Cancer Research, [2]Haematology, Royal Marsden Hospital, [3]Division of Molecular Pathology, Institute of Cancer Research, Sutton, United Kingdom, [4]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States

Background: Multiple myeloma remains incurable in spite of advances in treatment. In the UK, the combination of dexamethasone, thalidomide, cisplatin, doxorubicin, cyclophosphamide and etoposide (DTPACE) continues to play a

role in patients with relapsed/refractory multiple myeloma (RRMM), either as a bridge to stem cell transplant, or for rapid tumor debulking. Recently, bortezomib has also been included (VDTPACE) - this combination was introduced by the Arkansas group in the Total Therapy 3 (TT3) study, where MM patients received this as induction prior to tandem autologous stem cell transplant (ASCT), resulting in enhanced response rates and prolonged survival. However, due to the intensity of both VDTPACE and DTPACE, these regimes have not been adopted by many centers and results outside the Arkansas group have therefore been rarely reported. At the Royal Marsden Hospital (RMH) we have used (V)DTPACE in selected cases where standard therapies are deemed inadequate, including newly diagnosed patients with specific high risk features, salvage treatment for those who were primary refractory and in patients with RR disease.

Aims: To assess response rates, impact on stem cell harvest and tolerability in myeloma patients treated with (V)DTPACE at RMH.

Methods: We retrospectively reviewed the medical notes for all myeloma patients treated with (V)DTPACE at RMH between 2010 and 2015. Our primary objective was ORR defined as PR or better. Secondary objectives included number of stem cells harvested (if applicable) and toxicities (as per CTCAE v4.0 criteria). Patient demographics including age, gender and prior treatment exposure were also analyzed.

Results: Between 2010 and 2015, 53 patients received DTPACE and 26 received VDTPACE. The median age was 55 years with a male predominance (61%). 7/79 (9%) patients received treatment upfront due to high-risk disease features, including 2 patients with plasma cell leukemia and 2 with extensive extramedullary disease at presentation. 8/79 (10%) were primary refractory (<PR) to first-line therapy while the rest (64/79, 81%) had RRMM receiving median 2 (range 2-8) prior lines of therapy including thalidomide (72%), bortezomib (75%), lenalidomide (46%) and autologous stem cell transplant (47%). All patients had EDTA clearance scan as well as cardiac assessment prior to treatment. 15/79 (19%) received 1 cycle (V)DTPACE, 58/79 (73%) received 2 and 6/79 (8%) received 3. 49/79 (62%) proceeded to transplant of which only 4 failed to mobilize stem cells. Mean stem cell harvest was $2.64x10^6$/kg. The ORR (≥PR) observed following DTPACE was 100% (20% CR) in newly diagnosed, 100% in primary salvage and 51% (13% CR) in RR patients. Following VDTPACE, ORR was 100%, 71% and 82% (6% CR) respectively. Commonly reported toxicities included Grade 3≥ neutropenia (94%) and Grade 3≥ thrombocytopenia (48%). No thrombo-embolic events or grade 3≥ neuropathy were reported. At analysis, 39/79 (49%) patients were alive. There were no treatment-related deaths. Survival data is currently analysed and will be presented at meeting.

Summary/Conclusions: Our results demonstrate the efficacy of VDTPACE in newly diagnosed and relapsed/refractory patients, in spite of prior exposure to thalidomide or bortezomib. Importantly this regimen can safely be used to salvage patients with an insufficient response to conventional first-line therapy. VDTPACE had no impact on stem cell mobilization, and was well tolerated with no treatment-related deaths reported.

PB1959

THE ROLE OF COMORBIDITY ON EARLY MORTALITY IN MULTIPLE MYELOMA. A SINGLE INSTITUTION POPULATION-BASED STUDY EMPHASIZING THE NEED FOR STANDARDIZATION

R Ríos-Tamayo[1,*], JJ Lahuerta[2], J Sáinz[1], MJ Sánchez[3], DYL Chang[3], JJ Jiménez-Moleón[4], JM Puerta[1], T Rodríguez[5], JL García de Veas[5], P Garrido[1], PA González[1], L Moratalla[1], E López-Fernández[1], A Romero[1], M Jurado[1], J Martínez-López[2]

[1]Hematology, University Hospital Virgen de las Nieves, Granada, [2]Hematology, University Hospital 12 de Octubre, Madrid, [3]Granada Cancer Registry, Andalusian School of Public Health, [4] Preventive Medicine and Public Health, University of Granada, [5]Immunology, University Hospital Virgen de las Nieves, Granada, Spain

Background: Multiple myeloma (MM) is a very heterogeneous and complex disease with variable survival. The variability in the outcome cannot be fully explained by the current systems of stratification. Early mortality (EM) remains a serious obstacle to further improve the recent trend towards increased survival demonstrated in recent years (Ríos-Tamayo et al, 2015). However, the definition of EM is not standardized, precluding a proper comparison between studies. Furthermore, no study has systematically focused on the impact of comorbidity on EM in MM to date.

Aims: The aim of this study is to assess the impact comorbidity on the outcome of MM patients, in terms of EM, in a large cohort of real-life patients. On the other hand, all relevant studies on this topic to date have been critically analyzed.

Methods: All newly diagnosed symptomatic MM patients recorded in our population-based registry from January 1985 to December 2015 were analyzed. The study was divided into six periods of five years. Twenty baseline comorbidities were studied, along with common prognostic factors. EM was measured at three key cutoff points: two (EM2), six (EM6) and twelve (EM12) months. Univariate and multivariate binary logistic regression models were used to test independent variables as risk factors for EM.

Results: Six hundred and thirty-one MM patients were recruited in our MM clinical registry during the period of study. A complete assessment of comorbidity was available in 426 patients (68.6%) at the moment of diagnosis. Excluding patients not fit for MM-directed therapy, the percentage for EM2, EM6 and EM 12 was 10.6%, 20% and 28.6%, respectively. For the whole cohort, only age and serum creatinine were independent risk factors for EM in all the cutoff points analyzed. The presence of respiratory disease and light chain MM (borderline) were associated with EM2, whereas the ISS III and liver disease were predictors for EM6, and finally, the lactate dehydrogenase level, the hepatitis virus C infection and the presence of respiratory disease were significantly associated to EM12. Table I highlights recent studies on this topic. The differences in the type of study as well as in the cutoff point used preclude appropriate comparisons.

Table 1. Results of recent studies on NDMM early mortality.

Abbreviations: NDMM= Newly diagnosed multiple myeloma, EM2=Early Mortality at two months, EM6=Early Mortality at six months, EM12=Early Mortality at twelve months, a,% EM according to estimated glomerular filtration rate (<30, 30-59 or >30 ml/min), b% EM within 24 months.

Summary/Conclusions: The role of comorbidities in EM of MM patients remains to be determined. However, our study confirms the crucial role of renal failure and provides some evidence about the time-dependent impact of specific comorbidities in detailed cutoff points for EM. We suggest that all three cutoff points should be analyzed in the future, in order to allow comparisons between studies.

CARFILZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN JAPANESE PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA

M Ri[1,*], K Suzuki[2], T Chou[3], I Sugiura[4], N Takezako[5], K Sunami[6], T Ishida[7], T Izumi[8], S Ozaki[9], S Iida[1]

[1]Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, [2]Department of Hematology, Japanese Red Cross Medical Center, Tokyo, [3]Department of Internal Medicine, Niigata Cancer Center Hospital, Niigata, [4]Division of Hematology and Oncology, Toyohashi Municipal Hospital, Toyohashi, [5]Department of Hematology, National Hospital Organization Disaster Medical Center, Tachikawa, [6]Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, [7]Department of Gastroenterology, Rheumatology and Clinical Immunology, Sapporo Medical University School of Medicine, Sapporo, [8]Department of Hematology, Tochigi Cancer Center, Utsunomiya, [9]Department of Hematology, Tokushima Prefectural Central Hospital, Tokushima, Japan

Background: Carfilzomib (CFZ) is an epoxyketone proteasome inhibitor that binds selectively and irreversibly to the constitutive proteasome and immunoproteasome. The combination of CFZ with lenalidomide (Len) and dexamethasone (Dex) (CRd) has shown efficacy in a phase 3 study (ASPIRE) in relapsed multiple myeloma (Stewart et al, 2014).

Aims: This phase 1 study was designed to evaluate the safety, tolerability, efficacy and pharmacokinetics of CRd regimens in Japanese patients with relapsed or refractory multiple myeloma (RRMM). This was a company sponsored trial (Ono Pharmaceutical Co., Ltd.).

Methods: Adults with RRMM who had received at least 1 prior treatment were eligible. CFZ was administered as a 10-minute infusion on days 1, 2, 8, 9, 15, and 16 of 28-day treatment cycles (20 mg per square meter on days 1 and 2 of cycle 1 and 27 mg per square meter thereafter) during cycles 1 through 12 and on days 1, 2, 15, and 16 during cycles 13 through 18. Len (25 mg) was given on days 1 through 21 during cycles 1 through 18. Dex (40 mg) was administered on days 1, 8, 15, and 22 during cycles 1 through 18. The efficacy endpoint included the rate of overall response (ORR). Treatment responses and disease progression were assessed by investigators based on the central laboratory results with the IMWG Uniform Response Criteria. All patients provided written informed consent.

Results: Twenty six Japanese RRMM patients were enrolled. The median number of previous regimens was 4 (range, 1-10). The median number of cycles dosed was 4 (range, 1-8 cycles). The proportion of patients with previous therapies of bortezomib and lenalidomide was 88.5% and 61.5%, respectively. A total of 53.8% of patients had high risk abnormal cytogenetics [t (4; 14), t (14; 16), del (17p) or hypodiploid]. In this study, CRd regimen used in ASPIRE study was well tolerated in Japanese population. The ORR was 88.5% (90%CI, 72.8 to 96.8). Subgroup analysis demonstrated that the ORR was not affected by previous therapies and abnormal cytogenetics. The median PFS and OS were not estimated because of the short follow-up period. The most common AEs included lymphocyte count decreased (53.8%), platelet count decreased

(53.8%), hyperglycemia (38.5%), hypophosphatemia (38.5%), constipation (30.8%), white blood cell count decreased (30.8%), and rash (30.8%). The most common Grade 3 or higher AE were lymphocyte count decreased (42.3%), platelet count decreased (23.1%), hypophosphatemia (19.2%), anemia (11.5%), neutrophil count decreased (11.5%), white blood cell count decreased (11.5%) and hyperglycemia (11.5%). Peripheral Neuropathy was observed in 15.4% but no Grade ≥3 or peripheral neuropathy with pain was reported. None of the patients experienced interstitial lung disease. The plasma CFZ concentration showed a rapid decrease after intravenous administration with T1/2 of 0.580–0.740h. The exposure of CFZ increased in a dose-dependent manner with the AUCinf of 326-445 ng*h/mL, Cmax of 1540-2030 ng/mL.

Table 1.

	CRd (N=26)

1 – 3	12/12 (100.0)
≧4	11/14 (78.6)
Prior therapies	
Bortezomib	
Naive	3/3 (100.0)
1 regimen	12/12 (100.0)
≧2 regimens	8/11 (72.7)
Lenalidomide	
Yes	14/16 (87.5)
No	9/10 (90.0)
Cytogenetic risk	
High risk	11/14 (78.6)
Standard risk/Unknown	12/12 (100.0)

Summary/Conclusions: This is the first study that CRd regimen was evaluated in heavily pre-treated MM patients (median 4 prior regimens). CRd regimen was well tolerated and showed a compelling efficacy in Japanese RRMM patients. A comparison of this study with CRd arm in ASPIRE phase 3 study showed that the results of the ORR were similar (88.5% and 87.1%), despite the more heavily pretreated patient population in this study (median 4 *vs* 2 prior regimens). The safety and efficacy of the CRd regimen in Japanese patients seems consistent with that reported in ASPIRE phase 3 study.

PROGNOSTIC SIGNIFICANCE OF EXTRAMEDULLARY DISEASE DETECTED BY PET/CT ON OUTCOMES OF AUTOLOGOUS TRANSPLANT IN MULTIPLE MYELOMA PATIENTS

U Yanamandra[1,*], M BR[2], A Reddy[2], K Agarwal[2], K Kant Sahu[1], N Varma[1], V subhash[1], P Malhotra[1]
[1]Clinical Hematology, [2]Nuclear Medicine, PGIMER, Chandigarh, India

Background: Multiple myeloma is a heterogenous disorder with varied responses to transplantation. In the past investigators have reported numerous staging systems, risk stratification models based on laboratory/clinical parameters and genetic information to predict these heterogenous responses. But the disease mostly negative by biochemical tests before transplantation making it a poor choice to predict responses. ^{18}F-FDG-PET/CT has numerous advantages in terms of ability to assess extra medullary disease in addition to the extent of active disease. The relevance of extramedullary disease in predicting response is scarce and evolving.
Aims: To study the role of pre-transplant EMD in the prognostication of multiple myeloma patients post autologous transplant.
Methods: All autologous transplant patients underwent ^{18}F-FDG-PET/CT as part of the pre-transplant workup. The conditioning and treatment protocols were not modified based on PET/CT findings. Extramedullary disease (EMD) on PET/CT was defined as FDG uptake more than Liver SUVmax at any extramedullary site (including soft tissues or lymphoreticular structures including spleen) of at least 5mm in size. We aimed at identifying the prognostic value of the pre-transplant type of lesions on PET/CT in predicting biochemical/clinical progression-free survival (PFS) and overall survival (OS). We also correlated the EMD status with pre-transplant biochemical markers (SPEP, UPEP, SIFE, SFLC, β2M and LDH). The revised IMWG criteria were used for defining progression.
Results: A total of 43 patients underwent pre-transplant PET/CT evaluation of which seven patients had EMD. On Cox proportional regression hazard model EMD had a hazard for post-transplant all-cause mortality of 5.46 times in patients than the medullary disease (p-0.045) (Fig 1A). The 6-year median OS in patients with medullary and extramedullary PET lesions were 80.6%, and 57.1% respectively as shown Fig. 1B. Kaplan-Meier analysis showed poorer OS in patients with EMD χ2 (1-0.496, p-0.481). There was no significant difference in clinical or biochemical EFS among patients with EMD. The median PFS (Clinical) in patients with medullary and extramedullary PET lesions were 77.8%, and 71.4% respectively (p-0.997). The median PFS (Biochemical) in patients with medullary and extramedullary PET lesions were 55.6%, and 57.1% respectively (p-0.352). Engraftment was delayed in patients with EMD (Neutrophil-11.57 *vs* 10.83 days, platelet engraftment - 13.0 *vs* 12.63 days) though the results were not significant (p-0.274, 0.85). Pre-transplant β2M and LDH were significantly higher in patients with EMD (p-0.036). A chi-square test was performed and no relationship was found between the PET positivity and pre-transplant UPEP, SPEP and SIFE with χ2 (1, 42)-0.737, p-0.391, χ2 (1, 43)-0.632, p-0.580 and χ2 (1, 42)-0.305, p-0.580 respectively.

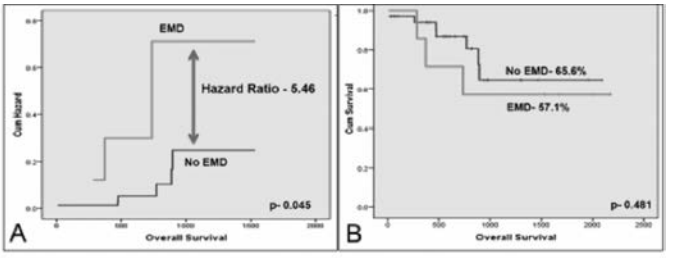

Figure 1.

Summary/Conclusions: EMD detected on ^{18}F-FDG-PET/CT has a higher hazard for mortality and significantly correlated with pre-transplant higher β2M and LDH levels. The Smaller sample size was a major limitation of the study and was responsible for certain differences in measured variables not being statistically significant. To conclude, detection of EMD by pre-transplant ^{18}F-FDG-PET/CT has a significant prognostic role in multiple myeloma patients undergoing autologous peripheral blood stem cell transplant.

ASSOSIATION BETWEEN ENDOTHELIAL AND PLATELET DERIVED MICROPARTICLES AND VENOUS THROMBOSIS IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA (MM) AND NON HODGKIN LYMPHOMA (NHL) - PRELIMINARY REPORT

L Usnarska-Zubkiewicz[1,*], M Podolak-Dawidziak[1], U Zalewska-Dorobisz[2], M Olszewska-Szopa[1], I Prajs[1], J Dębski[1], K Kuliczkowski[1]
[1]Department of Haematology, Blood Neoplasms and Bone Marrow Transplantation, [2]Dept of General and Pediatric Radiology, Wroclaw Medical University, Wrocław, Poland

Background: Multiple myeloma and non-Hodgkin lymphoma and its treatment are frequently complicated by development of venous thromboembolism (VTE). The incidence of thrombotic complications dramatically raise after highly prothrombotic therapeutic regimens e.g. with thalidomide and lenalidomide in MM.
Aims: The aim of this study was to examine whether procoagulant microparticles (MPs) derived from endothelial cells (EMPs) and platelets (PMPs) constitute an enhanced risk for venous thrombosis.
Methods: We studied 22 patients (pts) without history of VTE, 10/12 F/M, aged 24-84 years. There were 13 pts of MM (9 cases of IgG, 2 of IgA, 1 IgM and 1 non secretory MM) and 9 pts with nHL (5 cases of DLBCL, 2 anaplastic T cell lymphoma and 2 FL).All patients underwent routine coagulation tests. Flow-cytometry was used for quantification of endothelial cell (CD133+) microparticles (EMPs) and platelet (CD61+) microparticles (PMPs). In all pts ultrasound examination of venous system of the lower extremities was performed. Both deep and superficial veins of both limbs were evaluated. Conventional and Doppler imagination, as well as elastography and options to detect microcalcifications (micropure) were used.
Results: The ultrasound examination revealed the presence of vein thrombosis in 11 pts (group I, n=11). Five out of 11 pts with bilateral lesions in VSM (*vena saphena magna*, great saphenous vein) and lower leg veins or bilateral in VSM only comprised subgroup Ia. Six pts with unilateral blood clots in VSM formed group Ib. Thrombosis was observed in 7 pts with MM and 4 with nHL, and bilateral thrombotic lesions were demonstrated in 2 MM and 3 nHL pts. The remaining 11 pts showed no thrombosis (group II). The mean percentage of EMPs (CD133+) was 1,04±1,03, and it did not significantly differ between thrombotic (group I) and non-thrombotic patients (group II) 1,22±1,24 *vs* 0,85±0,77, p=0,406), but there was a trend for increased EMPs in the subgroup Ia (1,37±1,17). The percentage of PMPs (CD61+) was 13,14±4,68 and similar in all studied groups: group I 12,82±3,28 *vs* group II 13,45±5,92 (p=0,759),

including subgroup Ia (11,80±2,32). Mean plasma fibrinogen (FBG) concentration was 3,65±1,85 g/L and did not significantly differ in MM and nHL patients with and without thrombosis (4,06±1,90 *vs* 3,24±0,1,80 g/L, p=0,309). But FBG level in subgroup Ia was found to be significantly higher than that in the remaining patients (5,07±2,45 *vs* 3,23±1,48, p=0,047). Mean D-dimer level was 2,59±4,70mg/L, and there was not significantly different in patients with and without thrombosis (4,01±6,40 *vs* 1,16±0,97 mg/L, p=0,159), however D-dimer was elevated in subgroup Ia in comparison with that in group II (2,52±1,29 *vs* 1,16±0,97 mg/L, p=0,034).
Summary/Conclusions: Venous thrombosis was confirmed in 11 of 22 patients with newly diagnosed patients with MM and n-HL. In patients with many thrombotic lesions there was a trend for elevated activity of endothelial cells (EMPs), but not platelets (PMPs).

PB1964

GALECTIN-3 AS A PREDICTOR OF STATIN TREATMENT EFFICACY IN PATIENTS WITH MULTIPLE MYELOMA

B Samura[1,2,*]
[1]Department of Hematology, Zaporizhzhia Regional Clinical Hospital, [2]Department of Internal diseases, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Galectins are a family of lectin molecules that have emerged as key players in inflammation and tumor progression by displaying intracellular and extracellular activities. Increased expression of galectin-3 (Gal-3) has been associated with chronic myeloid leukemia, multiple myeloma, and chronic lymphocytic leukemia. Although modern treatment options for multiple myeloma produce high response rates, the interrelation between elevated Gal-3 and survival rate is not fully understood. Moreover, elevated Gal-3 associates with increased cardiovascular risk. In this context there is possibility to use statins in multiple myeloma patients to prevent unfavorable outcomes under control of Gal-3 level.
Aims: The aim of the study was to investigate an interrelationship between pre-treatment Gal-3 level and one-year survival rate in subjects with multiple myeloma.
Methods: One hundred twelve subjects with multiple myeloma who reached at least partial remission were enrolled in the study. All subjects gave their written informed consent to participation in the study. Patients were divided into 2 groups based on whether or not statins were included in their treatment: a statin group (n=51) and a no statin group (n=61). Among patients in the statin group, 31 patients received 20- mg/day atorvastatin and 20 patients received 40-mg/day atorvastatin. None of the patients had received any lipid-modulating medications, including statins or fibrates, before enrollment. Observation period was up to 1 year. Blood samples for biomarkers measurements were collected. ELISA method for measurements of circulating level of Gal-3, and NT-pro-brain natriuretic peptide (NT-pro-BNP) were used. Concentrations of Gal-3 and NT-pro-BNP for cumulative survival rate were tested.
Results: Within 1 year progressions were reported in 23 patients (8 statin users (15.7%) and 15 never statin users (24.6%) (P<0.05)). 92 cardiovascular events were reported in 36 patients, (12 statin users (23.5%) and in 24 never statin users (39.3%) (P<0.01)). Lipid lowering effect in statin users was associates with declined serum Gal-3 level, whereas in not statin users similar response was not appeared. No any changes in hemodynamics and other biomarkers between both cohorts were found. Univariate logistic regression had exhibited that Gal-3 (odds ratio [OR]=1.13; 95% CI=1.07–1.25; P=0.003), NT-proBNP (OR=1.05; 95% CI=1.03–1.08; P=0.001), and statin therapy (OR=1.06; 95% CI=1.01– 1.10; P=0.001) predicted one-year cumulative cardiovascular events. Gal-3 (odds ratio [OR]=1.09; 95% CI=1.05–1.19; P=0.02), and statin therapy (OR=1.05; 95% CI=1.01– 1.9; P=0.04) predicted one-year progression free survival. After adjustment on statin therapy, Gal-3 remained independent predictor one-year cumulative cardiovascular events (OR=1.07; 95% CI=1.05–1.10; p=0.001). When initial serum Gal-3 level has incorporated into prediction model, statin therapy was found as predictor for improving survival in patients with elevated serum Gal-3 level (>14 ng/ml).
Summary/Conclusions: Elevated pre-treatment galectin-3 level was found a powerful predictor of positive effects of statins in patients with multiple myeloma.

PB1965

CLINICAL SIGNIFICANCE OF OSTEOBLAST PRECURSORS AND OSTEOCLAST PRECURSORS IN EARLIER DIAGNOSIS AND MONITORING OF MYELOMA BONE DISEASE

R Fu*, H Liu, F Peng, L Li, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Multiple myeloma (MM) is a kind of plasma malignant tumor. Myeloma bone disease (MBD) is a most common complication of MM, with up to 80% of them developing osteolytic lesions.The primary diagnostic procedure for the detection of bone involvement in MM is conventional radiography. Limited sensitivity was an important disadvantage of conventional X-ray in MBD.
Aims: To find more sensitive markers to diagnose bone disease earlier and evaluate the effect of therapy.
Methods: we detected circulating osteoclast precursors (OCPs) and osteoblast precursors (OBPs) by flow cytometry, comparing with special biochemical markers, such as tartrate-resistant acid phosphatase isoform 5b (TRACP-5b), carboxy-terminal cross-linking telopeptide of type I collagen (CTX), osteocalcin (OCN) and procollagen I amino-terminal propeptide (PINP).
Results: The results showed that circulating OBPs in the newly diagnosed MM patients significantly decreased compared with the normal controls (7.14% *vs* 12.82%, *P*=0.045). While circulating OCPs in the newly diagnosed patients and remission patients were significantly increased than the normal controls (2.46% *vs* 0.17%, *P*=0.000; 1.87% *vs* 0.17%, *P*=0.000, respectively). According to X-ray, newly diagnosed patients were divided into stage A and B (without and with osteolytic lesions). Compared with the normal controls, circulating OBPs in stage A and B reduced (12.82% *vs* 7.47%, *P*=0.041; 12.82% *vs* 7.14%, *P*=0.010, respectively), while circulating OCPs elevated (0.17% *vs* 2.71%, *P*=0.001; 0.17% *vs* 2.37%, *P*=0.010, respectively). The levels of TRACP-5b and CTX in the newly diagnosed patients were higher than the normal controls (*P*=0.014, *P*=0.037) and remission patients (*P*=0.025, *P*=0.003), and they were significantly higher in stage B than the normal controls (*P*=0.015, *P*=0.002). However, PINP and OCN levels had no significantly changes in different stages.

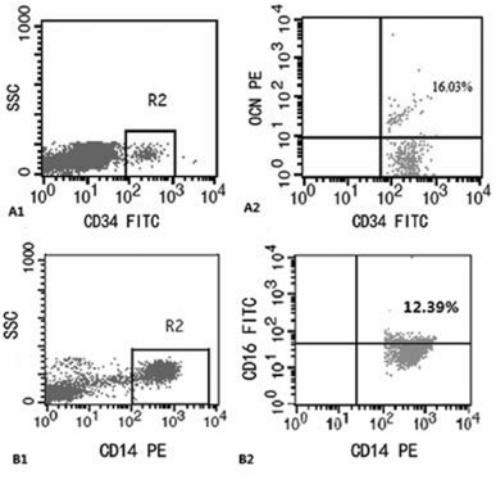

Figure 1.

Summary/Conclusions: In conclusion, abnormal circulating OBPs and OCPs were found earlier before X-ray in MM and still existed in remission patients, indicating that they maybe novel predictive markers for early diagnosing and monitoring bone disease.

PB1966

BORTEZOMIB IN COMBINATION WITH HIGH DOSE MELPHALAN AS CONDITIONING REGIMEN IS SAFE AND IMPROVES THE RESPONSE RATES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

B Dalla Palma[1,*], L Prezioso[1], F Accardi[1], I Manfra[1], F Aversa[1,2], N Giuliani[1,2]
[1]Hematology and BMT Unit, Azienda ospedaliero-universitaria, [2]Clinical and Experimental Medicine, University of Parma, PARMA, Italy

Background: High dose therapy followed by autologous stem cell transplantation (ASCT) is the standard of care as first-line treatment in eligible patients with newly diagnosed Multiple Myeloma (MM). High-dose Melphalan (HDM) is the standard conditioning regimen before ASCT. Recent evidence suggests that the depth of response after the induction therapy influences the progression free survival (PFS) and, in most studies, the overall survival (OS). To improve the depth of response after ASCT in transplant–eligible MM patients the introduction of Bortezomib (BOR) to high-dose Melphalan (HDM) in conditioning regimen has shown to be effective without increased hematological toxicity.
Aims: Aim of the study is to evaluate safety and response rates in patients treated with BOR+HDM as conditioning regimen before ASCT.
Methods: In this study we retrospectively analyzed, in a single center, 27 patients treated with BOR-HDM as conditioning regimen as compared to a historical cohort of 21 patients treated with HDM alone in order to evaluate the safety and the response rate of the combination treatment. All patients in both groups were treated with novel agents as part of induction therapy. The conditioning regimen consisted in HDM (100-200 mg/m2, depending on age and comorbidity) administered on day -2, and only for patients in the BOR-HDM group, a single-dose Bortezomib at the dosage of 1.3 mg/m2 on day -1. Stem cells were reinfused on day 0.
Results: Any significant difference was not observed between the two cohorts of MM patients analyzed regarding the median age at diagnosis (61 *vs* 59 years) and the dose of Melphalan. Distribution of ISS stage was similar in the

two groups, as well as that of high-risk cytogenetic or ultra high-risk features (ISS III plus high-risk cytogenetic). Moreover the response rates after the induction therapy was not statistically different in the two groups of patients analyzed. Any significant difference on hematopoietic recovery rates was not observed in BOR+HDM as compared to HDM alone, with a mean time to neutrophil recovery of 12 days (range 9-18) and to platelet recovery of 13 days (range 10-28) in both groups. BOR+HDM conditioning was well tolerated, with no increase of neuropathy occurrence. We then analyzed the response rate after ASCT, showing that the overall response rate was significantly higher in BOR-HDM group as compared to HDM (*P*=0.028) with a higher number of complete response (CR) (54% *vs* 17%). The number of stringent CR was also significantly higher in BOR-HDM as compared to HDM alone (3 *vs* 0).
Summary/Conclusions: In conclusion, this retrospective analysis suggests that BOR-HDM is safe as conditioning regimen with a higher response rate after ABMT in comparison to the standard HDM regimen, giving the rational design for randomized studies needed to assess whether this conditioning regimen is superior to HDM alone.

PB1967

OSTEONECROSIS OF THE JAW IN PATIENTS WITH MULTIPLE MYELOMA IN THE ERA OF MORE POTENT BISPHOSPHANATES
M Pavkovic[1,*], G Petrusevska[2], R Jovanovic[2], L Cadievski[1], O Karanfilski[1], S Genadieva-Stavric[1], L Cevreska[1], S Trpkovska-Terzieva[1], T Sotirova[1], A Stojanovic[1]
[1]Univeristy Clinic for Hematology, [2]Institute for Pathology, Medical Faculty, Skopje, Macedonia

Background: Long term use of bisphosphonates has been associated with increased incidence of osteonecrosis of the jaw (ONJ). ONJ is commonly precipitated by a tooth extraction or other stomatological procedure in patients treated with long term, potent, high dose intravenous bisphosphonates for the management of myeloma, breast or prostate cancer. ONJ is most commonly reported in patients with MM, but it can occur in all cancer patients treated with bisphosphonates for bone metastatic disease.
Aims: The aim of this study was to evaluate the incidence of ONJ in patients with myeloma treated with bisphosphonates during the last 11 years in our institution.
Methods: We have analyzed 422 patients diagnosed with multiple myeloma in our institution in the period of 2002-2013. Median age at diagnosis was 63 years (range: 36-91), median duration of myeloma was 3.9 years (3 months-14 years). Most common isotype of myeloma was IgG Isotype (62%) and almost 80% of patients had bone lesion at the time of diagnosis. Most common chemotherapy protocol was thalidomide based protocol with more than half of patients treated with thalidomide. Only 351/422 patients (83.2%) were treated with bisphosphonates.
Results: Incidence of ONJ in patients treated with bisphosphonates was 9/351 (2.6%). Median duration of bisphosphonates treatment was 28.5±19.4 months (range: 3-98 months). Most commonly used bisphosponate was i.v. pamidronate 175/351(49.8%), while 218/351 (62.1%) were treated with two or more types of bisphosphonates. Zolendronate was used in 79 patients (22.5%). 83 patients (23.6%) received oral forms of bisphosphonates; 56.2% patients were treated with i.v. forms of pamidronate, ibondronate, clodronate or zolendronate, and 85 patients (24.2%) received combination of oral and i.v. forms of bisphosphonates. Mean duration of bisphosphonates therapy was 33.8±21.7 months. When we compare the incidence of ONJ in the period before and after 2009 (year when we started to use zolendronic acid in the treatment of MM), we could notice a rise in the number of cases with ONJ. In the period 2002-2009 we have registered only 2/190 (1%) cases with ONJ comparing to 7/161(4,3%) patients with ONJ in the period 2009-2013. Despite the evident rise in the number of cases of ONJ in the era of more potent bisphsphonates, these difference was not significant (p=0.058).
Summary/Conclusions: The incidence of ONJ in our institution is similar to already referred incidence in other studies and it has become more common complication of bisphosphonate treatment since we have started to use more potent intravenous forms of bisphosphonates. High cumulative doses of bisphosphonates, type of used bisphosphonate, poor oral health, and dental extractions may be significant risk factors for ONJ development. Preventive measures like stomatological examination before bisphosphonates treatment and regular stomatological check-ups during bisphosphonates treatment must be considered.

Background: Pomalidomide in combination with low-dose dexamethasone (POM + LoDEX) has shown efficacy in patients with relapsed and refractory multiple myeloma (RRMM). In this patient population, POM + LoDEX prolonged progression-free survival (PFS) compared with POM alone (Richardson et al, *Blood,* 2014) and provided a PFS and overall survival (OS) benefit compared with high-dose DEX alone (San Miguel et al, *Lancet Oncol,* 2013), while demonstrating an acceptable safety profile. To evaluate the safety and efficacy of POM + LoDEX in Asian patients with RRMM, an additional study enrolling only Japanese patients was conducted.
Aims: This multicenter, single-arm, open-label phase 2 trial (MM-011) aimed to evaluate the efficacy and safety of POM + LoDEX in Japanese patients with RRMM.
Methods: Patients with progressive disease on or within 60 days of their last prior therapy and who had received ≥2 prior therapies, including ≥2 cycles of lenalidomide and of bortezomib (either separately or in combination) were included. Patients received oral POM 4 mg per day on days 1-21 and oral LoDEX 40 mg per day (20 mg if aged >75 years) on days 1, 8, 15, and 22, and the course was repeated every 28 days until disease progression, unacceptable toxicity, or withdrawal. The primary endpoint was overall response rate (ORR; ≥partial response) of POM + LoDEX according to the International Myeloma Working Group criteria. All pts provided written informed consent.
Results: Thirty-six patients were enrolled between December 2013 and July 2014 at 13 sites in Japan. The median age of patients was 64.5 years (range, 43-78 years); 11% were aged >75 years. Patients received a median of 6.5 prior anti-myeloma regimens (range, 2-15) and had a high tumor burden (81% had Durie-Salmon stage II or III disease). Thirty-five patients (97%) were refractory to lenalidomide, and 21 patients (58%) were refractory to both lenalidomide and bortezomib. At the data cutoff (February 3, 2015), 16 patients (44%) remained on treatment, and study drugs were discontinued in 20 patients due to disease progression (n=14 [39%]), adverse event (AE; n=2 [6%]), death (n=1 [3%]), and other reasons (n=3 [8%]). The ORR was 42% (n=15 [95% CI, 26% - 58%]), including complete response in 3% (n=1) and partial response in 39% (n=14) of patients. Median PFS was 10.1 months (median follow-up, 7.7 months), and at a data cutoff of September 25, 2015, 1-year OS was 58.5% (median follow-up, 11.3 months). In the 15 responders, median time to response was 1.9 months (range, 0.9-5.5 months), and median duration of response was not reached. The most common grade 3/4 hematologic AEs were neutropenia (n=23 [64%]), anemia (n=15 [42%]), and thrombocytopenia (n=11 [31%]). Pneumonia (n=3 [8%]) and decreased appetite (n=3 [8%]) were the most common grade 3/4 non-hematologic AEs. Peripheral neuropathy (all grades) occurred in 8% (n=3) of patients. No deep vein thrombosis or pulmonary embolism was reported. Overall, AEs were similar to those seen in other POM studies, and no new significant AEs were reported in patients in this study. Nine patients died on study (or within 28 days of the last dose of study drug), 8 due to multiple myeloma and 1 due to AE (pneumonia and aggravated asthma, suspected to be related to study drug).
Summary/Conclusions: POM + LoDEX is an effective treatment in heavily pretreated Japanese patients with RRMM, with an acceptable safety profile that is comparable to those seen on POM studies in RRMM in other regions.

PB1969

IMPACT OF ERYTHROPOIESIS STIMULATING AGENTS ON OVERALL SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA
S Ortiz Zuluaga[1,*], K Javier[1], C Villegas[1], MT Orero[1], M Roig[1], I Luna[1], M López[1], R Collado[2], D Ivars[2], PL Pérez[1]
[1]Hematology, [2]Hospital General Universitario de Valencia, Valencia, Spain

Background: Treatment with erythropoiesis stimulating agents (ESA) in oncologic patients remains controversial. Since 2007, the FDA has included the addition of a black box label warning and the implementation of a risk management program for ESA prescription. Regarding treatment with ESA in patients with multiple myeloma (MM), there are only three studies with discordant results.
Aims: The purpose of our study is to explore the impact of ESA on overall survival in a cohort of MM patients treated in our center.
Methods: Between 2002 and 2015, 212 patients were diagnosed of MM in our center. We excluded 55 patients: 23 patients with diagnosis of smoldering myeloma and 32 patients candidates for palliative care because of age and comorbidities. We collected demographic information, clinical and laboratory data, staging according International Score System (ISS), regimens of treatment, overall survival (OS) as well as information on erythropoietin use for all patients.

Results: One hundred and fifty five patients were included: 63 received recombinant human erythropoietin (rhEPO) at least 1 month. The median total dose was 440000 international units (IU) (range 40000-10920000). Patient's characteristics according EPO therapy are presented in table. Patients treated with rhEPO showed more advanced stages, higher creatinine levels and required hemodialysis more frequently. Nevertheless autologous stem cell transplantation was performed more frequently in non-EPO patients. There was no difference in first line therapy between rhEPO and non-EPO patients. The median OS in all patients was 31 months (CI95% 22.67-39.33) and we did not observe differences between EPO and non-EPO groups (35 *vs.* 31 months, Log Rank p=0.96). However, when looking at the influence of total EPO doses on outcome, we observed differences in OS between patients who received doses of EPO >400000 IU, *vs.* patients with lower doses or untreated (50 *vs.* 23 months, Log Rank p=0.047). Multivariate analysis (Cox Regression) showed, age, albumin, Beta 2 microglobulin and rhEPO doses as independent prognostic factors for OS.

Table 1.

	No rhEPO use	rhEPO use	p value
Patients:	94	63	
Age at diagnosis: median (range)	70 (33-89)	74 (36-87)	0.057*
Male/ Female	49 (51)/ 47 (49)	33 (54.1)/ 28 (45.9)	0.417**
Laboratory findings: median (range)			
Hemoglobin, g/dL	10.05 (4.7-15.7)	10.10 (6.7-14.1)	0.459*
Creatinine, mg/dL	1.11 (0.49-6.63)	2.21 (0.63-13.94)	0.0001*
Albumin, g/dL	3.55 (1.9-5.0)	3.5 (2.1-5.4)	0.647*
Beta-2 microglobulin mg/L	4.794 (1.140-36.247)	7.492 (1.955-48.960)	0.03*
ISS III, No., (%)	40 (41.7)	41 (67.2)	
Treatments: No., (%)			
Hemodialyzed patients	2 (2.1)	20 (32.8)	0.0001**
Autologous Stem Cell Transplant	15 (15.6)	3 (4.9)	0.043**
Melphalan-Prednisone (MP)	21 (21.9)	17 (27.8)	0,162***
Bortezomib Regimens	59 (61.5)	40 (65.6)	
Others Regimens	16 (16.7)	4 (6.6)	
Overall Survival: median (CI95%)	31 (20.58-41.42)	35 (18.61-51.39)	0.963 (Log-Rank test)

**UMW: U-Mann-Whitney, **Fisher test, ***Chi-square test*

Summary/Conclusions: The use of rhEPO does not have a negative effect in MM patients. Our study suggests that treatment with high doses of rhEPO could have a positive impact to improved OS. However, prospective randomized studies to confirm these data are required.

FDG-PET/CT IN MULTIPLE MYELOMA A CORRELATION OF SUV AND ISS SCORE

B Østergaard[1,*], AL Nielsen[2], O Gerke[2], JR Mortensen[1], JT Asmussen[3], TEJ Ormstrup[4], P Holdgaard[5], T Plesner[6], A Alavi[7], PF Høilund-Carlsen[2], N Abildgaard[1]

[1]Hematology, [2]Nuclear Medicine, [3]Radiology, Odense University Hospital, Odense C, [4]Nuclear Medicine, [5]Radiology, [6]Hematology, Vejle Hospital, Vejle, Denmark, [7]Nuclear Medicine, University of Pennsylvania, Pennsylvania, United States

Background: FDG-PET/CT is a promising methodology for staging, prognostication and response evaluation in multiple myeloma (MM). High intensity of FDG uptake measured as SUV (standard uptake value) at diagnosis is associated to more aggressive disease and reduced overall survival[1,2] However, it is unknown if the informative value is independent of other prognostic markers. 1) Bartel, T. B., *et al.* Blood 114.10 (2009): 2068-76. 2) Zamagni, E., *et al.* Blood 118.23 (2011): 5989-95.
Aims: We aimed to investigate the association of the intensity of FDG uptake in the most intense focal lesions and established prognostic markers in MM, including ISS and revised ISS (R-ISS).
Methods: As a part of a prospective study[3] with evaluation of new imaging technologies in MM we explored the first 35 included patients with treatment demanding MM. Patients were enrolled at diagnosis and studied with standardized baseline 18F-FDG-PET/CT prior to any given anti-myeloma treatment. Patients that had received steroids or bisphosphonates were excluded. Two experienced specialists, a nuclear medicine specialist (ANL) and a radiologist (JTA) evaluated the PET/CT. The lesion with the highest FDG uptake was described by a semi quantitative software ROVER for the values of lesion volume, SUVmax, SUVpeak, SUVmean and SUVmeancorr (SUVmean corrected for partial volume effects). Finally SUVmax was standardized to liver according to the Deauville criteria. Quantitative values were tested for correlation to prognostic indices ISS and revised ISS (R-ISS) using Kruskall Wallis test and Fischers exact test. STATA14 was used for analyses. 3) ClinicalTrials.cov. ID: NCT02187731
Results: One patient had incomplete ISS data. Thus 34 patients were included in the analysis. 19, 11 and 4 patients were stratified into ISS group I, II and III, respectively. 9, 24 and 1 patient were stratified into the revised ISS group R-ISS1, R-ISS2 and R-ISS3, respectively. SUVmax values were between 3.6Mbq/ml and 27.8Mbq/ml and lesion volumes between 0.9ml and 216ml. 6 patients had Deauville score 3, and 12 Deauville score 4, and 6 patients had Deauville score 5. FDG uptake (SUVmax) standardized to liver showed correlation to ISS (p=0.03) but not the R-ISS (p=0.85). Absolute SUVmax, SUVpeak, SUVmean, SUVmeancorr were not correlated to neither ISS nor R-ISS (p values (0.3-0.8).
Summary/Conclusions: 34 newly diagnosed MM patients were tested for association between FDG uptake values and the prognostic indices ISS and R-ISS. Only a marginal significant association between FDG uptake standardized to liver according to the Deauville criteria and ISS was observed. The use of FDG uptake values standardized to liver compensate for the general metabolic activity in the body and may therefore be more informative than absolute SUV values. Our cohort does not show a strong association between FDG SUV values and ISS or R-ISS, which may indicate that FDG PET offers prognostic information independent of R-ISS. At the meeting we will present an extended cohort. The association between FDG uptake values and prognostic factors in MM warrants further studies.

INFECTIONS IN MULTIPLE MYELOMA: AN UNDERSTIMATE RISK FACTOR OF COMORBIDITY

G Barila[*], N Compagno, A Liço, T Berno, F Cinetto, C Agostini, G Semenzato, R Zambello
Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, Padua, Italy

Background: Multiple myeloma (MM) represents the second most common haematological malignancy characterized by the proliferation of monoclonal plasma cells in the bone marrow. The natural history of the disease may be complicated by the occurrence of infections that can be related to the development of neutropenia (mostly therapy related) and/or hypogammaglobulinemia. Immunoglobulin (Ig) classes defect represents a major characteristic of this disease both in the indolent phase (smouldering MM, sMM), where immunoparesis constitute a risk factor for progression to active Myeloma according to the Spanish Group risk model, and in symptomatic Myeloma. Furthermore, this deficit can be worsen by concomitant chemotherapy.
Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM.
Methods: A cohort of 291 patients affected by MM (93 smouldering MM, 198 symptomatic MM) followed from 1996 to 2015 was retrospectively studied for the presence of severe infections (infections requiring hospitalization) during the natural history of the disease. Infections were distinguished in neutropenia related infections and not neutropenia related infections according to Absolute Neutrophil Count (ANC <1,000/µl or ANC>1,000/µl respectively). Durie-Salmon (DS) and ISS staging system were used for MM patients staging.
Results: Seventy-three out of 291 patients developed severe infections during the natural history of the disease (98 total events). The majority of these infections occurred in symptomatic MM patients (70 out of 73 patients with 93 out of 98 infections); as a consequence, infections were significantly associated to symptomatic MM ($p<0.001$, $\chi^2=34.76$). Among symptomatic patients, 40 patients (45 infections) developed infectious events at the time of the diagnosis and/or during induction therapy, while the other 30 patients (48 infectious events) received at least one prior therapy before the event. Interestingly, 26 events (28%) occurred in neutropenic patients while remnant 67 (72%) in not neutropenic patients. Furthermore, almost all neutropenia related infections were also therapy related (25/26, 96%), while almost 30% of neutropenia unrelated infections (20 out of 67) occurred in patients out of therapy. In particular, infections represented Myeloma defining event in 11 patients (12% of total infections, 16% of neutropenia unrelated infections). Thirty-nine of remnant 47 infectious events (83%) occurred in patients treated with novel agents with predominance of proteasome inhibitors based therapy with respect to IMIDs based therapy (26 *vs* 11), with 2 events occurring during combination therapy. DS stage III and ISS III were significant associated to severe infections (DS $p<0,05$, $\chi^2=5,5$; ISS $p<0,05$, $\chi^2=6,33$); furthermore, DS stage III and ISS stage III were statistically related to neutropenia unrelated infections ($p<0,05$, $\chi^2=6,3$), while there was no significant relationship to neutropenia related infections.
Summary/Conclusions: Severe infections represent a significant comorbidity in MM, in particular in symptomatic MM, while sMM patients are generally saved. Most of these type of infections involve not neutropenic patients characterized by high risk disease and developed during induction therapy. These results allow to stratify and to identify those patients who may eventually benefit from immunoglobulin supplementation.

PB1972

PREVALENCE OF OCULAR DISORDERS IN MULTIPLE MYELOMA

M Pennisi[1,*], L Berchicci[2], E Miserocchi[2], V Cacioppo[3], A David[3], A Scialdone[3], L Crucitti[1], I Lo Russo[4], G Modorati[2], V Montefusco[4], P Corradini[1,4]
[1]Dipartimento di Oncologia e Emato-Oncologia, Università degli Studi di Milano, [2]Dipartimento di Oculistica, Istituto Scientifico San Raffaele, Università Vita e Salute, [3]Dipartimento di oftalmologia, Fatebenefratelli e oftalmico, [4]Ematologia, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy

Background: Overall survival of multiple myeloma (MM) patients has increased significantly due to the availability of new drugs. However, since MM is an incurable disease, patients are exposed to repeated lines of therapy with different agents. It is therefore increasingly important to monitor the long-term side-effects of treatments. In the present study we focused on ocular disorders.

Aims: Assessing the prevalence of ocular disorders in patients treated or in follow-up for MM.
Methods: 87 symptomatic MM patients were enrolled in a prospective protocol which consisted in a complete ophtalmologic evaluation. Best corrected visual acuity (BCVA) was assessed; lens opacities were classified according to the LOCS III score; intraocular pressure was measured and was considered pathological if >21 mmHg; Schirmer test was pathological if <15 mm. Binary logistic regression analysis (univariate and multivariate) were conducted to relate ocular disorders to age, comorbidities (diabetes, hypertension, smoking, autoimmunity) and MM variables (time from diagnosis to last treatment and to ocular evaluation, cumulative dose of dexamethasone, exposure to lenalidomide, thalidomide, bortezomib and melphalan, previous autologous or allogeneic transplantation and graft-versus-host-disease).
Results: Median age was 63 years. Median number of previous lines of treatement was 2 (range 1-10). Median time from diagnosis to ophtalmologic evaluation was 37 months (range 2-160). Median cumulative dose of dexamethasone was 1600 mg (range 80-8480). Inadequate visual acuity was found in 35/71 pts (49%); severe visual loss (<20/40) was found in 13/71 pts (15%), 10 of which had pre-existing ocular history of lazy eye, myopia, pseudophakia, vitrectomy, retinitis pigmentosa and trauma. No relation was found with cumulative steroid dose, duration or type of treatment. Instead, age and history of hypertension resulted to be independent risk factors for visual impairment, also in multivariate analysis (age OR: 4.6 p=0.004; hypertension OR: 2.8 p=0.05). Retinal disorders (11%) were related to age and hypertension in multivariate analysis. Fifty percent of patients (44/87) had lens opacities of any grade: cataract was observed in 6/87 pts (7%), and in all cases was posterior subcapsular cataract LOCS III >/= 2; moderate lens opacities were observed in 32% pts (28/87), while 23% showed nuclear or concomitant nuclear/cortical opacities (LOCS III=2-3) and 9% posterior subcapsular opacities (LOCS III=1). Lens opacities related with age >63 years (OR: 4.0 p=0.009) and time from diagnosis >37 months (OR: 2.6 p=0.05) in multivariate analysis. No association was found with cumulative steroid dose or other drugs exposure. Only 1 patient showed elevated intraocular pressure. Inadequate tears production was observed in 52% pts (45/87), but no statistically association with treatments or comorbidities was observed.
Summary/Conclusions: Our study shows a high prevalence of visual impairment and early lens opacities in MM patients. We observed a higher prevalence of posterior subcapsular cataract compared to other cataract subtypes, unlike in the healthy population, probably due to the chronic systemic steroids exposure. A high prevalence of inadequate tear production was observed, as well. Interestingly, no significant increase in intraocular pressure was noticed, possibly because of chronic but pulse administration of steroids. Patients with hypertension show an increased risk of retinal disorders. We recommend an adequate ophthalmologist follow-up in treated MM patients.

PB1973

BENDAMUSTINE-BORTEZOMIB-DESAMETASONE (BVD) IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A REAL-LIFE EXPERIENCE

C Cerchione[1,*], L Catalano[1], AE Pareto[1], S Basile[1], L Marano[1], I Peluso[1], L Simeone[1], O Vitagliano[1], S Palmieri[2], F Ferrara[2], F Pane[1]
[1]Hematology, Ematologia e trapianto/au federico ii, [2]Hematology, AORN A.Cardarelli, Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, proved to be effective in relapsed, refractory and in new diagnosed Multiple Myeloma (MM).
Aims: It has been evaluated efficacy and tolerance of Bendamustine, in combination with bortezomib-dexamethasone (BVD) in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe. A regional retrospective real-life analysis of patients with rrMM who had been treated with BVD as salvage therapy has been performed.
Methods: 47 patients (25 M/22 F), with rrMM, median age at diagnosis 58.4 years (r. 36-82), median age at start of treatment 61.3 years (r.37-83) treated with several lines of treatments (median 6, r. 2-11), every refractory to all the drugs previously received (also Bortezomib), received BVD (Bendamustine 90 mg/sqm days 1,2; Bortezomib 1.3 mg/sqm days 1,4,8,11, Dexamethasone 20 mg days 1,2,4,5,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. ISS was equally distributed, and cytogenetic was evaluable in 9 patients, and in particular one del13q and one t(11;14). All the patients had previously been treated with schedule containing bortezomib and IMIDs, 90% of them with melphalan, 77% with cyclophosphamide, 34% with antracyclines and 30% had also received radiotherapy. 58% of them had undergone at least to a single auSCT. All patients were relapsed and refractory to last therapies received before BVD.
Results: Bendamustine was well tolerated, with grade 3 transfusion-dependent anemia in 29% of patients, and 41% grade 3 neutropenia (no ospedalization was required, no septic shocks were observed). No severe extrahematologic toxicity was observed, only grade 1 gastrointestinal side effect (nausea), treated by common antiemetic drugs. According to IMWG, after a median follow-up of 9 months (r.2-36), ORR was 57% (27/47: 2 CR, 3 VGPR, 14 PR, 8 MR) with 8 PD and 12 patients in SD, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 6 patients, BVD was, after having achieved a PR, a bridge to second auSCT, and for one patient a bridge to auSCT. Median time to response was 1.3 months (r.1-3), median OS from diagnosis was 61.4 months (range 6-151), median OS from start of Bendamustine was 9.3 months (range 2-36).
Summary/Conclusions: BVD has shown significant efficacy in a particular severe setting of patients, relapsed and refractory to all avaiable therapeutic resources, and in particular cases it could be considered as a bridge to a second autologous or allogenic BMT.

PB1974

SECOND MALIGNANCIES AND MULTIPLE MYELOMA. A SINGLE-INSTITUTION EXPERIENCE IN SPAIN

S Cerdá[*], B Ballina, V Martínez-Robles, N De Las Heras, Ja Rodriguez-Garcia, F Escalante
Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: Outcome of patients with Multiple Myeloma (MM) has improved significantly in the past decade. Therefore, the risk of developing second malignancies (SM) has become a relevant aspect to explore. Although the association of several treatments employed in this disease, such as alkylators, lenalidomide or radiotherapy and second malignancies is well known in the literature, subsequent neoplasms may also reflect the effect of other etiologic factors, host characteristics or environmental exposures. In previously reported series, MM patients with SM have consistently showed poorer prognosis.
Aims: Retrospective analysis of a cohort with a consistentof more than 15 years follow-up period.
Methods: We retrospectively analysed the incidence of SM in 296 consecutive patients with MM diagnosis in our institution between 1998 and 2014, focusing on epidemiological aspects as well as on survival analysis. Characteristics of patients: n=296. Gender: male/female: 172/124. Median age at MM diagnosis: 72 years (39-100).
Results: 44 different cancers in 43 patients (15%) were observed. They were mostly male (69.8%) *vs* female (30.2%) The median age at diagnosis was 73 years (46-94). Different neoplasms were separated in those appearing before or synchronously (n=27; 61%) *vs* after the MM diagnosis (n=17; 39%) with a mean developing time to the second malignancy of 67 (0-273) and 42 months (2-161) respectively. The majority presented solid tumors (n=39; 88.6%) in contrast to hematologic neoplasms (n=5; 11.4%). The largest group showed prostate (n=9), gynecologic (n=7), colorectal (n=6) and genitourinary (n=6) as more frequent types of cancer. Myelodysplastic Syndrome (MDS) represented 80% of patients with hematologic processes and typically appeared after the MM diagnosis. No acute leukemia was found in our series. The cumulative incidence of second cancers was 2.6% at 2 years, 10.4% at 5 years and 18.6% at 10 years. No differences were found in overall survival between MM patients with or without an associated second malignancy (p=0.23).
Summary/Conclusions: SM are a growing problem in cancer patients due to their larger survival. From our data, previous and solid neoplasms are most frequent than subsequent and hematologic neoplasms in MM patients. Further studies are necessary to assess the risk and etiology of SM in MM, although they seem not to represent a poorer outcome in terms of survival.

PB1975

A PHASE 2 TRIAL OF SMALL-DOSE BORTEZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (SVRD) AS CONSOLIDATION/MAINTENANCE THERAPY IN PATIENTS WITH MULTIPLE MYELOMA

T Sato[1], H Kuroda[2], Y Nagamachi[3], S Iyama[1], A Fujimi[4], Y Kamihara[1], Y Konuma[5], M Yoshida[1], S Ibata[1], A Tatekoshi[1], A Hashimoto[1], H Horiguchi[1], K Ono[1], K Murase[1], K Takada[1], K Miyanishi[1], M Kobune[1], Y Hirayama[6], J Kato[1,*]
[1]Department of Clinical Oncology and Hematology, Sapporo Medical University, School of Medicine, Sapporo, [2]Gastroenterology and Hematology/Clinical Oncology, Steel Memorial Muroran Hospital, Muroran, [3]Department of Hematology, Kiyota Hospital, Sapporo, [4]Department of Hematology and Oncology, Oji General Hospital, Tomakomai, [5]Department of Hematology and Oncology, Asahikawa Red Cross Hospital, Asahikawa, [6]Division of Internal Medicine, Higashi Sapporo Hospital, Sapporo, Japan

Background: Consolidation (two to four cycles of combination therapies) and maintenance (continuous therapy, usually with single agents, until the time of disease progression) are commonly used in clinical practice after induction therapy for patients with multiple myeloma (MM). There have been many trials to support the use of consolidation/maintenance to maintain the response achieved after autologous hematopoietic stem cell transplantation or conventional treatments and to improve patient survival with single agent or combination therapy. However, no definitive information is available regarding which drug or which combination of drugs is the most favorable for consolidation/maintenance. The combination therapy with bortezomib, lenalidomide and dexamethasone (VRD) is a powerful regimen for relapsed/refractory as well as newly

diagnosed MM as an induction therapy. However, severe adverse events (AEs) may become a problem when VRD is introduced without dose-reduction as a consolidation/maintenance therapy.
Aims: The aim of this multicenter, open-label, single-arm, phase 2 study was to determine the efficacy and safety of reduced-dose VRD regimen (small VRD: sVRD) in Japanese patients with MM in the consolidation/maintenance setting.
Methods: Eligible patients were age ≥20 and ≤80 years, with measurable symptomatic MM. Patients must have received at least 1 prior regimen and achieved at least a partial response (PR) by the International Myeloma Working Group (IMWG) Uniform Response Criteria. Patients received subcutaneous bortezomib (1.3 mg/m^2 on days 1 and 15), oral lenalidomide (10 mg on days 1-21) and oral dexamethasone (40 mg on days 1, 8, 15 and 22). The course was repeated every 4 weeks for 6 cycles. Patients with at least a PR at the end of cycle 6 could continue sVRD treatment. Patients discontinued therapy if they experienced progressive disease (PD) or unacceptable toxicity, if no more additional benefits could be expected, or if the patient/investigator decided to discontinue therapy for any reason.
Results: Sixteen patients were enrolled. All patients could complete 6 courses of sVRD treatment. The median duration of sVRD treatment was 8.0 courses (range, 6-28 courses), with 56.3% (n=9) and 25.0% (n=4) undergoing >6 and >12 cycles, respectively. The reasons for treatment discontinuation were completion of 6 courses (n=7, 43.8%), disease progression (n=3, 18.8%), secondary primary malignancies (SPM) of acute lymphoblastic leukemia (ALL) (n=1, 6.3%), AE of grade 2 pneumonia (n=1, 6.3%), or other (patient refusal or physician preference) (n=4, 25.0%). The overall response rate and the complete response (CR) rate were 100% and 43.8%, respectively. In particular, one patient with CR and two patients with very good PR (VGPR) at enrollment achieved stringent CR (sCR) during 6 courses of sVRD. In 9 patients with PR at enrollment, 1 achieved VGPR, but 8 remained in PR. Nevertheless, 2 out of 8 patients with PR after 6 courses of sVRD finally achieved VGPR or sCR after a total of 18 or 24 courses of sVRD, respectively. With a median follow-up time of 29.4 months, the median progression-free survival (PFS) and overall survival (OS) were not reached, while the PFS and OS rates at 2.5 years were 66.6% and 77.3%, respectively. Three patients died and their cause of death was disease progression in all cases. It is noteworthy that the three patients who discontinued sVRD treatment due to PD were the same three patients who died in spite of various post-study therapies. Univariate analysis demonstrated that disease progression as a reason for discontinuation of sVRD had a negative impact on OS. One dose modification of dexamethasone from 40 mg/day to 20 mg/day was required because of grade 2 hypertension after the 3rd course of sVRD. One patient had discontinued all study drugs because of grade 2 pneumonia after 6 courses of sVRD. There were no grade 3 or 4 hematologic or nonhematologic AEs. After enrollment, 2 new hematologic malignancies, *i.e.*, ALL in one patient and myelodysplastic syndrome (MDS) in another patient, were diagnosed.

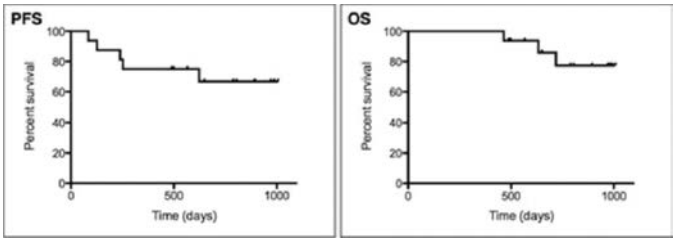

Figure 1.

Summary/Conclusions: Our sVRD regimen as a consolidation/maintenance therapy was well-tolerable and highly effective in patients with MM who achieved at least PR after any induction therapy. We conclude that the dosage of bortezomib and lenalidomide in our sVRD regimen may be able to reduce AEs and have preserved efficacy simultaneously in the consolidation/maintenance setting.

PB1976

BONE MARROW RETICULIN FIBROSIS AS A PROGNOSTIC MARKER IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED IN THE ERA OF NOVEL AGENTS

C Suriu[1,2,*], M Livne[2], V Sonkin[1], L Akria[1,2], M Barhoum[1], A Braester[1,2]
[1]Galilee Medical Center, Nahariа, [2]Faculty of Medicine in Galilee, Bar-Ilan University, Safed, Israel

Background: Different prognostic strategies are used in order to stratify newly diagnosed multiple myeloma (MM) patients at the time of diagnosis. The survival of MM patients has improved significantly in the last decade, attributed especially to the use of novel therapeutic agents (immunomodulatory drugs and proteosome inhibitors). Bone marrow (BM) biopsies from patients with MM at diagnosis may show different degrees of reticulin fibrosis, but its clinical significance is unclear.
Aims: To evaluate the prognostic impact of the BM reticulin fibrosis in our cohort of patients, treated in the era of novel agents.
Methods: We retrospectively reviewed the medical records of 51 patients treated between 2006 and 2014 at Galilee Medical Center, Nahariya, Israel. BM biopsies were graded for reticulin fibrosis (grades 0-3) based on the the European consensus report. Overall survival (OS) was measured from the time of diagnosis to the date of death or last follow-up. Progression free survial (PFS) was measured from the time of diagnosis to the date of progression or death. Univariate and multivariate survival analysis was performed using Cox Regression Model and Kaplan-Meier method with Log Rank (Mantel-Cox) test.
Results: 51 newly diagnosed MM patients were evaluated. The median age was 69 years (range: 47-88 years); 29 (56.9%) patients were male. The paraprotein type was: 28 (55%) IgG, 12 (23.5%) Light Chain and 9 (17.6%) IgA; 12 (24.5%) patients were ISS I, 12 (24.5%) were ISS II, 25 (51%) were ISS III. 31 (64.6%) patients were treated with chemotherapy, 12 (25%) were treated with chemotherapy followed by ASCT and 5 (10.4%) patients had conservative therapy. 41 patients (80.4%) were treated with novel agents at diagnosis. The median follow-up for the entire cohort after the diagnosis was 30.3 months (range 0.2-112.7 months). At the time of writing, 30 (58.8%) patients were living. For the statistic analysis we separated the patients into two groups: low grade fibrosis (grade 0-1) *versus* high grade fibrosis (grade 2-3). BM fibrosis characteristics did not differ significantly among patients with respect to age, sex, paraprotein type and albumin level. Patients with higher grade of fibrosis were more likely to have lower hemoglobin level (p=0.009), higher creatinine (p=0.007) and calcium level (p=0.008) with ISS III (p=0.002). Univariate analysis of overall survival (OS) showed that only age <65 (p=0.001), and treatment with novel agents (p=0.004) were significantly associated with better survival. Lower degree of fibrosis showed a tendency, not statistically significant for better survival: 72 mo *vs* 40 mo (p=0.14). On univariate analysis of PFS only lower grade of fibrosis was significantly associated with better survival (p=0.024) and a tendency for longer PFS with lower grade of fibrosis was seen in multivariate analysis of PFS (p=0.064). In subgroup analysis for patients treated with novel agents lower degree of fibrosis was still statistically significant for PFS (p=0.02).
Summary/Conclusions: In our cohort of patients, the degree of fibrosis was statistically significant for survival of MM patients, especially for PFS. This survival benefit is seen also in patients treated with novel agents. These results confirm that examination of the grade of fibrosis of the bone marrow at time of diagnosis of MM patients can provide better prognostic significance. These results should be validated in other cohorts.

PB1977

LEPTOMENINGEAL MYELOMATOSIS-A RARE COMPLICATION IN MULTIPLE MYELOMA

M Bommer[1,*], J Krönke[2], M Kull[2], D Bunjes[2], P Schwarzwälder[2], V Teleanu[2], C Langer[2]
[1]Hematology, Oncology and Infectious diseases, Alb-Fils Kliniken Göppingen, Göppingen, [2]Hematology, Oncology, Rheumatology and Infectious diseases, University of Ulm, Ulm, Germany

Background: Involvement of the central nervous (CNS) system in patients with Multiple Myeloma (MM) is a rare event, occuring mostly during late stage of disease. However, there are reports about an increasing incidence of extramedullary myeloma manifestations since the introduction of so called novel agents.
Aims: We therefore tried to optimize the diagnostic workup in patients with suspected neoplastic meningitis of Multiple Myeloma - so called leptomenigeal myelomatosis (LMM)-by incorporating different techniques.
Methods: Between 04/2005 and 10/2013 we identified 15 cases with CNS-MM. The involvement was confirmed by magnetic resonance imaging (MRI), cerebrospinal fluid cytology as well as by flow cytometry. Additionally, cIg-FISH and DNA probes mapping to chromosome bands 1q21.2, 9q34, 13q14, 14q32, 17p13, and 22q11 were applied to 4 of the 15 cases. In one case, high-resolution genome-wide screening for genetic alterations using SNP-array analysis (Affymetrix Microarray Human Genome SNP 6.0) was performed on the CNS involvement as well as on the corresponding bone marrow (BM) aspirate.
Results: The median time from initial diagnosis until the occurrence of LMM was 463 days. Only two patients presented with CNS manifestation within 180 days after initial diagnosis. Seven patients were diagnosed at late stage of disease e.g. after high dose melphalan treatment. At diagnosis of LMM, the median age was 59 years. The median cell count in the cerebrospinal fluid was 21/µl (Range 1/µl -1333/µl). All CSF samples showed malignant pleocytosis, confirmed by flow cytometry in 12/15 patients. cIg-FISH presented cytogenetically defined high risk features in all samples tested: 3 of 4 patients showed a translocation t(4;14), one patient had a 17p13 deletion. Using high-resolution genome-wide screening assays revealed different subclones at the two clinical sites (CSF, BM). Treatment for LMM consisted of intrathecal chemotherapy (9 of 15 cases) and radiation therapy (7 of 15 cases). Despite treatment, the outcome of patients with confirmed LMM was dismal with a median overall survival after diagnosis of LMM of 69 days. Only one patient survived longer than 2 years after diagnosis of CNS involvement.
Summary/Conclusions: By combining several technical procedures (MRI, cytology, flow cytometry, cIg-FISH and SNP-array analysis) it is possible to

identify the vast majority of patients with LMM. However, management of affected patients remains challenging and the survival is generally short after diagnosis of LMM.

PB1978

A PHARMACOKINETICS CLINICAL STUDY OF BORTEZOMIB SUBCUTANEOUS INJECTION VERSUS INTRAVENOUS INJECTION COMBINED WITH CHEMOTHERAPY IN CHINESE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA-INTERIM RESULTS

C Fu[1,*], D Wu[1],xZhu[1], S Jin[1], L Yan[1], S Yan[1], P Wang[1], Y Ge[2], M Chang[2]
[1]Hematology, [2]First Affiliated Hospital of Soochow University, Suzhou, China

Background: Bortezomib was licensed for administration as a bolus i.v. injection. This route of administration has demonstrated efficacy and safety in previously untreated patients with multiple myeloma (MM). However, the i.v. route can be a potential barrier to treatment for patients with poor venous access and limits prescribing flexibility. Subcutaneous (SC) administration of bortezomib showed the advantage in safety and comparable efficacy compared with IV administration.
Aims: However, there is no PK data of bortezomib SC administration for Chinese patients. Our trial was to investigate the pharmacokinetics of the two routes of administration in Chinese population. Demographic and baseline characteristic, pharmacokinetics and safety data till the first VD treatment completion were reported here. (ClinicalTrial.gov Identifier: NCT01812096)
Methods: This was a randomized, single-center, open-label study. The study included the following 4 sections: screening, VD regimen therapy (blood samples collection for PK analysis), extended treatment period (PAD regimen and/or subsequent ASCT) and follow-up period. 20 patients were determined to be randomly assigned in a 1:1 ratio to receive bortezomib subcutaneous or intravenous administration combined with chemotherapy. SC or IV bortezomib was administered at 1.3mg/m2, d1, 4, 8, 11, combined with dexamethasone (10 mg, bid, i.v., d1~2, 4~5, 8~9, 11~12) in the 1st cycle, every 21days, following 2-4th cycles of PAD regimen, bortezomib was SC or IV administered at 1.3mg/m2 on d1, 4, 8, 11; Doxorubicin 40 mg/m2, i.v.d1; Dexamethasone (Dex) 10 mg, bid, i.v., d1~2, 4~5, 8~9, 11~12;.every 28 days. Patients who were eligible for transplant underwent ASCT after the 4th cycle. Patients who were not eligible for transplant continued the 5-6th cycle treatment of PAD regimen. The blood samples for pharmacokinetics analysis were collected at the 15 time points d1, 11-14 of the first VD treatment. Patients had maximum 6 months follow-up after completing or terminating the treatment.
Results: From September 2014 to June 2015, 21 patients (10 patients in SC group and 11 in IV group) were enrolled in our study. 18 patients (10 in SC group and 8 in IV group) enrolled in the pharmacokinetic analysis. Median age in SC group was 56.8 yrs and 57.5 yrs in IV group. 81.82% patients had IgG isotype in the IV group and 40.00% patients had IgA isotype in the SC group. A Higher proportion patient had light chain isotype (20.00%) in the SC group. The median accumulative dose of bortezomib in VD treatment was much the same in each group. Mean maximum plasma concentration (Cmax) was 46.56ng/ml in SC group and 182.45ng/ml in IV group. Median time to Cmax (Tmax) was longer in SC group (0.25 h) than in IV group (0.03h). Mean bortezomib systemic exposure (AUClast) was similar between SC injection and IV administration (234.83vs266.75). Inter-patient variability in Cmax (percent coefficient of variations) was 24.76 in SC group and 30.79 in IV group. Treatment related TEAEs were reported in 7 of 10 patients (70%) in SC group and 9 of 11(81.82%) in IV group. Treatment related Grade≥3 TEAEs were reported in 2 of 10 patients (20%) in SC group and 3 of 11 patients (27.27%) in IV group. TEAE leading to drug discontinuation was only reported in 1 of 11 patients (9.09%) in IV group. No Serious TEAE was reported in either group. The incidence of neutropenia was higher in IV group.
Summary/Conclusions: In conclusion, our interim data suggest that SC administration is a promising alternative to IV administration. The efficacy and safety information will be further presented in the final results.
Acknowledgments: This study was funded by Xi'an Janssen Pharmaceutical Co, Ltd.

PB1979

CHEMOTHERAPY ADHERENCE IS FAVORABLE PROGNOSTIC FACTOR FOR ELDERLY PATIENTS WITH MULTIPLE MYELOMA WHO TREATED WITH FRONTLINE BORTEZOMIB CONTAINING REGIMEN

JH Moon[1,*], JY Kim[1], YJ Lee[1], SK Sohn[1], HS Lee[2], YS Kim[2], WS Lee[3]
[1]Hematology/Oncology, Kyungpook National University Hospital, Deagu, [2]Hematology/Oncology, Kosin University Gospel Hospital, [3]Hematology/Oncology, Inje University Pusan Baik Hospital, Pusan, Korea, Republic Of

Background: Elderly patients with multiple myeloma (MM) are vulnerable to adverse events and the patients' treatment goal may be different from young patients. For elderly patients with MM, the toxicity of bortezomib (BTZ)-based regimen causes frequent dose reduction and interruption of BTZ which could result in poor outcomes.
Aims: This study evaluated the adherence to chemotherapy and treatment outcomes for elderly patients who treated with frontline BTZ containing regimen and non-BTZ containing regimens.
Methods: This study retrospectively analyzed the outcomes of 146 elderly patients (≥65 years) with MM diagnosed from 2007 Mar to 2015 Mar. To evaluate the regimen adherence, the patients who treated with more than 4 cycles were regarded as favorable adherence group and the others as unfavorable adherence group. The effects of toxicity on the adherence to frontline regimen and long term outcomes were also evaluated in the current study.
Results: Among 146 patients, frontline therapy was VMP in 77 patients (52.7%), MP in 50 (34.2%) and CTD in 19 (13.0%). Median age at diagnosis was 70 years (range 65-90 years) and 85 patients (58.2%) were over 70 years old. ECOG performance status showed 2-4 in 49 patients (33.6%). ISS risk groups were stage I in 14 patients (9.6%), II in 64 (43.8%), and III in 68 (46.6%). Median cycles of frontline regimens were 5 cycles (range 1-9 cycles) with VMP and 6 cycles (range 1-77 cycles) with non-BTZ containing regimens (p=0.032). Maximal treatment response was ≥VGPR in 40 patients (51.9%) and 13 (18.8%) in VMP regimen and non-BTZ regimens, respectively (p<0.001). Regimen adherence was favorable in 49 patients (63.6%) and 52 (75.4%) in frontline VMP regimen and non-BTZ regimens, respectively (p=0.126). Major cause of non-adherence was side effects in VMP, while poor response and regimen change were major causes of non-adherence in non-BTZ regimens. Despite poor response to frontline chemotherapy in non-BTZ regimens, 3-year overall survival (OS) rate was not significantly different compared to frontline VMP regimen: 65.3±8.2% and 47.9±7.8% in VMP and non-BTZ regimens (p=0.159) because all the patients who showed poor response to frontline therapy received second-line BTZ containing regimens. However, among the patients with frontline VMP regimen, those with good adherence to chemotherapy resulted in better 3-year OS rate than those with poor adherence: 72.4±9.7% and 52.6±13.2% (p=0.002). In the multivariate analysis, ECOG performance status 2-4 (HR 3.409, 95% CI 1.133-10.261, p=0.029) and non-adherence to chemotherapy (HR 4.896, 95% CI 1.617-14.829, p=0.005) were poor prognostic factors for OS.
Summary/Conclusions: Frontline BTZ-containing regimen showed higher response rate than non-BTZ regimens and good adherence was associated with favorable long-term outcomes. However, regimen adherence was compromized for high incidence of adverse effects with BTZ-contaiing regimen. Therefore, understanding the risk of toxicities and adequate management of side effects needed to have favorable outcomes for the patients with BTZ containing regimen.

PB1980

PROGNOSTIC SIGNIFICANCE OF EXPRESSION OF MULTIDRUG RESISTANCE GENES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED WITH BORTEZOMIB-CONTEINING THERAPHY

Y Chernykh[*], A Golenkov, L Vysotskaya, K Belousov
Clinical haematology, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation

Background: Most drugs used to treat multiple myeloma, are substrates for protein multi-drug resistance. Their effectiveness is reduced in cells with increased expression of genes encoding these proteins. The proteasome inhibitor bortezomib is not a substrate for protein P-gp, encoded by MDR 1 gene.
Aims: The aim of our study was to examine the prognostic significance of the alternative (non-P-gp dependent) mechanisms of multidrug resistance (MDR) in the bone marrow aspirate in patients with newly diagnosed multiple myeloma (MM).
Methods: The study included 15 patients (6 men and 9 women) with established diagnosis of multiple myeloma stage III by Durie□Salmon system. The age of patients ranged from 50 to 78 years. The mRNA expression of MDR genes, 1 MRP, BCRP, LRP was determined by semi-quantitative RT-PCR in mononuclear fraction of the bone marrow aspirate. Numeric value corresponding to the amount of mRNA expression of each studied gene, represented as the ratio of the numerical values of the mRNA expression of each gene to a numeric value of mRNA expression of the gene GAPDH. All patients subsequently received treatment with bortezomib-containing chemotherapy schemes in the amount of 6 courses.
Results: Although the patients had not received cytostatic therapy, detected mRNA expression of all studied genes MDR. The average number of MDR gene transcripts was 1.7±0,24, MRP 1 1±0,14, BCPR 1,04±0,22, LRP 1,47±0,17 points. Because previous studies have shown that the proteasome inhibitor bortezomib is a basic drug for the treatment of MM is not a substrate of P-gp, the analysis of survival in subgroups of patients with the number of LRP gene transcripts above and below the mean. Overall survival of patients with increased expression of the gene was significantly worse than that of whom with reduced expression of LRP (17,1±3,65 *vs* 53, 9±10 months, P<0.005).
Summary/Conclusions: Increased expression of LRP gene exert a poor survival of patients with multiple myeloma for cytostatic treatment, the bortezomib containing chemotherapy programs.

THE STRATUS TRIAL (MM-010): ANALYSIS OF THE ITALIAN SUBGROUP OF PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA TREATED WITH POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE

M Cavo[1,*], P Corradini[2], F Di Raimondo[3], A Vacca[4], M Petrini[5], AM Cafro[6], T Caravita di Toritto[7], M Offidani[8], G Semenzato[9], R Zambello[10], A Lazzaro[11], F Patriarca[12], MT Petrucci[13], F Rodeghiero[14], M Simcock[15], A Slaughter[15], J Herring[16], T Peluso[15], A Palumbo[17]
[1]Seràgnoli Institute of Hematology, Bologna University School of Medicine, Bologna, [2]IRCCS Istituto Nazionale Tumori University of Milan, Milan, [3]Department of Hematology, University of Catania, Catania, [4]Department of Internal Medicine and Clinical Oncology, University of Bari Medical School, Bari, [5]Santa Chiara Hospital University of Pisa, Pisa, [6]Niguarda Ca' Granda Hospital, Milan, [7]Division of Hematology, S.Eugenio Hospital, Rome, [8]Clinica di Ematologia, AOU Ospedali Riuniti di Ancona, Ancona, [9]Venetian Institute of Molecular Medicine, [10]Department of Medicine, University of Padua, Padua, [11]Hematology Unit and Bone Marrow Transplant Centre, Hospital of Piacenza, Piacenza, [12]Hematology DISM, University of Udine, Udine, [13]Hematology Department, Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, [14]San Bortolo Hospital, Vincenza, Italy, [15]Celgene International Sàrl, Boudry, Switzerland, [16]Celgene Corporation, Summit, NJ, United States, [17]University of Torino, Torino, Italy

Background: There are few treatment (Tx) options and overall survival (OS) is short for patient (pts) with relapsed/refractory multiple myeloma (RRMM) who have failed or progressed on Tx with agents such as lenalidomide (LEN) and bortezomib (BORT) (Kumar et al, *Leukemia*, 2012). Pomalidomide (POM), a distinct immunomodulatory agent with tumoricidal and immunoregulatory effects, plus low-dose dexamethasone (LoDEX) is approved in the United States and European Union (EU) for the Tx of pts with RRMM who have had ≥2 prior Tx, including LEN and a proteasome inhibitor (BORT in the EU). Tx with POM + LoDEX has shown statistically greater survival benefits than Tx with high-dose DEX (San Miguel et al, *Lancet Oncol,* 2013) or POM alone (Richardson et al, *Blood,* 2014). POM + LoDEX has also demonstrated high overall response rates (ORRs) in pts with RRMM in the STRATUS trial (MM-010), a single-arm, open-label phase 3b study being conducted in 19 countries across Europe, with Italian pts constituting the largest national subset (Dimopoulos et al, EHA 2015).
Aims: To examine the efficacy and safety of POM + LoDEX in the Italian population of the STRATUS trial.
Methods: Pts with RRMM (progressive disease [PD] on or within 60 days of last prior Tx) who had experienced Tx failure with BORT and LEN, had received adequate prior alkylator therapy, and provided informed consent were eligible. Pts received POM 4 mg on days 1-21 of a 28-day cycle in combination with DEX 40 mg (20 mg for pts aged >75 yrs) on days 1, 8, 15, and 22. Thromboprophylaxis was required for all pts. Pts were treated until PD or unacceptable toxicity. Primary endpoint was safety.
Results: In the 219 pts enrolled in Italy, median age was 67 yrs (range, 42-84 yrs), 55% were male, and 37% of pts were International Staging System stage III. The median time since diagnosis was 5.5 yrs. Patients were heavily pretreated, with a median of 4 prior anti-myeloma regimens (range, 2-11), and most pts were refractory to LEN (95%), BORT (82%), or both LEN and BORT (78%). As of May 4, 2015, 2 pts (1%) were not treated, 54 pts (25%) were still on Tx, and 163 pts (74%) had discontinued. The most common reasons for discontinuation were disease progression (50%), death (10%), and adverse events (AEs; 5%). After a median follow-up of 11.3 mos, in the intention-to-treat population, the ORR was 37.9% (range, 31.4% - 44.7%), the median duration of response was 6.8 mos (95% CI, 4.9-10.8 mos), median progression-free survival (PFS) was 5.2 mos (95% CI, 4.4-6.4 mos), and median OS was 12.0 mos (95% CI, 10.6-15.2 mos). The most frequent grade 3/4 treatment-emergent AEs were neutropenia (56.7%), anemia (25.8%), thrombocytopenia (23.5%), and pneumonia (12.4%). Grade 3/4 venous thromboembolism (deep vein thrombosis and pulmonary embolism) and peripheral neuropathy was infrequent (2.3% and 0%, respectively). AEs led to dose reductions or interruptions of POM in 23.0% and 71.0% of pts, respectively, and the median relative dose intensity for POM was 0.90.
Summary/Conclusions: POM + LoDEX was active in this study subgroup, which was representative of the heavily pretreated MM-010 population. Efficacy outcomes, including PFS and OS, were consistent with those seen in previous trials. POM + LoDEX treatment was well tolerated, and no new safety signals were observed. AEs were appropriately managed, and discontinuations due to AEs were infrequent. This study confirms that POM + LoDEX is effective in patients with advanced RRMM, including those who have experienced failure of prior Tx with BORT and/or LEN.

PB1982

RISK OF HYPERTENSION (HTN) AND MALIGNANT HYPERTENSION (MHTN) IN PATIENTS TREATED FOR MULTIPLE MYELOMA (MM)

K Mezzi[1], A Chari[2,*], S Aggarwal[1], S Zhu[1], W Werther[1], D Felici[3], A Lyon[4]
[1]Amgen Inc., South San Francisco, [2]Mount Sinai Hospital Ruttenberg Treatment Center, New York, [3]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, United States, [4]NIHR Cardiovascular Biomedical Research Unit, Royal Brompton Hospital and Imperial College London, London, United Kingdom

Background: HTN is commonly reported in patients (Pts) with MM and may be associated with older age, disease-related complications, or sequelae of MM treatments.
Aims: To evaluate incidence rates (IR) of HTN and mHTN in treated MM Pts in the United States and the risk of mHTN development in MM Pts with pre-existing HTN.
Methods: Newly-treated adult MM Pts were identified from Truven MarketScan claims database from 1/1/05 to 3/31/14 using ICD-9 codes to identify disease state, HTN, mHTN, and comorbidities. Inclusion criteria were new diagnosis of MM with start of MM treatment, ≥12 months continuous enrollment (CE) prior to diagnosis, prescription drug coverage, and ≥30 days of CE following initial diagnosis. Non-MM Pts were matched on age (within+/-5 yrs), gender, and distribution of index dates to MM Pts. Risk of HTN and mHTN based on existing HTN and other cardiovascular (CV) comorbidities were evaluated over time.
Results: Study included 7895 MM Pts (38% with HTN history) and 23685 non-MM patients (24% HTN history). The IR of HTN in MM and non-MM Pts was 260 and 178 per 1000 person-years (PYRs), respectively. The IR of mHTN in Pts with and without HTN history were 10.25 and 3.29 per 1000 PYRs, respectively for MM patients; 4.25 and 1.88 per 1000 PYRs, respectively for non-MM Pts. Risk of HTN (HR: 1.30; 95% CI: 1.22, 1.37) increased 30% in MM *vs* non-MM Pts. MM Pts with (HR: 1.90; 95% CI: 1.26, 2.87) or without (HR: 1.54; 95% CI: 1.04, 2.28) HTN history had a higher risk of mHTN events during the observation period *vs* non-MM Pts. In MM Pts with HTN history, the risk of mHTN was significantly increased with the following comorbid conditions: cardiomyopathy (HR: 2.79; 95% CI: 1.20, 6.48), renal failure (HR: 2.13; 95% CI: 1.36, 3.34), and diabetes mellitus (HR: 1.59; 95% CI: 1.05, 2.39).
Summary/Conclusions: This study confirms that incidence of HTN and mHTN is higher in newly-treated MM Pts *vs* non-MM Pts. Existing HTN is a risk factor for MM Pts developing mHTN. Management of CV risk factors and comorbidities in MM Pts is important based on the increased risk of HTN and mHTN among these Pts.

PB1983

DIARRHEA INCIDENCE IN MULTIPLE MYELOMA PATIENTS TREATED WITH LENALIDOMIDE AND POMALIDOMIDE

M Capecchi[*], P Corradini, V Montefusco
Ematologia Trapianto di Midollo Osseo, Istituto Nazionale dei Tumori, Milano, Italy

Background: Daily clinical practice in hematology is increasingly relying on novel biological drugs, with new toxicity profiles that hematologists should learn to manage. Immunomodulatory drugs (IMiDs) have a pivotal role in the treatment of multiple myeloma (MM), and are typically administered as a continuous treatment. Thalidomide is a well know constipation-inducing agent. On the contrary, physicians are aware that lenalidomide (Len) may induce gastrointestinal (GI) disorders, in particular diarrhea, but little is known of this side effect. Moreover, no specific data on GI side effects are reported on the third-generation IMiD Pomalidomide (Poma).
Aims: Description of incidence and management of diarrhea in a retrospective cohort of Len- or Poma-treated MM patients.
Methods: One hundred and twenty-six consecutive Len-treated, and 59 Poma-treated MM patients were retrospectively analyzed in terms of diarrhea occurrence. In this analysis we included Len patients consecutively treated from June 2005 to December 2015, and Poma patients consecutively treated from August 2010 to September 2015. A descriptive analysis of diarrhea incidence, onset time, and response to treatments was performed.
Results: The median age of the 126 Len-treated patients was 65 years (range 35-87); 57 (45%) received one or two autologous stem cell transplants, and 12 (10%) patients received an allogeneic stem cell transplant before Len start; 55 (44%) patients received Len as a first line therapy, 32 (25%) patients as a second line therapy, and 39 (31%) as third or subsequent line of therapy. Thirty (24%) patients had diarrhea during Len treatment. Among these patients, 27 (90%) had grade 1 diarrhea, 3 (10%) patients had grade 2 diarrhea, and no patients had grade 3 or more diarrhea. Seventeen (53%) patients had abdominal cramps and 2 (6%) patients had rectal tenesmus. Diarrhea occurred at a median of 10 cycles. Almost all patients (29, 97%) had a correlation of diarrhoeic episodes with assumption of food, and most patients (24, 80%) reported persistent diarrhea during the rest period. Since some patients reported a worsening of diarrhea associated to fat consumption, 14 patients were advised to avoid diary products, and in 9 of them (64%) a benefit was observed. Loperamide was used in all cases, and 19 (63%) patients had a reduction of symptoms. Eleven (37%) patients had a poor control with loperamide and were treated with cholestyramine, which was effective in all cases. Nine (30%) patients had Len dose reduction, and 5 had a reduction of the diarrhea. In 19 cases Len was stopped, resulting in the rapid resolution of diarrhea in all cases. The same analysis conducted in 57 Poma-treated patients did not show any GI symptoms.
Summary/Conclusions: Adverse GI events are common in new targeted

drugs, and a better understanding of the underlying physiopathological mechanism is the basis for a correct management. In particular, IMiDs have a gastrointestinal toxicity profile with peculiar characteristics for the different generations. The first-generation IMiD Thalidomide is well known to be associated with constipation, sometimes very severe. The second-generation IMiD Len has an opposed GI toxicity profile, characterized by diarrhea. In our study diarrhea is mainly mild, but still quite disturbing. However, it seems that a combination of dietary counselling, along with loperamide and cholestyramine treatment may control this symptom. On the other side, we confirm that Poma doesn't have relevant GI side effects.

PB1984

TRABECULAR BONE SCORE (TBS) AND DEVELOPMENT OF FRACTURE IN MULTIPLE MYELOMA

EM Lee[1,*], YS Kim[1,2], HS Lee[1], LC Park[1], DJ Kim[1], JH Choi[1]
[1]Internal medicine, [2]Kosin Gaspel University of Hospital, Busan, Korea, Republic Of

Background: Osteolytic bone lesions are common complications in patients with multiple myeloma, and have impact on the quality of life because of the risk of fractures. Trabecular bone score (TBS) is a novel texture index derived from dual energy X-ray absorptiometry (DXA) of lumbar spine images, providing information of bone microarchitecture independent of bone mineral density.
Aims: The aim of this study was to test if TBS may be useful to predict bone fractures in patients with multiple myeloma.
Methods: TBS was calculated retrospectively from existing DXA images of the lumbar spine, in 20 patients with newly diagnosed multiple myeloma. We analyzed the development of fractures in these patients.
Results: The median age of the patients was 66 years (range, 49-77), and 15 patients (75%) were female. Fifteen patients had osteopenia (5 patients, 25%) or osteoporosis (10 patients, 50%) by using DXA. Osteolytic bone lesions were observed in 18 patients (90%) at the time of diagnosis. The median duration of follow-up was 31.9 months (95% CI, 20.1-43.7 months), 6 events (long-bone fractures in 5 events, vertebral fracture in 1) of fracture were occurred in 5 patients (25%). The mean TBS of lumbar spine (L1-4) in patients who experienced development of fractures (1.162±0.032 [95% CI, 1.122-1.201]) was lower than patients who did not (1.255±0.154 [95% CI, 1.170-1.3]), however, there was no statistical significance (p=0.061). Among TBS of individual lumbar spines, L2 showed significantly lower score in patient who experienced development of fractures (1.135±0.085 [95% CI, 1.030-1.241] *vs* 1.243±0.169 [95% CI, 1.149-1.336], p=0.032).
Summary/Conclusions: TBS of lumbar spine in patients with multiple myeloma could be helpful to predict development of fractures, however, further investigations are needed.

PB1985

BORTEZOMIB MAINTENANCE TREATMENT IN PATIENTS WITH MULTIPLE MYELOMA-A SINGLE CENTER EXPERIENCE

I Micheva*, S Dimitrova, R Rachev, H Varbanov, M Mehmed, V Gerov, A Antonov, L Gercheva
Haematology, University Hospital, Varna, Bulgaria

Background: The long-term maintenance therapy in multiple myeloma (MM) after definitive therapy may prolong remission and delay relapse. Bortezomib has been used as post-autologous stem-cell transplantation (ASCT) consolidation therapy. Other trials have investigated Bortezomib maintenance for ASCT patients, and for those who are ASCT ineligible.
Aims: To define the role of Bortezomib maintenance therapy (MT) in patients with MM after achieving complete response (CR) or very good partial response (VGPR).
Methods: 37 patients with newly diagnosed symptomatic MM with CR or VGPR after Bortezomib based induction regiments were included in the analysis. 23 patients received MT with Bortezomib 1.3 mg/m^2 once every 2 weeks. 14 patients remained on follow up until progression.
Results: 19 of the patients were men and 18 women with median of age 64,2 years. 11 cases were with IgA myeloma, 20 with IgG, and 6 with light chain myeloma. According to ISS 10 patients were in stage I, 7 in stage II, and 20 in stage III. CR was achieved in 13 (56,5%) of the patients in MT group and in 6 (42,8%) in the group on follow up. Total of 14 patients underwent ASCT - 10 (43,4%) from the patients on MT and 4 (28,5%) on follow up. After a median follow up of 31.8 months (range, 10-65 months) none of the patients on Bortezomibe MT progressed. In contrast, in the patients group on follow up, 12 from 14 patients progressed within median time of 24,17 months (range, 7-60 months). No correlation was found between the progression and myeloma type, ISS stage, type of response and ASCT.
Summary/Conclusions: Our results reveal undoubtedly the impotence of Bortesomib maintenance in patients achieved CR or VGPR.

PB1986

RELAPSED AND REFRACTORY MULTIPLE MYELOMA, EVOLUTION AND COMPLICATIONS SINGLE CENTER EXPERIENCE

I Ionita[1], L Cheveresan[1], M Iordache[1], D Calamar[1], C Ionita[2], D Oros[1], M Ionita[3], H Ionita[1,*]
[1]Hematology, [2]Surgery, [3]Internal Medicine, University of Medicine and Farmacy Victor Babes Timisoara, Timisoara, Romania

Background: Multiple myeloma (MM) is a malignant plasma cell disorder. It is the second most frequent haematological malignancy and characterized by malignant plasma infiltration or the bone marrow and is associated with an increased level of monoclonal protein in the blood and/or urine. The treatment of MM has undergone significant developments in recent years, and the new agents with potent anti tumor activity has considerably improved the survival of MM patients.
Aims: Retrospective evaluation of the therapeutic results, the evolution and complications of therapy with bortezomib, doxorubicin and dexamethasone (PAD) in the treatment of relapsed/refractory myeloma patients.
Methods: 62 patients were treated for median of four 28-day PAD cycles (1-8). Bortezomib was given at 1.3 mg/m2 (days 1, 4, 8,11), doxorubicin at 9 mg/m2 (days 1-4) and dexamethasone 20 mg p.o. (days 1-4, 8-11).
Results: 62 patients were evaluable for efficacy, 59% had refractory disease and 41% were relapsed. The median age was 65 years (37-80), 59% were male, 41% female. Serum protein electrophoresis revealed a localized band in 74% of patients, and immunoelectrophoresis or immunofixation showed a monoclonal protein in 85%. A monoclonal light-chain was found in the urine in 63%. Non-secretory myeloma was recognized in 3% of patients, whereas light-chain myeloma was present in 16%. Serum albumin less than 3mg/dl was found in 58% of patients. Conventional radiographs showed an abnormality in 81%. Median time from diagnosis was 16 months (2-115) and median number of prior therapy lines was 2 (1-5).Overall response rate of 58% was observed, 28% of patients achieved a complete response (CR), 22% a very good partial response (VGPR), 30% a partial response (PR). Stable disease (SD) was observed in 20%. The median progression free survival (PFS) was 15,2 months. The most common grade 3-4 toxic effects were neutropenia 14%, thrombocytopenia 12%, anemia 12%, infections 16%, peripheral neuropathy 10% and gastrointestinal disturbances 5%. One toxic death (1.1%) due to sepsis was noted.
Summary/Conclusions: The combination of bortezomib, doxorubicin and dexamethasone (PAD) is well tolerated and induced clinically signifiant responses and prolonged remission duration in patients with relapsed and refractory MM.

PB1987

BENDAMUSTINE, LENALIDOMIDE AND DEXAMETHASONE (BLD) COMBINATION THERAPY IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A SINGLE CENTER EXPERIENCE

L Ciuffreda*, D Diomede, RM Miccolis, G De Santis, C Buquicchio, TM Santeramo, G Tarantini
Haematology, Ospedale di Miccoli, Barletta, Italy

Background: Lenalidomide is an analogue of thalidomide with immunomodulatory properties and is effective and safe in the treatment of Multiple Myeloma. Lenalidomide (Len) plus Dexamethasone (Dex) is approved for the treatment of Relapsed/Refractory MM patients following at least 1 prior therapy. Bendamustine (Ben), a bifuncyional agent, shares properties of alkilanting agents and purine analogs. We report data on efficacy and safety of BLD in patients (pts) with relapsed/refractory MM.
Aims: Our aim was to evaluate effectiveness and feasibility of BLD regimen in pts with relapsed or refractory MM
Methods: From September 2014 through October 2015 9 pts with relapsed or refractory MM with 1-3 prior lines of therapy were treated with BLD regimen. The series included 9 pts, six females and three males; 5 pts with relapsed MM and 4 with refractory MM. Median age was 70 (range 55-73). All patients had symptomatic MM and had previously been treated with bortezomib-based regimen. Five patients received BLD as second line therapy, four as third line.Ben was administered intravenously at a dose of 75 mg/mq on day one and two of each cycle. Pts received lenalidomide 10 mg orally on days 1- 21 and oral dexamethasone 40 mg/day (days 1, 8, 15 and 22). Cycles were repeated every 28 days for a total of 4 courses. Maintenance therapy included lenalidomide 25 mg/day on days 1-21 and dexamethasone 20 mg/die (days 1, 8, 15 and 22) until progression. Pts received concomitant anti-thrombotic (aspirin 100 mg/day) and anti-viral prophylaxis and additional supportive treatment with granulocyte colony stimulating factor (G-CSF) in case of grade 3 or grade 4 neutropenia occurring during cycles.Safety assessment (clinical exhamination, hematological evaluation) was performed weekly during cycle 1 and monthly thereafter. Response assessment was performed after four cycles. Response assessment was based on the International Uniform Response Criteria.
Results: As Grade 3-4 hematological toxicity we observed: neutropenia (55%), thrombocytopenia (44%) and anemia (33%). Grade 3-4 non hematologic adverse events were: infection (22%), hyperglycemia (33%), fatigue (44%) and

diarrhea (11%). No thromboembolic events were reported. We did not observe peripheral neuropathies. One patient discontinued therapy because of prolonged neutropenia and thrombocytopenia. 8 patients were evaluated for response after four courses; 7 pts (87,5%) achieved al least a partial response (PR), including 3 (37,5%) very good partial response (VGPR) and 1 (12,5%) complete response (CR). 3 pts (after achieving VGPR) successfully harvested peripheral blood stem cells (PBSC).
Summary/Conclusions: In conclusion in our study BLD combination was well tolerated with a mild toxicity profile and has shown effectiveness in patients with relapsed or refractory MM. It could represent a reasonable option for relapsed-refractory MM pts, including transplant-eligible patients.

PB1988

OUTCOME OF PATIENTS WITH NONSECRETORY AND SECRETORY MULTIPLE MYELOMA AFTER FIRST LINE TREATMENT CONSOLIDATED WITH AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION THE SINGLE CENTRE EXPERIENCE

J Romejko-Jarosinska*, A Druzd-Sitek, A Borawska, M Kotarska, J Tajer, E Wojciechowska-Lampka, J Walewski
Department of Lymphoid Malignancy, Maria Sklodowska-Curie Memorial Cancer Centre & Institute of Oncology, Warsaw, Poland

Background: Nonsecretory multiple myeloma (NSM) is an uncommon type of multiple myeloma. It is defined as the presence of monoclonal plasma cells in bone marrow biopsy or in other organs and the absence of monoclonal protein in immunofixation in serum and urine. There are limited data about outcome after first line treatment with consolidation high dose chemotherapy following autologous hematopoietic stem cell transplantation (ASCT).
Aims: We retrospectively evaluated outcomes and predictive factors for overall survival (OS) and progression free survival (PFS) in all myeloma patients, in non-secretory myeloma (NSM) and in secretory myeloma (SM) groups, who received high dose chemotherapy and ASCT between 1998-2015 after first line treatment.
Methods: We identified 114 myeloma patients: 23 (20%) with non-secretory myeloma and 91 (80%) with secretory myeloma. Median time from first treatment to ASCT was 8 months (range 4–28 months). All patients achieved response to first line treatment: complete remission or partial response.
Results: The median OS and median PFS were 41 (range 2- 205) months and 25 (range: 2- 205) months, respectively. Five year OS and 5-year PFS were 70% [95%CI (59%, 79%)] and 42% [95%CI(31%, 53%)], respectively. For NSM and SM groups 5-year OS were 54%[95%CI (31%,77%) and 74%[95%CI(64%,75%)] respectively, (p=0.14) and 5-year PFS were 45%[95%CI(24%,66%)] and 41%[95%CI (29%,53%), respectively. (p=0.79). Age, sex, disease stage, disease status before ASCT, induction chemotherapy, radiotherapy had no influence on OS and PFS for all, NSM and SM groups in univariant analysis. The presence of monoclonal IgG protein in SM patients was associated with better OS compared to OS in NSM group (p=0.04) and the presence of monoclonal protein with kappa light chain in SM patients related to longer PFS compared to PFS in NSM group (p=0.05) in univariant analysis.
Summary/Conclusions: There were no significant differences in OS and PFS for non secretory and secretory myeloma patients after first line treatment consolidated by high dose chemotherapy and ASCT. However, patients with monoclonal IgG protein had significantly better OS than patients with NSM.

PB1989

PLASMABLASTIC LYMPHOMA (PBL) AND EXTRAMEDULLARY PLASMABLASTIC TRANSFORMATION OF PLASMA CELL MYELOMA (PCM): DIAGNOSTIC MORHOLOGICAL, IMMUNOHISTOCHEMICAL AND CLINICAL CHARACTERISTICS

CM Vadikolia[1,*], C Papadopoulou[1], G Mpokolas[1], G Pahiadakis[2], N Protogeros[1], E Papagrigoriou[1], S Milias[3], C Georgopoulos[1]
[1]Haematology Department, [2]Gastroenterology Department, [3]Histopathology Department, 424 Army General Hospital, Thessaloniki, Greece

Background: PBL is an aggressive growth of neoplastic cells that resemble B immunoblasts in morphology and are immunophenotypically indistinguishable from plasma cells and lack B cell markers. Even though it was first described in the setting of immune suppression and in fact underlying HIV infection and/or EBER positivity in the neoplastic cells are frequent, it is now increasingly identified in immunocompetent patients with extreme heterogeneity in terms of nodal and extra nodal involvement. However, extramedullary lesions with plasmablastic morphology are not uncommon in patients with PCM, where they usually develop in the course of a refractory disease. The differential diagnosis may be challenging in initial presentation and the complexity is further magnified as both entities have features that overlap with several other lymphomas with plasmablastic morphology.
Aims: To evaluate and compare morphological, immunohistochemical, molecular and clinical characteristics of patients with PBL and plasmablastic transformation of PCM.
Methods: We present patients with documented PBL, with liver and bone involvement, plasmablastic transformation of PCM with multiple sites of involvement in the oral cavity and the gastrointestinal tract and plasmablastic transformation of orbital soft tissue plasmacytomas.
Results: Histopathological examination showed large confluent plasmablasts with abundant cytoplasm and central oval vesicular nuclei with coarse chromatin pattern and prominent nucleoli. They mostly appear as large centroblasts and/or immunoblasts and cannot be readily classified as a B cell or a plasma cell neoplasm or have a more apparent plasma cell differentiation with a paranuclear hof, eccentric large nuclei and basophilic cytoplasm. Background necrosis, karyorrhexis and increased mitotic figures are prominent. Immunohistochemistry is similar with plasma cell neoplasms, positive for CD79a, MUM-1, CD38 and CD138 and the majority negative for CD45 and negative for CD20, PAX-5 and bcl-6. Perhaps the only difference detected in our cohort of patients was the expression of CD56 and CD10 which were negative in PBL. MYC is expressed in about 50% of cases. All patients have very elevated levels of LDH and poor risk cytogenetics. The clinical course is aggressive and response to treatment is poor, with evolution to plasma cell leukaemia in the non PBL patients and overall survival of no more than 6 months from the diagnosis of PBL or the plasmablastic transformation.
Summary/Conclusions: When an underlying plasma cell dyscrasia is not yet known, the distinction of a high grade aggressive lymphoma with plasmablastic features may be arbitrary, particularly if there are coexistent marrow involvement, presence of paraproteinaemia, bone lesions and a certain degree of plasmacytic differentiation. It is not clear in the literature whether those are entirely different entities or share a common pathogenetic mechanism. Systemic investigation towards the identification of novel markers and the refinement of our current combination of diagnostic tools may enable a more accurate distinction and definition.

PB1990

RETROSPECTIVE COMPARISON OF SAFETY AND EFFICACY OF BUCY AND HDM AS REGIMEN BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

S Jin*, Y Xu, J Zhou, C Fu, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Melphalan-based regimen is the standard regimen before autologous stem cell transplantation (ASCT) in the patients with multiple myeloma, but now melphalan is not on the China's market. There were positive data reported in other researches in terms of safety, response rate and long-term survival on busulfan combined with other alkylating agents as regimen before ASCT in MM patients.
Aims: This study retrospectively compare the data in our single center on MM patients with busulfan (BU) and cyclophosphamide(CY) as regimen before ASCT form December to June 2013 to December 2014 with the high-dose melphalan (HDM) regimen. long-term survival on busulfan combined with other alkylating agents as regimen before ASCT in MM patients.
Methods: 20 cases with BUCY and 17 cases with HDM regimen before ASCT in MM patients were compared in terms of incidence of adverse reaction, the rate of hematopoietic reconstitution, therapeutic effect evaluation and survival.
Results: There is no significant differences between age, gender, duration from diagnosis to transplantation, the type of disease and ISS stage, the number of cycles of induction chemotherapy and disease status before transplantation in the two groups. A 10-day of median myeloid hematopoietic recovery time was observed in both groups, and the median megakaryocyte hematopoiesis reconstruction time was 10-day and 11-day (P >0.05), respectively, in BUCY and HDM group. The incidence of liver function injury above grade 2 in BUCY group was higher than that in HDM group (30% *vs* 0, *P* <0.05), but there were no hepatic veno occlusive disease (VOD) occurs in both groups. And there was no significant difference in other all regimen toxicity, especially above grade 2 toxicity, and treatment related mortality (TRM) within 100-day of two groups were 0. The partial response(PR) rate after transplantation in BUCY group was significantly decreased (6/20 *vs* 0/20, *p*<0.05), while the patients in the HDM group were not observed this phenomenon. The median PFS of HDM group was 17 months, and the median PFS of BUCY group and median OS of both groups had not been reached yet.

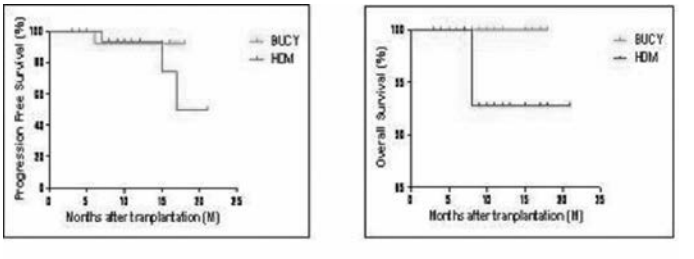

Figure 1.

Summary/Conclusions: BUCY regimen did not show weakness in safety and survival compared with HDM regimen, which prompt the possibility of BUCY regimen replacing the HDM regimen as the standard regimen in China.

PB1991

CYCLOPHOSPHAMIDE, THALIDOMIDE AND DEXAMETHASONE (CTD) AS INITIAL THERAPY FOR NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

J Vasquez[1,*], R Ruiz[1], K Aliaga[1], F Valencia[1], D Enriquez[1], V Palacios[2], S Quintana[1], L Casanova[3]
[1]Medical Oncology, Instituto Nacional de enfermedades neoplásicas, [2]Medical Oncology, Hospital Cayetano Heredia, [3]Medical Oncology, Instituto Oncologico Miraflores, Lima, Peru

Background: Major progress has occurred in multiple myeloma (MM) treatment in recent years. However, due to limited healthcare resources, newer agents are not readily available. In this setting traditional therapy such as oral cyclophosphamide, thalidomide and dexamethasone (CTD) represents an alternative for treatment in newly diagnosed MM.
Aims: To assess the clinical efficacy and toxicity of cyclophosphamide, thalidomide and dexamethasone.
Methods: Retrospective study with the regimen CTD (cyclophosphamide 400mg/m2 for 5 days, thalidomide 100mg/d increasing to 200 mg/day if tolerated, and dexamethasone 40mg weekly; in 28-day cycles), in patients with newly diagnosed MM treated at Instituto Nacional de Enfermedades Neoplasicas in Lima, Perú, between January 2008 and July 2013. Survival outcomes were estimated by Kaplan-Meier method.
Results: Fifty-nine patients were found to meet the selection criteria. Mean age was 56 years (27-68). Fifty-nine percent (n=35) were male. Salmon Durie stage III disease was present in 88.1%. The median number of treatment cycles delivered was 11 (range 4-12). After a median of 31 months follow-up (range 5-81), the overall response rate was 69.5%, with a 39% stringent complete response (SCR), complete response (CR) and very good partial response (VGPR), one patient (1.7%), three patients (5.1%), and nineteen patients (32.2%) respectevely. Median progression free survival (PFS) was 35 months. Five-year overall survival (OS) was 58.5%. The most common adverse events include neutropenia of all grades (44.1%), febrile neutropenia (grade III/IV 18.6/11.9%), severe infection (8.4%), deep venous thrombosis (6.8%). Out of 37 patients eligible for HSCT, 8 (21.6%) proceeded with it after this treatment regimen and 9 patients (24.3%) out of 37 are in maintenance. Treatment-related deaths occurred in 4 patients (6.7%) whose ages were 62, 64, 74, and 76 years-old.
Summary/Conclusions: CTD achieves durable responses with tolerable toxicity. This regimen represents a feasible and effective approach for MM patients in low income healthcare settings with tolerable side effects profile.

