Results: We found DNA strand incision of oxidatively damaged bases significantly impaired in primary AML cells as compared to UCB cells (p=0.003) suggesting a deficiency in BER glycosylases and AP endonuclease. In addition, 5/27 AML cell lines showed impaired DNA strand incision activity. We hypothesized that BER deficient cells harbor an increased number of oxidative base lesions as compared to BER proficient cells. Using a modified comet assay and LC-MS/MS we were able to show that increased numbers of unrepaired oxidative base lesions were indeed present in glycosylase deficient AML cells (comet assay: p=0.0001; LC-MS/MS: p=0.03). We then evaluated the activity of oxidative DNA glycosylases/AP endonuclease and found significantly decreased DNA strand incision activity in BER deficient cells as compared to proficient cells (p=0.002) further supporting the fact that these enzymes are impaired in BER deficient cells. Cytarabine is a cornerstone of AML therapy and has recently been shown to induce oxidative damage. Therefore, we tested for a potential effect of BER impairment on sensitivity to treatment with increasing concentrations of cyarabine and found that BER deficient cells are less sensitive to cytarabine treatment as compared to BER proficient cells (p=0.009). In further exploring the causes of BER deficiency, Sanger sequencing of key BER genes showed several single nucleotide polymorphisms but no consistent mutational pattern. However, gene expression profiling revealed decreased expression of nuclear OGG1 and MUTH1 proteins in BER impaired cells.
Summary/Conclusions: Taken together we found impaired BER in a substantial number of primary AML samples and AML cell lines potentially contributing to decreased sensitivity to cytarabine treatment.

DOUBLE INACTIVATION OF TET2 AND TET3 INDUCES HYPOMETHYLATING AGENT-SENSITIVE ACUTE MYELOID LEUKEMIA

K Maie[1,*], M Sakata-Yanagimoto[1,2], M Oshima[3], T Kato[1,2], H Muto[1,2], E Mouly[4], OA Bernard[4], H Koseki[5], A Iwama[3], S Chiba[1,2]
[1]Department of Hematology, Graduate School of Comprehensive Human Sciences, [2]Department of Hematology, Faculty of Medicine, University of Tsukuba, Tsukuba, [3]Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan, [4]INSERM U1170, Institut Gustave Roussy, Villejuif, France, [5]RIKEN Research Center for Allergy and Immunology, Yokohama, Japan

Background: TET enzymes are methylcytosine dioxygenases regulating gene expression by oxidizing methylcytosine. Loss-of-function *TET2* mutations are frequent in myeloid malignancies, but *TET3* gene mutations are rare. Thus, although *TET3* has similar function to *TET2* and its expression is regulated during differentiation in hematopoietic tissue, the role of *TET3* in the pathogenesis of these diseases has not previously been addressed.
Aims: The aim of our study was to investigate the role of extensive loss of hydroxymethylation activities by double inactivation of *TET2* and *TET3* in acute myeloid leukemia (AML).
Methods: Relationship of *TET2* and *TET3* expression in human AML patient samples was analyzed using the TCGA database. To investigate the cooperative and distinct roles of *Tet2* and *Tet3*, *Tet2*^{flox} and *Tet3*^{flox} mice were crossed. Then, neonates baring double floxed alleles and *Mx1-Cre* transgene were injected with pIpC. Genome-wide transcription and methylation profiles in granulocyte-macrophage progenitor cells (GMPs) from 4-6 weeks old *Tet2*/*Tet3*-null mice were examined by RNA-sequencing and reduced representation bisulfite sequencing (RRBS). We established primary cell lines from *Tet2*/*Tet3*-null bone marrow in RPMI 1640 with IL-3. Cells were treated with a hypomethylating agent, decitabine and cell viability was measured by WST-8 assay. The *Tet2*/*Tet3*-null cell line was then transduced with human *TET2* catalytic domain (*TET2*^{CD}) using the pGCDN-IRES-GFP retroviral vector. Recipient mice transplanted with bone marrow cells from *Tet2*/*Tet3*-null leukemic mice were treated with 5-azacytidine intraperitoneally.
Results: Human AML showed positive correlation in *TET2* and *TET3* expression. Concurrent *Tet2*/*Tet3* deletion induced fully penetrant, lethal AML with a median survival of 59 days, whereas single deletions of *Tet2* or *Tet3* were healthy within the observation period (Figure 1 A). Gene set enrichment analysis revealed that *Tet2*/*Tet3*-null GMPs were characterized by enrichment of several signatures, including interferon response, Stat3 signaling, TNF-α signaling via NF-κB, and p53 pathway. RRBS showed that *Tet2*/*Tet3*-null GMPs showed marked increase of hyper-differentially methylated regions (hyper-DMRs) compared with *Tet2*-null, *Tet3*-null, or wild-type GMPs. Hyper-DMRs were frequently observed in enhancer regions. Genes hypermethylated (≥20% difference compared with wild-type GMPs) at enhancers in *Tet2*/*Tet3*-null GMPs showed a significant trend toward downregulation in expression. Lethally irradiated syngeneic mice transplanted with bone marrow cells from *Tet2*/*Tet3*-null leukemic mice developed AML within 3 months. *Tet2*/*Tet3*-null leukemic cells were easily propagated in IL-3-containing medium *in vitro*. Decitabine inhibited proliferation of *Tet2/Tet3*-null leukemic cells and upregulated expression of surface Gr-1 and Mac-1, indicating myeloid differentiation of these cells. Recipient mice transplanted with the cell line developed AML. Retroviral overexpression of human *TET2* catalytic domain (*TET2*^{CD}) decreased proliferation of the cell line *in vitro*. Mice transplanted with the *TET2*^{CD} expressing cell line developed AML at longer latencies compared to those transplanted with the mock cell line (Figure 1 B). Progression of AML in recipient mice transplanted with *Tet2*/*Tet3*-null leukemic cells was significantly suppressed by the 5-azacytidine treatment (Figure 1 C).

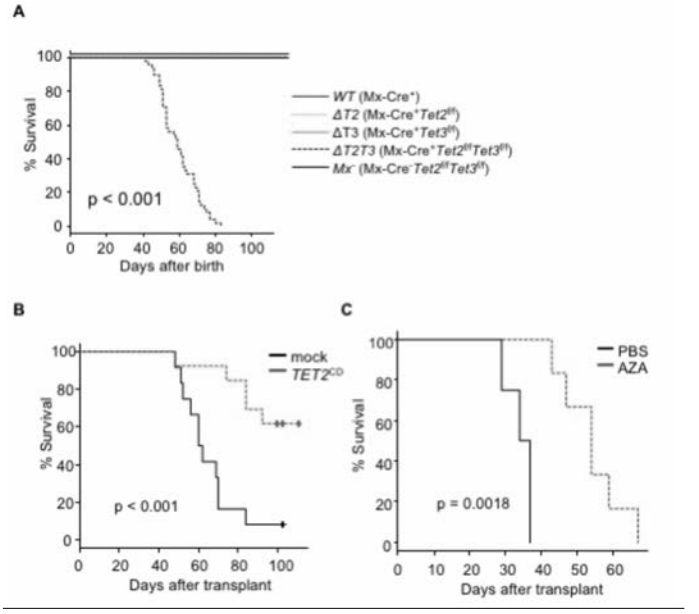

Figure 1.

Summary/Conclusions: Our results suggest that epigenetic dysregulation by concurrent loss of *Tet2* and *Tet3* plays important roles in the pathogenesis of AML. Hypomehtylating drugs may be useful in treating *TET*-deregulated AML

NGS IDENTIFIES MUTATIONS PROGNOSTIC OF RELAPSE AFTER ALLO-SCT AND NOVEL CLONE EMERGENCE AT DISEASE RECURRENCE: IMPLICATIONS FOR STRATEGIES TO PREVENT POST ALLO-SCT RELAPSE