PB1992

PROGNOSTIC FACTORS IN PATIENTS WITH BENCE JONES MULTIPLE MYELOMA

JL Garcia De Veas Silva[1], R Rios Tamayo[2,*], C Bermudo Guitarte[3], JC Rojas Noboa[4], R Duro Millán[4], T De Haro Muñoz[1]
[1]Clinic Laboratories, [2]Hematology, Complejo Hospitalario Universitario de Granada, Granada, [3]Clinical Biochemistry, [4]Hematology, Hospital Universitario Virgen Macarena, Sevilla, Spain

Background: Bence Jones Multiple Myeloma or Light Chain Multiple Myeloma (LCMM) is characterized by the production of only lights chains. It can be found approximately in 15% of MM patients and it is considered to have a worse prognosis than Intact Immunoglobulin Multiple Myeloma.
Aims: The aim of this study is to evaluate the prognostic value of serum free light chains (sFLC) at presentation in newly diagnosed LCMM patients.
Methods: 43 patients with LCMM were included in this study during a period of five years. sFLC levels were measured by nephelometry (Freelite, The Binding Site, Birmingham, UK) and sFLC ratio was calculated as K/L. Clinical and laboratory variables including sFLC, albumin, beta-2-microglobulin (B2M), creatinine, hemoglobin, calcium, LDH, M-protein size, plasma cell infiltration, presence of plasmacytoma and presence of lytic bone lesions) were recorded and evaluated for their impact on the patient's outcome. Statistical analysis was performed using SPSS 23. Overall survival (OS) was analysed by Kaplan-Meier method and curves compared by Log-Rank test.
Results: The median age of the patients included in the study was 69 years (range 59-75) and 51% were female. The median follow-up was 32 months (range 17-45 months) and during the period of study there were fourteen disease-related deaths. According to ISS; 28% patients had stage 1, 41% had stage 2 and 30% had stage 3. At diagnosis, the proportion of patients with renal impairment (creatinine>2 mg/dL), anemia (Hb<10 g/dL), hypercalcemia (Ca>11 mg/dL) and presence of bone lesions were 28%, 35%, 12% and 70%, respectively. The median percentage of BM plasma cells was 18% and 19% of patients had plasmacytoma at diagnosis. Altered sFLC ratio at diagnosis defined by K/L ratio <0.26 or >1.65 was observed in all the patients. Median sFLC levels in patients with kappa light chain restriction (n=20) was 413 mg/L (range 128-1612 mg/L) and in those with lambda light chain restriction (n=23) was 985 mg/L (range 270-2858 mg/L). The median sFLC ratio for kappa secretors and lambda secretors were 43 and 0.01, respectively. The cohort of patients was separated in two groups based on sFLC ratio cut-off of <0.01 or >43. The 5-years OS was significantly inferior in patients with high sFLC ratios (<0.01 or >43, 12% 5y-OS), compared with those with low sFLC ratios (between 0.01 and 43, 74% 5y-OS) with median survivals of 45 months and NR, respectively (p=0.017, HR=3.70, CI95% 1.15-11.87). Involved sFLC (iFLC) levels above the median values (kappa≥413 mg/L and lambda≥985 mg/L for kappa and lambda secretors, respectively) predicted a worse prognosis. The 5-years OS was 70% in patients with iFLC levels below the median and 0% in those with iFLC levels above the median, with median survivals of NR and 45 months, respectively (p=0.009, HR=4.33, CI95% 1.31-14.28). Other variables significantly associated with adverse outcome were B2M>3.5 mg/L (p=0.006) and albumin<3.5 g/dL (p=0.023). There was no significant correlation with the others variables.
Summary/Conclusions: sFLC ratio and involved FLC levels above median values at diagnosis are important risks factors of worse prognosis in patients with Bence Jones Multiple Myeloma.

PB1993

COMORBIDITY AS A FACTOR OF PROGNOSIS IN MULTIPLE MYELOMA

N Skvortsova[*], T Pospelova, I Nechunaeva, I Kovynev
State Medical University, City hematological center, Novosibirsk, Russia, Novosibirsk, Russian Federation

Background: Despite the modern possibilities of therapy, multiple myeloma (MM) is an incurable disease with a wide variety of outcomes, depending on the presence of risk factors. MM Classification based on the criteria of Durie/Salmon and the ISS, include, primarily, the risk factors associated with the disease itself. However, factors associated with the patient, such as comorbidities and organ dysfunction which further affect the outcome of the tumor, is still not fully integrated into the predictive model.
Aims: To analyze the effect of prognostic factors: age, sex, medical condition and comorbidities, as well as indices of comorbidity and Sharlson Freiburger, overall survival (OS) in patients with MM.
Methods: 206 patients with MM (91 men and 115 women) analyzed. Patients ranged in age from 36 to 81 years (median 68 years). The statistical analysis was used software package SPSS 23. Effect of studied factors on the long-term prognosis was estimated by odds ratios (confidence interval 0.95). In developing the model predicting the likelihood of an unfavorable outcome were used methods of correlation, factor and regression analysis.
Results: during the factor analysis, all investigated prognostic factors, such as somatic status, GFR <30 mL/min/1.73 m2, the presence of any tumor or metastasis of solid tumors, and had a significant effect on the agents. The prevalence of comorbidity in patients with MM at diagnosis was - 80%. The most common diseases have been associated disease of the gastrointestinal tract (88.4%), cardiovascular (78.6%), urinary (44.5%) and endocrine systems (26.8%). In assessing the prognostic impact on overall survival and an index of comorbidity Sharlson Freiburger index shows that both indices significantly affect the survival of patients with MM, depending on the increase in their score on the scales (P <0.001). Median survival in the evaluation of Freiburger index was 55.0, 29.5 and 19.5 months for 0, 1 and 2-3 scores, respectively. Sharlson comorbidity index also indicated a significant difference in the survival rate of patients corresponding to 0, 1-2, and ≥3 points.
Summary/Conclusions: so comorbidity patients affects the survival and effectiveness of treatment in patients with MM, reducing these figures.

PB1994

PLASMA CELL LEUKEMIA: A 10-YEAR SINGLE CENTER EXPERIENCE

AL Pinto[*], A Roque, MJ Mendes, G Ferreira, JC Almeida, LF Araújo, M Duarte, E Cortesão, M Gomes, C Geraldes, AI Crisóstomo, L Ribeiro
Clinical Hematology Department, Coimbra University Hospital Center, Coimbra, Portugal

Background: Plasma cell leukemia (PCL) is a rare disorder representing less than 5% of malignant plasma cell diseases and defined by the presence of clonal plasma cells in the peripheral blood with an absolute count of >$2x10^9$/L and/or >20% of the white blood cells. It presents either as primary disease (pPCL) or as a secondary leukemic transformation (sPCL) of multiple myeloma, and usually has an aggressive course and poor outcome.
Aims: To evaluate clinical features, prognostic factors and treatment outcome in patients with PCL.
Methods: A single center retrospective case-series study was performed. Data from patients diagnosed with PCL between January 2006 and December 2015 were collected and analysed.
Results: We identified 15 patients with PCL (5 male/10 female, median age

68 years, range 44-78) of whom 11 had pPCL and 4 sPCL. In sPCL the median time to leukemic progression was 22.3 months, with a median of 3 previous therapeutic lines. The subtype of monoclonal component found at diagnosis was IgG (n=7), IgA (n=2), IgE (n=1), light chain only (n=3) and non-secretory (n=2). Median plasma cell count in peripheral blood was $4.05x10^9$/L (range 0.3-60.5) with a median proportion of plasma cells of 32% (range 11-85).
At baseline, most of the patients had poor performance status with ECOG³2 (n=9), advanced stage disease classified at stage III according to International Staging System (n=11) and Durie-Salmon Staging System (n=10), and at least one end-organ damage (n=14). Extramedullary disease was present in 5 cases. Elevated lactate dehydrogenase was observed in 11 patients (median 338U/L, range 118-2610, N<248U/L) and β2-microglobulin in 12 (median 17.7mg/L, range 1.0-62.1). In 8 patients cytogenetic studies were carried out by conventional cytogenetic analysis and by FISH. Seven of them presented high risk cytogenetic alterations. Four patients received anthracycline-based regimens as first-line treatment, 2 single alkylating agents and 6 bortezomib or lenalidomide as additional or unique treatments. In 3 patients, with very aggressive disease and poor performance status, early death occurred, allowing only palliative treatment with steroids. Two patients underwent autologous hematopoietic stem cell transplantation after first line treatment. Eight patients achieved complete or partial response. The median overall survival (OS) was 4.5 months and OS at 2 years was 12.5%. Significantly longer OS was observed in patients responding to first-line treatment *versus* those who did not respond (median 9.6 *vs* 0.9 months, p=0.002); in patients who received bortezomib during the course of the disease (median 23.8 *vs* 0.9 months, p=0.022), and in patients with good performance status (ECOG <2) at the time of diagnosis (9.6 *vs* 4.1 months, p=0.024).
Summary/Conclusions: PCL is a rare disease with a poor prognosis, aggressive clinicobiological features and a low response rate to conventional treatment. Although our conclusions are limited by the small sample size, our study shows that good performance status and response to first-line treatment present a positive impact on survival. The use of bortezomib also appears to improve outcomes by lengthening OS.

PB1995

A SINGLE CENTRE EXPERIENCE OF DPACE-BASED THERAPY WITH LENALIDOMIDE OR THALIDOMIDE +/- BORTEZOMIB PRIOR TO AUTOLOGOUS TRANSPLANT IN MYELOMA

T Parker*, K De Abrew, R Lown, M Jenner
Haematology, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Background: DPACE (infusional Cisplatin, Doxorubicin, Cyclophosphamide, Etoposide and oral Dexamethasone) with Thalidomide and Bortezomib is used within the Arkansas Total Therapy Regimen for myeloma. We have used DPACE-based therapy for high-risk and poorly responsive myeloma prior to autologous transplant (ASCT).
Aims: To establish the toxicity and efficacy of DPACE based chemotherapy with a combination of thalidomide or lenalidomide and/or bortezomib as a stand alone therapy or prior to consolidation with autologous stem cell transplant in high risk or poorly responsive myeloma.
Methods: We conducted a retrospective review of 22 patients treated at a single centre with DPACE-based therapy between 2010-2015 incuding two who received DPACE-based therapy as two separate treatment lines. Overall survival and time to next treatment from commencement of DPACE-based therapy were estimated using a Kaplan-Meier method and the impact of categorical variables assessed using a log rank analysis. Median follow-up was 2.1 years.
Results: PS was 0 (72.7%) or 1 (27.3%). ISS at commencement of DPACE was I (27.3%), II (22.7%) and III (36.4%). 15 of 22 patients had FISH performed prior to DPACE of which 40% had 2 or more adverse abnormalities (gain 1q, loss 1p, loss 17p, t(4;14), t(14;16), t(14;20)). Patients received DPACE with an Immunomodulatory agent (Lenalidomide 62.5% or Thalidomide 37.5%) and 66% received Bortezomib. DPACE-based therapy was used as primary therapy in 4/24 (16.6%) for and as salvage for suboptimal response in 20/24 (83.3%). Two cycles were given in 22/24 (92%). Patients received a median of 2 units of red cells per cycle (range 0-8 in cycle 1, 0-12 in cycle 2). Median platelets transfusions equalled 1.5 (0-6) in cycle 1 and 3.5 (0-9) in cycle 2. All patients experienced grade 4 neutropenia with median duration of 6 days in cycle 1 and 5 days in cycle 2. Grade 3-4 sepsis occurred in 9/24 (37.5%) in cycle 1 and 7/22 (31.8%) in cycle 2. All planned patients harvested successfully. From start of DPACE-based therapy, median OS was 23.3 months. Median TTNT was 12.6 months. Treatment-related mortality was 1/24 (4.1%) due to sepsis. Following DPACE-based therapy, 12/24 (50.0%) achieved CR or VGPR. 15/24 (62.5%) were consolidated with transplant (one allogeneic). Consolidation with ASCT demonstrated a clearly superior OS (77.1% *vs* 0% at 2 years, p<0.001) and improved TTNT (median 33.1 *vs* 4.3 months, p=0.007). Lenalidomide did not impact on toxicity or response rates. There were no reported second primary malignancies in any patients.
Summary/Conclusions: DPACE-based therapy is an effective induction or salvage therapy prior to ASCT in high risk or poorly responsive myeloma. Toxicity is manageable and stem cell harvest is achievable. Time to next treatment and overall survival is significantly longer in those consolidated with stem cell transplant indicating that there is limited value in using PACE-based chemotherapy without stem cell transplant. Initial data does not indicate a difference between Lenalidomide or Thalidomide in toxicity, response rates or survival although longer follow-up is warranted to investigate this further.

PB1996

FLOW CYTOMETRY BASED MRD ANALYSIS VERSUS IMMUNOFIXATION ELECTROPHORESIS FOR RESPONSE ASSESSMENT OF MYELOMA PATIENTS ON TREATMENT

MUS Sachdeva[1,*], P Sharma[1], P Bose[1], N Varma[1], P Malhotra[2]
[1]Hematology, [2]Internal Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Minimal residual disease (MRD) analysis by multiparametric flow cytometry (MFC) is a sensitive method to evaluate treatment efficacy in patients of plasma cell myeloma (PCM), and also as a tool for predicting patient outcomes and guiding therapeutic decisions. In the present study, we compared MRD levels in patients of plasma cell myeloma after chemotherapy or autologous stem cell transplant (ASCT), assessed by MFC, with immunofixation electrophoresis (IFE) and also the serum M-band status.
Aims: To evaluate the utility of MFC (six colour - three tubes) assay for detection of residual disease in patients of PCM and compare it with results of serum protein electrophoresis (SPEP) for M-band and immunofixation electrophoresis (IFE) done at same time.
Methods: Twenty six PCM patients (16 males & 10 females) were included in the study with mean age of 55.5 (range 37-80) years. Nine patients were post-ASCT (day +100), and 17 patients were on chemotherapy (majority treated with combination of cyclophosphamide, bortezomib and dexamethasone) and had completed induction at time of MRD analysis. MRD was analyzed using a dual laser BD FACS Canto II. Pre-titrated cocktail of CD38, CD138, CD19, CD45, cytoplasmic Kappa and lambda light chain, CD56, CD81, CD27, CD28 and CD200 were used in 6-color combination of three tubes for MRD analysis. IFE and M-band detection were also performed and compared.
Results: Ten out of 26 patients had detectable residual disease by MFC and/or IFE. MRD by MFC was detectable in 8 patients with mean of 1.79% (0.004-6.44%), all eight belonging to post-induction chemotherapy group. Only 4 of these 8 patients (50%) revealed both IFE positivity and detectable M-band. Two out of these 10 patients were MRD negative, however revealed IFE positivity as well as detectable M-band in one, and the other patient was only IFE positive (Table 1). Remaining 16 patients did not show evidence of residual disease by any of the three methods. Statistical analysis between MRD-positive (8/26) and MRD-negative (18/26) groups revealed no significant difference between age and sex distribution, mean values of hemoglobin, leukocyte count, platelet count, serum creatinine, serum calcium and serum albumin and the mean percentage of plasma cells on bone marrow aspirate smears *(Mann-Whitney U test)*.

Table 1. Comparison of results of the 10 patients showing persistent residual disease by SPEP/ IFE/ MFC, along with plasma cell percentages on bone marrow aspirate smears.

S. No.	SPEP	IFE	MRD (%)	Plasma cells on morphology (%)
1.	Negative	Negative	0.07	2
2.	Negative	Negative	0.11	1
3.	Negative	Negative	0.41	1
4.	Negative	Negative	0.7	4
5.	Positive	Positive	0.004	1
6.	Positive	Positive	3.2	15
7.	Positive	Positive	3.4	0
8.	Positive	Positive	6.44	22
9.	Positive	Positive	0	2
10.	Negative	Positive	0	1

Summary/Conclusions: MRD detection by multiparametric flow cytometry is a sensitive technique and should be routinely performed in addition to immunofixation electrophoresis and serum protein electrophoresis for more accurate assessment of treatment-response, better prognostication and further management of plasma cell myeloma patients.

PB1997

DIAGNOSIS, PROGNOSIS AND RISK ASSESSMENT OF MULTIPLE MYELOMA: IDENTIFYING GAPS AND ADDRESSING EDUCATION NEEDS FOR HEMATOLOGISTS AND ONCOLOGISTS

E Van Laar[1,*], S Fagerlie[1], O Landgren[2]
[1]Medscape, [2]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States

Background: The diagnostic and prognostic criteria for multiple myeloma (MM) have rapidly evolved as the therapeutic landscaped has advanced. Furthermore, in 2014, the MM diagnostic criteria were revised to incorporate biochemical parameters in addition to traditional symptomatic criteria. These emerging

changes require that the clinician interpret and integrate this new information into clinical practice.
Aims: A 2-part study was conducted with the first part focused on identifying clinical gaps in prognosis and diagnosis of patients with MM and the second part focused on determining the effect of educational intervention designed to address the identified clinical gaps.
Methods: Education interventions for hematologists/oncologists were developed and posted online (http://www.medscape.org/sites/advances/multiple-myeloma). Two of the interventions used a 25-question self-assessment focused on identifying clinical practice gaps in MM while the third comprised a 20-minute video of a two MM expert discussion designed to narrow the knowledge and competence gaps of hematologists and oncologists. Learning in the video-based intervention was assessed by comparing each learner's responses to pre-education questions with responses to the same questions posed after education. The McNemar's chi-square test was used to assess whether the mean pre-assessment score was different from the mean post-assessment score. Activities were posted online July 2015 and data were collected through September 2015.
Results: Responses of 434 hematologist/oncologists who completed all assessment questions in at least one intervention during the study period were analyzed. At baseline, identified clinical gaps included: the inability to recognize clinical features of high-risk disease (82% incorrect), inability to identify tools for assessing prognosis (73% incorrect), inability to distinguish unfavorable (44- 56% incorrect) or favorable (47% incorrect) cytogenetics, inability to assign the International staging system (ISS) score (26% incorrect), inability to detect clinical relapse (49% incorrect), and inability to interpret the IMWG diagnosis criteria (40-79% incorrect). For the second phase of the study, the education intervention focused on IMWG guidelines in newly diagnosed MM and utilized a study group of matched hematologist/oncologist learners (N=58). After participation in educational intervention, 84-95% of hematologist/oncologists selected the correct answer regarding diagnostic criteria (Table 1).

Table 1. Post-education Outcomes.

IMWG Diagnosis Criteria Topic	Pre-education % Correct	Post-education % Correct	% Improved Learners	P-value
Abnormal Bone Marrow Plasma Cells	41%	95%	53%	P<.05
Serum Free Light Chain Ratio	60%	95%	38%	P<.05
Number of Lesions as Detected by MRI	31%	84%	55%	P<.05

Summary/Conclusions: Despite the publication and dissemination of recent guideline updates, clinician show gaps in knowledge of clinical diagnostic and prognostic criteria for MM. This study identified specific education needs of physicians treating patients with MM regarding diagnostic, prognostic and risk stratification and demonstrated increased knowledge after participation in a targeted online intervention. Learners showed a mean improvement of 49% (range: 38-55%) in knowledge of IMWG diagnostic criteria in post assessments. Future education is warranted on practical application of diagnosis criteria, laboratory thresholds, prognostic, and monitoring tools, and proper risk assessment in order to enhance prompt diagnosis and effective disease management.

PB1998

IDENTIFICATION OF MULTIPLE MYELOMA IN PATIENTS ATTENDING EMERGENCY SERVICES WITH SEVERE BONE PAIN

JL Garcia De Veas Silva[1], R Rios Tamayo[2,*], C Bermudo Guitarte[3], R Duro Millán[4], M Jurado Chacon[2], T De Haro Muñoz[1]
[1]Clinic Laboratories, [2]Hematology, Complejo Hospitalario Universitario de Granada, Granada, [3]Clinical Biochemistry, [4]Hematology, Hospital Universitario Virgen Macarena, Sevilla, Spain

Background: Bone metastases are due to a variety of primary tumors that include Multiple Myeloma (MM) and solid tumors (lung, breast, prostate). Its effects result in pain refractory to conventional analgesic treatments and osteolysis leading to pathological bone lesions. Sometimes, patients with age>50 years, intense and repetitive bone pain are treated with analgesics without assessing the possibility of a MM at Emergency Services (ES). Typically, after several visits to the ES because of progressive increase of pain and evidence of bone damage the patient is admitted to study a possible MM. Early study of the pathological bone lesions is crucial for a correct diagnosis and to increase the survival time of patients. The protocol "SPE+FLC" that uses serum free light chains determination (FLC) and serum protein electrophoresis (SPE) enables sensitive quantification of a possible monoclonal component in the study of MM.
Aims: The aim of our work is to study the diagnostic utility of the protocol "SPE+FLC".
Methods: During a period of 12 months, we studied 44 patients with age>50 years old, intense bone pain and recurrent visits to Emergency Service where imaging methods (X-Rays, CT scan and MRI) showed osteolytic lesions, vertebrae collapse and pathological fractures that may be associated a MM or metastasis from a primary tumor of unknown origin (TU). The protocol (SPE+FLC) was applied to every patient to study a possible MM and the determination of tumor markers to discard a TU with bone metastasis.
Results: The diagnosis was: MM in 16 patients (36%), TU with bone metastasis in 14 patients (32%) and 14 patients without tumoral pathology (32%). In MM patients, the median age was 68 years (range 58-75) and the median time from symptoms to diagnosis was 5 months (range 2-7) with a median number of visits to Emergency Service of 3. The diagnosis was intact immunoglobulin MM in 13 patients and Bence-Jones MM in 3 patients. According to ISS system for MM; there were 2 patients in stage 1 (12%), 4 patients in stage 2 (25%) and 10 patients in stage 3 (63%). During the study there were 3 MM related deaths. The protocol "SPE+FLC" had a sensitivity of 100%, specificity of 97%, PPV of 94% and PNV of 100%.
Summary/Conclusions: In patients with age>50 years, intense bone pain with pathological bone lesions, the application of the protocol "SPE+FLC" allow us to detect a possible MM in order to apply an early treatment and increase the survival time of the patient.

PB1999

LIGHT-CHAIN ESCAPE IN MULTIPLE MYELOMA: A NEW PATTERN OF DISEASE RELAPSE CHANGING BIOLOGY. A SINGLE-CENTER EXPERIENCE OF THREE CASES

L Torti[1,*], S Pulini[1], AM Morelli[1], F Bacci[2], A Spadano[1], P Di Bartolomeo[1]
[1]Department of Hematology, Transfusion Medicine and Biotechnology, "Spirito Santo" Civic Hospital, Clinical Hematology, Pescara, [2]Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Section of Hematopathology, Bologna, Italy

Background: Multiple Myeloma (MM) is characterized by the production of a monoclonal protein which can be an intact immunoglobulin, free light chain (FLC), both or, in rare cases, neither. The introduction of novel drugs has changed the natural history of the disease, leading to new manifestations of relapse. Light chain escape (LCE) defines a kind of relapse in which the FLC increase is not accompanied by a concomitant raise of the original monoclonal component (MC).
Aims: Disease biology and progression in MM is now thought to be the result of Darwininan-like evolution process: multiple pathological clones are present at MM diagnosis, possibly producing different monoclonal proteins. The cases presented here indicate that disease progression and relapse may be associated with selective outgrowth of a specific FLC producing clone.
Methods: Here we report three cases diagnosed with aggressive LCE between 2001 and 2015 at a single institution. We even include an interesting case of IgG lambda monoclonal MM who relapsed after double autologous stem cell transplantation (ASCT)changing face presenting like FLC MM lambda with a new rare IgD lambda monoclonal pattern.

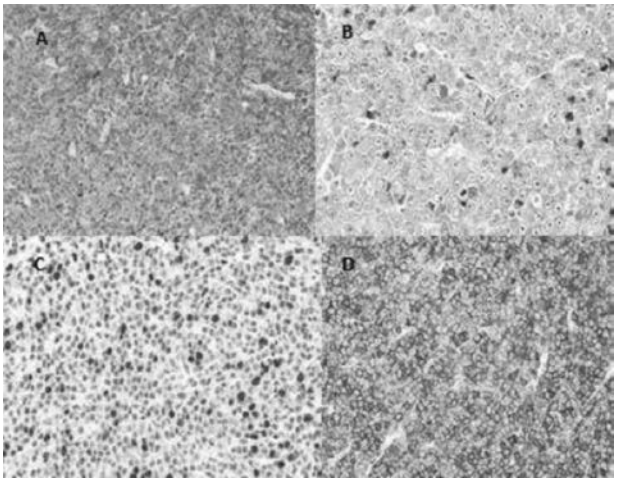

Figure 1. A) Histopathological examination of inguinal lymph node revealed plasmocytoma with immunostaining positive for chain lambda (40x). B-C-D) Bone marrow biopsy demonstrated plasmocytoma (Giemsa 40x), with Ki67 expression in bone marrow plasma cells >20% and immunostaining positive for lambda chain (20x). Case 1.

Results: Patient 1. A 63-year old woman was diagnosed with IgG-lambda (stage IA, ISS2) with trisomy of chromosome 5 and 9. Before the "new drug era"the patient received 3 cycles of chemotherapy according to VAD regimen, followed by tandem ASCT; she achieved a VGPR. After 9 years the patient developed an enlargement of right inguinal lymph node and then painless subcutaneous mass above left shoulder. Biopsy of the 2 nodular lesions confirmed extramedullary plasmocytomas (Fig1A). The patient did not show classic monoclonal protein but a new little MC IgDlambda protein with an abnormal secretion of serum FLC lambda. Bone marrow plasma cells were dysmorphic (Fig 1B), with high proliferation index measured by immunohistochemical staining Ki67>20% (Fig1 C) and positive for lambda chain assessement (Fig 1D). Serum

LDH levels at recurrence resulted high. Patient 2. A 64-year old man suffering from IgG-kappaMM stage IIIA, ISS2 underwent double ASCT and then was enrolled in PANORAMA study because of relapsing disease. He then started salvage therapy with lenalidomide and dexamethasone, but after 23 cycles he showed progressive disease with the features of LCE kappa. He presented a complex karyotype with trisomy of chromosome 9, 15 and gene rearrangement of 14q32, increase of LDH and plasmoblastic medullary cytomorphology. Patient 3. A 51-year old woman presented IgG-lambda MM stage IIIA ISS3 with extramedullary involvement (L5-S1) and deletion in 17p chromosome. She was treated according to VTD therapy followed by double ASCT and dexamethasone maintenance. She remained in remission of disease for 60 months until an increased amount of serum FLC lambda appeared and rapidly increased, with multiple vertebral bodies collapses and bone marrow infiltration of 40% atypical plasma cells showing various prognostically unfavorable genetic signs (1q amplification, 17p deletion, 13 deletion, 14q32 rearrangement).
Summary/Conclusions: These cases represent a documented series of a rare but clinically important mode of relapse. They suggest the potential selective pressure exerted by novel agents and highlight the importance of FLC monitoring in MM patients undergoing ASCT and/or treatment with biological and new drugs. LCE underlines the intraclonal heterogeneity of MM; it was recently associated with shortened overall survival. Hematologists should keep in mind this possibility of evolving biology of disease in the "high dose and novel agent era".

PB2000

DOMESTIC SUBCUTANEOUS SELF-INJECTION OF BORTEZOMIB IN MULTIPLE MYELOMA

C Cerchione*, D Nappi, I Migliaccio, D Salvatore, F Pane, L Catalano
Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: Bortezomib-based therapies are suggested as standards of care in management of patients with newly diagnosed and relapsed multiple myeloma. The recommended dose and schedule of Bortezomib is 1.3 mg/mq administred on days 1, 4, 8, and 11 of 21-day cycles, a regimen active and well tolerated. Subcutaneous administration of bortezomib could be a good option for patients, particularly those with poor venous access. It's known that home intravenous administration of bortezomib is feasible to adequately informed patients, because we have recently demonstrated that a solution of bortezomib powder in normal saline stored at 4°C remains stable for nearly one month.
Aims: Since 2009, in our unit all patients requiring bortezomib for the treatment of multiple myeloma perform intravenous injection of the drug at home, after having been supplied with the exact dose in saline solution, in ready-to-use plastic syringes, appropriately prepared under hood in sterile conditions. This procedure reduces the time spent by patients in hospital, improving convenience for patients and physicians. However, in some patients venous access may be difficult or sometimes unfeasible. As the drug is not histotoxic, subcutaneous administration is feasible, and this possibility is particularly attractive in domestic settings.
Methods: Safety and efficacy of subcutaneous injections of bortezomib at the same dose as i.v. administrations (1mg/sm, days 1, 4, 8, 11), but dissolved in smaller saline volume (max. 1ml), in association with oral dexamethasone 20mg/dd. 1-2,4-5, 8-9, 11-12, was verified in 108 patients affected by multiple myeloma, with poor venous access. In particular, the efficacy, evaluated as reduction of the monoclonal component during the i.v. period *vs* the s.c. period was performed in a subgroup of 12 patients.
Results: Results indicated an equivalence between the two administration modalities, according to other larger controlled studies. Based on these reports, 108 patients, requiring Bortezomib as part of anti Myeloma regimens, have been systematically treated by subcutaneous injections, performed at home. No significant side effects have been reported so far and quality of life is particularly improved. In particular, in 37 of them we have evaluated an equivalence between the subcutaneous and intravenous administration, according to other controlled studies.
Summary/Conclusions: The possibility to perform an antineoplastic regimen at home is particularly well accepted by all patients affected by multiple myeloma, with an achievement of a very good quality of life.

PB2001

AL AMYLOIDOSIS: REAL WORLD EVIDENCE FROM ARGENTINA

N Schutz, E Nucifora*, D Fantl[1], J Arbelbide, A Aguirre, V Otero, P Sorroche, B Cesar, G Gustavo, H Garcia Rivello, B Boietti, S Maria, L Posadas Martinez
Medicina Interna, Hematología, Hospital Italiano de Buenos Aires, CABA, Argentina

Background: AL amyloidosis is a challenge in clinical practice due to the difficulties in diagnosis and treatment. We present our experience from the RIA Amyloidosis Registry managing this patients.
Aims: To evaluate the characteristics and outcomes of patients with Amyloidosis in Argentina.
Methods: Ambispective cohort observational study of patients with AL Amyloidosis included in the Amyloidosis RIA Registry from January 2006 till July 2015. Review of electronic medical records by the amyloidosis team. Data were analysed with SPSS program using conventional descriptive statistics and Kaplan Meier survival curves.
Results: The RIA Registry includes 140 patients: 6% (9) AA amyloidosis, 7% (10) FAP amyloidosis; 8%(11) senil amyloidosis; 24% (36) localized amyloidosis; 18% (27) unidentified and 34% (47) AL amyloidosis. Multiple myeloma patients with amyloidosis were excluded from the Registry. We included in this study the 47 patients with confirmed AL amyloidosis. 64% (31) were males with a median age of 58 years (35-81). The main reasons for consultation were heart failure (81%); proteinuria (62%); nephrotic syndrome (30%); renal failure (26); peripheral neuropathy; autonomic disfunction and gastrointestinal complaints (10%). In the laboratory workup only 56% of patients had a measurable M protein spike. Nevertheless, all patients had detectable clonal free light chains by inmunofixation or serum free light chain assays. The most frecuente light chain involved was lambda. Data regarding proBNP or BNP were available in 34 patients and only 4 patients had normal results. Due to delay in the diagnosis 9 patients died before starting proper treatment. Other 6 patients were treated in other hospitals (no data available). From the 32 patients treated in our hospital: 5 patients received upfront cardiac transplantation followed by CYBORD; 20 patients received low dose CYBORD; 4 patients received IMIDs and 3 patients conventional chemotherapy (prior to 2008). Autologous bone marrow transplantation was performed in 10 patients. The response rate was: complete response in 18 patients; partial reponse in 7 patients; progressive disease 1 patient; not evaluable 6 patients. There were 7 deaths; 3 in complete reponse and 2 in partial response. The main causes of death were cardiac failure (5) and sepsis (2).The median overall survival of patients treated in our hospital was 86 months (IC95 27-144).
Summary/Conclusions: AL Amyloidosis is underdiagnosed in Argentina. The consequent delay in diagnosis and start of treatment has a huge impact in the quality of life and survival of this patients. Low dose CYBORD is a good treatment option with and adecuate response rate and safety profile considering the difficulties associated with amyloid organ damage. M spike and free light chains response do not always correlates with organ response which usually occurs much later. Therefore it is important to consider heart transplantation in young patients with severe amyloid myocardiopathy as it remains the main cause of death in this patients.

PB2002

RETROSPECTIVE STUDY OF THE EFFICACY, ECONOMY AND SAFETY OF TREATMENT WITH SUBCUTANEOUS INJECTION OF BORTEZOMIB IN DE NOVO PATIENTS WITH MULTIPLE MYELOMA

S Yan, P Wang, Y Xu, H Zheng, L Ma, S Jin, C Fu*, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Multiple myeloma(MM) is a clonal plasma cell malignancy. NCCN guidelines recommended bortezomib-based therapies as the first front-line treatment in patients with newly diagnosed and relapsed multiple myeloma. Oakervee H E, et al proved that PAD combination (bortezomib/doxorubicin/dexamethasone) can improve survival for previously untreated MM patients.Peripheral neuropathy(PN) is a well-known and unavoidable side effect of bortezomib, which is limited to the usage for some patients. The multi-centers clinical research suggested that subcutaneous administration of bortezomib was noninferior to the standard intravenous route of delivery but could reduce sideeffects of bortezomib, particularly in peripheral neuropathy. But China is lack of data about the usage of bortezomib.
Aims: To explore the efficacy and safety of subcutaneous injection of bortezomib in the treatment of de novo MM patients.
Methods: A total of 57 MM patients treated with bortezomib, adriamycin and dexamethasone form June 2008 to January 2015 were analyzed. Among them 28 received conventional PADiv with the intravenous bolus of bortezomib and another 29 received PADih with the subcutaneous injection of bortezomib. The efficacy and safety of two groups were evaluated.
Results: The overall response rate was 94.6% of all patients after four courses of PAD induction.67.9%, 32.1% in PADiv group and 60.7%,30.4% in PADih group achieved response>=VGPR and sCR/CR. The median follow-up of PADiv group was 40(1.5-73) months and PADih was 20(1.5-30) months. There was no difference of TTP and DFS between Two groups. But PADih group showed a more favorable OS (p=0.004)even though with a shorter period of follow-up. The statistical results showed that the most common hematologic toxicities of grade 3/4 in the PAD group were granulopenia(67.9%), leukopenia(67.9%), thrombocytopenia (67.9%) and anemia (35.7%), and non-hematologic toxicities of grade 3/4 mainly included infection (39.3%), constipation (25%), diarrhea (21.4%), peripheral neuropathy(21.4%), fever (21.4%), VZV infection (17.9%) and anorexia (17.6%). Accordingly, the hematologic toxicities of grade 3/4 in the PADih group were granulopenia(55.2%), thrombocytopenia (51.7%), leukopenia(41.4%), anemia(41.4%) and non-hematological toxicities were mainly constipation(34.5%), nausea(27.6%), anorexia(17.2%), diarrhea (17.2%) and vomiting(10.3%). A total of 27 patients(47.4%) treated with Velcade suffered from peripheral neuropathy. Incidence of PN of two groups even grade 3/4

showed no statistic difference. 39.3% PADiv patients were infected during the treatment and 3 died from severe pneumonia. The incidence of infection in PADiv and PADih group shows great difference(P=0.000). Among other grade 3/4 adverse reactions, only data of leukopenia(P=0.045) and VZV infection (P=0.023) show differences. Remarkably, six patients (21.4%) receiving PADiv due to severe PN reduced dose of Velcade or Suspended treatment. Patients treated with PADih did not appear serious infection. Average length of hospital stay per circle of PADih and PADiv group is 24, 15 days, respectively (P=0.000). Comparison of supportive therapies including G-CSF, platelets transfusion, resuscitation, prevention of infection, nutrition and bortezomib reduction or suspension through chi-square analysis showed that proportion of platelet transfusion and prevention of infection was statistically significant (P=0.094; P=0.091) when alpha=0.1. Ratio of resuscitation, anti-infection drugs, suspension or reduction of bortezomib in PADiv group is higher(P=0.009; P=0.002; P=0.011).

Summary/Conclusions: The PADih regimen by changing bortezomib from intravenous bolus to subcutaneous injection significantly reduced adverse events, improved the safety of clinical application of bortezomib without affecting curative effect, and had greatly improved the overall survival due to lower incidence of infection in the PADih patients. In addition, subcutaneous bortezomib could obviously reduce the length of stay in hospital per circle and incidence of infection and decrease the cost of treatment.

PB2003

THROMBOTIC MICROANGIOPATHY ASSOCIATED WITH BORTEZOMIB TREATMENT IN MULTIPLE MYELOMA

A Pedraza[1,*], A Gonzalez[1], C Vicente Ayuso[1], M Garcia Roa[1], L Sanchez[2], W Torres[1], S Toral[1], A Velazco[1], A Bobes[1], R BM Martinez[2], M Mateo[2]
[1]Hematologia y Hemoterapia, [2]Hospital Clinico San Carlos, Madrid, Spain

Background: Thrombotic microangiopathy (TMA) is a very diverse medical condition defined by the presence of microangiopathic hemolytic anemia (MAHA), thrombocytopenia and microvascular thrombosis, being characteristic of the MAHA schistocytes in peripheral blood. From an etiopatogenics point of view, it can be classified as primary, when there is clear evidence of a disorder caused by TMA, as the TTP and HUS, and secondary, when the TMA is a symptom of underlying conditions such as tumor processes, pregnancy, HIV infection, bone marrow transplant and exposure to certain drugs. Today, drug induced TMA is clearly recognized and it has been reported that at least 22 drugs involved in this process, including various chemotherapeutic agents (cyclosporine, mitomycin C, gemcitabine, bevacizumab, ect) and other substances such as vaccines, herbal products and homeopathic drugs.
Aims: We show the sixth case reported to date of bortezomib-induced thrombotic microangiopathy in MM.
Methods: 52 year-old woman diagnosed with multiple myeloma stage IIIA IgG Lambda ISS II with anemia and without thrombocytopenia, creatinine 0.84 mg/dL and glomerular filtration rate of 81 mL/min, discreet elevation of LDH and Beta2 microglobulin, monoclonal component of 2.2 g/dL IgG lambda and urine 6390 mg/dl, bone lesions in dorsolumbar vertebrae and medullogram with infiltration for plasmatic cells monoclonales of 25-35%. She starts first-line treatment with bortezomib, lenalidomide and dexamethasone. The eleventh day of treatment presents sudden increase of creatinine and a decrease in the filtration rate, oliguria, and the progressive decrease of platelets. In addition, hypertransaminasemia with hyperbilirubinemia and increased PCR, gradual rise in LDH and decreased haptoglobin documented. In the peripheral blood smear the platelet count was verified and frequent presence of schistocytes was reported. Within the analytical study, not immune anemia is found with a negative Coombs test, normal coagulation tests, serology, Shiga toxin in feces and negative pregnancy test, ADAMTS13 activity of 33% and negative ADAMS13 antibodies, and complement levels were normal. The treatment was started with plasmapheresis until all 12 sessions were completed with progressive improvement. After 5 additional cycles of chemotherapy with dexamethasone and lenaidomida without bortezomib, and an autologous stem cell transplant, she reached very good partial response.
Results: So far, 5 cases of post TMA bortezomib have been described in the literature (Table 1). The acute immunological reaction and the drug toxicity are the two recognized hypothesis that explain the development of thrombotic microangiopathy secondary to drugs. The variavility in the time of the beginning of the TMA in five cases, ADAMS13's different values and the absence of antibodies in one of them, suggests that not only the immune mechanism is involved in his etiopatogenia. Nevertheless, other drugs such as ticlopidine, produce MAT by a clearly immune mechanism unleashing a severe decrease of the activity of ADAMS13 by the production of antibodies anti ADAMS13. Though, the immunomodulatory capacity of the bortezomib inside the bone marrow microenvironment was demonstrated, still it is not known if such a condition could have any relation with the development of MAT; of fact, a case of microangiopathy successfully treated with bortezomib has been reported, arguing the blockage of plasma cells and B-lymphocytes autoreativos. On the other hand, other medicines like the monoclonal antibodies anti VEGF (ej. bevacizumab) that alter directly the angiogenesis have been associated with TMA. Bortezomib in addition from blocking the action of the proteasome, also suppresses the production and secretion of VEGF, which could be related to an altered angiogenesis and endothelial damage characteristic of TMA. For the treatment of MAT diverse empirical therapies were used, without restarting the bortezomib in any of five cases and the clinical being solved in all of them.

Table 1. Case reports of TMA associated with BTZ.

Study	Drug	Age/Sex	Time to onset of TMA	ADAMS 13	ANTI ADAMS13	TTO
Morita et al. 2008	TASPE BTZ	54/M	Day 8	36,5%	Negative	FFP (240ml/d) + Haptogobin suspension BTZ
Moore et al. 2011	BTZ	57/F	Day 2	12%	---	
Salmenniemi et al. 2012	TASPE BTZ	52/F	Day 11 after 5 cycles	---	---	PE (12)
Mehta et al. 2012	BTZ	70/F	Day 2 after 9 dose	31%	---	PE (1)
Kah-Lok et al. 2015	BTZ	61/F	Day 10 after 5 cycles	25%	---	Suspension BTZ
HCSC. 2015	BTZ	52/F	Day 11	33%	Negative	PE (12)

BTZ: Bortezomib, FFP: fresh frozen plasma , PE: plasma exchange

Summary/Conclusions: TMA must be recognized as a potentially serious secondary side effect to its administration of bortezmib in patients who develop MAHA, thrombocytopenia and acute renal failure.

PB2004

A SINGLE CENTRE REAL LIFE EXPERIENCE ON MULTIPLE MYELOMA (MM) PATIENTS: SUBCUTANEOUS (SUBQ) VERSUS INTRAVENOUS (IV) BORTEZOMIB (BOR)

MS Infante[*], I Gonzalez, C Muñoz, C Heras, MA Foncillas, K Marín, JA Hernandez
Hospital General Infanta Leonor, madrid, Spain

Background: The outcome of multiple myeloma patients (MM) has significantly improved over recent years, mainly due to the discovery of novel antimyeloma agents together with a better knowledge of the biology of the disease [Kumar *et al.* 2008]. One of these novel agents is bortezomib, the first in the class proteasome inhibitors introduced in the clinical practice approximately one decade ago. However, toxicity, especially peripheral neuropathy, as well as the intravenous route required for its administration are the two most significant bortezomib-related issues. To try to reduce the peripheral neuropathy, new guidelines for its management and the introduction of weekly schedules of administration have contributed to significantly decrease its incidence and the subcutaneous (subQ) administration has been recently introduce to avoid the intravenous (IV) route. Results obtained in phase I/II and III studies have confirmed that subcutaneous administration is feasible and represents an additional step towards the optimization of bortezomib use, resulting in a probably more convenient method than the IV route that is at least as effective.
Aims: To evaluate efficacy and tolerability of Bortezomib (IV *vs* sub Q) in standard combination myeloma regimens. Moreover, we compared the incidence of peripheral neuropathy.
Methods: We reviewed data of 50 consecutive MM patients treated at our Hematologic division between October 2008 to November 2015. Standard criteria were applied to evaluate response rate and neurotoxicity (NCI CTCAE national Cancer institute common terminology criteria for adverse events version 4.0).

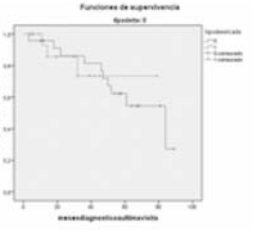

Figure 1.

Results: Our case serie is composed by 50 patients diagnosed with MM and treated in 1º line with combination regimen including Bortezomib (subQ or IV). Median age 75 years (range 39-89). 17/50 (34%) were administered VD regimen (7 subQ *vs* 10 IV), 27/50 (54%) patients were administered VMP (15 subQ *vs* 12 IV), 2/50 patients (4%) received poliQT VMCP/VBAD (IV Bortezomib) while 4 patients (8%) received VDT regimen as induction to transplant consolidation with subQ Bortezomib. Overall survival (OS) of the serie was 84 months (47-120 range) (Figure 1) with a free progression survival (FPS) of 23 months (19-30 range): no difference was found between subQ or IV Bortezomib regimen in terms of survival. There were 12 cases (24%) of neurotoxicity in our serie: 2/12 (16%) patients with VTD (subQ Bor) where the role of the inmunomoduladory drug in the toxicitiy must be considered; 6/12 (50%) cases

with IV Bor and 4/12 (33%) cases with subQ Bor: all 5/6 cases of neurotoxicity in IV Bortezomib were grade III with need of suspension of the drug. In subQ population there were 1 case with grade I toxicity and 3 cases of grade II neurotoxicity with reduction of the dose.
Summary/Conclusions: In our real life experience OS and FPS in our serie is notable, with 84 months and 23 months described. In terms of toxicity there were slightly more cases of neutorotoxicity in IV Bor population with higher grade of toxicity than the subQ population. In conclusion, the subQ formulation of bortezomib represents an additional step towards the optimization of bortezomib use, resulting in a more convenient route that is at least as effective as the IV route.

PB2005

REAL WORLD EXPERIENCE OF BORTEZOMIB RE-TREATMENT FOR PATIENTS WITH MULTIPLE MYELOMA AT FIRST RELAPSE

Y Reyal[1,2,*], R Popat[3], S Cheesman[4], A Rismani[3], S D'Sa[3], N Rabin[3], K Yong[1]
[1]Haematology, UCL Cancer Institute, [2]Haematology, St George's University Hospital, [3]Haematology, [4]University College London Hospitals NHS Trust, London, United Kingdom

Background: In the United Kingdom (UK), bortezomib (Velcade, Janssen) based triplet regimens are commonly used as first line therapy for both transplant eligible and ineligible patients. The efficacy of re-treatment with bortezomib monotherapy or bortezomib plus dexamethasone in subsequent lines of therapy has been previously reported. However there are limited data on re-treatment at first relapse, particularly with bortezomib-based triplet regimens which are more commonly used in current practice.
Aims: This study aimed to evaluate the efficacy of bortezomib triplet regimens at first relapse in patients previously treated with first line bortezomib. The safety of bortezomib as re-treatment was also assessed.
Methods: This was a retrospective analysis of MM patients at first relapse treated with bortezomib, who had also received bortezomib as first line therapy. Twenty three sequential patients from a single UK center who had achieved at least a partial response (≥PR) and a treatment free interval (TFI) of a minimum of 60 days from first line bortezomib treatment (*i.e.* not refractory) were identified. Response to treatment and disease progression were defined by the International Myeloma Working Group criteria.
Results: A triplet bortezomib combination was used as first line therapy in 78% of patients (n=18/23) with a median of five cycles given (range 4-8). No patient received maintenance therapy. The median time to best response (TTBR) was 3.5 months (range 0.7-9.0) and the median duration of response (DOR) was 14.9 months (range 4.7-44.5). The overall response rate (ORR) to bortezomib at first relapse was 87% (PR 39%, VGPR 35%, CR 13%). The median TTBR was 4.1 months (range 0.7 -15.0) and median DOR was 11.5 months (range 1.0-18.5). After first line bortezomib, the median time to progression (TTP) was 18.9 months (range 7.3-49.6) whilst it was 14.4 months (range 1.4-16.6) at first relapse. The median TFI was 20.7 months (range 2.0-62.8) after first line bortezomib and 10.4 months (range 1.0-14.0) after bortezomib re-treatment. Ten patients received ASCT at first line compared to 11 at first relapse. Treatment-related toxicity was also evaluated. At first line, eleven patients (48%) experienced peripheral neuropathy (PN) (all grade 1). There were three (13%) grade 3-4 non-hematological adverse events (AE), which were all infections. All but one patient restarted bortezomib at full dose at relapse. Only two patients (11%) required a subsequent dose reduction (for PN). Eleven patients (61%) experienced PN with first relapse treatment (all grade 1-2). There were two grade 3 AEs (diarrhoea and febrile neutropenia). All patients who relapsed for a second time were able to proceed to a third line regimen which was most commonly lenalidomide and dexamethasone.
Summary/Conclusions: This single center study in real life patients demonstrates that bortezomib combinations used at first line and sequentially at first relapse represent a valid treatment strategy for selected patients.

PB2006

FIRST EXPERIENCES WITH GENERIC BORTEZOMIB ADMINISTRATION ONE CENTRE EXPERIENCE

A Jungova[*], S Vokurka, P Jindra
Hemato-oncology department, Charles University Hospital Pilsen, Pilsen, Czech Republic

Background: Multiple myeloma (MM) is malignant haemato-oncology disease characterised by clonal proliferation of plasmocytomas. Disease treatment is started with induction therapy in the symptomatic phase of the disease. Regimens with combination of vincristine, doxorubicin and corticoid were used in the last century. From 2002 are used in the Czech Republic "new drugs" as thalidomide and bortezomib (several years later also lenalidomide). As standard induction regimen is VTD regimen recommended (bortezomib, thalidomide and dexamethasone). Original drugs with bortezomib (Velcade) are still used, but generics drugs with equivalent active substance are also on the market now. These generics should be equivalent with originals. According our first experiences none serious adverse events were presented, other complications were of similar character as with original bortezomib.
Aims: First experiences in administration of generic bortezomib, adverse events, patient's toleration.
Methods: During 11-12/2015 generic bortezomib was administered to 28 patients (altogether 80 applications) at our department
Results: Adverse events after generic bortezomib applications occurred in 28 patients. Anaemia (c.18%) and thrombocytopenia (c. 14%) were between most often complications. From complication of lower grade occurred tiredness (17%), infection (3%), neuropathy (8%) and diarrhoea (3%).
Summary/Conclusions: We administered altogether 80 generic bortezomib applications to 28 patients at Haematology and oncology department in 11-12/2015. During this time none serious complication occur and most of adverse effects were of I. and II. grade. These complications were similar to original bortezomib complications. Other comparison with original product in longer time is necessary.

DEVELOPMENT OF RAS-INDUCED ZEBRAFISH LEUKEMIA MODELS

E Alghisi[1], M Konantz[1], M Mione[2], C Lengerke[1,3,*]
[1]Department of Biomedicine, University Hospital Basel, Basel, Switzerland, [2]Karlsruhe Institute of Technology, Institute of toxicology and genetics, Eggenstein- Leopoldshafen, Germany, [3]Clinic for Hematology, University Hospital Basel, Basel, Switzerland

Background: The zebrafish has emerged as a versatile novel experimental model for studies on developmental hematopoiesis and leukemogenesis. Several oncogenes involved in human leukemia have been successfully overexpressed in zebrafish embryos. However, despite first encouraging results, these models often fail to fully recapitulate human myeloid malignancy, perhaps due to early lethality caused by transgene expression or lack of secondary events necessary for full malignant transformation.
Aims: Here we present a RAS overexpression zebrafish model that we plan to use for investigations on molecular mechanisms involved in leukemia initiation and progression and for drug screening that can identify novel anti-leukemic compounds.
Methods: We take advantage of the Gal4/UAS binary system and of existing transgenic lines and overexpress human oncogenic *HRAS* in zebrafish hematopoietic cells under the control of specific promoters (*fli.1, pu.1, runx.1, mpeg1*). The generated *HRAS*-transgenic fish lines are followed microscopically until the time-point of death or sexual maturity and hematopoietic cell development is studied correspondingly at embryonic (*fli.1*, *pu.1*), larval (*pu.1*, *runx1*) and adult stages (*runx1*) also by *in situ* hybridization/real-time PCR analysis of hematopoietic gene expression, flow cytometry, immunohistochemistry and/or blood smear morphological assessment.
Results: Different phenotypes were observed depending on the promoter driving the oncogene expression. *HRAS* induction via the early hematopoietic promoter *fli.1* affects primitive hematopoiesis inducing myelo-erythroid proliferation and delayed erythrocyte maturation resulting in an expansion of hematopoietic tissues (Alghisi *et al.* 2013). Unfortunately, studies at later stages are not possible in these fish due to their early lethality resulting from vascular defects and cardiac edema. Alternatively, *HRAS* expression driven by *runx1*, *pu.1* and *mpeg1* allows survival at these early stages permitting studies on larval and adult hematopoiesis. Interestingly, at 1 month, *runx1-HRAS* fish displayed a cellular expansion of hematopoietic stem/progenitor cells (HSPC) in the kidney marrow (KM), the zebrafish definitive hematopoietic compartment. Cytospin preparation and flow cytometric analyses revealed high numbers of undifferentiated stem/progenitor cells in both KM and peripheral blood of HRAS transgenic fish, suggesting that *HRAS*-overexpression in HSPCs expands this compartment by inducing its proliferation and perhaps additionally by impairing differentiation capacity. Furthermore, *mpeg1*-HRAS fish showed increased numbers of blood progenitors in the KM and abnormal gene expression of progenitor markers as demonstrated by qRT-PCR. Analysis of *pu.1*-HRAS juvenile fish is under way.
Summary/Conclusions: We are currently further investigating the effects of *runx1*-driven *HRAS* on the hematopoietic compartment and generate tools to explore potential cooperation of *HRAS* with other oncogenes during leukemogenesis. A screen analyzing compounds successfully suppressing the effects of HRAS on zebrafish hematopoiesis is underway and the results will be presented at the meeting.

PB2008

MOLECULAR AND CYTOGENETIC PROFILE OF PATIENTS WITH PRIMARY MYELOFIBROSIS

L Polushkina[1,*], I Martynkevich[1], V Shuvaev[1], E Petrova[1], L Martynenko[1], N Cybakova[1], M Ivanova[1], E Shabanova[1], I Zotova[1], T Zamotina[1], A Zhernyakova[1], A Savrilova[2], D Shikhbabaeva[1], M Fominykh[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]Republican Clinical Hospital of Tatarstan Republic, Kazan', Russian Federation

Background: Primary Myelofibrosis (PMF) is hematopoietic stem cell malignancy characterized by clonal proliferation of myeloid-lineage cells. The molecular basis of this event includes mutations in *JAK2, MPL* and *CALR* genes, called clonal markers (CM), cytogenetic abnormalities and epigenetic disorders. The variability of the clinical course among patients with PMF due to different CM and epigenetic status requires close analysis for possible stratification by risk groups.
Aims: The aim of our study was to estimate overall survival (OS) in PMF patients depending on the type of CM, cytogenetic and epigenetic features.
Methods: We have examined 89 patients with PMF. Median age was 59 years (range 19-82). For all patients the detection of V617F mutation of *JAK2* was done. *JAK2*-negative samples were tested for *MPL* 515 codon mutations (PCR-RFLP) and 9th exon mutations of *CALR* gene by direct sequencing. Seventy-three patients underwent the analysis of mutations in *EZH2* and *ASXL1* genes with high resolution melting method followed by direct sequencing of probably mutated samples. Karyotype research was done for 39 patients with available bone marrow samples.
Results: CM were detected in 64 patients: *JAK2*+ 46.1% (41/89), *CALR*+ 21.3% (19/89), *MPL*+ 4.5% (4/89) cases. No clonal markers were found in 28.1% (25/89) patients considered triple-negative (TN). Median survival of TN patients was the shortest and amounted to 4 years (p=0.041), *JAK2*+ 11.9 years. In *CALR*+ and *MPL*+ patients during follow-up of 10 and 4 years, respectively, median survival has not been reached. According to the results of cytogenetic analysis patients were divided into 2 groups: the first group included 20 patients with normal karyotype (NK) and 5-with del(13)(q22), del(20)(q12), add(6)(p25), del(6)(q15) single features; the second group consisted of 13 patients with complex abnormalities and unfavorable aberrations (+8, -7/7q-, i(17q), inv(3), -5/5q-, 12p-). Median survival in the first group was 7.4 years, in the second group-4.5 years. It should be noted separately that unfavorable karyotype frequency was distinct in groups with different CM: *CALR*+ 0% (0/8), *JAK2*+ 35% (6/17), TN 54% (7/13) cases (p=0.053). We have detected 18 mutations of *ASXL1* gene in 16 patients (21.9%): fourteen patients had single mutation and two patients harbored 2 mutations at once. Mutation frequency was significantly higher in *CALR*+ patients compared to *JAK2*+ (37.5% (6/16) and 6.9% (2/29), p=0.037, resp.) and in TN patients compared to *JAK2*+ (33.3% (8/24) and 6.9% (2/29), p=0.044, resp.). Two mutations in *EZH2* gene (2.2%) were observed in TN, *ASXL1*+ patients. Both cases characterized of high-risk progression of PMF. The first patient (men, 61-year-old, complex karyotype) progressed to blast phase rapidly from the diagnosis and died after 8 months. The second patient (men, 75-year-old, NK) had severe thrombocytopenia and died from hemorrhagic stroke after 5 months since the diagnosis.

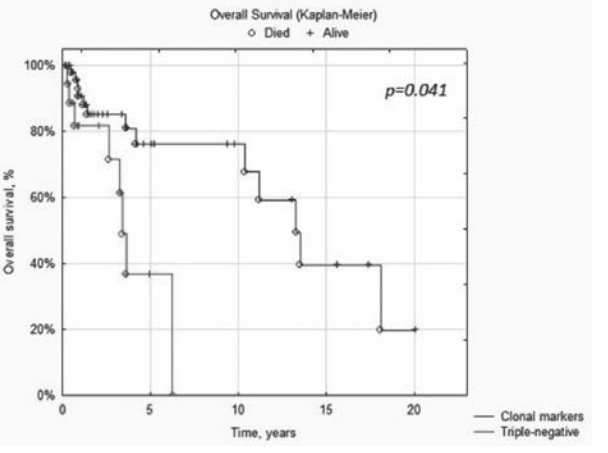

Figure 1.

Summary/Conclusions: Type of CM, cytogenetic aberrations and epigenetic changes can be correlated with different prognosis of PMF. The absence of CM and unfavorable karyotype are associated with reduced overall survival. The impact of epigenetic status on the prognosis in PMF patients requires further study.

PB2009

ASSESSMENT OF THE INTERLABORATORY VARIABILITY AND ROBUSTNESS OF JAK2V617F MUTATION ASSAYS: A STANDARDIZATION STUDY INVOLVING A CONSORTIUM OF 19 ITALIAN LABORATORIES

M Perricone[1,*], F Palandri[1], M Angelini[2], L Bagli[3], E Bellesia[4], M Donati[5], D Gemmati[6], B Giannini[3], P Zucchini[7], S Mancini[8], P Storti[9], S Trubini[10], G De Matteis[11], S Di Zacomo[12], M Favarato[13], MA Fioroni[14], M Gusella[15], G Maccari[16], F Navaglia[17], M Svaldi[18], L Toffolatti[19], L Orlandi[20], V Laloux[21], M Manfrini[22], A Cuneo[6], P Galieni[2], R Marasca[7], E Pazzaglia[5], A Sensi[3], A Tieghi[4], N Giuliani[9], P Leoni[8], D Vallisa[10], M Bonifacio[11], P Di Bartolomeo[23], V Fazio[14], D Gatti[18], F Gherlinzoni[19], R Paolini[17], M Plebani[15], M Tiribelli[16], F Cassavia[20], F Orsini[20], M Cavo[22], E Ottaviani[22], G Martinelli[22]

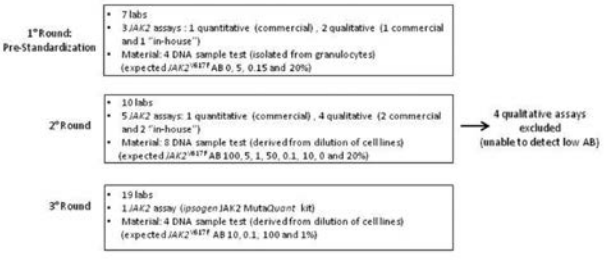
Seràgnoli', Bologna, [23]UOC di Immunoematologia-Medicina Trasfusionale-Lab. Ematologia, ASL Pescara Ospedale Spirito Santo, Pescara, Italy

Background: In chronic myeloproliferative neoplasms (MPNs), the quantification of the *JAK2*^{V617F} allele burden (AB) is crucial for diagnosis and prognosis assessment, and also for disease monitoring after allogeneic stem-cell transplantation. To-date, a plethora of techniques for *JAK2*^{V617F} determination is used over different molecular laboratories, with substantial differences in specificity and sensitivity. Given the need to provide reliable and comparable molecular results, the standardization of molecular techniques is of utmost importance.
Aims: The aims of this multicenter study were: 1) to evaluate the inter- and intra-laboratory variability in *JAK2*^{V617F} quantification in 19 Italian molecular laboratories; 2) to identify the most robust assay for the standardization of the molecular test; 3) to allow consistent interpretation of individual patient analysis results.
Methods: A network of 19 Italian molecular laboratories was established. The study was coordinated by the Institute of Hematology "L. and A. Seràgnoli", Bologna, and was developed in 3 different rounds (Fig. 1). In routine practice, 2 laboratories did not assess *JAK2*^{V617F} mutation whereas 7 used a qualitative approach and 10 performed a quantitative evaluation. Both reagents and DNA samples were provided by Werfen-IL SpA and QIAGEN. Raw data and runs validity were checked according to handbook recommendations. Statistical analysis was carried out by QIAGEN/Bologna University.
Results: In the 1st round, we aimed to investigate the inter-laboratory variability on different mutation loads. All laboratories using a quantitative approach were able to determine the expected *JAK2*^{V617F} AB. Conversely, laboratories using a qualitative approach did not detect the positivity of samples with a low AB (0.15%). To further investigate the inter-laboratory variability on low-positive samples, we developed a 2nd round, in which 3 additional laboratories were included. In this 2nd round, each laboratory performed 2 runs with *ipsogen* JAK2 Muta*Quant* kit and 2 runs with their routinely used method. None of the laboratories using qualitative "in-house" methods were able to detect low-positive samples, while quantitative results by *ipsogen* JAK2 Muta*Quant* kit showed only a small variability among different laboratories at low AB (0.1 and 1%; CV =0.42 and 0.24, respectively). The 3rd round was intended to confirm the robustness of the *ipsogen* JAK2 Muta*Quant* kit in a larger cohort of laboratories. The study was therefore extended to 9 additional laboratories. "Home-made" methods were excluded and all laboratories performed 2 runs with the *ipsogen* JAK2 Muta*Quant* kit. Quantitative results were well reproducible across all mutation loads. Only one laboratory failed to quantify 0.1% sample in one run. Importantly, all laboratories clearly distinguished between the 0.1 and 1% mutated samples (0.1 and 1%; CV =0.46 and 0.77, respectively).

Table 1. Design of the study.



Summary/Conclusions: The first result of the study is that a qualitative approach is not sensitive enough to detect the *JAK2*^{V617F} mutation at a low (≤1%) burden. Conversely, the *ipsogen* JAK2 Muta*Quant* kit resulted highly efficient and sensitive in the quantitative detection of all mutation loads. This study sets the basis for the creation of an Italian network of molecular laboratories focused on the diagnosis of MPNs, including not only *JAK2*^{V617F}, but also Calreticulin and *MPL* mutations. The network will aim to identify/standardize the most efficient and cost-effective techniques for the evaluation of these mutations, so to produce reliable and reproducible molecular data.

PB2010

PHARMACOLOGICAL ACTIVITY PROFILING OF PACRITINIB IN THE BIOMAP® HUMAN PRIMARY CELL PLATFORM

R Watson[1,*], S Al-Fayoumi[1], V Sharlene[2], A O'Mahony[2], E Berg[2], J Singer[1]
[1]Translational Sciences, CTI BioPharma, Seattle, [2]DiscoverX, South San Francisco, United States

Background: Pacritinib is an orally available kinase inhibitor with specificity for JAK2, FLT3, IRAK1 and CSF1R. Comprehensive mapping of the pharmacological profile of pacritinib should enable a better understanding of the mechanistic basis of pharmacological action and support the utility of pacritinib in physiologically-relevant therapeutic areas.
Aims: The main goal of this study was to explore the effects of pacritinib on biomarkers relevant to human disease using BioMAP® Human Primary Cell Systems. A secondary goal was to compare and contrast the profile of pacritinib using this platform with that of other clinically available kinase inhibitors, to gauge the potential for differentiating effects of pacritinib in the clinical setting.
Methods: Pacritinib was evaluated in the BioMAP® Diversity PLUS panel by DiscoverX Corporation. Twelve human primary cell based systems were stimulated with one or more well-described biological factors to activate multiple disease-relevant signaling pathways. Each primed system was then tested with four concentrations of pacritinib ranging from 26-711 nM, encompassing physiologically and clinically relevant concentrations of the free drug (~200 nM in plasma). Anti-proliferative activity of pacritinib was determined for several human primary cell types and 148 biomarkers were measured by high-throughput immune-based assay. Biomarkers impacted by pacritinib treatment were evaluated for dose-dependency, and compared to a reference database of compounds including ruxolitinib (Jakafi), a JAK2 inhibitor approved for use in myelofibrosis.
Results: Exposure to pacritinib resulted in anti-proliferative activity in human endothelial cells, T cells, B cells, and coronary artery smooth muscle cells at 711 nM. This effect was most pronounced in B cells, the only cell type in which proliferation was also impacted at the lower, clinically relevant range. Cytotoxicity was not observed in any of the cell types. In addition, pacritinib had prominent immunomodulatory activities in the BT system modeling T-cell dependent B-cell activation. In the BT system, pacritinib resulted in statistically significant, concentration-dependent decreases in soluble TNFα, IgG, IL-17A, IL-17F, IL-2 and IL-6. Statistically significant, but less pronounced effects were also observed on inflammatory, tissue remodeling, and hemostasis-related activities. A comparison of pacritinib's profile at 711 nM with that of 1 μM ruxolitinib in the BT system demonstrated that pacritinib had more inhibitory effects on immune biomarkers, with fewer effects on biomarkers in other systems modeling different tissue biology.
Summary/Conclusions: BioMAP® analysis indicated that pacritinib impacts several disease biomarkers in a manner that may translate to differentiated therapeutic benefit. For instance, pacritinib's marked inhibition of inflammatory cytokines IL-17A and IL-17F and TNFα is potentially beneficial in rheumatoid arthritis, atherosclerosis, and/or psoriasis. The information obtained in the BioMAP® platform provided valuable insights that enabled selection of follow-up studies to perform in relevant animal disease models. Moreover, pacritinib's profile was distinct from that of ruxolitinib, which may underlie some of the comparative differences observed in the clinical setting. In order to further characterize pacritinib's effects on human disease models in comparison to other compounds, an expanded follow-on BioMAP® study is planned.

PB2011

A NOVEL REAL-TIME PCR ASSAY SET FOR DETECTION OF DIVERSE CALR MUTATIONS IN MYELOPROLIFERATIVE NEOPLASMS

R Jäger[1,*], JD Milosevic Feenstra[1], E Bogner[1], B Gisslinger[2], M Schalling[2], S Turcan Debono[3], H Gisslinger[2], R Kralovics[1,2]
[1]CeMM - Research Center for Molecular Medicine of the Austrian Academy of Sciences, [2]Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, [3]HalioDx SAS, Marseille, France

Background: Mutations in the *CALR* gene have been found in a large proportion of patients suffering from myeloproliferative neoplasms (MPN). While 52bp deletions (Type 1) and 5bp insertions (Type 2) constitute >80% of *CALR* mutations, a variety of other insertion-deletion mutations have been reported, all within a 66bp mutational hotspot in exon 9 of *CALR*. Reliable and efficient detection of those somatic driver mutations is crucial for MPN diagnosis and patient management.
Aims: We previously characterized our MPN patient cohort for insertions and deletions in the *CALR* gene using a PCR-based fragment sizing assay in combination with Sanger sequencing. Here we compare the characteristics of this fragment analysis with a novel real-time PCR (qPCR) based assay set (*ipsogen* CALR RGQ PCR Kit, provided pre-launch by QIAGEN, Hilden, Germany).
Methods: Fragment analysis of *CALR* exon 9 was performed using high-res-

olution sizing of fluorescent dye labeled PCR products on a 3130*xl* Genetic Analyzer (ABI, Foster City, CA). The *ipsogen* CALR RGQ PCR Kit was applied according to the manufacturer's instructions in 7 separate hydrolysis-probe-based qPCR reactions per sample within the same run. The kit identifies Type 1 and Type 2 mutations using ARMS PCR, in which a primer mismatch prevents elongation on wild-type (WT) DNA. Minor variants of *CALR* mutations are detected through a PCR clamping approach using 3'-phosphate blocked oligonucleotides complementary to WT sequence. For both fragment analysis and the *ipsogen* assay we determined dynamic range and detection limits through serial dilution of mutant genomic DNA (gDNA) in WT gDNA, generating *CALR* mutational burden standards down to 0.01%.
Results: Using the *ipsogen* CALR RGQ PCR Kit, we re-tested gDNA from 48 MPN patients (10 Type 1, 10 Type 2, 18 minor variants, 10 *CALR* mutation negative) previously evaluated by fragment analysis. Concordance between both assays was 100%. While the *ipsogen* assay formally requires a per reaction input of 50ng gDNA freshly isolated from peripheral blood, our samples were from a mixed cohort of various storage time and isolation protocols. Moreover, we applied the *ipsogen* assay on a large proportion of our samples using DNA inputs of 25ng and 10ng, respectively. *CALR* mutational status could be confirmed for all those cases. We next determined the limit of detection (LoD) of Type 1 and Type 2 mutations for both the *ipsogen* assay and fragment analysis. While limit-of-blank-based calculation of LoD revealed 0.39% and 0.08% for Type 1 and Type 2 *ipsogen* assays, respectively, fragment analysis could reliably detect 2.5% but not 1% *CALR* mutational burdens. Determination of the dynamic range revealed linearity for the fragment analysis down to the 2.5% detection limit. For the *ipsogen* assays, linearity on the log-scale could be observed down to 1% and 0.5% *CALR* mutant burden for Type 1 and Type 2 assays, respectively. Within these dynamic ranges, standard curves could be produced with a correlation coefficient of >0.98.
Summary/Conclusions: While fragment analysis represents a rapid, cost-effective assay for screening larger cohorts in a multi-well format, the specific identification of Type 1 and Type 2 mutations requires Sanger sequencing in addition. The *ipsogen* CALR RGQ PCR Kit offers, at once, reliable detection of *CALR* mutations and specific identification of Type 1 and Type 2 mutations, requiring minimal processing and equipment (Rotor-Gene Q MDx, QIAGEN). Moreover, the *ipsogen* assay showed superior sensitivity over fragment analysis and might therefore be most suitable for tracking the dynamics of the malignant MPN clone.

PB2012

THE S100 PROTEINS AS MEDIATORS OF INFLAMMATION ARE INCREASED IN MYELOPROLIFERATIVE NEOPLASM AND DOWNREGULATED BY JAK2 INHIBITION

M Diklić[1], M Buač[2], O Mitrović[2], B Beleslin-Čokić[3], T Subotički[2], D Dragoslava[2], V Čokić[1,*]
[1]Laboratory of experimental hematology, [2]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, Belgrade, Serbia

Background: Chronic inflammation is associated with sustained myeloproliferation, while S100 proteins have been shown to regulate cell proliferation, differentiation and inflammation in pathological conditions. S100A8, A9 and A12 produced by cells of myeloid origin were mediators of inflammation, while S100A4 regulated cell proliferation in neoplasia. S100A4 and A12 are produced via activation of the JAK-STAT pathway, constitutively activated in myeloproliferative neoplasm (MPN).
Aims: This study analyzed the inflammation linked S100 proteins in MPNs: polycythemia vera (PV, n=16), essential thrombocythemia (ET, n=16), primary myelofibrosis (PMF, n=20), according to JAK2V617F and CALR mutation status, and healthy controls (n=8), and their regulation in *JAK2V617F* mutated human erythroleukemia cell line (HEL) during MPN simulated therapy.
Methods: *S100A4*, *A9* and *A12* mRNA levels in granulocytes and HEL cells are measured by real time PCR, while protein expression of S100A4, A8, A9 and A12 are examined in granulocytes and plasma of MPN using immunoblotting and immunoassay, respectively. In addition, S100A9 is determined by immunohistochemistry in bone marrow. Also, levels of S100A4, A9 and A12 are measured by real time PCR and immunoblotting in HEL cells incubated 48 hours with hydroxyurea and specific JAK2 inhibitor 1,2,3,4,5,6-hexabromocyclohexane (HBC). Mutations of *JAK2V617F* and *CALR* exon 9 are analyzed by DNA sequencing and allelic PCR.
Results: *S100A12* mRNA level is significantly increased in *JAK2V617F* heterozygous ET patients, but downregulated in *JAK2V617F* heterozygous PV patients and PMF without mutation (p<0.05). However at protein level, S100A12 is significantly increased only in granulocytes of ET patients without mutation (p<0.05) and plasma of PV and PMF without *JAK2V617F* mutation (70 ng/ml, p<0.01). Besides non significant modification at mRNA levels, S100A4 and S100A9 protein expression demonstrated a common significant increase in granulocytes (p<0.01), followed by increased quantity of S100A9-positive cells in bone marrow and S100A8/A9 proteins in plasma of MPN patients (51 and 28 ng/ml, p<0.01). Presence of *CALR* mutation augmented S100A8/A9 levels in plasma and granulocytes of ET and PMF patients. After 48 hour, hydroxyurea and specific JAK2 inhibitor HBC significantly decreased *S100A4* mRNA levels in HEL cells (p<0.01). Further on, protein expression of S100A4 and S100A9 are also significantly downregulated by hydroxyurea and JAK2 inhibitor HBC in HEL cells (p<0.05).
Summary/Conclusions: S100A4, A9 and A12 mRNA and protein levels are not generally influenced by *JAK2V617F* mutant allele burden. S100A4 and anti-inflammatory S100A8/A9 protein levels demonstrated stable elevation in contrast to sporadic pro-inflammatory S100A12 appearance in MPNs. Moreover, JAK2 inhibition reduced S100A4 and S100A9 levels in HEL cells. S100A8/A9 could serve as a clinical biomarker and therapeutic target in MPNs, with existing S100A8/A9 blockers permitted for clinical testing.

PB2013

HIGH SENSITIVITY MLPA ASSAY FOR THE DETECTION OF THE RECURRENT CALR, JAK2, KIT AND MPL MUTATIONS WITH ≥1% ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M Steenkamer[1,*], A Stuitje[1], L Atanesyan[1], K Stouten[2,3], M van de Werken[2], R Castel[2], S Savola[1]
[1]Tumour Diagnostics, MRC-Holland, Amsterdam, [2]Clinical Chemistry and Haematology, [3]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands

Background: Myeloproliferative neoplasms (MPNs) are chronic hematopoietic stem cell malignancies, characterized by clonal proliferation of blood cells. Recurrent mutations in CALR, JAK2, KIT and MPL genes are important molecular markers for classification and prognostication of MPNs. Multiplex Ligation-dependent Probe Amplification (MLPA) is a widely used technique for gene copy number detection, also allowing simultaneous identification of known point mutations. However, the sensitivity of standard MLPA is limited to a mutant allele burden of ≥10%. To overcome this limitation, we have introduced a high sensitivity MLPA assay enabling detection of an allele burden as low as 1% for the most frequent mutations in MPN.
Aims: To demonstrate the feasibility of a modified MLPA assay to detect ≥1% mutant allele burden using artificial positive DNA and cell line samples. Validation of this assay is done with MPN patient samples.
Methods: Salsa MLPA P520 MPN probemix was designed and optimized to detect ≥1% mutant allele burden of the eight most frequent mutations in MPNs: **CALR**, 52-bp deletion and 5-bp insertion in exon 9 (L367fs*46 and K385fs*47), **JAK2**, deletions in exon 12 (N542_E543del and E543-D544del), **JAK2**, substitution in exon 14 (V617F), **KIT**, substitution in exon 17 (D816V) and **MPL**, substitutions in exon 10 (W515L and W515K). The performance of the newly developed MLPA assay was optimized and tested on artificial positive DNA samples with 1% mutation burden. The performance of the assay was further validated using commercial reference DNA samples with 1% allelic burden of JAK2 V617F and KIT D816V mutations, as well as by using dilution series of a JAK2 V617F positive, UKE-1 cell line, where the allelic burden was confirmed by the Ipsogen MutaQuant assay. Validation on diagnostic MPN patient samples (n=167) was performed in a single-blind setting.
Results: Results obtained by high sensitivity MLPA assay were concordant with an allele-specific PCR results in MPN patient samples. Moreover, 2 novel cases with 1.4-5% JAK2 V617F burden, which were not detected by allele-specific PCR, were identified with our novel assay and confirmed by the Ipsogen MutaQuant assay. Furthermore, no false positive calls for mutations were obtained when testing on healthy human DNA samples (n=143).
Summary/Conclusions: Our results demonstrate that the P520 MPN MLPA assay is a reliable method for simultaneous detection of eight frequent mutations in MPNs, even when the patient DNA sample has a low (1-5%) mutant allele burden. These results merit further consideration of MLPA as a possible alternative for mutation testing for newly diagnosed MPN patients.

PB2014

FUNCTIONAL STUDY OF TWO NEW POINT MUTATIONS OF EPOR GENE IN PRIMARY FAMILIAL CONGENITAL POLYCYTHEMIA

E Peroni[1], AM Lombardi[1], F Gherlinzoni[2], PM Stefani[3], I Bertozzi[4], ML Randi[4,*]
[1]Dept of Medicine - DIMED, University of Padua, Padova, [2]Hematology Dept, Ca' Foncello Hospital, [3]Hematology, Ca,Foncello Hospital, Treviso, [4]Department of Medicine -DIMED, University of Padua, Padova, Italy

Background: Primary Familial Congenital Polycythemia (PFCP) is extremely rare. It is caused by mutations in the EPO receptor (*EPOR*) gene (locus 19p13.3-p13.2) resulting in hypersensitivity to erythropoietin EPO stimulus. In PFCP, in spite of reduced levels of serum EPO, mutated *EPOR* is ''switched on'' to stimulate red blood cell production by erythroid progenitor cells but without ''switch off'' mechanism.
Aims: Evaluate the functional effect of two *EPOR* gene novel mutations.
Methods: In our huge cohort of patients with erythrocytosis, we found 2 unrelated patients carrying novel mutations in *EPOR* gene. We performed a functional assay to evaluate the activation of EPOR signaling in these mutations:

first we created mutated plasmids to transfect K562 cell as model. 48h after electroporation, we performed a stimulating assay with EPO following a time course at 0', 5' 15' 30' and 45'. We finally studied the signaling cascade activity with Western Blot analysis.
Results: Both observed mutations were found in exon 8 of *EPOR* gene: c.1013G>A, p.Cys338Tyr and c.1022C>T, p.Thr341Met. The EPOR signaling cascade resulted more active in mutated cells than in WT cells when stimulated with EPO. 5' and 15' after stimulation, transfected cells with C338Y mutation showed higher phosphorylation of STAT5 compared to T341M mutation. We observed also a similar phosphorylation pattern of ERK occurring earlier than STAT5 (at 0' and 5'), while no signal of activity was detected in JAK2 and AKT cascades.
Summary/Conclusions: In this study, we report two new missense mutations of the *EPOR* gene, located in exon 8 as all the 22 previous described functional mutations. Exon 8 encodes the C-terminal negative regulatory domain of the protein. Both mutations here described impair the C-terminal negative regulatory domain of *EPOR* resulting in a gain-of-function in the EPOR signalling cascades, more relevant for C338Y than T341M mutation. These novel mutations, causing hyperactivity, increase proliferation and differentiation, and decrease of apoptosis of erythroid progenitor, sustain the erythrocytotic phenotype of our patients.

Myeloproliferative neoplasms - Clinical

PB2017

CLINICAL-BIOLOGICAL PROFILE AND RESPONSE TO IMATINIB IN MYELOID AND LYMPHOID NEOPLASM ASSSOCIATED WITH EOSINOPHILIA AND IDIOPATHIC HYPEREOSINOPHILIC SYMDROME
F Hernández Mohedo[1,*], JR Molina Hurtado[2], S Durán Nieto[3], A Mellado Gázquez[4], I Marchante Cepillo[5], A Jiménez Velasco[6], A Ruiz Calderón[7], G Garcia Donas[8], M Anguita Arance[9], JM Puerta Puerta[1], C Ruiz Nuño[6], P Lopez Garrido[1]
[1]Hematology, Complejo Hospitalario Universitario de Granada, Granada, [2]Hematology, Hospital Reina Sofía, Córdoba, [3]Hematology, Complejo Hospitalario de Jaén, Jaén, [4]Hematology, Hospital Torrecárdenas, Almeria, [5]Hematology, Hospital Puerta del Mar, Cádiz, [6]Hematology, Hospital Universitario de Málaga, Málaga, [7]Hematology, Hospital Riotinto, Riotinto, [8]Hematology, Hospital Juan Ramón Jiménez, Huelva, [9]Hematology, Hospital San Agustín, Linares, Spain

Background: Primary eosinophilic diseases are a broad and heterogeneous subgroup of hematological disorders with a very low incidence (SEER database age-adjusted incidence rate 0.036 per 100.000). They have been generally defined as peripheral blood eosinophilia (≥1.5x109/L), tissue infiltration and end-organ damage. According to the OMS-2008 classification, primary eosinophilic diseases are subdivide in a mayor category of myeloid and lymphoid neoplasms with eosinophilia and abnormalities of PDGFRA/B or FGFR1(MNP-Eo); chronic eosinophilic leukemia not otherwise specified (CEL-NOS), idiopathic hypereosinophilic syndrome (HES) and lymphocytic T variant hypereosinophilia (HES-L).
Aims: The MPN-Eo associated with abnormalities of PDGFRA/B frequently respond to low doses of Imatinib, while is controversial the role of Imatinib in idiopathic HES. In this study we show our series of HES, with the aim of describing the clinical-biological profile and the rate of responses to Imatinib in both subtypes of HES, with and without PDGFRA/B abnormalities.
Methods: We performed a retrospective and descriptive analysis in GAMFIN cooperative group (Andaluz philadelphia-negative chronic myeloproliferative neoplasm group) of diagnosed patients with hypereosinophilic disease (OMS-2008 and HDWG Workshop 2010 classification) and differential diagnostic algorithm of Tefferi *et al.* (Mayo Clin. Proc. 2010; 85:158-164). From 2005 to 2015 clinical and biological profile is analyzed with statistical software IBM SPSS.19
Results: We have analyzed a total of 20 cases of MPN-Eo, with an age-adjusted incidence rate of 0.029/100.000 habitants/year (2014 Andalucía Population Statistic), subdivided according to the OMS-2008 classification of eosinophilic diseases in:7 cases ofMPNs-Eo associated with abnormalities of PDGFRA(6)/PDGFRB(1), 1 case of CEL-NOS(t(8;13)(p12;q12)+21 and FISH FGFR1 positive), 1 HES-L case and 11 cases of idiopathic HES. Our series shows a similar distribution by sex (11M/9F) and a lower age at diagnosis in MPN with PDGFRA/B(41,14 *vs* 54,6; p=0.044). The most frequent clinical presentation was: constitutional syndrome (60%),lung disease (40%), heart disease (35%:71,4% vs18,2%, 0.049; in PDGFRA/B and HES), skin involvement (35%), bowel damage (25%), rhinitis/asthma (20%), adenopathy (10%) and myalgias(5%); 35% of patients with splenomegaly(71,4% *vs* 9,1%, p=0.013; in NMP-PDGFRA/B and Idiopathic HES) (p=0,013). Bone marrow karyotype was normal in all but 2 patients: 1 PDGFR-B (5q33) case and another CEL-NOS(8p). 25% cases were initially treated with Imatinib, and another 16 patients (55%) received it in second line. With a median follow-up of 94,33 months in the 6 cases of PDGFRA, 100% reach early hematological complete response (HCR: 6,20+/-4,60 weeks) and molecular response in 4 evaluable cases by FISH(MCR5+/-4,12 moths), 1 case PDGFRB, after 1 moth of follow-up, reach partial response (PR) and 1 case CEL-NOS(FGFR1+), is treated with low doses of PEG-IFN, but 6 months later progressed to lymphoblastic lymphoma. In the 11 cases of idiopathic HES, with a median follow-up of 28+/-29,16 months, 9 cases received Imatinib and six of them reached CHR (66%), while three patients discontinued the therapy (1: no response, and 2 intolerance). Finally, only three cases of Idiopathic HES treated with hydroxycarbamide reached CHR.
Summary/Conclusions: The incidence rate of HES, gender and age distribution, and clinical-biological profile, in our community of Andalucía, are similar to that previously described in other series. In the majority of patients with MPN-Eo we must tested a therapy with Imatinib, regardless PDGFRA or PDGFRB abnormalities, because a significant subgroups of patients respond, while responses in patients with PDGFRA or PDGFRB abnormalities are more frequents, deepest and fastest. The prognosis and survival depend on the tissue damage, especially cardiac injury, presents at diagnosis in 71,4% of patients with PDGFRA/B abnormalities, frequently irreversible. This suggests a clear recommendation to treat these types of MPN-Eo early, mainly with Imatinib at diagnosis, in order to avoid cardiac damage

PB2018

BASELINE CHARACTERISTICS AND RISK FACTORS FOR LEUKEMIA-FREE AND OVERALL SURVIVAL IN BULGARIAN PATIENTS WITH PRIMARY MYELOFIBROSIS-A NATIONAL COHORT STUDY

Background: Primary myelofibrosis (MF) is a rare form of BCR-ABL1(-) myeloproliferative neoplasm (MPN). Comprehensive research on the characteristic of this life-threatening condition has not been done in Bulgaria yet. Therefore, the Working Group of MPN of the Bulgarian Society of Hematology initiated a nationwide study.
Aims: To determine the prevalence of MF in the country, and to provide data on the baseline clinical and laboratory parameters and factors for leukemic transformation and overall survival (OS) of a national cohort of patients (pts) with the disease.
Methods: Data on 284 MF pts diagnosed and/or treated in 2014-2015 in 10 clinical centers covering the territory of the country with a population of 5242000>25-yrs of age were analysed. Major demographic, clinical and laboratory parameters, risk profiles according to the international prognostic system (IPSS) and the version for dynamic evaluation of risk (DIPSS and DIPSS-PLUS), and therapeutic approaches were evaluated at baseline as well as in regard to leukemia-free (LFS) and OS in 250 pts.
Results: A male/female ratio of 1.6:1 was determined. The mean age at diagnosis was 64.24 yrs (range 25-86 yrs). In 250 (88%) pts primary MF was diagnosed and in the other 34 (12%) secondary MF developed after another MPN. The most common symptoms were enlarged spleen (78%), anemia (58%), ≥1 constitutional symptoms (41%), thrombocytopenia (21%) and leukocytosis (20%). In 252 (91.2%) pts the diagnosis was confirmed with bone marrow histology and the severity of fibrosis was determined with silver stain in 77% of the cases. Molecular analysis was conducted in 179 (63%) pts and 113 (63.1%) were positive for JAK2 V617F mutation, including as expected 84% of secondary *vs* 60% of primary MF (p=.014). In primary MF, analysis revealed a significant association only between JAK2 mutation and platelet counts <100x10^9/L (p=.018) and transfusion dependence (p=.043). In 20 (7.4%) pts blast transformation was registered regardless of the primary or secondary nature of MF. Univariate analysis of parameters at the time of diagnosis revealed a significant association between inferior LFS and peripheral blood blasts >1% (p<.0001), leukocytosis >20x10^9/L (p<.0001), platelet counts <100x10^9/L (p=.001), hypercatabolic symptoms (p=.01), splenomegaly (p=.01), and treatment history with hydroxyurea (p=.03). Median OS was 6.2 yrs and as expected, it was significantly shorter in pts with leukaemic transformation (3.6 yrs *vs* 7.3 yrs, log rank test p=.002). According to the IPSS, DIPSS and DIPSS-PLUS pts were categorized predominantly in intermediate-high (IHR) and high risk (HR) groups: 68%>79%>87%, respectively. A significant association was confirmed between the OS and risk profiles (p<.0001). In total, 71% of pts required treatment (e.g. hydroxyurea, erythropoetin, androgen, interferon, corticosteroids, ruxolitinib). Splenectomy was performed in 4% of the pts, while RBC transfusions were indicated in 59%. Interestingly, therapy of any kind was significantly associated with better survival in all DIPSS-PLUS risk categories except for HR group who might be the candidates for novel therapies (p=.009 in low risk *vs* p=.002 in IHR groups *vs* p=.127 in HR).
Summary/Conclusions: The study provides, for the first time, nationwide data on the 5.4/100000 prevalence and basic features of Bulgarian pts with MF in regard to clinical and laboratory presentation as well as to prognostic parameters and OS.
Contributions: LG, MG, GM, GB designed the study and contributed equally to this work. MG, YT conducted data analysis. DT, DT, GD, GT, LS, MZ, NP, SD, TD, VG, VS, YP performed research and contributed equally to this work.

PB2019

DISEASE CHARACTERIZATION AND TREATMENT PATTERNS OF PATIENTS WITH MYELOFIBROSIS: ANALYSIS OF US CLAIMS DATABASES

M Mehra[1,*], G Wang[2], J He[1], J Bussolari[2], A Desai[1]
[1]Janssen Global Services, LLC, [2]Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF), a rare myeloproliferative neoplasm, is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis and aberrant cytokine expression. Patients (pts) present with splenomegaly, constitutional symptoms, moderate to severe anemia, thrombocytopenia and leukocytosis. MF has a profound negative impact on survival and quality of life. Presentation may be primary (PMF) or MF transformation from essential thrombocythemia (ET) or polycythemia vera (PV), or may be secondary from diseases such as myelodysplastic syndrome, leukemia, and lymphoma (Other MF). Management options include allogeneic stem cell transplantation, hydroxyurea, interferon alpha, alkylating agents, splenectomy, splenic radiotherapy, and the JAK1/2 inhibitor ruxolitinib.
Aims: Characterize disease and treatment patterns in pts with MF using 2 US health insurance claims databases.
Methods: The Truven Marketscan (Commercial Claims and Encounters and Truven Medicare) database was retrospectively analyzed to identify pts with MF diagnosed between 2006 and 2015 using ICD-9 codes 238.76 and 289.83. Pts aged ≥18 years with ≥1 month of history prior to diagnosis were included. Pts were categorized as PMF, post-PV/ET MF, or Other MF based on earliest MF diagnosis code. Demographic characteristics, constitutional symptoms, platelet counts, and treatment patterns were summarized. Treatment regimens were analyzed according to the following hierarchy (highest to lowest; "± O" referring to combination with any other treatment listed lower in the hierarchy): ruxolitinib±O, hydroxyurea±O, chemotherapy±O, stem cell transplant±O, splenectomy±O, radiation±O, best supportive care (BSC)±O, and steroids only. Sub-analysis of ruxolitinib uptake post launch (in 2011) will be presented.
Results: We identified 6795 pts with MF diagnosis between 2006 and 2015. Based on the exclusion criteria, 6123 pts were included; 3211 (52.4%) were male, and median age at diagnosis was 66 years. A total of 1425 (23.3%), 840 (13.7%), and 3858 (63.0%) pts had PMF, post-PV/ET MF, and Other MF, respectively. Prevalence of splenomegaly at baseline was 11.1% in PMF, 15.5% in post-PV/ET MF, and 7.8% in Other MF. Platelet counts at baseline (± 90 days of index MF diagnosis) were available for 149 (2.4%) pts; mean and median platelet levels were 270,323/μL and 218,000/μL, respectively; 16 (10.7%) pts had platelet counts of <50,000/μL and 116 (77.9%) had platelet counts of >100,000/μL (Table). Overall 3502/6123 pts (57.2%) received ≥1 regimens for MF. Mainstays of initial treatment included hydroxyurea±O (964 treated pts; 27.5%), and BSC±O (753; 21.5%). Only 425/3502 treated pts (12.1%) received ruxolitinib±O as first-line treatment; by category, pts receiving first-line ruxolitinib±O included 194/1390 treated pts (14.0%) with PMF or post-PV/ET MF and 231/2112 treated pts (10.9%) with Other MF. Hydroxyurea±O was the most common first-line regimen for pts with PMF or post-PV/ET MF (463/1390; 33.3%); BSC±O (517/2112; 24.5%) and steroids (615/2112; 29.1%) were the most common first-line regimens for pts with Other MF.

Table 1.

Table. Demographics, baseline characteristics, and treatment of pts with different types of MF at presentation

	Pts		
	PMF n = 1425	**Post-PV/ET MF n = 840**	**Other MF n = 3858**
Male, n %	829 (58.2)	401 (47.7)	1981 (51.4)
Age at diagnosis, median years (range)	67 (20-102)	65 (24-97)	66 (18-103)
Pts with splenomegaly within 1 year before and 90 days after MF diagnosis, n (%)	159 (11.1)	130 (15.5)	299 (7.8)
	PMF or Post-PV/ET MF n = 2265		**Other MF n = 3858**
Pts receiving treatment for MF, n (%)	1390 (61.4)		2121 (55.0)
Pts receiving ruxolitinib ± O as first-line treatment for MF, n/n pts receiving treatment (%)	194/1390 (14.0)		239/2121 (11.3)
Pts with baseline platelet counts, n (%)	**PMF n = 26**	**Post-PV/ET MF n = 15**	**Other MF n = 108**
Platelet count /μL within 90 days of diagnosis			
< 50,000	3 (11.5)	2 (13.3)	11 (10.2)
50,000-75,000	1 (3.8)	1 (6.7)	7 (6.5)
75,000-100,000	0	1 (6.7)	7 (6.5)
> 100,000	22 (84.6)	11 (73.3)	83 (76.9)

Summary/Conclusions: MF was typically diagnosed in pts aged ≥65 years, and was associated with splenomegaly or thrombocytopenia at baseline in a minority of pts. In the present database analysis, ~55-60% pts received treatment. Although ruxolitinib was approved in the US in 2011 for treatment of high- or intermediate-risk PMF or post-PV/ET MF, there is limited information in the database on its clinical use as a first-line treatment.

PB2020

RISK FACTORS AND OUTCOMES OF ASIAN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPNS) IN LEUKAEMIC TRANSFORMATION

G Kam*, ZY Myint, LH Lee, C Chuah, GC Wong
Department of Haematology, Singapore General Hospital, Singapore, Singapore

Background: Progression to acute leukaemia is a rare event in the natural his-

tory of the MPNs, namely essential thrombocythaemia (ET), polycythaemia vera (PV) and myelofibrosis. Prognosis in MPN patients with leukaemia transformation (LT) is almost universally fatal and no effective treatment is available.
Aims: As data on Asian patients with MPN in LT is lacking, we evaluated the risk factors and outcomes of Asian MPN patients with LT in this retrospective single centre analysis.
Methods: We reviewed the case records of 824 Asian patients with MPNs from our institution's IRB approved MPN registry. Patients with LT were compared with other patients in the registry who did not have LT on follow up.
Results: Among 824 MPN patients, 30 were identified to have LT from 2002 to 2015. The median follow up was 6.2years. Median age of LT was 72years and occurred at a median of 33.2years after diagnosis. 3.9% (n=22) of ET, 0.5% (n=1) of PV and 11.5% (n=7) of myelofibrosis patients progressed to acute leukaemia (p <0.05). Time to LT was longest for ET (11years), followed by myelofibrosis (3.9years) and PV (1.5years) (p=0.018). There was no impact of JAK2, Calreticulin and MPL mutations on LT (p=0.55). Patients with LT had lower Hb at diagnosis (12.7g/dL *vs* 14.8g/dL, p=0.001). A trend to higher presenting leukocyte count (15.5x 10^9/L *vs* 12.6x10^9/L, p=0.053) and older age of diagnosis of MPN (59.5years *vs* 56years, p=0.061) was seen in patients with LT (p=0.053). On log-rank test, MPN subtype (p<0.05), presenting Hb <10g/dL (p<0.05), presenting WBC ≥13x10^9/L (p=0.009), presenting platelet count ≥1000 x10^9/L (p=0.045) and age at diagnosis of MPN ≥60years (p=0.001) were factors for shorter time to LT. Use of hydroxyurea (p=0.17) and exposure to more than one cytoreductive agent (p=0.45) had no impact on LT. Using all covariates with a p value ≤0.10, we developed a model using Cox proportional hazard model to determine the relative effect of these variables on LT. The model included the above variables and presence of splenomegaly at diagnosis (p=0.071). A presenting leukocyte count ≥13x10^9/L (HR 5.73, 95% Confidence Interval [CI] 1.84-17.88, p=0.03) and presenting Hb <10g/dL (HR 8.05, 95%CI 1.66-38.95, p=0.01) were independent poor prognostic factors for LT. At LT, 43.3% (n=13) had complex/ adverse cytogenetics. 30% (n=9) had clonal progression compared to karyotype analysis at diagnosis (seven did not have prior cytogenetics results). Median survival after LT was 2.5months. A diagnosis of LT after 2009 (when azacytidine became available at our institution) was not shown to affect survival after LT (p=0.73). Outcomes were not different whether LT occurred below or above the age of 60years (p=0.73). One patient (3.3%) was lost to follow up. 63.3% (n=19) received supportive treatment including palliative chemotherapy. 16.7% (n=5) received azacytidine-based chemotherapy, while 13.3% (n=4) received an AML-type regimen/ allogeneic stem cell transplant and one (3.3%) received experimental treatment. Survival for the different treatment modalities was not statistically significant (p=0.19): palliative chemotherapy/ supportive care 1.5months, azacytidine-based 3.1months, intensive chemotherapy/ allogeneic stem cell transplant 8.1months.
Summary/Conclusions: As in published literature, outcomes for Asian MPN patients in blast phase are dismal. In this study, a presenting Hb <10g/dL and presenting WBC ≥13x10^9/L were predictors of LT in MPN. Existing treatment modalities are ineffective in attaining long term remission and have not improved survival over time.

PB2021

SAFETY AND EFFICACY OF RUXOLITINIB IN CLINICAL PRACTICE FOR PRIMARY AND SECONDARY MYELOFIBROSIS

M Breccia[1,*], A Andriani[2], M Montanaro[3], E Abruzzese[4], F Buccisano[5], M Cedrone[6], A Centra[7], N Villivà[2], F Celesti[3], MM Trawinska[4], A Di Veroli[5], B Anaclerico[6], G Colafigli[1], A Spadea[8], L Petriccione[9], G Cimino[7], R Latagliata[1], G Alimena[1]
[1]Dept Cellular Biotechnologies and Hematology-Sapienza University, [2]Nuovo Regina Margherita Hospital, hematology, Rome, [3]Belcolle Hospital, Hematology, Viterbo, [4]S.Eugenio Hospital, [5]Tor Vergata University, [6]S. giovanni Hospital, Hematology, Rome, [7]S. Maria Goretti Hospital/, Hematology, Latina, [8]IFO, Hematology, Rome, [9]Frosinone Hospital, Hematology, Frosinone, Italy

Background: Ruxolitinib, a JAK1 and JAK2 inhibitor, has been tested and approved for the treatment of primary and secondary myelofibrosis (MF). Reduction of spleen volume, improvement of constitutional symptoms and improved quality of life have been reported as major findings in sponsored randomized clinical trials.
Aims: Aim of our study is to report safety and efficacy of ruxolitinib in 98 patients affected by MF treated outside clinical trials.
Methods: Patients were collected and treated consecutively by the Lazio Cooperative Group for Ph negative myeloproliferative diseases.
Results: There were 45 males and 53 females, median age was 61.8 years (range 35.3-88). Forty-five patients were diagnosed as primary MF and 53 as evolution from a previous MPN: 31 after Polycythemia Vera, 20 after Essential Thrombocythemia and 2 were not specified. Median splenomegaly at baseline was 6 cm. At baseline, IPSS stratification revealed 4 patients with low risk, 27 with intermediate-1 risk, 42 as intermediate-2 and 23 as high risk. Seventy-seven patients (78.5%) experienced constitutional symptoms at baseline and out of 80 patients tested, 58 (72%) were $JAK2^{V617F}$ mutated. Overall, 40 patients received hydroxyurea as firstline treatment, 30 patients received other chemotherapeutic approaches, whereas 28 were treated with ruxolitinib frontline. Median time from diagnosis to start of ruxolitinib in the whole cohort was 34.6 months. All patients at the time of treatment were intermediate-2/high risk according to IPSS. Hematological parameters pre-treatment were: median haemoglobin level 10.4 gr/dl, median WBC count 11x10^9/l, median platelet count 239x10^9/l. Median splenomegaly pre-treatment was 10 cm. As regards initial daily dose, according to platelet count, 5 patients started with 5 mg BID, 7 patients with 10 mg BID, 26 patients with 15 mg BID and 60 patients with 20 mg BID, with a median initial daily dose of 20 mg BID. Fifty-eight patients (59%) required a dose modification during the first 3 months, which consisted in a dose reduction due to haematological toxicity in the majority of cases. After 24 weeks of treatment, 48% of patients experienced a clinical benefit with some degree of reduction in spleen volume: in particular, according to revised IWG-MRT criteria, 5 patients (5%) achieved a complete response (CR), 8 patients (8%) a partial response, 6 (6%) a clinical improvement (CI), 28 (28.5%) a spleen response, whereas 25 patients did not achieve any response and 24 were not evaluable. At 48 weeks, 52% of patients obtained a clinical benefit: of them 7 patients (7%) had a CR, 10 (10%) a PR, 6 patients (6%) a CI and 28 patients (28.5%) a spleen response. Overall, 66% of patients had disappearance of baseline symptoms burden. After 1 year, of 72 evaluable patients, 52% achieved and maintained a clinical benefit. Adverse events of special interest at any grade included anemia (39.7%), thrombocytopenia (25.5%), infections (16.3%, of which 10 were bronchopneumonia), fluid retention (3%), diarrhea (2%) and abdominal pain (2%). After a median follow-up of 16 months from start of ruxolitinib, median daily dose decreased to 10 mg BID and 21 patients (21%) discontinued the drug (8 for toxicity, 4 for progression, 4 lack of efficacy, 1 patient underwent BMT, 1 second neoplasia, 3 deaths).
Summary/Conclusions: The results of this retrospective multicentric analysis confirmed the efficacy of ruxolitinib outside clinical trials with more than half of treated patients achieving and maintaining a clinical benefit and most of them reporting relief from symptoms.

RESULTS IN ELDERLY CHRONIC MYELOMONOCYTIC LEUKEMIA PATIENTS TREATED WITH 5-AZACYTIDINE

DM Dunia[1,*], G Nuria[1], D Miguel[1], A Jaime[1], S Dolores[2], M Dolores[2], H Sonia[2], P Blanca[2]
[1]Hematologia, [2]Hospital universitario de Guadalajara, Guadalajara, Spain

Background: Two hypomethylating (HMT) agents,5-azacytidine (AZA)and decitabine have been approved by the FDA for the treatment of CMML. Initial data on HMT efficacy came from studies in patients with high-risk myelodysplastic syndrome (MDS), including, however, only a few cases of CMML. Hypomethylating agents are associated with overall response rates of approximately 30% to 40%, with complete remission rates of about 15%.
Aims: Evaluate efficacy and security of AZA in CMML patients.
Methods: we retrospectively collected clinical data of 8 patients (7 males/1 females) with a median age of 80 years (range72-86) diagnosed with CMML and treated with AZA, in our institution between 2010-2015.
Results: 5 (63%) patients were diagnosed as CMML-1 and 3 (37%) patients as having CMML-2 subtype. AZA was administered at 75mg/m2 daily for 7 days, every four weeks. Response was assessed after median number of 6 cycles. Our patient cohort received a median number of 17 cycles (3-30) of therapy. Overall survival was 42 months (25-74 months). Progression free survival was 23 months (4-28 months). The median time to first response was 4 months. Causes of death were: 3 patients (38%) did evolution to AML (median time to progression 3 months). 3 patients had a sepsis. 1 patient had a lung cancer.
Summary/Conclusions: AZA in elderly CMML patients is efficacy and safety. The response were quickly and cytopenias were controlled.

PB2023

ONLINE STREAMING YOGA IS A FEASIBLE NON-PHARMACOLOGIC MANAGEMENT STRATEGY IN MYELOPROLIFERATIVE NEOPLASM PATIENTS

J Huberty[1,*], R Eckert[1], K Gowin[2], A Dueck[2], R Mesa[2]
[1]School of Nutrition and Health Promotion, Arizona State University, [2]Mayo Clinic, Phoenix, United States

Background: Up to 84% of Myeloproliferative Neoplasm (MPN) patients report a reduced overall quality of life (QoL). While MPN patients often experience an array of disease and treatment-related symptoms, fatigue is the most frequently reported symptom (93%). Yoga may be an effective approach to improving symptom burden (i.e., fatigue) and QoL in MPN patients based on evidence suggesting yoga may improve fatigue and QoL in other cancer types. (e.g., breast, endometrial).
Aims: To examine the feasibility (i.e., acceptability, demand, practicality) of a home-based, online-streamed yoga intervention in MPN patients. A secondary aim was to examine the effects of yoga on self-reported symptom burden and QoL outcomes.
Methods: MPN patients were recruited nationally using social media. Participants were asked to complete 60 minutes of online-streamed yoga per week

and to complete online self-report surveys administered via Qualtrics (demographics, symptom burden (MPN-SAF TSS), and QoL (i.e., pain, anxiety, depression, sleep, sexual function via PROMIS). Surveys were administered at baseline (wk 1), mid-point (wk 7), and post-intervention (wk 12). Weekly yoga minutes were self- reported and collected weekly with adherence defined as achieving ≥60 min/wk.
Results: *Patients:* Two hundred and forty-four MPN patients completed the eligibility survey, 134 were eligible, 55 completed the informed consent and 38 participated in the 12-wk study. The most common reasons for ineligibility were a diagnosed mental illness (n=55) and already regularly performing mindful activity (n=46). Thirty patients had completed the intervention at the time of this analysis. Among those (N=30; mean age=55.8±9.2 years; mean BMI=25.0±4.4 kg/m^2;·86.7% female), polycythemia vera was the most prevalent diagnosis (43.4%), followed by essential thrombocythemia (36.6%) and myelofibrosis (20.0%). The majority of participants were diagnosed >3 years ago (63.3%) and were JAK*V617F* positive (70%). Baseline measures were as follows: MPN-SAF TSS mean=34.6±14.0; Fatigue mean=6.6±2.5; Anxiety mean=51.9±7.0; Depression mean=47.5±7.6; Sleep mean=49.7±6.8. *Yoga Participation & Safety:* Just over 43% (13/30) of study participants averaged ≥60 min/wk of yoga. Overall yoga participation averaged 59.3±32.0 min/wk. Overall, 68% of participants were either satisfied (32%) or very satisfied (36%) with online yoga and 75% of participants agreed (46%) or strongly agreed (29%) that they felt safe from injury while practicing. Only one adverse event was reported (irritated enlarged spleen). *Impact of Yoga Intervention:* From baseline to post-intervention, there were significant improvements in self-reported symptom burden (MPN-SAF TSS mean reduction of 4.77±8.29; p=0.004), fatigue (MPN-SAF TSS mean reduction of 0.83±2.15; p=0.003), anxiety (PROMIS mean reduction of 5.02±7.97; p=0.002), depression (PROMIS mean reduction of 2.89±7.73; p=0.049), and sleep (PROMIS mean reduction of 3.76±3.60; p<0.001). When examining the differences between those that averaged <60 min/wk compared to those that averaged ≥60 min/wk, there were no significant differences in outcomes.
Summary/Conclusions: A 12-wk, home-based, online-streamed yoga intervention is feasible for MPN patients. Although the sample size of this study was small, this study suggests that online yoga may be effective for improving MPN related symptoms and self-reported QoL outcomes (i.e., anxiety, depression, sleep). Interestingly, outcomes were not significantly different between those that averaged <60 min/wk of yoga compared to those that averaged ≥60 min/wk of yoga. Future research should explore the minimal dose needed for improved symptom burden and QoL in MPN patients. Additionally, a randomized controlled trial with an active control group will help to determine the effectiveness of yoga for self-reported patient outcomes.

PB2024

ASCITES A MANIFESTATION OF AGGRESSIVE SYSTEMIC MASTOCYTOSIS CAN SUCCESSFULLY BE TREATED WITH MIDOSTAURIN (PKC412)
I Dybedal[1,*], S Skipper Madsen[2], R Fykse Halstensen[3], V Stenberg[4], L Farkas[5]
[1]Hematology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [2]Medical Faculty, University of Copenhagen, Copenhagen, Denmark, [3]Internal Medicine, Nordland Hospital, Bodø, [4]Internal Medicine, Vestre Viken Hospital, Hønefoss, [5]Pathology, Oslo University Hospital, Radiumhospitalet, Oslo, Norway

Background: Systemic mastocytosis (SM) is a myeloproliferative neoplasia caused by uncontrolled proliferation and accumulation of pathological mast cells in one or more extracutaneous organs. The 2008 WHO classification divides SM into several subtypes including aggressive SM (ASM) with at least one "C finding." Among the four different "C findings" is palpable hepatomegaly with impairment of liver function, ascites and/or portal hypertension. Midostaurin (PKC412) is a new and so far not approved drug shown to have a strong inhibitory activity on neoplastic human mast cells carrying the D816V *KIT* mutation and with an acceptable side-effect profile.
Aims: The primary objective was to assess the clinical effect of PCK412 on ascites in patients with ASM. The secondary objective was to study the effects of PCK412 on other symptoms and findings in ASM patients.
Methods: All our patients with ASM and ascites were receiving midostaurin on a "compassionate use program" provided by Novartis. The 4 patients were ≥18 years and had a verified ASM according to the 2008 WHO classification. Liver biopsies, demonstrating mast cell aggregates, were performed in two of the patients. Portal hypertension was verified by abdominal ultrasound. All the patients had ascites and carried the D816V *KIT* mutation. The effect of PKC412 on ascites was evaluated by means of clinical examination, abdominal computed tomography and/or abdominal ultrasound.
Results: In all of the patients, PKC412 had a significant clinical effect on ascites. From having a need of pleuracentesis weekly or every second week, all of they became independent of pleuracentesis. Their quality of life enhanced dramatically. The patient with the most frequent need of pleuracentesis nearly died by peritonitis probably associated to all his interventions. The initial dosage of midostaurin was 100 mg twice daily. Two of the patients, further confirmed the efficacy of midostaurin by revealing relapse of ascites after having stopped with midostaurin because of sickness. In both cases the production of ascites ceased, and the need of pleuracentesis ended by reintroducing PKC412.
Summary/Conclusions: In all these patients with ASM, midostaurin had an excellent effect on ascites. Although this material is very small, all 4 out of 4 patients with ASM and ascites responded and became independent of paracentesis. The correlation between relapse of ascites when stopping midostaurin and disappearing when the medication was reintroduced, strongly supports a positive effect on ascites, which is a clinical finding that troubles many patients with ASM. It became nearly fatal for one patient in our material. In order to validate a significant effect of PCK412 on ascites in patients with ASM, studies on a larger population is needed.