L Quek[1,*], P Ferguson[2], M Metzner[1], I Ahmed[3], C Garnett[1], S Jeffries[4], K Piechocki[5], R Danby[6], M Raghavan[2], A Peniket[7], M Griffiths[5], A Bacon[2], J Ward[2], K Wheatley[3], P Vyas[1], C Craddock[2]
[1]Molecular Haematology, Weatherall Institute of Molecular Medicine, Oxford, [2]Centre for Clinical Haematology, Queen Elizabeth Hospital Birmingham NHS Foundation Trust, [3]Institute of Cancer and Genomic Sciences College of Medical and Dental Sciences, University of Birmingham, Birmingham, [4]West Midlands Regional Genetics Lab, Birmingham Women's Hospital, [5]West Midlands Regional Genetics Laboratory, Birmingham Women's NHS Foundation Trust, Edgbaston, Birmingham, [6]Department of Clinical Haematology, Oxford University Hospitals NHS Foundation Trust, [7]Department of Clinical Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Allogeneic stem cell transplant (allo-SCT) plays the central role in management of Acute Myeloid Leukaemia (AML). Relapse is the major cause of treatment failure after allo-SCT but little is known about either molecular predictors of relapse or the clonal structure of patients with recurrent disease post-transplant.
Aims: 1) Elucidate whether mutations detected at diagnosis are prognostic for disease relapse post-allo-SCT. 2) To characterise clonal structure at relapse following allo-SCT.
Methods: We performed targeted resequencing of 34 AML-associated genes in 113 adults who underwent allo-SCT for AML. In 30 patients we compared mutational profiles at diagnosis and at disease relapse post allo-SCT. Libraries constructed using Fluidigm Access Array were sequenced on a MiSeq platform. FASTQ files were mapped using a BWA aligner (Stampy) and variant calling performed using Varscan, GATK and Pindel. Recurrent somatic variants previously associated with AML were included in the analysis. Novel variants were validated by Sanger sequencing.
Results: Of the 113 patients studied, 91 (80.5%) had intermediate/ favourable and 22 (19.5%) adverse risk karyotype. We detected mutations in 102/113 patients with on average 2 mutations per patient at diagnosis. Our cohort was enriched for samples with mutations in *KIT*, *SRSF2* and *TET2* (p<0.05), but depleted for *NPM1* (p<0.05) compared with data from a previously published cohort of unselected *de novo* AML (CGARN, 2013). 49 patients relapsed post allo-SCT. In multivariate analysis mutations in *IDH1* and *WT1* were significantly associated with an increased relapsed risk (p=0.03 and p=0.013 respectively). *IDH1* and *TP53* mutations were associated with worse relapse-free survival (p=0.047 and p=0.049 respectively). Additionally, p53 mutations were associated with reduced overall survival (p=0.027). Molecular characterisation of paired diagnosis and relapse samples showed novel mutations in 20/30 patients. 11/20 (55%) had changes in mutation number, with or without cytogenetic change. 9/20 (45%) patients had new mutations at relapse not detected at diagnosis (VAF sensitivity of <0.5%). These included: *NRAS* (n=2), *TET2* (n=3) and *DNMT3A*, *IDH2*, *PHF6* and *WT1* in single patients. Multiple distinct mutational events occurred in 5/9 patients. In contrast, 5/30 (16%) had no detectable changes in either mutations or karyotype at relapse and 7/27 (26%) had cytogenetic changes only. Interestingly, in 4 patients changes in clonal structure were identified at relapse by mutational profiling only, with no cytogenetic changes detected. We could deduce clonal evolution from pre-existing clones by mutation profile in 6 patients; or from *de novo* clones with loss of pre-existing clones in 3 patients.
Summary/Conclusions: We identified novel mutations present at diagnosis in adult AML which appear to be associated with an increased risk of relapse after allogeneic SCT. The mixed clonal landscape at relapse suggests multiple genetic mechanisms are likely responsible for relapse. The emergence of novel mutations at relapse suggests that maintenance strategies using targeted therapies tailored to the mutational profile at diagnosis may be ineffective. Rather post-transplant interventions with a broader anti-leukaemic activity, such as donor lymphocyte infusions, or other immunotherapeutic approaches may be preferable. However, the emergence of novel mutations at relapse in NRAS, DNMT3A, TET2 and IDH2 suggests that novel therapies targeting RAS and DNA methylation pathways should be considered. These data, which require validation in a larger cohort, demonstrate that detailed molecular characterisation has the capacity to both predict relapse risk post allo-SCT and inform the design of maintenance strategies.

P563

HIGH PREDICTIVE VALUE OF COMBINED WT1 AND FLOW CYTOMETRY-BASED PRE TRANSPLANT MINIMAL RESIDUAL DISEASE ASSESSMENT IN ACUTE MYELOID LEUKEMIA

F Guolo[1,*], F Galaverna[2], P Minetto[1], M Clavio[1], D Guardo[1], A Kunkl[3], N Colombo[1], F Ballerini[1], C Di Grazia[4], A Ibatici[5], RM Lemoli[1], M Miglino[1], M Gobbi[1], A Bacigalupo[4]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genoa, [2]Chair of Hematology, University of Parma, Parma, [3]Service of Flow Cytometry, [4]Second Division of Hematology and Bone Marrow Transplantation, [5]First Division of Hematology, IRCCS AOU San Martino-IST, Genoa, Italy

Background: Allogeneic bone marrow transplantation (BMT) offers the greatest chance of cure for patients with high-risk acute myeloid leukemia (AML). Persistence of disease or high levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk after BMT. WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.
Aims: The aim of this study was to analyze the role of pre-BMT combined MRD assessment as predictor for post-transplant relapse risk and to evaluate its the predictive value when comparing different stem cell source and conditioning intensity.
Methods: We retrospectively analyzed the outcome of 224 consecutive AML patients receiving allo-BMT in first or second CR. Pre-BMT marrow samples were analysed for WT1 expression and MFC as MRD evaluation . Median age at transplant was 44 years. Disease phase was CR1 in 161 (72%) and CR2 in 63 patients (28%). One hundred sixty-three (73%) received myeloablative conditioning, whereas 61 patients (27%) received reduced intensity conditioning. Stem cell source was HLA-identical sibling in 79 (35%), haploidentical (HAPLO) in 59 (27%) and alternative donor in 86 (38%). Median follow-up was 59 months (95% CI 46.271.8 months). Relapse-free survival (RFS) was calculated from the time of BMT until last follow-up or documented leukemic relapse. Overall Survival (OS) was calculated from the time of BMT until death by any cause or last follow-up. A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5total events (threshold of $2.5x10^{-4}$residual leukemic cells) at four-color flow-cytometry. WT1 copy number/Abl copy number $500x10^4$ was used as cut-off value for abnormal WT1 expression.
Results: Relapse occurred in 63 patients (28%). Three-year estimate of RFS was 68.8% (median not reached). The cumulative incidence of relapse was significantly affected by occurrence of acute GVHD (lower for grade ≥2, p <0.05), donor source (lower for HAPLO, p<0.005), MRD status before BMT measured with any method (p <0.001 for WT1-based MRD, p<0.03 for MFC based MRD, p<0.0001 for combined MRD). Multivariate RFS analysis revealed that the combined MRD evaluation was the only independent predictor of RFS (p <0.001). Specifically, MFC-MRD was the strongest predictor of longer relapse free survival (p <0.001) since only two relapses occurred in the 24 MFC-MRD negative patients and 3-years RFS was 89.9%. Among MFC-MRD positive patients, WT1 MRD status stratified the risk of relapse as the 3-years RFS was 73.3% and 44.4%, respectively, for patients with normal or increase WT1, p <0.01 (Figure 1). The predictive value of MRD resulted independent from analyzed variables, however, patients with double positive MRD did slightly better when undergoing HAPLO BMT. Moreover, conditioning intensity did not affect RFS duration in MFC MRD negative patients. MRD evaluation was also a strong predictor of long term survival: 3- years OS was 73.5% for MFC negative and 36.7% for double WT1 and MFC MRD positive patients, respectively (p <0.001). Multivariate OS analysis showed that conditioning intensity and combined MRD evaluation significantly influenced OS duration (p <0.005 and <0.001, respectively).

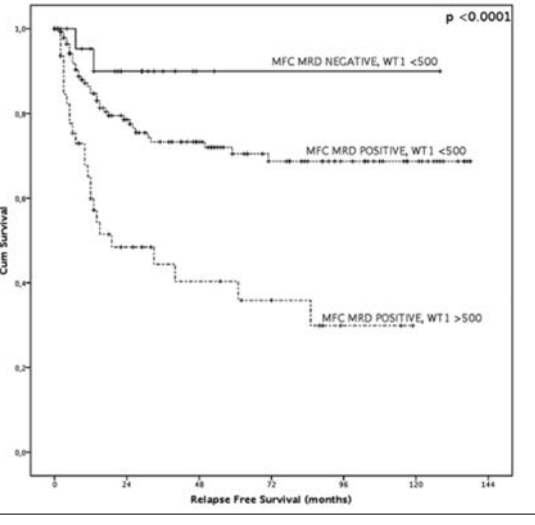

Figure 1.

Summary/Conclusions: Pre transplant MRD evaluation by WT1 and MFC on bone marrow samples is a reliable predictor of relapse risk. Patients with both negative pre-BMT MRD markers have a significantly longer RFS, while patients with both positive MRD markers display an higher risk of relapse. MRD prognostic information may improve the choice of the optimal conditioning intensity and stem cell source. Identifying patients who have an higher risk of relapse could open the way to apply pre-emptive therapeutic strategies to prevent AML relapse, from donor lymphocyte infusion to other innovative approaches.