QUALITY OF LIFE AND SYMPTOM BURDEN IN MYELOFIBROSIS PATIENTS: A REAL WORLD STUDY
T Ionova[1,2,*], L Anchukova[3], O Vinogradova[4,5], T Gritsenko[6], A Evseev[7], L Kozlova[8], K Kurbatova[1,2], G Kuchma[8], E Lomaia[9], A Lyamkina[10], E Machulaytene[11], A Myasnikov[7], T Nikitina[1,2], M Pankrashkina[4], T Pospelova[10], A Rodionova[1], E Usacheva[12]
[1]Multinational Center for Quality of Life Research, [2]Saint-Petersburg MultiSpeciality Medical Center, Saint-Petersburg, [3]Vologda Regional Clinical Hospital, Vologda, [4]Hematological City Center, Botkin City Clinical Hospital, [5]Pirogov Russian National Research Medical University, Moscow, [6]Samara State Medical University, Samara, [7]Republican Hospital named after V.A. Baranov, Petrozavodsk, [8]Orenburg State Medical University, Orenburg, [9]Federal Almazov North-West Medical Research Center, Saint-Petersburg, [10]Novosibirsk State Medical University, Novosibirsk, [11]Outpatient diagnostic department, [12]R.M. Gorbacheva Memorial Institute of Children Hematology and Transplantation, Pavlov State Medical University, Saint-Petersburg, Russian Federation

Background: Myelofibrosis (MF) is associated with poor prognosis, significant symptom burden, and worsened quality of life (QoL). Assessment of patient-reported outcomes is an effective way to identify patients' risks/benefits of MF treatment.
Aims: We aimed to study QoL and symptom burden in MF pts in a real world setting as well as to make comparisons in the groups depending on treatment modality.
Methods: A total 93 pts with MF were enrolled in the multicenter real world QoL study-64 (69%) with primary MF, 14 (15%) post-essential thrombocytopenia MF, 15 (16%) post-polycythemia Vera MF. Median age-59 years (range 28–90); male/female-37/56. All pts received the best available treatment (BAT, n=62) or ruxolitinib (n=31) for at least 6 months (median 12 months, range 6–238). High proportion of pts (79%) had IPSS intermediate or high risk. All pts completed the SF-36 QoL questionnaire, symptom assessment questionnaire CSP-MF and Patient Global Impression of Change (PGIC) tool; physicians collected information about disease and treatment from medical records. Integral QoL Index was calculated on the basis of SF-36 QoL questionnaire. For statistical analysis ANOVA, multiple regression and $\chi 2$ test were applied.
Results: 23 pts (24.7%) from 93 pts were full spleen reduction responders, 31 pts (33.3%)-moderate responders, 39 pts (42%)-non-responders. Number of full responders was higher in pts receiving ruxolitinib as compared to BAT (48.4% *vs* 12.9%, p<0.0001). QoL in all SF-36 scales was significantly worse in pts with MF comparing to healthy controls; the most pronounced impairment was observed in role physical functioning (39.8 *vs* 76.9), physical functioning (58.1 *vs* 85.3) and role emotional functioning (52 *vs* 77.1); Integral QoL Index in pts was lower than in healthy controls-0.3 *vs* 0.55 (p<0.0001). More than one third of pts had significant or severe QoL impairment: Integral QoL Index was 7 times less as compared to healthy controls. Pts receiving BAT showed more pronounced QoL impairment as compared to pts receiving ruxolitinib: they had worse physical functioning (51.3 *vs* 74.7), role physical and role emotional functioning (32.2 *vs* 61.3, 43 *vs* 75.3), general health (40.9 *vs* 53.6), vitality (43.9 *vs* 60.2), social functioning (58.4 *vs* 81), and mental health (52.1 *vs* 67), p<0.05; Integral QoL Index was significantly lower-0.24 *vs* 0.47 (p<0.0001). Positive changes in health condition measured by PGIC were reported in 67% pts receiving ruxolitinib *vs* 40% patients receiving BAT (p=0.01). The majority of pts (74%) exhibited at least one moderate-to-severe symptom; the most prevalent among symptoms were fatigue, inactivity, pain in bones/muscles, insomnia, dizziness and feeling of worry. These symptoms were more pronounced in pts on BAT comparing to pts on ruxolitinib (p<0.05). Inactivity appeared to have the most significant negative impact on QoL; multiple linear regression model indicated significant relationship between symptom severity and Integral QoL Index (R-squared=0.65, p<0.001) with the highest regression coefficient for inactivity (Beta-coefficient=0.6).
Summary/Conclusions: Patient-reported outcomes such as QoL and symptom burden in MF pts during treatment in a real world setting may be a solid supplement to clinical outcomes and may contribute to better disease control and improved quality of care of this difficult patient population. The data of this real world study demonstrate benefits of ruxolitinib therapy from patient perspective and support the results of clinical studies.

BFIBRINOGEN G-455-A GENE POLYMORPHISM: IS IT A FACTOR FOR ASPIRIN PLATELET INSENSIVITY IN PATIENTS WITH POLYCYTHEMIA VERA?
R Cacciola[1,*], E Gentilini Cacciola[1], E Cacciola[2]

[1]Experimental and Clinical Medicine, [2]Medical and Surgical Science and Advanced Technologies, Institute of Haemostasis, Catania, Italy

Background: Polycythemia vera (PV) is a myeloid neoplasm characterized by platelet activation and thrombotic risk. According to PVSG, the antithrombotic therapy includes low dose ASA. However, there are insensivity ASA PV patients. It is debated if inherited thrombophilia increases the polycythemic platelet activation and, hence, the ASA platelet insensivity.
Aims: Therefore, we evaluated βFibrinogen G-455-A gene polymorphism, as thrombophilic molecular mutation associated with increased platelet aggregation, platelet count, hematocrit (HCT), β-thromboglobulin (β-TG) and platelet factor 4 (PF4) as markers of platelet activation, fibrinogen (Fg), Platelet functional activity (PFA) as indicator of ASA platelet sensitivity and clot formation time (CFT), as indicator of aspirinated platelets contribution to clot firmness. We studied 40 patients (28 men, 12 women; mean age 64 years, range 35_85 years) with PV according to WHO criteria. Fifty subjects served as controls.
Methods: The mean duration of disease was 9 years. All patients were on phlebotomy and ASA (100 mg once day). The βFibrinogen G-455-A genotype was determined using a commercialized polymerase chain reaction kit with sequence-specific primers. Platelets and HCT were measured by automated analyzer. βTG and PF4 were determined by ELISA. PFA and CFT were measured by Platelet Function Analyzer (PFA-100) and by ROTEM delta, respectively.
Results: All patients had heterozygous βFibrinogen G-455-A. The mean platelet and mean HCT value were 428±180 x109/L and 47±3%. All patients had normal Fg (244±47mg/dl), high β-TG and PF4 (133±47 IU/ml *vs* 20±11 IU(ml and 45±21 IU/ml *vs* 6±2 IU7ml, respectively) (p<.0001 and p<.001, respectively), prolonged C/EPI closure time (CT, units: s, n.v. 84-160 s) (252±48 s) and normal CFT (CFT, units: s, n.v. 30-110 s) (50±7 s).
Summary/Conclusions: These findings suggest that βFibrinogen G-455-A gene polymorphism is not associated with ASA platelet insensitivity in patients with polycythemia vera.

PB2027

ESSENTIAL THROMBOCYTHEMIA WITH JAK2 V617F OR CALR MUTATION: TWO DIFFERENT PHENOTYPES

AS Vilches Moreno[1,*], L Guerrero Fernández[2], J Gonzalez Medina[3], R Ayala Díaz[3], J Martínez López[3], D Monteagudo Saiz[4], MÁ Andreu Costa[4], V Robles Marinas[2]
[1]Hematología y Hemoterapia, Hospital Universitario de Móstoles, Móstoles, [2]Hematología y Hemoterapia, Hospital de Cabueñes, Gijón, [3]Hematología y Hemoterapia, Hospital 12 de Octubre, [4]Hematología y Hemoterapia, Hospital Universitario de Móstoles, Madrid, Spain

Background: The JAK2 V617F mutation is found in 50-60% of cases of essential thrombocythemia while 30% of cases carry calreticulin gene (CALR) and 5% MPL substitution. Recent studies have analyzed the clinical and hematologic features in essential thrombocythemia and have demonstrated the phenotypically differences between JAK2 V617F and CALR mutations.
Aims: We analyzed a Spanish cohort of 101 cases of essential thrombocythemia with JAK2 V617F or CALR mutations. We studied the hematologic and clinical features, including the thrombotic and hemorrhagic events and we compared both groups in order to study different phenotypes in essential thrombocythemia.
Methods: We retrospectively analyzed a cohort of 101 cases of essential thrombocythemia diagnosed between 1990 and 2015. We examined the frequency of JAK2 V617F and CALR mutations, the clinical (Age, gender, thrombotic and hemorrhagic events) and hematologic features (platelets, leukocytes and hemoglobin counts) and the overall survival in these patients. The mutation load of JAK2 V617F was determinated with real-time quantitative PCR. For the detection of CALR exon 9 mutations, fragment analysis have been used. Statistical analyses were performed with SPSS software.

Table 1.

	JAK2 mutated	CALR mutated	p
Age at diagnosis, years	63 (range 24-90)	52 (range 28-83)	**0,007**
Gender (Male)	40%	60%	
Hemoglobin, (g/dL, mean ± SD)	14,3 ± 1,6	13,8 ± 1,4	0,227
Leukocytes (10^9/L, mean ± SD)	9,7 ± 3,5	9,4 ± 2,7	0,721
Platelets (10^9/L, mean ± SD)	707,794 ± 256,3	1.006,950 ± 482,2	**0,001**
Hematocrit (Percentage, mean ± SD)	42,4 ± 4,4	42,6 ± 3,1	0,914
Cardiovascular risk factors			
- Hypertension	45%	55%	0.044
- Mellitus Diabetes	85%	15%	1
- Dyslipidemia	69%	31%	0.084
- Obesity	92%	8%	0.712
- Smoking	67%	33%	0.832
Thrombosis	68,3%	31,7%	**0.020**
Bleeding	10%	90%	**0.012**
Antiaggregation	54,5%	45,5%	0.343

Results: In our study we identified 80% with JAK2 V617F mutation and 20% with CALR mutation (type 1, 70%; type 2, 25%; and others, 5%). The mean age of patients with CALR mutation was 52 years (range 28-83) and JAK2 patients was 63 years (range 24-90). The CALR group had more males (60%) compared to JAK2 group (40%) and were younger at diagnosis (P=0,007). The CALR group had higher platelet counts (1.006,950±482,2 x10^9/L *versus* 707,794±256,3L; p=0,001), lower hemoglobin concentration and lower leukocyte counts, not being statistically significant. Venous and arterial thrombosis were more frequent in JAK2 patients (30%; p=0,030) who had also more cardiovascular risk factors. However, thrombosis in these patients was not related to the platelet counts. Hemorrhages were more frequent in CALR patients (90%; p=0.012) and strongly associated with higher platelet counts (p=0.001) and less with low hemoglobin levels (p=0.227). We also observed that the two groups have similar overall survival.
Summary/Conclusions: In our study, we have observed that patients with CALR mutation were younger and they had higher platelet counts compared with JAK2 mutation group. CALR mutation patients showed a higher risk of developing hemorrhagic events while JAK2 mutation-positive showed a higher risk of venous thrombosis. Thrombosis events were also related to higher leukocyte counts and the presence of cardiovascular risk factors, which were more frequent in the JAK2V617F group. However, we did not find differences in overall survival between both groups. In conclusion, this study confirms that essential thrombocythemia with CALR or JAK2 mutations have biological and phenotypical differences. Therefore, it might be useful for a better understanding of the prognosis and treatment in this disease.

PB2028

CLINICAL IMPORTANCE OF B2 GLYCOPROTEIN I ANTIBODIES IN BCR-ABL NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

MZ Kocak[1], M Dagli[1], A Kutlucan[1], A Basturk[1,*], A Unlu[2], H Acar[3], L Kutlucan[4]
[1]Department of Internal Medicine, [2]Departments of Biochemistry, [3]Departments of Medical Genetics, Selcuk University, School of Medicine, [4]Konya Training and Research Hospital, Konya, Turkey

Background: Arterial and venous thrombotic events are observed to be higher in BCR-ABL negative Myeloproliferative Neoplasms (MPN) than the normal population. These complications are most important causes of morbidity and mortality. β_2 glycoprotein I antibody (β_2-GPI Ab) (anti-apolipoprotein H Antibodies) is an important marker of thrombosis in autoimmune diseases.
Aims: In our study, we aimed to evaluate the association of thrombosis and levels of β_2-GPI Ab in BCR-ABL negative MPN patients without no genetic predisposition to thrombosis.
Methods: Seventy one patients with BCR-ABL negative MPN and 62 controls were included. Exclusion criteria were present of cardiovascular risk factors, malignancy, active infection, renal failure, and being smaller than 18 years old. Genetic and laboratory testing (such as Factor V Leiden, prothrombin G20210A, activated protein C resistance and homocysteine) for thrombophilia were done in all patients and controls in order to evaluate accurately association between thrombosis and β_2-GPI Ab.
Results: Average level of β_2-GP Ab was 187 U/ml in all 133 persons (patient and control groups). Average level of β_2-GP Ab was 217 U/mL in 71 patients with BCR-ABL negative MPN and 160 U/mL in 62 controls. This difference was statistically significant (p=0.006). Subgroup analysis in patients are seen in Table 1. There was no difference between patients with or without history of thrombosis according to the β_2-GPI Ab levels (p=0.144).

Table 1. Relationship of β2-GPI Ab Level and History of Thrombosis in Patient Group.

		β2 Glycoprotein I Ab (U/mL) **		
History of Thrombosis	Number (%)	Median	Min-Max	p *
Present	27 (38 %)	187	15-696	0.144
Absent	44 (62 %)	242.5	34-763	
Total	71 (%100)	217.0	15-763	

Summary/Conclusions: Despite the known increased risk of thrombosis and hemorrhage in MPNs, mechanisms are still not fully clear. To our knowledge, our study is the first study evaluating the relationship between β_2-GPI Ab and thrombosis in BCR-ABL negative MPNs after genetic risk factors excluded. While β_2-GPI Ab level was significantly higher in patients with MPN than in normal subjects; no significant difference was determined between patients with or without thrombosis. Alongside β_2-GPI Ab, assessment of antibodies against domain IV-V of β_2-GP may be useful.

PB2029

NEW PROPOSED WHO CRITERIA FOR THE PV DIAGNOSIS: A CLINICAL OVERLOAD PROBLEM?

M Moreno[1,*], T Gómez-Casares[1], G Santana-Santana[2], JM González-Martín[3], C Bilbao[1], T Molero[1]
[1]Hematology, [2]Universitary Hospital of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain, [3]Estadística, Universitary Hospital of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: There are controversies regarding on which cell parameter may be more conveniently used as a surrogate criteria of an increased red cell mass (RCM), that is, hemoglobin (HB) level and hematocrit (HCT) value. According to the 2007/2008 WHO classification, HB level should be >18.5 g/dl in men and >16.5 g/dl in women and/or increased HCT. It has been argued that application of these criteria may result in an underdiagnosis of PV by excluding patients with actual RCM mass that is 25% above mean predicted value, but whose HB and HCT levels are below the WHO guidelines. Therefore, recently the WHO revised the criteria and in 2015 made a new proposal lowering the HB/HCT threshold to 16.5 g/dl/49% in men and 16 g/dl/48% in women.
Aims: We aimed to apply the proposed WHO 2015 criteria in order to determine whether this contribution in the identification of masked PV would compensate the work overload in our laboratory and clinical practise.
Methods: We selected samples of patients from routine analytical test that meet the new proposed WHO criteria from 22/12/2015 to 23/01/2016 and studied the presence of JAK2V617F mutation as mayor diagnosis criteria for PV. JAK2V617F mutation was determined qualitatively by amplification refractory mutation system polymerase chain reaction assay. We collected white blood count, erytrocytes and platelets levels as well. For statistical analysis has been used ShapiroWilk test to check the normality of the data of quantitative variables. The statistical program used was R Core Team (2014).
Results: In our study, there were 48 patients: 47 men and 1 woman. The median age of the patients was 48,5 years (range: 17-73). The median of HB was 17.7 g/dL (16.5-18.3) and the median HCT was 51.35% (48.1-55.4%). The number of positive JAK2V617F mutation was cero. The rest of analytical characters were: Erythrocytes (average 5.44 10e6/uL, 1.36-6.52), leykocytes (average 9.09 10e3/uL, 3.87-19.8) and Platelets (average 259.02 10e3/uL, 134-416).
Summary/Conclusions: Amont the 48 patients, none of them vas positive for JAKV617F mutation. Admission of new criteria would means a high increase in the numbre of patients to be evaluated, implying an enhane human and laboratory resource consumption, with a significant economic impact. Based on our results, we wonder whether these new proposed WHO criteria should be approved.

PB2030

PREVALENCE OF THE JAK2 V617F MUTATION IN SOME COHORTS OF THE CENTRAL SIBERIA (KRASNOYARSK REGION) POPULATION

I Olkhovskiy[1,2,*], A Gorbenko[2], M Stolyar[2,3], T Subbotina[2,3], E Vasiliev[2,4], M Mikhalev[2,5], V Moskov[4], T Olkhovik[5], N Philina[6], T Kolotvina[6], G Karapetyan[7], T Dyupina[7], V Babushkin[8,9], T Kaykova[9], G Gritsan[8,9]
[1]Krasnoyarsk Scientific Center SB RAS, [2]Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, [3]Siberian Federal University, [4]Krasnoyarsk regional hospital, [5]Krasnoyarsk city Clinical Hospital № 7, [6]Krasnoyarsk Regional Blood Center №1, [7]Road Clinical Hospital Station Krasnoyarsk Railways, [8]Krasnoyarsk State Medical University named after Professor V.F.Voino-Yasenetsky, [9]Krasnoyarsk Interdistrict Hospital ambulance named after N.S. Karpovich, Krasnoyarsk, Russian Federation

Background: Somatic mutation of the JAK2 V617F is associated with the pathogenesis of myeloproliferative neoplasms (MPNs) and it is an important diagnostic marker. However, V617F JAK2 was detected also at 0.2-1% of the adult population, without the MPN when using highly sensitive allelic load test (Xu X, et.al., 2007; Nielsen C., et.al., 2014). The V617F JAK2 mutation significantly increases the risk of both arterial and venous thrombosis, including cerebral vessels, visceral intestinal veins and especially Budd-Chiari syndrome (Smalberg JH, et.al., 2012). These causes of hospitalization may be the first manifestations of MPN.
Aims: Evaluate the frequency of the JAK2 V617F mutation in different cohorts of hospital patients and blood donors.
Methods: Allele-specific RT PCR was performed to detect of the JAK2 V617F allele load in whole blood samples among the following groups: healthy blood donors, patients who were included in the program of routine inspections, patients who were are hospitalized in general hospitals, as well as those who were directed by hematologist with suspected to MPN.

Table 1. JAK2 V617F mutation frequency among cohorts.

Cohort	Total surveyed	JAK2-V617F positive patients, n (%)	JAK2-V617F allele load, (%) (Me (Min-Max))	Age (Me (Min-Max))
Blood donors	1149	8 (0.7)	0.47 (0.07-2.58)	39 (18-67)
In baseline medical examination	1515	17 (1.12)	0.26 (0.05-0.18)	53 (45-80)
From not hematological hospital departments	1290	24 (1.86)	0.84 (0.04-48.8)	57 (16-90)
Directed by hematologist	903	301 (33.3)	32.0 (0.06-97.0)	54.0 (16-100)

Results: The frequency of the JAK2 V617F mutation was maximal when the patients were directed by a hematologist with MPN suspected (Table 1). Minimum prevalence was observed in healthy blood donors. Among patients from non-hematological hospital departments 12% cases (3 of 24 patients) with JAK2-V617F had ischemic stroke. Participation in voluntarily medical examination reveals patients with mutation but who have no any hematological abnormalities in 95% cases were directed by hematologist with suspected to MPN.
Summary/Conclusions: High risk of thrombosis and of the MPN development, as well as the potential risk of transmission of the transformed cell clone to recipients of the bone marrow and blood, raises the issue of screening for JAK2 V617F among some cohorts of patients. An analysis of "benefit - harm", taking into account the effectiveness of preventive measures will be the subject of additional studies.

PB2031

CLINICAL FEATURES OF LATENT/MASKED POLYCYTHEMIA VERA (SINGLE CENTER EXPERIENCE)

I Subortseva*, A Melikyan, A Kovrigina, T Kolosheynova, A Abdullaev, A Sudarikov, S Kulikov
National Haematology Research Center, Moscow, Russian Federation

Background: Polycythemia vera is a heterogeneous group of diseases. In patients who don't meet the World Health Organization (WHO) criteria for overt polycythaemia vera (PV), a diagnosis of latent/masked PV (mPV) can be determined. MPV is characterized by JAK2V617F positive, morphological features of bone marrow for PV according to WHO, but hemoglobin <18,5 g/dL in men and <16,5 g/dL in women.
Aims: The aim of this study was to identify clinical features of mPV as a separate group of PV.
Methods: The study included 81 patients observed in the outpatient department of National Research Center for Hematology from 2014 to 2015, 50 patients with PV and 31 patients with mPV.
Results: Distribution of patients by gender was statistically comparable. Patients with PV was older compared to mPV: median age was 56 and 44. Between the groups of patients with mPV and PV obvious difference in red blood cells ($5.37x10^{12}$/L ($4.1-6.5x10^{12}$/L) *vs* $6.94x10^{12}$/L ($5.4-8.8x10^{12}$/L)); hemoglobin (14,8 g/dL (10,0-16,7 g/dL) *vs* 17,8 g/dL (13,6-24,7 g/dL)); hematocrit (45% (30-52%) *vs* 53% (42-70%)). Median platelet counts higher in the group of patients with mPV compared with PV: the median was $644x10^9$/L ($179-1978x10^9$/L) *vs* $636x10^9$/L ($137-2437x10^9$/L). Differences of white blood cells was not reveale in the two groups. All the patients were V617F JAK2 positive. Determination of allele burden JAK2V617F performed 29 patients with mPV and 37 patients with PV. JAK2 allele burden was significantly higher in patients with PV compared to mPV: median 14% (3-57%) and 55.5% (24-86%) respectively. Thrombosis revealed in 38% (12 patients) with mPV and in 16% (10 cases) in the PV. It was mainly venous in the case of mPV with a high frequency of splanchnic vein thrombosis. Arterial thrombosis detected only in 4 cases.
Summary/Conclusions: Masked PV is a separate nosological variant of PV.

PB2032

CLINICAL FEATURES AND MOLECULAR MARKERS IN ESSENTIAL THROMBOCYTHEMIA

A Zherniakova*, I Martynkevich, V Shuvaev, L Polushkina, M Fominykh, V Udaleva, I Zotova, D Shichbabaeva, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Particular molecular marker detection (*JAK2 V617F, MPL, CALR*) or its absence (triple-negative (TN)) in essential thrombocythemia (ET) can be served as a basis of different biological neoplasm behavior.
Aims: The aim of this study was to investigate interactions (differences) between the presence of each molecular marker, clinical features and course of ET.
Methods: One hundred and fifty ET patients, who had been diagnosed at our institution according to WHO 2008 criteria. The following parameters were assessed: age, gender, complete blood count, clinical symptoms (weakness, headache, dizziness, arthralgia, constitutional symptoms, erythromelalgia, splenomegaly), thrombotic complications and bleeding. Overall survival (OS) in ET patients with different molecular markers were analyzed by Kaplan-Meyer method and compared between groups. Log-rank, ANOVA Kruskal-Wallis test and the Chi-square test with Yate's contingency correction were used for statistical analysis.
Results: Median age was 56 years (range 19-82), 110 patients (73%) was female. Median follow-up was 28 months (range 1-168). The following mutations were detected: *JAK2V617F (JAK2+)* n=115 (76,7%), *MPL*+ n=1 (0,7%), *CALR*+ n=14 (9,3%) and triple-negative (TN) molecular status was registered in n=20 (13,3%) patients. Complete blood count mean values (standard deviations) at initial ET diagnosis were: *JAK2*+: Hb 14.2 (17.6) g/dL, WBC 9.7 (3.7) $x10^9$/L, PLT 831 (273) $x10^9$/L. *MPL*+: Hb 12.3 g/dL, WBC 7.1$x10^9$/L, PLT 2079 $x10^9$/L. *CALR*+: Hb 13.8 (16.7) g/dL, WBC 9.3 (3.9) $x10^9$/L, PLT 1086 (453) $x10^9$/L. TN: Hb 13.6 (15.6) g/dL, WBC 11.4 (4.7) $x10^9$/L, PLT 777 (230) $x10^9$/L. The presence of *CALR* mutation was associated with significant higher platelets level (p=0.03). The symptoms frequencies according molecular markers groups were as followed: *JAK2*+: weakness-34.8%, headache/dizziness-20.9%, arthralgia-19.1%, splenomegaly -16.5%, erythromelalgia-8.7%, pruritus-5.2%, constitutional symptoms-4.4%. *MPL*+: weakness only (100%). *CALR*+: weakness-21.4%, headache/dizziness-7.1%, splenomegaly-21.4%, erythromelal-

gia-14.3%. TN: weakness-25.0%, headache/dizziness-25.0%, arthralgia-25.0%, splenomegaly-10.0%, erythromelalgia-10.0%, pruritus-5.0%. Thrombosis rates according molecular markers groups were: *JAK2*+ - 48.6%; *CALR*+ - 14.2% - and TN-30.0%. Bleeding frequency in *CALR*+ patients was 21.4% and for *JAK2*+ patients 6.9%. Overall survival (OS) was significant higher in *CALR*+ group compared to others (*JAK2*+ and TN, p=0.019).

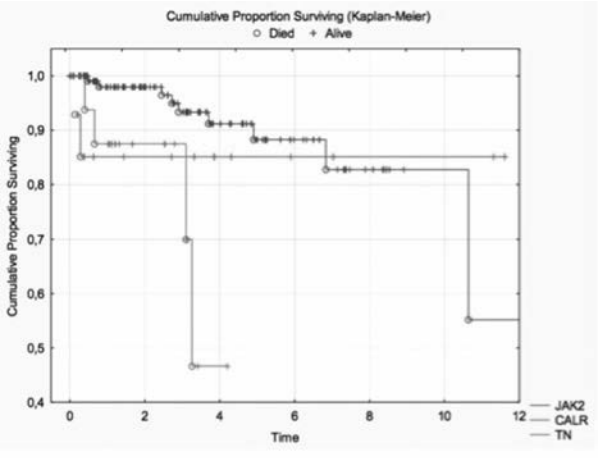

Figure 1.

Summary/Conclusions: The presence of *JAK2V617F* mutation in ET patients is associated with higher thrombosis risk, despite the fact of *CALR*+ patients had higher platelets level. OS in *CALR*+ ET patients was significant higher compared to *JAK2*+ and TN.

PB2033

IMPLEMENTATION OF THE JAK2 V617F MUTATION ANALYSIS IN THE DIAGNOSIS OF SUSPECTED MYELOPROLIFERATIVE NEOPLASMS IN CAPE TOWN

E Verburgh[1,*], E Poulet[2], K Shires[1], N Novitzky[1], C du Toit[1]
[1]Haematology, [2]Medicine, University of Cape Town, Cape Town, South Africa

Background: The Philadelphia-negative myeloproliferative neoplasms (MPN) are clonal hematopoietic stem cell malignancies characterized by overproduction of one or more myeloid lineages. The discovery of the JAK2 V617F (JAK2) mutation in 2005 was a crucial step towards unraveling the pathogenesis of the MPN and finally provided a clonal marker for the diagnosis of Polycythaemia Vera (PV), Essential Thrombocytosis (ET) and Primary Myelofibrosis (PMF). Previously diagnostic guidelines of MPN were fraught with controversy due to the absence of exactly such a defining feature. The JAK2 mutation makes it possible to definitely diagnose >95% of PV, and 50-60% of both ET and PMF cases.
Aims: We retrospectively analysed our tertiary care institution patient population in whom this test was requested since its inception in 2007. JAK2 was requested in two groups: patients presenting with thrombosis and with probable MPN. We looked at the role of the JAK2 mutation analysis in the diagnostic algorithm of MPN and in patients presenting with thrombosis.
Methods: We created a database with detailed folder review of 267 patients who had undergone the JAK2 test between 2007 and 2013 in Groote Schuur Hospital. The initial presentation of each patient was analysed for two variables, namely raised cell counts (cytoses) or thrombotic complications, or both. The diagnostic algorithm for MPN implementing the JAK2 analysis was applied to each patient. In addition to JAK2, patients with sustained erythrocytosis were investigated with serum erythropoietin (s-EPO), red cell mass (RCM) and bone marrow examination (BME).
Results: Mean age at testing were 51.2 years. Male gender predominated (n=153; 57.3%). In our population 30% (n=80) of all patients and 64.5% (n=78) of MPN patients were JAK2 positive; the other 2 JAK2 positive patients had mixed myelodysplastic-myeloproliferative syndrome. One-hundred-twenty-one patients were diagnosed with an MPN: ET patients (n=38) tested JAK2 positive in 34%; PMF (n=27) in 63% and PV (n=56) 86% positive. Of the 103 patients investigated for a sustained erythrocytosis, only 56 (54%) could be confirmed as PV. RCM and s-EPO indicated a relative erythrocytosis in 24 patients, the other 23 patients had erythrocytosis of undetermined origin. Sixty-seven patients presented with thrombotic complications: 26 with MPN diagnosis (39%) and 51 (61%) where MPN was ruled out. The diagnosis of MPN was associated only with those patients who exhibited sustained cytoses while presenting with thrombosis. MPN patients presenting with thrombosis were 0.7 times as likely to be JAK2 positive as negative, the difference was not significant.
Summary/Conclusions: The JAK2 mutation analysis was positive in the majority of our MPN population in accordance with published results but in a significant minority other methods of diagnosis remain important. The percentage JAK2 positivity in the PV population was lower than previously reported. Furthermore, almost half of patients investigated for sustained erythrocytosis did not fulfil criteria for PV. These patients with relative or undetermined erythrocytosis form a significant minority where current diagnostic and pathogenetic methods are lacking. Our analysis indicates that employing the JAK2 test to uncover an underlying MPN in patients presenting with thrombosis is unlikely to yield a positive result in the absence of sustained cytoses. Proven MPN patients presenting with thrombosis were just as likely to be JAK2 negative as positive.

PB2034

RUXOLITINIB IN MYELOFIBROSIS: A TWO-CENTRE EXPERIENCE

J Russell[1,*], KD Maw[2], C Gomez[2], M Mangi[2], I Whalley[1], S Sadullah[2]
[1]Haematology, Ipswich Hospital, Ipswich, [2]Haematology, James Paget University Hospital, Gorleston, United Kingdom

Background: Ruxolitinib, an oral Janus Kinase (JAK)1 and JAK2 inhibitor, was approved in the European Union in August 2012 for treating disease-related splenomegaly and constitutional symptoms in adults with primary myelofibrosis (PMF), post-polycythaemia vera myelofibrosis (PPV-MF), and post-essential thrombocythaemia myelofibrosis (PET-MF), following the results of two phase III trials (COMFORT-I and COMFORT-II). The James Paget University Hospital and Ipswich Hospital have treated 31 MF patients (24 and seven, respectively) with ruxolitinib since March 2013.
Aims: To assess the efficacy and safety of ruxolitinib in MF in the clinical setting.
Methods: Retrospective analysis of 31 MF patients treated with ruxolitinib from March 2013 to February 2016 at the James Paget University Hospital and Ipswich Hospital. Patients with greater than three months' follow-up were included.
Results: The patient group was 58% male, with a median age of 69 years (range 58–92). Ruxolitinib was first-line therapy in eight patients (26%) and second-line in 23 (74%). The indication for treatment was painful splenomegaly in 17 (55%) patients, constitutional symptoms in 13 (42%) and portal hypertension in one (3%). Fifteen patients (48%) had PMF, ten (32%) had PPV-MF, five (16%) had PET-MF and one (3%) had post-myeloproliferative disorder (unclassified)-MF. Seventeen (55%) patients had an International Prognostic Scoring System (IPSS) score of three (high risk), 13 (42%) had an IPSS score of two (intermediate risk-2), and one (3%) had an IPSS score of one (intermediate risk-1). Twenty-two patients (71%) were JAK2 V617F positive and one (3%) had a CALR mutation. The median duration of treatment was 17 months (range 5-35). Twenty-six patients (84%) had a therapeutic response. Of the 17 with painful splenomegaly, eight (47%) had >50% reduction in spleen length, six (35%) had <50%, and three (18%) had no change. Nonhaematologic adverse events (AEs) were uncommon and low grade. Weight gain was the most common, occurring in 25 (81%) patients. Minor infections, including oral candidiasis, were also common and easily treated. One patient, however, developed *Aspergillus* pneumonia after 17 months and died. The most common haematologic AEs were anaemia and thrombocytopaenia. All patients developed anaemia; nine (29%) required transfusions and 12 (39%) required erythropoietin. Nine patients (29%) developed thrombocytopaenia (grade 3/4 in three patients) which was managed by dose reduction, or drug interruption, without permanent discontinuation. Four patients (16%) progressed to acute myeloid leukaemia (AML) after a median of four months (range 3-15) and died. Another patient died after losing therapeutic response at 16 months. Our leukaemia-free survival, progression-free survival, and overall survival rate is 81% *vs* 80% in COMFORT-II at three years. Currently, 25 patients (81%) remain on treatment.
Summary/Conclusions: In our experience, overall response rate and tolerability to ruxolitinib was similar to the COMFORT-II trial. The most common non-haematologic AEs were weight gain and minor infections. Furthermore, in many cases weight gain was a desired outcome attributable to improved constitutional symptoms, spleen size, and nutritional status. Conversely, haematologic AE rates may be higher than in the trial setting. Anaemia was observed in all patients and thrombocytopaenia commonly required dose adjustments. There was also a higher than expected incidence of transformation to AML. Most AEs, however, were low grade and readily managed. The majority of patients remain on active treatment.

PB2035

CLINICAL SIGNIFICANCE OF ANISOCYTOSIS IN NEWLY-DIAGNOSED PATIENTS WITH PRIMARY MYELOFIBROSIS

M Lucijanic[1,*], V Pejsa[1], O Jaksic[1], Z Mitrovic[1], C Tomasovic-Loncaric[2], T Stoos-Veic[3], Z Prka[1], M Pirsic[1], V Haris[1], T Vasilj[1], R Kusec[1]
[1]Hematology department, [2]Pathology department, [3]Clinical Cytology and Cytometry Department, Universitiy Hospital Dubrava, Zagreb, Croatia

Background: Red cell distribution width (RDW) provides a quantitative measure of anisocytosis and it is associated with the presence of subclinical systemic inflammation and a poor outcome in a variety of diseases when elevated. Anisocytosis is a feature of primary myelofibrosis (PMF) but it's prognostic role in PMF has not yet been evaluated.
Aims: To determine whether anisocytosis bears prognostic significance in patients with PMF and its relation to disease features.

Methods: 33 newly-diagnosed patients with PMF were analyzed in this study. Baseline RDW values were obtained in addition to other routine blood analyses (CRP, LDH, complete blood count and iron metabolism parameters) and *JAK2* V617F mutational status. Patients were staged according to IPSS prognostic scoring system, liver and spleen size were assessed by palpation. The Mann Whitney U test, the Pearson correlation and the X^2 test/ the Fisher test were used where appropriate. Survival analyses were performed using methods of Kaplan and Meier, the log-rank test and the Cox regression analysis. All statistical tests were two-sided and P values <0.05 were considered significant.
Results: Median RDW was 19.0% (15.2% - 22.5%). RDW correlated significantly with hemoglobin (p=0.005), CRP (p=0.031), spleen size (p=0.036) and IPSS score (p=0.003). Patients with more pronounced anisocytosis had an inferior overall survival (OS)-very-high RDW (≥19.0%) *vs* high RDW (15.1% - 18.9%) subgroup, HR 5.37, p=0.002. RDW remained significantly associated with OS (p=0.002) in a multivariate model including IPSS score, hemoglobin level and CRP.

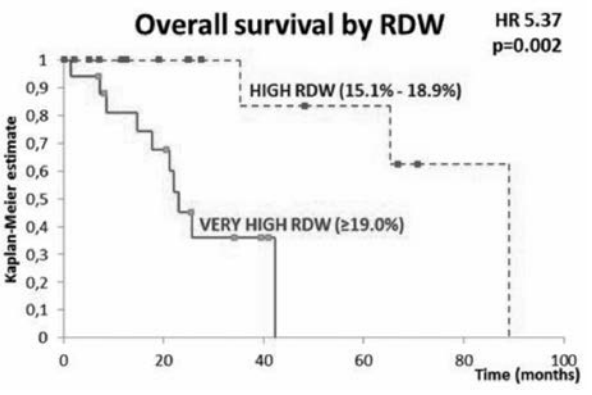

Figure 1.

Summary/Conclusions: PMF pathogenesis surpasses inflammation as only cause of anisocytosis. A higher degree of anisocytosis is associated with more advanced disease features and a decreased overall survival. RDW encompasses standard prognostic score and may help in the rapid detection of patients with an unfavorable prognosis.

PB2036

RISK FACTORS FOR THROMBOTIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS
E Simonovic[1,*], L Macukanovic-Golubovic[2], V Colic[1]
[1]Internal Medicine, General Hospital, Leskovac, [2]Internal Medicine, Clinic of Haematology, Nis, Serbia

Background: Myeloproliferative neoplasms (MPN) are a group of clonal hematopoietic stem cell malignancies, characterized by overgrowth of one or more blood lines with normal or nearly normal maturing of those cells in the bone marrow and extramedullary hematopoietic organs. MPN are acquired prothrombogenic conditions. The mechanism of increased predisposition to thrombosis in myeloproliferative neoplasms is not clear enough. It is thought that the mechanisms that lead to thrombosis in MPN are the following: increased blood cell mass; abnormal platelet function and the phenomenon of spontaneous aggregation. The following factors have been associated with the incidence of thrombosis: the increased level of products formed in the activation of platelets (thromboxane, p-selectin); increased microparticle formation as the part of a membrane with various cell structures of platelet origin; JAK2V617F mutation. In MPN patients an increased activity of coagulation system occurs due to resistance to the anticoagulant function of thrombomodulin.
Aims: The aim of this study is to monitor potential risk factors for the development of thrombotic complications in patients with Philadelphia-negative chronic myeloproliferative neoplasms.
Methods: During the five-year period we monitored the occurrence of thrombotic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with the polycythemia vera (PV) (61); 2. Group with essential thrombocythemia (ET) (28); 3. Group with idiopathic myelofibrosis (IMF) (25); 4. Group with unclassified myeloproliferative neoplasm (MPNs) (25). The following possible risk factors were monitored: age, leukocyte count, platelet count, the presence of JAK2V617F mutation, cardiovascular risk factors (smoking, hypertension, diabetes mellitus, dyslipidemia). We used methods of clinical, laboratory, ultrasound and CT scans.
Results: The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET and MPNs (p <0,01), and then in the group with PV (p <0,05). In all three groups, the incidence of thrombotic complications in patients older than 60 years was higher (p<0,001). The leukocyte count ranged from 2,2-17,1x10^9/L and the platelet count ranged from 10,2 -1856,5x10^9/L. The highest leukocyte count was recorded in the group of patients with PV and MPNs (p <0,001) and the lowest in the group of patients with the IMF (p <0,01). The highest platelet count was found in the group of patients with ET, and the lowest in the group of patients IMF. Thrombotic complications in those groups were more frequent in percentage with patients with leukocytosis, but statistical significance was present only in the group with MPNs. No statistical significance was detected between the platelet count and thromboembolic complications in either group. Thrombotic complications were more frequent in JAK2V617F positive patients, but the statistical significance existed only in the group with PV. Considering cardiovascular risk factors only hypertension was significantly more common in the group with PV and MPNs. The largest number of patients with thrombotic complications had two or more cardiovascular risk factors (p <0,05).
Summary/Conclusions: The patients over 60 years of age, as well as the presence of two or more cardiovascular risk factors are the most important for the incidence of thrombosis. Leukocytosis and JAK2V617F may be considered as potential risk factors for thrombosis in patients with myeloproliferative neoplasms, particularly with PV, ET I MPNs. Further follow-up and a larger number of subjects are needed. The follow-up of patients with unclassified myeloproliferative neoplasms has particularly important, which showed a high prevalence of thrombotic complications, and with the aim of their further differentiation.

PB2037

JAK2, MPL, AND CALR MUTATIONS IN CHINESE HAN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA
J Xu*
Clinical Hematology, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, China

Background: Essential thrombocythemia (ET) is a chronic Philadelphia chromosome-negative myeloproliferative neoplasm characterized by the overproduction of circulating platelets in the periphery due to the excessive proliferation of megakaryocytes in the bone marrow [1]. The recurrent Janus kinase 2 (JAK2) V617F mutation has been an important molecular marker for myeloproliferative neoplasms (MPNs) since its discovery in 2005 [2]. However, only 50-60% of ET cases are associated with the JAK2 V617F mutation. Among the 40% of patients with ET who lack the JAK2 V617F mutation, 3-5% carry mutations at codon 515 of the gene encoding the thrombopoietin receptor, a myeloproliferative leukemia virus oncogene (MPL) [3]. In 2013, somatic mutations in calreticulin (CALR) were found in 20 to 25% of patients with ET or primary myelofibrosis (PMF) [4,5]. Like JAK2 and MPL mutations, somatic mutations of Calreticulin (CALR) have been identified as a potentially powerful diagnostic tool for patients with ET [6].
Aims: we studied a population of patients with ET and analyzed the frequency of JAK2, CALR, or MPL mutations as well as patients' hematological characteristics.
Methods: The patients and the data were selected retrospectively from the myeloproliferative neoplasm database established for scientific research at the Department of Hematology of Drum Tower Hospital. A total of 110 patients with ET were enrolled (60 females and 50 males with a mean age of 55.7 years, range 13–88 years); they had been diagnosed at the Department of Hematology between 2012 and 2015 according to the WHO Classification of Tumours of Hematopoietic and Lymphoid Tissues (2008)[7]. The clinical and laboratory data were reviewed from medical records.
Results: Among the 110 patients tested, JAK2 V617F was the most common mutation, observed in 62 patients (56.3%), while CALR mutations were detected in 21 patients (19.1%). One patient (0.9%) carried the MPL W515L mutation. A mutation in JAK2 exon 12 was not detected in any patient. Two ET patients had both CALR and JAK2 V617F mutations. The incidence of triple-negative (negative for JAK2/MPL/CALR) patients was 25.5% (28/110).
Summary/Conclusions: In summary, we have described the mutation profile of our Chinese cohort of ET patients. CALR mutations are a useful diagnostic marker for JAK2/MPL-negative ET patients because they are typically mutually exclusive with a JAK2 mutation and are present in a relatively high frequency.

PB2038

WHAT IS THE SECRET OF THE JAK2 MUTATION ALLELE LOAD STABILITY IN SOME PATIENTS WITH MPN?
T Subbotina[1,2,*], I Olkhovskiy[1,3], R Shaikhutdinova[2], E Dunaeva[4], K Mironov[4], A Gorbenko[1], M Stolyar[1,2], E Vasiyliev[1,5], M Mikhalev[1,6], G Shipulin[4]
[1]Krasnoyarsky branch of Hematology Research Center Russian Ministry of Health Ministry of Health, [2]Siberian Federal University, [3]Krasnoyarsk Scientific Center SB RAS, Krasnoyarsk, [4]Federal Budget Institute of Science «Central research institute for Epidemiology», Moscow, [5]Krasnoyarsk regional hospital, [6]City Clinical Hospital № 7, Krasnoyarsk, Russian Federation
Background: It is known that the level of JAK2 mutation allele load in patients with myeloproliferative neoplasms (MPN) in the disease dynamics can be continuously stable and not be associated with clinical symptoms or effects of hydrox-

yurea (HU) (Theocharides A et al, Haematologica, 2008; Besses C et al, Br J Haematol, 2011). Reasons and mechanisms of this kind of «homeostasis» in the level of circulating mutation JAK2 positive cells in some patients are unclear.
Aims: Evaluate the level of JAK2 mutation allele load in MPN patients in the disease dynamics and HU effects.
Methods: This study included 14 JAK2 positive (V617F or exon 12 mutations) MPN patients. The informed consents from these patients were obtained. DNA was extracted from venous blood leukocytes. Quantification of JAK2 V617F and JAK2 exon 12 mutations allele load was performed by pyrosequencing method as described in (Dunaeva E et al Klin Lab Diagn, 2014). JAK2 variance (MUT) was calculated as a measure of relative changes in allele load between the baseline and follow-up sample (Theocharides A et al, Haematologica, 2008).
Results: Following variants were identified according to the level of JAK2 mutation allele load in the disease dynamics and HU effects (Table 1): 1) The level of JAK2 mutation allele load was increased more than twice (№3 and №13). Until now this patients do not have the significant clinical MPN manifestations and do not need HU-treatment; 2) The level of JAK2 mutation allele load was found to remain stable over follow-up time of observation independently of whether patients were already or not under HU treatment at the time of first sampling; 3) The level of JAK2 mutation allele load was reduced after HU treatment. We did not find any dependency between the allele load dynamics and patient's clinical status, disease phenotype, disease duration and venous blood cellular account.

Table 1. Characteristics of the patients included in the study.

№	Age of manifestation (years)	Sex	Disease	HU	% JAK2 mutation baseline	% JAK2 mutation last sample	JAK2 variance (MUT)	Time between two assessments (mo)
JAK2 V617F mutation-positive patients								
1	67	F	ET*	No	29	27	n.s.	6
2	70	F	PV	No	34	32	n.s.	10
3	71	F	PV	No	16	35	+115	18
4	59	F	Post-PV MF	Yes	82	86	n.s.	15
5	51	F	PV	Yes	78	73	n.s.	20
6	44	F	PV	Yes	69	77	+11	12
7	59	F	PV*	Yes	42	42	n.s.	27
8	45	F	ET*	Yes	8	7	n.s.	36
9	75	F	Post-ET MF*	Yes	14	10	-38	18
10	57	F	PV*	Yes	31	22	-29	6
11	59	F	PV	Yes	81	54	-33	36
12	35	M	MF	Yes	27	20	-27	15
JAK2 exon 12 mutation-positive patients								
13	61	M	PV*	No	15	40	+166	24
14	48	M	PV*	No	11	11	n.s.	4

**The allelic load was determined at the primary address to the doctor with MPN symptoms*

Summary/Conclusions: Our data suggest the JAK2 mutation allele load can remain stable for a long time in some patients. The observed increase of the mutation allele load in untreated patients probably will be to increase to the level of its stabilization at full development of the clinical MPN picture. The differences of the allele load dynamics between individual patients may be associated with the individual features of the intracellular signaling networks and will be the subject of additional studies.

PB2039

PLATELET COUNT AS A RISK FACTOR FOR HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E Simonovic[1,*], L Macukanovic-Golubovic[2], V Colic[1]
[1]Internal Medicine, General Hospital, Leskovac, [2]Internal Medicine, Clinic of Haematology, Nis, Serbia

Background: Myeloproliferative neoplasms (MPN) are a group of clonal hematopoietic stem cell malignancies, characterized by overgrowth of one or more blood lines with normal or nearly normal maturing of those cells in the bone marrow and extramedullary hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Bleeding can complicate the clinical course of IMF. It has been manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrolled esophageal bleeding. It occurs due to ineffective megakaryocytopoiesis, retention of platelets in the enlarged spleen, qualitative platelet disorders, acquired deficiency of factors V and vWF, disseminated intravascular coagulation. The increased platelet count affects the adsorption of the larger von Willebrand multimers onto the platelet membrane, thus acting to eliminate them from circulation and degradation.
Aims: The aim of this study is to monitor the platelet count as a potential risk factor for occurrence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.
Methods: During the three-year period we monitored the occurrence of hemorrhagic complications and platelet count in 120 patients of both sexes aged between 27 and 86 years, being diagnosed with Ph-myeloproliferative neoplasms. Patients were classified into the following groups: 1. Group with the polycythemia vera (PV) (51); 2. Group with essential thrombocythemia (ET) (24); 3. Group with idiopathic myelofibrosis (IMF) (20); 4. Group with unclassified myeloproliferative neoplasm (MPNs) (25). We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.
Results: Platelet count ranged from 2,2-2134,5,1x10^9/L. The highest platelet count was recorded in the group of patients with ET and MPNs ($p<0,001$) and the lowest in the group of patients with the IMF ($p<0,01$). There was no statistical significant difference detected between the groups of patients with PV and MPNs with regard to platelet count. The highest percentage of hemorrhagic complications was found in the group of patients with ET and IMF ($p<0,01$) and then in the group with MPNs. Hemorrhagic complications have been more frequent in patients with platelet count below 10x10^9/L ($p<0,05$) and in patients with platelet counts over 1000x10^9/L ($p<0,01$). Life-threatening bleeding complications were the most common in patients with platelet count below 5x10^9/L and in patients with platelet count over 1500x10^9/L. Haemorrhage was the cause of mortality in 15% of patients with MPN.
Summary/Conclusions: The platelet count can be considered as a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Further follow-up and a larger number of subjects are needed. The follow-up of patients with unclassified myeloproliferative neoplasms has particularly important, which showed a high prevalence of hemorrhagic complications, and with the aim of their further differentiation.

PROLIFERATING KI67 EXPRESSING B-CELLS ASSOCIATE WITH CD4+PD1+ T-CELLS IN MARGINAL ZONE LYMPHOMA

K Wickenden[1,*], N Nawaz[1], E Lakidou[1], A Wilson[1], K Straatman[2], S Wagner[1], M Ahearne[1]
[1]Cancer Studies, [2]Biochemistry, University of Leicester, Leicester, United Kingdom

Background: Specific microbial antigens have been implicated in the development and maintenance of several types of marginal zone lymphoma suggesting that an abnormal immune response is essential for driving B-cell proliferation. Reasoning that T-cell stimulation, especially from CD4+ T-cells, might make important contributions to promoting B-cell proliferation we carried out a detailed analysis of infiltrating T-cells in 8 cases of nodal marginal zone lymphoma.
Aims: The aim of the study was to undertake the first detailed study of T-cell subsets in marginal zone lymphoma in order to determine the relationship of individual subsets to proliferating lymphoma B-cells.
Methods: We carried out multiplex immunohistochemistry and validated the results to show that, for the combinations of antibodies employed, there was firstly no reduction in intensity after several rounds of staining and destaining and secondly that there was no significant carry over from one round to the next. The stained slides were scanned and, utilising a custom macro written for ImageJ software, we enumerated CD4+ T-cell subsets (TH1- $CD4^+TBET^+$, Treg - $CD4^+FoxP3^+$, follicular helper (Tfh) - $CD4^+PD1^+$ and follicular regulatory (Tfr) - $CD4^+FoxP3^+PD1^+$).
Results: In all cases $CD4^+$ T-cells constituted a major portion of infiltrating T-cells, mean 39.8% (range 13.5 to 70.3%). There were, however, large differences in the $CD4^+$ T-cell subset composition; Tfh cells varied from 2.5 to 36% of all $CD4^+$ T-cells whilst Tregs accounted for 2.7 to 24.7%. We also compared architecture of T-cell infiltration across cases and found that T-cells were not homogenously distributed and that $CD4^+PD1^+$ cell clusters could show some association or no association with $CD4^+FoxP3^+$ clusters and, in one case, repulsion from $CD4^+FoxP3^+$ clusters. In order to quantitate the associations we carried out Pearson correlations. For comparison normal tonsil showed a Pearson correlation of -0.4 *i.e.* no overalp, between $CD4^+PD1^+$ and $CD4^+FoxP3^+$ cells whereas there were varying degrees of association (range 0.3 to 0.8) for the lymphoma samples. By contrast proliferating $Ki67^+$ lymphoma B-cells associated with $CD4^+PD1^+$ cell clusters (Pearson 0.1 to 0.6) whatever the relation to $CD4^+PD1^+$ cells to $CD4^+FoxP3^+$ cells. To confirm this result we used an alternative method to analyse clustering (the Morisita index). This produced similar results with normal tonsil having a Morisita index of 0.2 for $CD4^+PD1^+$ and $CD4^+FoxP3^+$ whereas lymphoma samples showed higher degrees of association (range 0.3 to 0.9). The Morisita index also confirmed association between proliferating B-cells and $CD4^+PD1^+$ cells; normal tonsil 0.8 and lymphoma (0.4 to 0.8).
Summary/Conclusions: Collectively our data suggests an unsuspected association between $CD4^+PD1^+$ T-cells and proliferating lymphoma B-cells in marginal zone lymphoma.

PB2041

CLINICAL IMPLICATIONS OF MYD88 L265P MUTATION IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

A Sidorova*, E Zvonkov, A Sudarikov, N Severina, N Gabeeva, A Kovrigina, V Troitskaya, V Savchenko
National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: It is now well known fact that recurrent mutation in the MYD88 gene (L265P MYD88) is identified in about 90% of Waldenström macroglobulinemia, in approximately one-quarter of patients (pts) with diffuse large B-cell lymphoma (DLBCL) and in a minority of cases of other lymphoproliferative disorders. Evidence is beginning to accumulate that L265P MYD88 mutation in pts with DLBCL has strong association with clinical phenotypes and outcomes.
Aims: To evaluate the clinical implications of MYD88 L265P mutation in pts with DLBCL.
Methods: We analyzed the data of 75 pts (median age 50 years, range 18-77, 33/42 female/male ratio, 39 extranodal and 36 nodal disease) with de novo DLBCL diagnosed between 1999 to 2015 at National Research Center for Hematology. Pts were classified as germinal center B-cell-like (GCB) or non-GCB DLBCL using the Hans algorithm. For molecular analysis DNA was extracted from 56 cryopreserved and 19 formalin-fixed paraffin-embedded tumor tissue. The mutational status of a sample was determined by real-time PCR (RT-PCR).
Results: MYD88 L265P mutation was detected in 14(18,7%) out of 75 pts. Half of pts with MYD88-positive MYD88 L265P mutation DLBCL are older than 60 years compared with only 24,6% of those pts with MYD88 unmutated DLBCL. In terms of sex ratio the data show a double preponderance of males at MYD88 L265P positive DLBCL (9:5) as compared with MYD88 wild type DLBCL with the same number of males and females (33:28). There was equal distribution of pts across high-intermediate and high risk groups of the international prognostic index both in MYD88 mutated and MYD88 unmutated pts (71,7% *vs* 63,9%). The majority of pts in both groups had elevated serum lactate dehydrogenase levels, 12/14 (85,7%) and 47/61 (77%) respectively. Tumors with high Ki-67>80% expression were found in 13(92,8%) of pts MYD88 mutation *versus* 43(70,5%) pts with MYD88 wild type DLBCL. All 14(100%) pts with MYD88 L265P DLBCL were non-GCB DLBCL as compared to 42/61(72%) pts with MYD88 unmutated DLBCL. Eleven (78,6%) out of 14 pts with MYD88 mutation had extranodal lesions (p<0,05). Five (45,4%) of 11 cases MYD88 L265P extranodal DLBCL were present in immune-privileged site DLBCL (central nervous system, testis) *versus* 4(14,2%) out of 28 pts with MYD88 wild type extranodal DLBCL (p<0,05). The table summarizes baseline characteristics pts.

Table 1.

Patients Characteristics n=75 (%)		
	MYD88 mutation	MYD88 wild type
Number of patients	14 (18,7)	61 (81,3)
Sex (male:female)	9:5	33:28
Age at diagnosis, years.		
Median	58	49
Range	18-70	20-77
Over 60years old	7 (50)	16 (26,2)
Serum LDG		
Level > normal	12(85,7)	47(77)
Ki67 > 80%	13(92,8)	43(70,5)
International Prognostic Index		
Low	-	7 (11,5)
Low-intermediate	4 (28,6)	15 (24,6)
High-intermediate	3 (21,4)	20 (32,8)
High	7 (50)	19 (31,1)
Lymph node involvement	3 (21.4)	33 (54,1)
Extranodal sites:	11 (78.6)	28 (45,9)
Bone	2	8
Skin	2	4
Gastrointestinal tract	1	10
Adrenal	1	-
Breast	-	2
Immune-privileged site		
Testis	2	2
Central nervous system	3	2
Bone marrow	3 (21.4)	14 (22,9)

LDG: lactate dehydrogenase

Summary/Conclusions: It is apparent from the present study that MYD88 L265P mutation was significantly associated with extranodal DLBCL (78,6%) and prevalent in immune-privileged site DLBCL. Detection of MYD88 L265P mutation by RT-PCR could improve diagnosis non-GCB DLBCL as a complement to immunohistochemistry.

QUINACRINE SYNERGIZES WITH DOXORUBICIN IN INHIBITING THE SURVIVAL OF DLBCL CELL BY SUPPRESSING NF-KB AND ALTERING CELL-CYCLE PROGRESSION

Y Shujun*, O Guifang, Z Huilin, S Lixia, Z Ping,xZhijuan
Hematology Department, Ningbo First Hospital, Ningbo, China

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive B-cell non-Hodgkin lymphoma that affects patients of all ages with a wide range of clinical presentations. Although DLBCL is curable even in advanced stages, up to one-third of patients will not achieve cure with initial therapy. To test drug combinations that could improve the efficacy of chemotherapeutics used currently. We combined doxorubicin (dox) with quinacrine (qc), which inhibits the FACT complex that is required for NF- κB transcriptional activity.

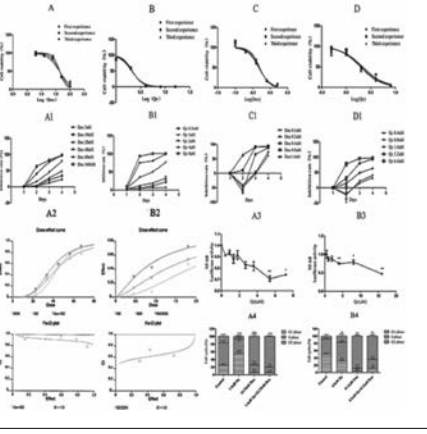

Figure 1.

Aims: The aim of this study was to test drug combinations that could improve the efficacy of chemotherapeutics currently used, such as dox, to Provide new and better drugs for clinical treatment of DLBCL.
Methods: Cells were maintained in RPMI-1640 medium supplemented with 10% FBS. All cells were kept at 37°C in a humidified atmosphere with 5% CO_2. Cell viability was determined by the MTT assay. The combination index (CI) was assessed by using Calcusyn software. Cells stained with propidium iodide (PI), the cell-cycle distribution was assessed by FACScan (BD) Biosciences analysis. Cells were infected with the NF-κB-luciferase Lentiviral construct and stably selected with puromycin. The influence of Qc on the activity of NF-κB was tested using luciferase assay system.
Results: Qc synergizes with dox in inhibiting the proliferation of DLBCL cell lines; Qc has the ability to suppressing NF-κB-dependent luciferase activity, which means qc inhibits the activity of NF-κB, as well as alrer the cell cycle of DLBCL cell lines.
Summary/Conclusions: Qc can inhibit the growth of DLBCL tumor cells, enhance the curative effect of chemotherapy drugs such as dox, its possible mechanism is qc could inhibit the NF-kB activity which plays key roles in DLBCL cell survival and chemotheraputic resistance, as well as alter the cell cycle progression.

PB2043

VALIDATION OF LST EUROFLOW® PROTOCOL BY MULTIPARAMETRIC FLOW CYTOMETRY IN SCREENING OF LYMPHOPROLIFERATIVE NEOPLASTIC DISEASE IN CHILE

A Berkovits[1,*], M Oyarzo[2], M Burotto[3], P García-Huidobro[1], M Zamora[1], D Araos[1]
[1]Clinical Laboratory Department, Immunology Section, [2]Pathology Department, [3]Hemato-oncology Department, Clinica Alemana de Santiago, Santiago, Chile

Background: Immunophenotype analysis by multiparametric flow cytometry (MFC) is an important tool, together with pathology, cytogenetical and molecular analysis, for the diagnosis, classification and treatment monitoring of hematological malignancies. The accurate identification of abnormal lymphocytes by MFC requires a unique standardized combination of fluorochrome-conjugated antibodies. The international consortium of standardization, Euroflow®, elaborated a lymphoproliferative disease screening panel (LST) aiming the identification of normal or aberrant B, T or NK lymphocytes in different tissues.
Aims: Confirm that the screening of lympholiferative disease using MFC analysis with LST Euroflow® panel, in an accurate method to recognize, quantify and characterize abnormal lymphocyte populations in lymphoma positive tissue biopsies in Chilean population.
Methods: Retrospective analysis of tissue and/or bone marrow samples sent simultaneously to both the pathology laboratory for biopsy (reviewed by only one expert hematopathology of our institution) and to immunology section of Clinica Alemana de Santiago for immunophenotyping analysis, since the implementation of LST Euroflow® protocol for lymphoproliferative disease screening. All tissues were processed in 8 colors FACSCanto cytometer by BD Bioscience II. The panels and fluorochromes used in every analysis were: CD4 and CD20 in PacB, CD45 in AmCyan, CD8 and SmIgl in FITC, CD56 and SmIgk in PE, CD5 in PerCPCy5.5, CD19 and TCRgd in PECy7, SmCD3 in APC and CD38 in APCCy7.
Results: One hundred and seventy-four samples with suspect of lymphoproliferative disease and concomitant pathology report in our institution were revised from June 2013 to December 2015. Exclusion criteria included Hodgkin Lymphoma and non-hematological neoplastic diagnosis by histology (14 and 11 tissues samples respectively). Fifty tissues were positive for lymphoproliferative disease by biopsy, including 16 follicular lymphomas, 12 diffuse large B cell lymphomas, 7 SLL/CLL, 5 mantle cell lymphomas, 3 lymphoplasmocytic lymphomas, 3 marginal zone lymphomas, 2 Hairy cell leukemia, 1 T gamma-delta lymphoma and 1 multiple myeloma. The screening analysis by MFC using LST panel showed abnormal and/or clonal population in 100% of positive lymphoproliferative disease biopsies. In the analysis of the non-neoplastic histological biopsies (87 samples), MFC detected subclinical clonal or abnormal lymphocytic population in 10 cases, being both negatives in 77. The sensitivity, specificity, positive predictive value and negative predictive value of LST for diagnosis of lymphoproliferative disease was 100%, 89%, 86% and 100% respectively.
Summary/Conclusions: Lymphoproliferative panel LST is an effective screening tool for lymphoma diagnosis in Chilean population in different tissues including bone marrow.

PB2044

IMPACT OF THE NAGASAKI ATOMIC BOMB ON THE INCIDENCE RATE AND OUTCOME OF FOLLICULAR LYMPHOMA

T Jo[1,*], M Yamashita[1], S Irie[2], K Horio[1], K Shigematsu[3], M Mine[4], T Aikawa[5]
[1]Hematology, [2]Pharmacy, [3]Pathology, Japanese Red Cross Nagasaki Genbaku Hospital, [4]Scientific Data Registry, Atomic Bomb Disease Institute, Nagasaki University, [5]Laboratory Medicine, Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan

Background: In Nagasaki and Hiroshima, approximately 75,000 and 120,000 citizens, respectively, died within 3 months of the 1945 atomic bomb explosions. Furthermore, 80,000 and 140,000 citizens, respectively, survived exposure. During the following 70 years, high-dose radiation exposure has induced various cancers, including leukemia; thyroid, lung, gastric, and colon cancers; and myelodysplastic syndromes (MDS). Additionally, approximately 10% of cancer-carrying patients of Nagasaki atomic bomb survivors have multiple primary cancers in various tissues. This high-dose radiation exposure not only increased the risk of developing various types of cancer, but also worsened the overall survival (OS) rate. We recently reported significantly shorter OS among Nagasaki atomic bomb survivors with MDS *versus* patients without such radiation exposure (Jo et al., Anticancer Research 2015).
Aims: We investigated whether high-dose radiation exposure would similarly affect the incidence rates and outcomes of follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL).
Methods: The youngest atomic bomb survivors are aged approximately 70 years, presenting a challenge to perform prospective cohort studies. Therefore, we conducted a retrospective cohort study of the incidence rates and outcomes of FL and DLBCL in cases diagnosed at our hospital between January 2004 and December 2013. The primary objectives were to compare the incidence rates of FL and DLBCL in atomic bomb survivors (A-Bomb) and non-A-Bomb patients, and determine the OS rates.
Results: Table 1 lists the number of patients. Seven and 51 A-Bomb patients and 49 and 91 non-A-Bomb patients had FL and DLBCL, respectively. The incidence rate of FL *versus* DLBCL was significantly less among A-Bomb patients than among non-A-Bomb patients (P=0.0009). There was no significant difference in OS between A-Bomb and non-A-Bomb patients with DLBCL (P=0.3065, hazard ration [HR]: 1.311, 95% confidence interval [CI]: 0.7813–2.198). In contrast to DLBCL, the OS rate was significantly lower in A-Bomb patients with FL than in non-A-Bomb patients (P=0.0092, HR: 5.425, 95% CI: 2.151–220.1). In both FL and DLBCL patients, there were no significant differences of background factors except for the median age between A-Bomb and non-A-Bomb patients. The respective median ages of A-Bomb and non-A-Bomb patients with DLBCL differed significantly at 75 (range, 62–91) and 73 (range, 17–93) years (P=0.0038). The respective median ages of A-Bomb and non-A-Bomb patients with FL also differed significantly at 80 (range, 63–90) and 60 (range, 28–80) years (P <0.0001). The age difference had no impact on the OS rate of DLBCL. Therefore, the shorter OS of A-Bomb patients with FL cannot be accounted only for the age difference between A-Bomb and non-A-Bomb patients. Some other unknown factors caused by high-dose radiation exposure of the Nagasaki Atomic Bomb could be linked to the OS difference.

Table 1.

Table 1. Numbers of atomic bomb (A-Bomb) and non-A-Bomb survivors with follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL)

	FL	DLBCL	Total	P-value*
A-Bomb	7	51	58	
Non-A-Bomb	49	91	140	
Total	56	142	198	0.0009

*Fisher's exact test

Summary/Conclusions: Compared with non-A-Bomb patients, A-Bomb patients had a significantly lower FL incidence rate and significantly shorter OS. We previously reported significantly reduced OS among MDS patients exposed to the Nagasaki atomic bomb. These data suggest an influence of atomic bomb exposure and warrant further study for etiological clarification.

PB2045

CD39 EXPRESSION ON CD4 T INFILTRATING LYMHOCYTES IN THE TUMOR MICROENVIRONMENT OF LYMPHOMAS

R Di Gaetano[1,*], V Gasparetto[1], B Callegari[1], MA De Benedetto[1], A Scapinello[2], G Tagariello[1]
[1]Haematology, [2]Pathology, Hospital, Castelfranco Veneto, Italy

Background: In tumor microenvironment (TME) a variety of mechanisms favor a tumor-protection, one of them is the accumulation of extracellular adenosine (ADO) by up-regulating activity of ectoenzime CD39. The generation of ADO from ATP metabolism is recognized as a mechanism for immunosuppressive function of regulatoty T cell (Treg), a component of the CD4+ T lymphocytes expressing variable functional molecules and involved in tumor escape.
Aims: It has been well-documented the increase of Treg in various solid tumor and the higher CD39 expression in some types of human cancer. We have evaluated the CD39 and the CD26 (an adenosine deaminase) on CD4+T infiltrating lymphocytes in lymph node with lymphoma to verify the expression of two markers and whether they could be an attractive features for analysis of TME of a non Hodgkin lymphoma (NHL).
Methods: We analyzed by flow cytometry (FC) immunophenotyping non-neoplastic (10) and B-NHL (48) lymph node samples. and we measured the CD26 and CD39 on CD4+ T lymphocytes in all tissues. Among B-NHL were 14 diffuse large B cell lymphoma (DLBCL) and 3 relapsed.

Results: Compared to non-neoplastic samples, CD4+T cells of NHL showed statistically significant difference on CD26 (67% *vs* 39.5%; *p* <0.001) and on CD39 (6% *vs* 34%; *p* <0.001). In NHL, compared to other entities the value of CD26 on DLBCL (39.5% *vs* 34%) and on the relapsed (39.5% *vs* 29%) was not significantly different; while CD39 on both groups, DLBCL (34% *vs* 54%; p <0.005) and relapsed (34% *vs* 74%; p <0.001), resulted significantly increased.

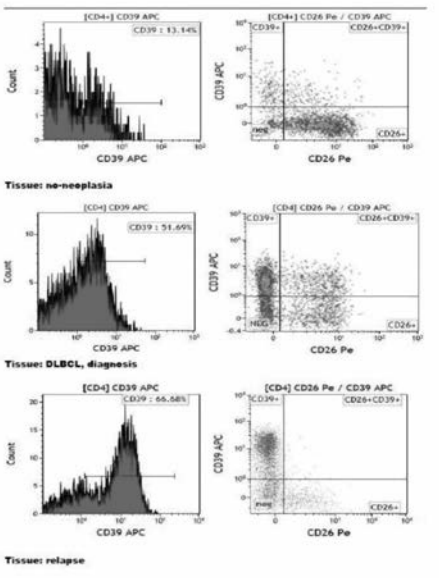

Figure 1.

Summary/Conclusions: Although the regulatory activity of immune system can employ a diversity of molecular mechanisms, the presence of enzymatically-competent CD39 on surface of infiltrating CD4+T suggest that the CD39 pathway can be a distinct mechanism utilized by Treg in TME of lymphomas. Furthermore, the tendency to the reduction (heightened in the relapsed) of CD26, connectable to a lower activity of adenosine deaminase, beside the up-regulated expression of CD39, could underlies an increased accumulation of extracellular ADO and its important role in Treg-mediated immune response suppression. Data of DLBCL, resembling the relapsed, tend to differentiate from other entities for a more suppressive functional profile. Together, these simple and fast assays obtained by FC support the finding that ATP-ectonucleotidase-adenosine system may have a role in mediating Treg activity also in lymphomas suggesting that CD39 represents a possible target for cancer immunotherapy.

SERUM PROTEOMIC PROFILES OF HODGKIN'S LYMPHOMA PATIENTS SHOW DIFFERENTIAL EXPRESSION ACCORDING TO EPSTEIN-BARR VIRUS STATUS

J Musacchio[1,*], JS Fischer[2], CH Garcia[2], PC Carvalho[3], A Scheliga[4], CG Ferreira[4], MG Carvalho[2]
[1]Hematology Service, Oncologia D'Or, Rio de Janeiro, [2]Federal University of Rio de Janeiro, [3]Oswaldo Cruz Institute, [4]Brazilian National Cancer Institute, RJ, Brazil

Background: Despite the advances in understanding of Hodgkin's lymphoma's molecular pathogenesis, its association with EBV remains unclear. In this study, we assessed serum protein profiles from EBV associated and non-associated Hodgkin's lymphoma patients and identified three differentially expressed proteins that are candidate biomarkers.
Aims: The aim of the present study was to identify and analyze differentially expressed proteins in pooled sera from patients with HL according to EBV status.
Methods: Blood samples were obtained from 16 patients with recently diagnosed HL before treatment. Blood samples from 10 healthy volunteers were also included. The inclusion criteria used for EBV non-associated HL were the negativity of EBV in buffy coat, plasma, and lymph node. Conversely, patients with EBV associated HL should have EBV detected in buffy coat or plasma, and lymph node. MALDI-MS was performed using a 4700 Proteomics Analyzer® (Applied Biosystems).
Results: The patients' median age at diagnosis was 26 years (range 15-56) and 38% were men. Our analysis revealed about 265 spots with a mean of 86 (35%) identified spots on each gel. Five spots were indicated as having different normalized volumes when compared to each other (p<0.05) (Figure1). Two up-regulated proteins were detected in patients with EBV non-associated HL, and identified as inter-alpha-trypsin inhibitor heavy chain H4 (ITIH4) and haptoglobin (HP). Only one protein, fibrinogen beta chain, was down-regulated in the serum from EBV-associated HL patients.

Table 1.

Protein	Ip	MM	Corresponding gene	Localization	EBV-negative vs EBV-positive	P value
Inter-alpha-trypsin inhibitor heavy chain H4	6.51	103489	*ITIH4*	3p21-p14	+2.85	0.025
Haptoglobin (isoforms)	6.13	45861	*HP*	16q22.3	+3.99	0.024
					+5.12	0.027
					+5.86	0.027
Fibrinogen beta chain	8.54	56577	*FGB*	4q28	-2.69	0.004

Table 2 - Identified proteins with differential expression higher than 2-fold change in Hodgkin's lymphoma patients according to EBV status

Ip= isoelectric point; MM= molecular mass

Figure 1 - 3D view representing the volume profile of 3 haptoglobin protein spots differentially expressed between all groups. A, B: control group; C, D: EBV associated HL group; E, F: EBV non-associated HL group.

Summary/Conclusions: We identified three serum proteins that may serve as potential biomarkers in HL, according to EBV status.The biological function of ITIH4 is still unknown. A possible role is the modulation of cell migration and proliferation during the development of the acute-phase response. These findings may suggest that EBV presence could inhibit ITIH4 expression. Serum HP levels in the lymphoma patients have also been described to be significantly higher than in the control group and have been correlated to response to treatment. These results suggest HP as a new tumor marker for lymphoma. Here HP is not increased in patients with advanced stage disease, but in absence of systemic EBV infection, which is in line with prior observations: a recent study described some phenotypes with a higher HP concentration (HP 1-1 and HP 2-1) are less prone to positive EBV serology. In spite of FGB has been described as a serum acute phase reactant protein, their levels were decreased in patients diagnosed with EBV associated HL. The cytokines IL-4, IL-10 and IL-13 have a protective effect against vascular injury leading to atherosclerosis, dose dependently down regulate the biosynthesis of fibrinogen, and some of these cytokines are known involved in the HL pathophysiology. In conclusion, the present study represents an initial and necessary step needed to identify proteins that are differentially expressed between patients with EBV associated and non-associated HL. We demonstrated that protein profiling of serum significantly, accurately and reproducibility distinguished EBV associated and non-associated HL patients. This is the first report combining analysis of serum proteomics of HL patients, according to EBV status, and the pooled sera approach as an appropriate initial approach. Following the identification of spots, future studies with more samples are still required to validate our results. Besides such validation could be performed in large scale by other techniques (e.g., ELISA-based methods).

EVALUATION OF NEUTROPHIL-LYMPHOCYTE RATIO IN PATIENTS WITH MYCOSIS FUNGOIDES

R Eren[1,*], N Nizam[2], MH Doğu[1], S Mercan[3], AV Turgut Erdemir[3], E Suyanı[1]
[1]Hematology, [2]Internal Medicine, [3]Dermatology, İstanbul Training and Research Hospital, istanbul, Turkey

Background: Neutrophil lymphocyte ratio (NLR), an indicator of inflammation, has been lately demonstrated as a prognostic factor in various lymphoproliferative disorders. However, the effects of NLR has not been investigated in mycosis fungoides (MF) patients yet.
Aims: The aim of this study is to investigate the relationship between the neutrophil-lymphocyte ratio (NLR) and treatment demand (systemic PUVA and/or chemotherapy), time to treatment, progression in stage, time to progression in stage in MF patients.
Methods: The data of 117 patients, who were followed with the diagnosis of MF at Department of Dermatology in Istanbul Training and Research Hospital between April 2006 and January 2016, were reviewed retrospectively. Neutrophil-lymphocyte ratio was calculated from complete blood count of patients at the time of diagnosis. The cut-off score for NLR was determined as 2 according to the median NLR level which was 1.96. Statistical evaluation was made by SPSS 15 package program. x^2,Fisher's exact test was used for evaluating categorical values and Mann Whitney U test for continuous values in patient groups.
Results: At the time of diagnosis, the median age of patients was 54 years (range, 21-90). 62 (53%) of the patients were female and 55 (47%) were male. 60 (51.3%) patients had stage Ia, 18 (15.4%) had stage Ib, 35 (29.9%) had stage IIa, 1 (0.9%) had stage IIIa and 3 (2.6%) had stage IVa disease. 77 (65.8%) patients required treatment during follow up. The median time from diagnosis to treatment was 2 (range, 0-64) months. 63 (53.8%) patients showed progression in disease stage. The median time from diagnosis to progression in stage was 23 (1-108) months. There was no significant difference in treatment neces-

sity, time to treatment, progression in stage, time to progression in stage in patients with a NLR≥2 and NLR<2 (p=0.331, 0.987, 0.065, 0.119 respectively).
Summary/Conclusions: Although NLR has been demonstrated to have prognostic role in various lymphoporliferative disorders, it seems that there is no association between the NLR and treatment demand (systemic PUVA and/or chemotherapy), time to treatment, progression in stage, time to progression in stage in mycosis fungoides (MF) patients.

PB2048

TO DOSE OR NOT TO DOSE: ARE IL-10 AND IL-10:IL-6 RATIO ACCURATE BIOMARKERS TO DETECT LEPTOMENINGEAL INVOLVEMENT IN SMALL B-CELL LYMPHOPROLIFERATIONS?

M Costopoulos[1,*], R Kim[1], S Choquet[2], K Maloum[1], C Algrin[2], C Houillier[3], C Settegrana[1], J Villemonteix[1], M Brissard[1], C Quiney[1], F Davi[1], V Leblond[2], H Merle-Beral[1], M Le Garff-Tavernier[1]
[1]Biological Haematology Department, [2]Clinical Haematology, [3]Neuro-oncology Department, Pitie-Salpetriere Hospital, Paris, France

Background: Identifying the etiology of neurological symptoms in blood malignancies is still a challenging issue. Lymphomatous meningitis (LM) is mainly described in aggressive B-cell lymphomas (diffuse large B-cell (DLBCL) and Burkitt lymphomas). Leptomeningeal involvement in small B-cell lymphoproliferations is a rare, poorly described condition, mentioned only in a few case reports. The diagnosis is suspected in patients with non-specific central nervous system (CNS) symptoms and non-specific results on medical imaging. The diagnosis is confirmed by cytology (detection of tumor cells) in the cerebrospinal fluid (CSF). However, its sensitivity is low due to the scanty amounts of CSF and the rapid cell death. During the past decade, new complementary approaches have been proposed including flow cytometry (FCM) and quantifications of soluble biomarkers. More recently, interleukin-10 (IL-10) has been described as a candidate to diagnose primary central nervous system lymphoma (PCNSL) and systemic DLBCL with CNS involvement. Dosages can be processed using multiplex techniques with the possibility to undergo simultaneous multiple dosages on small volumes.
Aims: The aim of our study was to evaluate the diagnostic value of interleukin IL-10 and IL-6 quantifications combined with the IL-10:IL-6 ratio in CSF of patients suffering from LM secondary to systemic small B-cell lymphoproliferations.
Methods: We carried out a retrospective monocentric study over 4 years on 23 patients suffering from small B-cell LM: 5 chronic lymphocytic leukemias, 3 mantle-cell lymphomas, 13 Waldenström macroglobulinemias (WM) and 2 unclassified B-cell lymphomas. All patients presented CNS symptoms and documented LM (revealed either by cytology or FCM) at the diagnostic stage or before intrathecal chemotherapy. IL-10 and IL-6 quantifications were performed in CSF using the *Cytometric Bead Array*® technique (BD Biosciences™) on a FACSCanto II flow cytometer (BD Biosciences™), with a limit of detection of 2.5pg/ml.
Results: As there is no well-defined IL-10 cutoff in the literature, we applied the IL-10:IL-6 ratio with a threshold set at 1 used to diagnose intra-ocular lymphoma. More than half of the patients (n=14) had an undetectable level of IL-10 along with low levels of IL-6, leading to an IL-10:IL-6 ratio <1 or *undeterminable* (group n°1). Patients in group n°2 also had ratios ≤1 but with detectable levels of IL-10. All patients with ratios≤1 (groups n°1 and 2) presented small B-cell lymphoproliferations with LM but no evidence of aggressive B-cell lymphoma. Patients in group n°3 had ratios >1. Two patients had PCNSL simultaneously diagnosed in the CSF and one patient had a WM transformed into DLBCL during follow-up. These 3 patients presented an increased IL-10 level (≥10 pg/ml). Thus, IL-10 and IL-10:IL-6 ratios in small B-cell lymphoproliferations unexpectedly differed from those observed in DLBCL. Our findings demonstrate the need of IL-10 and IL-6 quantification with the use of IL-10:IL-6 ratio in small B-cell lymphoproliferations to exclude any other aggressive B-cell malignancy. Interestingly, in WM patients with L, also called Bing Neel syndrome, IL-6 levels seemed higher (median: 10 pg/ml) than in other patients.
Summary/Conclusions: In conclusion, we describe for the first time that CSF IL-10 is not increased in small B-cell lymphoproliferations with LM. However, we report its usefulness in revealing more aggressive lymphomas in the context of either a transformation or when associated with another "hidden" lymphoma such as PCNSL. Supplementary data will be prospectively collected to confirm our results.

PB2049

PROGRESS IN THE DIAGNOSIS OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

A Debliquis[1,*], J Voirin[2], I Harzallah[1], M Maurer[3], F Lerintiu[4], B Drénou[5], G Ahle[6]
[1]Laboratoire d'hématologie, Groupe Hospitalier de la région Mulhouse Sud Alsace, Mulhouse, [2]Service de Neurochirurgie, [3]Laboratoire d'hématologie, [4]Anatomopathologie, Hôpitaux civils de Colmar, Colmar, [5]Service et laboratoire d'hématologie, Groupe Hospitalier de la région Mulhouse Sud Alsace, Mulhouse, [6]Service de Neurologie, Hôpitaux civils de Colmar, Colmar, France

Background: Central nervous system lymphomas are aggressive tumors requiring a prompt diagnosis for successful treatment. Stereotactic brain biopsy remains the standard procedure, but the time needed for histopathology is usually over 2 days.
Aims: During stereotactic brain biopsy, the trocar is rinsed with saline solution and we evaluated the contribution of cytomorphology and flow cytometry of this rinse fluid usually removed.
Methods: Eighteen patients with suspected localized brain lymphoma underwent stereotactic brain biopsy. Brain biopsy tissue sample and/or brain biopsy rinse fluid were analyzed by cytomorphology combined with flow cytometry. Eleven patients had both types of sample, four patients had only brain biopsy tissue sample, and three patients had only brain biopsy rinse fluid. Histopathology was used as a reference.
Results: Histopathology characterized ten diffuse large B-cell lymphomas and eight other diseases: three glioblastomas, one necrosis, one Erdheim-Chester disease, one cerebral vasculitis, one stroke and one anaplastic astrocytoma. Cytomorphology and flow cytometry showed lymphoma cells in nine out of the ten lymphomas. Three cytomorphology or flow cytometry negative results were reported for lymphomas in tissue samples due to low cellularity and biopsy sample conditioning. No lymphomatous cells were found by cytomorphology or flow cytometry in the eight other diseases. Rinse fluid results were consistent with histology in all cases studied (sensitivity and specificity, 100%). All lymphomas characterized by flow cytometry were: CD5-, CD20+, Ki67 high and CD10 was expressed in six out of the nine cases as in histopathology. CD44, CD184, BCL2, and BCL6 showed variable expression. The median time to result was 4.5 days (range, 2-10) for histopathology, while 5 h (range, 3-20) were required for both cytomorphology and flow cytometry.
Summary/Conclusions: Brain biopsy rinse fluid alleviates problems of tissue sample distribution compared to tissue sample. Its analysis performs diagnosis of B-cell lymphoma in a few hours and, associated with histopathology, allows a multidisciplinary diagnosis. This study shows that cytomorphology combined with flow cytometry on brain biospy rinse fluid is a new, fast, and useful strategy.

PB2050

CSF IGH REARRANGEMENT IN HIGH-RISK DLBCL PATIENTS TREATED WITH INTRATHECAL PROPHYLAXIS

MC Tisi[1,*], F D'Alò[1], S Bellesi[1], E Maiolo[1], E Alma[1], A Cuccaro[1], P Chiusolo[1], MT Voso[2], S Hohaus[1]
[1]Institute of Hematology, Catholic University Rome, [2]Department of Biomedicine and Prevention, Università Tor Vergata, Rome, Italy

Background: Central nervous system (CNS) involvement is one of the most serious and devastating complications for patients with diffuse large B-cell lymphoma (DLBCL). Patients with risk factors for secondary CNS localization as specific extranodal sites, bone marrow localization and high IPI score, are candidates for intrathecal prophylaxis. Cerebrospinal fluid (CSF) is routinely analyzed by cytology for the presence of lymphoma cells, while the role of the IgH rearrangement assay on CSF has not been studied in high-risk DLBCL patients treated with intrathecal prophylaxis.
Aims: To evaluate the incidence of IgH clonal rearrangement at diagnosis in high-risk DLBCL treated with intrathecal prophylaxis.
Methods: Patient population included 55 patients with aggressive B-cell lymphoma without CNS involvement, including 51 pts with DLBCL and 4 patients with unclassifiable lymphoma with intermediate features between DLBCL and Burkitt lymphoma. All patients were treated with R-CHOP-like regimens associated to intrathecal methotrexate prophylaxis given during the first 4 cycles of systemic therapy. Twenty-two patients were consolidated with ASCT. CSF samples at the first lumbar puncture were analyzed for IgH rearrangement. After CSF centrifugation, DNA was extracted through the EZ1 DNA Tissue Kit (Qiagen) using the BioRobot EZ1 (Qiagen). VH FR2-JH and VH FR3-JH rearrangement were amplified in two semi-nested PCRs by using the B-cell lymphoma kit-FL (Experteam), and analyzed by Gene Scanning on the ABI 3100 Genetic Analyzer (Applied Biosystem).
Results: A clonal IgH rearrangement in the liquor was detected in 16 of 55 patients (29%), while it was polyclonal or absent in remaining 39 patients. In 4/55 (7%) patients, the number of cells in the CSF was elevated. In the 4 patients with elevated CSF cells, IgH analysis showed a monoclonal band in 1 patient and a polyclonal rearrangement in 3 patients. The presence of clonal IgH rearrangement was associated with elevated (>40 mg/dl) protein levels in the liquor (*p=0.001*). In particular, only 3/30 (10%) patients with a normal CSF protein level showed a clonal IgH, while a clonal IgH rearrangement was present in 13/25 (60%) patients with elevated CSF protein levels. No association was found between detection of clonal IgH in CSF and patient characteristics, as age, stage, bone marrow or extranodal involvement, LDH and international prognostic index IPI. Eight patients with clonal IgH on CSF were serially analyzed at sequential lumbar punctures: the clonal IgH peak disappeared in 7 patients and persisted only in one patient. Three patients developed CNS relapse (5.5%), one of 16 patients with clonal IgH on CSF (6%) and 2 of 39 patients with polyclonal IgH on CSF (5%).
Summary/Conclusions: Clonal IgH rearrangements are frequently present in the CSF of high-risk DLBCL patients and tend to disappear during repeated CNS-directed prophylaxis. No association between detection of clonal IgH

rearrangement and risk of CNS relapse was found in patients treated with intrathecal methotrexate.

PB2051

HODGKIN'S LYMPHOMA AND AUTOIMMUNE DISEASES

B Rym*, F Talbi, Se Belakehal, S Chaib, N Demmane Debbih, Fz Ardjoun
Algiers, Algeria, Algiers, Algeria

Background: Hodgkin's lymphoma (HL) is a tumor disease of the lymphoid tissue characterized by presence of Reed-Sternberg cells. Autoimmune phenomena are associated with HL. They may precede the clinical presentation of HL, occur concurrently or later, either spontaneously or following treatment. The relationship between HL and autoimmune diseases has been reported as bi-directional, however there is a few data in general population.
Aims: Evaluation of the percentage of autoimmune diseases associated with HL on a retrospective study of 80 cases.
Methods: A retrospective study in the hematology department, conducted over a period of 5 years (from 2008 to 2012), which concerned 80 cases of HL.
The diagnosis is histological completed with immunohistochemistry using anti CD15 and anti CD30 anibody. Patients are classified according to the classification of Ann Arbor.We used prognostic classifications: the EORTC for localized stages and IPS for advanced stages.A clinical assessment is performed and includes: blood glucose, renal assessment, liver function tests, viral serology, a respiratory functional exploration, electrocardiogram and echocardiography. Patients are treated with ABVD chemotherapy associated with mantle radiotherapy.In front of presence of warning signs (palpitations, dyspnea, asthenia, bone pain, thrombosis) an immunological assessment is carried out in search of lupus anticoagulant, anticardiolipin, anti-histone antibodies, anti-nuclear factor, thyroid function tests (TSH, FT3, FT4, ATG, ATPO), cervical ultrasound. Biopsies are sometimes carried out in the context and the type of autoimmune disease and sought by the existence of clinically detectable lesions (biopsy of the salivary glands, skin...).
Results: Eighty cases were included, 5 (6,2%) of which, had an autoimmune disease diagnosed previously, simultaneously or after lymphoma. There are 4 women and 1 man. Autoimmune diseases were: lupus erythematosus, thyroiditis autoimmune, celiac disease, sarcoidosis. The diagnosis was made after lymphoma in 4 patients and before in 1 patient,no deaths were registered.

Table 1.

Patient	Antecedents	Histological type	Stage	Treatment	Outcome	Auto-immune disease type	Delays occured	Treatment	Decline
1	Thyroiditis autoimmune (hypothyroidism 3 years before diagnosis in Levothyrox)	1	II Aa	3 ABVD+ Radiotherapy	Complete remission	lupus erythematosus: Lupus anticoagulant +, anti histone +, cardiolipin +	3 months after diagnosis	Steroids	5 years
2	Absent	2	I Aa	3 ABVD + Radiotherapy	Complete remission	thyroiditis autoimmune: TSH collapsed low FT4 high ATPO high ACTG	10 months after RxT	Levothyrox	3 years
3	Absent	2	I Aa	4 ABVD + Radiotherapy	Complete remission	thyroiditis autoimmune: low TSH high-TPO	2 months after RxT	Levothyrox	1 year
4	Celiac disease since the age of 6 years	2	IIIBb	4 ABVD + Radiotherapy	Complete remission	Celiac disease	17 years before diagnosis	diet without gluten	6 years
5	Absent	2	II Ba	3 ABVD + Radiotherapy	Complete remission	Sarcoidosis: converting enzyme / CT mediastinal biopsy of the salivary glands and skin	25 months after diagnosis	Corticosteroid (restrictive pattern)	4 year

Summary/Conclusions: HL association with an autoimmune disease is estimated at 6.2%. There was an important prevalence of autoimmune diseases in girls with HL.The contribution of the activity of the autoimmune disease and immunosuppressive drugs in the development of HL is still not understood. It might be interesting to try to define a population at risk, by personal or family history of autoimmunity and regular and rigorous monitoring of patients during and after treatment with unusual clinical and biological signs.

PB2052

EFFECTS OF MICRORNA-21 ON APOPTOSIS BY REGULATING THE EXPRESSION OF PTEN IN DIFFUSE LARGE B-CELL LYMPHOMA

R Fu*, C Li, H Liu, Y Wang, W Song, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignancy and the most common subtype of non-Hodgkin's lymphoma in China. We found that plasma miR-21 level was significantly higher in B-cell lymphoma. However, the exact contribution of miR-21 in DLBCL remains unknown.
Aims: To determine the function and mechanism of miR-21 in DLBCL.
Methods: miR-21 and phosphatase and tensin homolog (PTEN) expressions were examined through real-time PCR and immunohistochemical methods. Moreover, the effects of antisense oligonucleotide (ASO) targeting miR-21 (ASO-21) were observed in DLCBL cell line.
Results: Results showed that miR-21 expressions in cell line and tissues of patients were significantly higher than those in normal controls, which were inversely correlated with PTEN expression. MiR-21 expression was significantly higher in stage III/IV patients than in stage I/II patients. After downregulating the miR-21 expression, apoptosis of DLBCL cells increased and PTEN protein was upregulated.

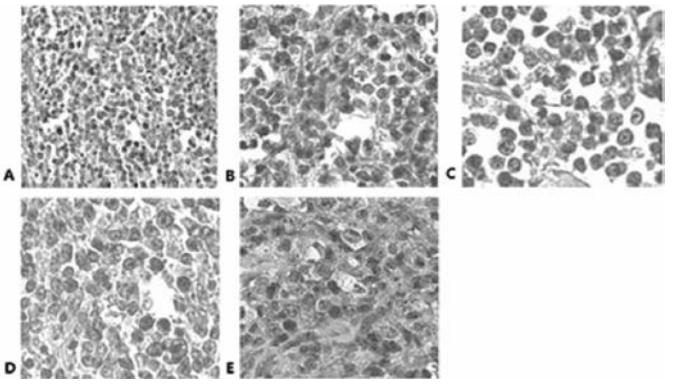

Figure 1.

Summary/Conclusions: These results suggested that miR-21 affects apoptosis of lymphoma cells by regulating the expression of PTEN in DLBCL, which may be associated with increased poor prognosis for DLBCL patients and represents a useful approach for DLBCL treatment.

PB2053

PROSPECTIVE COMPARATIVE STUDY BETWEEN CYTOLOGY COUPLED TO THE FLOW CYTOMETRY BY FINE NEEDLE ASPIRATION AND HISTOLOGY IN THE DIAGNOSIS AND CLASSIFICATION OF LARGE B CELL LYMPHOMA

MR Abbadi[1,*], SE Belakehal[1], L Sahraoui[1], FZ Ardjoun[1], A Kacimi[2]
[1]Hématology, [2]Histopathololology, HCA, algeria, Algeria

Background: Lymphoma B cells can be studied by flow cytometry (FCM) using fine needle aspiration (FNA) on suspensions of lymph node or extra nodal samples. The cytological analysis and the use of special immunophenotypic markers allows orientation of diagnosis.
Aims: Importance of the FCM coupled to morphology in ambulatory diagnosis of B-cell lymphoma.
Methods: Cases of NHL that were diagnosed primarily by FNA at our institution between january 2010 and december 2015. 180 samples were studied (140 lymph nodes and 40 extra nodal samples). 134 samples from the 121 evaluable patients referred for suspicion of lymphoma were studied: these patients were, a cytological study and a fine needle aspiration coupled with FCM. 10 antibodies were tested. Large B cell lymphoma was diagnosed in 37 patients (28%) of 33 lymph nodes, 2 pleural fluids and 2 subcutaneous masses. Histological examination with immunohistochemistry were performed in 31 patients: 23 lymph nodes, 1 bone marrow, 2 tonsillectomies, 2 vaginal, 1 skin, 1 bronchial and 1 nasal mass.
Results: In our study the mean age was 60 years, with a male predominance (Ratio =1.8). On the cytological analysis: all smears were monomorphic in most cases, with large cells appearance, regular nucleus and basophile cytoplasm. On CMF analysis, the diagnosis was de novo in 31 patients and at relapse in 6 patients. lymph node involvement in 33 cases (89%), extra nodel in 4 cases (11%). The markers (CD20, CD22, CD79b) positive in 100% of cases; CD5 positive in 45% with low expression. CD23 and CD10 were negatives in 90% of cases. Isotype restriction was lambda in 83%. Histological analysis: 26 cases Diffuse Large B-cell lymphoma (DLBCL), 3 cases B small-cell NHL, 1 case reactive hyperplasia (RH) and 1 case adenocarcinoma. Immunohistochemistry: CD20 was positive in all DLBCL. The correlation between the FCM and histology in the diagnosis of de novo large B cells NHL was 84%.
Summary/Conclusions: FCM enhances diagnostic ability of FNA cytology, playing a crucial role in a rapid and accurate differential diagnosis between RH, B-NHL and T-NHL. In addition, immunophenotyping of FNA samples contributes to a more precise sub classification of B-NHL when combined with histopathology.

PB2054

THE DURATION OF FIRST COMPLETE REMISSION OF DIFFUSE LARGE B CELL LYMPHOMA COMPARED TO NONGCB, MUM1/IRF4, AND EXPRESSION OF BCLXL AND KI67 IN IMMUNOCHEMOTHERAPY ERA

A Sofo Hafizovic[1,*], N Obralic[2], A Chika[3], N Bilalovic[3], A Dizdarević-Rekić[1], M Vila[1]
[1]Clinic of Hematology, [2]Oncology Institute, [3]Pathology Institute, Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina
Background: The cell has developed mechanisms for maintaining haemostasis. Apoptosis with its internal and external signalling pathways is one of those mechanisms.

Aims: To determine the impact of immune phenotype and oncogene characteristics on the duration of first complete remission with DLBCL
Methods: Study was retrospective-prospective. 60 patients were analysed with *de novo* DLBCL were treated and followed in Clinical Center University of Sarajevo. Follow up median was 47 months (3-91). Patients were divided into two groups: GCB and nonGCB. In the first line of treatment all patients received immunochemotherapy R-CHOP. Biopsy material was analysed for: CD20, bcl-6, CD10, MUM1/IRF4, bcl2, bclxl, bax, bad and bid. Statistics: spearman's analysis was used where p<0.05 was considered significant.
Results: Significantly positive correlation in the group IPI>2 was found with respect to bclxl expression p=0.044 and IPI>2 with respect to expression of Ki67 ≥50% p=0.035. Clinical stage III/IV has a significant negative impact on the duration of CR1 in the total group, p=0.005 and the group Ki67 ≥50% p=0.009. Duration of CR1 in the entire group had negative correlation when compared to MUM/IRF4 with p=0.024 and bclxl with p=0.013. Duration of CR1 is in negative correlation to the group nonGCB p=0.03 and Ki67 ≥50%, p=0.001.
Summary/Conclusions: found a significant negative correlation between the duration of first complete remission of DLBCL compared to nonGCB expression MUM1/IRF4, bclxl and Ki67.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: EXPERIENCE OF AN HOSPITAL IN NORTHEN SPAIN IN THE LAST 22 YEARS

V Martinez-Robles[1,*], S Calleja-Antolin[2], B Ballina[1], S Cerdá[1], S Fernandez-Ferrero[1], F Rondón[1], A Ahmadi[1], F Escalante[1], JA Rodriguez-Garcia[1]
[1]Hematology and Hemotherapy, [2]Immunology, Complejo Asistencial Universitario de Leon (CAULE), Leon, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a very unusual and disastrous dysfunction of the immune system leading to an uncontrolled cytokine storm that has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith. This disease is characterized by lengthy and overwhelming activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells. All this scenario produces an important hyperinflammatory condition and organ damage including fever, splenomegaly, cytopenias, coagulophaty and/or hypertrigliceridemia. Histiocyte Society (HS) criteria have been extensively applied for diagnosing HLH, however not all of them are usually showed at the initial presentation. HLH could be displayed in two different contexts: primary (genetic, usually in children, known as familial form) and secondary (acquired), caused by malignancy, infections, metabolic conditions or autoimmune disorders. This disorder is a life-threatening disease which should be suspected and treated as soon as possible.
Aims: Analyzing the casuistry of hemophagocytic syndromes, diagnostic criteria, treatment applied and evolution in our hospital and making a comparison with the current literature.
Methods: A retrospective analysis was carried out through the medical records of all patients with suspected diagnosis of HLH between 1994 and 2016 in one hospital. Age, clinical features, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study only 17 out of 49 patients met the requested criteria.
Results: The number of cases was 17 (M7/F10). The median age at diagnosis was 67 years, ranged between 4 and 84 years. Clinical development was fast in almost all patients, except in two of them with long-standing pancytopenia. The most frequent causes of consultation were fever and general syndrome. All of them met 5 or more of the criteria necessary for the diagnosis. sIL-2R level and NK activity were underestimated because they were not tested in more than half of the cases. All of them were secondary (11 malignancies, 4 infections, 1 autoimmune disease), unable to clarify the cause in 1 of them. Only 8 patients survived HLH (47%), although 6 died for other complications. 94/04 HLH treatment according to protocol was established in 5 of them. In the rest of them the triggering cause was treated. The most frequent causes of death were liver failure, infectious complications and bleeding. Test results were: hyperferritinemia (100%), hypertriglyceridemia (87.5%), liver enzyme alteration (52.9%), hypofibrinogenemia (33.3%), esplenomegaly (70.6%), hemophagocytosis in bone marrow (94.1%), 100% of tested patients presented high sIL-2R level.

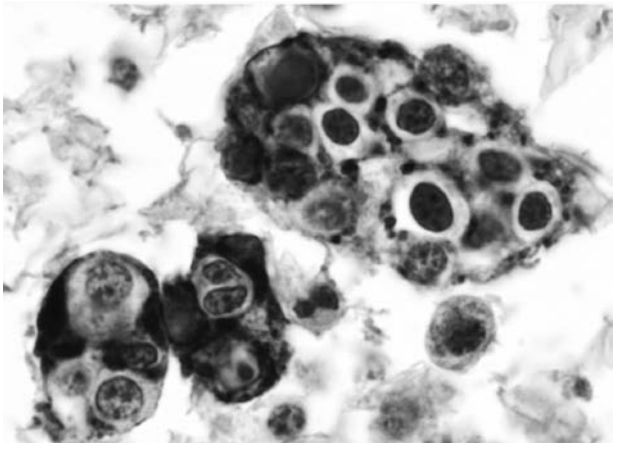

Figure 1.

Summary/Conclusions: Despite being a serious disease and with rapidly torpid course it remains underdiagnosed, obtaining the diagnosis, in most of the cases after hemophagocytosis phenomena is visualized in bone marrow. According to the literature, the main reasons for consultation and hospitalization are similar to those presented in our hospital. The response to treatment is difficult to compare because most of patients has been treated with different therapeutic regimens. In conclusion, it is always needed considering the possibility of a HLH diagnosis when we have a patient with fever and pancytopenia not clearly explained, and the importance of requesting simple test with high profitability such as ferritin and triglycerides in all suggestive picture.

PB2056

SPLEEN ENLARGEMENT AS ONLY MANIFESTATION OF NIEMANN PICK DISEASE TYPE C

L López de Frutos[1,2,*], P Alfonso[1,2,3], JJ Cebolla[1,2], P Irún[1,2,3], I Ballesteros[4], T Bernal[5], A Bustamante[6], M Gaona[7], P León[8], C Loureiro[9], E Ojeda[10], F Santos[11], P Giraldo[1,2,3]

[1]Spanish Foundation of Gaucher Disease and Other Lisosomal Disorders (FEETEG), [2]Aragon Institute for Health Research (IIS Aragón), [3]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER), Zaragoza, [4]Hospital Comarcal de la Axarquía, Vélez, [5]Hospital Universitario Central de Asturias, Oviedo, [6]Hospital Universitario Virgen del Rocío, Sevilla, [7]Hospital Universitario de Burgos, Burgos, [8]Hospital Universitario Dr Peset, Valencia, [9]Hospital do Meixoeiro, Vigo, [10]Hospital Puerta de Hierro, [11]Hospital Universitario La Paz, Madrid, Spain

Background: Niemann-Pick disease type C (NPC) is a rare autosomal recessive lysosomal storage disorder (LSD) characterized by multiple lipid storage triggering intracellular impairment trafficking. NPC shows a wide phenotypic spectrum (visceral, neurological and psychiatric manifestations), the most of patients develop symptoms in early childhood; however there are a subtype mainly identified in adults and characterized by aisle spleen enlargement and cytopenias raising the differential diagnosis with a hematologic malignancy.
Aims: The main objective of this study is report probands state NPC only-visceral phenotype and its characterization. Secondary aims are identifying if plasma lysosomal biomarkers can facilitate the differential diagnosis between LSD and haematological malignancies and if that only-visceral phenotype presented genetic differences with neurological phenotypes
Methods: Firstly, plasma lysosomal biomarkers as Chitotriosidase activity (ChT), CCL18/PARC and 7-Ketocholesterol (7-KC) concentrations were assessed trough biochemistry approaches ChT activity was evaluated through an artificial substract, CCL18/PARC concentration using ELISA technique and 7-KC employing liquid chromatography and tandem mass spectrometry. Lastly, genetic characterization of *NPC1* and *NPC2* genes were carried out. Clinical/analytical records were gathered from the information provided by physicians.
Results: In the last five years, 363 probands were recruited. 51 of them were identified at least one genetic variation reported as pathogenic or unknown significance (VUS) in NPC, 10/51 showed only-visceral symptoms related to NPC. Focused in only visceral cases, they were 35.0 (13.4-41.5) [median (Interquartil range)] years old and a ratio male/female 6/4. None developed neurological symptoms during following-up. Splenomegaly was 16.5 (9.2-18) cm under costal rib in all cases with size information and 1 case presented neonatal jaundice. Hemoglobin 14.5 (12.7-15.3) g/dL, platelets 121.5 (106-231.5) $x10^9$/L. Increased biomarkers: ChT activity 119.0 (69.0-266.0) nmol/mL/h, CCL18/PARC and 7-KC concentration were 156.0 (151.0-158.0) ng/mL and 190.3 (103.7-355.9) ng/mL respectively. Four patients had been splenectomized. The histological study showed numerous histiocytic cells, loaded with small vacuoles and lipid appearance ("foamy cells"). These cells were CD68+ and some of them were stained with hard Giemsa blue and PAS positive, diastase resistant, while others showed a slight positivity. Molecular variants identified in *NPC1*, reported as pathogenic or VUS, were: p.C177T, p.N222S, p.V664M, p.Q775P, p.N916S, p.P1007A, p.D1097N, p.A1151T, p.L1241*, p.R1274T and c.1998+8C>G. *NPC2* gene does not show any variations. All genetic variations were found in heterozygosity, 6/10 subjects presented two variants.
Summary/Conclusions: The biomarkers CCL18/PARC or 7-KC are increased in all cases that can be analyzed and they constitute good indicators of lysosomal storage disease that might facilitate the differential diagnosis with hematologic malignancies. None of the genetic variants found in *NPC1* were exclusively for this only-visceral phenotype.

PB2057

THROMBOPOIETIN MIMETICS AS "A BRIDGE TO RECOVERY". SINGLE CENTER EXPERIENCE IN FOUR PATIENTS WITH CHRONIC PRIMARY IMMUNE THROMBOCYTOPENIA

P Spina, S Impera, M Floridia, AM Todaro, M Salerno, F Castagna, D Caudullo, U Consoli*

Hematology, ARNAS Garibaldi, Catania, Italy

Background: The thrombopoietin (TPO) mimetics are approved for the treatment of chronic primary immune thrombocytopenia (ITP) and have the potential for use in several additional clinical settings. Treatment is usually indicated in patients with platelet counts <$30x10^9$/L and those with counts between 30 and $50x10^9$/L with bleeding or at risk of bleeding (*e.g.* planned surgery, dental extraction, parturition, active peptic ulcer). Although most ITP patients require initial or second line treatment, sometimes platelet levels or hemorrhagic manifestations are not clinically relevant and observation may represent an acceptable clinical strategy. Unfortunately, clinical management of chronic ITP may change over time because of the onset of new clinical condition that may require a temporary higher platelets number for a safe clinical management. Surgery, cancer chemotherapy, dangerous activities may temporarily change the therapeutic strategy of patients with chronic ITP. In these patients there is a significant probability of obtaining some improvement or remission but "on demand treatment" with short courses of therapy (often with corticosteroids, IVIg or TPO mimetics) although warranted to manage bleeding or high-risk of bleeding, are poorly investigated and not sufficiently addressed in the current guidelines.
Aims: In particular some patients with a otherwise "safe" platelet levels may require a temporary treatment to overcome the onset of new clinical conditions. Here, we report on four patients with refractory ITP who received TPO-mimetics as a bridge to recovery from surgical procedures or chemotherapy treatment for diagnosis of cancer.
Methods: Four patients with isolated ITP were given TPO mimetics to increase the platelet count prior to initiation their medical o surgical treatment. We reviewed their baseline clinical characteristics, and clinical course.
Results: We found that a short course of Romiplostim or Eltrombopag may increase the platelet counts enough to enable surgery or to complete chemotherapy. All 4 patients achieved sustained remissions requiring no further treatment. No rebound thrombocytopenia was observed after stopping Romiplostim and none of the patients had bleeding or thrombotic complications.
Summary/Conclusions: Our clinical experience shows that TPO mimetics treatment, in certain patients with milder chronic ITP, may be chosen as intermittent treatment to temporarily raise platelet counts to overcome upcoming surgery, chemotherapy treatment or other clinical conditions requiring a "safer" platelet level.

PB2058

EVALUATION OF INTRACRANIAL CEREBRAL BLOOD FLOW VELOCITIES IN SPLENECTOMIZED AND NON-SPLENECTOMIZED B-THALASSEMIA INTERMEDIA PATIENTS USING TRANSCRANIAL DOPPLER SONOGRAPHY

A Kanavaki[1], P Delaporta[1], D Kyriakopoulou[1], I Papasotiriou[2], K Spengos[3], A Kattamis[1,*]

[1]First Department of Pediatrics, University of Athens Medical School, [2]Department of Clinical Biochemistry, 'Aghia Sophia' Children's Hospital, [3]First Department of Neurology, University of Athens Medical School, Athens, Greece

Background: Beta-thalassemia intermedia (βTI) is a congenital hemolytic anemia with a widely variable clinical phenotype. A high incidence of clinically silent cerebral ischemic events (SCI) has been reported in splenectomized β-TI patients. These could be due to cerebral large-vessel disease.
Aims: Based on the example of sickle cell disease, we applied transcranial Doppler sonography (TCD) to evaluate cerebral vessels velocity as a possible indicator of cerebral vasculopathy in these patients.
Methods: We included in our study 30 patients with βTI, 17 patients with splenectomy (group A) and 13 non splenectomised ones (group B), aged between 13 and 63 years-old (median: 34, mean: 40). Non imaging TCD was performed in all patients and the TAMV values in the anterior (ACA), middle (MCA), posterior (PCA) cerebral and the basilar (BA) artery were measured. Nine of the patients have been also examined by brain MRI/MRA (7 patients from group A and 2 patients from group B).
Results: None of the patients had a TAMV value ≥200cm /sec. In group A the maximum TAMV of the examined vessels were 104 cm/sec MCA R, 139 cm/sec MCA L, 89 cm /sec ACA R, 93 cm/ sec ACA L, 59 cm /sec PCA R, 64 cm/sec PCA L, 75 cm/sec BA. In the same group the mean and median values were 72.4/ 75 cm/sec MCA R, 72/72.5 cm/sec MCA L, 66.3/67 cm /sec ACA R, 59/57 cm/sec ACA L, 43.5/43 cm/ sec PCA R, 43.5/ 41 cm /sec PCA L, 55.5/ 55 cm /sec BA respectively. In group B the maximum TAMV were 88 cm/sec MCA R, 93 cm/sec MCA L, 98 cm /sec ACA R, 93 cm/ sec ACA L, 55 cm /sec PCA R, 59 cm/sec PCA L, 68 cm/sec BA. In the same group the mean and median values were 69.6/ 66 cm/sec MCA R, 76.5/78 cm/sec MCA L, 69.7/69 cm /sec ACA R, 56.7/57 cm/sec ACA L, 38.5/37 cm/ sec PCA R, 43.6/44 cm /sec PCA L, 47.1/ 46.5 cm /sec BA respectively. We found no statistically significant difference ($p>0.05$) in the TAMV values for all examined vessels between the two groups. No statistically significant difference was found between the two groups concerning age, gender, hemoglobin and hematocrit levels. There was a statistically significant difference in PLT blood count that was elevated in splenectomised β-TI patients ($p<0.01$) as it was expected. From the patients who were also examined by MRI only one had a SCI lesion on MRI, but without any abnormality on TOF-MR angiography.
Summary/Conclusions: Our results do not show increased TAMV velocities and do not support the presence of large vessels vasculopathy in splenectomised β-TI patients. These findings agree with recent published data according to which SCIs in these patients might be due to microangiopathy or venous thromboembolism.

PB2059

FAT EMBOLISM SYNDROME IN 4 PATIENTS WITH NON-HB SS SICKLE CELL DISEASE

A Collins[1,*], T Bull[2], R Gahlaut[3], M Roberts-Harewood[4], A Yardumian[4], M Besser[2]

[1]Haematology, Addenbrooke's Hospital (Cambridge University Hospitals Foundation Trust), [2]Haematology, [3]Histopathology, Addenbrooke's Hospital (Cam-

bridge University Hospitals NHS Foundation Trust), Cambridge, [4]Haematology, North Middlesex University Hospital, London, United Kingdom

Background: Fat embolism secondary to bone marrow necrosis may occur in patients with sickle cell disease giving rise to respiratory, neurological and haematological complications - the so-called fat embolism syndrome (FES). FES is more common in non-SS genotypes.
Aims: We present 4 recent cases of suspected or confirmed FES in adult patients with Hb SC seen in our hospitals and review the clinical, radiological and histological findings of this under-recognised and potentially devastating complication of 'milder' forms of sickle cell disease.
Methods: Case 1. A 53 year old man with Hb SC was admitted with malaise, fevers and rigors. The following day he dropped his GCS and was transferred to ITU. MRI brain showed widespread small infarcts. He became pancytopenic. Bone marrow examination showed widespread necrosis. Follow-up MRI showed multiple microhaemorrhages. Despite supportive care including top up transfusions he retained a major neurological deficit. Case 2. A 50 year old woman with Hb SC was admitted with abdominal and joint pain. That evening, she deteriorated with hypoxia, pyrexia and tachycardia. CT showed no major PE. She was given antibiotics and transferred to ITU where exchange transfusion was initiated. A drop in the platelet count was noted. She suffered a cardiac arrested and died. At post mortem pulmonary fat embolism was found. Case 3. A 56 year old man with Hb SC was admitted with body pain and breathing difficulties and deteriorated within hours. Chest x-ray showed bilateral haziness. Despite antibiotics he deteriorated further with a fall in GCS and acute kidney injury and was transferred to ITU before being exchange transfused. CT showed cerebral oedema. An MRI performed a few days later showed numerous widespread small haemorrhagic foci. GCS remained low despite removal of sedation. Case 4. A 30 year old man with Hb SC was admitted with leg and arm pain. Over the following days he complained of back pain of an unusual severity. On the third day of admission, he suddenly deteriorated with hypoxia and confusion. He developed acute renal failure, deranged liver function tests and coagulopathy. He had a rapid drop in haemoglobin and platelets. He was admitted to the intensive care where an exchange transfusion was performed. MRI brain showed numerous microhaemorrhages. An MRI of his lumbosacral region showed extensive bone marrow change in keeping with the suspected diagnosis. He had a stormy few days on ITU but slowly improved and was discharged from hospital alive but with subtle cognitive issues.
Results: Fat embolism is an under-recognised phenomenon associated with major morbidity and mortality in sickle cell disease. The presentation may mimic a thromboembolic complication but is often characterized by a combination of venous and arterial infarction. It has a characteristic radiological appearance when involving the brain. Pancytopenia with high numbers of nucleated red cells is typical. LDH is often very high.
Summary/Conclusions: A high index of suspicion is required to make the diagnosis of fat embolism syndrome ante-mortem. In case reviews, a survival advantage has been reported in patients managed with exchange transfusions although this has not been verified by prospective studies.

PB2060

RESULTS OF STANDARD TREATMENT FOR APLASTIC ANEMIA IN CHILDREN

E Butina, E Vaskina*, N Minaeva
Immunogematology, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: Acquired aplastic anemia (AA) is a disorder characterized by pancytopenia, hypocellular bone marrow and an absence of infiltrative disease of the bone marrow. The incidence of AA in Russian Federation is 2-6 cases among 1 million children per year. The hematopoietic stem cell transplantation (HSCT) is the most effective treatment for AA. Immunosuppressive therapy (IST) including antilymphocyte globulin, cyclosporine is the standard therapy for patients who do not have a HLA-matched sibling donor.
Aims: Evaluation of results of treatment of children with acquired aplastic anemia in 2005-2015.
Methods: The study included 23 children with acquired aplastic anemia at the age from 3 to 18 years (median age - 11 years): 11 boys and 12 girls. Very severe disease was diagnosed in 12 patients, severe AA - in 8, non-severe AA- in three patients. The hemorrhagic syndrome with uterine, nasal and intestinal bleeding was observed in 25% of patients.
Results: Remission was achieved after the first course of IST in 12 patients. The second course of IST was held in 5 patients with very severe AA, including as a therapy for relapse in three patients. Early hematologic relapse was diagnosed in 2 patients, the later relapse - in 1 patient. HSCT from an related donor carried two children after the first course of ICT. Unrelated donor HSCT was performed in two patients after the second course of IST. Five patients at this time continue to receive cyclosporin therapy, two of these patients are dependent on transfusional support. One child was killed in a month from the beginning of ICT. Cause of death - sepsis, severe hemorrhagic syndrome. On 01.01.2016, 17 patients (77%) are in complete clinical remission.
Summary/Conclusions: Five year overall survival rate 95,6%. Event-free five year survival rate 80,3%.

PB2061

THE OUTCOME OF HIGH RISK LANGERHANS CELL HISTIOCYTOSIS (LCH) IN EGYPTIAN CHILDREN. A SINGLE CENTER EXPERIENCE

MS Sedky[1,2,*], A Hamoda[1,3], H Taha[4], I Zaki[5], O Hassanain[6], A Elhadad[1]
[1]Pediatric hematology Oncology, Children Cancer Hospital, Cairo, [2]Pediatrics, National Research Centre, Guiza, [3]Pediatric hematology Oncology, National Cancer Institute, [4]Pathology, [5]Radiodiagnosis, [6]Clinical research, Children Cancer Hospital, Cairo, Egypt

Background: High risk multi-system organs (RO+) Langerhans cell histiocytosis (LCH) including hemopoietic cytopenias, liver and spleen disease, have the highest mortality if failing first line treatment. Methotrexate (MTX) association with Vinblastine (VBL) and Prednisone (PRED) has been tried upfront and a second line cladribine (2cda) has been proposed in RO+LCH.
Aims: To present the outcome of RO+ LCH in a pediatric single centre population.
Methods: A total of 50 RO+ LCH patients, M/F 26/24, median age 1.7 years (0.19-10.1) treated between August 2007 and June 2015 were retrospectively analyzed. A first line VBL, PRED with MTX without a different second line was adopted till 2012 where methotrexate was omitted and 2cda was introduced as a salvage line.
Results: The 5 year overall survival (OS) is 69% and the event free survival (EFS) is 17%. At week 6 and 12, "better' response was obtained in 37(74%) and 33 (66%) patients respectively. Seventeen (34%) and 15 (30%) patients progressed and reactivated their disease respectively. At last follow up, 34 and 2 patients were in 'better' and 'worse' status respectively and 14 patients died. In univariate analysis, the factors that affected OS were hemopoietic cytopenias with 33%, 76% and 62% in tri, bi and monocytopenia respectively p0.017, hepatic affection with 25%, 93% and 61% in hepatic dysfunction, hepatomegaly and both respectively p 0.027, combined RO+ with 47%, 68% and 100%, in tri, bi and mono organ(s) respectively p 0.045, number of induction: 47% and 76% in one cycle and 2cycles respectively p0.026, failure of 1st line treatment: 27%, 76% and 50% in progression, reactivation and both respectively p <0.001,Salvage with 2cda 56%, and 45% without p0.001, progression salvage with 2cda 57% and 10% without p0.008. The factors that affected EFS were cytopenias with 0%, 19%, and 34% in tri, bi and monocytopenia respectively p0.015, bony CNS risk sites with 9% *versus* 27% if none p 0.06, MTX 26% with and 13% without p0.005. The factors that affected reactivation were: male gender p0.014, season autumn/winter p<0.01, lung cysts p0.043. The factors that affected disease progression were tricytopenia p <0.01, hepatic dysfunction p<0.01, hepatic dysfunction and hepatomegaly combination p0.04.
Summary/Conclusions: The outcome of RO+LCH in pediatric egyptian population remains satisfactory despite a high proportion of reactivation. Disease progression post induction carries a dismal prognosis without a salvage line. Hemopoietic tricytopenias and hepatic dysfunction carry the worst prognosis. Methotrexate as a 1st line and 2cda as salvage line are efficient in improving the outcome.

PB2062

GENDER DISPARITIES IN CARDIO-RESPIRATORY FITNESS AMONG A COMORBIDITY FREE ANEMIC POPULATION

R Shouval[1,2,*], S Katz[3], A Nagler[1], D Merkel[1], I Ben-Zvi[2], S Segev[4], Y Sidi[5], I Goldenberg[6], S Kivity[7], E Maor[6]
[1]Hematology and Bone Marrow Transplantation, [2]Internal Medicine F, [3]Sheba Medical Center, Ramat Gan, Israel, [4]Institute for Medical Screening, [5]Internal Medicine C, [6]Leviev Heart Center, [7]Internal Medicine A, Sheba Medical Center, Ramat Gan, Israel

Background: Anemia is a common hematologic disorder characterized by reduced absolute number of circulating red blood cells. It has been established as a poor prognostic factor in a variety of medical disorders. Nonetheless, the functional impact of anemia on cardiorespiratory fitness (CRF) in healthy individuals has mostly been explored in small interventional studies, simulating acute rather than chronic states.
Aims: Using differing criteria for anemia diagnosis, while analyzing males and females separately, the primary and secondary objectives were to evaluate the effect of anemia on CRF and overall survival, respectively, in apparently healthy adults.
Methods: We retrospectively analyzed 16,332 self-referred subjects undergoing exercise stress testing as part of a routine screening program. Subjects were non-smoking, free of diabetes, ischemic heart disease, or chronic kidney disease. Anemia was defined by either the World Health Organization (WHO) criteria (Hemoglobin (Hb) less than 13 g/dl and 12 g/dl for males and females, respectively), or Beutler and Waalens' (BW) criteria (*Blood, 2006*) (less than 13.7 g/dL and 13.2 g/dL for males younger and older than 60 years, respectively, and 12.2 for females). Fitness was categorized into age- and sex-specific quintiles according to Bruce protocol treadmill time. Multivariate logistic regression was used to evaluate the association between anemia and low CRF in the

baseline visit as well as during multiple visits. A multivariate Cox proportional hazards regression model was constructed for survival analysis.
Results: The mean age of the cohort was 46±10 years and 70% were men. Median follow-up was 10 years. Mean Hb levels were 13.09±0.96 and 15.05±0.96 among women and men, respectively (p<0.001), with higher proportion of anemia among women (10.8% *versus* 1.6% according to WHO criteria, and 15% *versus* 6.1% according to BW criteria, respectively; p<0.001 for both). Baseline visit anemia, according the WHO and BW criteria, was associated with a risk adjusted increase of 33% (1.06-1.66, 95% confidence interval (CI)) and 24% (1.01-1.52, 95% CI) for low CRF, respectively (p<0.05 for both). However, no association was observed in males, regardless of anemia threshold. These findings were corroborated in a repeated measures analysis of 71,200 sequential visits (Figure 1), where only in females, anemia resulted in a 38% (1.17-1.63, 95% CI) and 22% (1.05-1.40, 95% CI) increase in risk for low CRF (p<0.01 for both). Lack of regular physical activity, elevated body mass index, total cholesterol and fasting glucose levels were also independently associated with low CRF in the multivariate model, regardless of gender. With respect to survival, only anemia in men, as opposed to women, was associated with an increased risk for mortality, especially when adopting a more stringent criteria for diagnosis (hazard ratio of 3.06 (1.65-5.68, 95% CI) and 1.83 (1.06-3.17, 95% CI), using the WHO criteria and BW criteria respectively, p<0.05 for both).

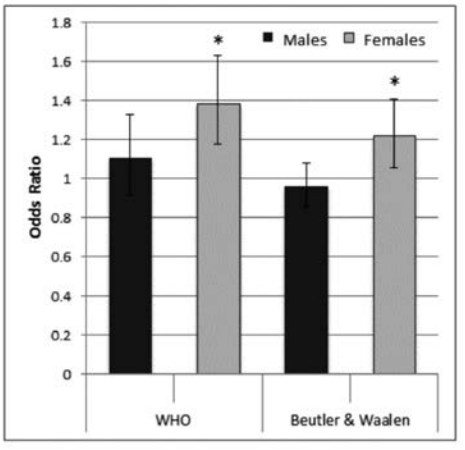

Figure 1 – Risk for low cardiorespiratory fitness, across sequential visits, in anemic versus non-anemic subjects. Bars represent 95% confidence intervals.
* p < 0.01 for incorporation in a logistic regression model.

Figure 1.

Summary/Conclusions: Anemia's functional and prognostic significance differs between genders in a cohort of comorbidity free subjects. Anemia, regardless of diagnostic criteria, was associated with low fitness only in females, while increased mortality was solely observed in males. Taken together our findings indicate differing anemia mechanisms and physiological responses between genders. Moreover, we suggest a functional and prognostic, rather than an epidemiologic approach, for setting anemia diagnosis thresholds.

PB2063

ASSESSMENT OF A COHORT OF BETA THALASSEMIA PATIENTS: NEW CHALLENGES

F Benmegherbi[1,*], N Benmouafek[2], L Cheriflouazani[1], A Benomar[1], I Boumedjadji[1], L Aissou[1], D Abdelmoumen[2], Y brahiti[2], M Bradai[1]
[1]Hematology, CHU Frantz Fanon, Blida, [2]Pediatric, Nafissa Hamoud Academic Hospital, Algiers, Algeria

Background: The combination of transfusion and chelation therapy has dramatically extended the life expectancy of Beta-thalassemic patients who can now survive into their fourth and fifth decades of life. The goal of long-term transfusional support is to maintain the patient's hemoglobin level at 9-10 g/dl. However, complications are still frequent and affect the patients' quality of life, particularly in countries with limited resources.
Aims: The main objective of this study is to determine the prevalence of prominent complications in a cohort of Algerian thalassemia patients.
Methods: This study was conducted to assess 81 polytransfused Beta-thalassemic patients, mean age 16 years (6-31), sex ratio: 37M/44G: We assess blood transfusion regime, pre-transfusion hemoglobin, iron overload, by serum ferritin level, hepatic iron concentration. Bone mineral density (BMD) measurements at lumbar and femoral regions have been done using dual x-ray absorptiometry. We assess Growth and pubertal maturation (Taner stage), and dosing gonadic hormone dosage, calcium, vitamin D, Parathyroid, and thyroid hormone.
Results: The pretransfusion hemoglobin level was maintained between 6 and 9 g/dl in 90% of patients. Additionally, 5% had levels less than 6 g/dL, 5% from 9 to 11 g/dL. Fifty-five percent of patients had undergone splenectomy at a median age of 9 years (range, 1-31 years). Ferritin levels ranged: 147 to 13500 ng/mL (median, 4992 ng/mL). Among 44 patients assessed, 77% had values of 15 mg/g dry weight or higher, 50% LCI>43 mg/gdw, 20% had moderate LCI 15 to 7 mg/gdw, only 1 patient <7mg/gdw. Hepatic biopsy, performed in 26 patients (assessed for bone morrow transplantation), all had hepatic fibrosis moderate to severe (Metavir score). BMD performed in 49 patients, prevalence of lumbar osteoporosis and osteopenia were 38% and 62%. Dosage of vitamin D performed in 34 patients:5 <10ng/ml, 17 [10-20ng/ml], 8 [20-30ng ml], 4 normal >30ng/ml. 12 patients receive Biphosphonate treatment. Short stature was seen in 65% of our patients. Hypogonadism was diagnosed in 22,9% of 74 patients who had reached pubertal age: 50% of hypogonadic females and males were receiving hormonal substitution. No patient had Hypoparathyroidism and primary hypothyroidism. 3 cases of primary amenorrhea, and 2 diabetes aged 17 and 31 years. Despite high ferritine serum no patients had heart disease requiring medication. The goal of long-term hypertransfusional support is to maintain the patient's hemoglobin level at 9-10 g/d. This threefold is rarely reached in our patients, for mixture of reasons (compliance, limited blood pack). Iron chelation has been formerly limited, reason of the high prevalence of hemochromatosis in the majority of our patients. Intensification of iron therapy is now assessed to obtain reversal tissues lesions. Well treated 90% of thalassemics patients reached normal puberty; in contrast, in our group of patients, only 20% achieved normal pubertal status after 16 years. Poor pubertal growth and impaired sexual maturation, and endocrine abnormalities in children, adolescents and young adults have been observed because of conventional treatment deficiency, substitutive hormonal therapy is indicated. BMD is a good index of bone status in patients with Thalassemia and should be done in these patients annual.
Summary/Conclusions: High prevalence of complications among our thalassemics signifies the importance of more detailed studies along with therapeutic interventions. The survival of patients with thalassemia major improving, but the prevalence of severe complications is still high.

PB2064

MYCOPLASMA PNEUMONIAE AS A CAUSE FOR NEUTROPENIA IN CHILDREN

M Papadopoulou[1], P Panagopoulou[2,*], V Koulourida[3], M Economou[4], E Papadopoulou-Alataki[3], E Haidopoulou[3], M Eboriadou-Petikopoulou[3]
[1]Infectious Diseases Laboratory, Papageorgiou Hospital, [2]4rth Paediatric Department, [3]Papageorgiou Hospital, [4]1st Paediatric Department, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Extrapulmonary manifestations of *Mycoplasma pneumoniae* infection are uncommon and include hematologic, gastrointestinal, musculoskeletal, dermatologic, and neurologic complications. Neutropenia on the other hand can be caused by a variety of causes including infections. The microorganisms that are commonly associated with neutropenia are: viruses (Epstein-Barr virus, Cytomegalovirus, hepatitis viruses, human immunodeficiency virus, parvovirus B19, influenza, measles), bacteria (Salmonella, Brucella, Bordetella pertussis, Rickettsia), mycobacteria and rarely fungi (disseminated histoplasmosis).
Aims: Based on the observation that some of our patients that were evaluated for neutropenia had serologic evidence of recent Mycoplasma infection we hypothesised that *Mycoplasma pneumoniae* might also *be* a cause of neutropenia in children.
Methods: To this aim we retrospectively studied the medical records of all patients that had been hospitalized in a tertiary pediatric department during a 17-month period because of a serologically proven *Mycoplasma pneumonia* infection (positive IgM antibody titers). The demographic characteristics (age, gender), the clinical presentation, medications and other laboratory parameters were also recorded. Neutropenia was defined as an absolute neutrophil count below the 3rd percentile for age and gender. Every patient was matched for age and gender with another patient with similar clinical presentation but in whom antibodies against *Mycoplasma pneumoniae* were not detected. Student's t-test and chi-square test were used for statistical analyses as appropriate.
Results: In total 290 patient were tested for Mycoplasma. Ninety patients (50 females) with positive IgM antibodies againt Mycoplasma pneumoniae were identified. Amongst them 18 patients (20%) were also found to have neutropenia (four severe, four moderate, and 10 with mild neutropenia). Mean age (±SD) was 7.11 (±3.67) years. Mean neutrophil count was 1045/mm^3. Thirteen patients (72%) presented with a respiratory tract infection, two were investigated because of fever of unknown origin, one for ITP, one for parotitis and one for cervical lymphadenopathy. All patients recovered from their neutropenia. This group was then compared with the patients that had negative antobodies for Mycoplasma, in which 7 cases of neutropenia were recorded (7.8%). Comparison with chi-square test based on a two by two table showed that this difference is statistically significant (p<0.05).
Summary/Conclusions: Infection with *Mycoplasma pneumoniae* is usually associated with hemolytic anemia. There are only a few reports of other hematologic toxicities in humans. In this study we showed that Mycoplasma infection

might be associated with a form of a transient post-infectious neutropenia in 20% of the study group. Given the fact that evaluation for neutropenia maybe time consuming and expensive, it is important for practitioners to be aware of this rare complication of Mycoplasma infection. Moreover, should this observation be confirmed, the administration of an appropriate antibiotic might be beneficial and shorten the duration of the neutropenia.

PB2065

EVANS SYNDROME: A RETROSPECTIVE STUDY OF 30 CASES

K Zahra*, C Hasnia, HM Hamza, Z Monia, BS Nesrine, A Bechir, BY Yosra, K Abderrahim
Hematology, Hospital Farhat Hached, SOUSSE, Tunisia

Background: Evans syndrome is a very rare autoimmune disorder in which an individual's antibodies attack their own red blood cells and platelets. Both of these events may occur simultaneously or one may follow on from the other. Usually idiopathic, it is also associated with lymphoproliferative disorders and autoimmune diseases.
Aims: Study the epidemiological, clinical, biological, etiological and therapeutic aspects of Evans syndrome.
Methods: This is a retrospective and analytic study about 30 cases of Evans syndrome observed in the hematology department of Sousse, over a period of 14 years.
Results: There were 18 men and 12 women (sex ratio=1,5) with a median age of 40 years. The circumstances of discovery were an anemic syndrome in all patients, mainly due to paleness and asthenia. Concerning biology, regenerative anemia was normocytic in 20 cases and macrocytic in 10 cases, thrombocytopenia below 100000/mm^3 was observed in all patients. There were also biological signs of hemolysis: hyperbilirubinemia, high LDH rate in all patients. Direct Coombs test was positive for Ig G + Complement, IgG and complement in 13, 8 and 9 cases, respectively. Evans syndrome was idiopathic in 20 cases and secondary to lymphoproliferative disorders in 5 cases, autoimmune disorders in 5 cases. All patients received corticosteroid treatment in addition to folic acid therapy and etiological treatment in the non idiopathic cases with complete remission in 10 cases. Immunosuppressive therapy (endoxan) was prescribed in 10 patients with complete remission in 5 patients. Anti-CD20 monoclonal antibody was prescribed in 8 patients with complete remission in 4 cases.
Summary/Conclusions: Glucocorticoids and/or intravenous immunoglobulins are the mainstay of the treatment in the majority of patients with Evans syndrome. When these treatments fail, patients often require cytotoxic drugs or splenectomy.

PB2066

THE STUDY OF THE SPECTRUM OF THALASSEMIC MUTATIONS AT THE NORTH-WEST REGION OF RUSSIA

Y Zhilenkova[1,*], S Bessmeltsev[2], A Kozlov[1]
[1]clinical chemistry, The North-West State Medical University n.a.I.I. Mechnikov, [2]hematology and transfusiology, the Russian Scientific and Research Institue for Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Beta-thalassemia - a hereditary disorders of hemoglobin synthesis, which are transmitted in an autosomal recessive inheritance. The main stage of the prevention of thalassemia is the molecular diagnosis of thalassemic mutations in the fetus conducted at 1st trimester of pregnancy. The possibility of this diagnosis is determined by the availability of data on the molecular defects of beta-globin gene in this region.
Aims: To examine the incidence of mutations of beta-globin gene in the North-West region for the development of measures for the prevention of beta-thalassemia.
Methods: Molecular diagnostic was performed at 65 patients (men - 31, women - 34, from 2 to 58 years) with a diagnosis of beta-thalassemia (minor and major), were examined and treated at The Consultative and Diagnostic Center for Children and The Russian Research Institue of Hematology and Transfusiology (Saint-Petersburg). All patients living in St. Petersburg, but have a different ethnic composition: 40% - Azerbaijanis; 33.8% - Russian, who (according to them) havn't Caucasian or Mediterranean roots; 11.3% - Bulgarians, Cypriots; 8.7% - Dagestan; 6.2% - patients of mixed families (one parent - Russian, the other - from the Caucasus or Mediterranean). Diagnos thalassemia set on the basis of red blood cells parameters (microcytosis - the MCV <80 fl, hypochromia - MCH <27 pg, Mentzer index <11.4) and hemoglobin fractions (Hb A2>3% and/or Hb F>1%). The material for the study served as the venous blood. Red blood parameters were determined on the hematology analyzer Sysmex XT-4000i (Sysmex, Japan), fractions of hemoglobin investigated by capillary electrophoresis (MINICAP, Sebia, France). Mutations of the beta-globin gene was determined by reverse- hybridization of method of biotinylated multiplex-PCR products (β-GlobinStripAssay, ViennaLabDiagnostics, Austria).
Results: In examined patients 5 homozygous (large form of thalassemia), 2 compound heterozygous and 58 heterozygous (small form) were applied. A total of 10 thalassemic mutation was found: codon 8 (-AA) - 38%; IVS 1.110 (G>A) - 27%; 5 codon (-CT) - 7%; IVS 1.6 (T>C) and IVS 2.1 (G>A) - 6%; IVS 2.745 (C>G), IVS 1.1 (G>A) iIVS 1.5 (G>C) - 4%; codon 8 \ 9 - 3%; -101 (C>T) - 1%.
Summary/Conclusions: The most frequent mutations of the beta-globin gene in St. Petersburg were codon 8 (-AA) - 38% and IVS 1.110 (G>A) - 27%.

PB2067

THE ETHNIC DIFFERENCE IN RBC-RELATED INDICES BETWEEN KOREAN AND UAE AND THE MUTATION PROFILE IN THALASSEMIA OF UAE: ONE-YEAR EXPERIENCE IN UAE AS THE KOREAN PHYSICIANS

HR Lee[1,2,*], S Hong[1,2], M Han[1,2]
[1]Department of Laboratory Medicine, Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates, [2]Department of Laboratory Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: Sheikh Khalifa Specialty Hospital (SKSH) of the United Arab Emirates (UAE) has been operating by Seoul National University Hospital of the Korea since February 2015. The rules of three [3 x red blood cells (RBC)=Hemoglobin (Hb), 3xHb=hematocrit (Hct)] has been used to evaluate RBC-related indices of patient samples. We empirically found out that Arab patients are showing the discrepancy in these ratios due to relatively low mean corpuscular volume (MCV) in comparison with Korean patients, although they are in the non-anemic state. Also, regarding the thalassemia, characterized by the microcytosis, the prevalence of thalassemia in Korea is much lower than those in UAE. Therefore, the microcytic feature of UAE patients and thalassemia have been the unique experiences to Korean physicians.
Aims: First, we analyzed the RBC-related indices of different ethnic groups (Korean *vs* Arab) and adult patients showing microcytic anemia, such as iron-deficiency anemia (IDA) and thalassemia. Second, we reported the mutation profile showing in thalassemia that diagnosed in our hospital during one-year.
Methods: We collected the additional blood sample for the complete blood cell (CBC) count from the SKSH staff who received a medical check-up and gave written consent to the study. Among the data obtained, we selected data from Korean and Arab staff who were in the non-anemic state according to the WHO criteria (Hb ≥13 g/dL in male and Hb ≥12 g/dL in female). RBC indices, such as the MCV, mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentration (MCHC), were measured. We also retrieved the CBC data from the IDA patients showing the ferritin level of lower than 10 ng/mL, and from the patients diagnosed as thalassemia through the Hb electrophoresis or *HBA1/HBA2* and *HBB* gene analysis.
Results: The data from 48 Korean staff, 53 Arab staff, 69 IDA patients, and 21 thalassemia patients were enrolled. The RBC-related indices are following according to the groups; MCV, 92.2±3.5 fL (range, 85.3-102.0 fL), 86.9±4.2 fL (73.7-94.4 fL), 72.0±7.1 fL (58.1-90.0 fL), 70.4±5.5 fL (61.1-82.5 fL), respectively; MCH, 30.8±1.4 pg, 28.2±1.9 pg, 21.3±3.3 pg, 21.6±2.5 pg, respectively; MCHC, 33.4±1.1 g/dL, 32.5±1.2 g/dL, 29.3±2.4 g/dL, 30.5±1.5 g/dL, respectively. The MCV, MCH, and MCHC of Korean are significantly higher than those of Arab (P <0.001, P <0.001, P=0.001, respectively). There are no significant differences in RBC-related indices between IDA and thalassemia patients in our study. For mutation profile of thalassemia, we analyzed total 22 adult and children thalassemia patients confirmed by gene analysis. Among 22 patients, 12 were α-thalassemia, seven were β-thalassemia, two were diagnosed with both α- and β-thalassemia, and one was diagnosed with both α-thalassemia and sickle cell anemia. The most common α-thalassemia was α$^+$-thalassemia trait due to 3.7-kb and deletion of *HBA1/HBA2* gene (7/14, 50.0%) and the most common mutation of β-thalassemia was c.92+5G>C mutation of *HBB* gene (5/9, 55.6%). Distinctively, the homozygous or heterozygous c.1-?_429+?del in the *HBA2* gene were detected in four α-thalassemia patients, which has not been reported previously.
Summary/Conclusions: There is the difference in the RBC size between Korean and Arab. We found out the unique deletion mutation of alpha-thalassemia. This is the report by one-year experience in UAE as Korean physicians. We expected to report the characteristics of RBC size and thalassemia mutation profile in UAE with accumulated experience in the future.

PB2069

THE INCIDENCE OF CD36 DEFICIENT MONOCYTE AND PLATELET AND ITS CORRELATION WITH DIABETES IN SOUTH KOREA

J Kahng[1,*], K Han[2]
[1]Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Bucheon, [2]Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: CD36, a synonymous term for platelet glycoprotein IV, GP (glycoprotein) IIIb, is an 88-kD glycoprotein that is expressed in such various cells as platelets, monocytes, macrophages, erythroblasts, capillary endothelial cells, adipocytes, epithelial cells in the kidney and cardiac myocytes. Hematologically,

it is used as a representative antigen of platelets and monocytes in flow cytometric differential cell counting. Various reports prove the existence of racial variations with regard to CD36 deficiency: 0.3% in Caucasians, 3-11% in Japan, 0.5% in Type 1 and 1.3% in Type II for Chinese, and 0.3% of the U.S. population. And other studies show decreased insulin sensitivity and postprandial hypertriglyceridemia as the metabolic manifestations of CD36-deficient subjects. However, there has been no report on the nature of CD36 deficiency for Koreans.
Aims: The authors aim to find out CD36 deficiency incidence of South Korea and any potential correlations between diabetes patients by studying blood samples from diabetes patients, leukopenic samples, and normal samples.
Methods: We collected data from 757 individuals including 521 leukopenic patients, 105 diabetes patients, and 131 normal subjects at Seoul St. Mary's Hospital, Seoul, Korea between August 2013 and March 2014. Routine CBC with WBC differential count with an automatic blood cell analyzer (DxH800) was performed in conjunction with analysis by flow cytometry by using Hematoflow with Cytodiff. The 5-color/6-marker reagents (Cytodiff panel) were CD36-FITC, CD2-PE, CD294-PE, CD19-ECD, CD16-PC5, and CD45-PC7 antibodies. To confirm the platelets, CD41a-PE/CD36-FITC dual staining was added. To confirm the monocytes, CD11c-PE/CD36-FITC dual staining and peripheral blood smear slide reviews were used. We strictly adhered to the manufacturer's manual for analysis: 100 uL of blood samples was mixed with 10 uL of Cytodiff reagent, and incubated for 20 min at room temperature. Lysing solution (Versalyse solution; Beckman Coulter) was used for 15 min to break down red blood cells. After washing, a flow cytometer (FC500) was used to collect 10,000 cells. The analysis software, self-gating and separating populations by automatic logic pathways, analyzed the Cytodiff results automatically. The gates were adjusted only in case of large debris contamination or incomplete separation of basophils and myeloblasts. Samples were all analyzed in duplicate.
Results: Of the 757 cases, 22 cases (2.91%) were either of type I (9 cases, 1.19%), or of type II (13 cases, 1.72%). Of 131 normal subjects, 4 cases (3.05%) were either of type I (1 case, 0.76%), or of type II (3 cases, 2.29%). Of 105 diabetes cases, 3 cases (2.86%) were of type II. And finally, of 521 leukopenic cases, 15 cases (2.88%) were either of type I (8 cases, 1.54%), or of type II (7 cases, 1.34%). Our t-tests showed no significant differences among the groups, and no correlation was found between diabetes and CD36 incidence, or between leucopenia and CD36 incidences (chi-square test and Fisher's exact test), with the odd ratios of 0.97 and 0.98, respectively. No significant difference was found between the 22 cases and the remaining 735 cases in terms of sex, age, previous illness, hemoglobin level, WBC count, monocyte count, and platelet count.
Summary/Conclusions: The overall incidence of CD36 deficient monocytes and platelets based on 757 Korean subjects was 2.91%, manifesting no significant difference from the Japanese or Chinese studies, and no evident correlation with diabetes.

Platelets disorders

OSELTAMIVIR IN THE TREATMENT OF PRIMARY IMMUNE THROMBOCYTOPENIA

HJ Campo Palacio*, RM Campos Alvarez, A Salamanca Cuenca
Haematology, Hospital Jerez de la Frontera, Jerez de la Frontera, Spain

Background: Primary immune thrombocytopenia (ITP) is an immune bleeding disorder with an increased destruction of autologous platelets. Autoantibody specificity is usually against GPIIb/IIIa in 70-80% of patients or GPIb in 20% of them. Firts-line treatment includes immunosuppressive and immunomodulatory agents, that is corticosteroids (CS) or intravenous immunoglobulin (IVIG). Splenectomy is considered for patients with persistent lack of response. However, about 20% patients are inexplicably refractory to both therapies. Recent studies in refractory ITP patients suggest an association between anti-GPIb autoantibody and a poor response to conventional therapies, as well as platelet desialylation. This leads to platelet elimination by hepatocyte Ashwell-Morell receptors, especially in the absence of macrophages. Therefore, it may be a role for sialidase inhibitors in ITP treatment. Oseltamivir phosphate conventionally serves as anti-influenza agent. It inhibits viral neuraminidase as well as glycolipids sialylation on human T cells surface. We report a case of an adult ITP patient who was resistant to multiple therapeutic approaches but was successfully treated with Oseltamivir phosphate.
Methods: A 64-year-old female was diagnosed with ITP. She was initially treated with high dose CS and IVIG, with a complete response (CR) that lasted for 15 years. She relapsed with severe thrombocytopenia and minor bleeding. Her platelet counts remained low despite using CS and IGIV, so she initiated recombinant human thrombopoietin (TPO) agonist reaching maximum dose without response, so we added danazol and rituximab, either with non response. During this period, she presented with lower gastrointestinal bleeding so she underwent a splenectomy. She continued with TPO agonist and Danazol to maximum doses. Three months after splenectomy she reached secure but fluctuating platelet counts, presenting a massive portal and mesenteric thrombosis. She started therapeutical LMWH with close monitoring of platelets count, and suspended TPO agonist as well as danazol. Two months later, she lost platelet response and had to iniciate different immunosuppressive drugs: Vincristine, Azathioprine, Mycophenolate Mofetil and Cyclosporin, without response. Patient's platelet was then assessed by flow cytometry and revealed a loss of terminal sialic acids in platelets surface as well as neuraminidase activity in plasma, data compatible with a platelet destruction mechanism independent of immune receptors that could justify refractoriness to prior treatments. An alternative therapeutic regimen with Oseltamivir phosphate, as a last resort for the management of this patient, was initiated. She was informed and consented. It was given orally 75mg twice daily for 5 days. Then, a new platelet assessment was done, demonstrating normalization of sialic acids expression. But thrombocytopenia persisted, so Azathioprine was added looking for a synergic effect. Nowadays, she continues treatment with Azathioprine twice a day and remains in CR for seven months
Summary/Conclusions: In this case, treatment with oseltamivir could restore platelet membrane, avoiding its destruction by the hepatic rethiculoendothelial system and allowing immunosuppressive drugs (Azathioprine) to control the immune destruction mechanism. At the present time Oseltamivir is not still approved for ITP. However, this case highlights the need for prospective studies to verify the effectiveness of this new approach and the possibility of new indications for this drug.

PB2071

MULTIPLE PHENOTYPIC EXPRESSION OF HARRIS PLATELET SYNDROME

A Das[1,*], HK Elias[2], G Guha[3], S Harris[4], HV Naina[5]
[1]Cardiology, Beth Israel Deaconess Medical Center, Boston, [2]Internal Medicine, Icahn School of Medicine at Mount Sinai St Luke's- Roosevelt Hospital, NewYork, United States, [3]School of Chemical and Bio Technology, SASTRA University, Thanjavur, India, [4]Division of Gastroenterology, UT southwestern, [5]Department of Internal Medicine, Plaza Medical center, Dallas, United States

Background: Harris platelet syndrome (HPS) is an autosomal dominant macrothrombocytopenia with mild to moderately severe thrombocytopenia and normal platelet function. HPS has been reported from healthy blood donors of the Indian subcontinent, particularly from the northeastern part of India including West Bengal.
Aims: A prospective study was done to characterize the different phenotypes of HPS among blood donors from West Bengal.
Methods: HPS is defined as healthy blood donors having a mean platelet volume (MPV) greater than 12 fL (normal <10 fL) with or without concomitant thrombocytopenia in the absence of any significant past history of bleeding disorder in either themselves or their first degree relatives. Blood samples were collected in ethylenediaminetetraacetic acid (EDTA) and analyzed using impedancemethod (Coulter SYSMEX X100, Tokyo, Japan).

Results: A total of 326 eligible blood donors were included in this study. Two hundred (61%) of the blood donors fulfilled criteria for a diagnosis of HPS. Three distinct phenotypes were observed. Fourteen (4%) was noted to have varying thrombocytopenia with normal MPV; 166 (51%) had anormal platelet count with giant platelets and 20 (6%) donors had classic HPS characterized by thrombocytopenia with giant platelets. HPS donors with low platelet count had a lower median platelet bio-mass compared with their normal counterparts, (13.62 *vs* 29.38, p<0.001).In comparing peripheral smears between controls (i.e normal platelet count and normal MPV) and the variants of HPS, no obvious difference was noted in the red blood cell morphology.

Table 1.

Blood Indices	Giant platelets with Normal Platelet Count (N=166)	Giant platelets with thrombovytopenia (N=20)	Normal MPV with thrombocytopenia (N=14)
Haemoglobin	13.74 ± 2.102	13.07 ± 2.250	12.84 ± 2.213
MCV	89.47 ± 6.720	88.45 ± 8.703	89.43 ± 6.915
Platelet Count	2.37 ± 0.609	1.02 ± 0.282	1.01 ± 0.278
MPV	13.52 ± 1.137	13.22 ± 0.879	10.61 ± 0.896
PDW	20.77 ± 3.001	20.48 ± 2.726	18.09 ± 1.889
Platelet Biomass	29.38 ± 6.761	13.62 ± 4.061	11.02 ± 3.494

Summary/Conclusions: A prospective population based study will be ideal to further explore the clinico-pathological significance of these variants of HPS.This study shows that HPS may manifest with isolated thrombocytopenia without giant platelets. It is important to reccognize this variant to avoid unnecessary investigations and treatment.

PB2072

FREQUENCY OF PLATELET FUNCTION DISORDERS IN PATIENTS PRESENTING WITH BLEEDING

A Memon*, S Adil
Department of Pathology & Laboratory Medicine, Aga Khan University Hospital, karachi, Pakistan

Background: Inherited platelet function disorders may present with bleeding of variable severity and unknown frequency and may be frequently missed. They are increasingly recognized as an important cause of bleeding, particularly in adolescent girls with menorrhagia. The prevalence of congenital platelet disorders in our population has not been established, however, these disorders are relatively more common in communities where consanguineous marriages are more frequent like in the Middle East and India, but very limited information is available in developing countries like Pakistan about their prevalence so we attempted to assess the frequency of these disorders in our population.
Aims: Considering the higher prevalence of consanguineous marriages in Pakistani population, it is assumed that the incidence of platelet disorder must be higher. Therefore, the purpose of this study is to determine the frequency of platelet function disorders in patients presenting with bleeding. Previous studies conducted in Pakistan observed all causes of bleeding disorders like Haemoglobinopathies, von willebrand disease, Hemophilia & others, but our study specifically focused on platelet function disorders because these can lead to severe bleeding and are frequently missed.
Methods: Cross sectional study done between March to October 2014 at section of Haematology Aga Khan University Hospital. 5mlof whole blood sample in sodium citrate tube was collected for detection of platelet functions disorders. Platelet rich plasma was made by centrifugation and was used for testing. Platelet function studies were performed by using aggregation platelet aggregometer (Chrono-Log aggregometer model 700). ADP, Collagen, Epinephrine and Ristocitin were used as agonists.
Results: 32 patients fulfilled inclusion criteria 18 females, 14 males with age range 3 years to 22 years. Out of these 32 patients 13 patients (40.62%) had platelet function disorder with female predominance (8 females, 5 males).Age ranges between 6 years to 22 years. Out of these 13 patients, 7 had Glanzmann's- thrombasthenia, 4 had Bernard-Soulier syndrome & 2 patients were labeled with Quebec platelet disorder.
Summary/Conclusions: 40% of these 32 patients had platelet function disorders. This is an ongoing study further data will be added on completion of specific period.

PB2073

ELTROMBOPAG USE IN SEVERE ITP AND BEYOND, A SINGLE CENTRE COHORT

A Taylor*, F Laskou, J Westwood, S McGuckin, M Scully
Haematology, University College London Hospital, London, United Kingdom

Background: Thrombopoietin receptor (TPO) agonists are licensed for immune thrombocytopenia purpura ITP). Potential for use in other thrombocytopenic conditions is being explored.
Aims: Our aim was to demonstrate the efficacy of eltrombopag in ITP -whether for severe disease or bridging therapy for surgery or chemotherapy. We also examined the use of eltrombopag in malignancy-associated thrombocytopenia, whether from disease or chemotherapy.
Methods: We retrospectively identified all patients who had received eltrombopag from a single institution. Patients were identified who had received eltrombopag as part of standard treatment pathways, as well as those for whom special consideration was sought (ie refractory thrombocytopenia in advanced malignancy). Eltrombopag was commenced from between March 2012 (as the first documented prescription time point) to January 2016. For ITP, we included those deemed to have a 'severe' phenotype according to the international consensus guidelines. All patients fulfilled these criteria, warranting second-line treatment beyond steroids and IVIg. Many had failed multiple previous lines or had comorbidities limiting options. For non-ITP thrombocytopenic patients, indication for eltrombopag was examined on a case-by-case basis, according to benefit *versus* risk, since prescription was off-label. The primary indication was to enable chemotherapy, based on oncology requirements for platelet counts >$100x10^9$/L.
Results: Our total cohort of 62 patients (36 males and 26 females) was treated over 8 years. This included 50 ITP patients requiring treatment for severe/refractory disease (n= 36), or bridging therapy (n=14). In the refractory group, 25 patients had primary ITP and 11 secondary ITP; including HIV (n=5), viral (n=2) malignancy (n=1) and other autoimmune aetiologies (n=3). Follow up was 1 to 85 months (median 12.5 months), with median 4 previous lines of therapy. Median time between ITP diagnosis and eltrombopag commencement was 24 months in the refractory ITP group. The delay was partially due to eltrombopag availability. In the overall ITP cohort (n=50), complete response (CR) was achieved in 28 patients (56%), partial response (PR) in 19 (38%) and no response (NR) in 3 patients (6%). Median time to response was 3 weeks (1 to 44 weeks). At follow up, 17 patients were in CR (34%) and 29 patients in PR (58%). Eltrombopag dose ranged from 25 to 100mg daily, with a median of 25mg (n=12). The difference in response at follow up was due to dose reduction, whilst maintaining haemostatic platelet counts. The malignancy-associated group included 12 patients. Eltrombopag use achieved CR in 6 patients (50%), PR in 3 (25%) and NR in 3 (25%).
Summary/Conclusions: In conclusion, eltrombopag use in the severe ITP setting achieved a response in 94% cases. For severe or refractory disease, dose reduction was possible once response achieved. Although not CR by strict definition, a safe platelet count could be maintained- typically >$50x10^9$/L- without bleeding sequelae. In the bridging cohort, eltrombopag proved a reliable means of improving platelet counts for intervention, without the problems associated with steroids or IVIg. Beyond ITP, eltrombopag may be of practical benefit during chemotherapy and other myelosuppressive treatment, to ensure optimal dosing of these therapies via platelet count support. Although our non-ITP cohort was small, CR was achieved in half of these patients. Further trials are needed to demonstrate which patients may benefit from eltrombopag during treatment for malignancy-associated thrombocytopenia.

PB2074

CHANGES IN PLATELET AGGREGATION DURING PREGNANCY AND THE IMMEDIATE POSTPARTUM PERIOD

B Hussein[1,*], A Maarouf[1], K Gomez[2], J Davies[2], D Obeng-Tuudah[2], A Riddell[2], R Kadir[2]
[1]Haematology, Nanakali Hospital for Blood Diseases and Cancer, Erbil, Iraq, [2]Haematology, Haemophilia Center and Thrombosis Unit, Royal Free Campus, UCL, London, United Kingdom

Background: Platelet dysfunction is implicated in uteroplacental disorders. During the early stages of gestation platelets have important roles in the process of placentation. Platelet function contributes to enhanced haemostasis at delivery. However, there is limited data on the changes of platelet function during normal pregnancy. Understanding physiological changes of platelet aggregation during different stages of pregnancy is helpful for better understanding of pathophysiology of abnormal placentation.
Aims: To assess platelet aggregation during three trimesters of pregnancy and immediate postnatal period in normal healthy women compared to control non-pregnant group.
Methods: Cross-sectional cohort study including a total of 46 women: 10 participants for each trimester, 10 postnatal cases and 6 control non-pregnant women. Case selection was based on specific inclusion criteria. 30mL of venous blood was obtained from each participant following consent. Light transmission aggregometry was performed with Dual channel Payton 600B aggregometer using six platelet aggregating agonist (epinephrine, adenosine triphosphate, collagen, ristocetin, arachidonic acid and U46619).
Results: The findings included reduced secondary aggregation curve appearance in pregnant and postnatal women when compared to control group, which was most apparent in the third trimester. Compared to non-pregnant controls, platelet aggregation induced by ADP and collagen were reduced during third trimester while epinephrine induced aggregation was reduced during the first trimester.
Summary/Conclusions: Reduced platelet reactivity in response to epinephrine during early pregnancy can be considered as a mechanism to reduce thrombosis and allow normal placentation while diminished ADP and collagen induced aggregation in third trimester could be a compensatory mechanism since pregnancy associated with hyper-coagulation particularly in late stages.

PB2075

PLATELET DISTRIBUTION WIDTH IS ELEVATED IN IMMUNE THROMBOCYTOPENIC PURPURA, BUT THE VALUES REPORTED IN XN-3000 AND ADVIA2120I WERE NOT COMPATIBLE

YK Lee*, M Kim, EJ Lee, E Lee, HJ Kang, HS Kim
Department of Laboratory Medicine, Hallym University College of Medicine & Hallym University Sacred Heart Hospital, Anyang-si, Korea, Republic Of

Background: Platelet distribution width (PDW) value as well as its unit is reported through different algorithms in different hematologic analyzers, and the correlation between PDW values in different hematologic analyzers has never been explored. Recently, PDW is indicated as a marker estimating the status of platelet production.
Aims: As the clinical significance of PDW is increasing, but not yet established, we analyzed the correlation between PDW values reported in Advia 2120i and XN-3000. We also compared the PDW values in immune thrombocytopenic purpura (ITP) and essential thrombocythemia (ET).
Methods: PDW was measured in 153 healthy individuals as a control group using both instruments. Twenty-three ITPs and 15 ITPs were tested using Advia 2120i and in XN-3000, respectively. ET group consists of 15 in Advia 2120i and 18 in XN-3000.
Results: In the control group, PDW did not correlated with platelet count, mean platelet volume (MPV), and age in Advia 2120i. In XN-3000, PDW did not correlated with platelet count or age, either, however, PDW significantly correlated with MPV ($y=2.034x-9.111$, $r^2=0.916$, $p<0.001$). PDW values reported in the two instruments did not correlate with each other ($y=0.184x+2.592$, $r^2=0.474$, $p<0.001$). The reference value was 40.0% ~ 64.2% in Advia 2120i, and 9.0 fL ~ 16.0fL in XN-3000. PDW was elevated in ITP in both instruments compared with control group (median PDW 63.1% *vs* 50.5% in Advia 2120i; 14.9 fL *vs* 11.9fL in XN-3000) with statistical significance ($p<0.001$). PDW was elevated in ET in Advia 2120i (59.1%, $p<0.0001$), but decreased in XN-3000 (10.0fL, $p<0.001$).
Summary/Conclusions: We analyzed the correlation of PDW values reported in Advia 2120i and XN-3000 for the first time, and showed that they are not compatible. PDW was affected by MPV in XN-3000, probably due to the calculation algorithm. PDW was elevated in ITP, suggesting the high proportion of large young platelets in this disease. However, the changes in PDW in ET were opposite in the two instruments, which requires further investigation.

PB2076

INTERLEUKIN 31 AS A MARKER OF ALLERGY IN IMMUNE THROMBOCYTOPENIA IN CHILDREN

AAG Tantawy[1,*], M Reda[1], D Abdel Aziz[2]
[1]Pediatric Department, [2]Clinical Pathology Department, Faculty of Medicine,Ain Shams University,Cairo,Egypt, Cairo, Egypt

Background: Allergy and autoimmunity are two potential outcomes of dysregulated immunity both are characterized by inflammatory reaction that leads to the injury of target tissues. Interleukin-31 (IL31) is a recently discovered cytokine expressed in many human tissues, predominantly by activated CD4(+) T cells and has integral role in allergy pathogenesis.
Aims: to evaluate the relation between ITP and allergy in children by questionnaire for allergic manifestations and measuring serum IL31 and serum IgE..
Methods: 62 ITP patients aged 1-18 years (median 6 years) were included, 36 had chronic ITP and 26 acute ITP, male to female ratio was 4:1, and were compared to 30 age and sex matched controls.All were subjected to: determination of allergy score by questionnaire, measuring IgE level (RAST method) and ELISA serum IL31 level assessment.
Results: Compared to controls, ITP patients had signinificantly higher allergy score ($p<0.001$), higher IL31 level ($p=0.000$), but non significant difference in serum Ig E levels.There was statistically significant higher IL31 level in allergy positive score ITP patients compared to allergy negative score patients ($p=0.000$), and statistically significant positive correlation between IL31 level and score of allergy ($r=0.646$, $p=0.000$).There was no correlation between serum IgE level and score of allergy,and no significant difference between patients and controls regarding serum IgE level. There was no significant difference between acute and chronic ITP in the score of allergy, IgE level or IL31levels, and there was no difference in these parameters between steroid responsive and steroid resistant ITP patients.
Summary/Conclusions: This preliminary study reveals that children with allergic manifestations are at higher risk to develop ITP, but this will not probably affect the clinical presentation, treatment outcome or prognosis of immune thrombocytopenia.

PB2077

SHORT AND LONG-TERM OUTCOMES OF SPLENECTOMY AND SURGICAL COMPLICATIONS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP) IN A SINGLE CENTER IN ALGERIA

H Brahimi[1,*], C Guezlane[1], Y Bouchakor-Moussa[1], R Benhizia[2], EM SI Ahmed[2], MT Abad[1]
[1]Hematology, EHS ELCC CAC, Faculty of Medecine, University of Blida 1, [2]Surgery, CHU Frantz Fanon Faculty of Medecine, University of Blida 1, Blida, Algeria

Background: Among several treatment of immune thrombocytopenic purpura, glucocorticoides are the first one resulting in a high rate of response; unfortunately most patients (pts) responding to this treatment fail to maintain durable response. Splenectomy, the second line treatment produces an important rate of durable responses, about 60-80%.
Aims: To report and evaluate the short and the long-term outcomes and surgical complications in adults and children with ITP who underwent splenectomy.
Methods: We rewieved the medical records of 142 pts who underwent splenectomy for ITP from 1987-2014. Response was defined as: complete response (CR): platelet count>100000/µl ; partial response (PR): platelet count >50000/µl, no response (NR) or failure: platelet count <50000/µl, relapse: loss of CR.142 patients were splenectomized: 44 males (31%) and 98 females (69%),Sex ratio=0,45.Median âge at diagnosis was 26,8 years (2-71); there were 101 adults and 41children .Median âge at splenectomy was 28,8 years (5-72). At the time of splenectomy, 31 pts were children (29%) and 111 were adults. 71 (50%) were splenectomized because they were corticostreroid dependency and 50% because they failed to corticosteroids. The median time from diagnosis to splenectomy was 25,1 months (2-156) The median platelet count at diagnosis was 27000/µl and the median preoperative platelet count was 60000/µl.
Results: Before splenectomy,134 pts(94,3%) received only steroids at initial treatment. 139 pts were vaccinated (pneumococcal vaccine) before splenectomy and after it. In pts with severe thrombocytopenia intravenous corticosteroids were done in 33 cases(23,2%).Laparoscopic splenectomy was performed in 54 pts and open splenectomy in 88 cases.In the post operative period, we noted wound infection in one case; 3 cases requiring open surgery because intra abdominal hemorrhage, one death resulting from neurological disorder related to adrenal insufficiency. Accessory spleen was removed in one patient. Prophylactic antibiotic therapy was systematic during the 2 first years. For 136 informative pts: the median follow up after splenectomy was 80,1 months.Good responses (CR+PR) was achieved at month 1 for 127 (89,4%) of pts: CR: 118 (83%),PR: 09 (6,3%) whereas the remaining (09) were refractory to splenectomy. After 1 year: 125 pts followed: 95 CR, 4 PR, 9 NR. After 2 years: 114 pts followed: 89 CR, 2 PR, 7 NR. Relapses are encountered in 24 (16,9%) pts with an median time of 28,6 months. 21 of these pts were treated, resulting of 12 CR, 03 PR and 06 steroids dependency (one was reoperated for an accessory spleen for relapse 4 years after the first splenectomy). Among the failures, a multiple myeloma apparead 43 months after the ITP ; In one case, the histological study revealed a non hodgkin lymphoma; the ITP has preceded an autoimmune disease in 4 cases (an autoimmune hemolytic anemia after 62 months, 2 cases of systemic lupus erythematous respectively after 42 and 100 months and 1 case of Biermer's anemia 128 months after the ITP) ; 2 cases of family ITP (one pt splenectomized and her daughter followed for ITP that preceded rheumatoid arthritis,2 sisters splenectomized have died, one in operative period by fatal h.emorrhage and the second 151 months after splenectomy after relapse as Evans syndrome.The median total follow up of the 142 patients was 103 months.
Summary/Conclusions: Our study documents that splenectomy si an effective treatment for ITP by the frequency of RC, the excellent outcomes of this procedure for patients with ITP and the mortality rate decreased. However predictive factors of success remain to be clarified.

PB2078

THROMBOPOIETIN RECEPTOR AGONIST SWITCH IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS: A RETROSPECTIVE COLLABORATIVE SURVEY FROM 4 SPANISH CENTERS

S Lakhwani[1,*], M Perera[2], F Fernández-Fuerte[3], MA Rios de Paz[4], M Torres[2], JM Raya[1], MT Hernandez[1]
[1]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, [2]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [3]Hematology, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, [4]Hematology, Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, Spain

Background: Thrombopoietin receptor agonists (TRA), romiplostim (ROM) and eltrombopag (ELT), have changed in the last years the treatment of ITP showing that there is both a increased platelet destruction and a suboptimal platelet production in ITP. Although both drugs activate the same receptor, mechanism of action is different and they don't activate the same intracellular signalling pathways. That explains why some patients respond to one and not to the other TRA and also the different side effect profile. There are few data evaualting the TRA switch in ITP.
Aims: To describe the reasons and the result of TRA switching in adult ITP patients of the four main centers of our region (Canary Islands) in Spain.
Methods: We retrospectively analized a total of 26 adult patients with ITP who were switched from ROM to ELT or *vice versa*. Clinical and biological parameters were recorded.

Results: Our series comprise 10 men and 16 women with a mean age of 55 years (range 16-84) when they received the first TRA. All the patients received steroids as the first line treatment. Before starting the first TRA, 9 patients (35%) received Rituximab, 7 patients (27%) received anti-D immunoglobulin, 5 patients (19%) received azatioprine, and only 8 patients (31%) had splenectomy performed. The mean number of previous lines before the first TRA was 2.7 (range 1-4), and 9 patients (35%) received a TRA as second line. ROM was the first TRA in 17 patients who switched to ELT with a median time of 8,8 months. In 9 patients ELT was the first TRA and median time to switch to ROM was 3,4 months. The main reasons for switching were lack of efficacy (n=10), patient's preference (n=8), side effects (n=5) and platelet-count fluctuation (n=3). The following table shows what happened in each of these situations. When switch was due to inefficacy, all the cases who received ROM first responded to ELT but only 66% of the patients who received ELT first reponded to ROM. Conspicuously the average of ROM maximum dose was only 4,5 µg/kg/week, very far from the maximum recomended dose (MRD), while the average of ELT maximum dose was 70 mg/day, very near to the MRD. All the changes due to patient preference were from ROM to ELT because of the route of administration. All the patients who switched due to side effects responded to both TRA. Three patients switched from ROM to ELT because platelet-count fluctuation with poor outcome: one did not respond and two responded to ELT but count fluctuation persisted. Six responders patients to the second TRA are now without treatment: four patients achieved a complete response with the second TRA and two patients underwent splenectomy after second TRA and they also achieved a complete response.

Table 1.

Reason for change	Group	First TRA	Second TRA response
Inefficacy 10 patients	4 ROM →ELT	ROM average dose 4,5 µg/kg/week	100% resp. ELT
	6 ELT → ROM	ELT average dose 70 mg/d	66% resp. ROM
Pat. preference 8 patients	8 ROM → ELT	100% resp. ROM	100% resp. ELT
Side effect 5 patients	2 ROM → ELT	-Headache	100% resp. ELT
	2 ELT → ROM	-Dermatitis -Diarrhea -Transaminase elev.	100% resp. ROM
Count fluctuation 3 patients	3 ROM → ELT	-33% no response ELT -66% resp. ELT with count fluctuation	

Summary/Conclusions: As previously reported, in our series we can observe that: When the patient respond to the first TRA and the switch is not due to inefficacy there is a high probability of responding to the second TRA (100% in our series). When the switch is motivated by lack of efficacy, the patient could respond to the second TRA specially if the first TRA dose is bellow the MRD.

PB2079

THROMBOPOIETIN-RECEPTOR AGONISTS (TPO-RAS) IN IMMUNE THROMBOCYTOPENIA (ITP): EXPERIENCE IN OUR CENTER

K Javier González*, S Ortiz Zuluaga, C Villegas DaRos, P Pérez Rodríguez, MT Orero Castello, M Roig Pellicer, I Luna Del Valle, M López Pavia, R Collado Nieto, D Ivars i Santacreu, A Cervero Martí
Hematology, Hospital General Universitario de Valencia, Valencia, Spain

Background: Thrombopoietin-receptor agonists (TPO-RAs), Romiplostim (ROM) and Eltrombopag (ELT) constitute an effective therapeutic option for patients with immune thrombocytopenia (ITP). However, several questions remain unclear concerning their use.
Aims: Our aim is to describe our experience with the use of TPO-RAs in ITP with particular reference to sequential treatment with both drugs, their use prior to invasive procedures and the prognostic factors for response.
Methods: We reviewed all patients with ITP who received treatment with TPO-RAs at standard doses in our department. The following variables were evaluated: age, gender, platelet count, previous treatments (including splenectomy), time of follow- up from diagnosis and response to TPO-RAs. Response was defined by the ITP International Working Group response criteria. Comparisons between categorical variables were made with χ^2 or Fisher exact test and Mann-Whitney U test was used for quantitative variables. Logistic regression was used to identify factors associated with response.
Results: Between October 2009 and December 2015, 49 patients were treated with TPO-RAs, 17 men and 32 women, with a median age of 67 years. 36 patients received treatment with ROM (32 as first line and 4 as second line TPO-RAs) and 34 with ELT (17 1st line, 17 2nd line), with a median platelet count of 19.000 (range 2000-78000) before starting treatment. The overall response with ROM was 83% (30/36) and 74% (25/34) for ELT. 10 patients were treated with TPO-RAs previous to invasive procedures, 6 with one dose of ROM and 4 with ELT for a month. 6 patients achieved response, 4 with ROM and 2 with ELT. 21 patients with ITP were treated with both ROM and ELT sequentially. Response was observed in 13 of 17 patients switched from ROM to ELT, including 2 of 3 non-responders to ROM. Three of 4 patients switched from ELT to ROM responded to treatment. Response rate for patients switched because of relapse after transient response was observed in 5 of 9 patients; in contrast, 8 patients switching because of poor tolerance or personal preference achieved response. There was no statistical difference between responders and refractory patients in terms of age, gender, platelet count before therapy, splenectomy or number of previous treatments (table 1). Patients who initially responded to corticoids had a higher response rate to TPO-RAs. In logistic regression only initial response to corticoids showed prognostic impact with a hazard ratio of 10,5 (p=0,005).

Table 1.

		Response	No Response	p
Gender	Male	14	3	p=1
	Female	26	6	
Age (median) years		66.5y (26-88y)	68y (34-76y)	p=0,638
Initial platelet count		19,500 (2000-74.000)	13,000 (4-78,000)	p=0,998
Splenectomy	Yes	12 (80%)	3 (20%)	p=1
	No	28 (82%)	6 (18%)	
Nº previous treatments	(1-2)	32 (82%)	7 (18%)	p=0,848
	(3-4)	8 (80%)	2 (20%)	
Initial response to corticosteroids	Yes	30 (75%)	10 (25%)	p=0,005

Summary/Conclusions: TPO-RAs are an effective salvage therapy for refractory ITP. Switching from one TPO-RAs to the other is an effective option. TPO-RAs could be a useful treatment option when aiming a rapid platelet count increase. Initial response to corticosteroids is the only predictive factor of response in our study.

PB2080

THROMBOCYTOPENIA AND FOLATE DEFICIENCY IN PREGNANT WOMEN

Y Ouarhlent[1,*], N Boudjerra[2], H Bounecer[3]
[1]Hematology, CHU of Batna, Batna, [2]Hematology, CHU of Benimessous, Algiers, [3]Epidemiology, CHU of Batna, Batna, Algeria

Background: Micronutrient deficiency among pregnant women is common, folate deficiency is seen in the developments ways countries in parturients having a low socioeconomic level in blood count it may be noted a thrombocytopenia.
Aims: To evaluate the thrombocytopenia observed in parturients deficient in vitamin B9.
Methods: this is a study of cases of thrombocytopenia observed in a cohort of 375 pregnant women with a B9 deficiency, followed antenatal care in the first trimester(T1), second (T2) and third (T3).
Results: the average age of pregnant women was 30.11±6.9 years. The average platelet in our sample is 223 + 89.38 10^3/ml, the average with extreme depending on the quarters is as follows: T1= 223 10^3/ml (34000-512000)/ml, T2= 226 10^3,(4500-512000) T3= 221,10^3/ml (31000-414000). The average serum folate is 7.36 + 3.19 ng/ml: T1= 7.6 (2.3 to 20.0) ng/ml, T2= 7.07 (2.2 to 14.2) ng/ml and T3=7.3 (2.0 to 18.0) ng/ml. The average red cell folate is 201 + 61.74 103ng/ml; T1=206,9 (65.0 to 397.0), T2=195,5(65-321) and T3= 202.6 (66-417). The correlation between red cell folate: and platelets is r=0.284 ** p=2,06.10-8 Regression thrombocytopenia was noted during treatment (B9 orally) during the first month in all cases.
Summary/Conclusions: This study shows that it is necessary to know this association because thrombocytopenia associated with deficiencies of vitamin B9 in pregnant women are frequent and rapid response to treatment of deficiency of vitamin B9.

PB2081

SAFE BUT FLUCTUATING RESPONSE TO TREATMENT WITH TPO MIMETICS IN PREGNANT PATIENT WITH REFRACTORY ITP

E Omenetto*, A Bertomoro, ML Randi, I Bertozzi, E Duner, V Rancitelli, F Fabris
Department of Medicine - DIMED, University of Padua, Padova, Italy

Background: Maternal platelet count less than 20x10^9/L has been associated with risk of spontaneous bleeding, postpartum haemorrhage, and placental abruption. 5% of newborns will be born with platelets less than 20x10^9/L and less than 1% will have bleeding complications. Primary treatment options for maternal ITP are similar to those of non pregnant adult patients: corticosteroids and IV-Ig are the first-line treatments.
Aims: Describe a case of use of TPO-mimetic during pregnancy in refractory ITP.
Methods: We report a case of a 25 years old Moldovan woman with refractory chronic primary immune thrombocytopenia (ITP), diagnosed on 2002. On 2006 the patient underwent splenectomy with a partial response and low dose of prednisone (2.5 mg/die) obtaining a stable remission (platelets 150 x10^9/L). During the follow-up the patient underwent abdominal CT scan, which was negative for an accessory spleen. In November 2013, the ITP recurred with petechiae and platelets were 6 x10^9/L; platelet associated autoantibodies against GpIIb/IIIa (HPA 1a/3a) and GpIb (HPA 5b/5a) were positives. Since the patient was refractory to full doses of prednisone (1 mg/kg) and IV-Ig (1g/kg for 2 days), she was treated with increasing doses of romiplostim, (NPLATE®) (1 mcg/kg up to 3,5mcg/kg) once a week for 26 weeks. The response to TPO-mimetic was fluctuating with both severe thrombocytosis and symptomatic thrombocy-

topenia needing platelet transfusions. The patient was then treated on April 2014 with Rituximab (375mg/m x 4 doses) with complete response.
Results: The ITP remission continued until April 2015, when at 21st week of gestation, relapsed (Figure 1). She was treated again with prednisone and two IV-Ig courses with transitory response. After an unsuccessful course with dexamethasone (40mg/kg) we obtained the patient informed consent for the use of romiplostim (1mcg/kg up to 10 mcg/kg) once a week for 3 weeks before delivery, without response. The elective caesarean delivery was performed on 26 week of pregnancy with the infusion of platelet concentrates due to a severe thrombocytopenia (platelets 3x10^9/L. Major bleeding complications did not occur, and baby's platelets were normal. After delivery, romiplostin was administered for other 10 weeks with fluctuating positive response (Figure 1). Because of the discontinuous response to romiplostim, we shifted to oral eltrombopag (Revolade® 50 mg/day) waiting for a new course with rituximab. Due to a severe thrombocytosis (platelet 1985x10^9/L) the TPO mimetic has been withdrawal after only one week. The response to rituximab was complete and stable, steroid was gradually tapered until suspension and the ITP remitted without any therapy so far.

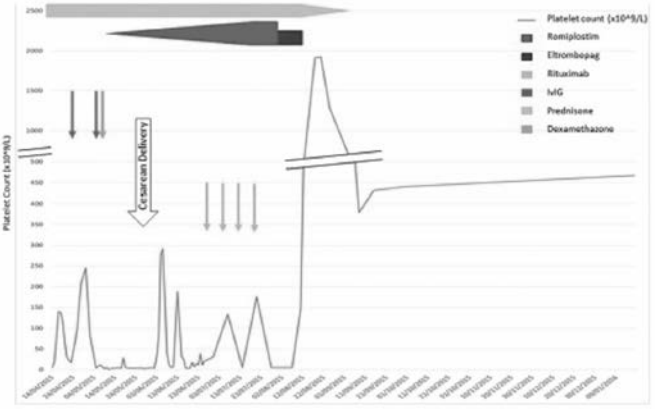

Figure 1.

Summary/Conclusions: There are few case report on ITP treated with romiplostim during pregnancy, and no one showing fetal complications. Although TPO mimetics have not been indicated in pregnant ITP, it may represent an important alternative treatment choice for refractory cases because its speed of activity and an high rate of success. In our patient, we obtained a positive response to romiplostim during the first recurrence of ITP and after delivery but both responses were discontinuous without finding the lowest effective dose. Therefore we tried a switch to eltrombopag after delivery, but the response to the standard initial dose was characterized by an extreme thrombocytosis. We can speculate that TPO mimetic are safe during pregnancy in ITP but they may require more customized dosages mostly after delivery. Instead, using rituximab we obtained a complete and longstanding response showing the effectiveness of the combination of drugs that act by different but complementary mechanisms.

PB2082

HIGH-DOSE DEXAMETHASONE IN TREATMENT OF CHILDREN WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA
M Sarhan*, A Elsharkawy, E Ahmed, B Elshibiny
Pediatrics, Faculty of Medicine - Mansoura University, Mansoura, Egypt

Background: Chronic idiopathic thrombocytopenic purpura (ITP) is a big dilemma in hematology. About one fifth of cases diagnosed as acute ITP takes a chronic course which known as thrombocytopenia that persists after twelve months after onset. Cellular immunity plays a central role in thrombocytopenia. Alterations in T cell subsets and decreased numbers and activity of regulatory T cells are common. Cytotoxic T cells may also mediate toxicity against platelets and megakaryocytes. Treatment strategy includes first line therapy as corticosteroids, IVIG, anti-Rh (D), and second line therapy as high dose dexamethasone, anti-CD20 (rituximab), thrombopoietin receptors agonist and splenectomy.
Aims: to evaluate the therapeutic response of a high dose dexamethasone in a series of Egyptian children with chronic ITP.
Methods: The study included 27 children with chronic ITP comprising 12 males (44.4%) and 15 females (55.6%). One child was withdrawn from the study due to acquired diabetes and hypertension with 26 patients completing the treatment course. Dexamethasone should be administrated by intravenous infusion in a dose of 40 mg/m^2/day on two divided doses for four consecutive days and repeated every 4 weeks for 6 cycles. DXA scan should be done as a baseline and after finishing therapy to evaluate bone mineral density of the patients. Repeated CBC, blood pressure, and blood glucose levels were evaluated through infusion days.
Results: Complete remission (CR) was achieved in 3 patients (11.1%) after the 1st dose, in 5 patients (18.5%) after the 2nd dose, in 5 patients (18.5%) after the 3rd dose, in 6 patients (22.2%) after the 4th dose, in 7 patients (26.9%) after the 5th dose and in 7 patients (26.9%) in the 6th dose. Assessment of the overall response after 1 months of course completion revealed that CR was achieved in 7 patients (26.9%) while remission (R) was achieved in 8 patients (30.8%) and 11 patients (42.3%) had no response. In the current study, on binary logistic regression, older age was the only significant predictor of treatment response.
Summary/Conclusions: High dose dexamethasone can be proposed as a first-line treatment for children with chronic ITP with tolerable side effects. Repeated cycles of therapy seem to be more efficient than only one cycle. Statistical significance of remission in older children, age can be considered as a predictor of treatment response.

PB2083

GAUCHER DISEASE WITH IMMUNE THROMBOCYTOPENIA (ITP): A CASE REPORT AND TREATMENT WITH ELTROMBOPAG
LM Borin*, L Verga, F Farina, A Aroldi, PE Pioltelli
Hematology Division, San Gerardo Hospital, Monza, Italy

Background: Gaucher disease (GD) is a rare multi-systemic metabolic disorder due to the accumulation of glucocerebroside in macrophages. The non-neuronopathic type is characterized by enlargment of liver and/or spleen, skeletal abnormalities, pancytopenia. Thrombocytopenia is usually related to hypersplenism and infiltration of bone marrow by lipid-laden macrophages namely Gaucher cells. Enzyme replacement therapy (ERT) restores the hemoglobin and platelet count in GD patients.
Aims: In GD ERT treated patients, immune thrombocytopenia (ITP) should be considered if persistent low platelet counts is found. Traditional treatmant regiments with steroid and splenectomy should be used with caution. Splenectomy may worsen bone lesions and steroids may induce osteopenia and joints avascular necrosis. Thrombopoietin receptor analogues (romiplostim and eltrombopag) are therapeutic option in ITP patients. The use of romiplostim is reported in 2 cases of GD patients. We report the beneficial use of eltrombopag in one patient who suffered from GD.
Methods: 18 YO female patient was diagnosed with Gaucher disease at age 14 (N307S/D399U) and she received imiglucerase. At age 21 she developed purpura and ecchymosis. The platelet count was 0/microL. Bone marrow biopsy (BM) showed a normal erytropoiesis and myelopoiesis and a large number of megakaryocytes. Autoantibodies were negative. A concomitant diagnosis of immune thrombocytopenia was achieved. 1 mg/Kg/die Prednisone and immunoglobulin were given without any response on platelet counts. Splenectomy was not considered due to known bone complication risk in splenectomised GD patients. The patient developed also a severe anemia due to metrorrhagia. Rituximab was given without any results on platelet count. Eltrombopag (dose 50 mg) was initiated raising platelet count from 3,000/μL to 25,000/μL. The dose was increased to 75 mg raising patelet count of 60,000/μL after 5 we3eks. Same dose Romiplostim is maintained for the last 6 months with platelet counts between 40,000 and 80,000/μL without any bleeding events. Repeated BMB showed slight increase of fibrosis and marked hyperplasia of atypical megakaryocytes.
Results: Thrombocytopenia is often present in GD and may be severe in approximately 15% of the patients. Persistent cytopenias may be caused by other underlying pathologies such as autoimmune disorders and it's important to recognize other causes. Before ERT era GD patients with hypersplenism and severe cytopenia were splenectomised. Risks of splenectomy include serious bacterial infection and vascular complications limiting its use in chronic refractory ITP. Splenectomy is avoided in Gaucher patients, because of risk of increasing of skeletal complications (bone infarcts, avascular necrosis). Stable bone marrow results regarding fibrosis in our patients are consistent with data from a recent 2-year follow-up of 100 ITP patients receiving Romiplostim treatment with no evidence of BM fibrosis.
Summary/Conclusions: For patients with type I Gaucher disease and concomitant ITP, adjunctive treatment with Eltrombopag was successful in maintaining haemostatic platelet counts without adverse effects. Traditional treatment based on corticosteroids and splenectomy should be used with caution or avoided in GD patients due to possible risk of Gaucher skeletal disease, osteopenia and avascular necrosis, usually determining increased morbidity in this cohort of patients. Use of TPO-RA should be considered in GD patients with ITP.

PB2084

IDIOPATHIC THROMBOCYTOPENIC PURPURA: DESCRIPTIVE AND RETROSPECTIVE STUDY OF 151 PATIENTS
R haifa*, A Bechir, B emna, BS nesrine, BY yosra, K abdrrahim
Hematology, Farhat Hached Hospital, Sousse, Tunisia

Background: Idiopathic thrombocytopenic purpura (ITP) is an autoimmune disease characterized by a variable intensity of thrombocytopenia related to the

presence of anti-platelet antibody originally of a destruction of platelets by the spleen macrophages associated with production Medullar quantitatively or qualitativement inadequate. The ITP treatment todate remains poorly standardized.
Aims: We report the results of a clinical study, biology and therapeutic study realized from 151 patients.
Methods: This is a retrospective and monocentric study of 151 patients with ITP (a platelet count <100 10 3/mm 3) collected in the department of hematology hospital Farhat Hached Sousse over a period of 10 years (2004-2014).
Results: The data of 151 patients were included in our study. The average age was 40 years (15-85 years). The sex ratio was to 0.42 (m/f). The average rate of platelets at diagnosis was 20 000 G/L (0-50000). Thrombocytopenia was discovered incidentally in blood cell in 21.2% of cases. In addition 78.8% of patients experienced a hemorrhagic syndrome of varying intensity but not binding prognosis in any case. Eight percent of these patients received platelet concentrate transfusions because of active bleeding. A functional anemic syndrome was present in 17.8% of patients. Regarding treatment, corticosteroid was prescribed first line in 92.1% of cases and only 7.9% of patients received immunoglobulin. The response rate was 83.4% with an complete responce estimated at 62.9%. A relapse occurred in 29.8% of patients and ITP evolves to chronicity in 47% of cases. Only 3 patients (2%) were splenectomized with a normalization of the number of platelets in a patient. 23 patients (15.2%) received treatment with rituximab, the response rate was 39%. After a mean follow-up 38 months, only one death was occurred and it wasn't related to PTI.
Summary/Conclusions: ITP is a rare disease that affects a middle aged population. It evaluate to a chronic mode, the prognosis is good and only a minority patient progresses to a severe form of the disease. Indeed, the rate of relapse or non-response is important and imposed using several therapeutic lines. Place of new treatments receptor agonists such as thrombopoietin (TPO) or new anti lymphocyte B therapies remain to be defined.

PB2085

SUSTAINED RESPONSES FOLLOWING STOPPED TREATMENT WITH ROMIPLOSTIM IN IMMUNE THROMBOCYTOPENIA: A SINGLE-CENTRE EXPERIENCE

L Torres Miñana*, MDM Perera Alvarez, M Torres Ochando, H Luzardo, T Molero Labarta
Hematology, H. Dr Negrin GC, Las Palmas de GC, Spain

Background: Thrombopoietin-receptor agonists (Tpo-RAs) are highly effective in immune thrombocytopenia (ITP). In the last years, cases of durable remission after Tpo-RA discontinuation in adults' ITP have been reported. This observation raises the possibility that these agents may restore immune tolerance to Tpo-RAs in some patients and supports the practice of down titrating the dose. In this moment, there are no studies that show association with the remission and the variables studied.
Aims: Our objective is to remark the results about the remission and the discontinuation to thrombopoietin-receptor agonists in our population.
Methods: We analyzed 28 patients in treatment with romiplostin from Dr. Negrin Hospital from 2009 to nowadays. Five of them were Primary ITP and 3 had a Secondary ITP (SLE, Crohn's Disease, and hypothyroidism). The average of previously received treatments before the use of romiplostin was either 1 or 2. 8 out of 28 patients, maintained the platelet response in spite of having discontinued therapy with Romiplostim. The discontinued therapy was performed in different ways: 1 patient's drug was decreased weekly to 1 µg/kg and then stopped. In another patient we maintained the dose but increased the interval between treatments to every 3 weeks until off treatment, and as to the remaining 6 patients, the minimal dose was performed every 2-3 weeks until suspension. All of them have maintained the platelet count without therapy.
Results: The median dose of romiplostim was 2 µg/kg weekly (range 1–10 µg/kg). The median duration of romiplostim treatment was 21 months (range 8-46 months). 8 patients (28%) responded (platelet count >100x109 /L without concomitant ITP therapy). In seven patients (26.3%) remission was sustained for longer than 6 months after discontinuing romiplostim therapy. Characteristics of these patients are outlined in Table 2.

Table 1.

N°	Median dose	Max dose	Platelets in the end of treatment	Median duration of treatment
1	1,5mcg/kg	2mcg/kg	146000/ul	12
2	1,5mcg/kg	4mcg/kg	366000/ul	1º: 24 2º: 15
3	<1mcg/kg	1mcg/kg	279000/UL	8
4	3mcg/kg	4mcg/kg	215000/ul	11
5	1mcg/kg	3mcg/kg	284000/ul	46
6	1 mcg/kg	1.5mcg/kg	176000/ul	30
7	1mcg/kg	4mcg/kg	269000/ul	34
8	6mcg/kg	6,5mcg/kg	220000/ul	9

Summary/Conclusions: There is more than one possible mechanism which might explain the lasting responses seen in our patients. For example, natural remission or a change in immune regulation through an impact on T regulatory cells with restoration of immune tolerance. In our retrospective study, and in the other reported studies, we found no relationship between the different variables (age and number of previous lines) or the response pattern (early or late) and the possibility of discontinuance. In addition, we observed that the use of demand doses does not predict the loss of long-term response. The thrombopoietin receptor agonists could be used for short term treatment to cover invasive procedures and to treat patients who are at risk of bleeding and are refractory to other therapies but prospective studies should be set up to confirm the observation of sustained response off therapy and to identify potential predictive factors of response.

PB2086

NEONATAL OUTCOMES OF PREGNANCY WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

A Bay[1,*], A Melekoglu[1], E Aktekin[1], M Yılmaz[2], E Sivasli[1]
[1]Pediatric Hematology, [2]Internal medicine, Gaziantep University, Gaziantep, Turkey

Background: Neonates born to mothers with idiopathic thrombocytopenic purpura (ITP) have an increased risk for neonatal thrombocytopenia and hemorrhagic complications.
Aims: The aim of this study was to determine the maternal and neonatal outcomes of pregnancies with ITP and also to identify risk factors that predicts neonatal thrombocytopenia
Methods: We performed a retrospective analysis of 40 pregnancies with ITP and their 40 neonates.
Results: Among the 40 neonates, thrombocytopenia (platelet count of less than 150×10^9/L) was detected in 15 neonates (37,5%) whom 8 of them had severe thrombocytopenia (platelet count of less than 50×10^9/L). Ten of the 15 neonates with thrombocytopenia required treatment to increase the platelet counts. There was statistically significant association between neonatal thrombocytopenia and maternal splenectomy history and maternal duration of thrombocytopenia. There was no statistically significant correlation between maternal platelet count and neonatal platelet count.
Summary/Conclusions: Clinicians should pay special attention in these neonates because of risk for development of neonatal thrombocytopenia. Maternal and neonatal outcomes in patients with idiopathic thrombocytopenic purpura is generally good.

PB2087

SAFETY AND EFFICACY OF RITUXIMAB IN ADULT IMMUNE THROMBOCYTOPENIA

C Biagiotti*, V Carrai, F Bacchiarri, M Di Gioia, G Raugei, A Bosi
Hematology, Careggi Hospital, Florence, Italy

Background: Immune thrombocytopenia is characterized by immune-mediated destruction and suboptimum production of platelets. Despite the absence of supporting evidence, the anti-CD20 chimeric monoclonal antibody rituximab has been effectively used off-label in the treatment of patients with primary immune thrombocytopenia (pITP).
Aims: The aim of this analysis is to describe our experience with Rituximab in patients affected by chronic ITP.
Methods: In this monocentric analysis we retrospectively evaluated 43 adult patients affected by chronic ITP resistant to 2 or more lines of therapy that were treated with four weekly infusions of 375 mg/mq rituximab to asses safety and efficacy.
Results: Of 43 patients treated with Rituximab, 39 were retrospectively evaluated. 20 F, 19 M. Median age was 60 years (range 29-91 years) and median platelets value at start treatment was 16.000/µl (range 5.000-40.000). 24/39 (62%) showed an initial response, 17/39 (44%) patients obtained complete response (CR) and 7/39 (18%) showed partial response (R). Of those achieving an overall response 4 (17%) patients relapsed, median time to relapse was 30 months (range 8-45). Of these 4 patients relapsed, 3 received re-treatment with four weekly infusions of 375 mg/mq rituximab and 2 patients achieved a complete response, one was no-responder. With a median follow-up of 22 months (range 2-95 months), 17/24 patients (71%) showed a lasting response out of treatment, of these 15 patients maintained a complete response with a median platelets count of 156.000/µl (100.000-362.000/µl) and 2 patients was in partial response. 7 patients underwent further line of therapy (6 treated with TPO-mimetics and 1 with splenectomy) During the follow-up, no opportunistic or severe infectious complications were observed.
Summary/Conclusions: In our limited experience these data confirm, over a long period of observation, the efficacy and safety of Rituximab treatment in the management of patients with resistant ITP and Rituximab used off-label may remain a valid option for treating persistent or chronic ITP in adults. Further investigations and specific clinical trials are warrented.

PB2088

EFFICACY OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

F Bacchiarri*, V Carrai, C Biagiotti, G Raugei, M Di Gioia, A Bosi

Hematology, AOU Careggi, Firenze, Italy

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibodies are produced to circulating platelets. The isolation of TPO and better understanding of its role in thrombopoiesis has led to the development of new highly effective tTPO analogs had some successes in treating highly refractory ITP patients but were taken out of development due to TPO-antibody induction.
Aims: The aim of this study is to describe our experience with thrombopoietin receptor agonists (TPO-RA).
Methods: From November 2008 and April 2015 54 patients (29 M; 25 F) were treated with TPO-mimetics: 38 underwent therapy with Romiplostim and 16 to Eltrombopag. Median age was 71 years (range 39-94 years). 8/54 (14%) patients received both of therapies: 5 (4 F; 1 M) switched from Romiplostim to Eltrombopag and 3 (3 M) switched from Eltrombopag to Romiplostim.
Results: In the group of patients treated with Romiplostim, 16/38 had already received more than 4 lines of therapy, while 10 were at the 3rd line of therapy, and 5 were at 2nd line. Only 2/16 patients who received Eltrombopag were at the 2nd line of therapy, and the others were at least at the 3rd line. The median platelet count was 17.000/µl at the start of Romiplostim and 10.000/µl in patients treated with Eltrombopag. With median follow-up of 36 months (4-74), we observed 33 responses (86%) with Romiplostim (19 complete response, 14 partial response) and 5 no responders; we had also 3 loss of response. In our study 18 (33%) patients stopped Romiplostim after a median time of 23 months (1-56): 6 for stable response; 2 for adverse events; 3 for loss of response; 2 underwent splenectomy; 5 for no response. The median platelet count at suspension of Romiplostim was 94.000/µl (2.000-739.000); the patients discontinued Romiplostim after a median time of 26,6 months. Now 7 patients are out of treatment with a stable platelet count (median time after discontinuation: 25 months). In patients treated with Eltrombopag 13 (81%) achieved a response (9 complete response, 4 partial response), 3 were no responders. 11 (69%) patients stopped Eltrombopag after a median time of 10 months (1-16): 5 for adverse events; 3 for no response; 2 for stable response; 1 for splenectomy. The median platelet count at suspension was 74.000/µl (2.000-739.000); the patients discontinued Eltrombopag after a median time of 11,1 months and now are out of treatment from 3 months.
Summary/Conclusions: Several studies reported Romiplostim and Eltrombopag to be highly effective against chronic ITP, with average immediate responses exceeding 80% in our study. TPO-mimetics have proved efficacy in patients with ITP and their use can be applied in several conditions: bridge to splenectomy, sustained response, switch and discontinuation.

PB2089

NOVEL PERSPECTIVES IN PATIENTS WITH REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIA FOLLOWING ELTROMBOPAG TREATMENT

M Kaliou*, E Gavriilaki, Z Bousiou, S Papadimitriou, G Papaioanou, K Tsirou, A Syrigou, M Iskas, A Anagnostopoulos
Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Primary immune thrombocytopenia (ITP) is characterized by an antibody-mediated accelerated destruction and inadequate production of platelets. Therapeutic strategies in ITP aim not only to increase and maintain platelet counts in safe levels without bleeding episodes but also to improve quality of life in this chronically ill patient population. Eltrombopag is the first oral thrombopoietin agonist approved for patients with ITP refractory to at least one line of treatment.
Aims: The present study aims to evaluate the safety and efficacy of etrombopag in clinical practice.
Methods: Eltrombopag was administered in 13 patients, 5 male: 8 female with a median age of 46 years (range 19-48) for a median 6.4 months (0.5-32.4). Patients had received 1 to 7 lines of treatment (median=1), including corticosteroids (13 patients), immunoglobulins (4 patients), rituximab (1 patient), vincristine (1 patient), cyclosporine (1 patient), romiplostim (1 patient), danazol (1 patient) and splenectomy (1 patient). In accordance with previous clinical trials, complete response to treatment was defined as a platelet count of ≥100x10^9/L.
Results: At initiation of eltrombopag treatment, the majority of patients (7/13) showed thrombocytopenia (WHO grade 4, <25x10^9/L). Initial dose was 50 mg, increased to 75 mg daily in 3 patients for optimal treatment. In 10/13 patients eltrombopag was administered in combination with corticosteroids that were gradually tapered by the fifth week of eltrombopag administration. Median platelet value by the second week of administration was 125x10^9/L (5-450x10^9/L); whereas, by the fourth week platelets increased to 185x10^9/L (16-500x10^9/L). At the end of follow-up, median platelet count was 132x10^9/L (60-400x10^9/L). All patients achieved complete response to treatment (platelet count≥100x10^9/L), except for one patient with a platelet count of 60x10^9/L at the end of follow-up. Regarding adverse events, one patient developed grade 2 hepatobiliary abnormalities and one patient grade 1 hemolytic anemia. Both adverse events resolved when the drug was temporarily discontinued. Only one patient switched to another treatment due to pulmonary embolism during the first month of treatment.
Summary/Conclusions: In the daily clinical practice eltrombopag is safe, well tolerated and highly effective in maintaining a safe platelet count when administered in ITP patients refractory to at least one line of treatment. Eltrombopag role in other subgroups of ITP patients remains to be investigated. In addition, larger studies with longer follow-up are needed to determine the incidence, predisposing factors and prophylactic measures to prevent severe adverse events.

PB2090

HIGH-DOSE DEXAMETHASONE AND ELTROMBOPAG IN CHRONIC IMMUNE THROMBOCYTOPENIA: A SINGLE INSTITUTION EXPERIENCE

D Magro[1], L Levato[1], E Piro[1], MG Kropp[1], S Molica[2,*]
[1]Hematology and Oncology Az. Osp. Pugliese Ciaccio Catanzaro, SOC Hematology, [2]Hematology and Oncology Az. Osp. Pugliese Ciaccio Catanzaro, SOC Hematology and Oncology, Catanzaro, Italy

Background: Eltrombopag is a thrombopoietin (TPO) nonpeptide mimetic that has been shown to raise the platelet count in both continued long-term administration and in a repeated short-term administration in chronic immune thrombocytopenia (ITP). However, information dealing with the concomitant use of eltrombopag and dexamethasone in patients with chronic ITP are lacking.
Aims: The purpose of this study was to assess the efficacy of eltrombopag in combination with dexamethasone in a consecutive, unselected series of patients with chronic ITP followed up in a single institution in the period May 2014- December 2015.
Methods: Eleven patients (6 F/ 5 M) with median age 53 years (range, 29-70) who had at least a 6-month history of ITP (median 26 months; range 6-220 months) were considered eligible for the present analysis. All patients had a platelet count lower than 30x10^9/Land bleeding manifestations were present in 7 out of 11. No patient had an active infection, drug-associated thrombocytopenia, positive serology for HIV, hepatitis B or hepatitis C, malignant diseases or was pregnant. After initiating eltrombopag (50 mg once a day)doses were adjusted to achieve and maintain a platelet count ≥50,000/µl as necessary to reduce the risk for bleeding. Eltrombopag dose did not exceed 75 mg/day. Dexamethasone 40 mg/day was given for 4 days every 28 days. Patients with glucose intolerance or diabetes needing therapy received an mitigated dose of dexamethasone (20 mg/day). Response and complete response (CR) were defined as an increase in platelets ≥30 <100x10^9/L and ≥100x10^9/L, respectively.
Results: All patients achieved a responseduring the treatment while a CR was obtained in 10 of 11 patients. Maximum response was reached after a median time of 12 weeks (range, 3-39). After a median follow-up time of 29 weeks (range, 8-89) response was still maintained in all patients while 5 patients lost CR. Four patients who lost CR were receiving maintainence therapy with eltrombopag (25 mg/day from a period ranging between 2 and 14 weeks). In the fifth patient CR was lost 7 weeks after treatment was interrupted because of pregnancy. Finally, the median probability of maintaining CR-free survival was 42 weeks.
Summary/Conclusions: Results of this study although limited by the small sample sizeand the lack of a comparative randomized design suggest that dexamethasone in combination with a thrombopoiesis stimulating agent led to a long-lasting remission of ITP. High-dose dexamethasone may modify the immunological milieu, resulting in an enhanced response to the thrombopoietin receptor agonist.

PB2091

THROMBOPOIETIN RECEPTOR AGONISTS IN THE TREATMENT OF PRIMARY ITP: EXPERIENCE OF APPLICATION IN CLINICAL PRACTICE ONE MEDICAL CENTER

I Zotova*, S Gritsaev, E Shilova, K Abdulkadyrov, A Chechetkin
Hematology, Russian Research Institute of Hematology, Saint-Petersburg, Russian Federation

Background: Therapy of thrombopoietin receptor agonists(aTPO-r) is a new approach to the treatment of patients with resistant primary ITP.Data on the effectiveness and safety of aTPO-r outside of controlled clinical trials is limited.
Aims: To study the efficacy and safety of prolonged use of aTPO-r in routine clinical practice in patients with chronic ITP in case of loss or inadequate response to at least one line of therapy. To evaluate the possibility of achieving a sustained response after the cessation of the aTPO-r therapy.
Methods: A retrospective analysis of aTPO-r threatment results in chronic ITP patients in the outpatient department in the period from 2010 to 2015.Romiplostim therapy received 45 patients(group 1) and eltrombopag therapy-15 patients(group 2).Efficacy was evaluated by levels of platelet response and the percentage of patients who managed to cancel or reduce the dose of drugs for concomitant ITP therapy.The main indicators of safety were incidence of adverse events,including thrombotic complications,bleeding and abnormalities in laboratory parameters.
Results: Twenty-one patients (47%) from 1 group and four (28%) from group 2 received two or more lines ITP therapy, nine of them underwent splenectomy.

Platelet response was achieved in 88% patients treated with romiplostim and in 93% eltrombopag. During aTPO-r therapy the majority of patients (92% from group 1 and 100% group 2) were able to completely cancel the previous long-term steroid therapy. Resistant to aTPO-r therapy were 8 patients-5(11%) from romiplostim group and 1(7%) eltrombopag group),three of them were splenectomised in future. The most frequent adverse events in romiplostim group were headache,arthralgia and dermatitis. This events were minimal and not require change in therapy.In eltrombopag group noted shot-term hepatotoxicity with the need for correction or therapy(dose reduction or treatment interruption)without additional hepatotropic therapy. Cancel aTpo-r therapy was required in connection with the development of thrombotic complications: 4% patients romiplostim group and 6% eltrombopag. Five patients (4 from the romiplostim group and 1 from eltrombopag) maintained a stable remission after discontinuation of aTPO-r therapy without any treatment.
Summary/Conclusions: Presented results confirm high efficiency,favorable safety profile aTPO-r,importance of this drugs in the modern ITP therapy algorithms,which was reflected in the inclusion of aTPO-r in national treatment standarts of ITP therapy.

PB2092

ELTROMBOPAG FOR CHRONIC IMMUNE THROMBOCYTOPENIA: A SINGLE CENTER EXPERIENCE

E Arshanskaya[1,2], S Semochkin[3,*], V Ivanova[1], V Ptushkin[1,2,3]
[1]Hematology, City Clinical Hospital n.a. S.P. Botkin, [2]Adolescent and Young Hematology, Federal Research Clinical Center for Pediatric n.a. D.Rogachev, [3]Oncology, Hematology and Radiotherapy, Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder that leads to peripheral destruction, as well as a decreased production of platelets. The incidence of ITP in adults is around 3-4 per 100000 people per year. The probability of spontaneous remission in adults is low. Up to 90% of cases become chronic, and 10% do not respond to standard therapy. Eltrombopag is a non-peptide thrombopoietin receptor agonist that has been approved for second-line treatment of ITP.
Aims: The primary aims of the study were to determine the efficacy and safety of long-term eltrombopag treatment in their own clinical practice.
Methods: Fifty adult chronic ITP patients who were refractory to previous ITP treatments (platelet count <30,000 cells/μL) were enrolled in the study in the period from October 2012 to December 2015. Treatment was started in all patients with 50 mg/d oral eltrombopag. Response was assessed at 1, 2, 3 and 12 months. The target platelet response was defined as an increase in the platelet count ≥50,000 cells/μL. The analysis is performed at the time of Februare 2016.
Results: The median age was 57.4 years (range, 18.2-87.1 years), and 35 patients were women. The median number of prior ITP treatments was 2 (range, 0-4), including 9 (18%) patients who had undergone a splenectomy and 14 (28%) - rituximab. The median ITP duration before eltrombopag treatment was 3.1 (range, 0.6-37.9) years. The median platelet count at baseline was 12,000 (range, 1,000-27,000) cells/μL. After 1 month 25 (50%) achieved the target platelet count (>50,000 cells/μL). The median platelet count reached 50,000 (range, 9,000-334,000) cells/μL. After 3 month 35 (70%) achieved the target platelet count with median platelet count is 84,000 (range, 9,000-334,000) cells/μL. After 12 month 37 (74%) achieved the target platelet count with median platelet count is 107,000 (range, 22,000-330,000) cells/μL. The current median duration of eltrombopag treatment was 14.8 (range, 1.1-40.3) months. 43 (86%) patients continued therapy, and 7 (14%) patients who have not achieved a response were excluded from the study for 2-3 months. On the likelihood of achieving a platelet response at 3 months do not affect gender, age, previous therapy (rituximab, splenectomy) and an initial platelet counts of less than or more 15,000 cells/μL (p>0.05). Twelve patients had bleeding episodes of mild to moderate severity. Thromboembolic events were not reported. Eltrombopag is a well-tolerated treatment. Most reported adverse effects have been mild-moderate and have not led to cessation of treatment.
Summary/Conclusions: Eltrombopag is well tolerated and effectively achieves target platelet counts in refractory adult chronic ITP patients.

PB2093

MANAGEMENT OF CHRONIC IMMUNE THROMBOCYTOPENIA, SINGLE CENTRE EXPERIENCE

C Ionita[1], I Ionita[2], L Cheveresan[2], D Calamar[2], M Ionita[3], D Oros[2], H Ionita[2,*]
[1]Surgery, [2]Hematology, [3]Internal Medicine, University of Medicine and Farmacy Victor Babes Timisoara, Timisoara, Romania

Background: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely.
Aims: To evaluate the treatment of ITP patients in Departament of Hematology, County Hospital, Timisoara during 10 years (I.2000-XII.2014).
Methods: A retrospective study for 325 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient's medical charts for the 12 months prior to their most recent visit.
Results: The average age was 43.2 years, with 57% women and 43% men. Median time from the diagnosis of ITP to the start of the observational period was 20 months. Prior to the observational period, 34% of patients have been splenectomized and the most used treatment was corticosteroids. During the observational period, 76% of the patients were treated. The most frequent reasons given for treatment was low platelet count (67%), followed by bleeding symptoms (53%). Corticosteroids represented 64% of treatments, followed by IVIg (20%), azathioprine (8%), rituximab (8%). Only a few patients (six) were treated with Nplate (Romiplostim). Splenectomies (15% of patients) and platelet transfusions (32% of patients) were performed during the observational period. For monitoring the platelet levels, 78% of patients visited their hematologist 1 to 10 times during the observation. Main reasons for a visit were low platelet count (46% of visits) and bleeding (37% of visits). Overall, 39% of patients required hospitalization. Mean duration of hospitalization was10,5 days.
Summary/Conclusions: The retrospective study of 325 patients provides therapeutic outcomes resulting from treatment methods from our department. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP, but lifethreatening bleeding rarely occur. Corticosteroids and splenectomy represent the most used treatments from our department.

PREGNANCY IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: OUTCOMES DEPENDING ON THE THERAPEUTIC APPROACH

M Vinogradova[1,*], E Mykhailova[2], T Kirsanova[1], Z Fidarova[2], R Shmakov[3]
[1]Hematology, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, [2]Hematology, Federal Scientific Center for Hematology, [3]Obstetrics, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: The management of paroxysmal nocturnal hemoglobinuria (PNH) during pregnancy recently has been challenging because of a high risk of severe maternal and fetal complications. Now pregnancy planning and eculizumab treatment changed the prognosis and made it possible to minimize complications associated with pregnancy in PNH.
Aims: To analyze the pregnancy outcomes in PNH depending on the therapeutic approach- using eculizumab or symptomatic treatment only. Establishment of effective and safe algorithms for the management of pregnancy, delivery and postpartum period in PNH patients is crucial to their quality of life.
Methods: From 1999 to 2015, we have analyzed 17 pregnancies in eight women with PNH, treated in our centers. Only three patients had planned the pregnancy, most of cases- 14 (82,4%) were unplanned. The median age at the start of pregnancy - 25 years (21-34). All of them were diagnosed with PNH following treatment for aplastic anemia (AA) with antithymocyte globulin, cyclosporine A and splenectomy in two cases before pregnancy. Most patients were in partial remission of AA at the time of pregnancy- 8 (47,1%), complete remission was achieved in 6 (35,3%). Three patients (17,6%) from 2013 exposed to eculizumab: two- started the treatment before conceiving, one-received eculizumab from third trimester. Other women received only symptomatic therapy (82,3%), such as anticoagulation with low molecular weight heparin in 29,4%, erythrocytes or platelets transfusion -35,3%, immunosupressive therapy -17,6%.
Results: The median of PNH granulocyte clone at the start of pregnancy was 74,7% (17,8-94,1). Progression of aplasia observed during 23,5% pregnancies, but it was not severe and special treatment delayed until the completion of pregnancy. No thrombotic events during pregnancy and postpartum have been observed. There were pregnancy complications: abortion threat 76,5%, fetal growth retardation syndrome 3/9, preeclampsia 2/9. Pregnancies resulted in the birth of healthy infants in 9 (52,9%) cases - three girls and six boys. There were no adverse effects in the newborns from PNH patients both on eculizumab and without it. Newborn health status differed from the norm only in the group of patients without the targeted therapy due to the presence of complications, mainly related to prematurity. Successful outcomes were in 3/3 pregnancies on eculizumab treatment and in 6 (42,9%) cases without the drug. Caesarean sections were performed in all of births, early surgical delivery (30-34 weeks)- in 4/9 cases (preeclampsia-2, placenta previa- 1, breakthrough hemolysis-1). Adverse pregnancy outcomes occurred only in patients not receiving eculizumab and amounted to 8/14 (57,1%). 28,6% cases of pregnancy in the midst of illness required the abortion for medical reasons. Spontaneous miscarriage was registered in 3 (21,4%) patients, fetal death on 27th gestation week- in one case (7,1%). Transfusion requirements increased in two pregnancies (14,3%) with symptomatic therapy, but did not increase on eculizumab. PNH granulocyte clone size decreased in 2/3 cases of eculizumab treatment during pregnancy.
Summary/Conclusions: Pregnancy in PNH with symptomatic treatment with a high probability ends adversely. The risk of complications during pregnancy and postpartum in PNH may be minimized by pregnancy planning and applying the management algorithm with eculizumab treatment. Despite the small number of observations, we can conclude that pregnancy outcomes in PNH patients with eculizumab are better than with symptomatic therapy. Our experience confirms that eculizumab can be safely used in PNH during pregnancy. This therapeutic approach may result in improved quality of life in PNH.

PB2095

EVALUATION OF THE IMPLEMENTATION OF A NURSE CASE-MANAGER FOR THE DIAGNOSIS AND FOLLOW UP OF PATIENTS WITH SYMPTOMATIC MULTIPLE MYELOMA

E Abella[1,*], R Ben Azaiz Ben Lashen[2], F García-Pallarols[1], E Gimeno[1], C Besses[1]
[1]Servei d'Hematologia, [2]Case-manager, Servei d'Hematologia, Hospital del Mar. IMIM, Barcelona, Spain

Background: An early diagnosis and prompt treatment of patients with symptomatic multiple myeloma (SMM) is essential. Hence, the reduction in the timing of diagnostic tests is a key element that allows to initiate early treatment and to avoid secondary complications. The nurse case-manager (NCM) has a crucial role reducing the time needed for the completion of tests and results as well as in the optimization of visits in order to start therapy as soon as possible. In addition, the NCM may improve the follow-up of patients by reducing admissions and random visits, thus potentially decreasing costs.
Aims: To assess the intervention of the NCM in relation to: 1) the time needed to establish the diagnosis and start treatment and 2) the follow-up process.
Methods: From September 2014 to January 2016 a prospective, single center study in patients with suspected SMM (interventional group; IG) was started. Results were compared to a control group (CG) of patients diagnosed of SMM in the two years previous to the study. Primary end-points were: 1. Time from referral to first visit in the Hematology Dept., 2. Time from referral to completion of diagnostic tests, and 3. Time from referral to initiation of treatment. Secondary objective was to assess hospital admission incidence during the first year of follow-up in both groups. The effect of the NCM in time to event variables was investigated using a multiple linear regression (MLR), using the corresponding time variable as the dependent variable (Log10 transformed due to left skewed distributions) and admission at diagnostic period as a confounder. Fisher exact test was used for assessing incidence ratios. In IG, a 11-item patient satisfaction questionnaire (PSQ) was obtained and a log of phone calls (PC) was recorded. This log collects all contacts to the NCM made by IG patients. Bilateral p value of 0.05 was considered statistically significant.
Results: During this period, 22 patients were studied in the IG and compared to a CG of 37 patients. Table 1 shows the results of the effect of the NCM in the three main end-points.The median value of PSQ was of 8,5/10, highlighting a significant patient satisfaction. A reduction in the incidence of admissions was observed (odds ratio: 1.20 p<0.05). During the study, 262 PC were collected and divided according to the discussed topic. 48.2% of PC were due to symptoms control: 85,7% were resolved by NCM or Physician and 14,3% were attended at the hospital. 26.7% of PC were related to treatment information: 86,6% were resolved by NCM or Physician and only 13.3% needed to attend the site. Finally, 25.1% of PC were related to schedule information and, of note, 98.4% were resolved during the call.

Table 1.

	control*	intervention*	p value[c]
Time referral, first visit (days)	16,6	7,6	0,022
Time first visit, completion of last test (days)	38,2	16,3	0,037
Time completion of last test-initiation of treatment (days)	45,0	24,4	0,044

*5% trimmed mean;
[c]p value of CM effect in MLR.

Summary/Conclusions: The incorporation of a NCM for the diagnostic and follow up of patients with SMM has allowed to reduce time from referral to visit, completion of tests and initiation therapy in the IG when compared with CG. Data collected during follow-up suggests that NCM involvement may lead to a decrease in hospital costs, with a significant patient perceived satisfaction. Further observation is warranted to confirm our preliminary findings.

PB2096

RELATIONS BETWEEN FAMILY FUNCTIONING AND HEALTH STATE OF PATIENTS WITH CUTANEOUS CHRONIC GRAFT-VERSUS-HOST DISEASE

Y Lu*,xZhang, J Zhang, Y Zou,xQin
The third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Chronic graft-versus-host disease(cGVHD) is a common complication after allogeneic hematopoietic stem cell transplantation(allo-HSCT). Patients with cutaneous cGVHD always changed much in appearance and many of them were in the bad health of psychology.
Aims: The aim of this study was to explore the relations between family functioning and health state of patients with cutaneous cGVHD.
Methods: A questionnaire survey was undertaken among patients with cutaneous cGVHD by the way of Family APGAR and COOP/WONGA. According to the scores gained from family APGAR index questionnaire, the patients were divided into two groups: family dysfunction group with scores between 0 and 6 and better family function group with scores between 7 and 10. The scores of each item gained from COOP/WONGA were further compared between the two groups and the correlations of the results were analyzed.
Results: 38.7 percent of the patients had good functioning families and 61.3 percent of them had defective functioning families.The differences between the two type families in the total healthy state, emotion, social communication, daily activity and pain had statistical significance (P<0.05). The family functioning had positive relation with the health state in patients with cutaneous cGVHD(r=0.901, P<0.01).The adaptability, cooperation, growth, emotion and intimation in Family APGAR questionnaire survey and ten items in COOP/WONGA had positive relations (r=0.711 ~ 0.925, P<0.05, P<0.01).
Summary/Conclusions: The relation between the family functioning and the health state of patients with cutaneous cGVHD is close. Medical workers should pay attention to the desirable effects of the good family functioning on these patients.