P564

PROGNOSIS AND TARGETED TREATMENT OF AML WITH DIFFERENT IDH MUTATIONS COULD BE INFLUENCED BY ADDITIONAL MUTATIONS

T Alpermann[1,*], C Haferlach[1], W Kern[1], K Perglerová[2], M Meggendorfer[1], T Haferlach[1]
[1]Munich Leukemia Laboratory, Munich, Germany, [2]MLL2, Praha, Czech Republic

Background: Precision medicine aims at specifically targeting different gene mutations, *e.g. FLT3*-ITD (by midostaurin), *DNMT3A* or *TET2* (by hypomethylating agents), *IDH1*R132 (by IDH304 or AG-120), *IDH2* (by AG-221), or *IDH1/2* (by AG-881). However, accompanying gene mutations bearing prognostic information or also being drugable targets and the cytogenetic background may need further attention before treatment decisions.
Aims: To investigate the mutation pattern and cytogenetic background of *de novo* AML with *IDH1*R132, *IDH2*R140, and *IDH2*R172 mutations.
Methods: 1360 patients (pts) with *de novo* AML were evaluated at initial diagnosis by morphology, cytogenetics and analysed for the three mutation hotspots *IDH1*R132, *IDH2*R140 and *IDH2*R172. Furthermore, *ASXL1*, *CEBPA*, *DNMT3A*, *FLT3*-ITD, *FLT3*-TKD, *MLL*-PTD, *NPM1*, *RUNX1*, *TET2*, *TP53,* and *WT1* were investigated. All pts were treated with intensive standard chemotherapy.
Results: In total, 111/1360 (8%) pts showed an *IDH1*R132 mutation (mut), 168 (12%) an *IDH2*R140mut and 35 (3%) an *IDH2*R172mut. Four of these pts were mutated in both *IDH1*R132 and *IDH2*R140. 50% of *IDH*mut occurred in FAB AML M1, 31% were found in AML M2, and 12% in AML M4. In all other FAB classes less than 5% of the *IDH*mut occurred or no *IDH*mut at all (AML M3). Distribution of the three *IDH*mut types within the FAB classes was equal. 78% (238/306) of *IDH*mut carried a normal karyotype. Most frequently *IDH*mut pts were also mutated in *NPM1* (51%), followed by *DNMT3A* (45%), *FLT3*-ITD (23%), *ASXL1* (17%), *RUNX1* (16%), and *MLL*-PTD (13%). *CEBPA*, *FLT3*-TKD, *WT1*, and *TP53* were rarely mutated in *IDH*mut pts. Of note, 50% of the *IDH*mut pts showed an additional targetable mutation. However, accompanying aberrations differed between the *IDH*mut pts: *IDH1*R132mut pts in 103/107 (96%) showed additional mutations, but in 87/107 (81%) a normal karyotype. 63% of these pts were *NPM1*mut, 60% showed a *DNMT3A*mut, 23% a *FLT3*-ITD, 10% an *ASXL1*mut, 10% an *MLL*-PTD, 9% a *RUNX1*mut, and only 3% a *TET2*mut. *IDH2*R140mut pts showed in 91% (150/164) of cases additional mutations, and a normal karyotype in 132/164 (80%) of cases. In comparison to *IDH1*R132mut pts they less frequently showed mutations in *NPM1* (52%) and less often in *DNMT3A* (36%). However, *IDH2*R140mut pts carried more often *ASXL1*mut (24%) and *RUNX1*mut (17%) compared to *IDH1*R132mut pts. 26% showed *FLT3*-ITD, 12% an *MLL*-PTD, and 2% a *TET2*mut. Interestingly, *IDH2*R172mut pts showed in only 27/35 (77%; p=0.005 compared to combined other *IDH*mut) cases mutations and in only 19/35 (54%; p<0.001) a normal karyotype. Additionally, only 3% of pts showed mutations in *NPM1* (p<0.001), only 11% in *FLT3*-ITD, but 36% a mutation in *DNMT3A*, 27% in *RUNX1,* 27% an *MLL*-PTD, 12% in *TET2*, and 10% in *ASXL1*. Therefore, the patterns of accompanying mutations differ significantly between the three *IDH* mutation groups, both regarding potential additional treatment targets and adverse risk markers. Regarding survival *IDH2*R172mut pts showed a more favorable outcome (57% 5-yr-survival) compared to *IDH1*R132 (37%, p=0.049) and *IDH2*R140 (37%, p=0.029) mutated pts. A favorable trend was also seen compared to *IDH* wild type (40%, p=0.067) (Figure 1).

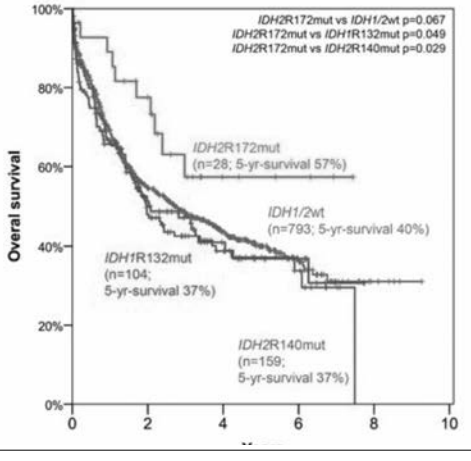

Figure 1. Overall survival according to *IDH* mutations (mut) and *IDH1/2* wildtype (wt) within the intermediate risk group according to the refined MRC criteria.

Summary/Conclusions: 1) Patients with *IDH1* and *IDH2* mutations show different aberration patterns; 2) *IDH1*R132, *IDH2*R140, and *IDH2*R172 show different outcomes; 3) treatment decision is challenging as diverse mutations with distinct targeted treatment options are simultaneously present; 4) *IDH2*R172 mutated patients might benefit from *IDH* targeting treatment, but other drugable targets might be addressed in parallel.

P565

DNMT3A AND IDH1 MUTATIONS WORSEN THE PROGNOSIS OF ELN GOOD RISK (CEBPA OR NPM1 MUTATED/FLT3 UNMUTATED) AML PATIENTS

J Marková *, O Fuchs, P Michková, A Kostečka, C Šálek, J Březinová, P Soukup, J Soukupová Maaloufová, A Vítek, P Cetkovsky, J Schwarz
Institute Hematology and Blood Transfusion, Prague 2, Czech Republic

Background: Patients with normal karyotype and *NPM1* mutations lacking *FLT3*/ITD (*FLT3*) as well as those having *CEBPA* mutations are regarded to have favorable prognosis according to ELN criteria. However, this classification does not take into account other aberrations frequently associated with *NPM1* and *CEBPA*, such as *DNMT3A* or *IDH1/2* mutations.
Aims: To test possible impact of *DNMT3A*, *IDH1* and *IDH2* mutations on outcome within the ELN good-risk *CEBPA* or *NPM1* mutated patients.
Methods: Presence of *FLT3*, *DNMT3A*, *IDH1* and *IDH2* mutations was detected by Sanger sequencing in 115 *NPM1* or *CEBPA* mutated patients with AML with an intermediate-risk cytogenetics (according to Grimwade *et al.*, 2010) diagnosed between 2001-2014. Median age at diagnosis was 57.5 years (range 23.7-81.9), the initial median WBC count was $33.1x10^9$/L (range 0.4-303.7). The male/female ratio was 59/56 and the median of follow-up was 11.6 months. All patients were treated by remission-inducing regimens and standard post-remission therapy± allogeneic stem cell transplant.
Results: For analyses, patients were divided into 6 groups: Group A: *NPM1*+ only (n=22); Group B: *NPM1+/FLT3*- with *DNMT3A* and/or *IDH1* mutation (n=25); Group C: *NPM1+/FLT3*+ regardless of *DNMT3A/IDH1* mutations (n=45) Group D: *CEBPA*+ only (n=22); Group E: *CEBPA+/FLT3*- with *DNMT3A* and/or *IDH1* mutation (n=5); Group F: *CEBPA+/FLT3*+ regardless of *DNMT3A/IDH1* mutations (n=6). *FLT3*, *DNMT3A* and/or *IDH1* mutations did not significantly influence the probability of achieving CR in *NPM1*+ patients. CR was reached by 18/20 (90.0%) patients within group A, 18/21 (85.7%) in group B and 28/39 (71.8%) in group C. Relapse was detected in only 5/18 (27.8%) group A patients, in 12/19 (63.2%) in group B and in 19/28 (67.9%) in group C. *NPM1* mutated patients with neither *FLT3* nor *DNMT3A/IDH1* mutations (group A) had significantly longer EFS (P=0.009) as well as OS (P=0.017; Figure1A) than group B (*DNMT3A* and/or *IDH1*) mutated ones. *FLT3*, *DNMT3A* and *IDH1* were strongly associated with monoallelic *CEBPA* mutation. 10/19 patients had at least one of these aberrations, compared with only 1/13 cases within a biallelic *CEBPA* mutated ones (P=0.004). Within the *CEBPA*+ cohort, *FLT3* and/or *DNMT3A* and/or *IDH1* mutations significantly decreased the chance of reaching CR on the one hand and increased the risk of relapse on the other. Only 7/11 (63.6%) patients within groups E and F (when analysed together) achieved CR compared with 19/20 (95.0%; P=0.012) cases in group D. 4/7 (57.1%) patients relapsed within groups E+F and only 3/19 (15.8%, P=0.018) patients belonging into group D. Presence of *FLT3* and/or *DNMT3A* and/or *IDH1* aberrations shortened significantly EFS (P=0.009) and OS of *CEBPA* mutated patients (P<0.0001). There was no difference between patients within E and F groups regarding EFS and OS (Figure 1B). *IDH2* mutations did not influence the prognosis of *NPM1*+ or *CEBPA*+ patients whatsoever (not shown).

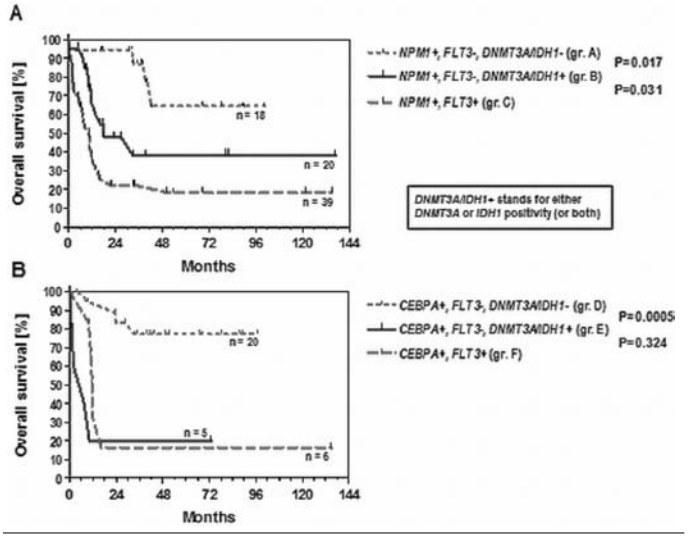

Figure 1. OS in genetic subgroups of *NPM1*+ (A) and *CEBPA*+ (B) patients.

Summary/Conclusions: Patients with *NPM1* or *CEBPA* mutations have favorable outcome only if they lack *FLT3* or *DNMT3A/IDH1* mutations. Not only *FLT3* but also *DNMT3A* and/or *IDH1* aberrations significantly shortened both OS and EFS of these patients. *FLT3*/ITD, *DNMT3A* and *IDH1* positivity coincide with monoallelic *CEBPA* mutation which might be the reason of inferior outcome

of patients with monoallelic *CEBPA* mutation as compared to those with biallelic *CEBPA* (usually lacking the additional mutations). We infer that only patients with *NPM1* or *CEBPA* mutation lacking the additional aberrations should not be transplanted in first CR.

P566

MUTATIONAL SPECTRUM ANALYSIS BY NEXT GENERATION SEQUENCING IN ADULT ACUTE MYELOID LEUKEMIA

H Wei[1], Y Wang[1], D Lin[1], B Liu[1], C Zhou[1], K Liu[1], B Gong[1], S Wei[1], G Zhang[1], X Gong[1], Y Liu[1], Y Li[1], R Gu[1], S Qiu[1], Y Mi[2], J Wang[2,*]
[1]Institute of Hematology and Blood Diseases Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, [2]Institute of Hematology and Blood Diseases Hospital,State Key laboratory of Experimental Hematology,Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Based on biological function and prognostic roles of these mutations, acute myeloid leukemia (AML) can be segregated into distinct subgroups. However, the spectrum of recurring alterations in larger cohorts needs further exploration and validation. Furthermore, it is not clear what genetic alterations co-operate with those initiating mutations to induce leukemia.
Aims: To investigate genetic alterations in a large cohort of adult AML and to explore potential mutations as therapeutic targets, we performed targeted high throughout NGS of 112 candidates in AML samples from 270 newly diagnosis patients.
Methods: After informed consent was obtained, 270 patients were investigated by a custom targeted NGS gene panel, which covered 112 genes associated with blood diseases. All exons of these genes were sequenced on an Ion Torrent semiconductor plat form and reads were mapped to NCBI hg19 RefSeq. Validation runs showed accurate results, with a mean of >97% coverage of the targeted regions at the average depth of 800X. Five genes mutations including FLT3-ITD, CEBPA, NPM1, CALR, and MPL were also detected by Sanger sequencing, since they are not accurately detected by NGS. Polymorphisms annotated in dbSNP 135 were excluded. All putative mutations were compared against multiple databases (*e.g.*1000genomes,COSMIC, PolyPhen, SIFT). To obtain more detailed genetic information, we also analyzed fusion genes including AML1-ETO, CBF-MYH11, and MLL translocations by RT-PCR, fluorescence *in situ* hybridization(FISH) and karyotype analysis.TP53 gene loss were determined by FISH, in addition to mutations detected by NGS.
Results: On average approximately three (2.84) genes per patient were mutated, and 76 (66.1%) of the 112 genes were revealed to be mutated in at least one patient. The most common gene abnormalities were FLT3 (21.85%), CEBPA (21.48%), NPM1 (20.37%), AML1-ETO (20.00%), N-RAS(19.36%).Mutation frequencies of CEBPA and N-RAS were higher than those reported in the literatures. Whereas, mutation frequencies of *DNMT3a* (10.37%) and *IDH2* (1.48%) were lower. According to the critical initiating step in the pathogenesis of AML, we grouped the adult AML into 9 groups (Figure 1). Then, we analyzed the co-operating mutation in these groups. AML1-ETO and CBFb-MYH11 make up CBF (core binding factor) leukemia. But they had different co-operating mutation constitutions. C-Kit mutations were the most common co-operating mutation for AML1-ETO. Whereas, N-ras mutations were most frequent one for CBFb-MYH11. N-ras mutations were common in all of groups, except NPM1 leukemia. N-ras mutations constituted 15% co-operating mutation in AML1-ETO, 44% in CBFb-MYH11, 30% in MLL translocation, 19% in CEBPA double mutation, 18% in secondary type, and 23% in others. Interestingly, we found 14.81% patients in our cohort had FAT1 mutations, which was not reported before. And FAT1 mutations could be found with high frequency in all of groups. FAT1 mutations could be found in 15% AML1-ETO, 19% CBFb-MYH11, 10% MLL translocation, 11% CEBPA double mutation, 11% NPM1 mutation, 9% in secondary type, and 19% in others.

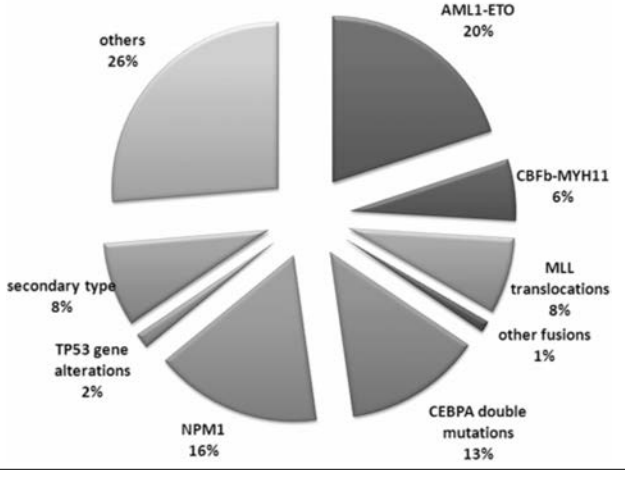

Figure 1. Adult AML were grouped into 9 groups based on the critical initiating step in the pathogenesis of AML.

Summary/Conclusions: Adult AML reveals a highly heterogeneous spectrum of candidate gene mutations. Here we provide an original and comprehensive overview of recurring mutations in AML. N-ras mutations are common in all AML entities, except NPM1 leukemia. These mutations have to be validated in a larger cohort with a focus on clinical implications accompanied by their use as therapeutic targets.

P567

NANOG EXPRESSION AS A RESPONSIVE BIOMARKER DURING REATMENT WITH HEDGEHOG SIGNAL INHIBITOR IN ACUTE MYELOID LEUKEMIA

S Kakiuchi[1,*], Y Minami[2], N Fukushima[3], Y Miyata[1], Y Mizutani[1], H Goto[1], K Kurata[4], S Kawamoto[1], K Yakushijin[1], H Matsuoka[1], T Naoe[5], H Minami[1]
[1]Department of Medical Oncology and Hematology, [2]Department of Transfusion Medicine and Cell Therapy, Kobe University Hospital, Kobe, [3]Department of Hematology and Oncology, Nagoya University Graduate School of Medicine, Nagoya, [4]Department of Hematology and Oncology, Kobe University Hospital, Kobe, [5]National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Cumulative evidence suggests that dormant self-renewing leukemic stem cells (LSCs) contribute to acute myeloid leukemia (AML) propagation and relapse by evading conventional chemotherapies that target cycling cells. Therefore, there is a great need to find innovative therapies for AML that eliminate LSCs by targeting their specific properties. Aberrant activation of the Hedgehog (Hh) signaling pathway is involved in maintenance of the LSC populations in several experimental systems. PF-0444913 (PF-913) is a novel oral small molecule inhibitor that selectively binds and targets Smoothened (SMO), a membrane protein regulating the Hh pathway. Treatment with PF-913 has shown promising results regarding safety, tolerability, and early signs of efficacy in the early phase study of hematologic malignancies, including AML (Jamieson, *et al. ASH*, 2011). However, the detailed mode of action and biomarkers remain to be elucidated in AML therapy with the Hh pathway inhibitors.
Aims: We examined gene profiling analyses and biomarkers using the pre-clinical model and clinical samples derived from AML patients during PF-913 therapy to clarify the mode of action and biomarkers in AML therapy with the Hh pathway inhibitors.
Methods: We used AML cell lines and patient-derived primary AML cells and bone marrow cells in PF-913 treatment. Using RQ-PCR assays, we examined the change of gene expressions in the canonical Hh pathway molecules. We carried out comprehensive gene set enrichment analysis (GSEA), and pathway analysis during PF-913 treatment both in the pre-clinical experimental systems and the clinical setting (bone marrow blast-rich mononuclear cells derived from AML patients during the PF-913 mono-therapy). We also examined cell cycle analyses using flow-cytometory, immunoblot and immuno-staining assays.
Results: In the immunodeficient NOD/SCID/IL2rg^{null}(NOG) mouse model and the *ex vivo* culturing system of AML cell lines, GSEA revealed that PF-913 treatment induced effects on the self-renewal signatures and the cell-cycling regulations associated with LSC-like properties. Moreover, GSEA revealed that PF-913 treatment in the clinical setting modulated the LSC-like signature, the cell-cycling regulation signature, and the chemokine activity signature in the AML bone marrow cells. Ki-67 immuno-staining of bone marrow derived from AML patients showed that PF-913 treatment temporarily increased cell-cycling status during shorter periods of treatment. We also examined the pluripotency factor, Nanog expression in bone marrow cells derived from AML patients during the PF-913 therapy, based on the previous report that downstream effectors in the Hh pathway, GLI1 and GLI2, directly bind to the Nanog promoter and that the GLI-Nanog axis promotes stemness and growth in several cancers. Change of Nanog transcripts was closely associated with the GLI-target genes in bone marrow blast-rich mononuclear cells derived from AML patients during the PF-913 therapy. Furthermore, by backing to the pre-clinical experimental systems, Nanog transcript level stringently and significantly decreased during PF-913 treatment. In the same pre-clinical model, immunoblot resulted PF-913 treatment decreased the expression of *Nanog* protein level, too.
Summary/Conclusions: Gene profiling analyses revealed that treatment with Hh signaling inhibitor, PF-913 modulates self-renewal and cell-cycling signatures in AML, and Nanog transcript can be a responsive biomarker during the therapy. Our findings imply that PF-913 treatment can improve AML therapy through sensitizing dormant LSCs to chemotherapy and overcoming residual LSC-like diseases in the bone marrow microenvironment.