PB2097

REAL-WORLD CHARACTERISTICS, TREATMENT PATHWAYS AND HEALTHCARE RESOURCE USE IN PATIENTS TREATED FOR RELAPSED REFRACTORY MULTIPLE MYELOMA IN SPAIN: PRELIMINARY RESULTS FROM THE PREMIERE STUDY

J Martinez-Lopez[1], P Martín-Regueira[2], A Zagorska[2,*], C Lefevre[2], C Roldán Acevedo[2], N Qizilbash[3], B San José[3], I Méndez[3], LF Casado Montero[4]
[1]Hospital 12 de Octubre, Madrid, Spain, [2]BMS, Princeton, United States, [3]Oxon Epidemiology Limited, Madrid, [4]Hospital Virgen de la Salud, Toledo, Spain

Background: The management of patients (pts) with multiple myeloma (MM) has changed considerably in recent years. Pts' life expectancy has significantly increased, and in some cases MM is now considered a chronic disease, with pts receiving multiple lines of therapies. Real-world data on health and resource-related outcomes of different treatment patterns may help promote more efficient resource allocation within the National Health System.
Aims: To describe baseline characteristics, treatment patterns and healthcare resource utilization (HCRU) in a cohort of pts treated for relapsed refractory (RR) MM in Spain.
Methods: The PREMIERE study is a retrospective chart review study conducted in a representative cohort of pts with RRMM in Spain. Enrolled pts were aged ≥18 years, had ≥1 prior treatment for MM, and began a new line of therapy (index therapy) during the recruitment period of 1st July 2010–30th June 2012 due to relapsing or refractory disease. Pts were followed from initiation of index therapy (index date) for 3 years, or until death, loss to follow-up, or enrollment into a clinical trial for MM. Using an interim data extraction from November 30th 2015, descriptive statistics of pt characteristics at initiation of index therapy were calculated, and treatment patterns and HCRU in pts with complete data at the end of the 3-year follow-up estimated.
Results: Overall, 100 pts were included in this interim analysis; 91.0% had received only 1 prior treatment for MM. 61.0% were male, 69.0% were aged ≥65 years; median weight was 70 kg (Q1–Q3: 62–80 kg). Median time from MM diagnosis to enrollment was 2.2 years (range: 0.1–15.5 years). Most pts had relapsed (74.0%) or refractory (13.0%) MM. The majority of pts were in MM ISS stage II (31.3%) or III (29.3%). Most common previous therapies were bortezomib (74.0%) and melphalan (68.0%). 28.0% of pts had received a stem cell transplant (all autologous), 96.4% (27 pts) were single transplantations, 2.6% (1 pt) was a double transplant. 56 pts completed the 3-year follow-up period. During the follow-up period, 50.0% (28 pts) initiated a subsequent 2nd line of therapy after index therapy, 23.2% (13 pts) initiated a 3rd RR line, and 7.1% (4 pts) initiated a 4th. In 2nd, 3rd, and 4th lines, the most commonly prescribed treatments were RevDex or bortezomib-based combination therapies. The most commonly prescribed classes of medications for index therapy were immunomodulators (24 pts, 42.9%; of whom 18 pts received RevDex), and proteasome inhibitors (17 pts, 30.4%; of whom 13 pts received VelDex). 11 pts (19.6%) received chemotherapeutic agents. Time from the start of index therapy to the next line differed between RevDex and VelDex, with longer treatment durations on RevDex (16.2 months) compared to VelDex (12.5 months; Table). However, duration of subsequent lines (after progression on index therapy) was longer for pts treated with VelDex as the 1st RR line (RevDex: 9.3 months; VelDex: 15.1 months; Table). HCRU during the time spent on-therapy with the index therapy during the 3-year follow up period showed overall higher resource use for VelDex treated pts, especially for hospital consultations (Table).

Table 1.

Table. Index therapies and healthcare resource use in patients with RRMM in Spain

	Index therapies (N=56)		
	RevDex [a] (n=18, 32.1%)	VelDex [b] (n=13, 23.2%)	Other [c] (n=25, 44.6%)
Line of treatment duration, months, mean (SD)			
Time from start of 1st line after enrollment to next line	16.2 (11.5)	12.5 (10.7)	11.2 (9.5)
Therapy duration	13.9 (10.1)	7.5 (7.1)	9.3 (8.5)
Subsequent therapy duration	9.3 (8.1)	15.1 (9.8)	9.2 (8.2)
Healthcare resource use during 1st line after enrollment, mean (SD)			
Hospital admissions	0.7 (0.7)	1 (0.8)	1.4 (1.3)
Clinical visits			
Hematologist visits	15.8 (8.8)	14.1 (15.3)	11.8 (14.7)
GP visits	2.2 (3.4)	5.8 (15.4)	2.2 (5.3)
Hospital outpatients' consultations	7.4 (10.0)	14.5 (19.8)	9.7 (19.0)

[a] RevDex: lenolidamide (oral) + dexamethasone (oral)
[b] VelDex: bortezomib (IV/SC) + dexamethasone (oral)
[c] Other: IMiDs other than RevDex (n=4), PIs other than VelDex (n=1), chemotherapy (n=11), PI+chemotherapy (n=3); PI+IMiD (n=1); chemotherapy+IMiD (n=2); PI+IMiD+chemotherapy (n=2); other (n=1)

Summary/Conclusions: These are the first data published describing treatment patterns and HCRU in Spanish clinical practice. The most common patterns for relapsed/refractory pts are bortezomib and lenalidomide-based schemes. Data should be interpreted with caution given the small sample size; final analyses of this study with the complete sample population will be presented at EHA.

PB2098

PHARMACOECONOMIC MODELLING OF TARGET THERAPY CHRONIC MYELOGENOUS LEUKEMIA: EARLY AND LATE SWITCHING

V Shuvaev[1,*], O Shukhov[2], M Fominykh[1], E Chelysheva[2], I Martynkevich[1], A Turkina[2], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]Hematology Research Center, Moscow, Russian Federation

Background: Early molecular response (EMR) achievement (*BCR-ABL*≤10% by IS) at 3 months of tyrosine kinase inhibitors (TKI) treatment of chronic myelogenous leukemia (CML) is recognized as an important prognostic marker of subsequent therapy efficiency and survival. The time point of TKI switch from first to second generations is one of the main differences between different CML treatment guidelines. The attractive perspective of further improvement in CML management is treatment free remission phase (TFR),-stop the TKI therapy in patients with deep sustained molecular response under thorough molecular monitoring.
Aims: The pharmacoeconomic modelling of comparison between early (3 moths) and late (6 months) switching from Imatinib to second generation TKI (TKI2) depending on EMR achievement (*BCR-ABL*≤10% at 3 months of treatment) with subsequent TKI therapy cessation in patients with stable long-lasting (2 years) deep molecular response (MR4.0=*BCR-ABL*≤0,01% by IS).
Methods: We have used previously described Markov chain model for CML management[1]. We constructed two model variances for early (3 months) and late (6 months) time points of switches from Imatinib to TKI2 depending on EMR achievement with subsequent TFR phase for patients with MR4.0 2-years duration. The model size was 700 newly diagnosed CML patients yearly and time horizon was 5 years. The transition rates (TKI response rates, MR4.0 rates, successful TFR rates) have been chosen from clinical trials (ENESTnd, TIDEL-II, STIM, FILMC, DADI and own data). We have recalculated the total costs from Russian roubles to Euros for clearly representation (February 2016).
Results: Early *versus* late switching lead to more frequent successful transition to TFR (13,59% for early switch and 10,46% for late switch). The early switching takes 8.54% more expenses (figure 1), but provided 6099 additional quality-adjusted life years (QALY). Incremental cost-effectiveness ratio for early compared to late switching is 543.2€ per 1 additional QALY, that is reasonable to economically based implementation. Sensitivity analysis shows that in case of TKI second generic substitution the costs for early and late switching should be equal. It can yield extra cost-free efficiency.

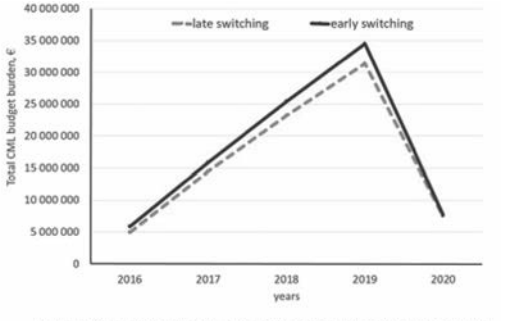

Figure 1. Chronic myelogenous leukemia budget burden for early and late switching strategy depend on early molecular response achievement.

Figure 1.

Summary/Conclusions: The pharmacoeconomic modelling can simulate budget burden for various modifications of diagnostic and therapeutic techniques in CML management with evaluation of its economical and clinical worth.

THE APPLICATION OF GENOMIC MEDICINE IN HAEMATOLOGY: THE CHALLENGES AND ETHICAL IMPLICATIONS

J Rubasingham[*]
Department of Medicine, Wexham Park Hospital, Slough, United Kingdom

Background: Two scientists walked into a Cambridgeshire pub in 1953 and announced that they had discovered 'the secret of life'. Since the discovery of DNA by Watson and Crick, the field of human molecular biology and genetics has grown in leaps and bounds over the last few decades. Although it took almost ten years for the first ever human genome to be sequenced, today, with technology referred to as the 'next generation sequencing', millions of fragments of DNA from a sample are analysed on parallel sequencing platforms, facilitating high-throughput sequencing and allowing the entire genome to be sequenced in less than a day, at a considerably less cost. The effects of these advancements have been felt in clinical haematology, arguably more so than in the other specialties, given the application of cancer genomics in haematology. 'Targeted therapy' and 'personalised medicine' have become the buzz words in any specialty dealing with cancer. Are these new developments the pinnacle of modern medicine as we are often led to believe?
Aims: Although there is an abundance of studies on the scientific aspects of genomic medicine, there is surprisingly sparse amount of literature exploring the ethical implications and challenges of genomic medicine, even more so as it applies to haematology. This study aims to evaluate the place of genomic medicine in clinical haematology and provide a critical appraisal, focussing on the challenges it poses and ethical implications that arise from it.
Methods: MEDLINE database was searched using the keywords 'genomic', 'haematology' and 'ethics' to identify the relevant literature. The governing principles of modern medical ethics were applied to the topic in question.
Results: Several issues were identified from studies looking at ethical issues arising from genomic medicine. A common theme was responsibility placed on researchers to disclose potentially beneficial genetic information to the participants or patients. This is further complicated when the patient has made an advance decision explicitly expressing that s/he would not want to be contacted should further information become available. Although most would respect the patient's autonomy in this context, some might argue (controversially) that depending on the gravity of information being withheld, a paternalistic approach would be warranted. A similar conundrum may also arise when a clinician may be aware of genetic information of potential benefit to a patient which they may have acquired from the patient's relative. Although next generation sequencing has made genomic medicine much cheaper, it still remains a commodity which is not commonly used in everyday clinical practice. There is inter-regional and intraregional variation in the availability of this specialist service, raising the ethical issues of resource allocation, justice and equity. Of recent times, there have been many large population based genomic studies such as the 1000 genomes project and the recently launched 100 000 genomes project in the UK. Although some of these projects obtain genomic data from patient populations who donate their genetic material with altruistic motives, it can open up opportunities for pharmaceutical companies to benefit financially from these studies, creating a very grey area in modern ethics.
Summary/Conclusions: Although there has been tremendous benefits to patients from the advances in genomic medicine, particularly as it applies to cancer genomics and targeted therapy in haematology, it is not without challenges. Several ethically ambiguous issues arise, particularly in the conduct of research in this rapidly advancing field.

PB2101

PROSPECTIVE MULTICENTER PROGRAM OF REMOTE CONTROL IN ANTIVITAMIN K ANTICOAGULANTS

M Gómez Crespo[1,*], A Pascual Martinez[2], C Teran Benzaquen[3], R Vidal Laso[3], P Llamas Sillero[3]
[1]Hematology, Fundación Jimenez Díaz, [2]Hospital Infanta Elena, [3]Hematology, MADRID, Spain

Background: The use of oral anticoagulant therapy with VKA (OAT) has progressively increased in the cardiovascular diseases, such as atrial fibrillation, valvular diseases,and venous thromboembolic disorders. The OAT is currently used in 1.7-2% of the population. The grade of anticoagulation control is a vital aspect in the quality of clinical care of these patients. The fact that they remain above or below the optimal range exposes the patients to an increased risk of bleeding or stroke. The new technologies of information and communication allow us to optimize the control of these treatments significantly improving their quality of life and safety
Aims: 1. To evaluate the efficacy and safety of remote control (RC) of OAT in a group of 100 patients. 2. To analyze the degree of satisfaction and quality of life of patients included in the program.
Methods: Prospective multicenter study of the first 100 patients included in our program. The study has been carried out from June 2015 to nowadays. The institutional review board waived informed consent for this health care program that was compliant with the Spanish law in force. The participating centers are: Hospital Universitario Fundación Jiménez Díaz, Hospital Universitario Infanta Elena, Hospital Universitario Rey Juan Carlos and Hospital General de Villalba. Patients were included if meeting the following inclusion criteria: a history of use of OAT for at least three months, a valid chronic indication for the treatment and patients that were capable of handling computerized devices. The exclusion criteria were: patients under age of 16 years, patients with severe diseases or with less than 3 month of treatment with OAT and those who expressed their desire not to participate in the study. We created a reference unit of OAT composed of doctors and specialized nurses: the doctors made the prescription and gave the specific instructions to the nurses. Once they were taught, they are in charge of the active education of patients.
Results: In the first 100 patients included, there there isn't any complication with the treatment and the preliminar results of the quality life surveys are very good. The patients were evaluated in the OAT clinics, and were included when meeting the above mentioned inclusion criteria. Once they had signed the informed consent. After work, in a remote service,we generated a note that was accesible online to the patients in the web Patient Folder. The medical note consists of the prescription. When the control was needed, patient can introduce the result of the digital INR in the same Patient Portal. This web interaction prevents unnecessary movements of the patients and/or family members. There is no separation from the center.
Summary/Conclusions: Our RC program is a new technological system that assists patients in the control of OAT from their home.The program consists in adapting new technologies to the healthcare system to gain in quality of life, with fewer complications, greater safety and comfort for patients and reducing travelling to the hospital and costs. With this program the patients are an actives subjects in the management of their disease.

PB2102

A NEW MODEL OF ORAL HYGIEN FOR REDUCTION AND PREVENTION OF MUCOSITIS IN PATIENTS UNDERGOING MYELOABLATIVE STEM CELL TRANSPLANTATION

V Stacchini[1,*], M Miceli[1], E Orciuolo[2], F Papineschi[2], L Iovino[2], M Gabriele[1], MR Giuca[1], E Benedetti[2], M Petrini[2]
[1]UO Odontostomatologia e Chirurgia del cavo orale, [2]UO Ematologia, University Of Pisa, Pisa, Italy

Background: Mucositis is a very common complication of allogeneic stem cell transplantation (allo-SCT). The damage due to radio-chemotherapy is combined with the risk of superinfection. Protocols of oral hygiene play an important role to prevent the onset of oral infections and may improve disconfort due to mucositis.
Aims: We are we presenting data on mucositis prevention using professional oral hygiene and specific dental aids.
Methods: We prospectively enrolled patients who underwent allo-SCT for haematological malignancies. We joined to standard procedures (toothbrush, clorexidine mouthwashes) a set of specific tools, with a daily schedule of application. An oral hygiene session was performed in all patients before the date of recovery. The protocol provide, from the first day of hospitalization, the use of: manual toothbrush with bristles of 0,12 mm of diameter, super-soft; antibacterial toothpaste containing colostrum and antimicrobial enzymes; antibacterial mouthwash containing lisozyme, lactoferrin, lactoperoxidase and extracted colostrum, fluorine, xilitole and aloe vera. From the day 1 after stem cell infusion: manual toothbrush with bristles of 0,10 mm of diameter, ultra-soft; mouthwash containing maltodextrin, propylene glycol, hydroxyethylcellulose, sodium hyaluronate, sodium saccarhin and citric acid. Patients were clinically supervised every day, until engraftment or resolution of mouth lesions, through clinical examination, WHO grading of mucositis, VAS scale for the pain.
Results: We prospectively enrolled 8 patients that underwent to myeloablative conditioning regiment with TBF for haematological malignancies, comparing results with an historical cohort. Results are expressed in figure.

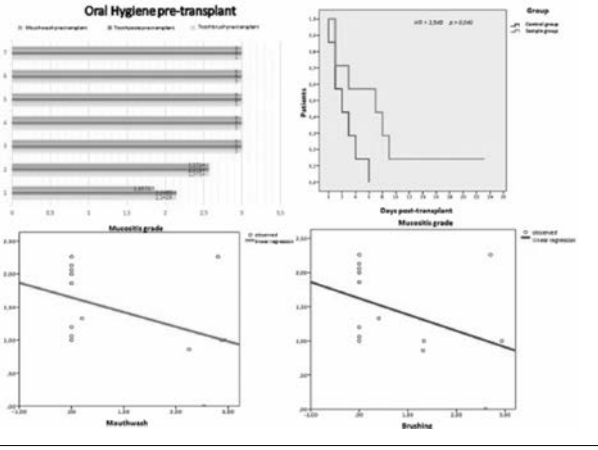

Figure 1.

Summary/Conclusions: Patients who followed a regular schedule of oral hygiene, before and after the transplant, had a lower pain reported in VAS scale, a significant lower level of mucosyte, and a later onset of mouth lesions, in comparison of patients who did not follow the procedure and in comparison of a control group, extracted by the clinical records of allo-SCTs of the previous

year. It has implication for the administration of analgesic drugs (opioids), notably lower in patients treated with protocol. This finding demonstrate the importance of oral hygiene in allo-SCT setting in preventing high-grade mucosytis, suggesting the institution of specific profession of dental hygienist for haematological patients.

PB2103

EVALUATION OF PRE-ANALYTIC AND POST-ANALYTIC PHASES OF THE COAGULATION LABORATORY IN HACETTEPE UNIVERSITY HOSPITALS

ZG Dikmen, F Akbiyik*
Medical Biochemistry, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: The pre-analytical and post-analytical phase in a test cycle contributes up to 93% of total laboratory errors. Our coagulation laboratory provides routine and stat tests for inpatients and outpatients in Hacettepe University Hospitals, including 1000 beds. Joint Commission International guidelines is followed in our laboratory; we document the unsuitable samples rejected by laboratory and we record critical value notifications, including the person who received the notification (physician, nurse or medical staff), the time and the date of communication. Hence, rejection of unsuitable samples and critical value notification are the quality indicators of our laboratory.
Aims: In this study, we aimed to evaluate the pre-analytical problems and critical values recorded on coagulation and hemostasis tests over one year period in 2015.
Methods: Venous blood samples for routine coagulation testing were considered unsuitable for analysis according to the following specimen rejection criteria of our laboratory; inappropriate clinical orders, inappropriate volume (inadequate blood to anticoagulant ratio), incorrect tube, clotting, delayed transport and visible hemolysis or fibrin following centrifugation. During day time and night shift, authorized laboratory secretary was responsible for reporting of critical values by telephone communication and reverse reading. The critical values in our laboratory were as follows; prothrombin time/international normalized ratio (PT/INR)>5, activated partial thromboplastin time (aPTT)>100 seconds, fibrinogen<100 mg/dL, factor levels<5% and anti-thrombin III<50%.
Results: Total coagulation test request was 155.945 in one year and *5.*090 tubes were rejected according to the rejection criteria of our laboratory. On overall, the more frequent pre-analytical problems could be referred as clotting (38.4%), following inappropriate volume (33.2%), inappropriate clinical orders (7.3%), misidentification (6.5%), hemolysis (6%), incorrect tube (3.8%), fibrin (3.3%) and delayed transport (1.5%), respectively. Among 155.945 tests performed in 2015, we reported 475 critical values, the ratio was 0.3% in total. The critical value notification ratio was 56% for INR, 23% for factor levels, 12.2% for fibrinogen, 5.5% for antithrombin III and 3% for aPTT. The critical value reporting rate was 97-99%, dropped call ratio was approximately 1-3% of all.
Summary/Conclusions: We detected an overall specimen rejection rate of 3.2% in coagulation laboratory. By documentation of rejected samples and periodic training of healthcare personnel, we expect to decrease sample rejection ratios below 1% and to improve total quality management of the laboratory. Our critical value reporting rate was 97-99%, and clinicians were notified of patients' life-threatening results within 15 minutes. We believe that rapid notification of abnormal test results has an impact on patient outcomes. This is the first report on the pre-analytical and post-analytical phases of coagulation laboratory in Turkey. To improve patient outcome, each laboratory has to establish its own specimen rejection criterias and reporting policy for critical values.

PB2104

DEVELOPMENT OF PATIENT-REPORTED OUTCOMES SYMPTOM MEASURE FOR PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMIA (NTDT-PRO)

A Taher[1,*], A Saliba[1], A Kattamis[2], R Ward[3], G Harding[4],xHu[5], D Mahmoud[5]
[1]American University Beirut, Beirut, Lebanon, [2]Aghia Sophia Children's Hospital, Athens, Greece, [3]University Health Network, Toronto, Canada, [4]Evidera, Bethesda, [5]Celgene Corp., Summit, United States

Background: Currently, there is no disease-specific Patient-Reported Outcomes (PRO) measure available to assess key symptoms experienced by patients with non-transfusion-dependent thalassemia (NTDT).
Aims: To develop a symptom outcomes measure for patients with NTDT for use in clinical trials.
Methods: A qualitative study was conducted to develop the NTDT-PRO symptom measure consistent with regulatory requirements. The instrument was developed based on concept elicitation interviews, input from clinical experts, and refined through a process of cognitive interviews. Concept elicitation interviews were conducted among a total of 25 NTDT patients recruited from three countries (Lebanon, Greece, and Canada). Findings from these interviews were used to generate an item pool, inform response options, and determine appropriate recall period. Cognitive interviews were subsequently conducted among subjects in Greece and Lebanon (N=21) to further support saturation and examine the relevance, clarity and understanding of the items among the target population. All interviews were conducted in person in the local language with written informed consent obtained, audio-recorded, transcribed and translated back into English for evaluation.
Results: Based on findings from concept elicitation interviews, saturation of important underlying concepts was obtained and a total of nine symptoms were included in the NTDT-PRO Version 1. Instructions and item stems were derived from patient language elicited during the interviews. An 11-point numeric rating scale (0-10) was used for the response options, anchored on either end by the absence of the symptom and extreme symptom. A daily recall period ("during the past 24 hours") was selected based on the day-to-day variability in the symptom experience. Findings from the cognitive interviews indicate that subjects understood the instructions and that the daily recall period was appropriate. Subjects understood the items as intended, with a few minor exceptions. Four items were deleted as they were not considered core symptoms, and one item was added to address the symptom both with and without physical activity. The NTDT-PRO Version 2 includes six items that address three key symptoms of tiredness, weakness, and shortness of breath both during physical activity and at rest.
Summary/Conclusions: The NTDT-PRO Version 2 consists of six items to assess the key symptoms of NTDT, including tiredness, weakness, and shortness of breath using a 24-hour recall period, with plans to further evaluate the measures in an ongoing observational study and for eventual inclusion into a randomized phase 3 study.

PB2105

IMPACT OF ECONOMIC CRISIS ON THE MANAGEMENT OF HEMOPHILIA PATIENTS IN GREECE

A Teli[1], V Gourtsa[1], G Lakaki[1], I Christou[2], M Economou[1,*]
[1]1st Pediatric Department, Aristotle University of Thessaloniki, [2]Pharmacy, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Economic crisis has had a major impact on public health in Greece during the last years, negatively affecting both ability for health insurance coverage and availability of medical services. As all patients suffering from chronic illnesses, hemophilia patients have had to face difficulties resulting from the austerity measures.
Aims: Purpose of the present retrospective study was to evaluate the impact of economic crisis on management of hemophilia patients for the 6 year crisis period (January 2010 - December 2015) in a single pediatric institution.
Methods: The study included hemophilia A patients followed at the Pediatric Center for Bleeding Disorders of Aristotle University of Thessaloniki, one of the two pediatric hemophilia centers in Greece. Data were recorded 23 for patients with severe hemophilia (FVIII <1%) or moderate hemophilia (FVIII 1-5%) presenting with a severe bleeding phenotype. Patients with inhibitor presence were excluded from the study. A subgroup consisting of 12 patients on regular prophylaxis throughout the studied years was separately evaluated. Data assessed included annual factor consumption (IU/kg) and annual cost for the years studied. The prices for factor concentrates were obtained from the Greek National Organization for Medicines. Changes in patients' family working status and subsequent insurance coverage were also recorded.
Results: Mean age of patients was 11.3 year (range 2-19 years). The mean annual factor consumption did not significantly differ between the onset of crisis and the following years in both groups studied (i.e. total and regular prophylaxis patients). Similarly, the average annual cost per patient did not significantly change during the crisis years for either group. In specific, mean factor consumption for the whole group at starting and closing years was 334.167±227.536 U/KG and 318.235±105.92 U/KG, respectively, with respective mean annual costs 114,864±82,097 and 108,989±62,862 euros. For the regular prophylaxis group mean factor consumption for starting and closing years was 350.16± 268482 U/KG and 318.235±105.92 U/KG, respectively, with mean annual costs 114,187±97,772 and 134,61±54,159 euros. With regards to employment and insurance ability, one patient lost coverage due to parents' unemployment. However, Social Security provided cost-free factor administration, enabling patient to continue his treatment. The only change recorded between crisis onset and following years was a significant increase in number of hospital visits required in order to have access to factor administration, as a result of limited amount of factor administered by the hospital at each visit for home treatment.
Summary/Conclusions: Although Greece has seriously suffered during the last years because of the economic crisis, provision for health has managed to survive - at least for hemophilia patients. Albeit, without some cost on the patients' part.

PB2106

TO PROMOTE THE MEDICAL QUALITY OF HEMATOPOIETIC MALIGNANCIES BY INTERGRATION OF QUALITY CONTROL CIRCLE AND PHS WIN-WIN CONCEPT

QL Jiang[1,*], QF Liu[1], WY Li[1], HS Wu[1], PL Hu[1], J Sun[1], CJ Zhao[2], H Huang[1], QS Mai[2]
[1]Nanfang Hospital, [2]Southern Medical University, Guangzhou, China

Background: Infection and bleeding contribute to about 2/3 and 1/3 of mortality

associated with hematopoietic malignancies in Nanfang Hospital, China. Patients, hospital staff, medical students and social groups were involved in this QCC.
Aims: To promote the medical quality, two rounds of Quality Control Circle (QCC) were carried out, with the aim to solve the above mentioned complications.
Methods: 1 The perianal infection is the most common infection for hematopoietic malignancies (up to 60%—100%, Ann Hematol. 2003; 82:S167). With severe immunodeficiency, the perianal infection rate was 17.2% in the bone marrow transplantation center (2013Apr.-Sep.). Then QCC1 was carried out following the 10 steps of Plan-Do-Check-Action. Bacterial colony culture experiments from perianal skin before and after sanitization were performed. Since warm aqueous solution of potassium permanganate are recommended for sanitization, such bacterial colony culture is also used to find a proper drug concentration, water temperature and soaking time *etc.* Eventually a tool kit was developed (CN patent No.201520820954.7) to ensure the standardization of procedures. 2 With the team of QCC1, we started QCC2 for decreasing mortality due to bleeding, the shortfall being the insufficient supply of platelets. Tackling of this condition is more complicated and demanding, which also exists in many developing countries. We integrated the functioning of PHS, which stands for patients (P); hospital staff (H); students and social workers (S); in accordance with the complementary advantages (Table 1) for co-operation. Four strategies were incorporated as: Establishing a professional team, systematic education, setting up a platelet donor bank and a new platelet harvest station.
Results: 1 The perianal infection rate gradually decreased from 17.2% to 5.25% and subsequently declined in the following year. Apparently each case of perianal infection could detrimentally prolong hospitalization by ≥2w and approximately 28,000 Yuan of expenditure for treatment, as well as witnessing >4,000/year such hospitalized cases in Nanfang Hospital and from amongst 40,000 new findings of leukemia in China, this QCC1 was awarded the first Prize of Chinese QCC in 2014. 2 Comparing 9 months(m) before QCC2 (2014Feb.-Oct.) and 9 m later (2014Nov.-2015July), we found that the number of platelet transfusions in the department of Hematology increased from 2815U to 3674U (130.5%) and the success rate of applications increased from 58.67% to 75.77%. Within 9 m, QCC2 helped to establish a professional team named as Blood and Bone marrow China (BBCn) which have conducted 19 public lectures, a proficient platelet donors Bank with 448 volunteers and donated 135U of platelet directly. Interestingly, a new platelet harvest station is under construction in Nanfang Hospital, which will harvest thousands of new blood platelets each year. Mortality due to bleeding will significantly decrease thereafter. Table 1. Analysis of patient, hospital stuff, student and society (PHS)

Table 1.

	Presence of	Absence of
Patient	Diseases Social relationships Option to select a hospital	Knowledge Psychological comfort Blood/Platelet Money
Hospital stuff	Knowledge Experience	Time Enthusiasm
Student &Society	Time Money Enthusiasm Blood/Platelet, etc.)	Information Training Trust

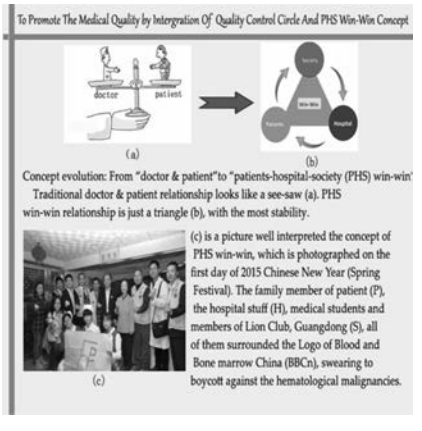

Figure 1.

Summary/Conclusions: QCC and PHS win-win concept could promote the medical quality of hematopoietic malignancies. Most beneficially, they will also alleviate the social conflicts between doctors and patients tremendously in China.

PB2107

PREGNANCY-ASSOCIATED ATYPICAL HEMOLYTIC UREMIC SYNDROME
T Kirsanova, M Vinogradova*
Hematology, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: Pregnancy-associated atypical hemolytic uremic syndrome (P-aHUS) is a rare catastrophic disorder defined by the occurrence of fibrin and/or platelet thrombi in the microvasculature, resulting in microangiopathic hemolytic anemia (MAHA) and thrombocytopenia without Shiga toxin and ADAMTS13 deficiency. An estimated incidence of P-aHUS is approximately 1 in 25,000 pregnancies during antepartum and puerperium. It is associated with a significant perinatal or maternal morbidity and mortality.
Aims: The evaluation of outcomes in P-aHUS. The establishment of adequate strategies for the timely diagnosis and treatment is very important to improve patient survival and pregnancy outcomes.
Methods: This is a retrospective analysis of aHUS during pregnancy treated in our center and other clinics via telemedicine between November 2010 and February 2016. Nine women mean age 30,4 years (range: 21-36) were diagnosed with aHUS. Most of them (8/9) presented postpartum, 1/9 developed aHUS in II trimester. All had MAHA, thrombocytopenia and severe organ dysfunction. 7/9 had at least one pregnancy before the onset of P-aHUS.
Results: Mean nadir hemoglobin was 60,3 g/L (range 46-69); mean nadir platelet count- 53,000/mm3 (range 16,000-100,000); mean peak serum creatinine- 454 mkmol/l (range 67-998), mean peak LDH- 2,953 IU/L (range 996–11,360). 6/9 required hemodialysis and mechanical ventilation. All underwent plasmaexchange or plasma infusion and all of them was appointed unfractionated or low molecular weight heparins. Signs of mild preeclampsia were observed in 8/9 patients with an average of 7 days (3-14) to debut P-aHUS, 4 of them were diagnosed with fetal death on 27-34 gestation weeks. Live births resulted in 5/9 of pregnancies on 28-38 weeks (median 32). Since the onset of the disease state of the patient rapidly deteriorated: acute renal failure was detected in 8/9 patients (6 cases performed hemodialysis), adult respiratory distress syndrome, requiring mechanical ventilation, was diagnosed in 6/9, 6/9 have pankreatit, neurological symptoms were accompanied by observations of 5/9, 2/9 observed in dilated cardiomyopathy and ischemic colitis in one case. The most common organ dysfunction was kidney failure (8/9). 8/9 patients received therapy with fresh frozen plasma. Treatment with eculizumab was started on 4 patients on 5-17 days from the time of P-aHUS debut (median, 7), but the full course was not held anyone: performed from 1 to 3 injections of 900 mg (median 1). All patients received prophylactic anticoagulation. Outcomes as a whole are extremely unfavorable: 5 of 9 patients died (3/5 causes of death-septic complications, thrombosis- 1, hemorrhage- 1), 2/9 - reached end-stage renal failure by 1 month, 2/9 gained the renal function impairment (CKD3-4) by last follow-up.
Summary/Conclusions: P-aHUS is a severe life-threatening disorder associated with a significant perinatal and maternal morbidity and mortality. We evaluated the outcomes of P-aHUS. Currently, they are extremely pessimistic now. Diagnostic and therapeutic approaches for this disease requires further study in order to optimize results. Clinical suspicion, early identification and effective approaches including target therapy can improve the pregnancy outcomes and prognosis in general.

PB2108

LAMIVUDINE FOR PREVENTION OF REACTIVATION IN OCCULT HEPATITIS B IN PATIENTS WITH NON-HODGKIN LYMPHOMA CD20+ UNDERGOING CHEMOTHERAPY: A COST-EFFECTIVE ANALYSIS
C Cerchione[1,*], A De Renzo[2], M Masarone[3], C Cimmino[4], M Di Perna[4], G Signoriello[5], M Persico[3], F Pane[1]
[1]Hematology, Università Federico II, [2]Ematologia e trapianto/au federico ii, Napoli, [3]Hepatology, Ospedale di Salerno, Salerno, [4]Hematology, Ematologia e trapianto/au federico ii, [5]Statistica, Università Federico II, Napoli, Italy

Background: Occult HBV infections (OBI) are defined by the persistence of HBV in the liver without serum HBsAg and HBV-DNA. They can represent a life threatening event during immunosuppressive CHT. OBI occur in approximately 18% of HBcAb+ patients. Guidelines suggest surveillance for HBV markers in immunosuppressed patients, in particular in treatment with monoclonal antibodies. In our study, the prevalence of OBI reactivation in NHL, in 498 patients of our centre, was 10.42% in HBcAb+ HBsAb- patients. In this work, a cost-effectiveness analysis regarding the use of Lamivudine for the prevention of reactivation in OBI in patients with NHL undergoing chemotherapy with or without Rituximab was performed. In fact, considering guidelines and literature, universal prophylaxis should have been applied to all HBcAb + HBsAg - patients. A cost-benefit issue arises: is it more cost-effective to treat all the HBcAb + HBsAg - patietns with Lamivudine to prevent the OBI reactivation occurence in a small quote of them, or may it be more effective a "wait and see" protocol?
Aims: Our idea was to perform a cost-effectiveness analysis, comparing the costs of prophylaxis of an eventual HBV reactivation and the "monitoring" approach that was used in our patients based on international guidelines.
Methods: The cost of Lamivudine prophylaxis was calculated in a time interval of 12 months, which encompasses the time of a standard Rituximab-containing regimen and a minimum time of follow-up. It has been noticed that, very often, NHL patients need more than one treatment to obtain remission, and, sometimes, if they do not obtain a CR, undergo to long-term "maintenance" with Rit-

uximab. These patients (HBcAb +) are at high risk of HBV reactivations, due to long periods of immunosuppression.
Results: Nevertheless, even if our calculations underestimated the costs of prophylaxis, the "monitoring approach" resulted cost-effective. Moreover, even though in our series no serious events in terms of morbidity and/or mortality occurred, in other papers a monitoring approach did not guarantee patients survival. These detrimental results could be ascribed to the delayed start of lamivudine treatment if the monitoring is not adequately strict. Also, it has been reported that performing only the transaminase monitoring should not be acceptable to prevent severe reactivations.

Table 1.

	Unitary Cost	n. patients	Total per patient	Duration [days]	Total
Cost of prophylaxis					
Lamivudine	€ 3,18	48	€ 152,64	360	€ 54.950,40
HBV DNA monitoring	€ 130,00	48	€ 6.240,00	6	€ 37.440,00
HBsAg monitoring	€ 17,00	48	€ 816,00	6	€ 4.896,00
AST/ALT monitoring	€ 5,74	48	€ 275,52	12	€ 3.306,24
Total	**€ 155,92**	**48**	**€ 7.484,16**		**€ 100.592,64**
Cost of HBV Reactivation					
HBV DNA monitoring	€ 130,00	48	€ 6.240,00	6	€ 37.440,00
AST/ALT monitoring	€ 5,74	48	€ 275,52	12	€ 3.306,24
Cost of DRG 205 [v24 Grouper]	€ 3.769,10	5	-	-	€ 18.845,50
Total	**€ 3.904,84**	-	-	-	**€ 40.746,24**

Drg 205: Liver disease except malignancies, cirrhosis, alcoholic hepatitis with cirrhosis.

Summary/Conclusions: Our monitoring approach resulted efficacious probably because of the monthly ALT assay was strictly observed.

PB2109

AN HPLC AND 1H NMR STUDY OF THE CYTARABINE DEGRADATION IN CLINICAL CONDITIONS TO AVOID DRUG WASTE, DECREASE THERAPY COSTS AND IMPROVE PATIENT COMPLIANCE

M De Nisco[1], C Cerchione[2,*], V Martinelli[2], N Pugliese[2], S Pedatella[1], L Catalano[2], M Manfra[3], N Marra[4], VD Iula[5], F Pagano[6], M Picardi[2], F Pane[2]
[1]Dipartimento di Scienze Chimiche, Università di Napoli Federico II, [2]Hematology, Ematologia e trapianto/au federico ii, Napoli, [3]Dipartimento di Scienze, Università della Basilicata, Potenza, [4]Oncoematologia, A.O.R.N. Santobono-Pausilipon Hospital, [5]Microbiologia Clinica, Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Napoli, [6]Dipartimento di Farmacia, Università di Salerno, Fisciano (SA), Italy

Background: Cytarabine, the 4-Amino-1-(β-D-arabinofuranosyl)-2(1H)-pyrimidinone, (ARA-C), is an antimetabolite cytidine analogue used worldwide as key drug in the management of leukaemia. As specified in the manufacturers' instructions, once the components-sterile water and ARA-C powder-are unpackaged and mixed, the solution begins to degrade after 6 hours at room temperature and 12 hours at 4°C.
Aims: To evaluate how to avoid wasting the drug in short-term low dose treatment regimens, the reconstituted samples, stored in the dark at 25° and 4° C, were analyzed every day of the test week by reversed phase *high-performance liquid chromatography* (RP-UHPLC) and high-field nuclear magnetic resonance spectroscopy (^{1}H NMR).
Methods: All the samples remained unchanged for the entire week, which corresponds to the time required to administer the entire commercial drug package during low-dose therapeutic regimens. The drug solution was stored in a glass container at 4 °C in an ordinary freezer and drawn with sterile plastic syringes; during this period, no bacterial or fungal contamination was observed. After one month, the samples presented evidence of a degradation product (0.8% of starting material), identified as 1-(β-D-arabinofuranosyl)-pyrimidine-2,4-(1H,3H)-dione (ARA-U).
Results: Our findings provide evidence of an optimal physico-chemical stability and microbiological sterility of ARA-C solution stored for one week in the dark, at 4°C. This encourages the use of the reconstituted drug for the time required for short-term multi-dose treatments, avoiding drug waste, patient stress and hospital crowding. Moreover, it seems possible to leave in the same container surplus of different ARA-C packages, improving the cost-effectiveness of the treatment without affecting its efficacy and safety. An additional advantage is the fact that patients are able to have the treatment administered at home.
Summary/Conclusions: Our results show that a solution of reconstituted ARA-C could be employed for a longer period that what suggested by the manufacturers. In fact, patients could receive a safe aliquot to be used at home for short-term treatments, thus optimizing the use of aliquot residues and avoiding vial manipulation and the production of special waste material.

COST ANALYSIS OF THE END OF LIFE CARE IN HEMATOLOGICAL MALIGNANCY PATIENTS

M Chiba[1,*], M Kurita[1], S Osawa[1], S Suzuki[2], E Sasai[1], K Sugai[2], S Hagiwara[3]
[1]Department of Nursing, [2]Hospital Information Management Office, [3]Division of Hematology, Internal Medicine, National Center for Global Health and Medicine, Shinjuku, Japan

Background: Most hematological malignancies remain chemo-sensitiveness even in the end stage, unlike solid tumors. Sometimes it is difficult to determine the timing to switch to palliative care. Therefore, aggressive treatments often apply to patients in the end of life (EOL). On the other hand, aggressive EOL care causes deterioration of patients' quality of life, depression among family members, and increase of medical expenses.
Aims: We analyzed the contents of medical treatment and the costs to clarify the issues of aggressive EOL care for patients with hematological malignancies.
Methods: Hematological malignancy patients who died in the hemato-oncology unit of a general acute hospital from September 2010 to August 2015, and as the control group, all patients who discharged alive in the same period were studied. The duration of hospital stay, medical cost, contents of treatment, treatment policy, intervention by palliative care team, disease, and disease status were analyzed. T-test and univariate analysis of variance were used to test the factors associated with the cost using SPSS version 23.
Results: We analyzed 2984 patients who were discharged alive and 164 patients who died in our hospital. In patients who died, the mean age was 65.3 years old, 116 (70.7%) were men. Diseases were 54 (32.9%) with multiple myeloma, 38 with (56.1%) malignant lymphoma, 27 (16.5%) with leukemia, 41 (25.0%) with myelodysplastic syndrome. Twelve (7.3%) were in complete response, 6 (3.7%) in partial response, 19 (11.6%) in stable disease, 105 (60.4%) in progression of disease, and 22 (13.4%) were with newly diagnosed disease. Treatment policies were 95 (57.9%) in aggressive anti-tumor and/or support therapy, 69 (42.1%) in palliative care. In patients who died in the hospital, mean medical cost of last hospitalization was 60,200 euro, and the duration of stay was 63.4 days. Those were significantly higher than the mean cost (14,550 euro, p<0.001) and the duration of hospital stay (23.3 days, p<0.001) of patients who were discharged alive. Though the number of patients who died was only 5% of total number of inpatients, the medical expense accounted for 18.5% of total medical cost in the hematology department. Although, the treatment policy was shifted from aggressive therapy to palliative care in most patients (68% in the last 2 weeks, and 71% in the last week), the medical cost per week increased (p=0.020). The half of the cost in the last 2 weeks was the fee for blood transfusion and antibiotics. In the last 2 weeks, 11 days of blood sugar monitoring, 9 times of blood examination, and 5 times of roentgenological examination was performed per patient. In the last week, intravenous hyperalimentation was given in 50.6% of patients, vasopressors was used in 31.7%, hemodialysis was performed in 8.5%, and 6.9% was admitted to ICU. Analysis using univariate analysis of variance revealed that the significant factors which contributed to saving medical cost were palliative care policy on admission (p=0.020), older age (p<0.001), and patients who have care giver(s) (p=0.048). The intervention by palliative care team did not affect the cost.
Summary/Conclusions: In this study, we clarified that aggressive EOL care was given in the most hematological malignancy patients. Blood transfusion and antibiotics were continued until death. Furthermore, prospective study on the aggressiveness of EOL care and quality of life is needed.

PB2111

AMBULATORY MANAGEMENT OF ANEMIA: A RETROSPECTIVE VIEW FROM AN ITALIAN MULTIDISCIPLINARY TEAM

L Del Corso[1], A bellodi[1], R Ghio[1], N Bardi[1], E Molinari[1], F Puppo[1], P Mangini[2], P Strada[3], S Beltramini[4], MT Van Lint[5], E Arboscello[1,*]
[1]Internal Medicine, Departement of hemato-oncology, irccs-auo san martino-ist, [2]13th Health District ASL3, Genova, [3]Immuno-Hematology and Transfusional Centre, [4]Pharmacy, [5]Hematology and Bone Marrow Transplantation, irccs-auo san martino-ist, Genova, Italy

Background: Anemia is one of the most prevalent clinic condition leading to a specialist medical consult. In 2014 our Internal Medicine unit started a Multidisciplinary Anemia Ambulatory (Internist, Immune-Hematologist, Hematologist) with the purpose to rapidly manage, diagnosis and treatment of anemic pts, giving a direct connection between general practitioners and hospital services.
Aims: Evaluate if Multidisciplinary Anemia Ambulatory and its diagnostic-therapeutic path, with the involvement of different Specialists, resulte in an improvement of the coordination and continuity of care, reducing sanitary cost in terms of hospitalization, drugs rationalization and quality of life for patients.
Methods: Retrospective analysis of 212 patients came to our attention for internist consult due to anemia from January 1st 2014 to January 2015.
Results: A total of 212 patients came to our attention for internist consult due to anemia: 165 female and 47 male, medium age 63,23 years (range 19-100). A precise classification of anemia was determined for 187 pts: 130 had iron deficiency anemia (IDA, 61,32%), 17 multifactorial anemia (inflammatory disorders, chronic kidney disease and combined deficiency, 8,02%), 16 combined deficiency anemia (iron and vitamins, 7,55%), 9 chronic kidney disease related anemia (4,25%), 7 anemia secondary to inflammatory chronic disorder (3,30%), 5 B12 deficiency (2,36%), 2 both folate and B12 deficiency (0,94%), 1 folate deficiency (0,47%). Twenty-five pts were not classified due to lack of data. Severity of anemia was defined according to WHO criteria: 53 pts (25%) presented mild anemia, 123 (58%) moderate anemia, 33 (15,6%) severe anemia.We considered comorbidities of internistic relevance, which could be worsened by anemia: cardiovascular (coronary heart disease, arrhythmias, heart failure), 30 pts; neurologic (ischemic and degenerative diseases), 19 pts; respiratory disease (COPD and asthma), 11 pts.Pts were treated according to clinical practice in relation to

type, severity and clinical manifestation of anemia.130 pts needed more than one access to ambulatory to correct anemia; data from the second access were: pt responders (normalization of Hb levels or improvement of at least 20 g/L): 78 pts; partial responders (improvement of Hb levels from 5 to 20 g/L): 34 pts; non responders: 18 pts. Fourteen pts needed at least 1 blood red cells transfusion, 12 with severe anemia and 2 with moderate anemia. A total of 93 pts needed deep diagnostic insight through specialist pathways, such as hematologic (4 pts), gastroenterologic (39 pts), gynecologic (37 pts), both gastroenterologic and gynecologic (13 pts). All pts were managed as outpatients, except for 8 pts which required hospitalization due to severity of clinical findings: 4 pts were hospitalized.Among IDA pts, 92 were treated with intravenous iron supplement: 32 with sodium ferric gluconate (SFG) (medium 16,68 vials, range 8-43) and 50 with ferric carboxymaltose (FC) (medium 1,04 vials).FC patients fully responded in 76% and 22% were partial responders.
Summary/Conclusions: These preliminary data shows that Multidisciplinary Anemia Ambulatory and its diagnostic-therapeutic path, with the involvement of different Specialists and Operative Unit, resulted in an improvement of the coordination and continuity of care, reducing sanitary cost in terms of hospitalization, drugs rationalization and quality of life for patients. More data will derive from the newborn Anemia Regional Register, which will lead to a better comprehension of the real size of anemia in our local epidemiology.

PB2112

DYNAMICS OF QUALITY OF LIFE IN ANEMIC PATIENTS WITH LYMPHO PROLIFERATIVE DISORDERS TREATED WITH RED BLOOD CELL TRANSFUSIONS AND ERYTHROPOIESIS-STIMULATING AGENTS
N Romanenko[1,*], N Potikhonova[1], S Tiranova[1], A Romanenko[2], M Zenina[1], S Bessmeltsev[1]
[1]Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, [2]Clinikal Neurology, Children Hospital of St. Olga, Saint-Petersburg, SANKT-PETERBURG, Russian Federation

Background: Anemia is a frequent complication of lymphoproliferative disorders (LPD) and antitumor therapy decreasing overall survival rate and Quality of Life (QoL). Anemia's pathogenesis is based on suppression by proinflammatory cytokines, decreasing erythroid precursor's sensitivity to serum erythropoietin and the myelosuppressive effects of chemotherapy. The main methods of anemia's correction are red blood cells transfusions (RBCsT) and using of erythropoiesis-stimulating agents (ESA). Both of them increase hemoglobin concentration and improve QoL. However RBCsT are used in patients with severe anemia and ESA are used to treat mild or middle anemia therefore alteration of QoL after correction may differ.
Aims: The aim of the work was to compare dynamics of QoL in LPD patients during anemia's correction using RBCsT and applying of ESA.
Methods: In this study anemic patients with lymphoproliferative disorders were included. The efficacy of anemia's correction by means RBCsT and applying of ESA was assessed in the base of clinical, laboratory methods and Quality of Life by using the questionnaire FACT-An.
Results: In the first group patients (n=54) with severe or middle anemia with initial Hb concentration of 70.0±1.6 g/l were included. To correct anemia they were prescribed RBCsT. After transfusions (Me=3 Units) the Hb level was increased up to 93.1±1.2 g/l. In the second group patients (n=77) with mild or middle anemia with initial Hb concentration of 88.4±1.4 g/l were included. All these patients were treated with erythropoiesis-stimulating agents. After ESA-therapy a positive response as increase of Hb concentration ≥20 g/l was in 52 (67.5%) out of 77 patients. Herewith the Hb concentration of patients with positive response increased up to 123.1±2.4 g/l. Analysis of dynamics of QoL patients after RBSsT revealed the significant alteration in "Physical well-being", "Emotional well-being", "Functional well-being" and "Anemia" scales. After EPO-therapy significant alteration were revealed in "Physical well-being" and "Anemia" scales. However in comparative analysis of QoL in both groups of patients the maximal improvement was revealed in the scale of "Physical well-being" (in the first group after RBCsT it was from 12.9±0.7 to 11.0±08 points; p<0.001, in the second one after ESA-therapy-from 11.6±0.7 to 9.6±0.7 points; p<0.02) and scale of "Anemia": after RBCsT it was from 41.1±2.0 to 34.2±2.1 points (p<0.001), after ESA-therapy-from 34.5±1.7 to 30.1±1.6 points (p<0.001).
Summary/Conclusions: RBCsT and ESA-therapy may significantly increase the Hb concentration and improve Quality of Life. However QoL of patients after ESA-therapy was better than after RBCsT because Hb concentration was achieved to normal level after applying erythropoiesis-stimulating agents. Nevertheless both methods for anemia correction are effective and ESA-therapy may be prescribed to prolong treatment of anemia after RBCsT.

PB2113

THE TREATMENT- ASSOCIATED SIDE EFFECTS IN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA
AM Gaman[1,2,*], MA Gaman[3]
[1]Pathophysiology, University of Medicine and Pharmacy of Craiova, [2]Hematology, Filantropia City Hospital, Craiova, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, Romania

Background: Idiopathic thrombocytopenic purpura (ITP) is a disease characterized by the presence of antiplatelet antibodies which accelerate platelet destruction and prevent the release of platelets from megakaryocytes, resulting in various types of bleeding. The primary objective of treatment is to prevent bleeding by increasing the platelet count by reducing destruction of antibody-coated platelets (e.g. corticosteroids, immunoglobulins, splenectomy) or by stimulating platelet production (thrombopoietin receptor agonists, TPO-RAs) with the fewest possible side effects associated with treatment.
Aims: To evaluate the side effects associated with treatment and the quality of life in patients with ITP treated with corticosteroids *versus* TPO-RAs.
Methods: We studied 34 patients with ITP hospitalized in the Clinic of Hematology of Craiova (informed consent obtained) in between 2013 and 2015. Twenty-five patients received corticosteroids (prednisone or high dose dexamethasone) as first line therapy and nine patients with refractory or relapsed ITP were treated with eltrombopag (50 mg once daily as initial dose, followed by 25 mg once daily after platelet count ≥150.000/μL). We evaluated the side effects associated with treatment in both groups. We mention that patients treated with eltrombopag did have not hepatitis B/C or HIV infection, severe cardiovascular diseases or risk factors for thrombosis.
Results: Nineteen patients (76%) treated with corticosteroids presented one or more complications: infections (fungal, bacterial, viral) - 10 cases, arterial hypertension - 4 cases, duodenal ulcer hemorrhage - 1 case, dyspepsia - 2 cases, decompensation of diabetes mellitus - 2 cases, hyperglycemia - 3 cases, cataract - 1 case, insomnia - 2 cases, anxiety - 1 case, peripheral edema - 4 cases. Five patients (55%) treated with eltrombopag presented: headache - 1 case, transient increase of alanin aminotransferase - 3 cases, indirect hyperbilirubinemia - 1 case.
Summary/Conclusions: The treatment with eltrombopag was responsible for less side effects (and also less severe) in comparison with the treatment with corticosteroids, and contributed to the improvement of the quality of life in patients with ITP.

PB2114

MANAGEMENT OF MYELODYSPLASTIC SYNDROMES WITH ERYTHROPOIESIS STIMULATING AGENTS (ESAS): A REAL-LIFE EXPERIENCE
C Cerchione[1,*], O Vitagliano[1], AE Pareto[1], M Di Perna[1], G Cerciello[1], I Soriente[2], F Alfinito[1], F Pane[1]
[1]Hematology, Ematologia e trapianto/au federico ii, Napoli, [2]Hematology, Ospedale Umberto I, Nocera Inferiore (SA), Italy

Background: ESAs are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the earlier stage of the disease can delay the need for RBC transfusion, hypothetically by slowing the disease course. It's matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.
Aims: Macrocytosis is one of the cytological hallmarks of dyserithropoiesis in MDS: an analysis of the erythropoietic response to ESAs therapy in a cohort of anemic non trasfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian register, was performed.
Methods: 159 patients, treated with standard-dose ESAs, have been retrospectively analyzed (Table 1). Data analysis was performed, according to IWG 2006 criteria, at the baseline, after 3 and 6 months of continuous treatment, with a subanalysis of the patients according to WHO and R-IPSS risk stratification. ESAs were started at mean Hb concentration of 9.43 g/dl, mean serum EPO concentration: 42 mU/L, after a mean time from diagnosis of 6 months (r.1-118).
Results: Overall response rate (ORR) was 83.6% (133/159), no difference among WHO and IPSS subgroups was found :75.6% achieved response after 3 months of treatment, while other 8% after 6 months. 2 patients with SD (non responders IWG), in which treatment was continued, achieved response after 9 months. In the macrocytic-responders group 85.5% exhibits again macrocytosis after 3 months, while 13% become normocytic. In the normocytic-responders group 91.7% exhibits again normocytosis, while 4/52 (8%) become macrocytic: in these 4 patients after 3 months there was a contemporary worsening in neutropenia and thrombocytopenia, with transfusion-dependence, regarded as first signs of progression of disease. Non responders were 27/159 (16.9%): in the macrocytic-non responders group 89% exhibit again macrocytosis after 3 months, while 11% become normocytic; in the normocytic group 80% exhibits again macrocytosis, while 20% become normocytic (r.1-23).
Summary/Conclusions: These preliminary data can suggest that, in the majority of MDS patients responsive to ESAs, the increase of Hb concentration occurs mainly stimulating erythroid production in MDS clones; in the minority of patients probably it happens recruiting residual polyclonal erythropoiesis. It is interesting to note that stimulating effects of ESAs last even when the expression of dysplasia progresses.

USE OF RADIATION THERAPY FOR THE TREATMENT OF SPLENOMEGALY IN NEOPLASTIC HEMATOLOGICAL DISORDERS
L Diaz[1,*], E Gonzalez[1], A Seguro[2], I Villanego[1], V Diaz[1], A Ureña[3], L Gutierrez[1], C Salas[1], J Jaen[1]

[1]Radiation Oncology, H.U. Puerta del Mar, Cádiz, [2]Radiophysics, H.U Rey Juan Carlos, Móstoles, [3]Radiophysics, H.U. Puerta del Mar, Cádiz, Spain

Background: Splenic irradiation has been used as first treatment for several hematological neoplasms, including chronic leukemia or myeloid malignancies, but with the availability of new drugs its application was restricted.
Aims: In selected cases, not only with palliative intentions, irradiation can be useful treatment modality
Methods: Our study included 13 patients: 5 with chronic lymphocytic leukemia, 6 with high-grade B-cell lymphoma and 2 with diagnose of polycythaemia Vera. In 5 patients the treatment was with radical intention (all of them with high grade lymphoma) and the rest were palliatives as treatment of pain or normalization of red blood cell that allows more time between transfusions. The doses were generally low with range between 5 and 10 Gy in 0.5Gy daily fractions because doses higher than 10Gy did not provide benefits according to literature.
Results: We got 5 complete responses confirmed by PET but after 2 years 2 of them relapsed and were treated with radiotherapy again with the same scheme and obtain the same response to the present day. In terms of palliative intention, splenic irradiation provided a relief of pail from 6 to 12 months, and in 4 patients the disease progressed without new splenic symptoms. One patient received 3 courses of radiotherapy for painful splenomegaly with a gap of 12, 9 and 6 months without acute toxicity and died due to non-splenic leukemia progression.
Summary/Conclusions: In selected patients who are not responsive, not suitable for systemic treatment or palliative, splenic irradiation can be an efficient therapy with little toxicity and sustained response over time. f of pail from 6 to 12 months, and in 4 patients the disease progressed without new splenic symptoms. One patient received 3 courses of radiotherapy for painful splenomegaly with a gap of 12, 9 and 6 months without acute toxicity and died due to non-splenic leukemia progression.

MOLECULAR DIAGNOSIS OF RBC ENZYMOPATHY BY MULTI-GENE TARGET SEQUENCING IN KOREA

DS Lee[1,*], Q Choi[1], SN Park[2], JA Kim[1], KO Im[2]
[1]Dept of Laboratory Medicine, Seoul National University College of Medicine, [2]Department of cancer molecular biology, Cancer Research Institute, Seoul, Korea, Republic Of

Background: RBC enzymopathy occurs due to the intrinsic deficiency or a defect in red blood cell (RBC) enzyme and defective function of RBC enzyme causes hemolysis. Practically, functional analysis of enzymes related to RBC enzymopathy are not available easily. Furthermore, differential diagnosis form paroxysmal nocturnal hemoglobinuria, hemoglobinopathy and congental dyseryhtropoiesis is required.
Aims: We aimed to investigate the frequnecy and patterns of gene mutation relevant to RBC enzyme in Korea.
Methods: We performed targeted sequencing in 15 patients suspected for RBC enzymopathy in whom RBC membranopathy was excluded after laboratory workup. Forty two genes were targeted including 20 genes relevant with enzymopathy and 17 genes relevant with RBC memebranopathy. For the differential diagnosis, Phosphatidylinositol Glycan Anchor Biosynthesis Class A (PIGA gene), 3 thalassemia genes (hemoglobin alpha1, hemoglobin alpha2, hemoglobin beta, and hemoglobin beta), and congenital dyserythropoietic anemia II gene (Sec23 homolog B) were included in target sequencing, additionally. Targeted sequencing of 42 selected genes was performed using IlluminaHiSeq 2500. Putative mutations were analyzed in comparison to normal reference control population.
Results: The mean sequencing depth for the 60 samples was 984X (range 534–1171X). PKLR mutation in 10 patients, ALDOB mutation in 1 patient and G6PD mutation in 1 patients. Of note, gene mutation related to PNH and thalassemia were detected in 2 patients; PIGA mutation in 1 patient and thalassemia alpha point mutation in 1 patient. Among 15 patients, no mutation was detected in 1 patient. Collectively, target sequencing revealed gene mutations related to RBC enzymopathy in 80% and gene mutations other than enzymopathy in 13.3% among 15 patients suspected for enzymopathy in Korea.

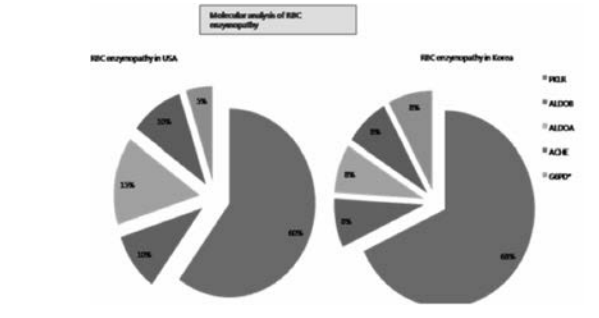

Figure 1.

Summary/Conclusions: Distribution of RBC enzymopathy mutations was similar between USA and Korea. Considering that 13.3% of patients showed gene mutaions unrelevant to RBC enzymopathy, molecular analysis of RBC enzymopathy is necessary for clinical diagnosis.

PB2117

A NOVEL IN-VITRO REVERSAL OF SICKLED ERYTHROCYTES BY COCOS NUCIFERA WATER AND HIGH K+ -ISOTONIC SOLUTIONS

O Ajayi[1,*], D Agbaminoja[2]
[1]Physiology, University of Benin, Benin City, [2]Medical Laboratory Science, Achievers University, Owo, Nigeria

Background: Red cell sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium chloride co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia, but their role in vaso-modulation is less defined. Blocking the potasium leakage has been suggested as a means of inhibiting dehydration and enhancing normal shape of the sickle cells. We investigated the in-vitro effect of various concentration of K^+ ion in physiological solutions (PSS) as well as in cocos nucifera water which is a natural drink known for its natural high potassium content and health benefits.
Aims: This study has therefore been designed to highlight the possibility of reversing the Na^+/K^+-membrane counter-movement in the extra cellular medium and observe the impact on sickled erythrocyte especially in the dehydrated

state using a natural medium with very high potassium but isotonic solution - Cocos nucifera water
Methods: Twenty blood samples from sickle cell anaemia subjects were collected and studied with different high potassium isotonic media. Firstly with Cocos nucifera water (with K^+ of 240mM); erythrocytes sickling test was done, then repeated after incubation with the fluid for 30 mins. Another part was treated with Sodium Metabisulphite ($Na_2S_5O_7$) solution to induce maximum sickling as controls, then later incubated with the fluid. Subsequently, we subjected the samples to different high concentrations of K^+ in Physiological Salt Solution (PSS) (40mM, 80mM, respectively) and their percentage sickling activities were enumerated using a thin blood smear stained with Leishman dye before and after the treatment. Later experiments to study the effects of the Cocos nucifera water on Osmotic fragility of red cells from different haemoglobin protein electrophoresis before and after incubation with coconut water.
Results: The result showwed statistically significant counts of discoid shaped cells in the blood samples incubated with 80mM and Cocos nucifera water ($P<0.05$, respectively) over the native and the sickled- induced samples while the 40mM PSS did not show significant discoid cells over the sickled cells ($P>0.05$). In 80mM K^+PSS, values of (18% against 78%; before and after treatment); Cocos nucifera (22% against 85%; before and after treatment) were obtained. In addition, all the samples treated with cocos nucifera water have significantly reduced osmotic fragilities ($P<0.05$, respectively) irrespective of their haemoglobin protein status.
Summary/Conclusions: High extracellular potassium in an isotonic medium could reverse the membrane permeability to K^+ exflux from the sickled erythrocyte by possibly overwhelming the Na^+/K^+ counter movement across the membrane thereby promoting rehydration through K-Cl cotransporter and ultimately reverses the sickling. The inhibition of Gardos channel is suggested as a possible mechanism in the interim, also cocos nucifera water has shown in this study, the tendency to reduce osmotic pressure lysis of sickle cells and possibly prolong its life span.

ERYTHROBLASTS IN PERIPHERAL BLOOD AS AN OCCASIONAL FINDING IN MULTIPLE SCLEROSIS PATIENTS TREATED WITH NATALIZUMAB
M Piris-Villaespesa[1,*], D Velasco-Rodriguez[1], J Marquet[1], S Lopez-Gonzalez[1], G Pinto-Solano[1], L Costa-Frossard[2], S Sainz de la Maza[2], E Monreal[2], JC Alvarez-Cermeño[2], J Villarrubia[1]
[1]Hematology and Hemotherapy, [2]Neurology, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Natalizumab (NTZ) is a recombinant humanized IgG4 monoclonal antibody directed against the α4 subunit of the α4 β1 (VLA-4) integrin of the lymphocytes. VLA-4 plays a critical role in erythropoiesis and is involved in mobilization of hematopoietic progenitors to peripheral blood. NTZ is used in autoimmune diseases such as multiple sclerosis and Crohn disease, and has been reported to induce CD34+ hematopoietic progenitor cells mobilization and erythroblasthaemia in multiple sclerosis patients.
Aims: To identify and report the presence of erythroblasts in peripheral blood in our cohort of NTZ-treated patients.
Methods: Peripheral blood smears (PBS) of patients treated with NTZ from September 2014 to February 2016 were retrospectively reviewed. PBS were prepared and dyed with May-Grünwald-Giemsa stain and examined by light microscopy by an experienced hematologist. The cohort included 53 patients treated on a monthly basis at different time points.
Results: A total of 82 PBS were reviewed in 53 patients. Fifteen of them (28.3%) showed 1 or more erythroblasts in peripheral blood. Mean time on treatment when PBS was reviewed was 20.5 months (1-74). Mean time on treatment when erythroblastaemia was documented was 14 months (1-71). Once erythroblastemia was described, mean follow up was 10.67 months. No hematologic malignancy was reported in these patients.
Summary/Conclusions: The pressence of erythroblasts in peripheral blood is usually a sign of alarm requiring further investigation since it is generally associated with severe underlying disorders. As previously data support, NTZ is a cause of erythroblastemia and should be taken in consideration in differential diagnosis in cases with erythroblasts in peripheral blood, at any time while on therapy. Knowledge of this frequent side effect is crucial for the correct interpretation of PBS in NTZ-treated patients and to avoid unnecessary diagnostic procedures. Investigation of the mechanisms underlying this effect is needed in order to estimate its repercussion and potential benefits.

PB2119

ROLE OF GENETIC DIAGNOSIS FOR PATIENTS WITH SUSPICION OF THALASSEMIA INTERMEDIATE/MINOR
D Babikyan[1,2,*], A Zakharyan[3]
[1]Medical Genetics, Yerevan State Medical University after Mkhitar Heratsi, [2]Center of Medical Genetics and Primary Health Care, [3]Hematology, Yerevan State Medical University after Mkhitar Heratsi, Yerevan, Armenia

Background: Armenia is situated in the link of Mediterranean and Indo-Mediterranean belts of thalassemia. However, due to the scarcity of information restricted only for very rare reported cases it was traditionally underestimated the need of provision of genetic analysis for thalassemia associated with variable degree of anemia and hematological findings. Our previous results from population screening study suggested rather low carrier frequency however with a higher rate for alpha than for beta thalassemia.
Aims: To provide sound data about the mutation spectrum of alpha and beta globin genes in Armenia and to assess the role of genetic testing for patients with ssuspected clinical phenotype, we carried out the first genetic analysis in a cohort of Armenian patients.
Methods: All 48 sporadic and 11 familial cases of Armenian ethnicity with suspicion of mainly thalassemia intermedia or thalassemia minor had genetic testing for alpha and beta thalassemia genes who have been defined by specific hematological features, mainly by hypochromia, microcytosis, and marked variations in size and shape of the red blood cells and/or suffering from minimal anemia. Screening of 22 beta globin gene and 21 alpha globin gene mutations common for the Mediterranean and Indo-Mediterranean regions was performed using multiplex PCRs of DNA purified from blood samples of affected cases and family members. Further biotinylated amplification products were reverse-hybridized to allele-specific oligonucleotides immobilized on membrane teststrips.
Results: 30 patients were diagnosed as simple heterozygotes for one of the following b^0 or b^+ globin gene mutations (-30 [T>A], cd8 [-AA], cd15 [TGG>TGA], cd44 [-C], IVS2.1 [G>A]) responsible for thalassemia minor or intermedia with specific hematological features. In 2 cases 3.7 alpha single gene and 20.5 alpha double gene deletion were detected, while a compound heterozygous genotype of alpha genes consisting of 20.5 alpha double gene deletion and a1 cd59 [GGC>GAC] (Hb Adana) mutation was detected in one patient. More interestingly, two patients were detected with simple heterozygous beta globin gene mutations (cd8 [-AA] or IVS1.110 [G>A]) with the co-inherited triplicated alpha globin gene rearrangement which indeed developed a clinical phenotype of intermediate beta-thalassemia. All 5 families were detected with alpha or beta globin gene mutations. Particularly, sibs in four families were detected with single b^0-mutations or 20.5 alpha double gene deletion. A proband of another family had compound heterozygous genotype for beta globin mutations (cd8 [-AA]/IVS2.848 [C>A]) and parents were carriers of the beta globin mutations along with anti-3.7 alpha globin gene triplication. 13 patients had no alpha globin neither beta globin gene mutations detected.
Summary/Conclusions: This is the first report of genetic screening of suspected thalassemia cases in Armenia. Despite of former pessimistic view on thalassemia in the country compared to the neighboring countries, 80% detection rate of mutations among symptomatic cases emphasizes the importance of development of genetic screening among patients with suspected phenotype with minor or intermediate thalassemia. Meanwhile, the genetic diagnosis has become possible only after having more differentiated clinical and hematological analysis. Furthermore, the screening data does not reject possibility of detection of other mutations, particularly in patients with no mutation through sequencing analysis which raises the importance of genetic testing. In contrast to the population screening data, beta thalassemia was found more frequent than alpha thalassemia. Further larger screening study is required to better understand and assess the role of mutations identified in heterozygous beta-thalassemia cases and the clinical-molecular relationships, as well as mechanisms leading to clinical and hematological severity in simple heterozygotes.

PB2120

IDENTIFICATION OF CARRIERS OF GENETIC ALTERATIONS IN THE HBB GLOBIN CLUSTER: HEMATIMETRIC AND BIOCHEMICAL DATA IN 462 HETEROZYGOTE INDIVIDUALS
J M Nieto*, M Guijorro, F De La Fuente-Gonzalo, FA Gonzalez, A Villegas, P Ropero, R Martinez
Hematology, Hospital Clinico San Carlos, Madrid, Spain

Background: The β globin cluster (HBB cluster) contains several genes differentially expressed over development. Most common alterations in this cluster are point mutations in the β globin gene (β^o, β^+ or β^{++}-mutations depending on the severity) that produce β thalassemia. Additionally, large deletions of one or more genes can occur in the HBB cluster, leading to *β like* thalassemias (εγδβ, δβ or β thalassemia) or Hereditary Persistence of Fetal Hemoglobin (HPFH). Homozygotes or compound heterozygotes for HBB cluster alterations present variable transfusional requirements, depending on the combination of inherited alterations. In many centers, identification of carriers of these alterations is commonly done at hematimetric and biochemical level. Thus, effective identification of carriers and discrimination between different types of HBB alterations at this level is necessary for an appropriate genetic counseling.
Aims: To describe the hematimetric and biochemical profile of individuals bearing heterozygous alterations in the HBB cluster in order to facilitate their identification.
Methods: Large deletions and β gene point mutations were identified by Multiplex Ligation dependent Probe Amplification (MLPA) and sequencing, respectively. Most common alterations in the HBA globin cluster were assessed with the Alpha-Globin StripAssay. Hematimetric data were obtained with a Coulter LH 750 analyzer. HbF and HbA2 levels were obtained by ion exchange HPLC.

In line with literature, individuals were categorized according to the type of deletion (εγδβº, δβº, HPFH or βº) or point mutation (βº, β^+ or β^{++}) in the HBB cluster. Coinheritance of alterations in the HBA globin cluster was a reason for exclusion. 462 carriers of alterations in the HBB cluster were finally included in the study.
Results: Means and standard deviations for hematimetric data variables, HbF and HbA2 levels for different HBB alterations are summarized in Table 1.

Table 1.

Table 1. Hematimetric and biochemical profile of individuals bearing heterozygous alterations in the HBB cluster.

Genetic alteration	n	Age	IIb (gr/dl)	MCV (fl)	MCH (pg)	RDW (%)	IIbA2 (%)	IIbF (%)

Mean±SD
Key features of each group are presented in bold

Summary/Conclusions: Within deletions, only βº deletions have elevated HbA2 levels (≥3,5%). The main differences between δβ thalassemia and HPFH were HbF levels, MCV and RDW. εγδβ thalassemia cases had variable features in relation to age; severe microcytic anemia was observed in neonates (4 out of 5 required transfusions) and marked microcytosis with mild anemia in *adults*. Many εγδβ thalassemias are caused by de novo deletions, so this condition should be suspected when severe microcytic anemia occurs in neonates, even if there is no history of familiar microcytosis. Roughly, 10% of δβ thalassemias have normal HbF (≤2%) and mimic an α thalassemia phenotype (microcytic and hypocromic red cells, normal HbA2 and HbF levels). When an alpha thalassemia trait is present, elevated RDW (≥16) makes us to suspect that the patient is actually a carrier of a δβº deletion. When a point mutation is present, phenotype aggravates accordingly to β globin production impairment. Generally, these individuals can be easily identified because of elevated HBA2 levels. In conclusion, phenotypes associated with alterations in the HBB cluster are frequently distinctive, although phenotypic overlap can be seen in a subset of cases and molecular analysis may be required.

PB2121

ERYTHROCYTES OF INDIVIDUALS WITH HEMOGLOBIN C TRAIT ARE DENSER AND SMALLER THAN ERYTHROCYTES OF OF INDIVIDUALS WITH HEMOGLOBIN S TRAIT

D Velasco-Rodríguez[1,*], JM Alonso-Domínguez[2], FA González-Fernández[3], J Villarrubia[1], M Tenorio[1], M Sopeña[4], L Abalo[4], P Ropero-Gradilla[3], J Martínez-Nieto[3], F de la Fuente-Gonzalo[3], G Moreno[1], A Jiménez-Martín[1], FJ López-Jiménez[1], F Cava[4]
[1]Hematology, Hospital Ramón y Cajal, [2]Hematology, Fundación Jiménez Díaz, [3]Hematology, Hospital Clínico San Carlos, [4]Hematology, Laboratorio Central de la Comunidad de Madrid BR Salud, Madrid, Spain

Background: Since HbS and HbC are by far the two most prevalent structural hemoglobinopathies in our geographical area, it seems reasonable to develop efficient and rapid tools to discriminate between them in daily practice. Carriers are asymptomatic, and clinicians need to accurately identify them and provide adequate genetic counselling to them in order to prevent the occurrence of homozygous or compound heterozygous offspring.
Aims: The aim of our study was to identify red blood cell (RBC) laboratory parameters of the complete blood count (CBC) that discriminate between HbAS and HbAC individuals.
Methods: The CBC of 355 HbAS and 104 HbAC subjects were run on an Advia 2120 analyser (Siemens Medical Solutions Diagnostics, Tarrytown, New York, USA). All of these Hb variants were detected by HPLC in the HA-8160 analyzer (Menarini Diagnostics, Florence, Italy) and further characterised according to their alkaline and acid electrophoretic pattern using cellulose acetate electrophoresis. Classic hematological parameters and RBC populations of the complete blood count (CBC) were assessed in all subjects. Independent sample t-test was used to compare laboratory parameters between HbAS and HbAC, and receiver operating characteristic (ROC) curves were plotted.
Results: The following parameters were significantly higher in HbAC than in HbAS: RBCs ($5.09x10^{12}$/L *vs* $4.91x10^{12}$/L, p=0.004), Hb (13.97 g/dL *vs* 13.47 g/dL, p=0.017), MCHC (35.35 g/dL *vs* 33.29 g/dL, p<0.001), RDW (15.16% *vs* 14.51%, p=0.002), HDW (2.68% *vs* 2.48%, p=0.001),%MICRO (7.35% *vs* 4.58%, p=0.006),%HYPER (3.04% *vs* 0.82%, p<0.001) and M/H (22.37 *vs* 4.59, p<0.001). The following parameters were significantly higher in HbAS than in HbAC: MCV (82.92 fL *vs* 79.15 fL, p<0.001),%MACRO (0.45% *vs* 0.27%, p=0.033) and%HYPO (4.51% *vs* 1.27%, p<0.001). When only HbAS and HbAC without iron deficiency and α-TT were evaluated, differences remained significant only in MCV, MCHC,%MICRO,%HYPER and M/H (Table 1).%HYPER (AUC=0.842), M/H (AUC=0.839) and MCHC (AUC=0.833) were the most efficient parameters to discriminate between HbAS and HbAC. A cut-off point of 1.15% for%HYPER provided a sensitivity of 79.9% and a specificity of 74.4%. A cut-off point of 34.55 g/dL for MCHC provided a sensitivity of 80.6% and a specificity of 72.1%. A cut-off point of 7.3 for M/H provided a sensitivity of 81.6% and a specificity of 76.7%.
Summary/Conclusions: RBCs of HbAC subjects are denser than HbAS erythrocytes, possibly because the K+:Cl− cotransporter may be more active in HbAC subjects, since lysine (HbC) is more positively charged than valine (HbS), and thus its binding to band 3 may be even further increased. If a patient with a variant Hb not yet identified shows hyperchromia (% HYPER >1.15% and/or MCHC >34.55 g/dL and/or M/H >7.3), the diagnosis is more likely to be HbAC.

PB2122

MUTATIONS FOUND, IN THE PROMOTER REGION OF THE B-GLOBIN GENE, IN ONLY ONE HOSPITAL IN MADRID

P Ropero*, FA González, JM Nieto, F de la Fuente-Gonzalo, A Villegas, R Martínez
Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: The β^+-thalassemia is characterized by reduced production of beta chains, which can be produced by mutations in the promoter area (either the CACCC or TATA box). Depending on the extent of reduction of beta globin chain, the β^+-thalassemia mutations may be classified into mild and silent. Silent β-thalassemia is characterized in the heterozygous state by normal MCV and MCH, normal or more frequently borderline HbA_2, and normal HbF. Globin chain synthesis ratio is only slightly imbalanced, and sometimes even normal. This phenotype may escape detection by the usual methods, so DNA study being necessary for proper identification. Compound heterozygosity of these mutations with a severe mutation always produces very mild thalassemia intermedia. Frequently the diagnosis is made in adulthood or even in the elderly. Mild β-thalassemia mutations are characterized by a residual high β-chain production, show moderate thalassemia-like hematological features and imbalance chain synthesis. This group of molecular defects includes transcriptional mutants in the proximal CACCC box and in the TATA box. Homozygotes or compound hetrozygotes for these mild mutations usually have thalassemia intermedia. So far a total of 37 alterations have been described in the promoter region, some of which are ethnic specific, -87 C>T are common in Mediterranean areas, while -29 A>G and -88 C>T are frequently found in blacks.
Aims: In this report we present a compilation of the mutations found, in the promoter region of the β-globin gene, in only one Hospital in Madrid.
Methods: The hematological parameters were determined with Coulter LH750 Analyzer. HbA_2 and HbF levels, as well as the different hemoglobins, were measured and analyzed by ion-exchange HPLC (VARIANT™ II). Hemoglobins were studied by capillary zone electrophoresis (CE) (Sebia). Genetic analysis of the β and Gγ globin genes was carried out by automatic sequencing and, in the case of α genes, by multiplex PCR.
Results:

Summary/Conclusions: All these mutations show the importance of the promoter region in the β globin genes. Except for the mutation located at the distal CACCC (-101 C>T) that presents a β-thalassemia silent, the rest behaves as a β-thalassemia mild, generally high levels of HbA_2 HbF and being the cause most likely the partial removal of competitiveness to limit transcription factors, facilitating their access to the promoters of both genes as the δ γ genes. Thus,

as seen, any alteration in the CACCC proximal box and the TATA box, cause a moderate decline in the synthesis of the β globin chain, which has been tested both cases of thalassemia intermedia that they made their debut in the second decade of life with a moderate clinical as when associated with a HbS where the disease is mild sickle cell anemia as there is a residual activity of 20% HbA. The identification of such mutations is important for a good genetic counseling that will provide information to individuals and couples at risk (both carriers) in relation to the mode of inheritance, the genetic risk of having affected children and history nature of the disease, including treatment and thus make an informed decision about their reproductive options.

PERFORMANCE EVALUATION OF RETICULOCYTE COUNT ADOPTING NEW CALIBRATOR XN CAL ON THE SYSMEX XN SERIES

HR Kim*, YK Lim
Chung-Ang University College of Medicine, Seoul, Korea, Republic Of

Background: Reticulocyte counts have been known as an accurate index of erythropoietic activity. Currently, automated hematology analyzer could measure the reticulocyte count with increased precision and accuracy. The newly introduced Sysmex XN (Sysmex Corporation, Kobe, Japan) has been introduced calibration of reticulocyte count that was not applied by the previous hematology analyzer XE series.
Aims: to clarify the effect of calibration, we evaluated the performance of reticulocyte counting with the Sysmex XN and XE series.
Methods: The XN-9000 was calibrated with new calibrator XN CAL and total 40 blood samples were analyzed to evaluate accuracy of reticulocyte count. The results from the XN-9000 and previous hematology analyzer (XE-2100) were compared with those obtained by manual reticulocyte count as reference method. The precision profiles of the XN-9000 were also evaluated with quality control materials according to Clinical & Laboratory Standards Institute (CLSI) document EP05-A3.
Results: There were perfectly matched results between the XN-9000 and reference method, however the XE-2100 consistently gave significantly lower values compared with reference method. In precision evaluation, the XN-9000 showed impressively improved precision profiles than those of the XE-2100.
Summary/Conclusions: Our study has shown that correlation between the two instruments are good, but the bias of reticulocyte count significantly exists in the XE-2100, thus the effort of calibrating reticulocyte is critical to minimize instrument-to-instrument difference. By calibrating reticulocyte count, the XN series could provide more accurate results of reticulocyte count, as well as improved precision.

Red blood cells and iron - Clinical

PB2124

EVALUATION OF A MORE EFFECTIVE TREATMENT REGIMEN AND DOSE OF RECOMBINANT HUMAN ERYTHROPOIETIN FOR MEDICATION OF ANEMIA IN PREGNANCY

V Demikhov[1,*], M Ayari[1], E Klimovskaya[2], E Zinovieva[3], I Mirov[2], E Demikhova[1]
[1]Research Clinical Center for Hematology, Oncology and Immunology, [2]Ryazan State Medical University named after I.P.Pavlov, [3]Ryazan Maternity Hospital №1, Ryazan, Russian Federation

Background: There is evidence that pathogenesis of anemia in pregnancy (AP) is multifactorial. It has not relation to ineffective erythropoiesis, caused by iron or folate deficiency only. Blunted erythropoiesis is one of main AP causes. According to our own data inadequately low production of erythropoietin (EPO) for the degree of the anemia found at more 50% of anemic pregnants. That is why recombinant human erythropoietin (rHuEPO) combined with iron is effective method in the therapy of anemic pregnant women, who had been ineffectively treated with iron alone. Because EPO does not cross the placenta, this protects the fetus from its use during pregnancy. Most recent studies show overall the effect of rHuEpo is of clinical benefit in treating of anemia in pregnancy. But there is no standard dose for this medication during pregnancy.
Aims: To carry out the comparative study to identify more effective treatment regimen and dose of rHuEPO for medication of AP.
Methods: Three groups of anemic pregnant women were enrolled. All groups were stratified according to age, gestational aged and initial mean Hb levels at anemic pregnant women. All of them met the following criteria for inclusion in the study: gestational age above 20 weeks, Hb concentration <9.5 g/dl, inefficiency of iron therapy alone for at least 4 weeks, and absence of pregnancy complications, or severe systemic diseases. The treatment protocol comprised a combined therapy with rHu-EPO (epoetin-α) subcutaneously and 200 mg iron sulphate orally daily. We used next regimens of rHuEPO dosing: Group 1 (n=18)-75 IU/kg three times per week (225 IU/kg per week); Group 2 (n=21)-100 IU/kg three times per week (300 IU/kg per week) and Group 3 (n=16)-120 IU/kg two times per week (240 IU/kg per week). We evaluated Hb levels weekly beginning before start of rHuEPO therapy during three weeks at all groups of anemic pregnants. The advance of target Hb level (10.5 g/dl for I trimester and 11.0 g/dl for II trimester) in 2 week of rHuEPO therapy we considered as complete response to the medication. Informed consent was obtained from all patients for being included in the study.
Results: Response to the rHuEPO therapy depended on the regimen of dosing (Table 1). The mean Hb levels, before and in 3 weeks after medication, in group 1 were 8.45±0.28 g/dl and 9.87±0.21 g/dl, in group 2-8.17±0.53 g/dl and 10.52±0.28 g/dl, in group 3-8.16±0.46 g/dl and 9.87±0.28 g/dl respectively (Fig.). We did not observe any serious adverse effects during the therapy with rHu-EPO.

Table 1.

Groups of anemic pregnant women	Regimen of dosing, IU/kg/dose	Weekly dose, IU/kg	The number of treated anemic pregnants with complete response to the medication (effectiveness of rHuEPO therapy) n (%)
1 (n=18)	75 three times per week	225	9 (50%)
2 (n=21)	100 three times per week	300	16 (76.5%)
3 (n=16)	120 two times per week	240	7 (43.8%)

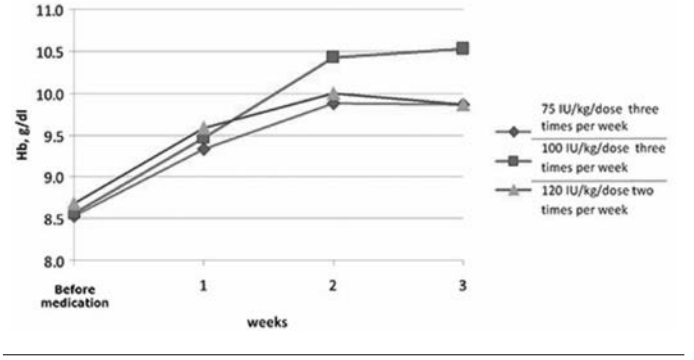

Figure 1. Comparison of hemoglobin trends in groups of anemic pregnant women who treated with different doses of rHuEPO.

Summary/Conclusions: Effectiveness of rHuEPO therapy is dose-dependent. The use of rHu-EPO at dose 100 IU/kg subcutaneously three times per week is more effective treatment regimen for medication of AP.

PB2125

ADENOTONSILLECTOMY IN SICKLE CELL DISEASE: IS TRANSFUSION NEEDED?

M Elshinawy[1,*], N Al Marhoobi[2], Y Wali[3]
[1]Pediatric Hematology, SQUH and Faculty of Medicine, University of Alexandria, Muscat & Alexandria, [2]ENT, Oman Medical Specialty Board, [3]Pediatric Hematology, College of Medicine and Health Sciences, Muscat, Oman

Background: Adenotonsillar hypertrophy in patients with sickle cell disease (SCD) can predispose to several complications including obstructive sleep apnea, vasocclusive crisis (VOC), pulmonary hypertension, and acute chest syndrome. Traditionally, all children with sickle cell disease (SCD) indicated for adenoidectomy and/or tonsillectomy have been exposed to exchange transfusion preoperatively aiming at reduction of both surgical and SCD-related complications.
Aims: To address the need for transfusion in patients with SCD undergoing adenotonsillectomy and to report its risks and benefits.
Methods: All patients with SCD admitted in SQUH for adenotonsillectomy from July 2006 till January 2015 were included in the study. Between 2006 and 2012, patients' files were reviewed for retrospective data recording. After 2012, the study has been prospective.
Results: The current cohort included 70 patients with SCD. They were categorized into three groups. (No transfusion, simple transfusion and exchange transfusion group). Almost 33% of patients with SCD didn't need any preoperative transfusion before surgery (23 out of 70 patients). There was no statistically significant difference between the 3 studied groups as regards the development of surgical or SCD related complication. Development of postoperative vaso-occlusive crisis and acute chest syndrome was comparable in the three groups. As an advantage, there was a markedly significant less blood used in patients given simple top-up transfusion as compared to exchange transfusion group. All results are shown in table 1.

Table 1.

Table (1): Pre- and Post-operative data of the three studied groups:

	Non-transfusion (group 1) n=23	Simple transfusion (group 2) n=33	Exchange transfusion (group 3) n=14	*P* value
Hb (g/dl) Mean± SD Range	8.4 ± 0.36 7.3-11.2	8.1 ± 0.21 6.8 – 9.8	9.7± 1.2 7.5 -12	<0.001 (1 vs 2& 2 vs3)
Hemoglobin S (%)	76.2± 19.2	73.1 ± 21.4	77.8 ± 14.3.3	>0.05
Preoperative transfused PRBCs - Total (ml) - Mean (±SD) - ml/kg	NA NA	6085 (184.4± 105.8) 9.1	12500 (892.9± 446.3) 17.7	0.0001 0.000
Postop. Surgical Complications: -No -Primary Hge -Secondary Hge	21 1 1	28 3 1	14 0 0	0.076
Postoperative Non-surgical Complications: - No -VOC - ACS	20 2 1	30 1 2	12 1 1	0.64

PRBCs: Packed red blood cells, Hb: Hemoglobin, Hge: Hemorrhage, Postop.: Postoperative, VOC: vaso-occlusive crisis, ACS: Acute chest syndrome

Summary/Conclusions: We conclude that it is safe to do adenotonsillectomy in patients with SCD with hemoglobin above 8 g/dl without any transfusion. Exchange transfusion before surgery is not indicated and it does not improve surgical or SCD-related outcome.

PB2126

CARDIAC AND HEPATIC IRON ASSESSMENT BY MR IMAGING IN PATIENTS WITH BETA THALASSEMIA: SINGLE CENTER EXPERIENCE

Z Karakas[1,*], Y Yilmaz[2], S Aydogdu[1], S Karaman[1], M Dursun[3]
[1]Department of Pediatric Hematology and Oncology, [2]Department of Pediatrics, [3]Department of Radiology, Istanbul Medical School, Istanbul, Turkey

Background: Cardiac and hepatic magnetic resonance imaging for iron load becomes more of an issue in patients with thalassemia. The planning of chelation therapy needs more guidance in terms of signs or markers.
Aims: The aim of the study is to assess the relationship between cardiac and hepatic magnetic resonance imaging (MRI) values with serum ferritin level, splenectomy status, and chelation therapy in patients with thalassemia major and intermedia.
Methods: A total of 117 patients (58 male, 59 female) with thalassemia major (n=90) and thalassemia intermedia (n=24) who were followed up in Istanbul Medical Faculty Thalassemia Center were enrolled in the study. Their cardiac and hepatic magnetic resonance imaging was evaluated by specialist radiologist and T2* with R2* values were calculated. The chelation therapy status and splenectomy status of patients was recorded. Patients were divided into three groups according to Cardiac T2* findings: high risk group (T2* MRI <10 ms), medium risk group (T2* MRI 10–20 ms) and low-risk group (T2* MRI >20 ms). The statistical analysis between MRI findings and chelation therapy was performed by SPSS 21 version.
Results: The mean age was 24,77±9,87 years. The mean length of disease was 21,36±10,11 years. Splenectomy was performed in 40 patients. Fifty-four patients used DFX (deferasirox), 13 patients used DFP (deferiprone), 6 patients received DFO (deferoxamine), 2 patients received DFO plus DFX, and one patient was administered DFX plus DFP. The mean level of ferritin was 2093 ±1,97 ng/ml (median 1252 ng/ml). The correlations of ferritin with MR parameters were executed and results were found as following: a weak negative correlation with Cardiac T2* values (p=0,00, r=-0,35), a strong positive correlation with Hepatic R2* and liver iron concentration (p=0,00, r=0,61; p=0,00, r=0,77 respectively). There was also weak positive correlation between ferritin and ALT and AST (p=0,00, r=0,39; p=0,00, r=0,36 respectively). The gender effect on findings was found Hepatic R2* (296,7 *vs* 495,8 Hz) and liver iron concentration (9,6 *vs* 15,8 mg/g) were significantly lower in females (p=0,00). When analyzed according to chelation therapy, there was no significant relationship apart from Hepatic T2* values which were significantly higher in patients receiving DFX (6,7 *vs* 3,9 ms; p=0,04). The ferritin (2291 *vs* 1262 ng/ml) and liver iron concentration (13,8 *vs* 8,7 mg/g) were significantly increased in patients with thalassemia major compared to intermedia group. The ferritin level was significantly decreased from medium risk group to low-risk group (4038 *vs* 1758 ng/ml; p=0,00). The liver iron concentration was significantly decreased from high risk group to low-risk group (21 *vs* 19 and 11 mg/g; p=0,03 and p=0,02 respectively).
Summary/Conclusions: Cardiac T2* and Hepatic R2* were better correlated with ferritin. When combined with negative correlation of ferritin with Cardiac T2* values, it may be supposed that the choice of chelation therapy may be done according to Cardiac T2* and Hepatic R2* results.

PB2127

A INSIDIOUS LINE BETWEEN THALASSEMIA INTERMEDIA AND LEFT VENTRICULAR NON-COMPACTION DISEASE: THE ROLE OF CARDIAC MAGNETIC RESONANCE

A Meloni[1,*], F Macaione[2], A Barison[1], V Positano[1], P Cavalli[3], C Gerardi[4], A Scaccetti[5], C Cosmi[6], MC Resta[7], S Novo[2], P Assennato[2], A Pepe[1]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Università degli Studi di Palermo, Policlinico "Paolo Giaccone", Palermo, [3]Day Hospital di Talassemia, Ospedale "V. Fazzi", Lecce, [4]Presidio Ospedaliero "Giovanni Paolo II" - Distretto AG2 di Sciacca, Sciacca (AG), [5]Servizio Immunematologia e Trasfusionale, Azienda Ospedaliera "S. Maria", Terni, [6]Clinica Pediatrica, Azienda Ospedaliero-Universitaria di Sassari, Sassari, [7]Struttura Complessa di Radiologia, Ospedale "SS. Annunziata" ASL Taranto, Taranto, Italy

Background: Differentiation of left ventricle non-compaction (LVNC) from hypertrabeculated LV due to a negative heart remodeling in thalassemia intermedia (TI) can depend on the selected cardiac magnetic resonance (CMR) criterion.
Aims: We verified whether the diastolic non-compacted to compacted myocardium (NC/C) ratio criterion could actually discriminate the abnormal trabeculations observed in β-TI from LVNC patients and we compared this diagnostic approach with the CMR criterion suggested by Grotoff M *et al.* (Eur Rad 2012), which has been reported to be highly sensitive and specific for the LVNC diagnosis.

Table 1.

Parameter	LVNC (N=20)	β-TI (N=18)	P value
Age (years)	48.19 ± 18.78	42.18 ± 7.20	0.209
Male sex, N (%)	16 (80%)	5 (27.8%)	0.003
LV EDVI (ml/m2)	107.50 ± 29.35	103.12 ± 27.46	0.582
LV ESVI (ml/m2)	54.45 ± 33.71	39.71 ± 12.69	0.222
LV SVI (ml/m2)	52.72 ± 16.81	65.88 ± 16.50	0.040
LV EF (%)	50.30 ± 17.78	61.29 ± 4.87	0.034
LV Mass Index(ml/m2)	90.06 ± 38.77	67.19 ± 12.72	0.093
RV EDVI (ml/m2)	83.15 ± 27.12	92.24 ± 35.27	0.382
RV SVI (ml/m2)	36.45 ± 23.41	36.53 ± 18.46	0.927
RV SVI (ml/m2)	48.00 ± 14.83	53.47 ± 19.79	0.399
RV EF (%)	59.90 ± 14.95	60.65 ± 9.82	0.891
Myocardial fibrosis, N(%)	9 (45%)	3 (16.7%)	0.086

Methods: CMR images were analyzed in 180 patients with β-TI consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network and 20 patients with proved diagnosis LVNC studied at FTGM MRI Lab in Pisa from 2002 to 2014. The CMR diagnostic criteria applied in β-TI patients were: a modified CMR Petersen's criterion proposed by Piga et al (Am J Haem 2012) based on a more restrictive ratio of diastolic NC/C >2.5 at a segmental level and the Grothoff's criteria (percentage of trabeculated left ventricular myocardial mass (LV-MM) ≥25% of global LV mass and a total LV-MMI NC ≥15 g/m2). In

the 20 patients with LVNC the final diagnosis was performed based on Grotoff's criteria and on the clinical/functional criteria for LVNC to further increase the pre-test probability of the disease.
Results: In β-TI patients at least 1 positive NC/C segment was found in 18 patients (10%). Compared with LVNC patients, in 18 β-TI patients the non-compaction areas were less frequent (3.70±2.22 *vs* 1.62±1.16; P=0.007). The LV-MM NC percentage and LV-MMI NC g/m2 were significantly higher in LVNC than in β-TI patients 27.21±2.45% *vs* 10.88±3.96%, P<0.001; 20.35±5.60% vs.7.30±4.77%, P<0.001). None of the β-TI patients fulfilled the Grothoff's criteria. The table shows the comparison of CMR parameters. LVNC patients had significant lower LV stroke volume index and LV ejection fraction and they had an higher frequency of myocardial fibrosis detected by the LGE technique, although the statistical significance was not reached.
Summary/Conclusions: Differentiation of LVNC from hypertrabeculated LV in β-TI patients due to a negative heart remodeling depends on the selected CMR criterion. Based on our data in all β-TI patients with a NC/C ratio >2.5 we suggest to use Grothoff's criteria to improve the specificity of the diagnosis of LVNC.

PB2128

GENOTYPE/PHENOTYPE PATTERN IN EGYPTIAN PATIENTS WITH SICKLE CELL DISEASE

AA Tantawy[1,*], NH Elsherif[1], TM Kamal[2], CA Kirolos[1]
[1]Pediatric Hematology & Oncology, [2]Molecular Genetcs, Ain Shams University, Cairo, Egypt

Background: Sickle cell disease (SCD) refers to all different genotypes that cause this clinical syndrome, yet secondary effectors genes are likely to modulate its phenotype.
Aims: This study aimed to evaluate genotype variation and allele segregation among SCD patients and its relation to the different clinical presentations.
Methods: This cross-sectional study included 38 SCD patients. Genotyping for beta thalassemia gene(BT) mutations was performed using polymerase chain reaction (PCR) and reverse hybridization. Assessment of genotype relation to phenotype was based on: Onset of the disease, transfusion history, baseline MCV, HbF%, frequency of pain episodes, and hospitalization, percentage of patients who suffered from acute chest syndrome, stroke and avascular necrosis, sickling score, echocardiographic, carotid doppler findings.
Results: The most common BT gene mutation among SCD patients was Codon 6[A>T] HbS/β^0 IVS1-1[G>A] (18%), then Codon 6[A>T] HbS/β+ IVS1-110[G>A] (8%). 55% of the patients were diagnosed by baseline Hb electrophoresis as Sβ+. Only 52% of sickle cell disease patients by genotype had MVC normal and 72% had HbA2 <3.6%. Eighty eight% of $S\beta^{0}$patients by genotype had low MCV, while half of Sβ +patients had HbA2 >5%. Although, we found a higher baseline Hb S% and a lower Hb F% among homozygous sickle cell patients compared with the 2 other groups, yet the results did not reach statistical significance Homozygous SCD patients had a significantly earlier age of onset, a higher baseline MCV and a lower HbF% compared with $S\beta^0$ and $S\beta^+$ patients, but a comparable baseline markers of hemolysis. Eighty percent of our studied Sickle cell patients had acute painful episodes, 18% suffered from at least one attack of acute chest syndrome, 5.3% had avascular necrosis of femur 15.8% had single episode of stroke while 6% had cardiac morbidity, 13% had impaired left ventricular contractility, (8%) had cardiomyopathy, none had pulmonary hypertension, and all had normal transcranial Doppler. We did not find significant difference between all 3 groups as regard the frequency of painful Crises, the need for hospitalization, the percentage of patients with avascular necrosis, cerebral stroke, acute Chest Syndrome and the sickling score. Causes for transfusion varied among different groups, the most common cause in homozygous sickle cell disease and sickle β^0 patients was painful crises and stroke (36%&20%), while in sickle β^+ thalassemia patients, the only cause was anemia(100%).This variation was not statistically significant, and all 3 groups had comparable mean pretransfusion Hb level, number of transfusion, transfusion requirement. Moreover, we did not find significant difference between the three groups as regard number of patients on Hydroxyurea treatment (76% among homozygous sickle cell patients, 67% among $S\beta^0$ and 75% among $S\beta^+$patients.
Summary/Conclusions: the presence and the nature of associated β-thalassaemia mutations influences the clinical presentation of sickle cell disease.

PB2129

DETECTING THE PREVALENCE AND AWARENESS OF CARRIER RATE OF THALASSEMIA IN A COHORT OF UNIVERSITY STUDENT POPULATION IN SRI LANKA

D Gunawardena[1,*], N Wasana[2], P Hearth[3]
[1]Haematology, [2]Allied Health Sciences, University of Sri Jayawardenapura, [3]Haematology, Medical Research Institute, Colombo, Sri Lanka

Background: The thalassemias are a group of autosomal recessive disorders caused by a reduction or absent production of one or more of the globin chains that make up the haemoglobin tetramers. Two main types, α and β thalassemias are seen according to the type of globin chain involved, and there are other types although not common such as δβ γδβ thalassemias which are identified. Thalassemias pose an increasing health problem for the Indian subcontinent and many Asian countries. Worldwide 56,000 conceptions have a thalassemia major of which approximately 30,000 are affected by β-thalassemia major and 3500 succumb to hydrops fetalis syndrome. Most of these patients are born in developing and low income countries where they create an enormous health burden. There is a significant increment of thalassemia carrier rate in Sri Lanka, probably an unestimated increment in alpha thalassemia. The increment of the number of patients with thalassemia form 2,094 in the year 2005 to 4,924 by the year 2010 in Sri Lanka is a major concern where further attention is necessary in investigating in to the failure of the general understanding and counselling the of thalassemia carriers. An analytical cross sectional study was done on 384 undergraduates in University of Sri Jayewardenepura, Sri Lanka during year 2015. Objective of this study was to determine the prevalence and awareness of thalassemia trait among the students of University of Sri Jayewardenepura.
Aims: Aim is to screen the university student population who are the next generation to be married and a potential group of the population where effective screening and genetic counseling for thalassemia can be done. This university represents students from all parts of the country and hence a cross section of the country is represented.
Methods: Venous blood was obtained from the students from the four faculties and pre tested self-administered questionnaire was used to gather information regarding awareness about thalassemia trait among the participants. Samples were analyzed by the fully automated hematology analyzer Sysmex SX 500i. The initial diagnosis of thalassemia carrier was done by using red cell indices of the analyzer report combined with the blood picture reported by the consultant haematologist. Final confirmation was done by quantifying the HbA2 levels by HPLC. (High Performance Liquid Chromatography)
Results: Of the 384 blood samples tested, 53 (13.8%) had hypochromic microcytic red cell indices (MCV <80 fL, MCH <27 pg) with normal iron studies. Fifteen students (3.9%) were possible alpha thalassemia carriers where they showed thalassemia indices with normal iron profile and HPLC (A2 levels <3.5%) with the blood picture showing typical changes of thalassemia carrier. Eleven students (2.9%) were carriers of beta thalassemia. Out of 384, twenty seven students (7%) showed a haemoglobin level between 7-11.5g/dl with no obvious thalassemia indices or blood pictures finding of thalassemia and they had low serum ferritin levels. Out of 384 questionnaires, only two hundred and twenty two (77.6%) were aware of thalassemia major and out of them, only hundred and sixty five (88.7%) knew that pre- marital screening could prevent thalassemia. This knowledge was mainly obtained by news items and television.
Summary/Conclusions: The awareness of thalassemia in the cohort of students tested was not satisfactory and it highlights the importance of introducing methods to improve their basic knowledge of the disease. This also detected the Beta thalassemia carrier rate to be 2.9% which are compatible with the results of the studies done previously on thalassemia in Sri Lanka, however there seems to be a trend in higher levels of suspected alpha thalassemia rate which was found to be 3.9% which needs attention. These need to be confirmed by genetic studies which are financially difficult in the current set up. An incidental finding of anaemia of 27 students was important in a young university student population who are the future workforce of the country. This study highlights the importance of continuing the screening campaigns specially the student screening programmes, pre-marital counseling and new born screening service that are of paramount importance in reducing the births of thalassemia major.

PB2130

REFRACTORY AUTOIMMUNE HAEMOLYTIC ANEMIA IN ELDERLY EFFECTIVELY TREATED WITH MYCOPHENOLATE MOFETIL

G Karras[1], M Alexandrakis[2], E Georgiadi[1], C Doxani[1], E Rouka[1,*], D Kyriakou[1]
[1]Laboratory of Hematology and Transfusion Medicine, University Hospital of Larisa, Larisa, [2]Hematology Department, University Hospital of Heraklion, Heraklion, Greece

Background: Autoimmune haemolytic anemia (AIH) is a rare disorder that sometimes may be lifethreatening. The treatment is not evidence based and corticosteroids, azathioprine, cyclophosphamide, rituximab, and mycophenolate mofetil have been used effectively although there is not enough evidence for the effectiveness and safety of the later one.
Aims: We present here 7 patients with AIH that were treated effectively with mycophenolate mofetil.
Methods: Seven patients, 6 males and 1 female aged 75-82 years were refered to our department diagnosed with autoimmune haemolytic anaemia 12 to 60 months ago. Three patients had received corticosteroids, azathioprine cyclophosphamide and rituximab without gaining a PR or better and without obtaining stable condition maintaining Hb levels about 9g/dl. Two patients obtained PR with costicosteroids and rituximab but relapsed within 6 months and could not get rid of the drugs for more than 4 months. The remaining 2 were on contineous corticosteroid treatment and occasionally rituximab for more than 4 years maintaining hemoglobin levels between 8 and 10 g/dl. All

the patients started mycophenolate mofetin for 3 months and corticosteroid tapering thereafter.
Results: Within 6 months 6 patients reached normal levels of haemoglobin and reduced DAT titer to equal or less than half. They continued the drug for 26-36 months when DAT was negative and remained in remmision for 15-22 months without any drug. The 7th patient continues taking mycophenolate for 5 years with haematological remission (Hb=14g/dl) but DAT (+). All the patients tolerated the drug very well without major adverse events. Lymphocytopenia grade 2 and hypoglobulinaemia grade was a common condition in all patients without infections. The 7th patient was prophylactically indroduced to antiviral therapy as well as to cotrimoxazol/azathioprine.
Summary/Conclusions: Mycophenolate mofetil is an effective and well-tolerated drug in elderly patients with haemolytic anemia refractory to conventional therapies.

PB2131

DIFFERENTIAL IRON STATUS AND TRAFFICKING IN BLOOD AND PLACENTA OF ANEMIC AND NON-ANEMIC PRIMIGRAVIDA SUPPLEMENTED WITH DAILY AND WEEKLY IRON FOLIC ACID TABLETS

H Shankar[1,2,3,*], N Kumar[4], R Sandhir[2], S Pandey[5], S Singh[5], D Rao[3]
[1]Epidemiology and Clinical Research, National Institute of Malaria Research, New Delhi, [2]Biochemistry, Panjab University, Chandigarh, [3]Biochemistry, All India Institute of Medical Sciences, [4]Reproductive Child Health, Indian Council of Medical Research, New Delhi, [5]Radiation Biosciences, Institute of Nuclear Medicine & Allied Sciences, Delhi, India

Background: Iron deficiency (ID) globally impact billions of people; mostly pregnant women. Anemia during pregnancy is mainly associated with ID; and prophylaxis includes daily supplementation of iron folic acid (IFA) tablets. During pregnancy, increased foetal iron demand leads to fluctuations in body iron reserves; thus supplemental iron is recommended to meet the iron demand. The effectiveness of weekly IFA supplementation in comparison to daily IFA intake during pregnancy is still shadowy, as the available data from well-defined clinical trials is inconsistent. The amount of quantifiable iron circulating in blood and stored in placenta, in both the supplementation schemes and their correlation with pregnancy outcomes is pre-requisite to reach any firm conclusion. Owing to this, the present study was conducted to providing better understanding of hemodynamics and molecular mechanism in human placental iron transfer.
Aims: To investigate the iron dynamics in anemic and healthy pregnant women supplemented with daily and weekly IFA supplementation and its relation with clinical outcome.
Methods: The subjects include non-anemic primigravida (NAP) (Hemoglobin (Hb) >11 g/ dl, N= 60) and anemic primigravida (AP) (8.0 <Hb <11 g/ dl, N=60) were followed across pregnancy at three time-points *i.e.* baseline (13-16 weeks of gestation), after three months (25-28 weeks) and 6 weeks postpartum. The subjects (NAP and AP) were randomly allocated to daily dose comprised 100 mg iron and 500 µg folic acid tablets and weekly dose contained two IFA tablets/ week till six weeks postpartum. Corresponding changes in hematological markers, iron status indicators viz. ferritin, iron and soluble transferrin receptor (sTfR) in blood and placental ferritin expression was studied. Birth outcome, gestational length, infant weight and placental weight were recorded. The statistical significance level ($p < 0.05$) between the groups were assessed by applying unpaired t-test using SPSS (version 20.0).
Results: Weekly IFA supplementation for three months has significantly altered the Hb, hematocrit and red blood cell (RBC) count ($p<0.05$) and increased the level of serum sTfR ($p<0.002$) at postpartum in AP. After three months of supplementation, serum iron and sTfR were significantly different ($p<0.01$) between the two supplemental groups in NAP; whereas, serum ferritin ($p<0.001$) was significantly high at postpartum in daily IFA group of NAP. Placental ferritin expression was increased in NAP supplemented with daily IFA in comparison to weekly IFA. The placentas obtained from AP supplemented with weekly IFA showed significantly low ferritin ($p<0.05$) expression when compared with daily IFA supplementation. However, birth outcome, infant weight, gestational length and placental weight were comparable in both the supplementation groups.
Summary/Conclusions: The placental ferritin expression and its serum level showed similar trend among anemic and non-anemic primigravidas supplemented with daily and weekly IFA tablets. Although, significantly lower placental ferritin was observed in AP supplemented with weekly IFA tablets; but there was not any difference in birth outcome, infant weight or gestational length between two supplementation groups. The modulation in iron transporter expression may be involved in anemic placentas to flux iron for developing fetus, thereby maintaining the healthy pregnancy. The results of this study revealed that blood iron status/ hematological markers may be helpful to assess the optimum amount of supplemental iron required during pregnancy.

PB2132

THE USE OF NEW ANTIVIRAL DRUGS FOR THE TREATMENT OF HEPATITIS C VIRUS (HCV) INFECTION IN PATIENTS WITH THALASSAEMIA: PRELIMINARY DATA ON SAFETY AND EFFICACY

P Ricchi[1,*], A Spasiano[2], S Costantini[2], P Cinque[2], B Ziello[2], M Caputo[3], E Assentato[3], A Lanza[4], A Filosa[2]
[1]AORN Cardarelli, Naples, Italy, [2]Oncoematologia, [3]Biologia Molecolare di Virologia Immunodiagnostica dei Trapianti, [4]Gastroenterologia, AORN Cardarelli, Naples, Italy

Background: Several adult patients with thalassaemia major (TM) and talassaemia intermedia (TI) following the failure of combination therapy with pegylated interferon (PEG-IFN) and ribavirin are still affected by Hepatitis C virus (HCV) infection and need to be treated with new antiviral drug. To date, no data are available on interaction between chelation treatment and new antiviral drugs.
Aims: Here we report our preliminary data on their efficacy and safety during different chelation treatments on the first four weeks of antiviral therapy.
Methods: Since December 2015, 17 patients with TM, 2 with TI, 2 with sickle cell/thalassaemia were considered for treatment. Twelve received Ledipasvir-Sofosbuvir, 7 Ledipasvir-Sofosbuvir-ribavirin, 1 sofosbuvir-ribavirin, one daclatasvir-sofosbuvir. All patients but three, were and continued to be under chelation treatment: five were under deferasirox (DFX), 3 under deferiprone (DFP), 2 under desferioxamine (DFO), 6 under alternate DFO/DFP, 1 under DFO and DFX combined treatment. During the first four weeks of therapy all patients had weekly monitoring of serum ferritin, liver enzymes, creatinin level, complete blood count and biweekly monitoring HCV RNA copies.
Results: All treatments were very well tolerated; patients receiving ribavirin still not presented significant increase in blood transfusion requirements. Following one week of treatment liver enzyme decreased significantly from baseline: mean±SD alanine transaminase (ALT) and aspartate transaminase (AST) decreased from 103±127 to 35±U/L ($p=0.03$) and from 83±85 to 33±27 ($p=0.02$) U/L, respectively; mean±SD ferritin level and HCV RNA copies decreased from 1556±1436 to 1334±1355 ng/ml ($p=0.68$) and from 1,650000±1472378 to 0 copies/ml ($p=0.000014$). A further decline was observed at fourth weeks in mean (± SD) ALT, AST and ferritin level which dropped to 28±29 U/L ($p=0.02$), 30±20 U/L($p=0.01$) and 1058±1011 ng/ml ($p=0.26$), respectively. No increase in glomerural filtration rate (GFR) and impairment in urinary albumin/creatinine ratio were observed among patients treated with DFX with respect to basal level. No event of neutropenia and agranulocytosis neither reduction in neutrophil count with respect to basal level occurred among patients treated with DFP
Summary/Conclusions: All treatments were effective in promptly drop viral copying. The observed reduction in ferritin level is likely linked to reduced hepatic lysis and shouldn't be used to modify chelation therapy. Our opening data show that chelation treatment is feasible and safe. The termination of treatments and further studies on larger population are needed to confirm these preliminary observations.

PB2133

CMR FOR MYOCARDIAL IRON OVERLOAD ASSESSMENT: CALIBRATION CURVE FROM THE MIOT PROJECT

A Meloni[1,*], V Positano[1], D De Marchi[1], A Maggio[2], A Quarta[3], MP Smacchia[4], D D'Ascola[5], M Missere[6], C Tudisca[7], A Pepe[1]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ematologia II con Talassemia, Ospedale "V. Cervello", Palermo, [3]Ematologia, Ospedale "A. Perrino", Brindisi, [4]Unità Operativa Complessa di ImmunoEmatologia, Policlinico Umberto 1, Roma, [5]Centro Microcitemie, Azienda Ospedaliera "Bianchi-Melacrino-Morelli", Reggio Calabria, [6]Dipartimento di Immagini, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, [7]Sezione di Scienze Radiologiche - Dipartimento di Biopatologia e Biotecnologie Mediche, Policlinico "Paolo Giaccone", Palermo, Italy

Background: The measurement of myocardial iron by T2* cardiovascular magnetic resonance (CMR) has been established as fundamental to the best practice management of thalassemia. However, iron calibration data in humans is limited and CMR calibration varies according to instrumentation and technique.
Aims: The aim of this study was to calibrate the T2*-CMR technique for non-invasive cardiac iron assessment, by considering a segmental approach.

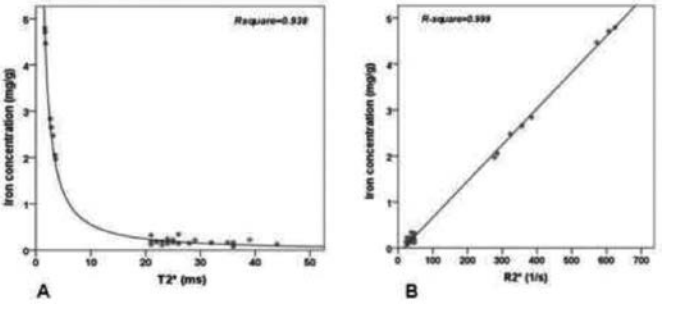

Figure 1.

Methods: Four human hearts were studied from transfusion-dependent

patients after their death within the MIOT network (Myocardial Iron Overload in Thalassemia). A multislice multiecho T2* approach was adopted. After CMR, used as guidance, the heart was cut in three short-axis slice and each slice was cut into different equiangular segments, the same ones in which the T2* was assessed. Tissue iron concentration in the segments was measured with inductively coupled plasma atomic emission spectroscopy.
Results: T2* and iron concentration were overall assessed in 36 myocardial segments: 6 in the first heart (year 2004), 6 in the second one (year 2004), 8 in the third one (year 2005), and 16 in the fourth one (year 2010), Figure 1A shows the segmental iron concentration (in milligrams per gram dry weight) plotted *versus* the correspondent segmental T2* value (in milliseconds). As expected, the relationship was not linear. In Figure 1B the R2* values (R2*=1000/T2*, in s^{-1}) were considered. Regression analysis yielded a linear calibration of the following form: $[Fe]_{R2^*}$=0.0079xR2*-0.1262 (R-square=0.999).
Summary/Conclusions: As in the only previously proposed calibration curve by Carpenter et al (Circulation 2011), we did not collected hearts with an intermediate iron burden. We found an excellent linear agreement between R2* and cardiac iron with a model similar to the calibration curve in the gerbil showed by Wood J et al (Circulation 2005). The results further validate the current clinical practice of monitoring cardiac iron *in vivo* by CMR.

PB2134

REDUCED INSULIN NEED IN PATIENTS WITH TYPE 2 DIABETES MELLITUS (T2DM)WITH IRON DEFICIENCY ANEMIA THREATED WITH SUCROSOMIAL IRON VS INTRAVENOUS SODIUM FERRIGLUCONATE. MULTICENTRIC PROSPECTIVE STUDY
G Giordano[1,*], A Parente[2], R Gigli[3], M Magri[1], G Berardi[4], B Carabellese[5], F D'Amico[2], L Luciano[2], R Fratangelo[2], G Niro[3], A Licianci[6], L Di Marzio[6], M Gasperi[7]
[1]medicine, Regional Hospital "A. Cardarelli", [2]molise university, [3]laboratory medicine, Regional Hospital "A. Cardarelli", [4]general medicine, asrem molise, [5]nuclear medicine, [6]hospital management, Regional Hospital "A. Cardarelli", [7]endocrinology, molise university, Campobasso, Italy

Background: About one out of four diabetic patient shows iron deficiency anemia. I.v. sodium ferrigluconate is frequently used as iron deficiency anemia therapy. The sucrosomial iron is a new compound used in the therapy, made of sucrose ester containing liposomal iron. Sodium ferrigluconate increases the amount of free radicals. The increase of free radicals increases inflammation. Inflammation reduces insulin sensitivity in diabetic patients.
Aims: To assess whether the use of sucrosomial iron involves less use of insulin in patients with T2DM with iron deficiency anemia
Methods: This study is a multicentric randomized study. We considered 40 T2DM patients with iron deficiency anemia, with TIBC saturation <10% and hemoglobin <10 g/dl, without documented infections, tumors or autoimmune diseases. All patients received diabetic diet. They received lispro insulin TID + glargine insulin once daily. In group A 20 patients, M: F=12/8, median age 75 years (R65-82), median blood glucose 230 mg/dl (R170-350), median CRP at onset 10 mm/lh (R2-22), were treated with sodium ferrigluconate 62.5 mg in 250 cc NS ic iv in 4 hours/day for 12 days. In group A, 10 patients had anemia by gastrointestinal hemorrhage, 5 by atrophic gastritis, 5 by insufficient intake. In group B, 20 patients, M: F=11/9, median age 78 years (R67-83), median blood glucose 220 mg/dl (R180-380), median CRP at onset 12 mm/lh (R2-20), were treated with sucrosomial iron 1CP 30 mg orallyx2/day for 30 days. In group B, 12 patients had anemia by gastrointestinal hemorrhage, 4 by atrophic gastritis, 4 by insufficient intake. Differences between the two groups were not statistically significant. Statistical analysis was done with Fisher exact test and with Chi Square test.
Results: In group A at day 6 of iron support the median values of CRP were 38 mm/lh (R4-127), with 5-documented infections (urinary 3, lung 1, skin 1); only 8 patients achieved blood glucose values <or=140 mg/dl with a median total lispro insulin dose of 42 U(R25-60) and glargine insulin dose of 22U (R10-28). In group B at day 6 of iron support the median values of CRP were 12 mm/lh (R2-12), with 2-documented infections (urinary 2); 15 patients achieved blood glucose values <or=140 mg/dl with a median total lispro insulin dose of 20 U(R12-23) and glargine insulin dose of 20U (R10-22).
Summary/Conclusions: In diabetic patients with iron deficiency anemia supported with sucrosomial iron the median lispro insulin need appears to be lower than that of the patients supported with i.v. sodium ferrigluconate. This study needs confirmation on a larger cohort of patients.

PB2135

HYPERFERRITINEMIA: CLINICAL COURSE AND THERAPEUTIC STRATEGY
V Papadopoulos[1,*], S Effraimidou[1], E Sevdali[2], E Papadakis[1], M Topalidou[1], K Kokoviadou[1], A Banti[1], M Speletas[2], A Kioumi[1]
[1]Hematology Department, Papageorgiou General Hospital, Thessaloniki, [2]Department of Immunology & Histocompatibility, School of Health Sciences, Faculty of Medicine, University Hospital of Larissa, University of Thessaly, Larissa, Greece

Background: Hyperferritinemia is a common laboratory finding, which requires assessment of iron status and investigation for underlying disorders, such as hereditary hemochromatosis, inflammatory and malignant conditions. True iron overload is found in approximately 10% of patients presenting with hyperferritinemia (Adams & Barton. Journal of Hepatology 2011;453-8). Although research of the last decades has given insight into new molecules and mutations and their role in iron homeostasis, the clinical consequences of all these mutations are not straighforward, and there are still cases of hyperferritinemia with no underlying cause identified.
Aims: Objective of the study is to assess the clinical course of patients with hyperferritinemia and the therapeutic manoeuvres performed.
Methods: Data was collected retrospectively for 17 patients with hyperferritinemia, followed up for a mean of 5.75 years. They were negative for classic HFE mutations (C282Y homozygosity, C282Y/H63D compound heterozygosity) and had no underlying malignancy, inflammation or alcohol abuse. Hepatic iron was assessed with MRI T2* or liver biopsy. The decision to propose therapeutic phlebotomy was based on presence of iron overload, eligibility for blood donation and patient preferences.
Results: Seven patients were heterozygous for ferroportin (FPN) R178Q mutation. At diagnosis their mean serum ferritin level (SF) was 2,017ng/ml (range 800-5077) and trasferrin saturation (TS) was normal. Three patients with moderate iron overload were offered regular phlebotomies once per month; iron overload was diminished, while SF did not change significantly. In the maintainance phase, phlebotomies were performed once in 3 months, and interrupted during pregnancy and puerperium. Patients without iron overload were encouraged to become blood donors. Seven patients, albeit negative for tested HFE and ferroportin mutations, had mild to moderate hepatic iron accumulation, with mean SF at 880ng/ml (range 435-1351); three of them had elevated TS, that is over 45%, and two had fatty liver on imaging studies. Venesections were performed to all of them, once in 1-2months initially and then every 3-6 months. Iron accumulation and SF were reduced even down to normal ranges; venesections were well tolerated at the aforementioned frequency. A patient homozygous for HFE-H63D mutation, with high SF and high TS, had no iron overload; SF was reduced without any intervention during the follow-up. A teenage girl with ferroportin polymorphism had isolated hyperferritinemia without iron overload nor high TS, which remained so after 8 years. A patient with hyperferritinemia, high TS and catarract, was tested positive for the light ferritin 5'-UTR iron response element (L-FT IRE) mutation, which has been identified in the so-called 'hereditary hyperferritinemia-catarract syndrome'. No iron overload was detected at diagnosis and after 5 years of follow-up. These changes of SF and TS from baseline values are depicted in the figure (blue lines: FPN heterozygotes, orange lines[wt]:no mutation identified).

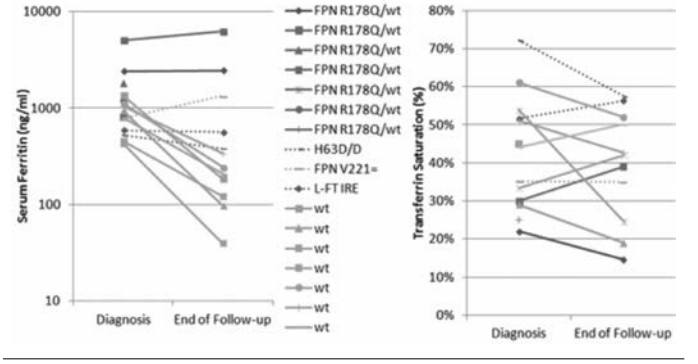

Figure 1.

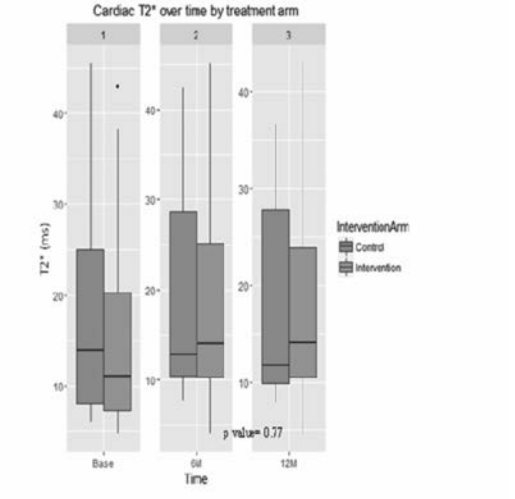
Summary/Conclusions: In all of the described cases, a benign course of the patients with hyperferritinemia is evident. Even in the cases with moderate hepatic iron overload, a less stringent phlebotomies program (once per 1-2 months, compared to higher frequency of weekly venesections, recommended for classic and juvenile hereditary hemochromatosis types by European Association for the Study of the Liver, Journal of Hepatology 2010;53:3–22) seems to provide satisfactory response, removing excess iron from tissues and being very well tolerated. This proposal could be incorporated into prospective trials, in order for clear evidence-based guidelines to be developed in the future.

PB2136

EFFECT OF L-TYPE CALCIUM CHANNEL BLOCKER (AMLODIPINE) ON MYOCARDIAL IRON DEPOSITION IN PATIENTS WITH THALASSEMIA MAJOR: A RANDOMIZED CONTROL TRIAL
N Alvi[1,*], F Tipoo[1], A Rizvi[1], Z Fadoo[1], A Imran[1], A Sadaf[1], A Shakoor[1], F Quadri[1], Z Sajjad[1], M Khurshid[1], U Fatima[1], S Ashiqali[1], S Colan[2], B Hasan[1]
[1]Aga Khan University, Karachi, Pakistan, [2]Boston Children's, Boston, United States

Background: Sideroblastic cardiomyopathy is a feared complication in Thalassemia Major (TM). Recent evidence suggests a role for L-type-Ca^{2+}-chan-

nels (LTCC), in addition to standard chelation therapy, in mediating myocardial iron-uptake.
Aims: Our primary objective was to determine the efficacy of Amlodipine in reducing myocardial iron-load when compared to controls. Changes in echocardiographic derived LV function, liver T2* and iron-content were also sought.
Methods: Participants managed for over a year with a transfusion need of ≥180 ml/kg/year, having received ≥10 blood transfusions in life-time and with serum ferritin ≥1000 ng/dL were invited. All patients with known hypersensitivity to amlodipine, history of developing tetany with calcium channel blockers or systolic blood pressures ≤ 2 SD for age at baseline and pre-existing cardiac conditions were excluded. Twenty patients in a 1:1 allocation ratio were randomized into the intervention and control arms. Conventional echocardiographic measures, global longitudinal strain (GLS), T2* CMR and liver T2* were obtained at baseline, 6 and 12 months. Continuous and categorical variables were reported as mean (SD and CI)/median (IQR) and frequency/percent respectively. Mann-Whitney U test and Fisher exact test were used. Change in outcomes with respect to time and treatment were tested using repeated measure ANOVA. P-value of <0.05 was considered significant.
Results: 10 participants in intervention arm (median age 18 IQR 15.8-19.3 years) and 9 controls (median age 16 IQR 13-18 years) were analyzed. The two groups were statistically similar at baseline. Adjusting for age, years on transfusion and chelation compliance, a statistically non-significant trend of improved cardiac T2* was seen from baseline (15.8ms, CI 6.9-24.6) to 6 months (T2*= 17.3ms, CI 8.8-25.9) in the intervention arm (p=0.77) when compared with controls. This change was sustained at 12 months (figure 1). MIC, conventional echocardiographic parameters and GLS, liver T2* and LIC did not change significantly throughout the study between the two arms.



Change in Cardiac T2* values from baseline at 6 months and 12 months by study group.

Figure 1.

Summary/Conclusions: Calcium channel blockers such as amlodipine show promise but larger clinical trials are needed to establish their role.

PB2137

IRON STATUS IN BETA THALASSAEMIA TRAIT
Y Yousafzai[1,*], S Khan[2], T Jalil[3], A Mir[4], K Ayaz[1], F Raziq[4]
[1]Institute of Basic Medical Sciences, Khyber Medical University, [2]Department of Haematology, Rehman Medical Institute, [3]Department of Pathology, Khyber Girls Medical College, [4]Department of Pathology, Rehman Medical Institute, Peshawar, Pakistan

Background: Iron overload remains the cause of morbidity and mortality in patients with beta thalassaemia major. Repeated transfusions and ineffective erythropoiesis lead to excessive iron stores in the body. However, not much is known about the status of iron in carriers of beta thalassaemia mutation. In Pakistan nearly 1/3rd population has iron deficiency and the policymakers have suggested global flour fortification with iron. This may have implications for the nearly 7% BTT population. Without knowing whether the BTT individuals are prone to develop iron overload or deficiency, this may be potentially harmful to such individuals.
Aims: The aim of this study was to determine whether carriers of beta thalassaemia trait could develop iron deficiency or iron overload.
Methods: Beta thalassaemia trait was diagnosed with HPLC (HbA2>3%) and serum Ferritin levels were measured using sandwitch ELISA method. A total of 101 individuals (50 males and 51 females) with BTT were assessed for serum ferritin levels. None of these subjects were on oral or injectable iron therapy or has any recent inflammatory event.
Results: Overall, 93% carriers of beta thalassaemia trait were anaemic whereas 7% had Hb within the normal range. Serum ferritin levels of 18.8% were low (mean serum ferritin while 8.3±4.25 ng/ml) while 75.2% individuals were iron replete. Interestingly, 6% individuals had serum ferritin levels higher (mean 911±788 ng/ml) than the reference range. This iron overload was more common in adults (4%) and males (4%). The results imply that iron deficiency a common occuring in beta thalassaemia trait individuals in Pakistan. However, a smaller proportion of carriers may also develop iron overload.
Summary/Conclusions: This pilot study was carried out to determine the status of iron balance in beta thalassaemia trait individuals. Both iron deficiency and overload were observed. These findings are significant and provide a rationale for more robust epidemiological studies.

PB2138

ACQUIRED IRON-REFRACTORY IRON DEFICIENCY ANEMIA (ACQUIRED IRIDA): A TUMOR RELATED DISORDER
R Angel F.[1,*], R Joan[1], C Vanesa[1], SG Jana[1], PC Anna[1], S Marta[1], T Josep[2], F Júlia[2]
[1]Hematology, [2]Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Mutations in the TMPRSS6 (matriptase-2) gene are associated with severe iron-refractory iron deficiency anemia (IRIDA) resulting from an overexpression of hepcidin. Microcytic anemia is the hallmark of this disorder. A similar form of acquired microcytic anemia has been observed in several situations, including benign tumors (1) or malignant tumors (1), treatment with m-TOR inhibitors (3).
Aims: To evaluate the prevalence of this acquired form of microcytic anemia.
Methods: From the group of patients with anemia studied in our red cell pathology unit for a year those with microcytic anemia and biochemical data similar to IRIDA were clinically evaluated.
Results: A total of 3911 anemia patients were studied for a year, including 882 (22.5%) with microcytic anemia. Nine of these 882 patients (1% of microcytic anemia, and 0.2% of total) showed a pattern similar to IRIDA. Main analytical data of these 9 patients are included the table below.
The microcytic anemia showed mixed inflammatory (increased SR and SF) and iron deficiency (low SI and high sTfR) signs. In all cases the diagnosis of the microcytic anemia was at the onset of the disease, and in 8 out of the 9 was related to neoplasia, including: renal carcinoma (2 cases), carcinomatosis peritoneal due to bladder neoplasia, disseminated mesotelioma, bladder carcinoma and lung carcinoma, renal lymphoma, disseminated neoplasia of probable bladder origin, rectal adenocarcinoma with a perirenal mass. Six of them died. The remaining case was an HIV patient with pneumocystis jirovecii pneumonia, after pneumonia treatment anemia disappeared.

Table 1.

Pt	Hb	MCV	HCM	PLT	Leu	SR	FE	TIBC	SI	SF	sTfR
51/M	93	69	20	590	10	90	3	44	6	849	7
71/M	119	76	24	552	9	80	2	27	8	927	5.4
69/M	98	75	24	454	15	84	1	25	4	1827	5.5
35/M	97	74	23	546	9	90	5	39	13	835	5.8
69/F	73	74	23	157	5	90	5	38	14	2097	4
55/F	87	77	24	473	5	87	7	42	17	635	4.4
78/M	116	74	25	117	13	92	15	51	29	1127	3.6
58/F	70	72	22	452	14	87	2	29	2	294	7.6
85/M	95	71	23	393	7	64	2	30	8	571	5.1

Pt: Patient age in years; M: male, F: female; PLT: platelet; Leu: leucocytes; SR: sedimentation rate in mm Hg; FE: serum iron in µmol/l; TIBC: total iron binding capacity µmol/l; SI: saturation index in%; SF: serum ferritin; sTfR: soluble transferrin receptor in mg/l (normal values: 1.5-4.5)

Summary/Conclusions: This microcytic anemia was rare, but it was related with malignant tumor with very poor prognosis, mainly involving kidney. Despite its rarity, this diagnosis should be considered owing to the poor prognosis. The term acquired IRIDA is proposed for this type of acquired microcytic anemia.

PB2139

GENOTYPE IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL DISEASE: RELATION TO VASCULAR COMPLICATIONS AND SUBCLINICAL ATHEROSCLEROSIS
A Tantawy[1,*], A adly[1], E ismail[2], Y Elhenawy[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Sickle cell disease (SCD) has a wide spectrum of complications.

Many factors contribute to the variability in SCD including genetic determinants.
Aims: To assess the relation between different genotypes among 38 children and adolescents with SCD and vascular markers, iron overload as well as vascular complications and subclinical atherosclerosis.
Methods: SCD patients (21 males and 17 females), in steady state were studied. All patients were subjected to full history and thorough clinical examination with special emphasis on history of sickling crisis, cardiopulmonary disease, acute chest syndrome, stroke, bone manifestations, nephropathy, spleen status, transfusion history and hydroxyurea/chelation therapy. Laboratory investigations included hematological profile, liver and kidney functions, markers of hemolysis (lactate dehydrogenase [LDH] and indirect bilirubin) and serum ferritin. Soluble CD163 (sCD163) was measured by enzyme linked immunosorbent assay while analysis of platelet microparticles (PMPs) was done by flow cytometry. Pediatric SCD severity index was assessed based on both clinical and laboratory variables. DNA genotyping was identified using on polymerase chain reaction and reverse hybridization. Echocardiography and assessment of carotid intima media thickness were performed.
Results: Based upon DNA genotyping, patients were categorized as either homozygous sickle cell disease (HbSS) or heterozygous sickle cell disease (Hb S/β); 24 (63.2%) patients had sickle cell anemia (SCA), 10 (26.3%) patients had sickle β^o thalassemia and 4 (10.5%) patients had sickle β^+ thalassemia. Comparison between patients with SCA (n=24) and those with sickle β-thalassemia (n=14) revealed no significant difference as regards age, sex, anthropometric measures, Tanner stage, family history or residency (p>0.05). A trend towards higher incidence of consanguineous marriage among families of patients with sickle β-thalassemia was found (p=0.082). Patients with SCA had significantly higher incidence of pulmonary hypertension, acute chest syndrome, frequent sickling crisis, avascular bone necrosis and nehropathy while those with sickle β-thalassemia had higher incidence of splenectomy, viral hepatitits and heart disease (p<0.05). The degree of hemolysis and iron overload was increased in sickle β-thalassemia patients compared with SCA group as shown by elevated transfusion index, LDH and serum ferritin (p<0.05). Patients with SCA displayed an evident state of inflammation, vascular injury and subclinical atherosclerosis reflected by high white blood cells (p=0.018), monocyte count (p=0.017), HbS, sCD163 levels (p<0.001), PMPs (p<0.001) and CIMT (p=0.029). Upon comparing genotypes among patients with mild/moderate *versus* severe disease, SCA genotype represented the higher incidence in severity (80.8%) followed by sickle β^o thalassemia (19.2%) while all patients with sickle β^+ thalassemia (n=4) were in the mild/moderate group. Genotype, in addition to HbS and parameters of vascular dysfunction (sCD163, PMPs and CIMT) were independently related to disease severity in logistic regression analysis. The cutoff values the studied vascular markers in relation to disease severity were determined.
Summary/Conclusions: Our findings could be of pathophysiological importance, because they provide evidence that genotyping may not only have a role in predicting disease severity in young SCD patients but it is potentially involved in determining the type of vasculopathy developed in those patients, allowing better individualized treatment.

PB2140

MARKED HYPERFERRITINEMIA (SERUM FERRITIN>10000MG/L). A POOR PROGNOSIS FACTOR

R Angel F.[1,*], R Joan[1], C Vanesa[1], SG Jana[1], PC Anna[1], S Marta[1], T Josep[2], F Júlia[2]
[1]Hematology, [2]Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Iron overload is a poor prognosis factor in patients with myelodysplasic syndromes or patients undergoing hematopoietic stem cell transplantation (HSCT) when considering a serum ferritin (Ft) of 1000 µg/l as a threshold. Marked hyperferritinemia (MHFT) is a hallmark of hemophagocytic syndromes and is a diagnostic criterion of the hemophagocytic lymphohistiocytosis.
Aims: The characteristics of patients with MHFT (Ft>10000µg/l) were studied.
Methods: Cases with hyperferritinemia (>1000 µg/l) and the characteristics of the patients with MHFT (Ft>10000 µg/l) were studied for a year. Serum Ft was evaluated using an Architect c.i. 16200 (Abbott Diagnostics).
Results: A total of 1056 samples presented Ft ≥1000 µg/l, 40 of which showed a MHFT(3.8%) in 25 patients. Of these, 12 died (48%) between 2 and 67 days after the determination, including: 4 non hematological neoplasias with metastasis; 3 with infection after HSCT; 2 with hemophagocytic syndrome associated with chronic myelomonocytic leukemia and diffuse large B-cell lymphoma (DLBCL); 1 respiratory infection during T-cell lymphoma treatment; 1 acute myeloid leukemia in pancytopenia postchemotherapy and 1 chronic lymphatic leukemia that evolved into a Hodgkin's lymphoma. Of the 13 who survived, 7 presented infection while undergoing HSCT (viral infection caused by CMV in three cases, type A influenza virus in 2 and 1 viral encephalitis; 1 fungal infection (aspergillus) and 2 bacterial sepsis (pseudomonas). The six remaining cases showed 2 hepatopathy (1 hepatic cirrhosis with MRSA sepsis and 1 on the onset of autoimmune hepatitis); 2 presented MHFT during chemotherapy (1 acute myeloid leukemia and 1 for DLBCL plus aspergillus infection); 1 was a myelodysplastic undergoing HSCT with severe previous transfusional hemosiderosis; and, finally, 1 with pancytopenia in a kidney transplanted patient.
Summary/Conclusions: MHFT is a poor prognosis factor and half of the patients died after a few days. In those who survived, MHFT appeared during infection, especially viral infections, in patients undergoing HSCT or receiving chemotherapy. In this regard, MHFT is a useful sign of viral infection. Further studies are warranted to confirm the clinical value of MHFT.

PB2141

LIPOSOMIAL IRON IS SAFE AND COST-EFFECTIVE IN HCV PATIENTS WITH TYPE II DIABETES AND ANEMIA DUE TO ESOPHAGEAL OR GASTRIC BLEEDING

G Giordano[1,*], A Parente[2], R Gigli[3], M Magri[1], G Berardi[4], B Carabellese[5], F D'Amico[2], L Luciano[2], R Fratangelo[2], G Niro[3], A Licianci[6], L Di Marzio[6], M Gasperi[7]
[1]medicine, Regional Hospital "A. Cardarelli", [2]molise university, [3]laboratory medicine, Regional Hospital "A. Cardarelli", [4]general medicine, asrem molise, [5]nuclear medicine, [6]hospital management, Regional Hospital "A. Cardarelli", [7]endocrinology, molise university, Campobasso, Italy

Background: HCV patients frequently show anemia due to esophageal or gastric bleeding and type 2 diabetes. Iron support reduces degree of anemia. Iron support might cause hepatic function worsening or hepatocellular cancer onset. Non transferrin bound iron may sustain inflammation and increase insulin resistance.
Aims: Aim of this study is to verify if sucrosomial oral iron support *vs* ferric gluconate iv iron support *vs* transfusional support is safe and effective in patients with HCV treatment with iron deficiency anemia.
Methods: 35 patients with HCV related anemia for esophageal varices and gastric bleeding with a median Hb level of 8 g/dl (R8-9.5 g/dl), were treated 15 with sucrosomial oral iron 30 mg 1 tablets t.i.d for 3 months (group A), 10 with i.v. ferric gluconate 62.5 mg/day for 15 days (group B) and 10 with 1 blood transfusion/day (group C) until Hb increase level of 1 g/dl was reached. Median Hb and glucose level in group A were 8 g/dl and 140 mg/dl respectively, in group B 9.5 g/dl and 130 mg/dl, in group C were 7 g/dl and 160 mg/dl. All patients received an abdomen echography to detect hepatocellular carcinoma (HCC) at 1, 3, 6 months.
Results: Patients in group A gained 1 g/dl Hb after 1 month (R 3-6 weeks), with a median blood glucose level of 130 mg/dl (R120-230) and a median cost of 30€/month (R 20-80), patients in group B gained 1 g/dl in 7 days (R 6-13 days), with a median blood glucose level of 310 mg/dl (R190-430) and a median cost of 1240€/month (R 830-2800), patients in group C gained 1 g/dl in 1 day (R 2-4 days), with a median blood glucose level of 210 mg/dl (R160-330) and a median cost of 400€/month (R 350-950). Only 1 patient in group B and 1 patient in group C developed HCC at 6 months. Worsening of liver function blood test was observed only in group C.
Summary/Conclusions: Liposomial iron is safe and cost-effective in HCV patients with type II diabetes and anemia due to esophageal or gastric bleeding.

PB2142

THROMBOCYTOPENIA AFTER IRON INFUSION: A CASE SERIES OF FOUR PATIENTS AND REVIEW OF LITERATURE

B Lioger[1,2,*], P Beurier[1], J Biogeau[1], AP Jonville-Bera[3], S Ollier[4], N Ferreira-Maldent[1], F Maillot[1,2]
[1]Service de Médecine Interne, University Hospital of Tours, [2]Université François Rabelais, [3]Pharmacologie clinique, centre régional de pharmacovigilance, University Hospital of Tours, Tours, [4]Médecine interne et immunopathologie clinique, Institut Universitaire du Cancer de Toulouse-Oncopole, Toulouse, France

Background: Among all the etiologies of anemia worldwide, iron deficiency remains the leading cause and might be present in 1 to 2% of adults. A thrombocytosis between 500 to $700x10^9$/L or more rarely a thrombocytopenia under $100x10^9$/L have also been described. The management of iron deficiency involves the research and treatment of a bleeding; an iron uptake quantification with a dietary survey followed by an oral or intravenous iron supplementation. However, published cases of secondary thrombocytopenia after an iron injection remain troublesome and underline our partial understanding of its mechanism of action.
Aims: The objective of our study was to describe the clinical and biological characteristics of thrombocytopenia occurring after iron infusion in patients.
Methods: Two strategies have been applied to collect cases. On one side, we have searched through the French Pharmacovigilance Database (FPVD); and on the other side, we have performed a systematic review. We used "thrombocytopenia" as high level term (MedDRA 11.0) and drug exposition was defined by the presence in the report of intravenous iron coded "suspect" according to the WHO criteria, whatever the level of causality assessment.
Results: This study found 9 patients (1M, 8F) having thrombocytopenia after intravenous iron products, four from the FPVD and five from the literature. The median age at diagnosis was 37 years old (range 16-90). The spectrum of iron supplementation included bleeding (n=6), malabsorption (n=1), a peritoneal dialysis (n=1), and an inflammatory anemia (n=1). The hemoglobin level was 5.7±2.3 g/L (range 3.1-9.6) with a median MCV 63 fL and a median platelet

counts of 172±133x10^9/L (range 102-434). Two patients had thrombocytosis before admission. Before intravenous iron products, four patients have received oral iron drugs and units of packed red blood cells for two patients. Treatment of intravenous iron consisted of iron sucrose (n=8) and ferric carboxymaltose (n=1). One patient was treated with intramuscular injection of iron sucrose. The median time to the onset of the thrombocytopenia was 3±2.4 days (range 2-8). The average decrease in platelets count compared to the baseline was 85%. The available bone marrow aspirations showed a megakaryocytic hypoplasia (n=4) or no abnormality of the megakaryocytes (n=2). Two patients have experienced hemorrhagic events. One has epistaxis and the other one purpuric ecchymosis. Only one patient received packed of platelets. We aimed to identify some subsets of patients according to their baseline characteristics. However, there was no difference between patients with early (<3 days) or late (>3 days) thrombocytopenia.
Summary/Conclusions: As we reported only nine cases in this study, we hypothesize that thrombocytopenia secondary to an iron infusion remains an uncommon adverse drug reaction. Our statement is also supported by the absence of similar data from the European Medicines Agency and the Food and Drug Administration. The appearance of thrombocytopenia does not seem specific of the intravenous form because some cases of thrombocytopenia have been reported with oral iron products. Withdraw of IV iron remained the first option of treatment and platelet transfusions was added if necessary. The main entity in the differential diagnosis of iron-induced thrombocytopenia is thrombocytopenia associated with IDA. In conclusion, clinicians should be aware of this possibility, as in one hand iron is the treatment of thrombocytopenia and on the other hand, iron might be the trigger of the thrombocytopenia.

PB2143

AUTOIMMUNE HEMOLYTIC ANEMIA IN CHILDHOOD. LONG TERM EXPERIENCE FROM A SINGLE CENTER
M Economou[1,*], A Teli[1], D Adamidou[2], P Panagopoulou[3], E Farmaki[1], A Kattamis[4]
[1]1st Pediatric Department, Aristotle University of Thessaloniki, [2]Blood Bank, Hippokration General Hospital of Thessaloniki, [3]4th Pediatric Department, Aristotle University of Thessaloniki, Thessaloniki, [4]1st Pediatric Department, National and Kapodistrian University of Athens, Athens, Greece

Background: Autoimmune hemolytic anemia (AIHA) is an immune mediated cytopenia rarely encountered in the first years of life. Childhood AIHA is characterized by diagnostic complexity in many cases and prognostic uncertainty in most, while therapeutic approach remains not well determined.
Aims: Aim of study was to report on the clinical presentation, management and long term outcome of cases with AIHA followed at a single pediatric hematology department during a 12year period.
Methods: The study was retrospective, covering the period between January 2004 and December 2015. Hospital files were used to record data including age at diagnosis, personal and family medical history, laboratory investigation, treatment, time of follow up, complications and relapses.
Results: During the given time period, 16 patients were diagnosed with AIHA. Mean age at diagnosis was 7.8 years (4 months-13 years) and mean time of follow up 5.08±4.18 years (4 months-12 years). A family history of autoimmune disorder was reported in 2/16 patients (12.5%). A known history of congenital hemolytic anemia was reported in 3/16 patients (18.7%) and of autoimmune thyroiditis in 1/16 patients (6.25%, while a history of recent infection was recorded in 11/16 patients (68.7%). In 12/16 cases (75%) AIHA was considered primary and in 4/16 (25%) found to be secondary to other conditions - EBV infection in 2 cases, systemic lupus erythematosus in one case and autoimmune lymphoproliferative syndrome in one case. Mean Hb at diagnosis was 6.29 ±2.22 gr/dl and median reticulocyte count 11.2% (0.8-32%) - 2 patients initially presenting with reticulocytopenia. In all but 2 cases (93.7%) direct Coombs test was IgG-IgG/C3d positive, in one case IgA positive and in one case initially negative. As to immunology studies, 8 patients presented with transient ANA, 1 patient with findings consistent with SEL (presence of ANA with low C3 and C4) and 2 patients with positive ATA (one already diagnosed with autoimmune thyroiditis). As to management, in 7/16 cases (43.75%) at least one urgent transfusion was required, while in 5/16 cases (31.26%) more than two. All patients received IVIG 1-6g/kg and solu-medrol pulse therapy at least once depending on clinical course, while 4/16 patients (25%) were put on monthly administration for 12 months. Oral prednisolone was administered in 11/16 patients (68.5%) for 3 to 118 months and cyclosporine in 7/16 patients (43.75%) for 3 to 24 months. In total, 6/16 patients (37.5%) required multiple pharmaceutical agents, *i.e.* IVIG, corticosteroids, cyclosporine and rituximab. As to complications, 4 patients presented with gall bladder lithiasis and 1 with growth retardation and adrenal insufficiency due to chronic corticosteroid use. With regards to clinical course, 3/16 patients (18.7%) presented with an acute course lasting for less than 3 months and 13/16 patients (81.3%) presented with a chronic course. Of these 13 patients, 8 presented with 1 or more (up to 6) relapses during follow-up.
Summary/Conclusions: AIHA in children may present with chronic course and unsatisfactory control of hemolysis, requiring prolonged immunosuppressive therapy. In addition, complications related both to disease and treatment may develop.

SHOULD WE ALWAYS USE THE MCV TO DEFINE ANAEMIA?
W Thomas[1,*], A Whiteley[2], A Cowley[1]
[1]Haematology, Plymouth Hospitals NHS Trust, Plymouth, [2]Lexacom, Banbury, United Kingdom

Background: How reliable is it to base testing serum ferritin on the presence of a microcytic anaemia? Traditional use of the term 'hypochromic microcytic anaemia' has fallen from favour. Most publications now concentrate on the 'microcytic anaemias'.
Aims: The aim of this study was to ascertain in a large regional teaching Hospital whether MCH or MCV is better at predicting for a low serum ferritin (SF) indicative of iron deficiency.
Methods: This study was based upon data extracted from our Hospital's laboratory information and results management system. Our large combined laboratory uses Sysmex XE2100 analysers. The majority of UK haematology labs use Sysmex analysers. We collected a year's worth of full blood count (FBC) data and paired the results with serum ferritin values that were just below the lower limit of normal range. The request for SF had to be made within 4 weeks of the FBC.
Results: Of the 501 patient samples that could be paired, a greater proportion of serum ferritin levels between 10 and 12 mcg/l inclusive, showed hypochromia in comparison to microcytosis (72% *vs* 31% respectively). The median results were: Haemoglobin 117g/l, MCV 83.6fl, MCH 26.6pg (men and women combined). Over a four day period by analysis of 100 consecutive samples microcytosis was observed to be the greater trigger for a serum ferritin request compared to hypochromia (39% *vs* 28% respectively). Over the same 4 day period, of approximately 7000 samples, hypochromia was seen in 6% and microcytosis in 3%.
Summary/Conclusions: In conclusion, although in the literature and in practice microcytosis is the predominant trigger for serum ferritin testing, it is hypochromia that has the better predictive capacity in our laboratory for the presence of iron deficiency. Clinicians need to look at the MCH and consider iron deficiency when the value is low, even in the presence of a normal MCV.

Cardarelli, Napoli, [3]Unità Operativa Complessa di Pediatria, Ospedale "Engles Profili", Fabriano, [4]Unità Operativa Talassemie ed Emoglobinopatie, Ospedale "Ferrarotto", Catania, [5]Servizio di Immunoematologia e Medicina Trasfusionale Area Metropolitana di Bologna, Policlinico S. Orsola "L. e A. Seragnoli", Bologna, [6]UO Sistemi Informatici, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [7]Dipartimento di Immagini, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, [8]Reparto di Radiologia, Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, Italy

Background: Few studies have evaluated the efficacy of iron chelation therapy in thalassemia intermedia (TI) patients.
Aims: Our study aimed to prospectively assess by quantitative Magnetic Resonance imaging (MRI) the efficacy of Desferrioxamine (DFO) and its advantages with respect to the absence of chelation therapy in non transfusion-dependent (NTD) TI patients.
Methods: Among the 185 TI patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network and with a MRI follow-up (FU) study at 18±3 months, we selected 65 NTD patients. Cardiac iron overload was assessed by the multislice multiecho T2* technique. LV function parameters were quantified by cine SSFP sequences. Liver T2* values were converted into liver iron concentration (LIC) values.
Results: We considered 18 patients who have not received any chelation therapy (50% males; mean age: 37.83±14.29 years) and 33 patients who had received DFO alone between the two MRI scans (51.5% males; mean age: 38.85±7.83 years). The two groups were comparable for age, sex and baseline MRI data. No patient treated with DFO had cardiac iron. At baseline only one non-chelated patient showed a pathological global heart T2* value (<20 ms) and he recovered at the FU. The percentage of patients who maintained a normal global heart T2* value was 100% in both groups. A significant increase in the right ventricular ejection fraction was detected in DFO patients (-3.48±7.22%; P=0.024). The changes in cardiac T2* values and in the global systolic biventricular function were not significantly different between the two groups (Table

1). In patients with hepatic iron at baseline (MRI LIC ≥3 mg/g/dw), the reduction in the MRI LIC values was significant only in the DFO group (-2.20±4.84 mg/g/dw; P=0.050). The decrease in MRI LIC values was comparable between the groups (P=0.155).

Table 1.

	DFO (N=33)	None (N=18)	P
Mean Diff Global Heart T2* (ms)	0.53 ± 5.70	-0.21 ± 3.82	0.767
Mean Diff N seg. with T2* < 20 ms	-0.45 ± 1.92	0.17 ± 0.79	0.239
Mean Diff Mid septum T2* (ms)	0.69 ± 9.79	-2.33 ± 5.82	0.256
Mean Diff LV EF (%)	0.71 ± 5.58	0.77 ± 5.51	0.977
Mean Diff LV EDVI (ml/m²)	-2.18 ± 15.29	-2.88 ± 14.93	0.891
Mean Diff RV EF (%)	3.48 ± 7.22	0.92 ± 4.79	0.244
Mean Diff RV EDVI (ml/m²)	-0.28 ± 17.73	0.56 ±14.43	0.881
Mean Diff MRI LIC (mg/g dw)	-1.36 ± 4.04	1.07 ± 5.38	0.110
Mean Diff Ferritin (ng/ml)	1.03 ± 151.15	26.27 ± 192.80	0.674

Summary/Conclusions: In this small population of sporadically or non transfused TI patients, DFO therapy showed no advantage in terms of cardiac iron but its administration allowed and improvement in right ventricular function and hepatic iron overload.

PB2147

CHELATION THERAPY IN NON-TRANSFUSION-DEPENDENT IRON LOADING ANEMIA. EXPERIENCE IN A TERTIARY HOSPITAL

R Del Orbe Barreto[1,*], B Arrizabalaga[2], X Martin Martitegui[2], S Erquiaga[2], JC García-Ruiz[2]
[1]Hematology, BioCruces Health Research Institute, [2]Hematology, Cruces University Hospital, Barakaldo, Spain

Background: Iron loading anemia (ILA) encompasses a group of inherited and acquired anemias characterized by ineffective erythropoiesis, low hepcidin levels, excessive intestinal iron absorption and secondary iron overload. This iron accumulation occurs more slowly compared to transfusion-dependent patients, and complications do not arise until later in life. It remains crucial monitoring and appropriately treat their iron burden, for this reason it is essential to manage it appropriately with iron chelation therapy, especially since phlebotomy is not an option in these patients.
Aims: To describe the clinical management of chelation therapy in patients with non-transfusion-dependent iron loading anemia.
Methods: This retrospective study was conducted at Cruces University Hospital in Barakaldo-Spain, from February 2009 to February 2016. Clinical data and results of Hemoglobin, serum ferritin and transferrin saturation, Liver Iron Concentration (LIC) and Cardiac T2* measured by MRI was obtained from patient's medical records. All patients were treated with Deferasirox 500 mg/day as compassionate use since none was transfused. Safety profile was studied in terms of gastrointestinal side effects, rash and change in serum creatinine and AST-ALT values.
Results: Seven patients were included (5 male, 2 female). Medium age was 57 years (min 26, max 74). 1 patient was diagnosed with non-severe Aplastic anemia/Paroxysmal nocturnal hemoglobinuria (AA/PNH), 3 with Glucose-6-phosphate dehydrogenase (G6PD) deficiency, 2 Congenital Dyseritropoietic Anemia (CDA) and 1 Refractory anemia with ring sideroblasts (RARS). None was splenectomized. Medium serum ferritin before treatment was 1109,5 ng/mL (min 644, max 1561) and after at least 12 months post-treatment was 538 ng/mL (min 86, max 969). In 5 patients LIC was evaluated after treatment, in 4 of them a reduction was observed. At baseline 4 patients were evaluated with T2* and anyone showed cardiac iron overload. No adverse events were observed in any patient.

Table 1.

			Pre-treatment						Post-treatment					
Age	Sex	Diagnostic	Serum Ferritin (ng/mL)	Transferrin saturation (%)	AST (U/L)	ALT (U/L)	Liver Iron Concentration (mg/g)	T2* (ms)	Serum Ferritin (ng/mL)	Transferrin saturation (%)	AST (U/L)	ALT (U/L)	T2* (ms)	Liver Iron Concentration (mg/g)
60	M	AA/PNH	1190	61,6	19	14	14		86	32,4	22	19		1,2
45	M	G6PD Deficiency	644	70	21	23	6,4	33	576	55	20	28		6,4
26	M	G6PD Deficiency	939	81	27	27	7	28	493	31	30	29		4,1
40	F	CDA	798	96,9	22	25	5,6		537	51	30	36		
74	M	RARS	1342	85,2	20	17	7,6		294	42	18	16		
38	M	G6PD Deficiency	1561	78,7	32	38	7,6	39	969	53,6	22	19	23	5,5
60	F	CDA	737	98	30	42	13,5	35	352	81	17	19	37,9	8,8

Summary/Conclusions: There are currently no standard clinical practice guidelines for the treatment of iron overload in Iron Loading Anemia. In our experience, using Deferasirox in this kind of patients is a useful and safely strategy to manage Iron overload. Prospective studies are needed to evaluate efficacy and safety of chelation therapy in this setting.

PB2148

EFFECT OF SICKLE CELL DISEASE AND SICKLE CELL TRAIT ON PARAMETERS OF BONE METABOLISM

B Andemariam[1,*], S Jones[1], L Xiao[2], W Zempsky[3], D Adams[4], M Hurley[2], P Taxel[2]
[1]Hematology/Oncology, [2]Endocrinology, University of Connecticut, Farmington, [3]Pediatrics, Connecticut Childrens Medical Center, Hartford, [4]Orthopedic Surgery, University of Connecticut, Farmington, United States

Background: Sickle cell disease (SCD) has sequelae for bone health including infarcts, low BMD and osteomyelitis. Sickle cell trait (SCT) is clinically silent but common in individuals of African descent (AD), many of whom are unaware of their status. Although SCD poses increased risk for low BMD and vitamin D, there are no data on the relationship between SCT status and BMD, vitamin D level, and serum markers of bone metabolism. We hypothesized that pre-menopausal AD women with SCT have a significantly lower BMD and higher serum bone turnover markers than race- and age-matched control AD women and are intermediate between healthy controls and subjects with SCD.
Aims: To compare BMD, vitamin D level, and serum bone turnover markers in pre-menopausal AD women with and without SCT and SCD.
Methods: To assess the effect of sickle cell disorders on bone homeostasis in pre-menopausal AD women, we recruited AD subjects with SCT and SCD following informed consent and compared serum and radiographic bone parameters to control ADs. We compared vitamin D level, hemoglobin (g/dL), body mass index (BMI), daily calcium intake, BMD of lumbar spine (L-spine), femoral neck (FN) and total hip (TH), as well as serum bone turnover biomarkers between control, SCT and SCD premenopausal AD women. Serum bone turnover markers included CTX, P1NP, osteocalcin, sclersostin, vitamin D binding protein, IGF-1 and iPTH. Subjects were 35-45 years old with regular menstrual periods, not taking oral contraceptives or medications that influence bone metabolism, and without known metabolic bone disorders. Statistical analysis included a one-way ANOVA test and two-group t-tests for comparing group means using SPSS statistical software.
Results: A preliminary data analysis was performed on 21 subjects including 9 controls, 5 with SCT, and 7 with SCD. The mean age of the cohort was 40.8±4.8 years, and mean BMI was 29.8±7.6 kg/m^2,.BMI was lower in the SCD group compared with SCT (24.5 *vs* 34.1 kg/m^2, p=0.01). Mean hemoglobin levels were lower in SCD (8.7±2.8 g/dL) *versus* control (12.7±0.9 g/dL) and SCT (12.3±2.8 g/dL) subjects (p=0.001). Daily calcium intake did not differ between groups. Mean vitamin D level for the entire cohort was 21±6 ng/dl and there was no difference between groups. BMD T-scores were normal for all groups at all anatomic sites; however, compared to controls, mean L-spine and FN BMD was significantly lower in the SCD group (1.4±0.2 g/cm^2,vs. 1.1±0.2 g/cm^2, p=0.04; 1.1±0.2 g/cm^2 *vs* 0.9±0.1 g/cm^2, p= 0.03, respectively). FN BMD in the SCD group was lower than SCT (p= 0.046). Overall, BMI correlated with mean TH BMD (r=0.666, p=0.001); and serum IGF-1 correlated with mean FN (r= 0.633, p=0.003) and mean TH BMD (r= 0.513, p=0.021). Mean serum sclerostin levels were significantly decreased in both SCT and SCD subjects (Control 2975±786, SCT 2141±402, SCD 1613±598, p=0.002). The groups did not demonstrate a difference in serum CTX, P1NP, osteocalcin, vitamin D binding protein or iPTH.
Summary/Conclusions: In this preliminary analysis we assessed parameters of bone metabolism in SCT and SCD compared with controls. In the overall cohort, IGF-1, a reflection of bone formation, positively correlated with FN and TH BMD. Sclerostin, an inhibitor of Wnt-signaling and bone formation, was decreased among SCT and SCD subjects, although the explanation is unclear. Further study in an expanded population is needed to verify and further elucidate the pathophysiologic basis of these findings.

PB2149

B-THALASSEMIA INTERMEDIA IN CHILDREN AND ADOLESCENTS: B CHAIN GENOTYPE IN RELATION TO DISEASE PHENOTYPE AND PULMONARY HYPERTENSION

I Ragab[1,*], A Hamed[1], S Abdel-Ghany[1], W El-Guindy[2], T Kamal[3], G El-Sayed[1], H Abdel-Naby[1]
[1]Pediatrics, [2]Pediatric Cardiology, [3]Genetics, Ain Shams University, Cairo, Egypt

Background: Prediction of β-thalassemia intermedia (BTI) phenotype from the genotype remains problematic.
Aims: Our aim is to study the different β-chain mutations in a group of Egyptian patients with BTI, its impact on clinical presentation, laboratory parameters and complications laying stress on pulmonary hypertension.
Methods: A cross-sectional study including 37 patients with BTI was performed in Pediatric Hematology Clinic, Children's Hospital, Ain Shams University. Revision of hospital records for age of diagnosis, blood transfusion, frequency, transfusion index over the last year and recording of complications as pubertal

delay, gall stones, leg ulcers together with splenectomy status and hydroxyurea treatment was performed. Physical examination for weight and height standard deviation scores, liver and spleen size then calculation of clinical score. Laboratory investigations included complete blood picture, initial hemoglobin electrophoresis, total, direct bilirubin, LDH, s.ferritin and β-Chain mutation analysis. 35 patients underwent echocardiography with recording of tricuspid regurgitant jet velocity and estimation of right ventricular systolic pressure.
Results: The studied patients had mean age of 10.3±4.55 years (range 4-18), female/male 20 /1.7, mean age at diagnosis 4.14±1.77 years (range 2-8), 10 (27.0%) had been diagnosed less than the age of 3 years, 19 (51.4%) between 3-6 years, 8 (21.6%) from 6-8 years, with a mean hemoglobin 6.38±1.26 gm/dl (4-10). Positive consanguinity was detected in 14 (37.8%) patients and positive family history in 20 (54.1%). 18 (48.6%) became transfusion dependent (TD), 9 (22.5%) patients had never been transfused, 8 (20.0%) receive one or two yearly transfusion, 23 (57.5%) receive more than two transfusions per year. Transfusion index ranged from 38-186 cc/kg/year in the TD group. Their mean height SDS -0.81±1.17; 75.7% of them had no obvious thalassemic facies, and5.4% had definite facies. Mild Pubertal delay was present in 16.22% and advanced delay in 5.41%. Splenectomy was performed in 5 (13.5%) patients; 64.86% were on hydroxyurea therapy. As regards β-chain genotype results, 14 (37.84%) have compound heterozygous with IVS1.6/codon6 and IVS1.6/IVS1.1and IVS1.1/codon2.7 most frequent genotypes, 10(27.03%) had heterozygous with IVS1.1 mutation most common, and 13 (35.14%) have homozygous mutations with IVS1.6 the commonest mutation with no significant difference between the three groups as regards age at diagnosis, hemoglobin at diagnosis. Mean pretransfusion hemoglobin was higher in heterozygous 8.90 ±1.29 gm/dl compared to compound heterozygous 7.29±0.61 gm/dl and homozygous 7.92±0.49 gm/dl. As Regards pulmonary hypertension (PHTN), Patients with PHTN had higher total serum bilirubin 2.15±0.71mg/dl, higher LDH 515.21±190.86IU/L, serum ferritin 1757.00 ng/ml (1082-2239), reticulocyte count 3.13±1.05% compared to those with normal pulmonary pressure 1.55±0.56 mg/ml, P=.009, 333.55±96.00 IU/L, P=0.001, 576.00 (296-1716) ng/ml, P=0.042; 2.45±0.55%, P=0.019 respectively; while they had lower initial hemoglobin level 6.41±1.43 gm/dl P=0.008. Compound heterozygotes formed 57.1%, heterozygotes 14.3% and homozygote mutations 28.6% of patients with PHTN compared to 30%, 30% and 40% in patients without PHTN, P=0.267.
Summary/Conclusions: Conclusion: Compound heterozygous are the most frequent β-chain genotype in patients with β-TI and it presents with more severe hemolysis and more frequent pulmonary hypertension.

Stem cell transplantation - Clinical

OUTCOME OF HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR NON-HODGKIN LYMPHOMA

T Xu*, J Chen, Z Jin, M Miao, C Fu, H Qiu,xTang, Y Han, A Sun, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Patients with non-Hodgkin lymphoma (NHL) who have relapsed or refractory disease, may not achieve long-term disease-free (DFS) even after autologous hematopoietic stem cell transplantation (auto-HSCT). The long-term survival or curability is still challenging. Given this situation, allogeneic (allo)-HSCT for the treatment of aggressive-relapsed or refractory NHL is appealing for the prospect of providing both a tumour-free graft and the graft-versus-lymphoma (GVL) effect. However, there have been only limited matched sibling dornor for allo-HSCT. For those patients who do not have suitable dornors, the related partially HLA-matched dornors may be a good choice. Related haploidentical (haplo)-HSCT may offer the opportunity to achieve long-term survival and cure for those select patients.
Aims: To explore the efficacy and safety of haploidentical hematopoietic stem cell transplantation(HSCT) for refractory-relapsed or highly aggressive non-hodgkin lymphoma(NHL) patients.
Methods: 26 refractory-relapsed or highly aggressive NHL patients who received haploidentical HSCT from Jan 2004 to Mar 2015 were analyzed retrospectively. 17 patients were treated with the conditioning regimen consisting of modified busulfan/cyclophosphamide(Bu/Cy) plus anti-human thymocyte globulin(ATG). 9 patients were given the regimen comprised of total body irradiation(TBI)/Cy plus ATG. All patients were pretreated with cyclosporin A(CsA), methotrexate(MTX), mycophenolate mofetil(MMF) and ATG to prevent graft-versus-host disease(GVHD).
Results: The patients included 4 cases of diffuse large B-cell lymphoma, 1 case of follicular lymphoma, 5 cases of B-lymphoblastic lymphoma/leukemia, 9 cases of T- lymphoblastic lymphoma/leukemia, 1 case of anaplastic large cell lymphoma(ALK-), 5 cases of peripheral T-cell lymphoma(NOS), and 1 case of NK/T-cell lymphoma. 19 patients were refractory or relapsed. All patients achieved full donor chimerism. With a median follow-up of 13.5(4-136) months, 20 cases(76.92%) survived, 15(57.69%) survived without lymphoma, and 7(26.92%) relapsed. 6 patients died, 4 because of recurrence/progress, 2 because of the complication of HSCT. 8 patients developed acute GVHD grades II-IV, which risk at 100 days was 30.80%. The risk of chronic GVHD at 2 years was 25.10%. The estimated 2-year recurrence rate was 42.20%. The estimated 1-year overall survival(OS) and disease-free survival(DFS) rate was 84.60% and 61.10%, respectively. The 2-year OS and DFS rate was 71.60% and 48.90%, respectively. Univariate analysis showed that disease status (complete remission/ not complete remission) before haploidentical HSCT may be a factor affecting OS and DFS.
Summary/Conclusions: Haploidentical HSCT is effective for relapsed-refractory or highly aggressive NHL. It may prolong DFS in part of those patients and even cure them.

PB2151

HIGH-SENSITIVE MONITORING OF CHIMERISM IN BLOOD AFTER HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDHOOD LEUKAEMIA

AK Haugaard[1,*], HO Madsen[2], HV Marquart[2], S Rosthøj[3], TN Masmas[1], K Müller[1], CJ Heilmann[1], M Ifversen[1]
[1]Department for Children and Adolescents, [2]Department of Clinical Immunology section 7631, Rigshospitalet, University Hospital of Copenhagen, [3]Section of Biostatistics, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, Copenhagen, Denmark

Background: We hereby report from a study aiming to evaluate the ability of microchimerism to predict relapse in a retrospective Danish cohort. Final results are pending. Relapse is the primary treatment failure after haematopoietic stem cell transplantation (HCT) for acute leukaemia in childhood, with a cumulative risk of 20-35%. Early detection of increasing minimal residual disease (MRD) or recipient chimerism is increasingly important to monitor imminent post HCT relapse. Chimerism analysis by polymerase chain reaction (PCR) of short tandem repeats is the gold standard and has a sensitivity of 1-5%. However, chimerism analysis based on real time, quantitative PCR (RQ-PCR) analysis (microchimerism) is more sensitive, with a reported detection level of 0.1-0.01%. We aimed to evaluate the ability of microchimerism to predict relapse in a retrospective Danish paediatric cohort.
Aims: It is the purpose of this study to evaluate the ability of microchimerism to predict early relapse following allogeneic SCT in children with leukaemia, with clinical and molecular relapse as primary outcome parameters. Microchimerism will be compared to results from detection of MRD in bone marrow and to standard STR-PCR based chimerism analysis.
Methods: Children transplanted for acute lymphoid (ALL) or acute myeloid

leukaemia (AML), between 2008 and 2014 at the Department for Children and Adolescents, University Hospital of Copenhagen, were included. Microchimerism was analysed on peripheral blood DNA using a commercially available kit (GenDx), based on allele-specific RQ- PCR of insertions/deletion polymorphisms. Results were compared with bone marrow MRD analysis and with standard, peripheral blood (PB) chimerism in DNA from unseparated whole blood, and PB cells positive for CD66b, CD4 and CD8. Transplant related data was collected from the European society for Blood and Marrow Transplantation (EBMT) database. We defined complete chimerism (CC) as no detectable recipient-cell chimerism at any time point, stable mixed chimerism (SMC) as a single increase below upper sensitivity limit, and increasing mixed chimerism (IMC) as two or more increases or a single increase above upper sensitivity limit.
Results: We included 59 children (ALL n=34, AML n=25), seven of these were re-transplanted due to relapse or rejection. Two transplants were excluded from further analysis due to lack of available DNA. Median age at HCT was 9 (1-8) years, and median follow up time was 23 (1-72) months. In total, 686 samples of frozen DNA were available for analysis, with a median (range) of 11 (2-22) samples per transplant. HCT was performed in 1st complete remission (CR) in 30 (47%), 2nd CR in 23 (36%), 3rd CR in 6 (%) and five (8%) performed without remission. Transplant characteristics and outcome data are displayed in Table 1. Seven children (21%) with ALL and 9 (36%) with AML relapsed, a median of 7 (1-52) months from HCT. One child re-transplanted in second remission subsequently relapsed again. In total, seventeen (29%) children died a median of 266 (60-1391) days from latest HCT, 10 (59%) of relapsed disease and 7 (41%) from transplant-related causes. For standard chimerism, 12/16 with IMC relapsed, *versus* 2/16 and 3/25 with SMC and CC, respectively. Cumulative incidence between the groups SMC, CC and IMC was statistically different for relapse (P<0.0001), and remained so after grouping CC and SMC.

MULTIPLEX REAL TIME PCR SYSTEM FOR CHIMERISM MONITORING AFTER ALLOGENEIC HEMATOPOIETIC STEM CELLS TRANSPLANTATION
I Fevraleva[1,*], N Risinskaya[1], E Parovichnikova[2], A Sudarikov[1]
[1]Department of Molecular Hematology, [2]Department of Hematological Oncology and BMT, National Hematology Research Center, Moscow, Russian Federation

Background: Modern chimerism techniques require high sensitivity and capacity to predict relapse after allogeneic hematopoietic stem cells transplantation (allo-HSCT) several months prior its clinical presentation. These techniques have to be simple in use, time saving and inexpensive permitting repetitive measure in the course of treatment. Here we propose multiplex real time polymerase chain reaction technique targeted to unique polymorphic sites in recipient/donor alleles conforming these requirements.
Aims: To develop high sensitive and versatile test-system based on multiplex real time PCR technique for donor/recipient chimerism analysis after allo-HSCT.
Methods: We have used the panel of primers and molecular probes, proposed by M. Alizadeh et al., targeted to biallelic polymorphisms sites (insertions/deletions) in the human genome. All probes were modified by one of four fluorescent dyes: FAM, R&G, ROX and Cy5, and appropriate quenchers: BQH1 or BQH2. Genomic DNAs of donors and patients were isolated from the bone marrow or peripheral blood. Informative markers for each donor/recipient pair were selected by initial screening. For special cases (sibling transplantation) with no informative markers found among Alizadeh set we extend analyzed panel with additional primers and Taqman probes for other genome SNPs (for example rs1801131, rs1801133, rs587776796). Chimerism was detected also with STR-PCR using COrDIS Plus multiplex kit for amplification of 19 polymorphic STR-markers and amelogenin loci ("GORDIZ"Ltd., Moscow, Russia).
Results: We have combined twenty pairs of primers and twelve Taqman fluorescent probes into seven parallel real time PCR multiplex reactions. Each of seven simultaneous PCR was analyzed by four channel, detecting FAM, R&G, ROX and Cy5 fluorescence. Alleles present only in donor or recipient DNA were considered informative and used for chimerism monitoring. Sensitivity of the method was estimated in control experiments with serial donor/recipient DNA sample dilutions. The same sample dilutions were analyzed with classic method, based on PCR of short tandem repeats (STR-PCR) followed by fragment analysis of the PCR-products. Multiplex method proposed detects as low as 0.03% recipient DNA admixture to donor DNA, while the standard STR-PCR method accuracy is limited to 1%.
Summary/Conclusions: We have developed fast multiplex Taqman real time PCR technique for evaluating polymorphic alleles informative for donor/recipient chimerism analysis after allo-HSCT. Method is convenient, simple, time saving, more sensitive and could replace classic STR-PCR approach.

PB2153

TREOSULFAN-BASED CONDITIONING AND UNMANIPULATED PERIPHERAL BLOOD HAPLOIDENTICAL TRANSPLANTATION (HAPLOSCT) FOR PRIMARY REFRACTORY AND RELAPSED AML: RESULTS IN 63 PATIENTS
F Lorentino[1,*], M Bernardi[1], M Carrabba[1], C Messina[1], A Forcina[1], E Sala[1], F Pavesi[1], L Vago[1], B Gentner[1], R Milani[2], F Giglio[1], M Morelli[1], R Greco[1], C Corti[1], J Peccatori[1], F Ciceri[1]
[1]Hematology and Bone Marroww Transplantation Unit, [2]Laboratory Medicine-Cytomorphology, San Raffaele Scientific Institute, Milano, Italy

Background: Allogeneic stem cell transplantation is the only potentially curative therapy for primary refractory (PR-AML) and relapsed acute myeloid leukemia (R-AML) patients (pts). HaploSCT could be an option for eligible pts whose clinical status warrants expedient treatment and who could benefit from a more potent alloreactivity.
Aims: Retrospective analysis of 63 consecutive pts with PR-AML and R-AML who received a first unmanipulated haploSCT at our center
Methods: We retrospectively analyzed 63 pts undergoing a first unmanipulated haploSCT from January 2006 to December 2015. PR-AML was defined as the failure to achieve hematological remission following induction treatment.
Results: Median age was 56 years (y) (20-77); 40% of pts were classified as PR-AML after a median of 2 induction courses (1-5), while 60% of pts had R-AML (51% 1st and 9% 2nd relapses). Median blast cell count in bone marrow was 33% (55-93%); median HCT-comorbidity index by Sorror *et al.* (HCT-CI) was 2 (0-8). Overall, 51% of pts received a reduced intensity conditioning (RIC) regimen based on Treosulfan (14 g/m2/d from -6 to -4), Fludarabine (30 mg/m2/d from -6 to -2) and anti-thymocyte globulin (ATG); 49% underwent a myeloablative conditioning (MAC) based on the same Treosulfan-Fludarabine schedule with the addiction of TBI 4Gy and ATG (23%) or Melphalan 70 mg/m2/d from -2 to -1 (26%). Source of stem cells were T-cell repleted G-CSF-mobilized peripheral blood stem cells from haploidentical familiar donors. All pts received post-grafting immunosuppression with mycophenolate mofetil and sirolimus; moreover, pts undergoing the Treo-Flu-Mel conditioning received post transplant Cyclophosphamide (PTCy) as backbone for GvHD prophylaxis. The complete remission (CR) rate was 78% after a median of 30 days (d) (21-41). Neutrophil engraftment occurred in 92% of pts with a median of 16 d (9-51). The 100-d cumulative incidence (CI) of grade ≥2 acute GvHD (aGvHD) was 30±10% and of grade≥3 aGvHD 19±8%; the 2y CI of chronic GvHD was 14±8%. With a median follow-up for survivors of 24 months (4-95), the 2y probabilities of leukemia-free survival (LFS) and overall survival (OS) were 13±7% and 14±7%, respectively. For pts who achieved CR, the 2-y LFS and OS were 17±8% and 18±8%, respectively; CI of relapse at 1y and 2 y were 45±13% and 53±14%, respectively, with a median time to relapse of 160 d (47-727); CI of non-relapse mortality (NRM) at 1y and 2 y was 30±12%, with a median time of 63 d (42-375). In univariate analysis, the only factors influencing 2y-LFS were the intensity of conditioning regimen (29±14% for MAC and 5±4% for RIC recipients, p 0.05) and HCT-CI (35±13% if ≤2 and 4±3% if >2, p 0.01). In a Cox-multivariate model including pts age, blasts percentage, cytogenetic risk, HCT-CI, intensity of conditioning regimen, GvHD prophylaxis backbone (ATG *vs* PTCy), disease status (PR- *vs* R-AML) and interval from diagnosis to haploSCT, the only predictive factor for better LFS was an HCT-CI ≤2 with an hazard ratio of 0.46 (95% confidence interval: 0.2-0.8, p 0.01).
Summary/Conclusions: A consistent proportion of PR-AML and R-AML pts can achieve CR after an unmanipulated haploSCT. Median time to relapse of 160 days opens the window to early post transplant treatment aimed at a remission prolongation and enhancement of immune control.

PB2154

BIOSIMILARS OF FILGRASTIM HAVE AN EQUIVALENT EFFICACY WHEN USED AFTER PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

C Nicol[1], C Henry[1], P Delepine[2], C Tripogney[2], C Buors[3], G Guillerm[1], MA Coutourier[1], C Berthou[1], A Tempescul[1,*], JC Ianotto[1]
[1]Clinical Hematology, Teaching Hospital Brest, [2]EFS Brest, EFS Bretagne, [3]Laboratory Of Hematology, Teaching Hospital Brest, Brest, France

Background: The biosimilars of G-CSF are sometimes the object of discussions about their efficiency and their harmlessness compared to historical products. Their use and efficiency for mobilization of the peripheral stem cells (PBSCH) or the regeneration post-reinjection of these CSP were little studied.
Aims: We wished to compare the efficacy of two products, biosimilars of filgrastim, Ratiograstim® and Zarzio®, compared to the original products in post-autograft stimulation.
Methods: Between February, 2008 and November, 2014, we identified all the patients who underwent autologous stem cell transplantation (ABSCT), in our Sector of Intensive Care, for of a lymphoma or of a multiple myeloma. The patients with lymphoma had a conditioning regimen by standard BEAM chemotherapy meanwhile the patients with myeloma had a high dose Melphalan (HDM) conditioning regimen. The reinjection of the PBSC was made 24 hours after the end of conditioning chemotherapy. All of the patients were stimulated by daily injection of G-SCF from J5 post-transplant until reach 1 giga/L of PNN. We collected the information concerning the times of hospitalization, the results of blood counts, transfusion needs, clinical data and infectious complications. The results) are expressed in median.
Results: We supported 187 patients (114 men and 73 women) for autologous stem cell transplantation (lymphoma/myeloma=99/88). We treated 51 consecutive patients Neupogen®-Amgen Inc (26 lymphoma and 25 myeloma, respectively), 74 patients Ratiograstim®-Ratiopharm AG (44 lymphoma and 30 myeloma) and 62 patients Zarzio® Sandoz AG (29 lymphoma and 33 myeloma). Within the patients with lymphoma, length of hospital stay was 22 days (16-64 days). The median use of filgrastim was for a period of 7.5 days (4-13 days). Cytopenias were deep in CSP post-reinjection with at least 10 days to less than 1 giga/L leukocytes and 13 days to less than 50 giga/L of plates. There was no difference for the results ragardinf the different types of filgrastim. The percent of patients transfused in red cells was 85%, and platelets 99%, without differences between the products. Three patients had bone pain (all under Ratiograstim®). Ten patients transferred into intensive care unit (ICU) because of infectious complications (5 under Zarzio® and 4 under Ratiograstim®). Four patients died within 100 days, two of them were under Neupogen®. Within the patients with myeloma, length of hospital stay was 16 days (13-42 days) and the administration of filgrastim was for period of 7.5 days (1-16 days). Cytopenias lasts for 6 days, under 1 giga/L leukocytes (the minimum of 6 days under Zarzio®, p=0.03), 0 days under 9 g/dL of hemoglobin (non-significant) and 6 days under 50 giga/L platelets s (more than 7 days within Neupogen®, p=0.04). The percent of patients transfused in red cells was 26% and in platelet 91%, without differences between the products. Eighteen patients had bone pain (9 under Ratiograstim® and 6 under Neupogen®). Four patients transferred into ICU (2 in Neupogen®). No patients died within 100 days post-autograft.
Summary/Conclusions: We compared the efficacy and safety in post-autologous of three G-CSF products, two biosimilars and one originator product. This retrospective analysis shows that for most of the parameters studied, the tree products have similar efficacy and side effects. By analyzing these results we concluded that biosimilars as well as princeps products may be use for stimulation after peripheral blood stem cell transplantation.

PB2155

DIAGNOSTIC VALUE OF SERUM STREM-1, PROCALCITONIN AND CRP IN PATIENTS WITH FEBRILE NEUTROPENIA

C Michel*, D Teschner, P Stein, M Theobald, E Wagner, M Radsak
Third Department of Medicine (Hematology, Oncology, and Pneumology), University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: The triggering receptor expressed on myeloid cells (TREM)-1 is a transmembrane glycoprotein predominantly expressed on neutrophils and monocytes/macrophages and an important regulator of inflammatory responses. Under inflammatory conditions, TREM-1 is released in a soluble form (sTREM-1) which is of diagnostic value in patients with pneumonia or sepsis in the absence of neutropenia. Severe sepsis in patients with autologous stem cell transplantation is the most abundant cause of death in the first 30 days after transplantation. Early diagnosis of sepsis and adjustment of medical treatment might improve outcome of these patients. Up to date, the potential and diagnostic value of sTREM-1 to predict sepsis and outcome in neutropenic patients undergoing stem cell transplantation has not been explored.
Aims: The aim of our work is to elucidate the diagnostic value of soluble TREM-1 and the correlation with procalcitonin and CRP in patients with febrile neutropenia.
Methods: Blood serum was obtained from 12 male and 5 female inpatients (n=17; median age 62 -IQR 58 to 63y) with a hematological malignancy (8 multiple myeloma, 9 lymphoma) undergoing high dose chemotherapy, followed by autologous stem cell transplantation and presenting for the first time with fever (axillary temp. >38.3°) and neutropenia (PMN <500/µl). sTREM-1 was measured with our self made sTREM-1 ELISA. Procalcitonin and CRP were measured by immunoassays under routine laboratory conditions.All human studies were performed in accordance with the declaration of Helsinki and were approved by the Landesaerztekammer Rhineland-Palatine Ethics Committee according to the institutional guidelines.
Results: At the first episode of febrile neutropenia, the patients had increased levels of CRP of 91 (IQR 42.5 to 161.5) mg/l and PCT of 0.29 (IQR 0.16 to 1.5) ng/ml. Despite severe neutropenia (leukocyte count median 30 (IQR 20 to 60) /nl, median sTREM-1 levels were increased with 33.7 (IQR 14.7 to 98.5) pg/ml. In 12 of 17 patients a bacterial blood infection was documented by positive blood cultures. Patients undergoing a bacterial sepsis showed significantly upregulated levels of sTREM-1 in serum (p=0.001). Additionally elevated sTREM-1 levels significantly correlated with elevated PCT level (r^2=0.30; P=0.02). No significant correlation was found between sTREM-1 and CRP (r^2=0.04; p= 0.42) or CRP and PCT (r^2=0.18; p=0.08).The response to initial empiric antibiotic treatment as well as the subsequent development of serious complications were independent of sTREM-1 levels during first episode of fever. All patients survived 30 days after autologous stem cell transplantation.
Summary/Conclusions: We detect elevated levels of sTREM-1 in patients with febrile neutropenia after high dose chemotherapy and autologous stem cell transplantation in the absence of measurable amount of neutrophils and monocytes. Increased level of sTREM-1 significantly correlates with PCT and sepsis. Our results suggest that sTREM-1 might be a useful marker for the early detection of sepsis also in neutropenic patients. However, it is currently unclear whether the malignant hematological disease itself, chemotherapy or autologous stem cell transplantation have an influence on the serum level of sTREM-1. Therefore further prospective studies are on the way to evaluate of sTREM-1 as a clinically relevant or alternative sepsis disease marker in neutropenic patients compared to other well-known markers like PCT or IL-6.

PB2156

OUTCOMES OF HIGH GRADE GASTROINTESTINAL GVHD POST-HSCT IN CHILDREN

V Uygun[1], H Daloğlu[1], S Öztürkmen[1], G Karasu[2], V Hazar[3], A Yeşilipek[1,*]
[1]MedicalPark Antalya Hospital Pediatric BMT Unit, Bahcesehir University School of Medicine, Antalya, [2]MedicalPark Göztepe Hospital Pediatric BMT Unit, Bahcesehir University School of Medicine, [3]Pediatric Hematology Oncology Unit, Medipol University School of Medicine, İstanbul, Turkey

Background: The high grade acute graft *versus* host disease (aGVHD) of typically involved organs (skin, gastrointestinal system (GIS) and liver) have specific features of therapeutic challenges, among which high grade GIS aGVHD has a distinctive and remarkable place in this context.
Aims: Our study intend to bring out the risk factors and clinical course of high grade gastrointestinal system (GIS) GVHD in children.
Methods: This is a retrospective analysis of 28 pediatric patients presented with a clinical diagnosis of stage 3 and 4 acute GVHD of the GIS who were selected from allogeneic hematopoetic stem cell transplantation (HSCT) performed. The demographics, the regimen used for conditioning and GVHD prophylaxis, clinical characteristics of GVHD including follow-up, laboratory parameters during GVHD, treatment modalities used for GVHD, response assessment in every week, complications of GVHD, and survival data were recorded.
Results: Patient and transplant characteristics were summarized in Table 1.

Table 1.

Characteristic	Value	
Diagnosis	Acute Leukemia 7 (25%) MDS 7 (25%) Fanconi anemia 5 (18%) Immunodeficiency 4 (14%) Hemoglobinopathy 2 (7%) Other 3 (11%)	
Donor and HLA match	Sibling n:2 Parent n:7 (four full-match, three haploidentical) Unrelated n:19 (six 10/10 and thirteen 9/10)	
Conditioning Regimen	Myeloablative n:23 Reduced Intensity regimen n:5	
Cell Source	Bone Marrow n:19 (68%) Peripheral Blood n:8 (29%) BM+PB n:1 (3%)	
GVHD prophylaxis	CsA and MTX n:17 CsA and MP n:5 Other n:6	
Median (range) onset day of GVHD	14 (5-217)	
Median (range) onset day of GIS GVHD First day of stage 3	21 (5-224) 32 (7-230)	
Treatment modalities		
Photopheresis	20	
Mesenchymal stem cells	18	
ATG	6	
MTX	6	
Sirolimus	6	
Other (rituximab, infliximab..)	3	
Survival		OAS
Dead	13 (46%)	2,4 months (1,4-6,4)
Alive	15 (54%)	17,3 months (3,0-56,3)

Summary/Conclusions: Overall survival at 3 months after the onset of stage 3 or 4 gut GVHD was 54%. Better outcome than the adult data might be related with more usage of bone marrow as a stem cell source or different character-

istics of pediatric gastrointestinal system. In general, GVHD started 14 days post-HSCT, extended to GIS GVHD in a week and progressed to high grade GIS GVHD in 10 days. The initial day of GVHD, days to extending to GIS GVHD and progressing to high grade did not influence the mortality. Melphalan and ATG usage in conditioning regimen and the drugs used in GVHD prophylaxis were not associated with survival. Low albumin level at any time of the severe GIS GVHD was associated with high mortality possibly due to more inflammatory GIS state of lost patients. Because ATG usage in the treatment of GIS GVHD significantly increased the mortality in our study, it should not be used in a routine manner. Better but not significant outcome with non-immunosuppressants seems a better treatment approach. Today best approach to GIS GVHD is to prevent and recognize it early. Treatment without immunosuppressive therapy like Photopheresis and mesenchymal stem cells seems a better approach which deserves further research with more patients.

PB2157

EFFECTIVENESS AND TOXICITY OF SECOND AUTOLOGOUS STEM CELL TRANSPLANTATION AS SALVAGE THERAPY FOR RELAPSED OR PROGRESSIVE MULTIPLE MYELOMA

R El Fatmi*, M Bahri, D Balloumi, N Ben Abdeljelil, L Torjemane, A Lakhal, S Ladeb, T Ben Othman
[1]Centre National de Greffe de Moelle Osseuse de Tunis (CNGMO). Faculté de médecine de Tunis. Université Tunis El Manar, Tunis, Tunisia

Background: Multiple myeloma (MM) is still an incurable disease despite the introduction of novel therapy. Relapse or progression (R/P) following autologous stem cell transplantation is common. Therapeutic options may include novel agents often followed by second ASCT.
Aims: We aimed to evaluate the effectiveness and toxicity of salvage ASCT in R/P multiple myeloma.
Methods: We retrospectively analyzed the outcome of patients who underwent second autologous stem cell transplantation as salvage therapy for R/P MM, between February 2007 and February 2014.
Results: Thirty four patients underwent salvage ASCT. Conditioning regimen was melphalan 200 mg/m^2(n=32) or 140mg/m^2 (n=2). The median age was 54 years (36- 60 years) at first ASCT and 57 years (37- 63 years) at second ASCT. Twenty patients (59%) were men. Median duration of response after first ASCT was 28 months (4-61 months), 6 patients (17%) relapsed within the first year of ASCT. Twenty nine (85%) patients received a salvage therapy: Thalidomide-Dexamethasone (n=17), Bortezomib based (n=10), Lenalidomide-Dexamethasone (n=1) and Melphalan-Prednisone (n=1). Median interval between first and salvage ASCT was 37.6 months (9-72 months). Twenty one patients (72%) were at least in partial response before second ASCT. Non relapse mortality (NRM) was 9%. Response was assessable at 3 months post-ASCT in 30 patients: 25 patients (83%) achieved at least partial response, 4 had progressed disease and 1 stable disease. After salvage ASCT, 9 patients received thalidomide maintenance therapy. The median progression-free survival (PFS) after second ASCT was 12 months (0.7-35 months) and median overall survival (OS) was 21 months (0.7-65.4 months).
Summary/Conclusions: Salvage ASCT is an effective therapeutic option for relapsed or progressive multiple myeloma although associated with a high NRM.

PB2158

THE EFFECT OF THE DHAP REGIMEN ON STEM CELL MOBILIZATION AND TRANSPLANT OUTCOMES OF PATIENTS WITH NON-HODGKIN LYMPHOMA WHO ARE CANDIDATES FOR UP-FRONT AUTOLOGOUS STEM CELL TRANSPLANTATION

JY Kwak[1,*], HY Yhim[1], SY Jeon[1], JA Kim[2], DH Yang[3], HS Kim[4]
[1]Internal Medicine, Chonbuk National University Hostpital, Jeonju, [2]Internal Medicine, Catholic University of Korea College of Medicine, Seoul, [3]Internal Medicine, Chonnam National University Hwasun Hospital, Jeollanam-do, [4]Department of Nursing, Chonbuk National University, Jeonju, Korea, Republic Of

Background: Data on dexamethasone, cytarabine, and cisplatin (DHAP) as a mobilization regimen, compared to high-dose cyclophosphamide (HDC), for up-front autologous stem cell transplantation (ASCT) in non-Hodgkin lymphoma (NHL) are limited.
Aims: The aims of this study were to compare the efficacy of peripheral blood stem cell (PBSC) mobilization of DHAP regimen with HDC in combination with G-CSF in patients with aggressive NHL who were candidates for up-front ASCT, and to investigate the effect of DHAP mobilization on overall survival (OS).
Methods: We conducted a multicenter, retrospective cohort study on patients who were diagnosed with aggressive NHL and treated with CHOP or rituximab-CHOP and subsequent PBSC mobilization using HDC (4.0g/m^2) or DHAP (cisplatin 100mg/m^2 D1, cytarabine 4.0g/m^2 D2, dexamethasone 40mg D1-4) plus G-CSF regimens for up-front ASCT in 3 Korean institutions between 2004 and 2014. Successful mobilization was defined as collected CD34+ cell count ≥5.0x10^6/kg, but mobilization failure was defined as collected CD34+ cells <2.0x10^6/kg.
Results: Ninety-six patients (57 male, 39 female) with a median age of 48 years (range, 18-66) were included. Thirty-one patients (32.3%) received DHAP regimen and 65 (67.7%) received HDC. Diffuse large B-cell lymphoma (DLBCL, 54.2%) was the most common histologic type, and remaining included peripheral T-cell lymphoma (PTCL), not otherwise specified (28.1%), anaplastic lymphoma kinase-negative anaplastic large cell lymphoma (12.5%) and angioimmunoblastic T-cell lymphoma (5.2%). The number of total CD34+ cells collected per patient was significantly higher in the DHAP group than the HDC group (median, 16.1 *vs.* 6.1 × 10^6/kg, *P*=0.001). More patients in the DHAP group achieved successful mobilization compared to the HDC group (87.1% *vs.* 61.5%; *P*=0.011), whereas the rate of mobilization failure was higher in the HDC group (33.8% *vs.* 3.2%; *P*=0.032). In multivariate analysis, no bone marrow involvement (odds ratio [OR], 4.60 [95% CI, 1.20-17.61]), no prior radiotherapy (OR, 11.78 [1.68-82.39]), WBC counts at first apheresis day >1,785/uL (OR, 9.25 [2.89-29.58]), and the DHAP regimen (OR, 4.12 [95% CI, 1.12-15.17]) were independent predictors for successful mobilization. Febrile neutropenia developed 3 patients (9.7%) in DHAP group, which was less frequent than HDC group (N=21 [32.3%], *P*=0.043). Of the 96 patients, 2 patients did not proceed to up-front ASCT (1 failed mobilization, 1 patient's refusal). Following the reinfusion of PBSC, median time to neutrophil/platelet engrafts did not significantly different according to mobilization regimen. With a median follow-up of 57.4 months (range, 9.1-143.4), the 5-year OS rates were not significantly different between the DHAP and the HDC groups (74.0% *vs.* 72.2%; *P*=0.936). Because of the heterogeneous histologic types in the study, additional subgroup analyses were performed separately based on the histologic types, but the OS in patients with either DLBCL or PTCL was not different according to the mobilizing regimens (*P*>0.05).
Summary/Conclusions: Our study showed that the DHAP regimen was associated with higher efficacy for PBSC mobilization and less frequent episodes of febrile neutropenia compared to the HDC regimen. Although there was no clinically meaningful OS improvement in the DHAP group, the DHAP regimen reduced significant rates of mobilization failure. Therefore, DHAP plus G-CSF can be effective in patients with NHL undergoing up-front ASCT.

PB2159

IMPACT OF THE METHYLENETETRAHYDROFOLATE REDUCTASE (MTHFR) C677T GENE POLYMORPHISM ON CLINICAL OUTCOMES OF HLA-MATCHED SIBLING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

MF Mohammed Saleh[1,*], AM Kamel[2], EA El Beih[1], OM Herdan[3], GT Ebid[2], R Abdel Fattah[4]
[1]Clinical Hematology Unit, Internal Medicine Department, Assiut University Hospital, Assiut, [2]Clinical Pathology Department, National Cancer Institute, Cairo University, Cairo, [3]Internal Medicine Department, Assiut University Hospital, Assiut, [4]Medical Oncology Department, National Cancer Institute, Cairo University, Cairo, Egypt

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is widely used to treat various hematological malignant and bengin diseases. The occurrence of complications following HSCT-as graft *versus* host disease (GVHD), hepatic veno-occlusive disease (VOD), oral mucositis (OM), drug induced hepatic and renal adverse events- is highly variable and dependent on a multitude of host, donor, and treatment factors. Identifying important genetic variables will allow for better prediction of HSCT-related outcomes, that could help to develop targeted interventions. A common genetic polymorphism, C677T, has been described for Methylenetetrahydrofolate reductase (MTHFR);results in amino acid changes, at codons 222. The homozygous 677TT genotype has been shown to have 30% of the MTHFR wild-type enzyme activity in vitro, and the heterozygous (CT) genotype has approximately 60% of wild-type enzyme activity (Liew and Gupta, 2015 *Eur J Med Genet,* 58, 1-10).
Aims: To evaluate impact of the C677T polymorphism of 5,10-methylenetetrahydrofolate reductase (MTHFR) on the clinical outcomes of patients treated using human leukocyte antigen-matched sibling stem cell transplantation as acute GVHD,VOD,severe oral mucositis (SOM), drug induced hepatic and renal toxicity, transplant related mortality(TRM) and overall survival(OS).
Methods: The study subjects were 46 patients receiving allogeneic HSCT at a bone marrow transplantation unit in Nasser institute for research and treatment from 2010 to 2014,with complete clinical records ; and DNA available for genotyping. MTHFR genotyping was performed by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP).Acute GVHD was assessed using conventional criteria (Jacobsohn and Vogelsang, 2007 *Orphanet J Rare Dis,* 2, 35), necessity of parenteral nutrition used to identify SOM, and VOD of the liver was defined according to McDonald et al.(1993 *Ann Intern Med,* 118, 255-67).We evaluated renal and hepatic toxicity based on peak serum creatinine and peak total bilirubin, AST, and ALT levels during the first 30 days after allogeneic HSCT.TRM was defined as death by any cause during the course of treatment, other than the relapse of underlying disease.
Results: Median age at the time of HSCT was 22 years (range 3-42 years); 32 patients (69.6%) above ≥18 years, and the median follow-up period of survivors was 21 months. Acute myeloid leukemia (AML) was the most common

underlying diagnosis 23 patients (50%) of them 12 (26%) are in complete remission 1 (CR1).The most commonly used conditioning regimen consisted of Busulfan (BU), and Cyclophosphamide (CY) (n=26, 56.5%). All received peripheral blood stem as a stem cell source with mean CD34+ stem cell dose (6.6±2.3) 10^6/kg. Twenty-seven patients (58.7%) were males. Methotrexate (MTX) in addition to Cyclosporine (CsA) was used as GVHD prophylaxis in 40 patients (87%).The frequencies of the MTHFR C677T genotypes in patients were 43.5% (20 patients) for 677CC, 50% (23 patients) for 677CT, and 6.5% (3 patients) for 677TT ;the allelic frequency of the 677T was 31.5%. Recipient MTHFR677 in CT or TT showed higher incidence of acute GVHD (7/26) 26.9% *versus* (2/20) 10% in CC, but not statistically significant; p=0.26. MTHFR C677T in CT or TT showed higher incidence of hepatic toxicity (11/26) 42.3% *versus* (5/20) 25% in CC; also higher transplant related mortality (5/26) 19.2% *versus* (2/20) 10% in CC, but not statistically significant; p=0.22 & 0.45 respectively.In log rank survival analysis,recipients with variant allele MTHFR 677T were associated with lower non statistically significant overall survival; p=0.15.VOD was diagnosed in 1 patient (2.2%) and had heterogeneous status of the polymorphism, MTHFR 677 CT genotype.

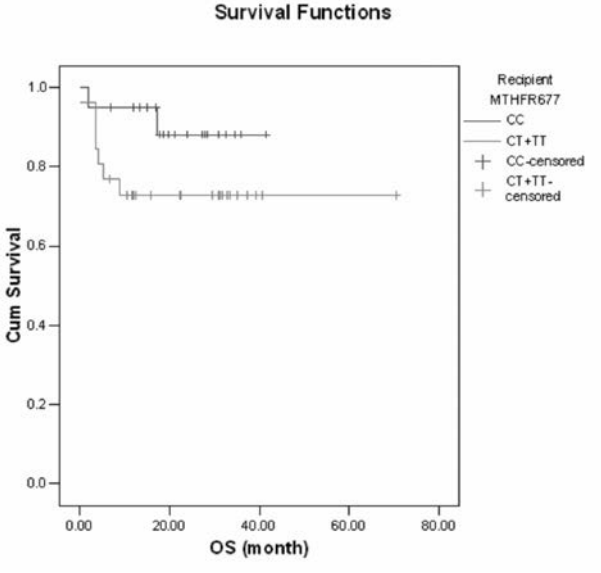

Figure 1.

Summary/Conclusions: Genotyping for MTHFR C677T before HSCT could have clinical significance, not statistically proven in our study, in prediction patients at high risk of developing poor outcomes. Large multicentric, highly standardized prospective studies are needed to identify such potential pharmacogenetic markers with sufficiently strong evidence to be used in clinical practice.

TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY IS STRONGLY ASSOCIATED WITH SEVERE GRAFT VS HOST DISEASE POST UNRELATED ALLOGENEIC TRANSPLANT FOR HEMATOLOGIC DISEASES

I Sakellari[1,*], I Batsis[1], Z Bousiou[1], D Mallouri[1], V Constantinou[1], M Iskas[1], A Vardi[1], S Papadimitriou[1], AK Panteliadou[1], C Smias[1], E Yannaki[1], A Fylaktou[2], A Tsombanakou[1], C Vadikoliou[1], P Kaloyannidis[1], T Natse[3], G Bamihas[3], E Gavriilaki[1], A Anagnostopoulos[1]
[1]Haematology department - BMT unit, George Papanicolaou Hospital, [2]Immunology Department, Hippokration Hospital, [3]Nephrology Department, George Papanicolaou Hospital, Thessaloniki, Greece

Background: Allogeneic hematopoietic cell transplantation (HCT) is a curative treatment in hematologic disorders, but morbidity and mortality remain high. Transplant-associated thrombotic microangiopathy (taTMA) is a multifactorial and often fatal syndrome.
Aims: In a retrospective single-centre study we aimed to investigate the incidence of taTMA in patients (pts) undergone HCT from unrelated donors (URD) and identify prognostic factors and treatment outcome.
Methods: We enrolled consecutive pts who underwent URD HCT from 2003 to 2015. TaTMA diagnosis was based on EBMT criteria: increased (>4%) schistocytes in peripheral blood, thrombocytopenia, increased lactate dehydrogenase and decrease in Hb concentration. Anti-thymocyte globulin (ATG, rabbit) was used as standardised part of the conditioning in almost all pts (total dose of 5-7.5mg/kg). Anti-GVHD prophylaxis consisted of cyclosporine or tacrolimus plus methotrexate in myeloablative and mycophenolate mofetil plus cyclosporine in reduced intensity and toxicity conditioning transplants. Upon identification of taTMA, all possible causative factors were fully investigated. The mainstay of treatment strategy was withdrawal of calcineurin inhibitors, plasma infusion and plasma exchange combined with corticosteroid administration and in refractory cases, humanized anti-CD20 monoclonal antibody (Rituximab).
Results: We studied 179 pts (74 male, 105 female), aged 37±14 years, who underwent HCT from matched HLA A/B/C/DRB1 (8/8, n=88) and allele or antigen mismatched (n=91) URD. Grafts derived from peripheral blood (157), bone marrow (18) and umbilical stem cells (4). Conditioning regimens were myeloablative (139), reduced intensity (28) and toxicity (12). Median follow-up was 11.5 (0.1–147.4) months.TaTMA was diagnosed in 29 (16.2%) pts (12 male, 17 female), aged 34±12 years, 78 (9–721) days post-HCT for acute leukemia (21), Hodgkin (3) and non-Hodgkin (1) lymphoma, MDS (2), MPD (1) and aplastic anemia (1). Conditioning regimens were myeloablative in 24 (12 TBI-based) and reduced intensity in 5 pts. Among pts with taTMA, 10 (34%) presented severe (grade III-IV) acute GVHD, 15 (52%) extensive chronic GVHD, 12 (41%) bacterial, 2 (7%) fungal and 21 (71%) viral infectious episodes. In univariate analysis age, gender, diagnosis, disease phase, previous lines of treatment, conditioning (intensity and TBI-based), ABO and HLA incompatibility, infections, acute and chronic GVHD were studied. The presence of taTMA was associated with severe acute and extensive chronic GVHD (p=0.001 and p=0.035 respectively) and TBI-based conditioning (p=0.043). In multivariate analysis, severe acute GVHD was the only independent factor associated with taTMA (β=3.4, p=0.038). Regarding treatment-outcome, 8 pts responded to cyclosporine cessation and plasma infusions. The rest (21) underwent plasma-exchange sessions; in 14 the syndrome resolved, 1 responded to additional Rituximab treatment, while 6/21 pts were refractory and eventually succumbed. Treatment-related mortality was 33.3% (9/29) in taTMA pts and was directly associated with refractory microangiopathic syndrome in 6/29 (20.6%).
Summary/Conclusions: Despite the progress achieved concerning classic thrombotic thrombocytopenic purpura and haemolytic uraemic syndrome in terms of diagnosis and novel therapies, taTMA seems to be a far more complex syndrome. Since the pathogenetic factors leading to taTMA are not fully elucidated, treatment of this syndrome often fails. According to our findings, GVHD was the most predisposing factor for the development of taTMA, possibly related to associated endothelial damage.

PB2161

THE BENEFITS AND PITFALLS OF PERIPHERAL BLOOD STEM CELLS MOBILIZED BY ETOPOSIDE: THE EFFECT OF CUMULATIVE DOSAGES OF ETOPOSIDE

D Kim[1,*], KW Kang[1], SR Lee[1], HJ Sung[1], SJ Kim[2], CW Choi[1], BS Kim[1], Y Park[1]
[1]Hematology & Oncology, Korea University School of Medicine, [2]Hematology & oncology, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Successful collection of adequate hematopoietic stem cells is necessary for autologous stem cell transplantation (AutoSCT). However, the optimal mobilization strategy for transplantation has still not been established. High dose cyclophosphamide with granulocyte-colony stimulating factor (G-CSF) is one of the most widely used mobilization strategies; however, in a proportion of patients, it fails to secure the collection of sufficient cells. Therefore, effective and safe alternative mobilization strategies are required.
Aims: We conducted a retrospective study to determine the impact of etoposide mobilization strategy for AutoSCT in patients with lymphoid malignacies.
Methods: We compared the effectiveness and safety profiles of chemomobilization using three regimens: intermediate-dose etoposide (750 mg/m^2) followed by the late addition of G-CSF, high dose cyclophosphamide and G-CSF, and G-CSF alone. A total of 116 patients (60 multiple myeloma, 56 lymphoma) who underwent autologous stem cell transplantation (autoSCT) were included in this study.

Table 1.

Table 1. Predictive factors for platelet engraftment

	Univariate analysis	Multivariate analysis	
Factor	*P* value	HR (95%CI)	*P* value
Sex	0.472		
Age	0.985		
Underlying disease	**0.001**		
Stage	0.649		
Heavy pretreatment	0.471		
CR at transplantation	0.983		
Mobilization strategies	0.095		0.078
Cyclophosphamide (reference)		1	
Etoposide		0.559 (0.337 – 0.928)	**0.025**
G-CSF		0.91 (0.547 – 1.514)	0.717
Time from diagnosis to mobilization	0.111		
Time from mobilization to transplantation	**0.049**		0.068
≤ 30 days (reference)		1	
> 30 days		0.684 (0.455 – 1.028)	
Infused CD 34⁺ cell count	0.242		**0.009**
≥ 5×10⁶/kg (reference)		1	
< 5×10⁶/kg		0.534 (0.334 – 0.855)	
Cumulative etoposide dose	**< 0.001**		**0.003**
< 2.5g (reference)		1	
≥ 2.5g		0.502 (0.319 – 0.790)	
Type of G-CSF	0.909		

Results: Median CD34+ cell yield was significantly higher in the etoposide group (12.3x10^6/cells/kg) compared to the cyclophosphamide group (4.99x10^6, cells/kg) and the G-CSF group (3.8x10^6/cells/kg) (p<.001). The rate of successful mobilization (≥5x10^6/cells/kg) was also significantly higher in the etoposide group (86.1%) compared to the cyclophosphamide (49.1%) and the G-CSF group (22.2%) (p <.001). There were no significant differences in neutrophil and platelet counts at the nadir between the etoposide and the cyclophosphamide group. Severe febrile neutropenia and mobilization-related mortality were not observed in any group. However, platelet engraftment was slower in the etoposide group compared to the other groups (p=0.029). Furthermore, the proportion of delayed platelet engraftment (≥30 days) was also greater in the etoposide group than in the cyclophosphamide and the G-CSF group (20.6% *vs* 6.7% *vs* 3.8%, p=0.032). In multivariate analysis, the etoposide mobilization strategy (p=0.025) and the high cumulative etoposide dose (≥2500 mg, p=0.003) were significantly associated with delayed platelet recovery.
Summary/Conclusions: Intermediate dose etoposide with the late addition of G-CSF may be an effective mobilization strategy. However, high cumulative doses of etoposide, including systemic chemotherapy, mobilization, and conditioning of autoSCT may delay platelet engraftment.

PB2162

SUCCESSFUL PERIPHERAL BLOOD STEM CELL MOBILIZATION WITH A COST-EFFICIENT FIXED SINGLE-DOSE PLERIXAFOR SCHEDULE IN POOR MOBILIZERS

C Greil*, C Kiote-Schmidt, G Fink, S Hildenbeutel, R Bosse, J Duyster, M Engelhardt, R Wäsch
University hospital Freiburg, Freiburg, Germany

Background: Collection of hematopoietic stem cells (HSC) from the peripheral blood (PB) is routinely conducted prior to high-dose chemotherapy and autologous transplantation. Despite safety and efficiency of current apheresis procedures including mobilizing chemotherapy and granulocyte colony-stimulating factor (G-CSF), there is still a significant rate of mobilization failures due to different patient-dependent factors necessitating additional agents like plerixafor. A standardized strategy for its application in poor stem cell mobilizers is still lacking.
Aims: To evaluate the efficacy of a cost-efficient fixed single-dose of plerixafor in poor mobilizers on successful HSC mobilization.
Methods: We analyzed 46 patients who underwent autologous HSC transplantation at our academic center between 2011 and 2015 and received plerixafor because they were expected to be poor mobilizers due to low counts of CD34+ cells in PB samples prior to apheresis or after a first apheresis day with insufficient yield or as a rescue strategy after insufficient harvest with previous mobilizing chemotherapy. We examined CD34+ cell counts in PB and in apheresis products to identify those patients who were able to collect a sufficient CD34+ cell count for transplantation after a single application of plerixafor.
Results: Plerixafor could be safely administered, leading in 83% and 48% to apheresis yields of >2 and >4x10^6 CD34+ cells/kg body weight (bw) and correlating with median CD34+ PB cell counts of 8.0 and 17.8/µl, respectively. Of note, 35/46 (76%) patients showed a substantial benefit of plerixafor *vs* G-CSF alone, with increased PB CD34+ cells (13.3 *vs* 4.7/µl, p=0.0001) prior to apheresis and 4-fold higher CD34+ cell numbers per single apheresis (1.2 *vs* 0.3x10^6 CD34+/kg bw, respectively, p=0.00005). A patient subset of 24% had <5/µl PB CD34+ cells before plerixafor application and profited less from additional plerixafor administration.
Summary/Conclusions: As the number of patients with extensive pretreatment, including new immunomodulatory drugs and with long disease courses will even increase in the future, it is highly important to develop selection criteria for patients with expected benefit of additional plerixafor application, also with regard to cost efficiency. Our data suggest that most patients in preemptive and rescue settings with <5/µl CD34+ cells detectable in PB may fail to substantially benefit and should therefore be carefully selected, whereas those with >5/µl PB CD34+ cells can greatly benefit of a single application with median CD34+ apheresis yield increases of 2.9 and median total apheresis collections of 4.6x10^6/kg bw.

PB2163

AVASCULAR NECROSIS OF BONE IN ADULT PATIENTS SURVIVING MORE THAN 2 YEARS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN YEARS 2001-2012 - EXPERIENCE OF SLOVAK TRANSPLANTATION CENTRE

M Martišová[1,*], E Bojtárová[1], L Roziaková[1], M Mistrík[1]
[1]Clinic of Hematology and Transfusiology of Medical Faculty of Comenius University, University Hospital Bratislava, Bratislava, Slovakia

Background: Avascular necrosis (AVN) of bone is the most debilitating late skeletal complication of stem cell transplantation (SCT) that often remains underestimated.
Aims: To evaluate potential risk factors of AVN, its clinical manifestation and treatment in patients after SCT.
Methods: One hundred thirty-five patients surviving more than 24 months after allogeneic SCT in years 2001-2012 in Slovak Transplantation Centre were evaluated retrospectively for AVN. All patients were disease-free after SCT for malignant and non-malignant hematological diseases. AVN was confirmed by magnetic resonance imaging or scintigraphy. We investigated correlations between AVN and primary diagnosis (malignant/non-malignant), conditioning regimens, donor and patient gender, type of donor (related/unrelated), HLA match, AB0 compatibility, source of stem cells (peripheral/bone marrow), immunosuppressive therapy, GvHD (acute/chronic), exposure time and cumulative dose of corticosteroids. We analysed time to first symptoms, time to diagnosis of AVN, number of joints, most affected sites, correlation between joint pain and imaging exams, types of treatment and their results.
Results: Seven patients surviving 30-169 months (median, 69 months) after SCT developed AVN (5.2%). We experienced more AVN in male patients (83%), but found no correlation with other factors. Cumulative dose of corticosteroids was 0-5264mg (median, 3960mg) and exposure time was 0-327 days (median, 53days). Patients developed arthralgias 9-56 months (median, 28 months) after SCT. AVN was confirmed 1-17 months (median, 6 months) after onset of the symptoms and 14-62 months (median, 36 months) after SCT. We confirmed AVN of 19 joints (2.71 joints per patient)-hip (12), shoulder (5) and sacroiliacal joints (2). We recognized higher incidence of AVN in patients who suffered from AVN of at least one joint, although the other affected joints weren't always marked as painful (hip: 8 painful joints in correlation with 12 joints with proved AVN in 6 patients; shoulder: 4 painful joints in correlation with 5 joints with proved AVN in 3 patients). We confirmed bilateral occurrence of AVN of hip joints regardless of the number of painful hip joints. Because of lack of MRI of painful knees we weren't able to evaluate the rate of AVN although knees were the second most painful joints. AVN of sacroiliacal joints was asymptomatic. Conservative treatment was performed in shoulder joints, surgical treatment was performed just in hip joints - 4 of 6 patients underwent total hip replacement (THR) of 6 joints. Age median of patients undergoing THR was 26 years. One patient in an early stage of AVN underwent forrage and 1 patient was on conservative treatment while waiting for THR. Out of 6 THRs we experienced no septic or aseptic loosening in an early post-operative period. We followed the patients after THR for 11-143 months (median, 30 months). Out of 6 replaced hip joints we experienced deliberation of acetabular and distal femoral component in 1 patient, 8 years after implantation. Reimplantation was performed without any complications.
Summary/Conclusions: Avascular necrosis occurred more in male patients in our study. We didn't define any other risk factor for AVN. We observed the highest incidence of AVN of hip joints with 100% bilateral occurrence, where imaging exams were more sensitive than corresponding clinical symtomatology. Surgical methods of AVN treatment remain to be gold standard for higher stages of AVN of hip joints with favorable benefit-risk ratio.

PB2164

HIGH FERRITIN LEVELS IN FEVER OF UNKNOWN ORIGIN: POSSIBLE FIRST SIGN OF HEMOPHAGOCYTOSIS IN BMT PATIENTS?

Y Yaman[1,*], V Hazar[1], E Sarıbeyoğlu[1], K Ozdilli[2], S Anak[1]
[1]Pediatric hematology, [2]Medipol Mega University Hospital, istanbul, Turkey

Background: Fever of unknown origin is a major problem in transplant patients. The management of prolonged fever without any signs and symptoms of a specific microorganism such as bacteria, virus or molds is controversial and debateful.
Aims: While checking other biological parameters of FUO, we also included ferritin to rule out hemophagocytosis.
Methods: Between January 2015-February 2016 out of 37 allogeneic transplantations (21 MFD, 3 haploidentical, 12 MUD, 1 cord blood), 6 patients (4 girls/2 boys, 3 MFD/ 3 MUD, 2 malignant diseases/ 4 nonmalignant disease) developed high fever with hepatosplenomegaly at median day 28 (14-45 days). They were treated with broad spectrum antibiotics, they were all receiving prophylactic viral treatment with acyclovir and prophylactic flucanozol. No microbiological agent causing the fever could be detected. In patients with fever more than 5 days, CT scan of the chest, abdominal ultrasonography were performed, without any diagnostic findings. At the onset of fever none of the patients had GvHD.
Results: The ferritin levels of these patients were found to be very high (median 93.486 ng/ml, 3587-381.300 ng/ml) Other major parameters of hemophagocytosis such as hypertriglyceridemia, pancytopenia etc were not detected. The patients were treated with steroids and fever resolved in all patients within 48 hours. One patient died of graft rejection, one patient received steroid and plasma exchange due to severe multiorgan dysfunction. They received steroids for a median of 29,5 days (24-34 days).
Summary/Conclusions: In transplant patients fever can be sometimes very hard to manage. If a microbiological cause of fever could not be detected we think that checking the ferritin level is very important, even if some of the diagnostic parameters for hemophagocytosis are missing. High ferritin levels could be the first sign of hemophagocytosis in these patients and it can be treated with steroids excluding etoposide to secure the graft.