A NOVEL NEXT-GENERATION SEQUENCING BASED ASSAY FOR FLT3/ITD MUTATIONS IS SENSITIVE AND SPECIFIC AND CAN BE USED TO DETECT MINIMAL RESIDUAL DISEASE IN AML PATIENTS

M Levis[1,*], J Miller[2], Z Xie[3], V McClain[3], A Carson[3], T Stenzel[2]
[1]Oncology, JOHNS HOPKINS UNIVERSITY, Baltimore, [2]LabPMM, [3]Invivoscribe, San Diego, United States

Background: FLT3/ITD mutations are common in AML and confer a poor prognosis. A sensitive, specific assay for the detection of minimal residual disease

(MRD) in FLT3/ITD AML could guide decisions on transplant or maintenance therapy. To date, polymerase chain reaction (PCR) based assays for MRD in FLT3/ITD AML have been hampered by competition from the wild type allele, limiting the overall sensitivity to approximately 1 cell in 100. While several groups have reported the development of MRD assays for this disease, none of these diagnostics have been developed in concert with bioinformatics software under a quality system with the intent of being submitted to regulatory authorities as a harmonized assay available to the international community. We have developed a sensitive and specific MRD assay for FLT3/ITD mutations using next-generation sequencing (NGS).

Aims: We report here the development of an assay for FLT3/ITD mutations using a next-generation sequencing (NGS) platform.

Methods: Exons 14 and 15 are amplified by PCR and the products were detected by a refined NGS technique developed at Invivoscribe, Inc. Initial validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish a sensitivity equivalent to detection of at least one ITD-containing cell out of 10,000 with a minimum input of 100,000 cell equivalents of DNA.

Results: We tested a series of 15 bone marrow aspirate samples from patients previously diagnosed with FLT3/ITD AML. All patients gave informed consent according to the Declaration of Helsinki. The investigator conducting the MRD assay was blind to the clinical information about the sample- no information was provided beforehand regarding the presence or absence of FLT3/ITD mutation, its length, or the mutant-to-wild type allelic ratio. All patients tested were in clinical remission by IWG criteria (J. Clin Oncol 2003; 24:4642) and all samples were derived from the first pull aspirate material used for the clinical confirmation of that remission. In all samples, both the standard CLIA-certified assay for the FLT3/ITD mutation (J Mol Diagn 2003; 5:96) as well as standard multi-parameter flow cytometry (for a leukemia-associated phenotype) were negative for detectable FLT3 mutations or cells with a leukemia phenotype. The first 4 samples were from patients who were newly-diagnosed, had just completed induction therapy, had achieved first CR, and were awaiting consolidation therapy. In all 4 cases, the FLT3/ITD mutation detected at diagnosis was detected in these remission samples, with mutation levels ranging from 1.35E-05 to 1.74E-04. Three samples were from patients who had relapsed and had responded to salvage therapy, achieving a CR2. In these 3 cases, the original FLT3/ITD length mutation was detected, with mutation levels ranging from 1.38E-06 to 1.11E-04 mutant ITD reads/total reads. Six samples were from patients who had undergone allogeneic transplant in remission. The samples were collected during routine post-transplant surveillance, 2-5 years after transplant. No mutation was detected in any of these patients, all 6 of whom are alive and disease free 2.5-5.5 years after transplant. Finally, 2 samples were from patients who had undergone allogeneic transplant for FLT3/ITD AML in first CR. At 2 and 6 months post-transplant, respectively, bone marrow aspirates from these 2 patients confirmed ongoing morphologic remission, with 100% donor chimerism in both the marrow and the T-cell compartment, and a negative standard assay for FLT3/ITD mutations. Using DNA from these same time points, the MRD assay detected FLT3/ITD mutations at levels of 3.67E-03 and 1.04E-04 mutant ITD reads/total reads, respectively. Both of these patients relapsed with AML carrying the detected FLT3/ITD mutation within 6 months.

Summary/Conclusions: This novel MRD assay is specific, and is 2 orders of magnitude more sensitive than current commercially available assays for FLT3/ITD mutations. We anticipate that this assay will be broadly available to the public soon, and will have a significant impact in the clinical management of this disease.

Background: We have overcome the limitations of 40 years of *ex vivo* testing

Aims: The aim of this study is to determine the ability of Vivia's novel test (based on studying the ex-vivo sensitivity to drugs) to predict the complete remission (CR) rates after induction chemotherapy with cytarabine (Ara-C) and idarubicin (Ida) in 1st line AML.

Methods: This has been an observational clinical trial where bone marrow samples from adult patients diagnosed with *de novo* AML in Spanish centers from the PETHEMA group were included. Whole marrow samples maintaining their Native Environment were incubated for 48h in well plates containing Ara-C, Ida, or their combination. Pharmacological responses are calculated using population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant.

Results: 390 patient samples were used to calculate the dose response (DR) curves for Ara-C alone, Ida alone, and their synergism. For clinical correlation we used 142 patients with median 56 years. The strongest clinical predictors were the Area Under the Curve (AUC) of the DR of Ara-C (P=1.34E-05), and the AUC of IDA (P=3.9E-05). The GAM models revealed a significant relationship (RSquare=0.452 and deviance explained=45%) between these predictors and higher probabilities of post-induction resistance. Figure 1A shows a table illustrating the correlation between clinical outcome (columns) and the test predictions (lines). Using the cut off determined by the GAM models. The test obtain a high Specificity and Positive Protective Value (95% and 80,77%) and a lower sensitivity (50%) with a general prediction of a 81,69%. Interestingly, the 5 cases that the test identify as resistant but were clinically sensitive have high level of minimal residual disease. On the other hand, the test does not properly identify 21/142 that are clinically resistant and the test predicts as sensitive (bottom left quadrant right panel). This mismatched subgroup mimics the problems from molecular markers where a resistant clone present in a minority of leukemic cells cannot be detected yet drives the patient response. Consistent with this analysis, adding the cytogenetic risk factor to the *ex vivo* results, identifying the high risk population by molecular markers that might be present in a minority of the cells, significantly improves the correlation; Figure 1B shows the 90% overall correlation achieved in 117 patient samples adding the cytogenetic risk factor, with a major improvement in the sensitivity from 50% to 72%. Both approaches lead to substantial improvements in estimated overall survival.

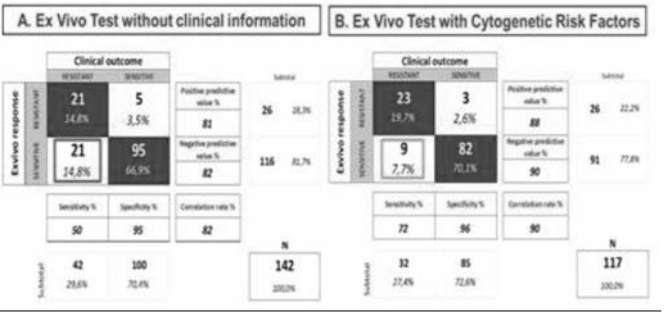

Figure 1. Clinical correlation of the *ex vivo* test alone (A, left) or adding the cytogenetic risk factor (B, right).

Summary/Conclusions: This novel test is able to predict the clinical response to Ida+Ara-C induction with overall correlation and predictive values of 80%, higher than ever achieved. Considering this result and current clinical response rate of 66.7% (70% in this study), clear clinical benefits can be achieved with the use of the test. Adding the cytogenetic risk profile further increase the correlation to 90%. Thus this novel test may be valuable information to guide 1st line patient therapy

P570

RECURSIVE PARTITIONING ANALYSIS FOR GENETIC STRATIFICATION AND PROGNOSTICATION OF ACUTE MYELOID LEUKAEMIA

S Fleming[1,*], J Reynolds[2], A Wei[1,3]

[1]Department of Malignant Haematology and Stem Cell Transplantation, Alfred Hospital, [2]Biostatistics, Faculty of Medicine Nursing and Health Sciences, [3]Australian Centre for Blood Diseases Research, Monash University, Melbourne, Australia

Background: The rapid evolution of molecular genetics has resulted in a diverse range of genomic variants that have been variably linked to patient prognosis in Acute Myeloid Leukaemia (AML). Standard regression analysis does not adequately address the complex multigene interactions that may positively or negatively influence individual patient outcome. Recursive partitioning is an alternative approach that empirically computes and ranks in order of importance, all possible prognostic combinations to create a stepwise decision tree resulting in the categorical partitioning of the AML population into subgroups of patients with independent prognosis. Through utilizing Random Forest analysis which repeatedly reforms the decision tree utilizing both subsets of the data and of the variables to avoid the tendency for over-fitting the data to the data set enhancing the generalizability of the decision tree.
Aims: To demonstrate the utility of an algorithmic machine-based learning approach to define independent prognostic subgroups using cytogenetic and genomic variants derived from The Cancer Genome Atlas (CGA) analysis of 200 patients with AML.
Methods: Clinical and mutational data was collected from the CGA AML dataset with cases limited to an age of <70 years. Exome sequencing data from the CGA dataset (http://cancergenome.nih.gov) was analysed utilising Integrated Genomics Viewer (IGV) v2.3 with statistical analysis performed utilising R (R foundation for statistical computing) v3.2.3 and the rpart (v4.1-10), randomForest (v4.6-12) and randomForestSRC (v2.0.7) modules. The analysis was restricted to the 20 most commonly identified mutations within the CGA dataset to exclude uncommon mutations.
Results: The analysis set included 173 patients with complete clinical and genetic information. Of these 143 were aged <70 years. The median overall survival for the entire cohort was 24 months with a median follow-up of 40.5 months. Recursive partitioning analysis was performed with a minimum "bucket" size of 8 patients (5% of the total dataset) and a complexity parameter of 0.001 reflective of the relative complexity acceptable within the model. This resulted in a decision tree that highlighted the importance of favourable risk karyotype and mutations affecting *TP53*, *RUNX1*, *DNMT3A*, *NPM1* and *FLT3-ITD*. (Figure 1). In non-CBF AML a striking adverse prognostic impact was observed for *TP53*, *RUNX1* and *DNMT3A* mutations, particularly when these were in combination with other 'driver' mutations, such as *NPM1* and *FLT3-ITD*. Random Forest Analysis confirmed the prognostic importance of these mutations and predicted an error rate of 37.08% for the predictive model in determining survival for patients within this dataset, thus predicting a greater than 62% probability of correctly predicting survival outcome with these factors. CBF-AML and normal karyotype AML negative for high-risk prognostic molecular markers carried a favourable risk (median OS NR and 27 months, respectively). Patients with high-risk disease included those with *DNMT3A*mut (median OS 11 months), *TP53*mut (median OS 12 months), *RUNX1*mut (median OS 11 months) and adverse-risk karyotype (median OS 12 months). Patients with *FLT3*-ITD (median OS 24 months) had an intermediate prognosis in the absence of other high-risk markers. *CEBPA* double mutants did not appear in the decision tree, likely reflective of the low occurrence rate of *CEBPA* mutations in the dataset.

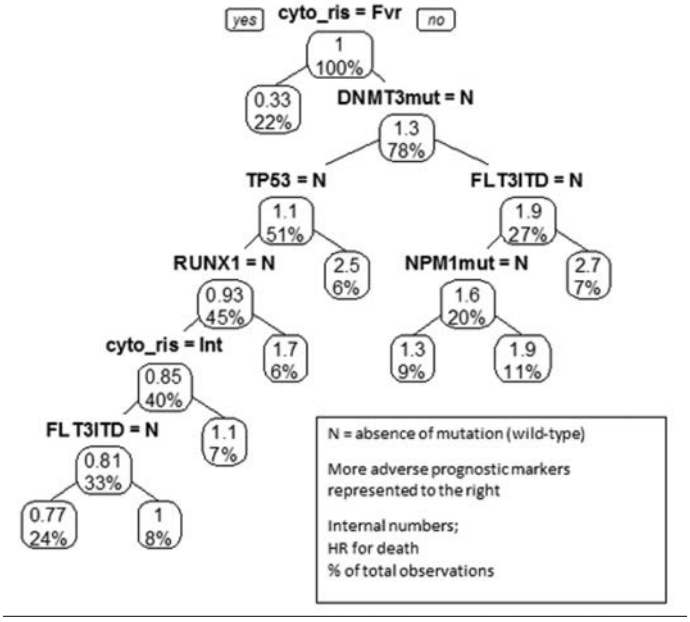

Figure 1.

Summary/Conclusions: Recursive partitioning analysis allows for the formulation of a non-biased analysis tree and highlights the importance of combinations of mutations in determining prognosis for patients with AML. The impact of mutations affecting *TP53, RUNX1* and the combination of mutations affecting *DNMT3A* with other driver mutations was prognostically relevant in patients with intermediate and poor risk karyotype. Confirmation of this decision tree approach using larger datasets will further refine the accuracy and value of this novel algorithmic approach for prognostically sub-classifying AML.

P571

CD7 AND CD34 CO-EXPRESSION IDENTIFY A SUBPOPULATION OF NUCLEOPHOSMIN 1-MUTATED ACUTE MYELOID LEUKEMIA (NPM1+ AML) PATIENTS WITH INCREASED RISK OF RELAPSE

A Porwit[1,2,*], C Hojilla[2], M Thomas[3], M Sukhai[3], S Kamel-Reid[2,3], T Zhang[4], A Schuh[5], M Minden[5]
[1]Pathology, Lund University, Lund, Sweden, [2]Pathology, University Health Network, [3]Cancer Genomics Program,, Princess Margaret Cancer Center, [4]Cancer Genomics Center, University Health Network, [5]Leukemia Program, Princess Margaret Cancer Center, Toronto, Canada

Background: *NPM1* mutated AML has been considered as a subset of AML patients with relatively good prognosis. However, multiple studies have shown clinical variability in *NPM1* mutated AML.
Aims: Using combined flow cytometry and next generation sequencing (NGS) data we have sought to identify prognostic factors, which would help in individual risk-assessment in *NPM1*+AML.
Methods: Blasts from 83 *NPM1*+ AML patients diagnosed Jan 2012 to Aug 2015 at UHN, Toronto, were analyzed. 76 patients received induction treatment, mostly with daunorubicin 60 mg/m^2 for 3 days and cytarabine 100 mg/m^2 (age >60 years) or 200 mg/m^2(age <60 years) daily for 7 days. At diagnosis, all cases were immunophenotyped using a 4-tube, 10-color flow cytometry panel (1). 30x10^5 cells were analyzed using Navios and Kaluza software (Beckman Coulter). Cases were classified according to 3 immunophenotypic patterns depending on the degree of monocytic differentiation (1: no monocytic differentiation; 2: a monocytic subset, and 3: predominantly monocytic). FLT3-ITD/TKD and NPM1 mutations were identified using fragment analysis on an ABI Genetic Analyzer 3100 /3130 platform. NGS using the TruSight Myeloid Sequencing Panel (Illumina) was performed in 68 patients.
Results: Among 83 NPM1+ AML patients, 69 patients had normal karyotype, 10 had cytogenetic abnormalities and 4 failed. 7 patients were excluded from statistical analysis due to early death. 47 patients achieved complete remission (CR) and 29 relapsed with 11 subsequent deaths. Average time to relapse from diagnosis was 10.5 months. Presence of FLT3 ITD mutation (39 pts) and immunophenotypic marker expression patterns 1-3 were not significantly associated with relapse-risk. However, aberrant expression of CD7+ alone or especially CD34/CD7 co-expression (even in a small subset of leukemic cells) was significantly associated with relapse-risk, independent of FLT3 ITD or TDK mutational status. Figure 1 shows examples of CD7 negative case (left), CD7 in a subset of blasts with minimal CD34/CD7 population (middle) and most blasts CD7/CD34+ (right). CD7+ and CD7- group of patients did not differ significantly in clinical characteristics. However, CD56 was more often expressed in CD7+ patients who relapsed. NGS revealed a heterogeneous mutational profile of known leukemogenic genes. At diagnosis, 15 aberrations (copy number alterations (CNAs), n=10; uniparental disomies (UPDs), n=5) were identified in 25% of patients. None of the studied mutations were significantly associated with increased relapse risk. Interestingly, *PTPN11* mutation showed increased frequency in the group with CD7 expression but was found mostly in patients who remained in CR. Otherwise there was no significant association between NGS results and immunological marker expression patterns. At relapse, 56 genomic alterations (CNAs, n=46; UPDs, n=10) were detected in 55% of patients indicating an increase in genomic complexity.

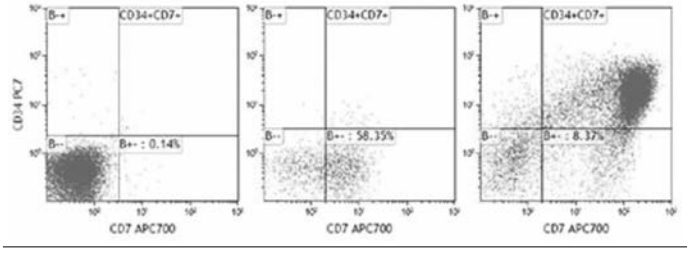

Figure 1.