PB2165

CLINICAL ASSESSMENT OF PATHOGENETIC VIRUSES IN HEMORRHAGIC CYSTITIS AFTER ALLOGENEIC CELL TRANPLANTATION: HOW HIGH IS HIGH FOR URINE BK POLYOMA VIRAL LOAD

A Papalexandri*, D Mallouri, V Konstantinou, P Zerva, E Koravou, M Kalliou, I Batsis, E Yannaki, T Touloumenidou, C Smias, A Anagnostopoulos, I Sakellari
Hematology Department and HCT Unit, G.Papanikolaou Hospital, Thessaloniki, Greece

Background: Hemorrhagic cystitis (HC) after allogeneic hematopoetic cell transplantation (allo-HCT) has been recognized to be a relatively common severe complication with increased morbidity requiring hospitalization. Apart from conditioning toxicity, the most common pathogens implicated are cytomegalovirus (CMV) and BK-polyoma virus (BKPV). Data concerning the clinical relevance of molecular monitoring of these viruses in urine are scarce.
Aims: We conducted a retrospective study enrolling patients who developed cystitis after allo-HCT to evaluate the urine viral load of both CMV and BKV that is potentially associated with HC.
Methods: CMV and BKPV viral load in urine and CMV in plasma were measured with RQ-PCR in symptomatic patients with cystitis. Macroscopic hematuria (+/-clots) led to the diagnosis of hemorrhagic cystitis.
Results: Twenty-nine patients (female=14, male=15), aged 16-61 years (median 35) who developed cystitis after allo-HCT and for who viral load data were available for both pathogens were included in the study. Patients suffered from hematological malignancies and underwent allo-HCT following myeloablative (21) or reduced intensity conditioning regimen (8). The majority of patients (17/29) received graft from a matched volunteer, 8/29 from siblings and 4 from a haplo-identical relative donor. Median time for the onset of cystitis was 48 days (7-677). Fourteen out of 29 (48%) patients experienced HC requiring hospitalization. CMV viral load in urine was positive in 7/29 samples (median: 1270 copies/ml, range: 180-1490000). Concordant CMV viremia was documented in 15 patients (median: 2570 copies/ml, range: 26-81000). BKPV viral load in urine was positive in 23/29 patients (median $2{,}5x10^7$ copies/ml, range: $1{,}18x10^2$-$3{,}2x10^{10}$). Bacterial infection by klebsiella pneumonia was documented in one patient. Hemorrhagic cystitis was significantly associated with BKPV viral load: $2{,}5x10^7$ in HC patients *vs* $1{,}9x10^4$ in non-HC, p=0.018. A cut- off of $5{,}1x10^4$ copies/ml could strongly predict the development of hematuria in ROC analysis. CMV viral load in urine and plasma tended to be higher in HC patients without a significant difference: (i) in urine: 106575 *vs* 523 copies/ml and (ii) in plasma: 9004 *vs* 2584 copies/ml for HC *vs* non-HC patients respectively, p=ns. No other clinical or biological factors could predict the development of HC. Cytology was available in 9 patients with HC but only two were found positive (BKPV load $>1x10^8$ copies/ml in both patients). Patients were treated with antiviral agents, mostly val/gancyclovir and foscarnet and cidofovir was added in persisting cases. In 12 patients with HC, >2 consecutive samples were available after the first documentation of BK (median 5, 3-7). In these patients a slow reduction of BK load was observed (median reduction: 0.9 log in 30 days) and all the patients maintained a high BKPV load ($>1x10^5$in 9/12) regardless of the resolution of cystitis.
Summary/Conclusions: In our study BKPV was related with the development of hemorrhagic cystitis after allo-HCT, with viral loads higher than $5{,}1x10^4$ copies/ml strongly predicting hematuria. Despite the fact that CMV was also detected, CMV viruria or viremia were not found to be significant co-factors. Prospective studies are warranted to answer the benefit of viral molecular monitoring in urine among transplanted patients.

PB2166

THE ANALYSIS OF PATIENTS WITH POOR MOBILIZATION AND MOBILIZATION FAILURE: CAN RDW BE A PREDICTIVE FACTOR?

N Buyukkurt, P Aytan*, I Kozanoglu, E Maytalman, M Yeral, C Gereklioglu, S Solmaz, A Korur, H Ozdogu, C Boga
Hematology, Baskent University Adana Medical and Research Hospital Bone Marrow and Transplantation Centre, ADANA, Turkey

Background: Autologous hematopoetic stem cell transplantation (AHSCT) has been routinely used in the treatment of hematologic malignancies. Stem cell collection procedure from the patients has been accomplished with apheresis equipments. G-CSF is usually used alone or with chemotherapy for the purpose of the mobilization.
Aims: The aim of the present study is to assess retrospectively the patients who had been mobilized with different chemotherapy protocols between 2012 and 2016 and to analyze the patients with poor mobilization or mobilization failure and to determine the possible causes.
Methods: This study has been planned as a cross sectional study in a center that has been a member of EBMT and had been accreditated by JACIE between the years 2012 and 2016. All the data were obtained from the hospital data bases. Spectra Optia (Terumo BCT, Denver, USA) which utilizes continous flow centrifuge technique was used for the collection of stem cells. Peripheral and product CD 34 counts were done with FACS Canto II (BD Bioscience, USA) device and ISAGE method. Mobilization techniques used in the patients had been planned in accordance to the standart application (SOP number; KIT-KU009) methods. The patients with CD34 counts less than 20 cells/uL had been defined as “poor mobilization” whereas patients with stem cell counts less than 2x106/kg in product had been accepted as “mobilization failure”. In the day of stem cell collection peripheral blood count (Sysmex, XN 1000, Tokyo, Japon) had been performed and RDW, hemoglobin and platelet counts were noted.
Results: In our center there has been a total of 27 poor mobilization cases (8.82%;23 patients) between 2012 and 2016. A total of 279 stem cell apheresis procedures had been performed during the same period and in 35 cases (12.54%) mobilization failure was observed. 5 of the patients in the poor mobilization group had 3 consequtive chemotherapy protocols (1 patient radiotherapy), 12 of them received 2 consequtive and 6 of them received 1 chemotherapy protocolIn this group mobilization was tried to be accomplished with G-CSF alone in 6 patients, with G-CSF and plerixefor in 2 patients and with chemotherapy and G-CSF in 15 patients. For the comparison of RDW, Hb and platelet numbers among the mobilization groups, first day laboratory results of the patients had been used. There were no statistically significant difference with respect to platelet and Hb levels among the groups; however, the RDW was found to be significantly lower in the patients with successfull mobilization when compared with the patients in the poor mobilization and mobilisation failure groups (median [minimum-maximum] values were 15.4(12.08-25.20),16.4 (13.3-21.6) and 16.3(13.5-24.9) in successfully mobilized, poorly mobilized and mobilization failed groups (p=0.029). Mobilization failure was observed during stem cell collection in 6 of the 60 patients in 2012, 5 of 63 patients in 2013, 4 of 44 patients in 2014 and 7 in 49 patients in 2015. The median number of chemotherapy before mobilization procedure was 2 (1-3), and the median platelet levels during peripheral CD34 count was 95500/µL (10000-384000/µL). The median CD34 cell count from the peripheral blood was 9 cell/µL(0-17) and the median percentage of CD34 was 0,03(0,00-0,11).
Summary/Conclusions: Our results support the hypothesis that multiple chemotherapy independent from age results in poor mobilization and mobilization failure. RDW was shown to be lower in patients with successfull mobilization compared with poor mobilization or mobilization failure patients. The role of RDW in prediction of mobilization success has to be clarified in further studies.

PB2167

SUCCESSFUL REDUCE OF 60 PATIENTS FOR REFRACTORY/RECURRENT LEUKEMIA BY ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION AND PROPHYLACTIC IMMUNOTHERAPY

W Jingbo*, F Xinhong, C Haoyu, Y Yuming, Z Weijie, X Song, H Junbo, Y Fan, G Jiangying, L Qian, Z Shuqin, L Mengqi
Hematology Department, Aerospace Center Hospital Of Peking University, Beijing, China

Background: Refractory /Recurrent leukemia always has a poor prognosis.
Aims: To retrospectively evaluate the results of allogeneic hematopoietic stem cell transplantation and Prophylactic Immunotherapy for Refractory/Recurrent leukemia.
Methods: From June 2012 to January 2015, 60 patients with high-risk leukemia were enrolled, including 18 cases of ALL, 37cases of AML and 5 case of CML-BP. The average leukemia burden was 53(20-95)% in bone marrow. All patients received HLA haplo-identical stem cells transplantation from parent or sibling donors. Myeloablative conditioning regimens consist of 7cases of BuCy, 26 cases of TBI/FLAG, 15 cases of TBI/Cy, and 12 cases of FLAG that followed by reduced-intensified BUCY. All patients received cyclosporine A, MMF and methotrexate for GVHD prophylaxis. All patients received DLI,DC-CIK and NK according to different status after allogeneic HSCT .Analyzed outcomes were hematological engraftment, incidence of acute and chronic GVHD, incidence of relapse, and nonrelapse mortality (NRM), Overall survival and Disease-free survival.
Results: The MNC and CD34+ for transfusion were $9.08(7.02\text{-}24.4)*10^8$/Kg and $3.42(0.8\text{-}12.1)*10^6$/Kg. All 60patients achieved stable engraftment. The median time of ANC≥$0.5*10^9$/L was 16 (8-23) days. And for platelet ≥$20*10^9$/L, the median was 22 (8-150) days.38 patients developed acute GVHD, the accumulative incidence of aGVHD was 66.4%, the accumulative incidence of II-IV grade aGVHD was 35%, and the accumulative incidence of III-IV grade aGVHD was 15%. 26 patients developed cGVHD (12 patients extensive, 14 patients limited), the accumulative incidence of cGVHD was 88.2% and for extensive type, the accumulative incidence was 67.4%. The accumulative incidence of CMV infection was 54.1%, and the accumulative incidence of EBV infection was 16.3%. 10 patients developed virus cystitis. The number of Bacterial and fungal infected patients were51 and 27, respectively. The median follow-up time post transplantation was 11(1-36) months, 14 patients relapsed and the accumulative incidence of relapse was 27%. For AML, ALL and CML-BP patients, the accumulative incidence of relapse were26.6%, 34.8□and 0□, respectively.The median follow-up time post transplantation was 11months, 21 patients died and the main causeswere relapse (11 cases), infection (5 cases), cGVHD(2 cases) and diffuse alveolar hemorrhagediffuse alveolar hemorrhage(3 cases). Among 60 patients, 39 patients survived. The one-year and two-year accumulative incidences of OS were61.8% and 49.5%, respectively. The one-year and two-year accumulative incidences of DFS were 53.8% and 47.8%, respectively.For AML, ALL and CML-BP patients, the two-year accumulative incidence were 52.6%, 34.4% and66.7%, respectively. The non-

relapse mortality was 10. The one-year and two-year accumulative incidences of NRM were 19.4% and 28.4%, respectively.
Summary/Conclusions: Our clinical results have shown that the salvaged HSCT is a promising modality for treatment of high-risk AL with high leukemia burden.

PB2168

STEM CELL MOBILIZATION WITH HIGH DOSE ETOPOSIDE PREDICT AND IMPROVE THE OUTCOME OF AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN PATIENTS WITH REFRACTORY OR RELAPSED LYMPHOMA

Y Cai[1,*], L Wan[2], C Wang[1]
[1]Hematology, Shanghai general Hospital, [2]Hematology, Shanghai general Hospital, Shanghai, China

Background: Autologous hematopoietic stem cell transplantation is an effective treatment for refractory and relapsed lymphoma patients.Most studies show that chemotherapy sensitivity is an important prognostic factor for these patients.A significant proportion of patients with relapsed and refractory lymphomas fail to respond to conventional salvage therapy and never proceed to transplantation, most often due to chemotherapy-resistant disease.Etoposide is an epipodophyllotoxin that has a topoisomeraseII-inhibiting function and causes DNA-strand breaks. Several groups have described the effectiveness of etoposide alone or in combination regimens to mobilize PBSCs.
Aims: We report a respective study in treating 88 patients with relapsed or refractory lymphomas who received high-dose etoposide (VP16) in mobilization plus autologous peripheral blood stem cell transplantation as rescue therapy.To investigate the efficacy of stem cell mobilization with high-dose etoposide and granulocyte colony stimulating factor followed by autologous peripheral blood stem cell transplantation in patients with relapsed or refractory lymphoma as salvage therapy. We hypothesized that the response to high-dose etoposide may predict the outcome of ASCT.
Methods: From November 2005to December 2014, 88 patients with refractory or relapsed non-Hodgkin's lymphoma (NHL, n=61) or Hodgkin lymphoma (HD, n=27) received high-dose etoposide (VP16 20~25mg/kg/d ×2) and G-CSF for stem cell mobilization. The median age of 59 male and 29 female patients was 33 years (range 16–60)Patients' remission status prior to mobilization were partial remission (PR) (n=39) and progressive disease (PD) (n=49). All patients underwent autologous peripheral blood stem cell transplantation (auto-PBSCT). Conditioning regimen was BEAM (n=30) or CBV (n=58).
Results: Among 88 patients, 65 (73.9%) patients had response. 36 of 39 (92.3%) PR patients had response, 30 of 49 (61.2%) PD patients had response. Median follow-up was 21.5 (1~85) months after stem cell transplantation. 58 (65.9%) patients achieved CR, 18 (20.45%) patients attained PR, 10 (11.36%) patients suffered disease progression, 1 (1.1%) patients relapsed, and 1 (1.1%) patient died of bone marrow failure. Among PR group, the estimated 2-year DFS for patients who had response and no response to etoposide were 83.6% and 33.0% respectively. In PD group, the estimated 2-year DFS for patients who had response and no response to etoposide were 69.4% and 26.7%, respectively. P <0.01. The estimated 2-year OS for responders and non-responders were 72.0% and 25.9%, respectively. P <0.01 .
Summary/Conclusions: Stem cell mobilization with high dose etoposide and G-CSF followed by auto-PBSCT was beneficial in the treatment of refractory lymphoma. Disease-free survival over 2 years can be achieved in some patients. Patients' response to high dose etoposide was correlated to 2-year DFS and OS, which could also predict the outcome of auto-PBSCT for those patients. Utilizing high dose etoposide, we can select some chemotherapy-sensitive patients from refractory lymphoma. The outcome of autologous transplantation is correlated to the response of high dose etoposide.

PB2169

EFFECT OF TRANSFUSION OF THE THIRD PARTY UMBILICAL CORD BLOOD ON HAPLO-IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

W Jingbo*, F Xinhong, C Haoyu, Y Yuming, Z Weijie, X Song, H Junbo, Y Fan, G Jiangying, L Qian, Z Shuqin, L Mengqi
Hematology Department, Aerospace Center Hospital Of Peking University, Beijing, China

Background: Cord blood stem cells have multiple functions in haploidentical stem cell transplantation
Aims: To retrospectively evaluate the effect of the third party umbilical cord blood on haplo-identical hematopoietic stem cell transplantation.
Methods: From June 2012 to May 2015, 125 leukemia patients were enrolled, including 41 cases of ALL, 62cases of AML, 12 cases of MDS, 7 cases of CML-BP, 2 cases of acute mixed leukemia and 1 case of Blastcell dendritic cell tumor. Inclusion criteria: 1) AL patients; 2) halpo-identical HSCT; 3) 3/6 matched cord blood was available. Patients were divided into two groups, ie. groupA (HSCT, n=65) and groupB (HSCT plusumbilical cord blood transfusion group, n=60). Myeloablative conditioning regimens consisted of BuCy, TBI/FLAG, TBI/Cy, and FLAG that followed by reduced-intensified BUCY. The median dose of mononuclear cells in groupA and B were $8.58x10^8$/kg and $9.01x10^8$/kg, respectively. The median dose of CD34+ cells fortransfusion in each group were $3.67x10^6$/kg and $2.94x10^6$/kg, respectively. The dose of grafted UCB MNCsand CD34+ cells for groupB were $3.5x10^7$/kg and $2x10^5$/kg, respectively. All patients received cyclosporineA,MMF and methotrexate for GVHD prophylaxis. The endpoints of this study were hematological engraftment,incidence of acute and chronic GVHD, incidence of relapse, transplant-related mortality(TRM), non-relapsemortality(NRM), Overall survival(OS) and Disease-free survival(DFS) in each group.
Results: The median follow-up time was 17(3-29) months in groupA and 18(3-35) months in groupB.Patients in groupA reached a sustained ANC of more than $0.5*10^9$/L at a median of 11 days, whereas 14 daysin groupB. Platelet more than $20*10^9$/L occurred at a median of 19 days in groupA, whereas 17 days in groupB (P= .4). The rate of aGVHD was not significantly different in the two groups, 56.9% in groupA and 48.3% in groupB (P= .21). The accumulative incidence of II-IV grade aGVHD was 35.4% in groupA and 30% in groupB (P= .42). The incidence of chronic GVHD was 79.2% in groupA and 71% in groupB (P= .47). The incidence of extensive type was lower in groupB, 69.2% *vs* 35%, P=0.09. The incidence of CMV was lower in groupB, 80% *vs* 60% (P= .01). The accumulative incidence of EBV was lower in groupB, 35.4% *vs* 3.3% (P<0.01). At two years, the accumulative incidence of relapse was 24.4% in groupA and 17.2% in groupB, P=0.13. The two-year accumulative incidence of OS was 72.9% in groupA and 84.8% in groupB, P=0.07. The one-year accumulative incidence of DFS in each group were 65.7% and 79.4%, respectively, P=0.03.
Summary/Conclusions: Our clinical results have shown that HSCT with transfusion of the third party umbilical cord bloodis a promising modality for induction of immunity reconstitution. Better survival results may benefit from lower incidence of GVHD and virus infection. $x10^8$/kg and $9.01x10^8$/kg, respectively. The median dose of CD34+ cells fortransfusion in each group were $3.67x10^6$/kg and $2.94x10^6$/kg, respectively. The dose of grafted UCB MNCs and CD34+ cells for groupB were $3.5x10^7$/kg and $2x10^5$/kg, respectively. All patients received cyclosporineA,MMF and methotrexate for GVHD prophylaxis. The endpoints of this study were hematological engraftment,incidence of acute and chronic GVHD, incidence of relapse, transplant-related mortality(TRM), non-relapsemortality(NRM), Overall survival(OS) and Disease-free survival(DFS) in each group.

PB2170

ENGRAFTMENT POST AUTOLOGOUS STEM CELL TRANSPLANT FOR MULTIPLE MYELOMA IS UNAFFECTED BY LENGTH OF STEM-CELL STORAGE- EXPERIENCES FROM THE ROYAL MARSDEN HOSPITAL, UK

S Chavda*, R Mellor, C Pawlyn, A Smith, M Ethell, M Potter, C Anthias, C Dearden, M Kaiser
Haemato-oncology, Royal Marsden Hospital NHS Foundation Trusts/ Institute of Cancer Research, London, United Kingdom

Background: Multiple myeloma(MM) is the is the second most common bone marrow cancer with almost 5000 patients diagnosed in the UK each year, accounting for 10% of all haematological malignancies. Triplet chemotherapy followed by autologous stem cell transplantation (ASCT) is the gold standard induction treatment in younger fit patients and has significantly improved overall survival rates. A second ASCT at relapse can also improve subsequent remission duration. Peripheral blood stem cell (PBSC) harvest and storage is, therefore, routinely performed by transplant centres with the aim to collect enough cells to enable patients to undergo two ASCTs over the course of their treatment. As survival of patients with MM has dramatically improved in the era of novel agents, duration of storage and associated costs incurred have increased. It is therefore important to examine the feasibility and clinical utility of long term cell storage. There is conflicting data on viability of stored stem cells, with some studies reporting reduced $CD34^+$ count and cell viability over time, and others reporting successful transplantation outcomes with stem cells stored for up to 11 years.
Aims: We analysed the effects of stem cell storage duration on time to engraftment in patients undergoing ASCTs for MM in our centre.
Methods: We undertook a retrospective analysis of all patients undergoing ASCT for MM between 2008 and 2015. Patients undergoing tandem ASCTs were excluded. Days to engraftment was defined as number of days from stem cell infusion to neutrophil count >0.5 $X10^9$/L.
Results: 406 patients underwent ASCT between 2008 and 2015, with a median patient age of 65 years (range 25-78 years). 80.3% of patients (n=326) underwent one ASCT and 19.7% (n=80) underwent two. Of those patients receiving a second stem cell transplant, 81.2% percent had stem cells stored for between 0-60 months at the time of second transplant, and 18.8% for between 61-170 months. 80% of patients required only one therapy regimen prior to ASCT and 79% of patients were in a complete remission or very good partial response pre-transplant. Novel agents (bortezomib, lenalidomide and thalidomide) were used in 95% of cases as front-line therapy. PBSCs were stored on average for 32 months before being used. Melphalan 200mg/m^2 was used as conditioning chemotherapy pre-transplant (140mg/m^2 in renal impairment or medical comorbidities) with stem-cell return on Day 0. All patients successfully engrafted.

There was no significant difference in time to engraftment in all patients with PBSCs stored between 0-60 months (11.3 days+/-2.3 days) and 60-170 months (11.0 days+/-2.6 days), p=0.42 (Student's unpaired t test). The longest period of time PBSCs were stored was 165 months with successful engraftment at 12 days. 19.7% of patients had stem cells stored between 60-120 months (n=80) and of these 22.5% of patients went on to have second autograft using stored PBSCs. All patients with PBSCs stored for more than 120 months went on to have a second successful ASCT (n=3). These patients were all treated with novel agents prior to ASCT.
Summary/Conclusions: Our results show that prolonged periods of PBSC storage does not affect stem cell engraftment in MM patients undergoing ASCT. These results support the rationale of ongoing long-term PBSC storage in the era of novel agents as salvage ASCT remains an important treatment option for relapsed or progressive MM.

PB2171

REVIEW OF THE EFFECTIVENESS OF PALONOSETRON IN PREVENTION OF NAUSEAS AND VOMITS INDUCED FOR MELPHALNAN IN AUTOLOGUS TRANSPLANT OF HEMATOPOIETIC PROGENITOR CELLS

C Saenz Fernandez*, M Pereiro Sanchez, A Rodriguez Vazquez, N Martinez Torrens, A Gomez Marquez, JL Sastre
Hematology, Complexo Hospitalario Universitario de Ourense, Ourense, Spain

Background: Prevention of nauseas and vomits induced for melphalan in autologus transplant of hematopoietic progenitor cells is an important issue. There is not an standar of care until now. In our work we review the effectiveness of Palonosetron for these patients.
Aims: Assess the effectiveness and security of Palonosetron in the prevention of nauseas and vomits induced for melphalan at high dose (200mg/m2) in autologus transplant of hematopoietic progenitor cells
Methods: Observational study, descriptive and retrospective in which have been included patients older than 18 year old diagnosed of multiple myeloma and with autologus transplant of hematopoietic progenitor cells during the period March 2009-February 2014 which received Melphalan 200mg/m2 in day -4. For prevention of nauseas and vomits a dose of Palonosetron 250mcg was administer intravenous half an hour before the infusion of Mephalan was started. The identification of the subjects was done through the computer program of prescription, validation and preparation of cytostatic mixtures Oncofarm®. To assess the effectiveness a survey was used where patients had reflected nauseas and vomits during the four days after the administration of Mephalan and the notes of nursing and medical staff on the medical records. The variables used were, age, sex, toxic habits (tobacco, alcohol), scale of basal activity ECOG, digestive disease, regular medication, previous chemotherapy and anticipatory nauseas and vomits
Results: 31 patients were included, 20 women (64.5%) and 11 men, mean age 59.4 years old. The 77.4% were not smokers and the 80.6% declared drink less than 30 grams of alcohol per week. At the moment of the transplant one patient had ECOG 1, and all the other patients ECOG 0. Nine patients (29%) were suffering some sort of digestive disease (Dyspepsia, peptic ulcer, hiatus hernia, gastroesophageal reflux disease or obstruction). The 71% (n=22) was been treated with opioids, antacids and/or benzodiazepines. The schemes of chemotherapy previous given were Bortezomid + Dexamethasone (n=24), Bortezomid +Thalidomide + Dexamethasone (n=5), Bortezomid + Dexamethasone + Cyclophosphamide (n=2), lenalidomide (n=3) and Vincristine + Doxorubicin + Dexamethasone (n=1). The 12.9% of the patients had nauseas or vomits in the last cycles. At the moment of the admission for the transplant only two patients had anticipatory nauseas. In the first 24 hours after mephalnan infusion and palonosetron administration 54.8% (n=17) suffered an episode of nauseas (eight patients grade 1, eight grade 2, and one grade 3), and only nine had vomits (seven grade 1, one grade 2 and one grade 3). Between the next 24-96 hours 19 patients (61.3%) had nauseas (14 grade 1, two grade 2 and three grade 3), and 12 patients (38.7%) vomits (nine grade! and three grade 2). As rescue medication levomepromazine was used in the 35.5%. all the others were treated with metoclopramide, dexamethasone, domperidone and/or benzodiazepines. The only adverse effect documented after Palonosetron administration was constipation (n=2, 6.4%).
Summary/Conclusions: We can confirm the effectiveness and security of palonosetron in the prevention of nauseas and vomits induced for high dose of Mephalan. The results are similar to those reported in the available bibliography.

PB2172

STENOTROPHOMONAS MALTOPHILIA BLOODSTREAM INFECTION IN CHILDREN WITH HEMATOLOGIC DISEASES

C Albayrak*, D Albayrak
Pediatric Hematology Department, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey

Background: Stenotrophomonas maltophilia (S. maltophilia) causes serious infections in immunocompromised hosts which early use of susceptible antibacterial may be lifesaving.
Aims: We investigated the clinical characteristics of S. maltophilia bloodstream infection (BSI) in children with hematologic diseases.
Methods: We retrospectively reviewed the medical and microbiological records of all consecutive episodes of S. maltophilia BSIs in children with hematologic diseases and hematopoietic Stem Cell Transplantation (HCT) recipients at the University Hospital (Samsun, Turkey) between January 2006 and January 2016.
Results: Among 762 patients identified as S. maltophilia BSIs during 10-year period, 26 children were identified as hematologic diseases; 7 ALL, 3 AML, 2 Fanconi anemia, 5 aquired aplastic anemia, 2 Diamonnd Blackfan anemia, 1 Griscelli syndrome, 1 Diskerotozis Congenita, 1 Ataksia telengiektasia, 1 JMML, 1 MPS type I, 1 Hereditery spherocytosis and splenectomy, 1 JRA and macrophage activation syndrome. Fifteen of them were HCT recipients. Other eleven of them have been treated with immunesupresive drugs. Fifteen (58%) patients were female. The median patient age was 8.6 years (range: 0.6–18 years). Five patient have cutaneous infection (ecthyma gangrenosum). *in vitro* susceptibilities to trimethoprim-sulfamethoxazole (TMP-SXT) were 100%.
Summary/Conclusions: S. maltophilia BSIs may cause to sepsis, especially in patient with severe neutropenia, shock, and pneumonia. It should be in mind when fever, sepsis and ecthyma gangrenosum finding continued although the use of standard antibiotics of febril neutropenia. TMZ-SXT should be first treatment choice for S. maltophilia BSIs in hematologic patients based upon drug susceptibility testing.

PB2173

FEASIBILITY AND SAFETY OF BENDAMUSTINE, ETOPOSIDE, CYTARABINE, MELPHALAN (BEEAM) CONDITIONING REGIMEN BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN 33 PATIENTS WITH MALIGNANT LYMPHOMA

M Bedoui[1,*], P Brault[1], S Glaisner[2], R Elias Shamieh[2], F Kuhnowski[1]
[1]Hematology, Institut Curie, PARIS, [2]Hematology, Institut Curie, Saint Cloud, France

Background: High-Dose Chemotherapy supported by Autologous Stem Cell Transplantation (HDC/ASCT) is considered the treatment of choice for relapsed/refractory or high risk malignant lymphoma. However, several questions on efficacy and feasibility of HDC/ASCT remain, such as the best candidates for this strategy, the optimal conditioning regimen, and acute and late effects. To date, few comparative randomized trials have been performed, and no regimen has demonstrated superiority to another. The commonly used conditioning regimens is BEAM (BICNU...). To overcome the sourcing out of Carmustine in France we have decided to replace this product with Bendamustine, demonstrated significantly superior efficacy compared with standard therapy in B cell lymphoma, and this based on the work published by Visani and al in 2011.
Aims: We report our experience in a retrospective study concerning 33 patients treated with this conditioning regimen
Methods: From July 2012 to February 2016, 33 patients with median age 56 (28 -70) years, 8 had more than 65 years, Sex ratio (M/F) 22/11, underwent this procedure. This regimen BeEAM combined Bendamustine 100 mg/m² d-7 to d-6; Etoposide 200 mg/m² d-5 to d-2; Cytarabine 200 mg/m² twice daily d-5 to d-3; Melphalan 140 mg/m² d-1 and the reinjection of hematopoietic stem cell was done at d0. We did a reduction of 30% of Cytarabine and Etoposide doses because of age (6 patients). The diagnosis was NHL in 30 cases, composite hemopathy in 2 cases, and HD in 1 case. 30 patients had advanced stage disease (III-IV) of Ann Arbor classification, and a Bulky disease in 4 cases. For 10 patients with DLBCL in first line treatment, the IPIaa was ≥2 in all cases. 15 patients received intensification followed by ASCT in first line treatment, 12 in relapse disease and 6 were primary refractory. The median number of previous line therapy was 2 (1-4). The status at the time of ASCT was evaluated by PET/CT in 29 cases. 23 were in complete remission (CR) and 6 in partial remission (PR). 4 patients was evaluated only by CT-scan (3 PR, 1 CR).
Results: Among the 33 patients treated, the number of autologous CD34+ cells infused was systematically >to 2x10^6 CD34+/kg, and we observed that the median time to myeloid engraftment (ANC>0.5x10^9/l) was 8 days (4-16), and the median time to platelet engraftment (≥20x10^9/l) was 15 days (6-39). The digestive toxicity was important with 16 patients who present a diarrhea grade III-IV, and 23 oral mucositis grade III-IV. One patient presented a veno occlusive disease (VOD) treated with Defibrotide®. We observed 3 cases of cardiac toxicity (3 heart failure grade III partially reversible with medical treatment), 5 renal failure grade I-II. One patient died due to a septic choc with multidrug resistant bacteria before hematological recovery after transplant, producing an overall transplant related mortality (TRM) of 0.03%. 2 patients died at distance of intensification by other causes (one patient with multiple infections caused by opportunistic agents, and the other one with secondary myeloid hemopathy) and the others 30 patients still alive, 29 in continuous CR.
Summary/Conclusions: The new effective regimen BeEAM is not safe in this population of patients with High Risk malignant non Hodgkin and Hodgkin lymphoma. The switch of Carmustine to Bendamustine in the intensive conditioning regimen, required a randomized trial to compare BeEAM and BEAM in new conditioning strategies, and advances in the supportive care will probably reduce transplantation related mortality (TRM). Limited data are available to optimize elderly patients selection for transplantation while minimizing the risk of TRM.

PB2174

ACQUIRED HYPER-IGM SYNDROME FOLLOWING CD20 MAB THERAPY FOR EPSTEIN-BARR VIRUS (EBV) REACTIVATION POST-ALLOGENEIC STEM CELL TRANSPLANT (ALLO-SCT)

FP Tambaro[1,*], S Luponio[2], MR D'Amico[1], WG Wierda[3], G De Simone[1], L Del Vecchio[4], C Pignata[5], V Poggi[6], M Ripaldi[1]
[1]Bone Marrow Transplantation, Ospedale Pausilipon, [2]Hematology, Università Federico II, Napoli, Italy, [3]Leukemia, MD Anderson Cancer Center, Houston, United States, [4]Biotecnologie Avanzate, [5]Pediatria, Università Federico II, [6]Ematologia, Ospedale Pausilipon, Napoli, Italy

Background: EBV reactivation can be a complication of allogeneic stem cell transplant (allo-SCT) that may lead to EBV-related B Cell Post Transplant Lymphoproliferative Disorder (PTLD).Preemptive treatment with the CD20 mAb rituximab eliminates CD20+ lymphocytes, thereby blocking virus replication, is indicated for rising EBV viral load.
Aims: Here we report 2 cases of acquired hyper-IgM syndrome as a late complication in kids who underwent allo-SCT and received rituximab for treatment of EBV reactivation.
Methods: An 11 yo boy and 8 yo girl underwent allo-SCT in 10/2008 and 8/2010 for ALL and Hemophagocytic Lymphohistiocytosis (HLH), respectively. Patient (pt) and allo-SCT characteristics are shown (Table).
Results: EBV reactivation occurred on day +59 and +33 with 34860 and 40325 EBV DNA copies in the pt with ALL and HLH, respectively. Pts received rituximab (Table) with complete elimination of viremia. Both pts developed hypogammaglobulinemia (IgM, IgG and IgA) post-transplant and received IVIG (0.5 g/kg) monthly for the first 3 months after transplant, then every 3 months, thereafter. The pts developed recurrent sino-pulmonary and enteric infections treated with antibiotics beginning 30 and 18 months post-all-SCT for the ALL and HLH pts, respectively (Figure). In the setting of these recurrent infections, and supportive IVIG, both pts developed progressive increase in IgM level. The ALL pt began to lose full donor chimerism, with no evidence of ALL relapse. He also had recurrent autoimmune thrombocytopenia, which responded to IVIG.Neither pt nor respective donor had mutation in CD154. Flow cytometry for the ALL pt showed decreased mature lymphocytes (CD19+ IgG+), memory lymphocytes (CD19+CD27+IgM+), switched memory (CD19+CD27+IgM-), and transitional lymphocytes (CD 19+CD27+IgM+), and no plasma cells in blood. Flow cytometry studies are ongoing for the HLH pt.

Table 1.

	Pt 1	Pt 2
Diagnosis/SEX	ALL/ Male	HLH /Female
Conditioning Regimen	TBI Thyotepa Cyclophospamide ATG	Busulphan Cyclophospamide ATG
GVHD prophylaxis	CSA MTX	CSA
Donor	MRD (10/10)	MRD 9/10
Cell source/ CD 34+ x 10^6/kg	BM / 4.7	BM / 4.5
PLT day / ANC day	+14 /+14	+19 /+19
Infections	None	Staph. Warneri
aGVHD/Grade/organ	II skin	II skin
GVHD treatment	MPDN 0.5mg/kg	MPDN 1mg/kg
EBV reactivation day /copies	+59/34860	+33/40325
EBV treatment	Rituximab 375 mg/m^{2}x 3 weeks	Rituximab 375 mg/m^{2}x 2 weeks

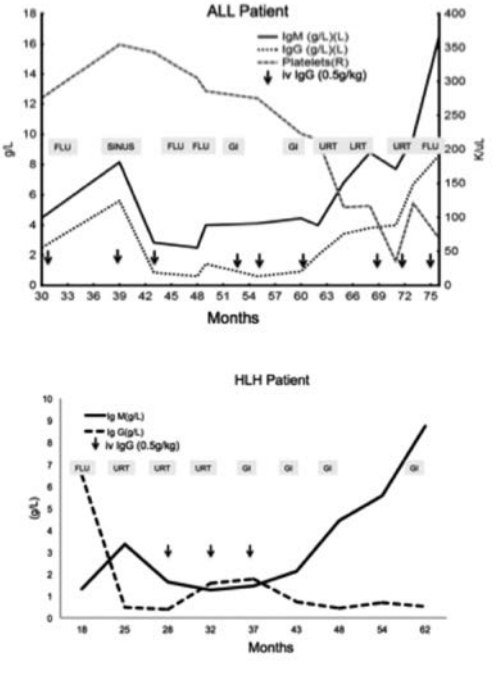

Figure 1.

Summary/Conclusions: We hypothesize that both EBV and rituximab played roles in development of these cases. EBV is responsible of B cell proliferation, maturation arrest, defective DNA repair, leading to hematological neoplasms. EBV infection and reactivation are also associated with autoimmune disorders, transiently elevated IgM during viremia, and monoclonal gammopathy after allo-SCT. Preemptive treatment with rituximab eliminates CD20+ cells where the virus replicates, thereby blocking EBV proliferation, but reduces lymphocyte counts for more than 6 months post BMT, which can alter immunological surveillance. These cases demonstrate development of acquired hyper-IgM syndrome as a late complication of EBV reactivation treated with rituximab post-allo-SCT, which is not previously described. We recommend diligent prolonged monitoring of IgM level post-allo-SCT, particularly in patients who develop autoimmune cytopenia or recurrent infections.

PB2175

BORTEZOMIB AND HIGH-DOSE MELPHALAN AS CONDITIONING REGIMEN BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA: EXPERIENCE IN A UNIVERSITARY HOSPITAL

DM Dunia[1,*], M Dolores[2], S Dolores[1], G Nuria[2], D Miguel[2], A Jaime[2], G Helga[2], V Alejandro[2], H Sonia[2], P Blanca[2]
[1]Hematologia, [2]Hospital universitario de Guadalajara, Guadalajara, Spain

Background: The combination of bortezomib and high-dose melphalan (HDM) is an attractive approach to improve the efficacy of the conditioning regimen. Furthermore, this association was expected to be safe because bortezomib and melphalan do not share common toxicities (mainly neurologic toxicity for bortezomib and hematologic toxicity for HDM). We followed a phase 2 study of the Intergroupe Francophone du Myélome (IFM) (Blood 7 Jan 2010, 115 (1); 32-36).
Aims: 1) to evaluate response rates after intensive therapy; 2) to assess the toxicity of this new conditioning regimen.
Methods: We reported 29 Multiple Myeloma (MM) diagnosed patients [18 Males/11 Females, median age 59 years (34-73)]. Patients were treated between February 2010 and December 2015 to receive Bortezomib and melphalan as conditioning regimen (Bor-HDM). Bortezomib was administered subcutaneous at 1 mg/m2 on days -6, -3, 1, and 4. Melphalan was administered intravenously at 200 mg/m2 on day -2. All patients received induction treatment with VCD (Bortezomib 1,3 mg/m2 S.C. D1, D4, D8, D11; Cyclophosphamide 600mg/m2 D1, D8; Dexamethasone 40 mg D1, D4, D8, D11) 6-8 cycles/21 days. Overall, 80% of patients achieved PR, including 8%VGPR and 12% patients with CR before ASCT. Peripheral blood stem cells [median 2.83x106 CD34+ cells/kg (1.97-4.39)] were infused on day 0.
Results: There was no engraftment failure. Neutrophils (ANC ≥0.5x109/L) and platelets (≥20x109/L without transfusion) recovered in median times of 11 days (range, 11-13 days) and 13 days (range, 11-18 days), respectively. Patients were discharged from the transplantation unit in median times of 27.5 days (range, 21-25 days). There were two treatment-related deaths, at +11 day of candidiasis (C. glabrata) and +15 day caused by Enterobacter sepsis. Some serious adverse events were reported: 1) Infections (51% patients): bacteremia was documented: 4 *Staphylococcus epidermidis*, 1 *Enterococcus faecalis*, 1 *Pseudomonas aeruginosa.* 1 Salmonella diarrhea and 1 pneumonia; 2) Mucositis: grade 4 non-hematologic toxicities were mucositis of upper and lower digestive tract sites (10%); the most frequently reported grade 1 or 2 adverse events were digestive (diarrhea, mucositis 55%). It should be noted that peripheral neuropathy (PN) was present at the time of ASCT in one patient and did not get worse after Bor-HDM treatment. At time of reporting, median follow-up time from induction therapy was 30 months (range, 3-72 months). Overall survival was 75%. 2 patients relapsed at 3 and 9 months after ASCT, and they died of progressive disease. Evaluation of response rate at 100 days after ASCT upgraded in 35% patients (reached CR/sCR).
Summary/Conclusions: Our experience shows that Bortezomib can safely be combined with HDM as a preparative regimen followed by ASCT. This regimen was well tolerated with no increased toxicity. Engraftment was not affected by the addition of Bortezomib. PN did not worse after this conditioning regimen.

PB2176

MONITORING MINIMAL RESIDUAL DISEASE IN AUTOLOGOUS CELLULAR THERAPY PRODUCTS COLLECTED BY APHERESIS-EXPERIENCE OF A THERAPY CELLULAR CENTER

S Ferreira[*], F Amado, S Lopes, F Bordalo, C Pinho, S Roncon
Cellular Therapy, IPO PORTO, Porto, Portugal

Background: The autologous transplant of peripheral blood stem cells (PBSC), harvested by apheresis on oncologic patients after high-dose chemotherapy and/or radiotherapy, is a therapeutic strategy used in hematologic diseases and solid tumors. Some studies suggest that incomplete disease eradication before collection could lead to the reinfusion of tumor cells and be associated with patient relapse and a lower survival. The search for minimal residual disease (MRD) has been performed in some centers through highly sensitive genetic techniques, contributing to improve the clinical decision and the patient outcome.

Aims: This study aims to evaluate the percentage of MRD-contaminated grafts in patients proposed to hematopoietic transplant with initial genetic alterations in our hospital.
Methods: A retrospective study was performed from May 2006 to February 2016. The inclusion criteria was patients with genetic alterations at diagnosis or relapse. The research was performed using fluorescent *in situ* hybridization (FISH) or/and real time polymerase chain reaction (RT-PCR) techniques. The data was analysed using an excel program.
Results: MRD was researched in samples of PBSC collected from 39 male and 28 female patients (n=67), with a median age of 51 years old (7 months-70 years). Their diagnosis were: non Hodgkin's lymphoma (NHL) n=24, multiple myeloma (MM) n=16, neuroblastoma n=17, acute myeloid leukemia (AML) n=5, acute lymphoblastic leukemia (ALL) n=2, Hodgkin's disease (HD) n=2 and Ewing's sarcoma (Ewing S.) n=1. Only 6 grafts were MRD positive, but with a very low tumour cell contamination (1-2%): 1 AML with *PML-RARA* fusion RNA; 1 ALL with *BCR-ABL* mRNA; 2 MM with deletion of 13q14; 1 Ewing S. with translocation of 22q12; 1 neuroblastoma with deletion of 11q23. Three contaminated grafts were eliminated: 2 patients (1 AML and 1 neuroblastoma) were proposed to different chemotherapy lines, undergone new mobilization and collection program and received a negative cellular therapy product; the ALL patient died before the second mobilization. Two MM patients were infused with the autologous grafts. In the remaining patient (Ewing S.), we performed a positive selection of CD34+ cells after thawing and before graft infusion. At present, 2 patients are alive and in complete remission, 9 and 10 years after treatment (Ewing S. and AML); 3 patients deceased 1, 7 and 4 years after transplant (2 MM and 1 neuroblastoma, respectively).
Summary/Conclusions: As it was a very small and heterogeneous sample, conclusive remarks of the role of MRD significance in stem cells grafts are not possible. In the same way, we only performed one *ex vivo* tumoral purging with identical results to those found on literature. Future prospective trials should address physicians to choose which is the best option to eradicate tumor cells (chemotherapy pretransplantation or immunotherapy postransplantation).

PB2177

VERY LOW INCIDENCE OF NEUROTOXICITY WITHOUT ANTICONVULSANT PROPHYLAXIS DURING THE CONDITIONING REGIMEN WITH BUSULFAN IN PATIENTS UNDERGOING STEM CELL TRANSPLANTATION
MM Rivera Franco*, E Leon Rodriguez, C Balderas Delgado
Hematology-Oncology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Background: Since neurotoxicities, including seizures, have been reported with the use of busulfan (BU), it is a trend to administer anticonvulsant prophylaxis during a conditioning regimen with this alkylating agent in patients undergoing hematopoietic stem cell transplantation (HSCT). On the other hand, anticonvulsant medications interact with busulfan metabolism, affecting its serum concentration and therapeutic activities, and have their own side effects on the patient which can alter the outcome of the transplant.
Aims: To analyze the frequency of neurotoxicity in patients who underwent stem cell transplantation with conditioning regimen including high doses of busulfan, without anticonvulsant prophylaxis, at INCMNSZ, from November 1998 to January 2016.
Methods: A retrospective analysis was performed in 97 patients receiving high-dose BU as part of their HSCT preparative regimen, at INCMNSZ, determining the frequency of seizures and other neurotoxicities.
Results: Ninety seven patients undergoing stem cell transplantation with conditioning regimen including busulfan, from November 1998 to January 2016, were included. Patients (male, 59%) had a median age of 33 years (range 15-61). The patients had a following range of underlying diseases: myelodysplastic syndrome (n=17, 17.5%), chronic myeloid leukemia (CML, n=13, 13.4%), acute lymphoblastic leukemia (LLA, n=19, 19.6%), acute myeloid leukemia (AML, n=31, 32%), or others (n=17, 17.5%). Patients who underwent an autologous transplant received high doses of busulfan, 16 mg/kg (n=24, 25%), and doses of 12mg/kg (n=73, 75%) were given for allogeneic transplant patients. None of the patients received anticonvulsant prophylaxis. Only one patient (1%), transplanted in 2011, presented seizures after the administration of BU, and was treated with phenytoin and benzodiazepines without further crisis.
Summary/Conclusions: From the beginning of our transplant program no anticonvulsant prophylaxis was given to patients receiving BU-based conditioning regimen for HSCT. Since neurotoxicities were not reported, we continued deferring the anticonvulsant prophylaxis. According to this data, we emphasize that in our experience, seizures are not frequent side effect of conditioning regimens including high dose busulfan, and therefore, anticonvulsant prophylactic regimens are not always necessary.

PB2178

SUCCESFUL STEM CELL COLLECTION IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) PATIENTS OVER 65 YEARS OLD
V Martinez-Robles, N De Las Heras, B Ballina, Ja Rodriguez-Garcia, F Escalante*
Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: High-dose therapy plus autologous stem cell transplantation (ASCT) is considered the standard of care for front-line treatment of younger patients with newly diagnosed multiple myeloma (NDMM). Eligibility for this procedure are based in almost all health institutions on chronological age more than on biological or functional age.
Aims: Retrospective analysis of characteristics of the mobilisation and collection procedures of NDMM ASCT-candidates patients from 2009 to 2014 comparing 2 groups of age: under *vs* over 65 years old.
Methods: 54 mobilization and apheresis procedures were analysed. 36 patients were under-65y (median 57y, range 48-65y) and 18 in over-65y (median 68y, range 66-71y). Induction Regimen were Bortezomib-based schemes in 50 of 54 patients and 4 received chemotherapy-based scheme before collecting Peripheral Blood Stem Cell (PBSC). PBSC collection was programmed after -at least- 3rd induction cycle. The virtual absence of failures of collection with Bor-Based schemes have permitted us to program mobilisation at any time of induction phase, even after the last cycle, without any complications or failures on the collection. Almost all patients were mobilized with granulocyte colony stimulating factors (G-CSF) alone. Only 1 patient was mobilized with cyclophosphamide and GCSF. Plerixafor was added in predifined by CD34 account poor mobilizers.
Results: G-CSF doses administered was different between the 2 groups of age: group under-65y received a median dose of 10 mcg/Kg/24 hours and the over-65y group a median dose of 10 mcg/Kg/12 hours. Median days of GCSF administration was similar: 5 days. There were no differences on mobilisation failure and/or on the indication of plerixafor administration (7/36 *vs* 2/18, p=ns) The number of aphaeresis needed to reach the CD34 target was similar: median= 1 (range: 1-3). The amount of CD34 cells collected was similar, with no statistical difference: median of 6.35 (2.5-17.67) *vs* 5.8 (2.6-11.6)x10E6 CD34/kg cells between groups. There were no differences in complications after the procedure (bleeding, readmissions ...) between groups. There were no differences in terms of safety and engraftment of ASCT between groups.
Summary/Conclusions: Mobilisation and collection of PBSC in NDMM over-65y patients with current induction schemes is feasible and without differences in terms of efficacy and safety (number apheresis, number of harvested cells, need of plerixafor ...) compared with under-65y group. New induction Bor-Based schemes have a good profile in terms of mobilisation and collection of PBSC, independently of the age Age "per se" is not a restriction to collect stem cells to support an ASCT.

PB2179

DIFFERENCES IN ATTITUDE TOWARDS HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) BETWEEN PHYSICIANS AND NURSES
O Pasvolsky*, U Rozovski, M Navon, A Pek, J Dreyer, T Klebovsky, I Vaxman, A Shacham, L Shargian, P Raanani, M Yeshurun
Instiute of Hematology, Beilinson Hospital, Petach Tikva, Israel

Background: Hematopoietic stem cell transplantation (HSCT) is a highly intensive medical procedure and the medical staff at a transplant unit experiences high levels of psychological distress. Since doctors and nurses differ in their clinical training, the level of professional indoctrination and in the duration and nature of exposure to the patients, we hypothesized that they hold different perspective towards the procedure.
Aims: To study how doctors and nurses perceive HCST and whether professional perspectives affect the attitude of physicians and nurses towards the procedure.
Methods: This is a single center study. All the nurses and physicians at our transplant unit were asked to fill out an electronic questionnaire that included 24 items. Five of the items were scenarios, each describing a clinical situation in which transplant is one of the therapeutic options. In order to ensure that the answers do not reflect differences in medical knowledge, there were only minimal or no medical clues to guide participants in these scenarios. Following each scenario, participants had to rank on a 1 to 5 Likert Scale whether they would undergo transplant or recommend it to their close relatives or friends under these circumstances, if this were their doctors' advice. Participants were also asked to rank their level of confidence in the transplant procedure. In addition, we included a work satisfaction questionnaire and basic demographic details were also documented.
Results: We delivered the questionnaire to 51 members of the medical staff, 23 doctors and 28 nurses, who work at our department. The median age was 40 (range: 24 to 78) years and 32 (63%) were females. Nurses were younger, more of them were unmarried and they had less professional experience. Nurses and doctors had similar distributions of male to female ratios, country of origin and both groups expressed similar levels of professional and religious beliefs. When asked directly, physicians and nurses expressed similar level of confidence in the process of HSCT. Intriguingly, only 21 (42%) of responders expressed a high degree of confidence in allogeneic transplantation, while 31 (62%) expressed a high degree of confidence in autologous transplantation. However, almost all doctors (20/21, 96%) but only 50% of nurses (14/28) expressed high levels of confidence in reduced intensity conditioning HSCT (P=.002). When asked if they would undergo transplant or recommend it to their close relatives, in 3 of 5 scenarios presented to responders significantly

more nurses were reluctant to undergo transplant despite their doctors' recommendation.
Summary/Conclusions: At our transplant unit, the attitude of physicians and nurses towards HCST differs significantly. Physicians perceive the procedure in a more positive way and tend to consider undergoing HSCT themselves or recommend it to their relatives if indicated. Nurses more often tend to consider palliative care and express more critical attitude towards the procedure. This study exposes fundamental differences in the professional point-of view and we call for open discussions around these issues in which the various perspectives are expressed and acknowledged. We believe that this approach will ultimately improve the communication and prevent unnecessary confrontations among medical staff.

PB2180

ARTERIAL HYPERTENSION IN LONG-TERM SURVIVORS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
C Arranto[1,*], T Burkard[2], O Pfister[2], J Halter[1]
[1]Hematology, [2]Cardiology, University Hospital Basel, Basel, Switzerland

Background: Improvement of transplantation techniques and supportive care lead to an increasing number of long-term survivors after allogeneic hematopoietic stem cell transplantation (HSCT). Recipients of allogeneic HSCT have a higher prevalence of cardiovascular risk factors.
Aims: To determine the prevalence of ambulatory hypertension in patients after HSCT.
Methods: Patients ≥1 year after allogeneic HSCT were included during their annual hematological check at University Hospital Basel, Switzerland. Blood pressure (BP) was measured on both arms in the office after 5 minutes rest. Arterial hypertension (HT) was defined as BP ≥140/90 mmHg. 24h ambulatory BP measurement (ABPM) was performed with a device for noninvasive continuous BP monitoring on the same day. 24h-, day- and nighttime HT was defined as ≥130/80, ≥135/85 and ≥120/70mmHg, respectively. Non-dipping was defined as a nocturnal BP decrease of <10%.
Results: 66 patients were enrolled between April 2015 and December 2015. Median age at study entry was 56 (range 22-73) with median 9 (range 1-29) years after transplantation. 47% of the patients were female. Nine (14%) patients had a BMI ≥30kg/m^2, 19 (29%) patients had a sedentary lifestyle and 12 (18%) patients were current smokers. Fifteen (23%) patients had treatment with calcineurin inhibitors and 4 (6%) patients had cortison. Thirty patients (45%) had office HT: Isolated systolic, isolated diastolic and combined HT was documented in 17, 2, and 11 patients, respectively. Systolic BP difference between arms of ≥20mmHg was measured in 3 patients. 24h- HT was documented in 41 patients (62%) with 6 systolic, 8 diastolic and 27 systolic and diastolic HT patterns. 32 (48%) patients had day-time HT and 54 (82%) patients had nighttime HT. 48 (73%) patients were non-dippers. White-coat HT and masked HT was diagnosed in 2 (3%) and 12 patients (18%), respectively. 32 (48%) had treatment with antihypertensive drugs. However, 23 patients were still hypertensive, 17 patients detected with office BP and further 6 patients were hypertensive on ABPM.
Summary/Conclusions: Arterial hypertension is common in patients after allogeneic HSCT and is often missed by office BP measurements only. ABPM detects patients with relevant night-time hypertension. ABPM may lead to better treatment of hypertension.

Abstract withdrawn.

PB2182

THE TROUBLE THAT HEMATOLOGISTS DEALING WITH: VARICELLA-ZOSTER AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION
M Comert Ozkan[*], I Nizam Özen, I Dolaşık, E Kaya, MA Erkurt, I Kuku
Adult Hematology, Inonu University, School of Medicine, Malatya, Turkey

Background: Reactivation of varicella zoster virus (VZV) is a common event in patients undergoing allogeneic and autologous bone marrow transplantation (BMT).
Aims: The morbidity associated with VZV reactivation and post-herpetic neuralgia results in an impairment of the quality of life, which may also lead to an increase in transplantation related costs and hospitalization. Determining the risk factors for VZV reactivation was aimed.
Methods: We retrospectively analyzed the incidence, clinical outcome, and risk factors for VZV infections in 237 adult patients undergoing BMT between Jan 2011 and Feb 2016 in Inonu University Bone Marrow Transplantation Unit. All of the patients were treated with acyclovir prophylaxis for 3 months after the allogeneic BMT and 30 days for autologous BMT.
Results: Fourteen (5.9%) of the patients developed VZV reactivation. Five (35.7%) of them were autologous BMT and 9 (64.3%) were allogeneic BMT patients. All of the patients were presented with pain and dermatomal zoster. A median day of VZV was 413 days (range 63-820) after transplantation for autologous BMT and 302 days (range 61-1140) for allogeneic BMT. Twenty-one percent (n=3) of VZV reactivation occurred in the first 100 days and 14% (n=2) after the first 24 months. Six (66.6%) of allogeneic BMT patients were under immunsupressive treatment (cyclosporine±mikofenolat mofetil) and 1 (11.1%) had lymphocytopenia when VZV was clinically detected. Sixty-six percent (n=6) of patients with VZV who were treated with allogeneic BMT were acute myeloid leukemia patients. Sixty-four percent (n=9) of the cases was presented in January-march peirod. The most frequent complication was post-herpetic neuralgia. There was no statistically significant difference between the type of hematologic diseases, type of transplantation and lymphocyte count through VZV reactivation. But season of the year (winter) revealed statistically significant difference in VZV reactivation. ($p<0.05$)
Summary/Conclusions: VZV reactivation rates of our BMT unit is significantly lower than the literature especially in autologous BMT. But winter season was defined as an risk factor for VZV reactivation. Longer acyclovir phrophylaxis after autologous BMT and additional phrophylaxis programme for winter months for 2 years after the BMT can be an effective strategy for VZV prevention. Another important key point can be the CD4/CD8 evaluation. Acyclovir phrophylaxis can be maneaged with CD4/CD8 numbers. Phrophylaxis can be continued until the normal CD4/CD8 values.

PB2183

PROPHYLAXIS OF GRAFT VERSUS HOST DISEASE IN PATIENTS WITH APLASTIC ANEMIA AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION WITH BONE MARROW DONOR DERIVED MULTIPOTENT MESENCHYMAL STROMAL CELLS
O Koroleva[1,*], L Kuzmina[1], E Mikhaylova[2], E Parovichnikova[1], Z Fidarova[2], V Vasilyeva[1], M Drokov[1], I Shipunova[3], N Petinati[3], N Drize[3], I Galtseva[1], V Savchenko[1]
[1]BMT, [2]Hematology department, [3]Physiology of hematopoiesis laboratory, National Research Center for Hematology, Moscow, Russian Federation

Background: Aplastic anemia (AA) is a rare disease characterized by bone marrow failure and pancytopenia. Allogeneic bone marrow transplantation (allo-BMT) is a standard treatment for young patients with a HLA-identical sibling donor. Incidence of acute and chronic graft *versus* host disease (GVHD) is 13% and 14%, respectively. If paroxysmal nocturnal hemoglobinuria clone (PNH) is detected in AA patients the incidence of acute and chronic GVHD increases up to 47% and 70%, respectively. It is known that multipotent mesenchymal stromal cells (MMSC) injection for GVHD prophylaxis after HLA-identical sibling donor transplants significantly decreases incidence of GVHD (ClinicalTrials.gov ID-NCT 01941394).
Aims: Estimate the effectiveness of MMSC injection for GVHD prophylaxis in patients with AA after allo-BMT.
Methods: Nine patients (6 males and 3 females) with AA received allo-BMT from HLA-identical sibling donor in our center between December 2011 and December 2015. Median patients age at the time of transplantation was 24 years (range 17-33). PNH clone was detected in 8 patients (the median granulocytes PNH clone size was 2,5% /range 0,19-97,1%/). PHN clone with intravascular hemolysis (LDH more then 1,5 ULN) was revealed in 2 patients. There were no thrombotic events in all patients. Eight patients received allo-BMT as first line therapy, for one patient allo-BMT was performed for relapse after immunosuppression therapy. The non-myeloablative conditioning regimen was used (ATG (100mg/kg) for 4 days, fludarabine (100mg/m^2) for 4 days, and cyclophosphamide (100mg/kg) for 4 days). For graft *versus* host disease (GVHD) prophylaxis cyclosporine and methotrexate were used. MMSC were infused intravenously at the moment of WBC count recovery to 1*109/l. On average, 1.09 (1.0-1.2)x106 MMSC per kilogram of the patient's body weight were injected.
Results: One patient had graft failure at day + 30 after allo-BMT. Other patients had stable engraftment. Leucocytes recovery occurred at median 21 days (range 17-25). Patients had no complications after MMSC injection. Only in 1 out of 8 patients (12,5%) acute GVHD was diagnosed, despite the presence of PNH clone in 7 out of 8 patients. Acute GVHD with liver involvement (grade III) was developed at 27 days in the patient with chronic hepatitis B virus infection. PNH clone elimination in 6 patients occurred during 1-18 mounts after allo-BMT. All 8 patients had undulating mixed donor chimerism (85-100%) at different time after allo-BMT. One patient with mixed donor chimerism has graft rejection at day + 286. No chronic GVHD in any patients developed. All patients are alive with a median follow-up 16 months (range 1-49).
Summary/Conclusions: We can suggest that in patients with AA bone marrow donor MMSC administration at the moment of leukocytes count recovery after allo-BMT is an effective method for acute GVHD prevention.

BK VIRUS INFECTIONS IN PATIENTS WITH UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
B Antmen[*], I Sasmaz, B Karagun, M Serbest
Pediatric Bone Marrow Transplantation Unit, Adana Acibadem Hospital, Adana, Turkey

Background: Hemorrhagic cystitis (HC) is a well-known complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT) that can be categorized as early-onset or late-onset. Early-onset HC is usually caused by adenovirus or cytomegalovirus whereas late-onset HC mainly by polyomavirus BK. BU-containing myeloablative conditioning, unrelated donors and GVHD has been reported as risk factors increasing the chance of infection in bone marrow-transplant patients. Furthermore reactivation of human polyomavirus BK (BKV) may cause polyomavirusassociated nephropathy or polyoma virus-associated hemorrhagic cystitis.
Aims: We aimed to present 17 patients with BK polyoma virus (BKV) ascociated hemorrhagic cystitis and 2 patients with BK polyoma virus associated hemorrhagic cystitis and nephritis.
Methods: Between 2013 and 2015, 90 patients received an allogeneic BMT at Acibadem Adana Hospital Pediatric Bone Marrow Transplantation Unit. 17 patients experienced BKV associated hemorrhagic cystitis and nephritis. BKV was detected in the urine analysis and blood by PCR (polymerase chain reaction) in all patients.
Results: We presented 17 patients with BKV infection, age ranging from 3 to 20 with an average of 11.7 years. They underwent allo-HSCT due to thalassemia major (9 patients), aplastic anemia (3 patients) and leukemia (5 patients). The patients were treated with hydration, continuous bladder irrigation, ciprofloxacin, cidofovir and weekly intravesical hyaluronic acid instillation for four weeks. Ten patients showed complete resolution of hematuria. Three patients with refractory following therapy also received hyperbaric oxygen. Hemodialysis was performed in two patients who developed renal failure due to nephritis.
Summary/Conclusions: Past exposures with the BK virus is widespread but significant consequences of infection are uncommon in the immunocompetent population. Reactivation of infection occurs under conditions of immunosuppression such as during GVHD treatment with patients who underwent HSCT. Early detection and treatment is crucial for successful management of BKV cystitis and nephritis. Neverthless even when treated with all the modalities, in some patients treatment faillure can be observed.

PB2185

IMPACT OF DISEASE STATUS ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF REFRACTORY AND RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA
J Cao, X Tang*, X Zhu, A Sun, H Qiu, Z Jin, M Miao, F Chen, X Ma, S Xue, X Wu, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Treatment of refractory and relapsed acute lymphoblastic leukemia (ALL) remains challenging. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only potential curative approach for these patients. However, whether patients will benefit by achieving remission before transplant remains controversial.
Aims: To evaluate the impact of disease status on the outcomes of allo-HSCT in the treatment of patients with refractory and relapsed ALL.
Methods: We retrospectively analyzed the outcome of 52 patients with refractory and relapsed ALL, including 19 cases in advanced stage, such as: nonremission (NR) and 33 cases in more than second complete remission (≥CR2), who underwent allo-HSCT after myeloablative conditioning regimen in our department.
Results: 51 patients engrafted successfully, the transplantation-related mortality (TRM) rate of NR and ≥CR2 was 10.5% *vs* 12.1% (P=0.815). The incidence of acute GVHD(aGVHD) was 52.6% *vs* 57.6% (P=0.730), including 42.1% *vs* 33.3% (P=0.527) with mild (grade I-II) aGVHD and 10.5% *vs* 24.3% (P=0.399) with severe (grade III-IV) aGVHD, and chronic GVHD(cGVHD) was 41.6% *vs* 57.9% (P=0.660). With a median follow-up of 12(1.8-44.5) months, the cumulative relapse rate was 47% *vs* 34.3%, P=0.425) of NR and ≥CR2. The estimated 2 year overall survival (OS) and 2 year leukemia-free survival (LFS) rate were 42.6% *vs* 45.7% (P=0.487) and 46.3% *vs* 46.2% (P=0.571) respectively. Multi-parameter analysis results showed that, OS and LFS was significantly better in patients with the appearance of cGVHD□For relapsed patients, OS was significantly better with first CR duration>6 month and time to transplant ≤2 months.
Summary/Conclusions: In this retrospective single center study, we can distinctly note that the survival of patients in NR and ≥CR2 before transplant is similar. Thus, it is suggested that allo-HSCT is an effective salvage therapy for patients with refractory and relapsed ALL and transplantation can be conducted directly for those who could not tolerate salvage chemotherapy. However, given the limited number of patients and observation time, an expanded sample size and prospective cohort study is needed to confirm the results.

Background: CMV infection represents one of the main cause of morbility and mortality after stem cell transplantation (SCT). Type III interferons (IFNs), including IFNl1 (IL29), IFNl2 (IL28A) and IFNll3 (IL28B), are thought to display potent antiviral and immunomodulatory properties in vivo, which may partially overlap with those exerted by type I IFNs. Type I and Type III IFNsl both generate an antiviral state by triggering the JAK-STAT pathway, ultimately upregulating the expression of interferon-stimulated genes. Rs12979860 single nucleotide polymorphism (SNP) in IL28B gene region is well known to influence the spontaneous and treatment-induced clearance in HCV infection. Although the relevance of such a SNP in other vir. CMV infection represents one of the main cause of morbility and mortality after stem cell transplantation (SCT). Type III interferons (IFNs), including IFNl1 (IL29), IFNl2 (IL28A) and IFNll3 (IL28B), are thought to display potent antiviral and immunomodulatory properties in vivo, which may partially overlap with those exerted by type I IFNs. Type I and Type III IFNsl both generate an antiviral state by triggering the JAK-STAT pathway, ultimately upregulating the expression of interferon-stimulated genes. Rs12979860 single nucleotide polymorphism (SNP) in IL28B gene region is well known to influence the spontaneous and treatment-induced clearance in HCV infection. Although the relevance of such a SNP in other viral infections is still debated, Bravo *et al.* recently documented a protective effect of the T allele against CMV infection in the Allogeneic SCT (Journal of Medical Virology 2014,86:838). Al infections is still debated, Bravo *et al.* recently documented a protective effect of the T allele against CMV infection in the Allogeneic SCT (Journal of Medical Virology 2014,86:838).
Aims: the current study was aimed at investigating whether the IL28B polymorphism Rs12979860 may affect the CMV reactivaction in the setting of Autologous SCT (Auto-SCT).
Methods: From October 2014, 67 patients undergoing an Auto-SCT for hematological malignancies were included in the study. The patients, with a median age of 56 years (range, 16-66 yrs), were distributed according to the underlying disease as follows: 75% had Multiple Myeloma, 16% non Hodgkin Lymphoma, 6% Hodgkin Lymphoma and 3% Acute Myeloid Leukemia. The Rs12979860 IL28B SNP (C/T) genotype was determined by Melthing analysis on DNA derived from peripheral blood samples. CMV DNAemia was determined by quantitative Real-Time PCR with a limit detection of 50 copies/mL (Artus, Qiagen). Patients were monitored for CMV DNAemia weekly for three months after transplantation.
Results: According to the lowest frequency of TT genotype harboring in general population, the detected genotypes were CC in 31 patients (46%) CT in 27 (40%) and TT in only 9 (14%). Although not statistically significant, a CMV reactivation (symptomatic and asymptomatic) was higher in patients carrying TT genotype (n=7 ;77.7%) with respect to patients carrying CC (n21.;67.7%) and CT genotype (n=12; 44.4%). According to the logistic regression analysis, the incidence of CMV reactivation was significantly lower in patients carrying IL-28B CT compared to the cumulative group of patients with CC and TT genotype (44.4% *versus* 70% ; p=0.039, CI 95%, OR 2.91) (codominat genetic model).
Summary/Conclusions: Our data suggest that in the Auto-SCT setting the carriage of IL-28B CT genotype might express a protective effect against CMV infection

MAJOR QUALITY PARAMETERS OF LONG-TERM CRYOPRESERVED CORD BLOOD UNITS - A SINGLE CENTER EXPERIENCE
F Bordalo*, F Amado, S Ferreira, C Pinho, S Lopes, S Roncon
Cellular Therapy, IPO PORTO, Porto, Portugal

Background: Cord Blood (CB) is a well-recognized source of stem cells for hematopoietic transplant. Its main advantage is to be stored for long-term with a ready availability for the intended recipient and no risk for the donor.
Aims: The aim of this study was to evaluate the quality of 15 cord blood units cryopreserved in our direct donation bank. for the intended recipient and no risk for the donor.
Methods: All these units were processed without red cells reduction, in a 24 hours period after collection, then were cryopreserved with a controlled-rate freezer and transferred to a liquid nitrogen container. We used cryogenic bags (Kapton/Teflon), highly resistant to very low temperatures. However, due to missing data we do not considered these CB units suitable for transplant. In this study, the CB were thawed and washed based on the New York Blood

Center method in our ISO 7 cleanroom, inside of an air flow cabinet. We performed cellular counts, viability assays (by flow cytometry using 7-aminoactinomycin), sterility testing (bacterial and fungal cultures) and clonogenicity (colony-forming units-granulocyte/macrophage - CFU-GM - growth). The correlation between CD34+ cell and CFU-GM counts was evaluated by linear regression analysis.
Results: The CB units were stored during 11-20 years (mean 16±3). We analyzed 12 CB because 3 bags were broken during storage (20%); this percentage is much higher than that found in our daily practice (4%), which may be caused by the long cryopreservation period. Visual examination of the product showed evidence of hemolysis in 10 CB and fibrin clots in 1. The recovery of total nucleated cells (TNC) was 73±14%; CD34+ cells enumeration 48.3±29.3x10^5 and CFU-GM quantification 28.5±19.3x10^4. The TNC and CD34+ cells viability was 70±8% and 91±5%, respectively. We obtained a strong positive relationship between CD34+ cell and CFU-GM (R^2=0.758). We found 4 contaminated CB, one of them was already positive after processing (*Enterococcus faecalis, Escherichia coli and Streptococcus mitis)*. We hypothesize that the pre-freezing hemocultures were not representative of the product; however, we cannot exclude a cross-contamination during the storage.
Summary/Conclusions: Despite our small serie, the results of cellular viability, purity and potency indicate that long-term cryopreservation does not negatively affect the quality of CB units for further use, even in the presence of contamination, hemolysis signs and aggregates. We think that every cord blood bank should have an expert to help transplant physicians select the best cord blood for his patient based on the control quality results performed before final release.

PB2188

PERIPHERAL BLOOD HEMATOPOETIC STEM CELLS (PBSC) MOBILIZATION WITH GENERIC VERSION OF PLERIXAFOR: AN EXPERIENCE AT A NORTH INDIAN TERTIARY CARE REFERRAL INSTITUTE
K Sahu[1,*], A Khadwal[1], U Yanamandra[1], T Sehgal[1], N Jain[1], A Jain[1], M Sachdeva[1], G Prakash[2], P Malhotra[2], S Varma[2]
[1]PGIMER, Chandigarh, India, [2]Internal Medicine, PGIMER, Chandigarh, India

Background: Plerixafor is used to mobilize hematopoietic stem cells in cancer patients into the bloodstream. Developed by AnorMED, plerixafor was approved by the U.S. Food and Drug Administration (FDA) on 15 December 2008. Henceforth, Genzyme (USA based company) took a step forward and launched plerixafor from benchside to bedside. Brilliant success story of this new molecule was hindered by the expensive cost thereby debarring large population of world from the benefit of this drug. Many Indian companies (eg. Hetero and panacea pharmaceutical companies) took the challenge to curb down the cost price and have come up recently with *generic version* of plerixafor. For a successful outcome of Hematopoetic Stem cell transplant a minimum dose of 2x106/Kg CD34+ cells are required. Standard mobilisation procedure involves use of G-CSF or GM-CSF alone in combination with chemotherapy. Those with certain risk factors like old age, previous multiple chemotherapy regimens, radiotherapy, bone marrow involvement with disease and exposure to agents like lenalidomide etc. may not mobilise adequately. We share our experience with *generic* plerixafor which is approximately 4-4.5 times cheaper than the original molecule and yet efficacious.
Aims: To study the efficacy of *generic* plerixafor which is approximately 4-4.5 times cheaper than the original molecule.
Methods: Study was conducted from December 2013 to February 2016 (26 months). In total, 66 transplants were carried out (autologous= 35 and allogeneic= 31) in our institute. Generic plerixafor was used along with G-CSF for in autologous PBSCs mobilisation in 20 out of 36 instances (Multiple myeloma =7, Hodgkins lymphoma=6, Nonhodgkin's lymphoma=6, APML= 1).
Results: Mean age of the patients was 39.5 years (range 17-63 years) with 13 males and 7 females. Average interval from disease diagnosis to transplant interval was 18.4 months (range 6- 96 months). Number of prior chemotherapy regimens used ranged from 2-4 and 6 patients also got radiotherapy in addition. Conditioning regimens used were-(1) Inj. melphalan=7, (2) BEAM regimen=10, (3) LACE regimen =2, (4) CY-TBI=1. Inj. Plerixafor was given in dose of 24 microgram/kg on day 4 and/or day 5 of G-CSF (10 microgram/kg/day) mobilisation depending on peripheral blood CD34+ cells (when available) and the yield of first harvest. Most of the patients (14 out of 20) required a single dose, while the remaining six needed an additional dose. Majority of patients (17 out of 20) underwent two apheresis session while two required single session. One had initial mobilisation failure with GCSF and 2 doses of plerixafor. But he subsequently mobilised successfully after 14 days with repeat GCSF and single plerixafor dose. Mean CD34+ cells obtained was 5.44x10^6/kg (range 2.7-13.13x10^6/kg). Neutrophilic and platelet engraftment occurred on day+13 (range 10 -20 days) and day +16 (range 10-36) respectively. Median units of PRBC and Platelet (SDAP) transfused were 3 (range 0-13) and 7 (2-15) respectively. There was only one death on day +7 due to acute cardiomyopathy.
Summary/Conclusions: Generic version of plerixafor with GCSF is an effective and safe strategy to mobilise stem cells.

PB2189

PREDICTIVE FACTORS FOR RELAPSE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA SUBMITTED TO ALLOGENEIC STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE
D Pastore[*], M Delia, P Carluccio, A Ricco, A Russo Rossi, C Germano, C Pasciolla, P Pinto, P Casieri, F Albano, G Specchia
Hematology with Transplantation,University of Bari, Policlinico, Bari, Italy

Background: Adults with high risk acute myeloid leukemia features at diagnosis, primary induction failure (PIF) or with recurrent disease have a poor outcome after chemotherapy and are candidates for allogeneic stem cell transplantation (allo SCT). However, the relapse rate in these patients remains a matter of concern.
Aims: Aim of the study is to identify the main factors influencing acute myeloid leukemia (AML) relapse after allo SCT in a single center.
Methods: 118 adult AML patients (median age 42 y [range 16-68], 50 M/ 68 F) received an alloSCT at our Institution from 2000 to 2015. Donors for HCT were HLA-matched related donors in 68/118 (57%) and "alternative donors" (matched unrelated or haploidentical donors) in 50/118 (43%) transplantations. The source of hematopoietic stem cells was peripheral blood in 110/118 (93%) and bone marrow in 8/118(7%) patients; 90% patients underwent a myeloablative conditioning regimen and 10% a reduced intensity regimen. Disease status (1st CR *versus* not[2nd/3nd CR and "active disease"]), molecular-cytogenetic risk(intermediate *versus* poor-risk), response to first chemotherapy(responders *versus* primary induction failure/PIF), time from diagnosis to transplantation (more or less than 6 months), stem cell source (bone marrow or peripheral blood), donor type (matched related or alternative), severe acute GvHD (grade IIII-IV), chronic GvHD, serological risk CMV status were analyzed as predisposing factors for relapse. Multivariate analysis was performed with the variables identified as relevant at univariate analysis.
Results: Transplantation for AML was done in 1st CR in 53/118 (44%) patients and not in 1st CR in 65/118 (56%) patients. Thirty-nine patients (33%) were PIF and 83/118 (70%) transplants were done within 6 months from diagnosis; 28/118(23%)patients were classified as poor molecular-cytogenetic risk. Twenty-six (18%) suffered GvHD grade III-IV and 32%, 15% and 8% of evaluable patients developed limited, moderate and severe cGvHD. The 2-year relapse incidence was 55%: 36% for patients in CR1 and 75% for patients not in CR1(p=0.001). At multivariate analysis the disease status (1st CR)(p=0.02 HR 0.73, 95%CI 1.0-2.8) and cGvHD(p=0.001 HR 0.2, 95%CI 0.1-0.4) were the factors associated with a lower relapse incidence. Donor type, molecular-cytogenetic risk, response to first chemotherapy, stem cell source, acute GvHD did not seem to significantly influence relapse.
Summary/Conclusions: In our experience allogeneic transplants performed in 1stCR and cGvHD were the main factors influencing the risk of relapse in adult patients with AML. Transplanted patients not in 1st CR and without cGvHD may be a "high relapse risk group" that could benefit from pre-emptive therapy post transplantation also with new drugs.

PB2190

COMPARABLE OUTCOME OF ALLOGENEIC VERSUS AUTOLOGOUS HEMATOPOIETIC PERIPHERAL BLOOD STEM CELL TRANSPLANTION IN ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE AND FLT3-ITD NEGATIVE
H K Mahmoud[1,*], A ElHaddad[1], O Fahmy[2], M Samra[1], R AbdelFattah[1], Y ElNahass[1], G Fathy[3], H ElAshtoukhy[4], F ElRefaey[1]
[1]National Cancer Institute, [2]Cairo University, [3]Nasser Institute, Cairo, [4]faculty of medicine, Banha, Egypt

Background: Optimal post-remission treatment for acute myeloid leukemia with normal karyotype (AML-NK) in first complete remission (CR1) is still not well-defined.
Aims: To compare the outcome of allogeneic *versus* autologous peripheral blood stem cell transplantation (PBSCT) in adult AML patients regarding toxicities of transplant procedure, transplant-related mortality (TRM), disease free survival (DFS) and overall survival (OS).
Methods: 43 patients were included; 34 patients (with a median age 28 years) received myeloablative allogeneic PBSCT from a matched sibling donor while 9 patients (with a median age 36 years) received PBSC autograft. All patients had a normal karyotype, FLT3 ITD negative and were in CR1.
Results: After a median follow up of 21.5 months (0.3– 46.5), the cumulative 2-year OS and DFS in the allogeneic group were 73.5% and 70.6% respectively compared to 74.1% and 64.8%, respectively in the autologous group (p=0.690 and 0.768). Increasing number of consolidation cycles (>3) and lower CD34 +ve stem cell dose were associated with lower relapse rates and higher DFS in the autologous group.
Summary/Conclusions: Preliminary data show comparable outcome of autologous compared to allogeneic PBSCT in patients with AML-NK and FLT3 ITD negative in CR1. In absence of matched sibling donor, autologous PBSCT may provide acceptable post-remission therapy for patients with low risk molecular profile.

Abstract withdrawn.

PB2192

CAN RED CELL DISTRIBUTION WIDTH BE A NEW PARAMETER FOR PREDICTING HIGHER CD34+ CELL COUNT IN THE HARVEST?

E Gunduz[1,*], H Uskudar Teke[1], N Andic[1], A Musmul[2]
[1]Hematology, [2]Biostatistics, Eskisehir Osmangazi University, Eskisehir, Turkey

Background: The red cell distribution width (RDW) is a simple and unexpensive parameter and is traditionally used for differential diagnosis of anemias. However, the number of articles mentioning about the relationship between RDW and human disorders has increased over the past decades. In tranplantation practice, the peripheral blood is the most common source of hematopoietic stem cells. There are many factors affecting the success of stem cell mobilization.
Aims: In this study, we tried to find a relationship between increased RDW and CD34+ cell count in the harvest.
Methods: Fifty patients who underwent stem cell mobilization between March 2014 and October 2015 are included in the study. Mean age was 56.82± 10 years, 28 (%56) patients were male and 22 (%44) patients were female. Diagnosis were multiple myeloma (n=32), non Hodgkin lymphoma (n=9), Hodgkin lymphoma (n=6), primary amyloidosis (n=1), Waldenstrom's macroglobulinemia (n=1) and testicular carcinoma (n=1). Mobilization regimens were cyclophosphamide plus G-CSF in 35 (%70) patients, G-CSF alone in 2 (%4) patients, etoposide plus G-CSF in 2 (%4) patients and salvage chemotherapy plus G-CSF in 11 (%22) patients. Five (%10) patients had a history of radiotherapy. Bone marrow infiltration for patients except myeloma was found in 6 (%35) patients. Patients received mean 1.61± 0.6 lines and 4.94±2.6 courses of chemotherapy.
Results: RDW was not correlated with peripheral blood CD34+ cell count (r=0.064, p=0.75, n=28) and CD34+ cell count in the harvest (r=-0.14, p=0.34, n=50). Other parameters previously reported to affect stem cell mobilization (age, weight, number of chemotherapy courses before mobilization, hemoglobin, white blood cell count, absolute neutrophil count, absolute lymphocyte count, platelet count, albumin, LDH) were also evaluated. Peripheral blood CD34+ cell count (r=0.694, p=0.001, n=50) and the number of chemotherapy courses before mobilization (r=-0.451, p=0.008, n=28) were found as the only parameters that affect CD34+ cell count in the harvest. In order to assess the effect of increased RDW on the CD34+ cell count in the harvest; above 16 was set as a cut-off for increased RDW and patients were divided into 2 groups. Sex, primary diagnosis, stage, bone marrow infiltration, mobilization regimen, chemotherapy courses, radiotherapy, comorbidities, number of leukapheresis days were not different between two groups. LDH was the only parameter different between 2 groups. It was found higher in the increased RDW group (p=0.005). Although peripheral blood CD34+ cell count and CD34+ cell count in the harvest were not different statistically between 2 groups, the numbers were lower in the increased RDW group (10.48±5.94 *vs* 8.07±5.01).RDW was not correlated with peripheral blood CD34+ cell count and CD34+ cell count in the harvest in both groups.
Summary/Conclusions: To our knowledge, this is the first study evaluating the relationship between RDW and stem cell mobilization in cancer patients. Although it has not been definitely established, it seems reasonable to suggest using RDW far beyond the differential diagnosis of anemias. Stem cell mobilization can be a potential candidate in this era.

PB2193

THE INFLUENCE OF HAPLOTYPE HLA-C(C1/X,C2/X) IN EVOLUTION AFTER HSCT

D Bratu[1,*], I Constantinescu[2], A Moise[2]
[1]Haematology, [2]Immunogenetics, Clinical Institute Fundeni, Bucharest, Romania

Background: Haplotypes of patients with acute leukemia like ligands or not for inhibitories and activatories donors KIR allele in HSCT are subjects of studies in a few specialised clinics; it is an evidence that haplotypes can be protective or not against postHSCT complication, easier to try to demonstrate at patients with genoidentical donors.
Aims: Haplotype HLA-C(C1/X,C2/X), homozygot and heterozygot variants (HLA-C1/C1,HLA-C1/C2,HLA-C2/C2) seems to have influence at patients with acute leukemia after HSCT.
Methods: Eighteen pairs patients-donors are evaluated: patients with acute leukemia, lymphoblastic and non-lymphoblastic and their genoidentics donors. One patient have HLA-C1/C1 haplotype, seven HLA-C1/C2, ten HLA-C2/C2. Following the impact of inhibitory KIR2DL1, like ligand for C2,KIR2DL2, KIR2DL3 for C1, activatory KIR2DS1 for C2,KIR2DS4 for C1, on survival and complication development, we proved the protective effect of presence of HLA-C2/X haplotype, HLA-C1/X, respectively. The source of HSCT was PBSC. The method used was PCR-SSP (Innotrain DIAGNOSTIK GMBH, Dynal BIOTECH PEL-FREEZE). The complications like graft *versus* host disease acute and chronic, relapse, TMA and the recovery with leucocytes and thrombocytes are followed.
Results: Presence of HLA-C1 haplotype is protective in presence of KIR2DS4 (activatory allele) with statistical significance for thrombocyte recovery but no influence against aGVHD and relapse; in presence of KIR2DL2, KIR2DL3 (inhibitory allele) against relapse, TMA, a/cGVHD, leucocytes and thrombocytes recovery, without statistical significance. HLA-C2, in presence of KIR2DS1, and also in presence of KIR2DL1 protective against TMA and relapse, cGVHD, also leucocyte and thrombocytes recovery, without statistical significance, except aGVHD (no influence) and observation for absence HLA-C2 with protective effect against relapse (...missing ligand").
Summary/Conclusions: Presence of HLA-C1/X,HLA-C2/X4 improve survival and offer minor protection against most complication at patients with acute leukemia and related donors with 100% allele match, in presence of both types of KIR alleles.

PB2194

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PEDIATRIC PATIENTS WITH MIXED PHENOTYPE ACUTE LEUKEMIA

JA Park[1,*], H Chueh[2], JY Lim[3], YT Lim[4]
[1]Pediatrics, Inje University Haeundae-Paik Hospital/ Inje University College of Medicine, [2]Pediatrics, Dong-A university hospital, Busan, [3]Pediatrics, Gyeongsang National University Hospital, JInju, [4]Pediatrics, Busan National University Hospital, Busan, Korea, Republic Of

Background: Mixed phenotype acute leukemia (MPAL) is a rare disease accounting for about 2-5% of all acute leukemia, and patients with MPAL have poor prognoses, particularly in patients with T/myeloid immunophenotype. However, there is no standardized treatment for MAPL and no consensus about the incorporation of hematopoietic stem cell transplantation (HCT) as an integral part of therapy. Due to its rarity, outcomes of HCT for pediatric MPAL have not been fully determined.
Aims: We investigated outcomes of HCT for pediatric patients with MPAL with multicenter study.
Methods: We retrospectively analyzed transplant outcomes for 12 pediatric patients with primary MPAL, undergoing HCT between 2001 and 2014 in 10 institutes in Youngnam province, Korea. By WHO 2008 classification, 1 (8%) had MPAL with t(v;11q23); MLL rearranged, 9 (75%) had MPAL, T/myeloid, NOS, and the remaining 2 (17%) had MPAL, B/myeloid, NOS. Before HCT, 10 patients were in first complete remission (CR), 1 patient in second CR, and one patient relapsed and had persistent disease. Donor was matched-related in 6, matched-unrelated in 2, umbilical cord blood (UCB) in 2, and autologous in 2, respectively. Conditioning regimen was busulfan, cyclophosphamide and/or melphalan based myeloablative (MA) in 10 patients and busulfan and fludarabine based nonmyeloablative (NMA) in 1 patients. One case of autologous transplant used cyclophosphamide, etoposide, cytarabine and BCNU as a conditioning regimen. For prophylaxis of GVHD following allogeneic HCT, cyclosporine and short-term methotrexate were used.
Results: Median age at the time of HCT was 9.0 years (range, 1.3-13.3 years), and median interval between diagnosis and transplantation was 6.1 months (range, 2.8-14.2 months). Cumulative incidences of neutrophil and platelet engraftment by day 28 were 100%. After median follow-up of 6.2 years (range, 0.8-17.4), 9 of 12 patients survived. Cumulative incidence of treatment-related mortality (TRM) and relapse were 9% and 35.8%. Event-free survival (EFS) and overall survival (OS) after HCT were 64.2% (50%>78%, 95% CI) and 72.7% (59%>86% 95% CI), respectively. WHO classification did not significantly affected EFS after HCT for pediatric MPAL patients (p=0.371).
Summary/Conclusions: Many studies have reported that patients with MPAL had poor prognosis, and patients with T/myeloid phenotype had a worse outcome than patients with B/myeloid phenotype. We found that WHO classification 2008 for MPAL was not significantly associated with patients' outcome after HCT and that patients with MPAL, T/myeloid, NOS had more favorable outcome compared to historical data. Our data suggested that HCT may improve the outcome of pediatric patients with MPAL, particularly T/myeloid phenotype. This study needs to be confirmed in larger, prospective studies including more pediatric MPAL patients.

PB2195

THE ROLE OF LYMPHOCYTE RECOVERY AFTER HIGH DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA AND MULTIPLE MYELOMA

M Todorovic Balint[1,*], J Jelicic[1], J Bila[1], B Balint[2], B Andjelic[1], D Antic[1], A Sretenovic[1], D Vujic[3], N Kraguljac Kurtovic[1], D Sefer[1], D Sefer[1], V Djurasinovic[1], M Smiljanic[1], V Vukovic[1], B Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [2]Institute for transfusiology and hemobiology, Military Medical Academy, [3]Institute for mother and child health care " Dr Vukan Cupic", Medical faculty University of Belgrade, Belgrade, Serbia

Background: In Non Hodgkin lymphoma as well as in Hodgkin lymphoma (HL) and multiple myeloma (MM), lymphocyte recovery after autologous stem cell transplantation (ASCT) has been reported to have association with clinical outcome, but also with contradictory data.
Aims: The aim of study was to evaluate the role of parameters that may be associated with outcome after ASCT.
Methods: The study included 61 patients with relapsed/refractory HL (34 males/ 37 females) aged 30 years (range 18-46) and 85 MM patients (42 males/ 43 females) aged 54 years (range 36-65) who were treated with high dose chemotherapy followed with ASCT. Advanced stage of HL disease (Ann Arbor III-IV) had 41.0% patients. Majority of patients had constitutional B symptoms (88.5%) and bulky disease (54.1%). Low IPS had 15 patients (22.6%). All patients received ABVD therapy and in the course of relapse or refractory disease, DHAP as first salvage therapy, and BEAM (54 patients, 88.5%) or CBV (7 patients, 11.5%) as conditioning regimen due to ASCT. The average value of collected $CD34^+$cells was $11.3x10^6$/kg (range 2-$24x10^6$/kg) in the volume of 250 ml (range 100-900ml). The mean aplasia duration was 11 days (range 6-28 days). After ASCT 29 patients achieved CR (47.5%), 21 patients PR (34.3%), 3 had SD (4.9%) and 8 patients (13.1%) had PD. Median time to recovery of absolute lymphocyte count on $500x10^6$/l (ALC500) was 15 days (range 9-32). Regarding MM population, majority of patients had IgG (59, 69.4%) and IgA (12 pts, 14.1%) type of MM. According to the clinical stage (CS) 6 pts (7.1%) had I, 16 (18.8%) II, and 63 (74.5%) III CS. Renal impairment was present in 15pts (17.6%). MM patients were initially treated with protocol VAD (29 pts, 34.1%) or CTD (56 pts, 65.9%) and high dose Melphalan (200mg/m^2) was conditioning regimen prior to ASCT in the first treatment line. The average value of collected $CD34^+$cells was $6.5x10^6$/kg (range 2-$96x10^6$/kg) in the volume of 300 ml (range 100-660ml). The mean aplasia duration was 8 days (range 4-26 days). After ASCT only 1 patient (1.2%) had PD, while 22 (25.9%) had PR and the rest achieved at least VGPR (52, 73.0%). Median time to ALC500 recovery was 15 days (range 9-23days).
Results: In HL patients survival after ASCT was 39 (2-100) months, and OS was 70 (16-192) months. Patients with low IPS (0-2) had better survival compared to those with high IPS score (≥3) (Log Rank=3.68, p=0.05). Survival after ASCT was markedly influenced by prolonged recovery duration of ALC500≥18 days (Log Rank=4.54, p=0.03). However, the duration of ALC500 recovery was not in correlation with treatment response (p>0.05). Furthermore, survival was significantly inferior in patients with PD or SD after ASCT (Log Rank=6.07, p=0.014). As expected, treatment response after ASCT significantly influenced OS (Log Rank=11.27, p=0.004). Multivariate Cox regression among independent prognostic factors in univariate analysis (IPS, therapeutic outcome and ALC500 recovery) pointed out therapeutic outcome at D+100 and delayed ALC500 recovery as the most important parameters that influenced both OS and EFS (p<0.05). In MM patients survival after ASCT was 29 (2-115) months, and OS was 48 (16- 127) months. However, delayed recovery of ALC500 after 18^{th}. day from ASCT did not influence neither OS nor survival after ASCT.
Summary/Conclusions: According to results of Cox regression analysis in HL, no responders at D+100, and delayed recovery of ALC500 are parameters of inferior prognosis and shorter survival. However, similar cut off values of ALC500 are not predictable in MM patients.

Stem cell transplantation - Experimental

PB2196

COMPARISON BETWEEN SERUM AND FECAL CALPROTECTIN AS MARKER OF GRAFT-VERSUS-HOST DISEASE

E Metafuni*, S Giammarco, D De Ritis, M Rossi, A Bacigalupo, S Sica, P Chiusolo
Hematology Department, Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

Background: Graft-versus-host disease (GvHD) is one of the complication occurring after hematopoietic stem cell transplantation (SCT) responsible for high morbility and mortality. The main strategy to reduce GvHD-related mortality is the correct diagnosis and prompt steroid administration. In the last few years, different proteins have been evaluated as reliable biomarker of GvHD. In our experience, fecal calprotectin (FC), a heterodimer of two S100 family proteins S100A8/S100A9 secreted by activated macrophages, appeared useful to differentiate gut GvHD from liver/skin GvHD, and to distinguish between gut GvHD and enteritis due to other causes.
Aims: The aim of our study was to compare fecal (FC) and serum (SC) levels of calprotectin in a cohort of patients (pts) submitted to SCT, in order to define if a correspondence there was between the two determinations in the same patient (pt).
Methods: We enrolled 21 pts submitted to SCT in our department since December 2009 al July 2012, 9 females and 12 males, with a median age of 55 years (range 35-63), affected by acute lymphoblastic leukemia in 2 cases, acute myeloid leukemia in 14 cases, non-Hodgkin lymphoma in 1 case, myeloproliferative disease in 1 case and myelodisplastic syndrome in 3 cases. Conditioning regimes was MAC in 2 pts and RIC in 19 pts. GvHD prophylaxis was performed with short course methotrexate plus CSA in 15 cases and with CSA+MMF in 6 pts. Donor was related in 14 cases and unrelated in 7 pts. Serum and stools samples were provided for each pt at the time of GvHD onset and, for pts who did not developed GvHD samples were collected around day +30. Calprotectin detection was made using commercial ELISA kit for Calprotectin assay on stools and serum samples.
Results: Fourteen pts (66,7%) developed acute GvHD after a median time of 25,5 days (range 6-80): grade I in 3 pts (21,4%), grade II in 3 pts (21,4%), grade III in 7 pts (50%) and grade IV in 1 pt (7,2%). Organ involvement was: isolated skin in three pts, skin and liver in one pt, isolated liver in 2 pts, isolated gut in 2 pts, gut and skin in 5 pts, skin and gut and liver in one pt. FC median level was 198,9 mg/Kg (range 58.4-500) in pts with aGvHD and 32.2 mg/Kg (range 15.6-89) in the others (Mann Whitney, p=0.0005, Fig 1A), while SC median level was 2756.5 ng/ml (range 173.3-10690) in pts with aGvHD and 1328 ng/ml (range 410.9-4241) in the others (Mann Whitney, p=0.22, Fig 1B). Among pts with aGvHD, FC median levels was 134.9 mg/Kg (range 58.4-292.3) in pts with grade I-II aGvHD and 396.6 mg/Kg (range 95.2-500) in grade III-IV (Mann Whitney, p=0.029), while SC median level was 231.2 ng/ml (range 173.3-5575) in pts with grade I-II aGvHD and 3601 ng/ml (range 868.5-10390) in grade III-IV (Mann Whitney, p=0.4). Finally, FC median level was 396.6 mg/Kg (range 142.1-500) in pts with gut aGvHD and 115.2 mg/Kg (range 58.4-292.3) for non-gut aGvHD (Mann Whitney, p=0.02, Fig 1C), while SC median level was 3232.25 ng/ml (range 868.5-10390) in pts with gut aGvHD and 2312 ng/ml (range 173.3-5575) in non-gut aGvHD (Mann Whitney, p=0.57, Fig 1D). Figure 1: A) median FC level in pts with (yes) or without (no) aGvHD; B) median SC level in pts with (yes) or without (no) aGvHD; C) median level of FC in pts with gut or liver/skin GvHD; D) median level of SC in pts with gut or liver/skin GvHD.

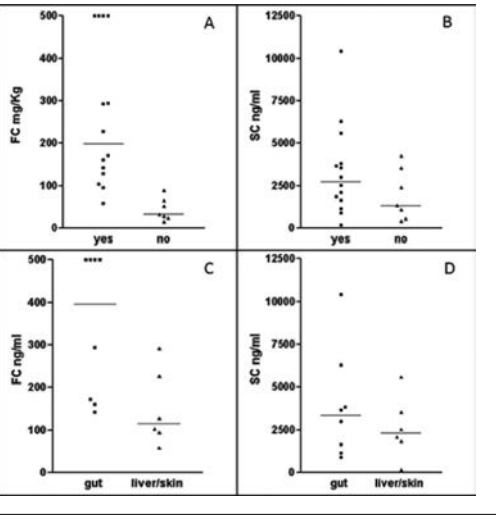

Figure 1.

Summary/Conclusions: There was no correspondence between serum and fecal camprotectin. Our studies suggest that fecal but not serum calprotectin levels may be considered a marker of gut GvHD after SCT.

PB2197

ANALYSIS OF CHIMERISM AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE STUDY OF GENETIC POLYMORPHISMS ASSOCIATED WITH THROMBOPHILIA

E Butina*, N Minaeva, G Zaitseva, A Kiseleva
Immunogematology, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: Currently, much attention is paid to the development of simple and relatively inexpensive methods of diagnosing hematopoietic chimerism.
Aims: To study the possibility of using gene allelic variants of thrombophilia as markers chimerism after allogeneic hematopoietic stem cell transplantation (allo-HSCT).
Methods: The results of examination of 10 patients, which in 2015 was performed allogeneic HSCT. Donors of hematopoietic stem cells for 8 patients were siblings, donors for 2 patients were selected from the Bone Marrow Transplant Registry. In all cases the donors and recipients were HLA-identical class I and II. Allo-HSCT utilizing a myeloablative regimen was performed in 7 patients. HSCT in the mode of increased intensity was used in 3 patients. The gene polymorphisms were analyzed by polymerase chain reaction in real time. In order to identify information markers analyzed gene polymorphism F2, F5, F7, F13, FGB, ITGA2, ITGB3, PAI-1, MTHFR: 665, MTHFR: 1286, MTR, MTRR. Chimerism was investigated at 28, 42, 56, 70, 100, 120 days after HSCT.
Results: Genetic differences were detected in 9 of the 10 donor-recipient pairs (from 1 to 7, median -5). The greatest number of distinctions obtained in the study of allelic variants of the gene FGB (7 out of 10 couples). In the analysis of gene MTHFR: 1286 differences were detected in 6 pairs; ITGA2, ITGB3, PAI-1- in 4 pairs, F13, MTHFR: 665, MTRR - in 3 pairs. For each pair were chosen polymorphisms that act as molecular markers allow to differentiate donor and recipient cells after HSCT. In three cases, the donors and recipients were homozygous for different alleles of one gene. In other cases, an identification mark considered polymorphism, in which one allele was common to both donor and recipient, the second - only for specific recipient. Complete donor chimerism was established in 7 patients on day 28 after HSCT.
Summary/Conclusions: Genetic polymorphisms associated with thrombophilia meet the basic requirements of the markers hematopoietic chimerism: analysis is based on the identification of regions of the genome that differ one nucleotide sequence; investigated two allelic variants of the gene; frequency of occurrence in the population of homo- and heterozygous for this is sufficient for the detection of genetic differences at 90% of donor-recipient pairs.

PB2198

IMMUNE RECONSTITUTION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA: THE EFFECT OF CLINICAL FETAURES

G Rossi[1,*], AM Carella[1], R Angarano[1], MM Greco[1], M Merla[1], C De Waure[2], GS Leuconoe[2], MM Minervini[1], N Cascavilla[1]
[1]Hematology and Stem Cell Transplantation Unit, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, [2]Department of Hygiene, Catholic University of Sacred Heart, Rome, Italy

Background: The reconstitution of different immune cell subsets after allogeneic stem cell transplantation (allo-SCT) occurs at different timelines. Anyway, majority of studies following allo-SCT focused on levels of the single cell line while recovery of the entire immune system was generally reviewed. Similarly, few reports addressed on the effect of clinical factors on the restoration of immunity and studies on bone marrow (BM) samples are lacking
Aims: Thus, we prospectively investigated changes in lymphocyte and dendritic subsets after allo-SCT in BM samples with respect to minimal residual disease (MRD), GvHD, infections and HSCT type.
Methods: BM samples from patients (n=25) with acute myeloid leukemia(AML) who underwent to allo-SCT were collected from january 2012 and december 2014 at specific time-points: +1, +3 and +6 months after transplant. Lymphocyte subpopulations (B cells, hematogones,T cells, helper/inducer T cells, cytotoxic/suppressor T cells, regulatory T cells (TREGs), natural killer (NK) cells) and dendritic cells (plasmocytoid and myeloid) were investigated using 6-color flow-cytometry. In order to assess differences in cell subsets between cases and BM healthy controls the Mann-Whitney test was applied. A p-value ≤ 0.05 was considered significant.Variation of cell subsets at + 1,+3, +6 months after transplant was evaluated using the Friedman test.Post-hoc pairwise comparisons with Bonferroni correction for multiple comparison were carried out.
Results:. Significant differences between patients and controls were found with respect to TREGs, T cells, helper/inducer T cells and NK cells. In particular, patients showed a significantly higher level of TREGs and NK and a significantly lower count of T- and helper/inducer T cells at +1 and +3 months from transplant. B cells and hematogones was significantly increased at six months from transplant while no differences between TREGs were found at this time point. Significant effect of timelines from transplant was found for B cells, regulatory T cells, T cells, helper/inducer T cells and cytotoxic/suppressor T cells. A statistically significant raise was found from +1 to +6 months for T cells and cytotoxic/suppressor T cells and from +1 to +3 months for helper/inducer T cells and cytotoxic/suppressor T cells. On the contrary, a statistically significance decrease was observed at any time for TREGs count. Univariate analysis showed a statistically significant association between cytotoxic/suppressor T cell count and the presence of infection (p=0,027) with patients having viral or bacterial infection showing higher counts. No differences were found for any other association.
Summary/Conclusions: In conclusion, immune reconstitution following allo-SCT on BM samples was similar to data reported from peripheral blood.Viral and bacterial infectionsplay an important role in increasing cytotoxic/suppressor T cells.

Thrombosis and vascular biology

PB2199

A SINGLE CENTRE EXPERIENCE MEASURING RIVAROXABAN LEVELS WITH A SPECIFIC ANTI XA ASSAY AND THE EFFECT ON THE STANDARD COAGULATION SCREEN

A Niblock*, P Murray, AM Kearney, G Benson
Haematology, Belfast City Hospital, Belfast, United Kingdom

Background: Direct oral anticoagulants drugs are now commonly used in clinical practice. Rivaroxaban inhibits free factor Xa and hence prothrombinase activity as well as clot bound Xa, thus effectively blocking thrombin generation. One main advantage over vitamin K antagonists is that blood coagulation monitoring is not necessary. However introducing a static change into a dynamic cascade always raises concern. The concentration may potentially need to be measured in certain clinical situations. These may include urgent surgery, perioperative management, thromboembolic events, bleeding events and suspected overdose. All routine coagulation screens performed in Northern Ireland are undertaken on a Sysmex Coagulaometer using the Innovin reagent. The Regional Specialty Coagulation Laboratory uses a Stago analyser with the STA Neoplastine CI+ reagent. The effect on the coagulation screen by rivaroxaban is known to vary between analysers making interpretation difficult.
Aims: To assess the effect of rivaroxaban on the current coagulation screen to help aid clinicians in making urgent decisions. To assess the variation of rivaroxaban concentrations between patients invivo rather than a controlled dilutional experiment.
Methods: Recording the dose and time from last drug ingestion we were able to measure the effect on the standard coagulation screen with both analysers. On the same samples the rivaroxaban concentration was measured with the specific anti-Xa rivaroxaban assay. Each recruited patient had their age, renal function and other co prescribed medications recorded to assess variation within these parameters. As a control, healthy volunteers on no anticoagulation had their rivaroxaban levels measured. The volunteers' rivaroxaban levels ranged from 15-21ug/l and therefore we assume no drug is present when levels fall into, and below, this range.
Results: The effect on the PT and APTT was variable between analysers. The PT, in line with previous publications, was more sensitive than the APTT at smaller drug concentrations. The Neoplastine CI plus reagent on the Stago analyser was more sensitive than the Innovin reagent to rivaroxaban concentrations. The Neoplastine CI PT was prolonged in all samples taken within 17 hours of rivaroxaban ingestion. Our results compare with University Hospital Hotel Dieu (Paris) which found peak concentrations up to 400ug/l and trough concentrations up to160ug/l. However our results demontrated more variation with some patients have a higher rivaroxaban level than expected 600ug/l. These patients were also taking verapamil. We noted the SPC advises rivaroxaban not to be used in patients who are receiving concomitant combined P-gp and moderate CYP3A4 inhibitors unless the potential benefit justifies the potential risk 2. There is a positive correlation between rivaroxaban concentration and Neoplastine CI PT reagent with prolongation up to a certain concentration and beyond this the effect on Neoplastine CI PT appears to plateau. The patients with a rivaroxaban concentration in excess of 600ug/l had a similar PT than those with a rivaroxaban concentration of 450ug/l.

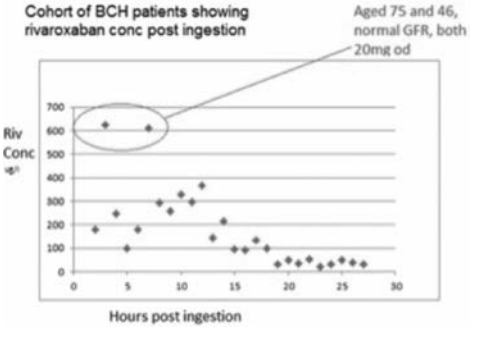

Figure 1.

Summary/Conclusions: The PT, provided it is sensitive to rivaroxaban, is a quick test and may be useful to ascertain rivaroxaban presence or not but given the plateau effect, not necessarily reassurance that rivaroxaban levels are excessive. Although smaller amounts of rivaroxaban (<100ug/l) may still be present when the PT is normal its clinical significance and its anticoagulant needs to be judged on a case by case basis. Rivaroxaban anti Xa assay will quantify the drug concentration however turnaround time is slower. There is significant variation in rivaroxaban when co prescribed with other medications utilising CYP3A4. Although the results demonstrated when used with an inhibitor the elevated rivaroxaban concentration may not necessary have addition anticoagulant effect this raises the concern when the opposite siituation arises. If a patient is found to have a clot while on rivaroxaban it may be appropriate to check the rivaroxaban specific anti Xa to ensure its therapeutic especially when patients have co prescribed CYP3A4 inducers.

PB2200

FREQUENCY AND MANAGEMENT OF VENOUS THROMBOSIS IN ADULT ACUTE LEUKEMIA PATIENTS AT A TERTIARY CARE HOSPITAL OF PAKISTAN

S Sarwar[1,*], U shaikh[2]
[1]Oncology, [2]Oncology/Hematology, Aga Khan University Hospital Karachi Pakistan, Karachi, Pakistan

Background: Solid tumors are well associated with thromboembolic complications, but the incidence of thrombosis is not widely studied in patients with acute leukemia and their management which is a great challenge. However this may be obscured by the significant morbidity and mortality due to other complications such as bleeding and infections.No established guidelines are present to treat these difficult patients. Case-controlled studies of patients with cancer revealed a fourfold increase in thromboembolic occurrence in acute leukemia, with about the same rate in acute myelogenous leukemia (AML) and in acute lymphocytic leukemia (ALL). Among patients with acute leukemia, thrombosis has the highest incidence in acute promyelocytic leukemia (APL) .Of interest, increased thromboembolic events take place even prior to the diagnosis of acute leukemia, similar to the situation seen in solid tumors, indicating that a prothrombotic state is present even at the earliest phase of leukemia. The use of central venous catheter and chemotherapeutic agents such as L-asparaginase and other medicine used in the treatment of hematological malignancies particularly steroids may play an important thrombogenic role.
Aims: To determine the frequency of venous thrombosis and treatment strategy in patients with acute leukemia at a tertiary care Hospital of Pakistan.
Methods: Retrospective, observational study of case charts of hospitalized patients with diagnosed case of acute leukemia at department of oncology Aga Khan University Hospital Karachi during the 18 months period (January 2014 to June 2015). Data was retrieved by using ICD 9 coding for acute leukemia patients. Investigations were obtained from electronic medical record system. Finally data was analyzed for frequencies and percentages by using SPSS version 19.
Results: Total of 107 patients presented during the study period. Among them 76 were males and 31 were females with median age ranges from 18 to 60 years. These patients were stratified into 2 major groups according to type of leukemia.63.5% patients were with Acute myeloid leukemia in which 4.7% patient developed venous thrombosis among them highest in APML 22.2% while 36.4% patients were with acute lymphocytic leukemia(ALL) in which 2.5% of patients developed venous thrombosis. Three patients were treated successfully with LMWH during their consolidation phase of chemotherapy.
Summary/Conclusions: Venous thrombosis in acute leukemia is not uncommon which can lead to fatal results if left untreated. Anticoagulation with intermittent use of LMWH for 3-6 months with close monitoring of platelet counts would be the appropriate option for treatment.

PB2201

CYTOMETRY OF HBA1C

F Malergue[1,*], A Van Agthoven[1], C Godefroy[2], EM Rabellino[2]
[1]Beckman Coulter Immunotech, Marseille, France, [2]Beckman Coulter Inc, Miami, United States

Background: In the field of routine diabetes testing, flow cytometry does not play an important role.
Aims: In an innovative effort we try to show that the application of flow cytometry of a widely accepted parameter as HbA1c can improve the understanding of the course of the disease and can be applied to other diseases as well.
Methods: In a new experimental assay, blood was diluted in an environment that removed the red cell membrane and precipitated hemoglobin. The particles of precipitated and condensate hemoglobin look similar to normal red cells in flow cytometry. The precipitation is irreversible and the particles in physiological conditions can be stained with a fluorescent conjugated monoclonal antibody against HbA1c. In an inhibition assay with hemoglobin in solution it was shown that the accessibility of the HbA1c antigen did not differ between soluble and condensate hemoglobin. Another property of the condensate particle in flow cytometry is that the side scatter of the particles reflects the hemoglobin content of the original red cell. The cellular hemoglobin content of samples that were analyzed on a Sysmex hematologic analyzer and the mean values of the side scatter of the same samples that were treated as above for flow cytometry showed good correlation.
Results: A good correlation was also found with conventional HbA1c measurements. From 120 diabetic patients, the HbA1c percentage values were obtained by taking the mean of three different methods as measured by a ref-

erence laboratory. The blood samples of these patients were also analyzed by cytometry and the quotients of the side scatter and the HbA1c staining reflecting the HbA1c percentage were compared with the HbA1c reference values. Frozen hemoglobin particles with a known HbA1c percentage were used as a reference. The novelty of this assay is that using flow cytometry, the HbA1c percentage can be measured cell by cell. This permits to see beyond the mean value of HbA1c percentage of a sample. Presenting a lower deformability, cells with the highest HbA1C concentration may play a crucial role toward microvasculature obstruction. To further assess the validity of the approach of red cell age measurement, we collected from 26 diabetic patients the booklets in which they had administrated several glucose values every day over a time-span of several months. At the moment of collection of the booklets, blood samples were taken and cytometry of HbA1c was performed. The glucose values of the booklets, showed considerable varieties during a day. Therefore a mean daily glucose was used. The comparison of the two sets of data showed a striking correlation.