Summary/Conclusions: Expression of CD7 and/or CD34 were associated with early relapse and/or mortality. The genetic mutational profile of NPM1+ AML is heterogeneous, suggesting that no one specific genetic driver may be responsible for leukemogenesis and affect prognosis. *PTPN11* mutation seems to be associated with better prognosis in NPM1+ AML.

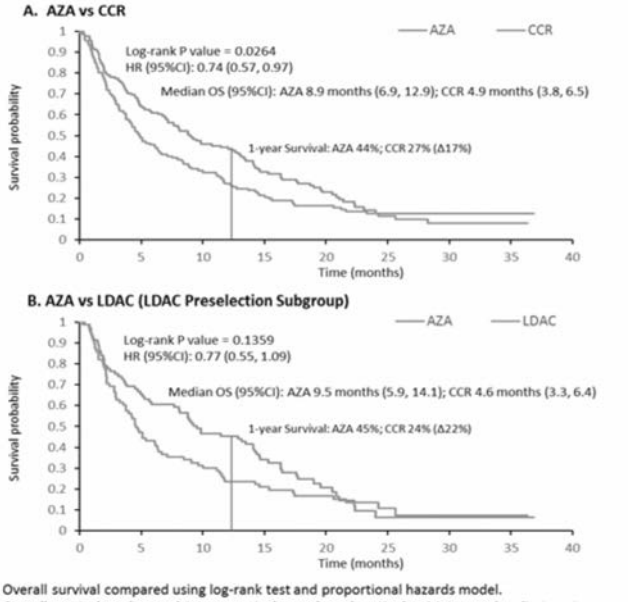
Background: Reports of patients (pts) with therapy-related acute promyelocytic leukemia (t-APL) have increased in recent years (yrs) and retrospective studies have suggested that their outcomes were similar to those of pts with *de novo* APL. More recently, arsenic trioxide (ATO)/all-trans retinoic acid (ATRA) has been shown to be the most effective therapy in *de novo* APL with low/intermediate Sanz score (Lo-Coco F. *et al.* NEJM, 2013). So far, this regimen has not been evaluated systematically in t-APL pts.
Aims: To describe clinical outcome in a large series of t-APL pts and to compare outcomes after treatment with ATO/ATRA with that after chemotherapy (CTX) and ATRA.
Methods: We retrospectively studied 76 t-APL pts (median age, 59 yrs; range, 18-80 yrs), treated between 1998 and 2015 within seven study groups/institutions of the US and Europe. Pts had received i) CTX/ATRA (n=34; either daunorubicin/idarubicin and ATRA for induction and different CTXs+ATRA for consolidation), ii) ATO/ATRA (n=19; according to Lo-Coco F. *et al.* NEJM, 2013 (n=16) or Burnett AK, *et al.* Lancet Oncol, 2015 (n=3)), iii) CTX/ATO/ATRA (n=17; according to Gore SD, *et al.* JCO, 2010), and ATRA only (n=6).
Results: In 63 of the 76 t-APL pts, a solid cancer was the primary malignancy, with breast cancer being the most common (n=28), followed by prostate (n=9), head&neck (n=7) and gastrointestinal cancers (n=6). In five of the 76 pts, a hematologic neoplasm was the primary malignancy (non-Hodgkin lymphoma, n=4; Hodgkin lymphoma, n=1). Eight pts had received cytotoxic treatment for autoimmune/rheumatological diseases. The median latency period between diagnosis of primary malignancy/disease and occurrence of t-APL was 4 yrs (range, 1-27 yrs). Sixty pts were of low/intermediate Sanz score. The four therapy groups were comparable in all baseline characteristics except for age (p=0.004) and platelet counts (p=0.003); pts treated with ATRA only were significantly older and had lower platelets. Response data were available for 74 pts. Complete remission after induction therapy was achieved in 82% of the CTX/ATRA pts, in 100% of the ATO/ATRA pts, in 94% of the CTX/ATO/ATRA pts and in 33% of the ATRA pts. Early death rate for the intensively treated group was 6% (CTX/ATRA, n=3; CTX/ATO/ATRA, n=1; ATO/ATRA=0) and 50% in the ATRA group. Only two of the 76 pts relapsed (both of the CTX/ATRA group), both pts were successfully salvaged and went on to allogeneic transplant. Ten pts died in remission (relapse of the prior malignancy, n=5 (CTX/ATRA, n=2, ATRA, n=2, CTX/ATO/ATRA, n=1); infections, n=2 (CTX/ATRA, n=1 and ATO/ATRA, n=1); adverse events during treatment, n=2 (CTX/ATRA, n=1 and ATO/ATRA, n=1); reason unknown, n=1 (CTX/ATRA)). With a median follow-up of 2.4 yrs, the estimated 2-year relapse-free survival was lower in pts receiving CTX/ATRA (80%; 95%>CI: 66-97%) as compared to pts treated either with ATO/ATRA (93%; 95%>CI: 82-100%) or CTX/ATO/ATRA (94%; 95%>CI: 83-100%). The estimated 2-year overall survival (OS) rate for pts receiving CTX/ATRA was again lower (85%, 95%>CI: 73-98%) as compared to pts treated either with ATO/ATRA or CTX/ATO/ATRA (94%, 95%>CI: 84-100%, each). Two-year survival was not evaluable for pts treated with ATRA. Regarding toxicity, there was a trend towards less frequent febrile neutropenia of grade ≥3 in pts treated with ATO/ATRA as compared to CTX/ATRA or CTX/ATO/ATRA (p=0.06).
Summary/Conclusions: The ATO-based regimen for first line treatment of t-APL pts was associated with excellent and sustained response rates. These data demonstrate the important potential of ATO/ATRA in the primary management of t-APL pts.

P573

AZACITIDINE (AZA) *VS* CONVENTIONAL CARE REGIMENS (CCR) IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) WITH MYELODYSPLASIA-RELATED CHANGES (MRC) IN AZA-AML-001 PER CENTRAL REVIEW

JF Seymour[1,*], H Döhner[2], AC Schuh[3], RM Stone[4], M Minden[3], J Weaver[5], S Songer[5], C Beach[5], H Dombret[6]
[1]Peter MacCallum Cancer Centre, East Melbourne, United States, [2]Universitätsklinikum Ulm, Ulm, Germany, [3]Princess Margaret Cancer Centre, Toronto, Canada, [4]Dana Farber Cancer Institute, Boston, [5]Celgene Corporation, Summit, United States, [6]Hôpital Saint Louis, Institut Universitaire d'Hématologie, Paris, France

Background: Patients (pts) with AML-MRC are generally older and more likely to have poor-risk cytogenetics, leading to poor prognosis (Weinberg, *Blood*, 2009). A subanalysis of the AZA-AML-001 (AZA-AML) trial evaluated safety and efficacy of AZA *vs* CCR in 158 pts diagnosed with AML-MRC per local assessment (Seymour, ASH 2014). Subsequently, AML-MRC classification was adjudicated centrally according to WHO criteria (Vardiman, *Blood*, 2009).
Aims: Determine the difference in frequency of AML-MRC classification between local and central assessments in AZA-AML, and evaluate the treatment (Tx) effects of AZA *vs* CCR and AZA *vs* low-dose ara-C (LDAC) in the centrally confirmed AML-MRC pt cohort.
Methods: Pts aged ≥65 yrs with newly diagnosed AML confirmed by central review, ECOG PS 0-2, intermediate- or poor-risk cytogenetics, and WBC ≤15x10^9/L, classified as having AML-MRC per WHO criteriaΔΔ are included in these analyses. Pre-randomization, the most appropriate of 3 CCR was preselected for each pt: intensive chemotherapy (IC, standard 7+3), LDAC (20mg SC BID x10d/28d), or best supportive care (BSC) only. Pts were then randomized to preselected CCR or AZA (75mg/m^2/d x7d/28d). Overall survival (OS) was compared for AZA *vs* CCR in all AML-MRC pts, and for AZA *vs* LDAC in the LDAC preselection group. Overall response rate (ORR) included complete remission (CR)+CR with incomplete hematologic recovery (CRi) (IWG 2003).
Results: Upon central review, a much larger pt cohort was identified than based on local reports. In all, 262/488 pts (54%) fulfilled WHO criteria for AML-MRC: AZA n=129, CCR n=133 (IC n=24, LDAC n=79, BSC n=30). In the AZA and CCR arms, respectively, median age was 76 yrs (range 64-90) and 75 yrs (65-87), 51% and 54% had poor-risk cytogenetics, 27% and 22% had ECOG PS=2, and median blasts were 65% (27-99) and 70% (26-100). At baseline (BL) only 79 pts (30%) were reported to have had prior MDS. BL characteristics for LDAC-preselected AZA and LDAC pts were comparable except for ECOG PS=2 (31% *vs* 19%, respectively) and poor-risk cytogenetics (42% *vs* 58%). Median numbers of Tx cycles were: AZA 5 (range 1-27), IC 2 (1-3), LDAC 2 (1-22), and BSC 3 (1-9). OS for all AML-MRC pts was improved with AZA *vs* CCR (HR 0.74 [95%CI 0.57, 0.97], *P*=0.026; Figure 1 A): median OS was 8.9 *vs* 4.9 months, respectively, and 1-yr survival rates were 44% *vs* 27% (Δ17% in favor of AZA). ORR was 25% *vs* 17% with AZA *vs* CCR, respectively (*P*=0.17). In LDAC-preselected pts, median OS with AZA *vs* LDAC was 9.5 *vs* 4.6 months, respectively (HR 0.77 [0.55, 1.1], *P*=0.14; Figure 1 B) and 1-yr survival rates were 45% *vs* 24% (Δ22% in favor of AZA). ORR was higher with AZA *vs* LDAC: 27% *vs* 14%; *P*=0.050. Rates of grade 3-4 cytopenias were similar among AZA, IC, and LDAC, except that febrile neutropenia was less frequent with AZA (23%) than with LDAC (33%) or IC (39%).