Summary/Conclusions: Showing proof of principle of HbA1c cytometry and the possibility to read the memory of the blood, other parameters can be read. Within the assay cellular hemoglobin content can be read against time. Also the representation of cells of a certain age can be established. Both these parameters could be of interest for diseases like anemia.

PB2202

INHERITED AND AQUIRED THROMBOPHILLIAS IN WOMEN WITH RECCURENT PREGNANCY LOSS- 5 YEAR EXPERIENCE

E Miljkovic*, D Markovic, M Vucic
Hematology, Clinical Center Nis, Nis, Serbia

Background: Inherited thrombophilias are the leading cause of maternal thromboembolism and are associated with an increased risk of certain adversy pregnancy outcomes including second and third trimester fetall loss, abruptions, severe intrauterine growth restriction and early onset severe preeclampsia. The antiphospholipid antibody syndrome (APS) is an acquired autoimmune thrombophyllia in which vascular thrombosis and/or reccurent pregnancy losses occur in patients having laboratory evidence for antibodies againts phospholipids or phospholipid-binding protein cofactors in their blood. Pregnant women with these highly thrombogenic conditions are at very high risk for both thromboembolism and adverse pregnancy outcomes.

Aims: Aim was to determine the presense of inherited or acquired thrombophillias in women with reccurent pregnancy losses (RPL).

Methods: Women with RPL were tested for heterozygosity for the factor V Leiden and prothrombin G 20210A mutations, homo and heterozygosity in the type 1 plasminogen activator inhibitor gene (PAI-1) and the thermolabile variant of the methylentetrahydrofolate reductase gene (MTHFR). They were also tested for deficiencies of protein C, protein S and antithrombin, as well as for antiphospholipid antibodies-anti beta 2 glycoprotein I antibodies, anticardiolipin antibodies and lupus anticoagulant assays.

Results: From January 2011 till January 2016, 445 women were tested for the presense of inherited or acquired thrombophillias because of reccurent pregnancy loss or treatment of infertility. Median age of patients was 33.2 (19-46). 18 women (4%) was negative for both inherited or APS and others 427 (96%) were positive. Criteria for APS fullfilled 68 patinets (15.2%), 10 patients (2.2%) had only APS and 58 patients (13%) had APS with some of inherited thrombophillias. 246 patients (94.6%) were positive for one or more inherited thrombophillias. The most common inherited thrombophillia was PAI1 mutation, found in 313 women (70%).then MTHFR mutation found in 303 women (68%).Heterozygous mutation for Factor V Leiden was found in 45 women (10%) and heterozygous mutation for protrombin G 201210A in 16 women (3.6%). 173 women were positive for 1 inherited thrombophillia (38.9%), 222 for 2 (49.9%) and 21 women (4.7%) for 3 inherited thrombophillias. 105 patients (40.3%) with low molecular weight heparin plus aspirin (LMWH/ASA) or ASA alone had successfully pregnancy outcome-live birth.

Summary/Conclusions: Some form of thrombophillia-inherited or acquired was found in most of tested women with reccurent pregnancy loss (96%) and 273 patients (61.3%) had more then one thrombophillia. With adequate anticoagulant therapy patients with these conditions had chance for successfully pregnancy outcome.

THROMBOLYTIC THERAPY USING UROKINASE FOR MANAGEMENT OF CVC IN HEMODIALYSIS: OUR EXPERIENCE

A Bruzzese[1,*], A Bruzzese[2], G Battista[3], C Larosa[3], M Alviano[3], P Orlando[3], V Bruzzese[3]
[1]Dipartimento di Biotecnologie ed Ematologia, Università "La Sapienza", Roma, [2]UOC Nefrologia e Dialisi, Policlinico Universitario, Messina, [3]UO Emodialisi, ASP 5 RC, Taurianova, Italy

Background: The need to use the CVC (central venous catheter) for hemodialysis is an occurrence in growth, related to the aging of the population on dialysis and the high prevalence of the disease and thrombotic angiosclerotica-uremic coaugulativa of the subject. The CVC is almost always a second best solution precisely in those subjects with situations of vascular compromise and/or coagulation disorder that does not allow the creation of the FAV (arteriovenous fistula). For this reason, the CVC meets very often malfunction situations for intraluminal thrombotic events. The malfunction of the CVC is directly related to the duration of use, for a higher probability of thrombotic affixing on the inner wall with the passage of time. However, some patients show that they are prepared to meet very early in the CVC occlusive events, probably due to altered Hemorheological situations, not always clearly defined. In the case of thrombotic occlusion of the CVC is sweeping the use of thrombolytic agents to try to ricanalizzarli. Among the various substances being used for the urokinase thrombolytic there is, even if the bleeding risk potentially related to its use has hampered the use on a large scale.

Aims: We conducted a retrospective case series of patients on hemodialysis with CVCs pertaining to a single dialysis center over the past 15 years, from 2001 to 2016, analyzing the effectiveness of the use of urokinase for "declotting" of CVC for hemodialysis and the manner of its use, in the search for better therapeutic efficacy with the lowest risk of adverse events.

Methods: We have analyzed 48 cases of patients with CVC, inserted in 35 patients, for whom it was deemed appropriate to proceed with declotting urokinase due to malfunction for thrombotic occlusion. Even in our series, despite the routine filling of the lumen of the catheter with heparin sodium or sodium citrate between a dialysis and the next, the thrombotic complication of the CVC was very common, affecting in time 27% of the CVC. Our usual therapeutic protocol for the declotting of the CVC with urokinase included the following steps 1) slow-fill with positive pressure of each lumen of the CVC with a solution of 25,000 IU/ml of urokinase, by reason of the priming volume indicated by the manufacturer of the CVC and reported in writing on the same; 2) wait/bus station 30 minutes, carefully avoiding the marketing of the drug circle; 3) the total intake of the luminal contents and a few ounces of blood; 4) at a high pressure irrigation with saline solution.

Results: In our experience, 75% (36/48) of cases of CVC occluded by thrombosis were already passed on successfully with urokinase. We detected in some cases the need for repeated short-term treatment of thrombolytic therapy with urokinase, in subjects in which the position of the tip and or the side holes of the catheter had assumed a decubitus position on the vessel wall in which the CVC was allocated. In these people, the success rate of the individual thrombolytic treatment resulted however very high.

Summary/Conclusions: In our series, the unblocking of the CVC for hemodialysis with thrombolytic therapy using urokinase has proved very effective, without being burdened by any adverse reactions and/or side effects related to treatment.

PB2204

THROMBOTIC COMPLICATIONS IN HEMATOLOGIC MALIGNANCIES

M Popescu[1,*], D Georgescu[1], M Balea[1], M Tevet[1], O Patrinoiu[1], M Murat[1], F Mihai[1], C Dragan[1], V Popov[1], AN Ciuhu[2]
[1]Hematology, Colentina Clinical Hospital, [2]Oncology and Palliative Care, St Luke Hospital, Bucharest, Romania

Background: In patients with cancer there is an increased risk of thromboembolism, especially in certain types of solid tumors and hematologic malignancies. Occurrence of venous thromboembolism in patients with cancer is linked to a hypercoagulable state due to synthesis of pro-coagulants factors or local hypoxia. The risk of thrombotic complications increases during chemotherapy, hospitalization or surgery. Thrombosis is a frequent complication in acute leukemia as well, but its pathogenesis is not entirely known, being probably determined by a combination of factors related to the patient, disease and treatment regimens used.

Aims: To analyze the causes of thrombotic complications in patients with hematologic malignancies, excluding those with myeloproliferative neoplasms, multiple myeloma treated with immunomodulatory agents and acute promyelocytic leukemia, known to be associated with increased risk of thrombosis. Also, we excluded cases of catheter-related thrombosis.

Methods: We analyzed data of 41 patients with hematologic malignancies admitted in our institution during a period of 9 years which presented with at least one episode of thrombosis.

Results: There were 23 females and 18 males. The diagnosis distribution was: 4 cases of acute myeloid leukemia, 1 case of hairy cell leukemia, 1 case of acute lymphoblastic leukemia, 1 case of myelodysplastic syndrome, 2 cases of Hodgkin Lymphoma, 27 cases of Non-Hodgkin Lymphoma, 5 cases of multiple myeloma. The median age was 65 years (ranges from 37-81 years). After location of thrombosis, there were 37 cases of venous thrombosis, 4 cases of arterial thrombosis, 2 cases of DIC. Additional risk factors besides cancer were identified in 8 cases, including recent history of splenectomy, secondary thrombocytosis, phospholipidic syndrome, presence of clone of paroxysmal nocturnal hemoglobinuria, status post-autologous stem cell transplantation and chronic venous insufficiency. No additional risk factors were identified in the other patients. Inherited thrombophilia was not tested, but personal and family history was not suggestive for thrombophilia in the reported cases.

Summary/Conclusions: Thrombosis is the second cause of death and a major cause of morbidity in cancer patients, and improving antithrombotic prophylaxis

and treatment in this subset of patients may have important prognostic implications. An important issue is to identify patients at risk in order to establish proper prophylaxis. Score models were elaborated based on site of cancer, hemoglobin value, platelet and leukocyte count, and body mass index. However, in a subset of patients additional risk factors besides cancer could not be identified. Furthermore, in some patients thrombosis occur in the setting of severe thrombocytopenia. In this context, it could be important to identify some biological markers for thrombosis, such as the well known and used D-Dimer, and other studied markers, but not yet in clinical use, such as tissue factor, P-selectin or VEGF. We present an important lot of patients with hematologic malignancies and thrombosis, of note that most of these patients had no identifiable risk factors of thrombosis. Moreover some of these patients developed thrombosis in the setting of severe thrombocytopenia in the absence of DIC. We find important to identify biological markers useful in patients with cancer to predict thrombosis. We intend to screen patients with hematologic malignancies and thrombosis for D-Dimer, tissue factor and VEGF.

PB2205

TREATMENT AND OUTCOME OF PEDIATRIC CEREBRAL SINOVENOUS THROMBOSIS: A SINGLE CENTER EXPERIENCE

S Aytac*, I Altan, B Kuskonmaz, I Yaman Bajin, S Unal, B Tavil, M Cetin, M Tuncer, F Gumruk
Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: Pediatric cerebral sinevenous thrombosis(CVST) is a rare but potentially life threatining condition with a 3-12% reported mortality rate. Clinical findings mostly depend on the initial age at presentation, anatomic localization and extent of thrombosis, presence of infarct and /or symptomps of increased intracranial pressure, intracranial hemorrhage. Moreover, it was reported that most of those children with CVST have diffuse neurologic findings on admission.
Aims: We aim to analyse treatment and prognosis of childhood CVST.
Methods: In this study we retrospectively evaluate clinical presentation, underlying disorders, risk factors (genetic and acquired), anticoagulant treatments and prognosis of our 34 patients with CVST diagnosed between January 2009 to June 2015 at Hacettepe University Faculty of Medicine, Ihsan Doğramacı Children's Hospital.
Results: In this study we retrospectively evaluate clinical presentation, underlying disorders, risk factors (genetic and acquired), anticoagulant treatments and prognosis of our 34 patients with CVST diagnosed between January 2009 to June 2015 at Hacettepe University Faculty of Medicine, Ihsan Doğramacı Children's Hospital. There were 14 female and 20 male children with a median age of 7.3 years(1 month to 17,5 years). When we grouped initial ages 9 (26%) patients were under one year of age and 14(41%) patients were older than 10 years of age on admission. Initial complaints include headage(n=15;44%), seizures(n=5;15%), loss of consciousness (n=4;12%), focal neurological impairment (n=6;%17), diffuse neurological impairment (n=1; 3%) and pseudotumor cerebri (n=3; 9%). Risk factors included underlying disorders (Nephrotic syndrome, Acute leukemia, homocysteinemia, Behçet disorders, etc.) were found to be positive in 59% of the children and 15(44%) of them had hereditary prothrombotic risk factors (Heterozygous Factor V G1691A mutation (n=4), Homozygous Factor V G1691A mutation(n= 2), Heterozygous Prothrombin G20210A mutation(n=2), homozygous MTHFR C 677T mutation (n=4), PAI 4G/5G mutation(n=2)). Nearly all patients were given anticoagulant treatment and initial treatment were mostly included LMWH(73%) with an median 6 months (1 month to 9 months)of treatment period and 66% of them obtained partial or complete resolution of thrombosis with treatment. Mortality rate was 6%.
Summary/Conclusions: This study shows that CVST was more common under 10 years of age (60%)in our group however there was no increased rate of CVST for the neonatal period which was found to be 11% inconsistently lower than the reported rate(57%). Neonatal CVST occured more than half of the patient without a known prothrombotic or underlying risk factors.

PB2206

MANAGEMENT OF PEDIATRIC THROMBOSIS IN A SINGLE TERTIARY CARE MEDICAL CENTER

F Yus Cebrian[1,*], C Coello de Portugal[1], N Fernandez-Mosteirin[1], R Rupay Rojas[1], M Andrade Campos[2], P Delgado Beltran[1], JM Calvo Villas[1]
[1]Haematology, [2]Hospital Miguel Servet, Zaragoza, Spain

Background: Venous and arterial thrombosis is increasingly encountered in the pediatric population.
Aims: The aim of this retrospective study was to summarize our experience regarding clinical characteristics, diagnosis and management of pediatric thrombosis in a single tertiary care medical center.
Methods: We reviewed clinical files of patients (pts) under 18 years old diagnosed of arterial thrombosis (AT) and/or venous thromboembolic (VTE) events in our institution between March 2006 and June 2015. Clinical data, thrombotic risk factors (TRF), thrombophilia test results, thrombosis location and therapy were analized.
Results: 49 AT and/or VTE events were diagnosed in 48 pts, median age at diagnosis was 1 year (0-17); 24 pts were infants (25% neonates) and 24 (50%) >1year; out of 48 pts, 29 were ♂ and 19 ♀. Clinical presentation: arterial isquemic stroke 19 (38.7%), lower extremities deep venous thrombosis (DVT) 13 (26.6%), cerebral venous sinus thrombosis 8 (16.3%), portal and inferior vena cava thrombosis 4 (8.2%), lower extremity arterial ischemia 2 (4.08%), purpura fulminans 1 (2.04%), subclavian vein thrombosis 1 (2.04%) and suprahepatic vein thrombosis 1 (2.04%). Age classification of pts was: 18 (37.5%) newborns: <1 month; 6 (12.5%) infants: <1 year, 12 (25%) children: 1-13 years and 12 (25%) adolescents: 14-17 years. According to the age classification the most common clinical presentations were arterial isquemic stroke in newborns 12 (66.6%); DVT 2 (33%) and portal/ inferior vena cava thrombosis 2 (33%) in infants; cerebral sinus thrombosis 4 (30%) in children and DVT 6 (50%) in adolescents. Adquired risk factors included systemic sepsis and oncologic diseases in 15 and 6 pts, 4 central venous catheter carriers, 3 congenital heart disease (CHD), 2 systemic sepsis + CHD, 4 artery malformations, 1 immobilization after ankle injury, 1 hormonal contraceptives therapy + sepsis, and 1 *perinatal hypoxic*-ischemic *encephalopathy*. The most important risk factor for thrombosis was systemic sepsis. In 12 cases no risk factors for thrombosis were found. Thrombophilia testing was performed in 36 cases (73.4%). Thrombophilic risk factors were found in 9 pts 25%: 2 prothrombin G20210A mutation, 1 prothrombin G20210A + MTHFR mutations, 1 R506Q mutation, 1 Protein S decreased, 1 lupus anticoagulant, 1 Protein S decreased + lupus anticoagulant and 1 antiphospholipid-like syndrome. Anticoagulation therapy was initiated in 3 pts with unfractioned heparin to achieve therapeutic aPTT and 30 pts received enoxaparin at a mean dose of 1 mg/kg/12 h to achieve anti-Xa therapeutic level. Median duration of anticoagulation was 3 months. Median number of anti-Xa level was 6.96 (1-22), and range controls 4.61 (0-19). Intraarterial fibrinolytic therapy followed by enoxaparin was administered in 1 pt with stroke, 4 pts with stroke were antiaggregated with AAS. No anticoagulation/ antiaggregation was given to 15 pts. Overall recurrence rate of thrombosis was 6.2% (3/48); mortality rate 4.1% (2/48). Mortality was related to underlying diseases: 1 pt perinatal hypoxic encephalopathy and 1 pt tumor progression. Gastrointestinal bleeding linked to anticoagulation was observed in 1 pt.
Summary/Conclusions: The distribution of thrombosis was similar to already published. Acquired thrombotic risk factors were associated with both AT and VTE. We must be cautious about interpretation of thrombophilia test because the haemostatic system is still developing. Adjustment in enoxaparin dosage to target anti-Xa level is a valuable tool for anticoagulant therapy in pediatric thrombosis.

PB2207

CEREBRAL STROKE IN A CHILD WITH CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE II

A Ozcan[1], T Patiroglu[1], H Acer[2], H Gumus[2], S Senol[3], M Karakukcu[1], MA Ozdemir[1], E Unal[1,*]
[1]Department of Pediatrics, Division of Pediatric Hematology Oncology, [2]Department of Pediatrics, Division of Pediatric Neurology, [3]Department of Radiology, Divison of Interventional Radiology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background: Congenital Dyserythropoietic Anemia type II (CDA II) belongs to a subtype of bone marrow failure syndromes characterized by monolineage involvement and typical morphological abnormalities in erythroid precursor cells resulting with different degree of hyporegenerative anemia. Moreover reticulocytosis, which is not corresponding to the degree of anemia (ineffective erythropoiesis) with jaundice and splenomegaly are major diagnostic criteria. Causative gene is located at *SEC23B*. Although stroke among children is rare, it can cause significant morbidity and mortality.
Aims: Herein we present three years old boy who had diagnosed with CDA II and eventually experienced stoke.
Methods: A newborn male baby referred to us with complaints of icterus and anemia. From his medical history it was learned that his parents were consanguineous. Initial physical examination showed pallor, icterus, hepatosplenomegaly and cryptorchidism. Laboratory finding showed anemia, reticulocytosis, hyperbilurinemia. Bone marrow aspiration showed morphological abnormalities of the erythroblasts. The genetic studies showed double heterozygous mutations in SEC23B.Regular transfusions were started. At age of four he admitted to emergency department with complaints of aphasia and physical examination showed facial paralysis. The MRI revealed acute infarcts at left frontal lobe and digital subtraction angiograph showed occlusion of left internal carotid artery suggestive of fibromusculer dysplasia. Enoxiparine was started. And he is under outpatient control without any neurological sequel.
Results: Pediatric stroke is an important cause of long-term disability, In our recent manuscript we observed seizures in 53%, long-term significant neurological deficits in 67%, and death in 14%. Risk factors for stroke in childhood are different from those traditionally observed in adults. Over 100 risk factors for stroke in children have been reported, but in up to one third of patients, no cause is identified, and these cases are classified as idiopathic. In literature search we did not encounter any individual with CDA II who had stroke.
Summary/Conclusions: To best of our knowledge this case presentation reports an interesting combination of CDA and stroke. This combination can

be coincidental but clinicians who manage patients with CDA must be vigilant about the neurological complications including stroke.

PB2208

CROATIAN EXPERIENCE OF THROMBOPHILIA TESTING-A HUGE VARIETY OF REFERRING PRIMARY PHYSICIANS, DIFFERENT INDICATIONS, AND PATIENTS' CHARACTERISTICS

D Pulanic[1,*], M Vodanovic[2], M Kos[3], A Kustura[3], A Boban[4], J Belev[2], S Zupancic Salek[1], D Nemet[1]
[1]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Medical School University of Zagreb, Faculty of Medicine J.J. Strossmayer University of Osijek, [2]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, [3]Medical School University of Zagreb, [4]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Medical School University of Zagreb, Zagreb, Croatia

Background: Thrombophilia is a predisposition to thrombosis and is not disease per se, but exposes carriers to increased risks for thrombosis compared with non-carriers. Some earlier studies showed also association between thrombophilia and adverse pregnancy outcomes. However, it is still a matter of intense debate who should undergo comprehensive and expensive laboratory testing for thrombophilia and its usefulness in clinical practice.
Aims: The aim of this work was to analyze indications, patients' characteristics and specializations of referring primary physicians who requested thrombophilia testing with hematology consultation.
Methods: We analyzed patients referred for thrombophilia testing with hematology consultation to the Coagulation Outpatient Unit of the Division of Hematology, Department of Internal Medicine, University Hospital Center Zagreb, Zagreb, Croatia, from 2013-2014. Study was approved by the Medical ethic committee.
Results: There were 351 new patients sent from different specialists for thrombophilia work-up, median age 38 years (range 18-82 years), and among them majority were female patients (68.1%). The most frequent specialists who requested testing of the patients were gynecologists (30.2%), followed by internal medicine specialists with different subspecialisations (20.5%), cardiologists (11.96%), hematologists from other institutions (9.4%), family physicians (9.1%), neurologists (7.7%), vascular surgeons (5.1%), ophthalmologists (1.7%), and others. The most common indication for thrombophilia testing was personal history of venous thromboembolism (VTE) (deep vein thrombosis, pulmonary embolism or both) in 50.9% of analyzed patients. Among patients who had VTE, 64.4% had idiopathic VTE and 18.9% had recurrent VTE. The most common causes of secondary VTE were trauma, surgery and immobilization (34.3% of secondary VTE). The second most common indication for thrombophilia testing were gynecology/obstetric reasons (recurrent or even the first time miscarriages, pregnancy complications (intrauterine fetal growth restriction, preeclampsia, abruption placentae), and sterility) among 28.5% of all patients (41.8% of female patients). Other indications for request for thrombophilia testing with hematology consultation were stroke (5.7%), varicose veins (5.4%), recurrent thrombophlebitis (5.1%), myocardial infarction (1.9%), retinal vein thrombosis (1.7%), and other. More than 1 reason for testing had 14.5% of patients, and 25.15% of patients had positive family history for VTE. In addition to request for laboratory hypercoagulable work-up, 27.9% of the patients confirmed that were active smokers.
Summary/Conclusions: Although in general majority of patients sent for thrombophilia testing with hematology consultation were younger people with previously unprovoked VTE, there was huge variety of indications and different kind of specializations of primary physicians who requested testing. Gynecologists as referring physicians and gynecology/obstetric reasons were especially frequent, what might change in the following years with new data about clinical indications and usefulness of thrombophilia testing.

PB2209

ANTIPHOSPHOLIPID ANTIBODIES, PREGNANCY AND SPONTANEOUS MISCARRIAGES. EXPERIENCE FROM A RECENTLY OPENED CENTER

C Muñoz Novas[1,*], C Heras Benito[1], I González Gascon y Marín[1], MS Infante[1], Y Mena[2], M Zafra[2], MA Foncillas[1], K Marín[1], JA Hernández Rivas[1]
[1]Hematology, [2]Ginecologia y Obstetricia, Hospital Infanta Leonor, Madrid, Spain

Background: Antiphospholipid syndrome (APS) is an autoimmune disorder characterized by the appearance of arterial or venous thrombotic events and/or obstetric complications in the presence of antiphospholipid antibodies (aPL). These include: lupus anticoagulant (LA), anticardiolipin antibodies (aCL), and anti-beta2 glycoprotein I antibodies (aβ2GPI). APLs are found in up to 40% of women who suffer recurrent miscarriages and/or fetal deaths. LA has been associated with preeclampsia, intrauterine growth retardation (IUGR) and fetal loss. ACA are linked to preeclampsia and late fetal loss. The aβ2GPI to preeclampsia, IUGR and late fetal loss. The presence of any of them in pregnancy is a predictor of adverse outcome and should be considered a high risk factor for venous thromboembolism (VTE). The management of these patients could be controversial, especially in cases with moderate-high titles of LA and/or aCL with neither thrombotic nor obstetric signs, although this approach has not been tested in prospective clinical trials. The combined therapy of acetylsalicylic acid (ASA) and low molecular weight heparin (LMWH) has shown efficacy and birth rates close to 80%, with less toxicity than other schemes including corticosteroids and/or immunoglobulins
Aims: determine the prevalence and clinical significance of the aPL in women with recurrent miscarriages and obstetric complications
Methods: Retrospective analysis of patients with a previous history of recurrent miscarriages or fetal deaths, between 2009 and 2015, referred to the hematology consultation in which the presence of aPL was confirmed in two separate determinations at least 12 weeks apart
Results: The presence of aPL was confirmed in 20 patients and 13 were diagnosed according to the Sydney classification criteria for APS. The accompanying clinical manifestations in those patients with positive aPL were: recurrent miscarriages in 18/20 (90%), median of 3 abortions <12 weeks; VTE disease 2/20 (10%); 1 patient with a history of fetal loss at 24 weeks; 1case of eclampsia in previous pregnancy and 1 case of IUGR (See table). The antibody most frequently involved was aCL, present in 13/20 (65%). The LA was observed in 9/20 (45%), including this group, the only 2 cases with VTE in the series and the only case with IUGR. 25% (5/20) of the patients had more than one positive aPL, one of these patients had having a previous history of pulmonary embolism (PE) before the diagnosis of APS. After the diagnosis of APS 18/20 cases (90%) had new pregnancies including 15 full-term newborns and 3 ongoing pregnancies. All these patients were treated with ASA and LMWH at prophylactic doses, with monitoring levels of anti-Xa. Once treatment was established the only complication was one pregnancy loss at weeks eight of gestation in an obese patient who did not reach levels of anti-Xa at prophylactic range, but later had a successful pregnancy by increasing the dose of LMWH. There were no fetal deaths or new cases of VTE or hemorrhagic complications.

Table 1.

Table. Patient's Characteristics

Patients	Age	aPL type	Previous miscarriage s	Thrombosis	Associated thrombophilia	Others
1	36	LA+, aCL IgG+	4			
2	33	aCL IgG, IgM+	3			Autoimmune hepatitis
3	41	aCL IgM+	3			
4	46	aCL IgG+	3			
5	35	aCL IgM+	1			
6	41	LA+, aβ2GPI IgG+	2			IUGR*
7	38	aCL IgG+	1			
8	32	LA+,aCL IgM+	2			
9	38	LA+, aCL IgG+	1	PE	Prothrombin 20210A heterozygous gene	
10	28	LA+	3			
11	31	aCL IgG+IgM+	3			
12	40	aβ2GPI IgG+	1		Suspected Protein S deficit	ANAS+, anti SS-, anti Fib
13	46	aCL IgG+IgM+	6			
14	34	LA+	4			Gestational diabetes. Obesity
15	38	aCL IgG+, IgM+	0			Eclampsia in previous pregnancy (32 weeks preterm newborn)
16	26	LA+	0	Postpartum DVT		
17	35	LA+	3			
18	36	aβ2GPI IgM+	2			
19	45	LA+,aCL IgM+	2			
20	40	aCL IgG+	2			

*presented when the patient was evaluated by hematology; treatment was initiated and it was resolved before the end of the pregnancy.

Summary/Conclusions: Combination therapy with ASA and LMWH is safe and effective in the secondary prevention of obstetric complications in patients with APS. As in other series, our study confirms that more than one positive aPL determination and LA positivity are associated with an increase of the number and severity of complications in patients with APS. Further studies to improve the current evidence for the management of these patients are needed.

PB2210

INFLUENCE ADRENOCORTICOTROPIC HORMONE ANALOG SEMAX ON FUNCTIONAL ACTIVITY OF BLOOD CELLS DURING IMMOBILIZATION STRESS

M Golubeva[*]
Biology Faculty, Moscow State University, Moscow, Russian Federation

Background: Bokgraund It is known that many disease states are associated with impaired red blood cell membrane. It is the activity of these blood cells associated normal microcirculation. At present, special attention is given to researchers semax neuropeptide derived from pituitary adrenocorticotropic hormone. The peptide penetrates the blood-brain barrier and has an impact on a number of functions of the central nervous system. Experiments have shown that peptide can affect blood cells, particularly red blood cells. The red blood cells increase the biochemical reactivity and functional only activated platelets. Change erythrocytes platelet biochemistry is very important for understanding the interaction of blood cells in hemostasis. It was found that the immobilization of the animal's body are also changes of erythrocyte membrane.
Aims: The aim of this work was to determine the effect of Semax on the functional activity of red blood cells and their interaction with platelets and the influence of these processes immobilization stress.
Methods: To reproduce the experimental stress reaction used immobilization

stress by fixing the rats on their backs for 60 minutes. In *in vitro* experiments semax in the concentration range 10-1 - 10-10 M is added to a pool of platelet-rich plasma (PRP), or PPP and the mixture washed erythrocytes (e) and change in aggregation was determined by the action of ADP. In experiments *in vivo* semaks administered intravenously prior to or after the immobilization was determined and osmotic fragility of erythrocytes and the platelet aggregation in normal and by animals immobilized.
Results: *in vitro* experiments have shown that, when added to semax pool PRP concentration of 10-10M only caused a significant enhancement of platelet aggregation. Adding PRP mixture of washed red blood cells significantly increased platelet aggregation. When added to the mixture PRP + erythrocyte as a peptide, and directivity of physiological saline retained reactions. *in vivo* experiments demonstrated that intravenous administration of semax at a dose of 1 mg/ml in a physiological standard had no significant effect on platelet aggregation. In the study of changes in the wholesale electricity market it has shown that semaks increases resistance of the membrane of red blood cells, reducing the percentage of haemolysed cells. The prophylactic administration of semax as well as the administration of the peptide on the background of immobilization stress significantly increased the resistance of erythrocytes to hemolysis.
Summary/Conclusions:. Our studies have shown that neuropeptide semaks, on the one hand, no significant effect on hemostasis in a physiological condition, and with another - increased stability of the erythrocyte membrane to the stressor exposure.

A CASE REPORT OF FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS WITH CNS DEMYELINATION COMPLICATED WITH THROMBOSIS
S Ciraci[1], A Ozcan[2], Mm Ozdemir[2], Scc Chiang[3], B Tesi[4], Ma Ozdemir[2], M Karakukcu[2], T Patiroglu[2], S Doganay[1], H Gumus[5], Yt Brysecon[3], E Unal[2,*]
[1]Department of Radiology, Division of Pediatric Radiology, [2]Department of Pediatrics, Division of Pediatric Hematology Oncology, Erciyes University, Faculty of Medicine, Kayseri, Turkey, [3]Centre for Infectious Medicine, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockolm, Sweden, [4]Centre for Infectious Medicine, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockolm, [5]Department of Pediatrics, Division of Pediatric Neurology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background: Hemophagocytic lymphohistiocytosis (HLH) is a fatal disease affecting infants and very young children, including high fever, hepatosplenomegaly and pancytopenia. Hemophagocytic syndrome may be spontaneous or secondary to infection, malignancy or autoimmune disease, and mechanisms involved are poorly understood. The main histopathologic feature is increased proliferation and activation of macrophages with hemophagocytic lymphohistiocytosis throughout the reticuloendothelial system.
Aims: We present a case with cranial involvement of HLH showing diffuse infiltration of white matter complicated with intracranial thrombosis.
Methods: A 5 year-old girl with fever, and pancytopenia was referred to our hematology unit. Also she had a history of recurrent infections. Her parents were consanguine. Lymphadenopathy, and hepatosplenomegaly were detected in physical examination. Ultrasound examination displayed hepatosplenomegaly and intraabdominal free fluid. Hemophagocytic lymphohistiocytosis was revealed on bone marrow aspiration biopsy. Anomaly in NK and T lymphocyte cytotoxicity and degranulation tests was determined. İn genetic analysis, syntaxin gene mutation was depicted. Immunosuppressive therapy was performed to the patient, diagnosed with familial HLH. Brain MR imaging was performed because of the suspicion of cranial involvement. On MRI diffuse hyperintense signal changes of cerebral white matter on T2-W and T2 FLAIR images, showing demiyelination were detected. There wasn't any mass effect, contrast enhancement and restricted diffusion on MRI. A repeated brain MR performed a month after the first cranial imaging, showed an acute infarct involving left temporooccipital region. Follow up images showed that the infarct was disappeared but white matter lesions was stable on the brain MR imagines. The cerebral white matter lesions were stable but hyperintense signal changes were appeared in cerebellar white matter, accepted as progression. She was died in despite of immunosuppressive therapy.
Results: Hemophagocytic lymphohistiocytosis (HLH) is a syndrome of pathologic immune activation, in association with a variety of triggers and is prominently associated with cytopenias and combination of clinical signs and symptoms of extreme inflammation. The histopathologic findings of HLH in pediatric patients with cranial involvement is various. The common CNS involvement of HLH is leptomeningeal infiltration of lymphocytes and histiocytes/macrophages with a sterile CSF lymphocytosis. If parenchymal involvement occurs perivascular infiltrations are seen. In more severe cases, demiyelination and tissue necrosis of the cerebral white matter may be seen. The previously reported MR findings of HLH with cranial involvement, include diffuse leptomeningeal and perivascular enhancement showing infiltrations of histiocytes and lymphocytes, T2W hyperintense white matter lesions on cerebrum, cerebellum and spine, parenchymal necrotic lesions with ring enhancement and diffuse atrophy of the cerebrum and cerebellum. In our patient we displayed diffuse white matter lesions in cerebrum and cerebellum showing demiyelination on T2W MR sequences. There wasn't any contrast enhancement or restricted diffusion. The spine was normal.
Summary/Conclusions: The HLH treatment is an induction therapy including steroid amd chemotheuropetics. Without therapy, survival of patients with HLH is very short, especially in familial form and cranial involvement. CNS involvement may occur at the beginning or during the treatment. Patients with CNS involvement should be treated with intrathecal agents. Depiction of the cranial involvement, is important for patient's survival and treatment. All patients with HLH should had brain MRI, even if asymptomatic.

PB2212

VENOUS THROMBOEMBOLISM IN WOMEN USING HORMONAL CONTRACEPTION. FINDINGS FROM A SINGLE CENTER
AS Vilches*, A Latorre, J Cachá
Hematología y Hemoterapia, Hospital Universitario de Móstoles, Móstoles, Spain

Background: Venous thrombosis including deep-vein thrombosis (DVT) and pulmonary embolism (PE) is considered a multifactorial disease associated with genetic and acquired risk factors. In women of reproductive age, the main cause of venous thromboembolic disease (VTD) is the hormonal contraception. However, other risk factors interact to produce VTD.
Aims: Identifying the risk factors for DVT and PE, may intervene in risk situations and limit the occurrence of VTD with its potential morbidity and mortality.
Methods: We reviewed the characteristics of our series of 103 women with objectively confirmed VTD associated with hormonal contraception. We analyzed its clinical data and thrombophilia studies which were performed in more than 80% of them and included anticoagulant proteins, genetic tests, antiphospholipid antibodies and factor VIII level. Statistical analysis was performed with SPSS 18.0 software. bidi-font-size:12.0pt;font-family:Calibri;mso-ansi-language:EN'>.
Results: The mean age of our patients was 29±7.4 years old. A high percent of them (46%) had a body mass index >25 Kg/ m². The most important clinical risk factors for venous thromboembolism were inmmobility (31%), family history (27%) and polycystic syndrome (9.8%). The combined oral contraceptive including antiandrogen and third generation progestogen were the most frecuently used for our patients. Thrombophilia test revealed factor V Leiden in 13%, prothrombin mutation in 20%, antiphospholipid syndrome in 3%, protein C deficiency in 0%, protein S deficiency in 2.4%, antithrombin deficiency in 0% and increased factor VIII (>195%) in 18.7%.

Table 1.

Patients, N	103
Clinical characteristics	
Mean age (years ± SD)	29 ± 7.4
Body mass index (Kg/m2 ± SD)	25.8 ± 5.9
Body mass index >25 Kg/m²	25 (46.3%)
Risk factors for venous thromboembolism	
Immobility	29 (30.9%)
Family history	23 (27.4%)
Polycystic ovary syndrome	9 (9.8%)
Type of combined oral contraceptive	
Including antiandrogen	27 (52.9%)
Including second generation progestogen	3 (5.9%)
Including third generation progestogen	21 (41.2%)
Venous thromboembolism characteristics	
Pulmonary embolism	45 (44.6%)
Proximal deep vein thrombosis	53 (52.5%)
Upper-extremity deep vein thrombosis	3 (3%)
Thrombophilia tests	
Factor V Leiden	11 (12.9%)
Prothrombin mutation	18 (20.5%)
Antiphospholipid syndrome	3 (2.9%)
Protein C deficiency	0 (0%)
Protein S deficiency	2 (2.4%)
Antithrombin deficiency	0 (0%)
Increased factor VIII (>195%)	14 (18.7%)

Summary/Conclusions: Contraceptive use remains the most important risk factor for VTD in women of reproductive age. We observe additional risk factors such as obesity, immobilization, polycystic ovary syndrome or family history of VTD and certain thrombophilic defects. G20210A prothrombin and G1691A factor V Leiden mutations as well as elevated factor VIII (which has been associated to blood group non O) are frequent in women at a fertile age and should be part of thrombophilia study. Defining high risk patients may improve interventions in risk situations (e.g. administering antithrombotic prophylaxis or discontinuing contraceptive use after lower limb trauma) in order to prevent VTD. Finally, the increased thrombotic risk of antiandrogen and third generation contraceptives should be also taken into account.

PB2213

THE RICK OF THROMBOEMBOLISM IN SURGICAL AND ONCOLOGICAL PATIENTS WITH ANTITHROMBIN III, PROTEIN S AND PROTEIN C DEFICIENCY
I Fotopoulou*, E Kokkalis, P Masoura, S Kotsali, H Vorilla, A Nikolopoulou
Laboratory of Hematology, General Hospital of Patras 'St. Andrew', Patras, Greece

Background: Thrombophilia is a condition where the blood has an increased tendency to form clots. Blood clots can cause problems such as deep vein thrombosis (DVT) or pulmonary embolism. Natural coagulation inhibitors in hemostasis are Antithrombin III (ATIII), Protein S (PS) and Protein C (PC). Congenital AT III deficiency is an autosomal dominant disorder in which an individual inherits one copy which encodes AT III. This condition leads to increased risk of venous and arterial thrombosis. This form is most commonly diagnosed during childhood after a child has had a thrombotic event. Severe congenital AT III deficiency, in which the individual inherits 2 defective genes, is a rare autosomal recessive condition associated with increased thrombogenesis, typically noted in the neonatal period or early infancy. This condition is rarely compatible with life. Acquired AT III deficiency is a deficiency of antithrombin primarily due to consumption, such as disseminated intravascular coagulation (DIC). Protein S deficiency may be hereditary or acquired; the latter is usually due to hepatic diseases or a vitamin K deficiency. Protein S deficiency usually manifests clinically as venous thromboembolism (VTE). Protein C deficiency is a congenital or acquired condition that leads to increased risk for thrombosis. Congenital PC deficiency is one of several inherited thrombophilias, which are a heterogeneous group of genetic disorders associated with an elevated risk of venous thromboembolism.
Aims: The aim of this study is to measure AT III, P S and P C in patients from oncology department, urology department and the department of obstetrics and gynecology.
Methods: The study took place of observation at the general hospital of Patras (Greece) and included a total of 280 patients (male and female). The blood of patients was examined and the ATIII, P S and P C values were recorded. AT III measurement is a chromogenic determination based on an amydolitic method. Moreover the control of P C include the study of the functionality and antigenicity with chromogenic method. Also, the control of P S is based on the study of the functionality and the antigenicity of free P S (batch method).
Results: We studied 280 patients. From these patients, 200 were surgery patients from gynecological and urological department and 80 were patients from oncology department (table 1). Results for surgical patients were: AT III deficiency 4 patients (2%), P C deficiency 2 patients (1%) and P S deficiency 1 patient (0,5%). Furthermore, results for oncological patients were: AT III deficiency 3 patients (3.75%), P C deficiency 2 patients (2,5%) and P S deficiency 1 patient (1,25%).

Table 1.

Total patients		AT III deficiency	P C deficiency	P S deficiency
	110 female	3(2,7%)	2(2%)	0(0%)
200 surgical				
	90 male	1(1%)	0(0%)	1(1%)
	47 female	2(4%)	1(2,1%)	1(2,1%)
80 oncological				
	33 male	1(3%)	1(3%)	0(0%)

Summary/Conclusions: It is a fact that, either oncological or surgical patients are associated with a number of complications, mainly thrombosis. In addition deficiency in a classic coagulation factor is a high rick of venous thrombosis. The obvious conclusion to be drawn is that, measurement of AT III, P S and P C should be performed. Thus we should evaluate the impact of VTD or pulmonary embolism on the survival of these patients.

PB2214

ANTICOAGULANT TREATMENT WITH APIXABAN IN INHERITED ANTITHROMBIN DEFICIENCY

N Bermejo*, R Sigüenza, I Casas, FDA Pérez-Leal, MH Bañas, F Ibáñez, S Cáceres, JM Bergua
Hematology, Hospital San Pedro de Alcántara, Cáceres, Spain

Background: Apixaban, a direct inhibitor of activated factor X, has at least the same efficacy and safety as vitamin K antagonists (VKA) for secundary prevention of recurrent venous thrombosis in adults, but no data in patients with inherited Antithrombin Deficiency are available.
Aims: Evaluate apixaban as a valid anticoagulation alternative in adults patients with inherited Antithrombin Deficiency and difficulty for treatment with VKA.
Methods: We report a case of a 49-year-old man with Crohn disease, on long-term anticoagulation with low molecular weight heparin (LMWH) by recurrent episodes of venous thrombosis due to inherited Antithrombin Deficiency. Due with the difficulty for treatment with VKA because his severe Crohn disease, it was decided to maintain anticoagulation with intermedie doses of LMWH (therapeutic doses were associated with rectal bleeding). To obviate LMWH-associated osteoporosis, the use of calcium and vitamin D supplementation, and weight-bearing exercise were recommended. Proximal femur bone and lumbar spine density measurements were taken at baseline and each 6 months. Two years later, significant osteopenia was observed at the proximal femur bone, so heparin was replaced by 2.5mg/12h apixaban. Nine months later, he has not suffered thrombotic recurrence neither bleeding complications, but there were not any changes in bone densitometry.
Results: This is the first description of the use of apixaban in secundary prevention of recurrent venous thrombosis induced by Inherited Antithrombin Deficiency. Our patient on long-term anticoagulation with apixaban has not experienced bleeding or thrombotic complications months after transitioning to apixaban, but osteopenia has stayed without changes.
Summary/Conclusions: We believe that apixaban may be considered as a valid anticoagulant alternative in adults with inherited Antithrombin Deficiency and difficulty for treatment with VKA, although until results of prospective randomised trials are available, we recommend caution in using apixaban in patients with inherited thrombophilia. However, LMWH-associated osteopenia does not seem to improve after transitioning to apixaban.

PB2215

RELATIONSHIP BETWEEN TYPE AND INTENSITY OF ANTICOAGULANT THERAPY AND RECURRENCE OF ARTERIAL THROMBOSIS ON ANTIPOSPHOLIPID SYNDROME

R Siguenza*, N Bermejo, I Casas, FDA Perez, H Fernandez, F Ibañez, S Cáceres, JM Bergua
Hematology, Hospital San Pedro de Alcantara, Cáceres, Spain

Background: The optimal type and intensity of anticoagulant therapy for the treatment of Antipospholipid Syndrome (APS) remain controversial issues, particularly for arterial thrombosis.
Aims: We investigated if there are difference between the development of recurrence of arterial thrombosis on APS taking anticoagulant therapy with vitamin K antagonist (VKA), antiplatelet therapy with ASA, or both VKA and ASA.
Methods: Retrospective we investigated the development of recurrence arterial thrombosis in 23 patients consecutive diagnosed in our hospital of APS with previous arterial thrombosis, from 1 February 2000 to 31 December of 2015. The patients ages were between 25 to 88, gender 39.1% male and 60.9%. Patients were treated well with ASA 100 or 300 mg either VKA for objective 2.5 INR, adding or ASA 100 mg depending on the thrombotic risk (depending on the location of thrombosis and the presence of thrombophilia and established cardiovascular risk factors). 10 patients present Stroke, including Cryptogenic Ischemic Stroke, 6 present Transient Ischemic Attack, 4 Myocardial Infarction, and 3 other periferical arterial thrombosis (ocular, laberintical and popliteal). Of this 23 patients, suffered recurrence arterial thrombosis 4 of 12 were taking AAS, 4 of 8 patients taking VKA, and 1 of 3 taking VKA and ASA. The statistical analysis was performed with Pearson test realized by JMP 9.
Results: We not found statistically significant difference between the APS patients taking VKA, ASA or VKA and AAS and the development of recurrence arterial thrombosis (OR 0.12, IC 95% -0.21 -0.46, p=0.73).
Summary/Conclusions: Although we found more patients with APS development recurrence arterial thrombosis taking AAS than VKA, we cannot establish an association between recurrence of arterial thrombosis and treatment without VKA. The location of thrombosis and the presence of classical cardiovascular risk factors do not seem to be good predictors of thrombotic recurrence. Future studies that delineate thrombotic risk in APS and evaluate current and novel anticoagulants as well as non anticoagulant therapies are required.

Transfusion medicine

PB2216

HOME BLOOD TRANSFUSION, A SAFETY OPTION IN SPAIN

C De La Mata Espinosa*, P Caballero, N Madrid
Hematología, Hospital Universitario San Rafael, Granada, Spain

Background: The terms "Home medical care" generically designate a wide range of support services for palliative patients and people with disabilities. The designation includes everything, to improve quality of life for both the patient and the family. Quite often chronic and terminally ill patients who are being treated with Domiciliary Hospitalization usually require a blood transfusion. Commonly the form of action is to transfer the patient to the hospital. In many cases, this transfer can be uncomfortable and painful for the patient and implies costs of medical transport or transfer costs assumed by the patient.
Aims: San Rafael Hospital in Granada, Spain provides a Home medical service for chronic patients and palliative patients. A recent initiative of the Haematology Department of the Hospital is to offer home transfusions which aims to reduce the demand for emergency services and the need for hospital admission. To carry out this activity we must emphasize that all blood transfusion must ensure the patient safety, always carried out by qualified personnel of Home Hospitalization units (HHU).
Methods: San Rafael Hospital has a written a standard operating procedure, reviewed by the hematologist and the personal of the Medical Blood Bank. Before performing the blood transfusion, the patient (or the person authorized to sign Relation to Patient) has signed Informed Consent Form.
Results:, 100% of home transfusions in our Center have signed informed consent. A copy is recorded in the patient's history. Before the blood transfusion, the patient is visited by the HHU which is composed by a Physician and a qualified nurse, which has verified that the place where it is going to be performed the activity, has the minimum requirements. Patients who have requested this service had oncological diseases and are palliative patients. 88% transfusions of the total had been red blood cells and 11% platelet units. No reaction has been registered. After transfusion, the doctor UHD had visit the patient to assess the improvement and to make the following diagnostic tests.
Summary/Conclusions: The Home blood transfusion is an accessible and safety alternative for chronic patients and palliative patients in Granada Spain that decrease associated costs, reduce the hospital admissions and demand on acute services.

PB2217

EVALUATING THE EVALUATORS. EXPERIENCE OF A CENTER AND STATE OF ACCREDITATION IN TRANSFUSION MEDICINE IN ANDALUSIA

JR Garcia Fernandez*, F Lopez Berenguel, JJ Perez Guerrero
Hematologia, Hospital de Baza. Servicio Andaluz de Salud, BAZA, Spain

Background: In transfusion medicine implementing a quality management system certified by an external entity,allows the development of a safe and efficient activity, while contributing to the involvement of all staff to improving a continuous quality system. In Spain there are two entities accredited byENAC for certification in transfusion: Transfusion Accreditation Committee (CAT) and the Agency for Health Quality of Andalusia (ACSA), although the latter with a specific program limited to transfusion centers
Aims: To describe the situation related to quality management system in transfusion medicine in Andalusia, a region in the south of Spain.
Methods: On the basis of data published by the CAT and ACSA we exposed the number of certified centers in Andalusia compared to national data. The experience of the local hospital was also evaluated Baza as externally certified center.
Results: 1. Although only half transfusion centers are certified by CAT, 100% of them are validated by the ACSA specific program. 2. 34% of centers accredited in Spain are accredited in Andalusia. 3. The relationship with the referral hospital and transfusion center seems to be the most important predisposing factor for a certification program. With respect to the certification program in the form of management is notfully adapted to "little" hospital, because if it's true that there is a hospital responsible for haemovigilance, hemotherapy isn't an exclusive dedication for him. In the aspect of non-conformities, the effort in a program of continuous improvement quality is very significant. Comparing our data center initial certification (2010) in which the 3rd edition of the standards was used, with reaccreditation (2014) which use the 4th. Table 2 shows comparative nonconformity according to the specific field deviations observed: it is noteworthy that the percentage remains the same, the most frequent on the requirements of quality control system.
Summary/Conclusions: 1. The implementation of a management system certified qualityby an external entity is a clear need in all transfusional centers involved, although the percentage of certified centers in Andalusia is less than 50%, representing a 34% of the certified centers nationwide. 2. Certification of CAT hospital is the only feasible option, but its adaptation to community hospitals is so complicated which is evident in the low number of certified centers. 3. Continuous quality improvement represents an additional workload sometimes unacceptable, it would be required a limited version adapted to district centers.

Table 1. Transfusion centers and hospital of public national health service in Andalusia, classified in provinces. Between parentheses certified centers.

	Huelva	Sevilla	Córdoba	Cádiz	Málaga	Jaén	Granada	Almería	TOTAL
Transfusion Centers	1(1)	1(1)	1(1)	1(1)	1(1)	1(1)	1(1)	1(1)	8(8)

PB2218

ERYTHROCYTE'S GENOMIC IN RUSSIAN MULTITRANSFUSED HEMATOLOGICAL PATIENTS

L L Golovkina[1,*], A Stremoukhova[1], M Vasiljeva[1], R Kalandarov[1], T Pushkina[1], G Atroshchenko[1], B Khasigova[1], E Parovichnikova[2]
[1]Immunohematology, [2]Bone Marrow Transplantation, National Research Centre for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, Russian Federation

Background: The patients suffering with ineffective hematopoiesis and peripheral cytopenias need frequent RBC transfusions. There are minimum two populations of red blood cells (RBC) in transfused within the four previous month patients-own and donor's. This situation is called posttransfusion chimerism and serological blood typing becomes unreliable. It's known about the immunogenicity of such blood group antigens as A, B, D, c, C, E. e in antigen-negative patients. DNA analysis is available for clinical use in various situations, especially in identification of blood group antigens in multitransfused hematological patients.
Aims: true blood group identification in multitransfused hematological patients
Methods: The blood samples drawn into citrate, EDTA anticoagulant were serotyped for RhD, Rh C/c and RhE/e antigens by anti-D, anti-C, anti-C^w, anti-c, anti-E and anti-e monoclonal antibodies (Moabs) (Hematolog, Russia). Hemagglutination typing in gel columns ID-Cards "DiaClon ABO/D+Reverse Grouping" and "DiaClon Rh-subgroups+K" (Bio-Rad, Switzerland) were used for confirmation of mixed chimerism in transfused patients: agglutinated cells forming a red line on the surface of the gel and no agglutinated cells formed compact button on the bottom of the microtube. DNA extraction was followed by commercial PCR-SSP kits with primers for typing ABO, *RHD, and RHCE (BAG,* Germany).
Results: We serotyped blood samples from 2055 Russians hematological patients (HP) in 2015. The problems in blood group (BG) identification for ABO system were caused by posttransfused chimerism (PTCh) in 32 primary patients (1,6%) and for Rhesus system-in 64 primary patients (3,1%). 24 patients provided informed consent for genotyping. All patients suffered with idiopathic or symptomatic cytopenia or separate anemia (aplastic anemia -5, different forms of acute leukemia -3, myelodisplastic syndrome -4, multiple myeloma-2, β-thalassemia -1, PNH-1, unidentified anemia-6, partial red cell aplasia-1, with renal transplant -1) and were transfused before hospitalization to National Research Centre for Hematology. Two patients had a problem with identification in ABO BG: 50% chimerism was detected with anti-A and anti-B Moabs in one and 50% no agglutinated RBC with anti-A-in another one. Genotyping revealed B1B1 and A1B1 BG in these patients. We couldn't identified Rhesus phenotype in 23 HP: RhC-in 17 (percent of agglutinated RBC ranged from 40 to 90), Rhc-in 13 (agglutinated RBC 50%>90%), RhD-in 4 (agglutinated RBC 20%>90%), RhE-in 18 (agglutinated RBC 30%>90%), Rhe-in 7 (agglutinated RBC 50%>95%), RhC^w-in 3 (agglutinated RBC 5%>50%). So PTCh for 1 Rh antigen was detected in 5 HP, for 2 Rh antigens-in 7, for 3-in 6, for 4-in 5 and for 5 Rh antigens-in one. The presence of RhC^w was confirmed in two HP with 50% RhC^w chimerism by genotyping. Molecular method predicted the presence of RhC in 5 HP with chimerism from 20% to 95%, Rhc-in 9 HP (chimerism ranged from 40% to 90%), RhD-in 3 (chimerism ranged from 20% to 90%), RhE-in 9 (chimerism ranged from 30% to 90%) and Rhe-in 3 HP with chimerism 95%. Monitorig of BG in all HP after four month.
Summary/Conclusions: The determination of ABO and Rhesus phenotypes is very important for previously transfused patients and for patients with known irregular antibodies. The erythrocyte's genomics has enabled the application

of molecular methods to transfusion medicine and allows preventing the alloimmunization to the most clinically significant blood group antigens.

PB2219

RHD VARIANTS INCLUDING REGULATORY TYPE RHNULL IN RUSSIANS

L L Golovkina[1,*], A Stremoukhova[1], R Kalandarov[1], T Pushkina[1], M Vasiljeva[1], G Atroshchenko[1], V Surin[2], A Doescher[3], T Schaffert[4], S Penickova[5], E Parovichnikova[6], V Savchenko[7]
[1]Immunohematology, [2]Gene ingeneering, National Research Centre for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, Russian Federation, [3]For research and development, Red Cross Blood Transfusion service, Oldenburg, [4]Molecular genetic, BAG Health Care GmbH, Lich, Germany, [5]Marketing, BAG Health Care GmbH, Prague, Czech Republic, [6]Bone marrow transplantation, [7]General director, National Research Centre for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, Russian Federation

Background: In clinical transfusions the D antigen of the Rhesus blood group system (BGS) is the third most relevant behind the A and B antigens of the ABO BGS Approximately 1%>2% of Caucasians show weak expression of D antigen on the RBC surface, which is caused by various types of mutations in the *RHD* gene. There are three D antigen variants in RH system: weak D, partial D and Del. It's essential to know D variant distribution in each population in order to define whether a patient has a high or low probability to produce anti-D alloimmune antibodies during erythrocyte's transfusion therapy.
Aims: to determine the distribution of D antigen variants in Russians.
Methods: Blood samples from 5100 Russians. 65 people have been investigated in our lab due to diminished D expression, discordant results with different anti-D reagents, or D negative samples with atypical Rh phenotype. D antigen was typed with 5 serological methods saline and indirect antiglobulin tests. The blood samples were serotyped for Rh C/c and Rh E/e antigens by corresponding Moabs. DNA extraction was followed by commercial SSP-PCR kits with primers for typing *RHD, RHCE,* 11 weak D types, partial D (BAG, Germany). Mutations in *RHD* (for confirmations of weak D type 3 - two cases and weak D type 15 - one case) and *RHAG* genes was detected by direct Taq cycle-sequencing, computer based sequence analysis and comparison with reference sequences from Genbank™.
Results: In 2014-2015 years we revealed low expression of RhD antigen in 109 (2%) persons by screening. Genotyping 65 of them revealed six weak D types in 62 persons: weak D type 3 (47,7%; n=31; phenotypes-C+c+E-e+ in 28 cases, C+c-E-e+ in two and atypical one C-c+E-e+) and weak D type 1 (27,7%; n=18; phenotypes-C+c+E-e+) were the most frequent. Weak D type 2 was detected in 12,3% (n=8; phenotypes-C-c+E+e+), weak D type 15-in 4,6% (n=3; phenotypes-C+c-E-e+, C+c+E-e+ and atypical one C-c+E+e+), weak D types 4.2 (DAR; phenotype C-c+E-e+) and weak D type 6 (phenotype C+c+E-e+)-each in one person (1,5% accordingly). All except 2 weak D types were identified by serological methods, and the most sensitive method was antiglobulin test in gel columns. Two cases with RhCe and RhcE phenotype were D-negative in all serological methods, and only molecular method allowed identifying weak D type 15. More one sample with diminished D expression was partial D variant DNB with phenotype C+c-E-e+. Two erythrocyte's samples had true D-negative phenotype: one - *RHD*ψ with phenotype C-c+E-e+, and first in Russia (since 1926) we found regulatory type Rh_{null} with predicted phenotype D+C+c+E-e+ in woman with meningioma. *RHAG* sequencing shows polymorphism in exon 4 of the *RHAG* gene at position 571 (C >T) which leads to an earlier Stop-codon (amino acid position 191 [R191]) and the additional mutation at position 724 of exon 5 (G >A).
Summary/Conclusions: The distribution of D variants in Russians was identified. These data may help to improve the transfusion strategy of the D variant.

PB2220

EVALUATION OF PROTEINURIA IN B-THALASSEMIA MAJOR PATIENTS WITH AND WITHOUT DIABETES MELLITUS TAKING DEFERASIROX

M Karimi[1,*], A Avazpour[2], S Haghpanah[1], F Toosi[2], A Badie[3]
[1]Hematology Research Center, Shiraz University Of Medical Sciences, Shiraz, Iran, [2]Pediatrics, Hematology Research Center, Shiraz University Of Medical Sciences, [3]Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran

Background: Beta-Thalassemia is the most common heredity disease in Iran. Regular blood transfusion is critical to sustain life and normal growth. Deferasirox is an oral chelator. One of the side effects of the Deferasirox is proteinuria.
Aims: This study aimed to investigate the safety of deferasirox on kidney function in diabetic and non-diabetic Beta-Thalassemia Major patients.
Methods: In this cross-sectional study, 70 patients who take deferasirox (Exjade-Novartis) 20-40mg/kg/day were studied. Exclusion criteria included patient with renal failure, proteinuria, hepatitis B, hepatitis C and the patients who refused to continue the study to the end. Subjects were divided into diabetics and non-diabetics groups. Spot urine protein/creatinine ratio, Urinary analysis, Alanine transaminase, Aspartate Transaminase, Creatinine, Fasting Blood Sugar, Blood Urea Nitrogen and serum ferritin were checked every 3 months. Patients were followed for a period of one year.
Results: In the 9th month after therapy there was a significant relationship in mean change of Spot urine protein/creatinine ratio between diabetic and non-diabetic (p=0.011). Spot urine protein/creatinine ratio in diabetic and non-diabetic group was 0.19±0.18 and 0.1±0.05, respectively which showed no significant relationship between the two groups at the end of study (P=0.162). E, Fasting Blood Sugar, Blood Urea Nitrogen and serum ferritin were checked every 3 months. Patients were followed for a period of one year.
Summary/Conclusions: The results of our study showed that consumption of deferasirox is safe since there was no significant relationship between Spot urine protein/creatinine ratio in diabetic and non-diabetic group. Deferasirox consumption is not associated with increased proteinuria in diabetic patients compared to non-diabetic group having only a transient proteinuria.

PB2221

COMPARISON AMONG PERIODS FOR HEMOGLOBIN EQUILIBRATION AFTER BLOOD TRANSFUSION

A Tantiworawit[1,*], K Karndumri[1], C Chai-Adisaksopha[1], A Limsukon[2], D Pruksakorn[3], S Karndumri[3], T Rattanathammethee[1], S Hantrakool[1], E Rattarittamrong[1], L Norasetthada[1]
[1]Internal medicine, Division of Hematology, [2]Intermal Medicine, [3]Orthopedic, Chiang Mai University, Maung Chiang Mai, Thailand

Background: Target hemoglobin (Hb) varies among different clinical situations but mainly at 7 g/dL. Many institutes include ours follow Hb and hematocrit (Hct) after transfusion at 4 hours for achieving target level. But previous study showed that equilibration after red cell transfusion was at 24 hours. We sought to find out the appropriate time point after red cell transfusion. The result may help physicians to provide earlier and proper treatment.
Aims: This research was aimed to determine the equilibration time point of Hb and Hct after red cell transfusion.
Methods: This is a prospective randomized trial conducted from December 2014 to August 2015 at Chiang Mai University Hospital. Inclusion criteria was adult patient who received 1 unit of red cell without active bleeding and hemolysis. Number of patient was calculated by match pair method from previous study. Hb and Hct were measured at baseline before transfusion. Patients were randomized into 3 groups according to baseline characteristics to follow Hb and Hct at 1, 4 or 24 hours after transfusion. Mean difference of Hb and Hct were compared between each group.
Results: Sixty patients were eligible in this study. Median age was 51 years old. There was male predominance (83.33%). Most common indication for transfusion was post-operative anemia (88.33%). There were 20 patients per each group. All baseline characteristics were not significantly different in each group which included age, sex, body weight, body surface area, transfusion indication, creatinine clearance, transfusion volume, congestive heart failure history, diuretics use, fever, intravenous fluid, blood group, baseline Hb and Hct. The median volume of red cell transfusion was 260.00, 262.50 and 257.50 ml for each group (P=0.638), Baseline median Hb before transfusion was 8.60, 8.50 and 8.60 g/dL for each group (P=0.553). Baseline median Hct before transfusion was 26.65, 26.30 and 27.05% for each group (P=0.570). Mean difference of Hb level among different time point at 1, 4 and 24 hours was 1.21, 1.19 and 0.95 g/dL for each group (P=0.109), Mean difference of Hct level among different time point at 1, 4 and 24 hours was 3.62, 3.63 and 3.09% for each group (P=0.398). The equilibration of Hb and Hct after red cell transfusion was not statistically different between these three groups.
Summary/Conclusions: The equilibration of Hb and Hct after transfusion was not different at 1, 4 and 24 hours. Target Hb and Hct can be determined at 1 hour after transfusion which can provide early further treatment.

PB2222

WHY ARE WE LOSING OUR PRECIOUS BLOOD DONORS?. A SYSTEMATIC REVIEW FROM PAKISTAN

A Memon[*], B Moiz
Department of Pathology & Laboratory Medicine, Aga Khan University Hospital, karachi, Pakistan

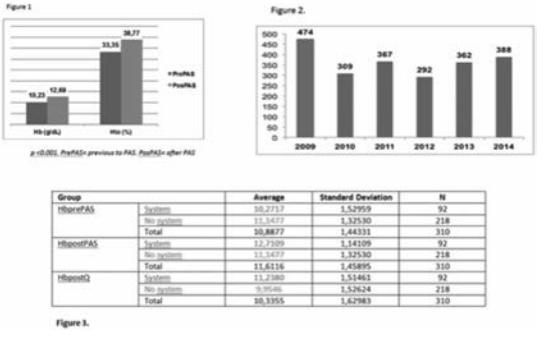
Background: Worldwide, a great majority of blood donors are deferred and many of these deferrals are for temporary reasons. This may cause loss of precious blood donors. This is also a common practice in Pakistan. Given the limited number of blood donors in our setting it is undesirable to defer a significant number of blood donors. This systematic review was conducted to document the various reasons for temporary deferral in Pakistan.
Aims: To carry out a systematic review of the surveys addressing the reasons of temporary blood donor deferral in Pakistan.
Methods: PAKMEDINET, GOOGLE SCHOLAR, PUBMED, CINAHIL and EMBASE search engines were used for literature search by using following terms '' pre donation deferrals Pakistan'', ''temporary reasons for blood donation deferrals'', ''questionnaire related deferrals in Pakistan'' and'' temporary blood donor deferrals Pakistan'' from January 2010 to December 2015. Studies which addressed transfusion transmitted infections and permanent causes of donor deferrals were excluded. Case reports were also excluded. Finally 4 relevant

studies were selected and reviewed and results were analyzed by using SPSS version 21. Forest plot was made to analyze these studies and p value <0.05 was taken significance.
Results: The search generated 8459 records for the year 2010 to 2015. 4 relevant studies were selected and reviewed. These studies were carried out in various blood banks located in different provinces of Pakistan. Based on the collective findings of these studies; anemia 31%, low blood pressure 21%, medications 8%, donation in last 3 months 8% and low weight for age 5% were identified to be the commonly observed factors for temporary blood donor deferral.
Summary/Conclusions: Anemia was found to be the most frequent cause of temporary blood donation deferral in our population. It is important to provide donors with a clear message regarding their deferral status. They should be encouraged to come again after their deferral period. Public awareness and education regarding blood donation may decrease deferral rates and can prevent an unfavorable impact on the donor as well as on blood donations.

PB2223

RESULTS OF AN ANEMIA PREOPERATIVE'S CIRCUIT CORRECTION AS TECHNIQUE TO SAVE BLOOD IN MAJOR GYNECOLOGICAL SURGERY SINCE 2010 TO 2015 IN A THIRD NEVEL HOSPITAL
MA García Ruiz[1,*], AB Ortega López[2], P Romero García[1], E Morente Constantin[1], A Martínez Tellerias[2], M Jurado Chacón[1]
[1]Servicio de Hematología y Hemoterapia, [2]Servicio de Anestesia y Reanimación, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Anemia is not only the biggest risk factor for transfusion, but also an independent predictor of perioperative mortality and morbidity, including more infectious complications and increased hospital stay. Its prevalence in surgical patients varies in the range from 10 to 70%, depending on their definition and the type of intervention. Iron-deficiency anemia is the most common cause in the patient's proposal for mayor gynecological surgery (MGS).
Aims: This surgery presents a transfusion rate of 14% and secondary to perioperative anemia without bleeding complications of 13%. Since late 2010, with the creation of a multidisciplinary group of saving blood (PAS). We implemented a circuit for the correction of preoperative anemia in patients scheduled for this surgery with the aim to reduce the rate transfusional. We propose a retrospective study to analyze the effectiveness of this strategy saving blood.
Methods: The proposed patients for MGS with Hb<12 g/dl, we programed, in susceptible cases, the administration of iv iron (sucrose and carboxymaltose) for 2-4 weeks before surgery. The day before the intervention, we monitored a preoperative blood count to assess treatment response and we measured the proportion of transfused patients. 103 patients were included in PAS until February 2015 (Figure 1). 5 patients were transfused: 2 due to hemorrhagic postoperative complications and 3 due to preoperative anemia.



Group		Average	Standard Deviation	N
HbprePAS	System	10,2717	1,52959	92
	No system	11,1477	1,32530	218
	Total	10,8877	1,44331	310
HbpostPAS	System	12,7109	1,14109	92
	No system	11,1477	1,32530	218
	Total	11,6116	1,45895	310
HbpostIQ	System	11,2380	1,53461	92
	No system	9,9546	1,52624	218
	Total	10,3355	1,62983	310

Figure 3.

Figures.

Results: Hemoglobin of the patients, which were included in our protocol, an average of 2.46 g/dl and 5.42% hematocrit increased, being the response to treatment statistically significant. We study the evolution of the number of red blood cells concentrates transfused in the gynecology before and after the implementation of our strategy. We observed a decrease of 34.8% in 2010, 22.6% in 2011, 38.4% in 2012, 23.6% in 2013 and 18% in 2014 compared to 2009. (Figure 2). Regarding the incidence of perioperative transfusion, the percentage of patients transfused included in the PAS is 4.9%, while in the historical cohort is 26.5% and this difference being also statistically significant (p <0.001). We compare our patients with a historical cohort obtained from the database at our center, selecting all patients undergoing major surgery gynecological (MSG) available from 2008 to the implementation circuit that meet the same criteria for our group. Preoperative hemoglobin (Hbpre) before (HbprePAS) was analyzed and after our intervention (HbpostPAS), postoperative hemoglobin (HbpostIQ) and the incidence of perioperative transfusion in both groups. Hb levels were compared with a general linear model and the percentage of transfusion with the chi-square test. P value <0.05 was considered significant. The historical cohort was constituted with 223 patients. Before treatment with iv iron patients exhibit inferior circuit Hbpre the cohort historical statistically significant (p <0.001). After PAS, the change in Hb is statistically significant (p <0.001), so that the Hbpre of treated patients is 12.7 g/dl *versus* 11.14 g/dl group untreated. The average value of the HbpostQ is also superior in our group significantly (p <0.001). Figure 3.
Summary/Conclusions: This circuit is effective to correct the preoperative anemia of the patients proposed for MSG. This protocol has improved Hb levels and preoperative hematocrit of these patients. The results were statistically significant. Treatment with intravenous iron for the correction of preoperative anemia in GMS as blood conservation strategy is effective to increase Hbpre statistically significant. Patients included in the circuit have a lower incidence of transfusion and have greater HbpostQI that patients not treated with iv iron. This protocol has improved Hb levels and preoperative hematocrit of these patients. The results were statistically significant. This measure seems effective in reducing the transfusion risk.

PB2224

EFFECT OF THIOCYANATE ON THE ACTIVITY OF BLOOD CLOTTING FACTOR VIII
N Shurko[1,*], D Taras[1], D Olha[2]
[1]Laboratory biochemistry of blood, [2]Hematology, State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

Background: The transmissions of viral agents have been associated with blood transfusion, particularly with the factor coagulation concentrates (for example, factor VIII, vWF, factor IX and prothrombin complex). The blood clotting concentrates should have not only a high specific activity, but to be viral safety. The safety of the final plasma protein concentrates has a paramount importance. The specific steps for the inactivation of the virus have been included in each process to enhance the safety of the products by reducing the virus load during manufacturing. Currently, there are several technologies to help ensure the safety of plasma products: solvent-detergent method, heat treatment, sodium caprylate and low pH, chromatography, nanofiltration and chemical reagents (for example, sodium hydroxide, guanidine chloride, sodium or ammonium thiocyanate) for purification of proteins and sanitizing chromatography systems.
Aims: studies of the effect of ammonium thiocyanate (NH_4SCN) on the activity of blood clotting factor VIII (FVIII).
Methods: The commercial concentrate of FVIII («Immunate») was initial raw material for the work (working activity 1.6 IU/ml). Determination of activity of FVIII conducted the one-stage clotting method which is based upon the activated partial thromboplastin time (APTT) and using of congenital severe hemophilia A plasma or artificially prepared of FVIII deficiency plasma as a substrate. To investigate the effect of NH_4SCN on the activity of FVIII, to enzyme working solution were added a buffered solutions of different concentrations of reagent. Removing of NH_4SCN was performed in stages by ultrafiltration (used the filters Amicon Ultra-0.5 10k; Centrifuge Eppendorf 5702-R).
Results: Virus inactivation by NH_4SCN is shown earlier in studies of various scientists. NH_4SCN was used as an antiviral agent in the manufacture of factors coagulation from plasma of blood. We conducted the study of this effect on the activity of clotting FVIII, to determine the possibility of its use in the manufacture of investigational factor. Experimental studies were performed in stages: in the reaction mixture was added buffered solutions of various concentrations of NH_4SCN and was measured activity of FVIII. As a result of the research we showed that thiocyanate reversibly inhibits the activity of the investigated FVIII (Table.1). When it had removed from the reaction mixture, factor activity recovered.

Table 1. Comparative characteristics of FVIII activity depending on the concentration of thiocyanate.

№	Concentration, NH_4SCN, M	Time, s	Activity of factor VIII, IU/ml
1	0.1230	> 180	not determined
2	0.0610	>180	not determined
3	0.0240	90	0.16
4	0.0122	69	0.74
5	0.0024	63	1.24
6 (control)	0	60	1.6

Summary/Conclusions: Thiocyanate may be used for antiviral treatment and as the eluting agent of coagulation FVIII in chromatographic process purification.

PB2225

TRANSFUSION PROTOCOLS OF BLOOD CENTRE OF ASL CASERTA (MANAGEMENT AND MONITORING)
MR Dell'aversana[*], E Munno, G De Caprio, A Orefice, G Salerno, G Donciglio, S Misso
Servizio Trasfusionale, ASL Caserta, Aversa, Italy

Background: The red blood cell is an immunologically competent cell for the presence of various exposed antigens, inherited genetically. Transfusion is a medical procedure extremely important, and certainly not without risks. Our Trasfusion Centre implemented transfusion protocols to ensure that all patients

have best treatment possible; these protocols provide for the identification of two groups of patients:chronic and acute. The first transfusing compatibility with the Rh, kell Duffy, Kidd, MNS systems with apheresis or filtered red blood cell, the seconds one with Rh and Kell systems compatibility, by decomposition of red blood cells. This is possible thanks to the availability of blood guaranteed by the excellent cooperation with voluntary associations, particularly for the production of red blood cells by apheresis.
Aims: The aim of our study was to evaluate the effectiveness of our transfusion protocols and their impact on health patients (immunological complications)
Methods: A retrospective study was done on all patients transfused in 2015 year, the patients were divided in chronic and acute and we studied the percentage of immunization and the most frequent antibody (computer system Eliot Enginnering Health)
Results: In the year 2015 were carried out 14,277 transfusions to 7000 patients (2500 chronic and 4500 acute). There were no immunizations in chronic patients while in the acute patient the percentage was 0.6%. The identified antibodies were: anti-D: 36.4%, anti-K: 27%, anti-E: 15%, anti-C: 1%, anti-c :6%, anti-e: 3%, anti FyA :2%, anti-Fyb: 1%, anti M: 3.4%, anti LeA :2.2%.
Summary/Conclusions: The results show that the cases of immunizations are all at the expense of acute patients, this confirming as the transfusion protocols guarantee the best possible therapy trying to preserve all chronic patients from ineffective transfusions. The frequencies of the detected antibodies reflect the immunogenicity scale. The choice to transfuse the chronich patients respecting such scale have preserved to immunizations. These protocols may seem expensive for the company budget assigned to the blood transfusion service, the savings are long-term evident in reality as it reduces the number of immunized patients and then the cost of their management.

PB2226

INDICATIONS FOR TRANSFUSING NAT UNTESTED BLOOD PRODUCTS ARE THESE RATIONAL?

S A Ali*, F Karim
Pathology and laboratory Medicine, Aga Khan University Hospital, Karachi, Pakistan

Background: Blood transfusion is a life-saving therapeutic option in many conditions. However, blood transfusion is never safe and is associated with risks of transfusion transmitted infections (TTI). To minimize the risk of TTI, all blood donations are screened for infectious diseases as per W.H.O standard. In emergency situation where blood products are required urgently and screened products are unavailable, it may be necessary to transfuse unscreened or partially screened blood products. Some of the indications where use of such products can be justified include: Critical Laboratory Results (defined as Hb <7gm/dl and platelets <20x10^9/L), active bleeding, emergency surgical/ radiological intervention and sepsis. Irrational transfusion of unscreened blood puts a patient at risk of acquiring an infectious disease which can cause severe long term complications. So it is very important they must only be transfused in dire need when screened products are not available and transfusion is the only life-saving option. In our hospital all products are serologically tested and then all seronegative samples undergo molecular testing known as Nucleic acid testing (NAT). The rate and indications of dispensing NAT untested blood products in our hospital is unknown
Aims: The aim of this study is to recognize the indications for transfusing NAT untested blood products and assess whether these are rational or not.
Methods: This was a clinical audit conducted by Blood Bank, Section of Haematology, Department of Pathology and Laboratory Medicine, The Aga Khan University Hospital. The Study duration was from May-July 2015. All the request forms received to Blood bank requesting release of NAT untested blood products were reviewed. Additional information regarding the need and indication was extracted from the online integrated laboratory data and medical record chart of patients. Data was recorded on a predesigned proforma. Statistical package for social sciences version 19 was used for data analysis.
Results: During the study period, 254 requisition slips were received to blood bank for 234 patients. Six hundred and seventy two NAT untested blood products were released during study period. The products released included: 154 packed red cell, 493 random donor platelets and 25 whole blood units. Most of the cases where blood bank was not able to provide screened blood were from Section of Clinical Haematology (n=61, 24**%**) followed by General Surgery (n=46, 18%) and Internal Medicine (n=40, 16%). The location of patients was Emergency room (n=58, 23%), Operating room (n=46, 18%), Wards (n=45, 18%) and special care units (n=28, 11%). In 224 out of 254 (88.2%) requests, the indications for transfusion were rational. The most common indication for the release of NAT untested products was Critical Laboratory results (n=106, 42%) followed by Surgical/Radiological Intervention (n=65, 26%) active bleeding (n=53, 21%) and sepsis (n=12, 5%). Seven percent (18/254) of the requests were not fulfilling any of the indication and transfusion in these cases was not justified. Majority of these requests (n=14, 77.8%) were from oncology day care transfusion area.
Summary/Conclusions: Majority of the indications for transfusion of NAT untested products were rational (93%). Few cases of irrational transfusion of NAT untested products were identified. The audit identified the areas in the hospital which need re-inforcement on the rational use of NAT untested blood products.

PB2227

A NEW PROTOCOL FOR OBTAINING PLATELET RICH IN GROWTH FACTORS (PRP). A DESCRIPTIVE STUDY IN 15 PATIENTS AND COMPARISON WITH RESULTS PUBLISHED IN LITERATURE

J Alcaraz Rubio*, JM Sánchez López
Ciencias de La Salud-Grado en Medicina-Facultad de Ciencias de la Salud, Ucam Universidad San Antonio de Murcia, Cobatillas-Murcia, Spain

Background: The diversity of procedures for obtaining platelet and plasmatic growth factors, the absence of control in most of them and the growing field of clinical application, makes them necessary methods adequately structured, documented, controlled and tested, playable by any author. The present series of clinical cases aims to introduce and test a specific technique for obtaining PRP, with precise characteristics both production and final composition of compound got, in 15 hematological healthy patients, comparing our results with those obtained by other procedures scientifically tested.
Aims: introduce and test a specific technique for obtaining PRP, with precise characteristics both production and final composition of compound got, in 15 hematological healthy patients, comparing our results with those obtained by other procedures scientifically tested.
Methods: 15 caucasian patients were selected, 8 male and 7 female with age range between 35 and 65, healthy haematologically. The procedure for obtaining the PRP, consisted of a single centrifugation of the blood sample for 30 minutes at 3500 rpm in a angular shaft of 16 tubes centrifuge serie (CEMCON 2) and micropipetting the protein fraction rich in platelet and plasmatic growth factors and cell through open technique under aseptic conditions in horizontal laminar flow hood Grade A at a temperature of 22 ° C, with the use of leucoplatelet or Buffy-coat layer (PRP rich in leukocytes).
Results: No correlation between the amount of concentrated platelets and the amount of growth factors finally obtained was observed. The protocol set forth concentrated levels of platelets and leukocytes approximately 3 to 5 times higher than baseline levels with a predominance of mononuclear. Levels of growth factors from 7-10 times greater than the patient's baseline levels, with little variation in them. The growth factor levels were stable in the blood of each patient within 24 h of treatment between 7 and 9 times higher compared to the previous baseline. Compared with other procedures discussed in the literature; This method achieves concentration between 1.5 and 3 times more platelets in the final product, with a purification of growth factors overall type VEGF and TGF-B clearly superior.
Summary/Conclusions: the technique disclosed is more effective since concentrate achieves greater amount of platelets and growth factors and efficient since it maintains a serum protein in these stable sera of patients after 24 hours of administration thereof.

PB2228

PEDIATRIC PATIENT WITH BOTH LEUKOCYTE ADHESION DEFICIENCY II AND BOMBAY BLOOD GROUP

Y Yaman[1,*], S Aydın[2], C Acıpayam[3], E Sarıbeyoglu[1], F Genel[4]
[1]Pediatric hematology, Medipol Mega University Hospital, istanbul, [2]Pediatric hematology, İzmir Behçet Uz Childrens Hospital, İzmir, [3]Pediatric hematology, Kahramanmaraş Medical Faculty, Kahramanmaraş, [4]Pediatric Immunology, İzmir Behçet Uz Childrens Hospital, İzmir, Turkey

Background: Leukocyte adhesion deficiency type II (LAD II) is a rare autosomal recessive inherited immunodeficiency disease that induces frequent, recurrent infections, persistent leukocytosis, severe mental and growth retardation and impaired wound healing. Therewithal, Bombay blood group is rare phenotype that is characterized by deficiency of H, A and B antigens on red cell surface.
Aims: LAD II and Bombay blood group have rarely been present together because both of them associated with a global defect in common pathway of fucose metabolism.
Methods: 11-year-old boy was evaluated due to diarrhea. He was born to healthy first degree consanguineous parents at term with a birth weight of 1.250 gr (<3th). He had a history of hospitalization for intrauterine growth retardation during first three weeks of life. As an infant, he suffered from delayed separation of the umbilical cord. He developed multiple recurrence infections such as pneumonia, diarrhea, fever and recurence skin abscess. On the examination, his height and weight were both below the third percentile for age. He had 2 cm of hepatomegaly and 4 cm of splenomegaly. Physical examination revealed the dysmorphic features such as coarse facial appearance, flattened nose, long prominent philtrum. He had numerous scars of abscess in the bilateral inguinale region. On neurological examination, he had severe growth and psychomotor retardation (Figure 1). İnitial laboratory evaluation revealed elevated white blood cell count (72.1x10^3/µL) with neutrophilia (80% neutrophils, 20% lymphocytes). His hemoglobin level was 11.6 g/dL and his platelet was

456,000/mm3. The other blood parameters of the patient were normale. His disease was identified Leukocyte Adhesion Deficiency (LAD) which was characterized by recurrent infections, persistent leukocytosis, delayed separation of the umbilical cord and severe mental and growth retardation.
Results: The presence of Lea, Leb, and H antigens on the erythrocytes of patient was investigated by hemagglutination tests performed with commercial monoclonal antiserums (ALBAclone, Alba Bioscience, United Kingdom) derived from mouse. At same hospital, his blood grouping was again interpreted as O Rh D positive by the ABO and Rh typing on gel card. Forward reverse grouping on tube showed the blood group to be O Rh D positive. Indirect Coomb's Test and antibody screening was 4+ reactivity, direct Coomb's Test (DCT) of patient was negative. It was found to be incompatible with strength of 4+ agglutination in all cross match by reverse analysis conducted with erythrocytes of A1, A2, B and O blood group. Reaction with anti H lectin was negative. The blood group was finally interpreted as *Bombay blood group with naturally occuring anti-H antibodies* in plasma. The moleculer basis of LAD II was demonstrated according flow cytometric results; the deficient expression of the CD15 adhesion molecules on the surface of leukocytes while expression LFA-1 (CD11a/CD18), Mac-1 (CD11b/CD18), p150/95 (CD11c/CD18) are normal.
Summary/Conclusions: When a patient with Bombay Phenomenon is detected, the investigation for leukocyte adhesion deficiency type 2 must been done.

PB2229

TRANSFUSION IN THE PRESENCE OF MULTIPLE ALLOANTIBODIES PLUS COLD-REACTIVE AGGLUTININS/DAT+
JR Garcia Fernandez*, F Lopez Berenguel, S López Hinojosa
Hematologia, Hospital de Baza. Servicio Andaluz de Salud, BAZA, Spain

Background: Transfusion in the presence of allloantibodies is a common procedure in blood-banks. The challenge appears when alloantibodies are multiple and associated with "benign" antibodies or another inespecific laboratory finding that cover up the clinically significant antibodies. The grade of difficulty grow up if the presentation of alloantibodies is detected at the same time rather than in succession.
Aims: We exposed two cases of multiple clinically significant alloantibodies, classified as group I (antibodies that react at 37ºC and that cause a significant majority of transfusion reactions, related to systems: AB0, Rh, Kell, Duffy, Kidd and Ss).
Methods: We describe the last two complex positive inmunohematological studies perfomed in our community hospital
Results: Case1: Pluripathological woman 86 years old, without pregnancies and without previous studies in our hospital. She has received just one transfusion of 2 red cells concentrates, two years before in another hospital. IAT Positive in emergency room with subsequent study in table 1. Probability to find compatible 0 positive blood: 2%. Case 2: Man 68 years old with sever hepatic disease, multiple blood transfusion in the past 7 years due to gastrointestinal bleeding. He needs urgent transfusion for the same reason. Previously he has developed several alloantibodies successively as reported in table 1. Probability to find compatible 0 positive blood: 6%. The challenge of transfusion in these cases are associated with four facts: 1. Number and specificity of alloantibodies; 2. Timing of apparition of alloantibodies; 3. Absolute necessity of blood transfusion in life-threatening situations; 4. Presence of others events that difficult the identification of alloantibodies: cold-reactive antibodies, positive direct antiglobulin test.

Table 1. Antibodies detected in blood transfusion recipients.

	Blood Group	Fenotyphe	Antibodies	Other facts
Patient1 Woman 86 y	O POS DcEe	K(-) k(+) Fya(-)Fyb(+) JKa(-)JKb(+) M(-)N(+) S(-)s(+)	Anti-C Anti-K Anti-Fya Anti-JKa	DAT + Autocontrol +
Patient 2 Man 68 y	0 POS DCe	K(-) k(+) Fya(+)Fyb(+) JKa(+)JKb(-) M(+)N(+) S(-)s(+)	Anti-E Anti-c Anti-JKb Anti-S	Cold-reactive antibodies + (Anti-I)

Summary/Conclusions: The presentation of multiple anti-erythrocytes alloantibodies associated with non-specific/bening serological findings in life-threatening situations required and appropriated and immediate evaluation of the patient to decide if transfusion can be delayed or not, simultaneously efforts can be made in order to identify the facts clinically significatives to avoid serological related conditions that mask the real problem focussed in antibodies group I related. We think that transfusion of incompatible blood, in a hemodynamic unstable patient due to others diseases, should be avoided. If anaemia is the exclusively cause of instability we should consider the risk of transfusing incompatible blood.

PB2230

ANALYSIS OF PLATELETPHERESIS DONOR DEFERRAL RATE, CHARACTERISTICS AND ITS PREVENTABILITY
MH Dogu[1,*], I Sarı[2], S Hacıoglu[2], A Keskin[2]
[1]Hematology, Istanbul Training and Research Hospital, Istanbul, [2]Hematology, Pamukkale University Faculty of Medicine, Denizli, Turkey

Background: Plateletpheresis is a procedure included in donor apheresis in which the donor blood is passed through an extraction machine, the platelets are extracted, and the remainder is returned into the circulation. Donor selection is important because donors are the only source for meeting blood product needs.
Aims: In our study we aimed to evaluate deferral reasons in applications for plateletpheresis donation and reveal determine the preventable ones among them.
Methods: The persons who were admitted to our Blood Center to be plateletpheresis donors during the period between August 2013-February 2014, after a demand/request for platelet suspension was issued by the clinics. Their eligibility for being plateletapeheresis donors was decided
Results: A total of 1098 persons have applied to be plateletpheresis donors; 1045 were male and 53 female. A total of 787 persons were found to be eligible for being plateletpheresis donors; 772 were male and 15 female. 891 units of apheresis platelets were obtained from apheresis donors, including double units collected from 104 of them. Applications of 311 persons were deferred due to various reasons. The most common reason for donor deferral was inappropriate vascular access in 80 persons (25.7%, 69 males, 11 females). This is followed by abnormal laboratory values in 57 persons (18.3%) and drug use (most commonly analgesics) in 46 persons (14.7%).
Summary/Conclusions: During the assessment of blood product donors, proper selection of the candidates should be considered very carefully in order to not to harm the donor but to supply the demand of the recipient properly. When the deferral reasons were evaluated, improvement of in-hospital technical reasons and education sessions for people in order to increase the social awareness may substantially decrease the deferral rates.

PB2231

RED CELL PHENOTYPING AMONG MULTITRANSFUSED EGYPTIAN THALASSEMIC PATIENTS
M Sarhan[1,*], M Fouda[2], D Ghannam[2], S Abdelaziz[2], A Elemery[2]
[1]Pediatrics, [2]Clinical Pathology, Faculty of Medicine - Mansoura University, Mansoura, Egypt

Background: Thalassemia is an inherited hemolytic disorder caused by partial or complete deficiency of α or β-globin chain synthesis. Regular transfusions are essential for patients with thalassemia to maintain growth and development during childhood and to sustain good quality of life during adulthood. The development of hemolytic alloantibodies and red blood cell (RBC) autoantibodies complicates transfusion therapy in patients with thalassemia.
Aims: of this research is to determine the prevalence of red blood cells antigens among multitransfused thalassemic patients attending Mansoura University Children Hospital, Mansoura, Egypt and a sample of blood donors, as an approach for prevention of alloimmunization.
Methods: The present study comprised 70 mulitransfused thalassemic patients. They were 38 males and 32 females and in addition 65 adult male donors. All were subjected to Laboratory tests for blood group antigens (ABO), and (Rh system, Kell system), using ID-cards, Also a CBC was done.
Results: 1) Blood group O is the most prevalent blood group in our patients but B group is the most prevalent in our donors. 2) Kell negative group is prevalent in the patients compared to the donors. 3) There is significant difference between the patients and the donors in Rosenfield: (1,2,3,4,5) and (1-2-3,4,5), More prevalent in the donors, But Rh (1,2-3-4,5) is prevalent in the patients *versus* the donors. 4) There is significant increase in (c), (E) and marginal increase of (k) antigens in donors *versus* the patients. 5) Patients below five years old showed significant increase of negative kell group and Rosenfield Rh (1,2-3-4,5). 6) No relation between sex and blood group phenotypes of the patients. 7) Significant increase of kell negative group and Rosenfield Rh (1, 2-3-4,5) in patients who were younger in age of first transfusion and who received frequent transfusions. 8) High incidence of pallor in patients with blood group O. Also patients with Rosenfield Rh (1,2-3-4,5). 9) Splenectomizd patients had significantly higher incidence of negative kell group and Rosenfield Rh (1,2-3-4,5).
Summary/Conclusions: From the present study, in order to minimize the hazards of blood transfusion, especially the immunological reactions the following could be done: 1) Pre transfusion matching of blood for ABO and Rh D antigens is important as a routine work, which helps in determining the true blood groups and it assists in the identification of suspected alloantibodies and selection of antigen-negative RBCs for transfusion. 2) Extended phenotype matching of blood for Rh (other than D) and Kell have been proposed as effective method which could reduce morbidity in thalassemic patients.

PB2232

SHOULD BLOOD DONORS WITH HARRIS PLATELET SYNDROME BE EXCLUDED FROM PLATELET DONATION?
A Das[1,*], HK Elias[2], S Harris[3], HV Naina[4]
[1]Cardiology, Beth Israel Deaconess Medical Center, Boston, [2]Internal Medicine, Icahn School of Medicine at Mount Sinai St Luke's- Roosevelt Hospital,

NewYork, [3]Division of Gastroenterology, UT southwestern, [4]Department of Internal Medicine, Plaza Medical center, Dallas, United States

Background: Harris platelet syndrome (HPS) is an autosomal dominant macrothrombocytopenia with mild to moderately severe thrombocytopenia and normal platelet function. HPS has been reported from Indian subcontinent blood donors, especially from the northeastern part of India. Approximately a third of blood donors from state of West Bengal have been found to have HPS.The Indian NACO 2007 guideline recommends one bag of PRC from 350 ml of whole blood should have a platelet count above 3.5 $X10^{9/l}$.

Aims: We designed a study to assess whether PRC (platelet rich concentrate) obtained from those with HPS contained adequate platelets as recommended by the Indian guidelines.

Methods: HPS is defined as healthy blood donors having a mean platelet volume (MPV) greater than 12 fL (normal <10 fL) with or without concomitant thrombocytopenia in the absence of any significant past history of bleeding disorder in either themselves or their first degree relatives. In our study, we collected 350 ml of blood from each donor and via Platelet Rich Plasma Separation Method (PRPSM) we separated out PRC and PRBC in separate bags.A CBC was performed at the time of donation and from PRC bag blood collected in EDTA tubes, and analyzed using SYSMEX XP-100.

Results: A total of 28 donors were included. The median age of the donors was 33 years(21-62) and 21 (75%) were male.Pre donation CBC showed a median platelet count of 1.93±0.54 $X10^{9}$/ L (0.99-2.98 $X10^{9}$) and platelet count from PRC showed a median platelet count 1.16±1.77x10^{9}/ L(0.03-8.25$X10^{9}$) which is much below the national guidelines. It is possible that platelet yield is lower in these donors as during separation, the platelet concentration gradient was influenced by the larger platelet size [1].

Table 1.

Platelet Indices:	Pre Donation Platelet Indices (n=28)	Platelet indices from PRP (n=28)
MPV(Mean)	13.66±1.99 fl	10.00±2.02 fl
Platelet Count (Median)	1.93±0.54 x10^{9}/L (0.99-2.98x10^{9}/L)	1.16±1.77 $X10^{9}$/L (0.03-8.25x10^{9}/L)
PDW(Mean)	19.80±2.95	13.87±4.64
Platelet Biomass(Mean)	26.91±1.16	15.4±9.41

Summary/Conclusions: This study shows that PRC from HPS donors are not able to keep the international standard and should not be used in the future. Our study is the first one to date to assess the candidacy of those with inherited giant platelet disorders being blood donors.

ARIAD®

ICLUSIG®
(ponatinib) tablets

Unlock efficacy for resistant or intolerant CML and Ph+ ALL patients:

Iclusig®▼ opens up new perspectives for your CML patients.

– Once daily
– Can be taken with or without food[1]

Fast response

Median time to MCyR in CP-CML responders: 2.8 months[1,2]
Median time to MMR in CP-CML responder: 5.5 months[1,2]

Deep response

38 % of CP-CML patients reached MMR or even better[1]

Durable response

87 % of CP-CML responders maintained MCyR at 28 months[1]

* **Iclusig** is a tyrosine kinase inhibitor (TKI) indicated in adult patients with[1]

- chronic phase, accelerated phase, or blast phase chronic myeloid leukaemia (CML)
  - who are resistant to dasatinib or nilotinib;
  - who are intolerant to dasatinib or nilotinib and for whom subsequent treatment with imatinib is not clinically appropriate;
  - or who have the T315I mutation
- Philadelphia chromosome positive acute lymphoblastic leukaemia (Ph+ ALL)
  - who are resistant to dasatinib;
  - who are intolerant to dasatinib and for whom subsequent treatment with imatinib is not clinically appropriate;
  - or who have the T315I mutation

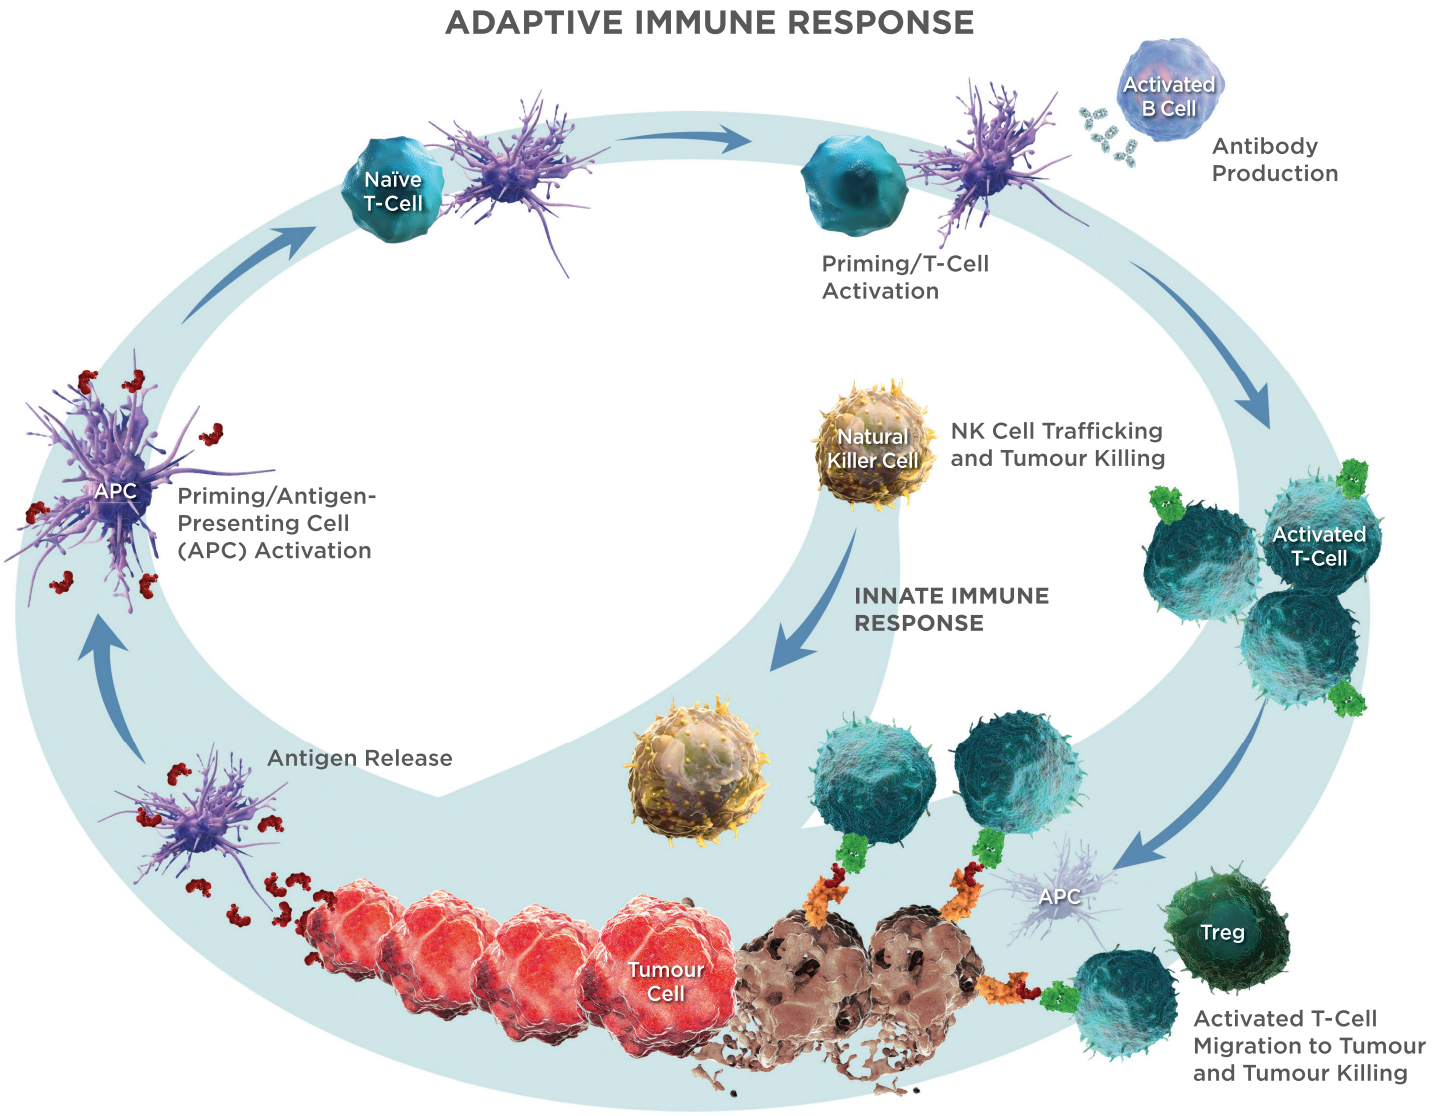
PRESCRIBING INFORMATION – Iclusig® ▼ (ponatinib) ▼ This medicinal product is subject to additional monitoring. Antineoplastic agent, protein kinase inhibitor, ATC code: L01XE24.
Presentation: Film-coated tablets containing 15 mg or 45 mg of ponatinib (as hydrochloride). **Indications:** Iclusig is indicated in adult patients with chronic phase (CP), accelerated phase (AP), or blast phase (BP) chronic myeloid leukaemia (CML) who are resistant to dasatinib or nilotinib; who are intolerant to dasatinib or nilotinib and for whom subsequent treatment with imatinib is not clinically appropriate; or who have the T315I mutation, and in adult patients with Philadelphia chromosome positive acute lymphoblastic leukaemia (Ph+ ALL) who are resistant to dasatinib; who are intolerant to dasatinib and for whom subsequent treatment with imatinib is not clinically appropriate; or who have the T315I mutation. **Dosage and administration:** Therapy should be initiated by a physician experienced in the diagnosis and treatment of patients with leukaemia. Haematologic support such as platelet transfusion and haematopoietic growth factors can be used during treatment if clinically indicated. Before starting treatment with ponatinib, the cardiovascular status of the patient should be assessed, including history and physical examination and cardiovascular risk factors should be actively managed. Cardiovascular status should continue to be monitored and medical and supportive therapy for risk factors optimised during treatment with ponatinib. The recommended starting dose is 45 mg once daily. Response should be monitored according to standard clinical guidelines and treatment discontinuation considered if a complete haematological response has not occurred by 3 months. It should also be discontinued when there is evidence of disease progression or severe adverse reactions. Tablets should be swallowed whole and not crushed or dissolved, and may be taken with or without food. Dose adjustments – The risk of vascular occlusive events is likely to be dose related. In a patient suspected of developing an arterial or venous occlusive event, Iclusig should be immediately interrupted. After the event is resolved, the decision to re-start treatment should be directed by a benefit-risk assessment. Dose modifications, or interruptions, should be considered for haematological and non-haematological toxicities. Treatment should be withheld in the case of severe adverse reactions. Dose modifications are recommended for neutropenia or thrombocytopenia unrelated to leukaemia, pancreatitis and elevation of lipase/amylase and prescribers should consult the SmPC for full details. When adverse reactions have resolved, or become less severe, dose escalation back to the prior daily dose may be considered, if clinically appropriate. Dose reductions may be considered for patients who have achieved a Major Cytogenetic Response and the SmPC should be consulted for risk-benefit and monitoring details. **Contraindications:** Hypersensitivity to ponatinib or to any of the excipients. **Warnings and precautions:** *Myelosuppression* – Iclusig is associated with severe thrombocytopenia, neutropenia, and anaemia. The frequency of these events is greater in patients with AP-CML or BP-CML/Ph+ ALL than in CP-CML. A complete blood count should be performed every 2 weeks for the first 3 months and then monthly or as clinically indicated. *Vascular occlusion* – Arterial and venous thrombosis and occlusions, including fatal myocardial infarction (MI), stroke, retinal vascular occlusions associated in some cases with permanent visual impairment or vision loss, stenosis of large arterial vessels of the brain, severe peripheral vascular disease, kidney artery stenosis, the need for urgent revascularization procedures have occurred with Iclusig; these events were more frequent with increasing age, or in patients with prior history of ischaemia, hypertension, diabetes, or hyperlipidaemia. Iclusig should not be used in patients who have suffered an MI, prior revascularisation or stroke, unless there is a positive benefit-risk assessment; other treatment options should also be considered. Monitoring for thromboembolism and vascular occlusion should occur throughout treatment with Iclusig, which should be stopped immediately if an event occurs. If decreased vision or blurred vision occurs, an ophthalmic examination (including fundoscopy) should be performed. Hypertension (including hypertensive-crisis) has occurred with Iclusig and can contribute to the risk of arterial thrombotic events, so blood pressure should be monitored at each visit and any associated symptoms treated urgently. Iclusig should be interrupted in the event of uncontrolled or treatment resistant hypertension. *Congestive heart failure* – Fatal and serious events have occurred with Iclusig including events associated with prior vascular occlusion. Patients should be monitored and treated as clinically indicated, including interruption of Iclusig. If serious heart failure develops, Iclusig should be discontinued. *Pancreatitis and serum lipase* – Iclusig is associated with pancreatitis. The frequency of pancreatitis is greater in the first 2 months of use. Check serum lipase every 2 weeks for the first 2 months and then periodically thereafter. Dose interruption or reduction may be required. If lipase elevations are accompanied by abdominal symptoms, Iclusig should be withheld and patients evaluated for evidence of pancreatitis. Caution is recommended in patients with a history of pancreatitis or alcohol abuse. Patients with severe or very severe hypertriglyceridaemia should be appropriately managed to reduce the risk of pancreatitis. *Lactose* – Iclusig contains lactose monohydrate. Patients with rare hereditary problems of galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption should not take this medicinal product. *Effects on ability to drive and use machines* – Adverse reactions such as lethargy, dizziness and vision blurred have been associated with Iclusig. Therefore, caution should be recommended when driving or operating machines. *QT prolongation* – a thorough QT study has not been performed; therefore a clinically significant effect on QT cannot be excluded. *Hepatotoxicity* – Iclusig may result in elevation in ALT, AST, bilirubin, and alkaline phosphatase. Hepatic failure (including fatal outcome) has been observed. Liver function tests should be performed prior to treatment and periodically, as clinically indicated. *Haemorrhage* – Serious and fatal haemorrhagic events have occurred with Iclusig, most commonly cerebral and gastric bleeding. Most events were associated with grade 3 & 4 thrombocytopaenia. Iclusig should be interrupted for serious and severe events. *Hepatic impairment* – Caution is recommended when administering Iclusig to patients with severe hepatic impairment. *Renal impairment* – Caution is recommended when administering Iclusig to patients with estimated creatinine clearance of <50 mL/min or end-stage renal disease. *Elderly patients* – Are more likely to experience adverse reactions. *Paediatric population* – The safety and efficacy of Iclusig in patients less than 18 years of age have not been established. **Interactions: Co-administration of Iclusig with strong CYP3A4 inducers should be avoided;** caution should be exercised with concurrent use of Iclusig and strong CYP3A inhibitors and a starting dose of 30 mg considered; caution should also be exercised with concurrent administration of substrates of P-glycoprotein (P-gp) or breast cancer resistant protein (BCRP). Caution should be taken with concomitant use of anti-clotting agents in patients who may be at risk of bleeding. Pregnancy and breastfeeding: Women of childbearing age should be advised not to become pregnant, and men should be advised not to father a child during treatment. An effective method of contraception should be used during treatment - **it is unknown if Iclusig affects systemic hormonal contraceptives so an alternative or additional method should be used.** There are no adequate data from the use of Iclusig in pregnant women. Studies in animals have shown reproductive toxicity. If Iclusig is used during pregnancy, the patient must be informed of the potential risk to the foetus. Breastfeeding should be stopped during treatment. **Undesirable effects:** *Very common ADRs (≥1/10)* – Upper respiratory tract infection, insomnia, anaemia, decreased platelet count, decreased neutrophil count, decreased appetite, headache, dizziness, hypertension, dyspnoea, cough, abdominal pain, diarrhoea, vomiting, constipation, nausea, increased lipase, increased alanine aminotransferase, increased aspartate aminotransferase, rash, dry skin, bone pain, arthralgia, myalgia, pain in extremity, back pain, muscle spasms, fatigue, asthenia, peripheral oedema, pyrexia, pain. *Common ADRs (≥1/100 to <1/10)* – Pneumonia, sepsis, folliculitis, pancytopenia, febrile neutropenia, decreased white blood cell count, hypothyroidism, dehydration, fluid retention, hypocalcaemia, hyperglycaemia, hyperuricaemia, hypophosphataemia, hypertriglyceridaemia, hypokalaemia, decreased weight, cerebrovascular accident, cerebral infarction, peripheral neuropathy, lethargy, migraine, hyperaesthesia, hypoaesthesia, paraesthesia, transient ischaemic attack, blurred vision, dry eye, periorbital oedema, eyelid oedema, cardiac failure, myocardial infarction, congestive cardiac failure, coronary artery disease, angina pectoris, pericardial effusion, atrial fibrillation, decreased ejection fraction, peripheral arterial occlusive disease, peripheral ischaemia, peripheral artery stenosis, intermittent claudication, deep vein thrombosis, hot flush, flushing, pulmonary embolism, pleural effusion, epistaxis, dysphonia, pulmonary hypertension, pancreatitis, increased blood amylase, gastrooesophageal reflux disease, stomatitis, dyspepsia, abdominal distension, abdominal discomfort, dry mouth, increased blood bilirubin, increased blood alkaline phosphatase, increased gamma-glutamyltransferase, pruritic rash, exfoliative rash, erythema, alopecia, pruritis, skin exfoliation, night sweats, hyperhidrosis, petechia, ecchymosis, skin pain, exfoliative dermatitis, musculoskeletal pain, neck pain, musculoskeletal chest pain, erectile dysfunction, chills, influenza-like illness, non-cardiac chest pain, mass, face oedema. *Uncommon ADRs (≥1/1000 to <1/100)* – Tumour lysis syndrome, cerebral artery stenosis, retinal vein thrombosis, retinal vein occlusion, retinal artery occlusion, visual impairment, myocardial ischaemia, acute coronary syndrome, cardiac discomfort, ischemic cardiomyopathy, arteriospasm coronary, left ventricular dysfunction, atrial flutter, poor peripheral circulation, splenic infarction, venous embolism, venous thrombosis, hypertensive crisis, kidney artery stenosis, gastric haemorrhage, hepatotoxicity, hepatic failure, jaundice. **Denmark packages & prices:** 15 mg: 60 tabl. 45 mg: 30 tabl. See prices at www.medicinpriser.dk Danish prescription group: BEGR, hospitals only. **Marketing Authorisation Holder:** ARIAD Pharma Ltd., Riverbridge House, Guildford Road, Leatherhead, KT22 9AD, United Kingdom. **This text has been rewritten and/or abbreviated compared to the authorised summary of product characteristics (2016-03-22). The summary of product characteristics can be ordered free of charge from ARIAD. Product information may differ internationally. Date of preparation:** April 2016; UK/ICLG/15/0060.

The Science Behind **Immuno-Oncology**

The science behind Immuno-Oncology is based upon the understanding of the mechanisms tumours use to escape the immune system and how these can be modulated to promote tumour destruction.[1]

At Bristol-Myers Squibb, we are committed to furthering the science and understanding of Immuno-Oncology through our research and development, as well as by supporting educational activities.



For more information, please visit the I-O section of Booth 202