Overall survival compared using log-rank test and proportional hazards model.
Overall survival median and 1-year survival rates based on Kaplan-Meier product limit estimates.

Figure 1. Median overall survival for patients with AML-MRC.

Summary/Conclusions: Over one-half of all newly diagnosed AZA-AML pts met the WHO definition of AML-MRC in central review *vs* one-third in local review, suggesting potential under-diagnosis of MRC in the community. This difference may also reflect challenges in diagnosing dysplasia. MDS and AML may reflect a continuum of myeloid disease, particularly in this pt population. Pts with AML with MDS-related changes may respond preferentially to AZA. In both the locally (Seymour, ASH 2014) and centrally identified AML-MRC cohorts, AZA provided a clinically meaningful effect with prolonged OS and improved 1-year survival rates.

P574

IMPACT OF PHYSICIANS' CHARACTERISTICS ON DECISION MAKING IN ELDERLY ACUTE MYELOID LEUKEMIA

P Bories[1,2,*], S Lamy[3], C Simand[4], S Bertoli[2], S Malak[5,6], L Fornecker[4], S Moreau[6,7], A Nebout[8]
[1]ONCOMIP Cancer Network, [2]Department of Hematology, Toulouse University Institute of Cancer - Oncopole, [3]INSERM Unit 1027, Faculty of Medicine, Toulouse, [4]Department of Hematology, Strasbourg University Hospital, Strasbourg, [5]Department of Hematology, Curie Institute, Saint Cloud, [6]Ethics Commission of the French Society of Hematology, Paris, [7]Department of Hematology, Limoges University Hospital, Limoges, [8]UR 1303 ALISS, INRA, Ivry-sur-Seine, France

Background: Outside clinical trials, therapeutic options offered to elderly acute myeloid leukemia(AML) patients (pts) are limited. They can be summarized as intensive chemotherapy (ICT), low-intensity therapy or best supportive care (BSC) depending on patient- and disease-related prognosis factors. Although scoring systems have been proposed to rationalize this clinical decision-making, there is a strong heterogeneity in clinical practice which is still poorly understood. Indeed, cancer management study mainly focused on the patients' determinants of care but very few have assessed the influence of physicians' characteristics and none in AML. In behavioral sciences, attitudes towards risk and ambiguity are crucial psychological traits that may explain medical choices and practices. These characteristics are connected with theoretical models of decision under uncertainty which can be divided in Expected Utility (EU) and Non-Expected Utility (Non-EU) models. Choice patterns in decision tasks known as Allais and Ellsberg paradoxes allow classifying individuals in these two classes of models.
Aims: Our study investigated the impact of physician's characteristics on their medical decisions regarding selected clinical vignettes of older AML pts that highlight distinct and difficult representative situations derived from clinical practice.
Methods: Physicians' demographical and occupational characteristics were collected through a national cross-sectional web survey among French onco-haematologists. We also assessed their attitude regarding risks by the self-reported individual willingness to take risks in the daily life on a 0-10 Likert scale (Dohmen & al, 2011) and the response to the binary lottery choice questions of the Allais paradox (Kahneman & Tversky, 1979) for identifying respondents conforming to EU. A last question used two certainty equivalents elicitations (Abdellaoui & al, 2011) in an Ellsberg paradox setting in order to define an index of ambiguity attitudes. The physicians were asked to decide how to treat (ICT, low-intensity therapy or BSC) elderly AML patients presented in clinical vignettes. We present the results for vignette with highest heterogeneity (cf. Figure 1).

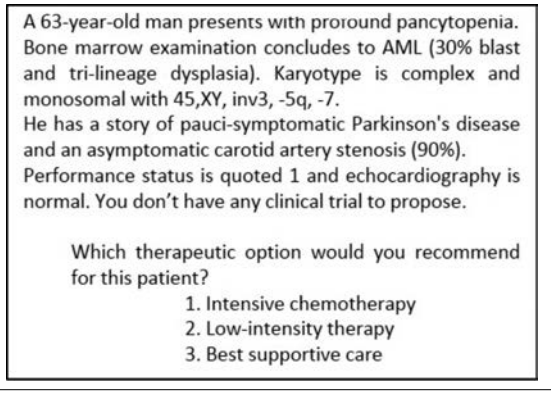


Figure 1. Clinical vignette.

Results: Among the 211 physicians who responded to the survey, the median age was 42 years old [inter-quartile range (IQR): 32-52], 54% were male, 72.5% were consultant or professor, 70.6% worked in academic center, 78% were Hematologists, 61% were involved in AML care in their daily practice. Regarding Likert scale of willingness to take risk, median was 5 (IQR 4-7). Regarding the Allais paradox, EU, non-EU and undefined status represented respectively 42.2%, 44.5% and 13.3%. Regarding attitudes towards ambiguity, averse, neutral, seeking and undefined attitudes represented respectively 43.1%, 16.6%, 15.6% and 24.7%. From the clinical vignette we observed that 51.7% choose ICT, 45% favored low-intensity therapy and 3.3% BSC. Using the elicited treatment recommendation in the vignette as the explained variable, a multivariate logit model (N=159) on variables identified from the bivariate analyses highlighted the following trends: the probability of recommending ICT was 60% lower for women compared to men (p=0,012). Risk averse respondents tended to recommend less ICT (p=0,075) as well as EU respondents (p=0.126). Ambiguity averse respondents tend to recommend more ICT (p=0,073).
Summary/Conclusions: These preliminary results show that physicians' attitudes towards risk and ambiguity, *i.e.* physicians' non professional characteristics, may influence their clinical practice when dealing with older AML pts.

P575

THE ADDITION OF GEMTUZUMAB OZAGAMICIN (GO) TO INTENSIVE CHEMOTHERAPY SIGNIFICANTLY IMPROVES COMPLETE RESPONSES CR RATES AND OVERALL SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

C Sartor[1,*], C Papayannidis[1], A Candoni[2], M Malagola[3], G Marconi [1], E Tenti[1], M Manfrini[1], G Simonetti[1], E Zuffa[1], MC Abbenante[1], S Parisi[1], S Paolini[1], S Lo Monaco[1], E Franchini[1], E Ottaviani[1], MC Fontana[1], A Padella[1], V Guadagnuolo[1], R Fanin[2], D Russo[3], G Martinelli[1]
[1]DIMES, Institute of Hematology, University of Bologna, Bologna, [2]Hematology, Santa Maria della Misericordia University Hospital, Udine, [3]Chair of Hematology, Unit of Blood Diseases and Stem Cell Transplantation, University of Brescia, Brescia, Italy

Background: Young patients affected by non APL-Acute Myeloid Leukemia (AML) achieve complete remission (CR) using conventional induction chemotherapy with anthracycline plus cytarabine-based regimens in about 55-70%. The addition of Gemtuzumab Ozogamicin (GO) as third or fourth drug demonstrated to improve clinical outcome, in terms of CR rates.
Aims: We retrospectively evaluated and compared the efficacy of different induction schedules, in terms of CR rates and (OS), administered to two groups of AML patients. Group 1 (n=139) was treated with a GO (MyFLAI or MyAIE schedules); group 2 (n=270) received a non-GO based regimen including or not Fludarabine (FLAI, FLAN, FLAG, 3+7 or DAE).
Methods: From 1997 to 2014, 409 patients with newly diagnosed AML were treated in 3 Italian Institutions. According to karyotype (performed in 392/409 patients), FLT3 (available for 244/409 patients), and NPM1 mutational status (available for 157/409 patients), based on the NCCN-2013 risk stratification criteria, 35.2% of the patients were considered at High Risk (HR) (31.6% and 36.4% in the two groups, respectively) and 7.6% at low risk (LR) (7.8% and 7.0%, respectively).
Results: The complete remission (CR) rate after induction was 81.4% and 70.4% for Group 1 and 2, respectively (p=0.008). Deaths during induction (DDI), occurring in the first 50 days from 1st line therapy, were 4/139 (2.9%) in Group 1 and 22/270 (8.1%) in Group 2. Patients treated with GO showed a better OS than patients of Group 2; the 5-years OS in the two groups was 54.01% and 34.9%, respectively, and different according to age (54.0% and 34.9% respectively (p<0.001) in patients <60 years, 30.2% and 13.5% respectively (p=0.001) in patients >=60 years). Notably, the analysis on subgroup of HR patients showed a significantly better OS in Group 1 than in Group 2 (p=0.007, 5-year OS 47.7%; 21.0% respectively) and EFS.
Summary/Conclusions: Our conclusion is that adding GO to any induction regimen is an independent and strong predictor of better OS and higher CR rate. Patients with SR and HR AML could therefore benefit from this new approach to AML front line treatment in terms of OS if compared with other standard regimens.

HOSPITALIZATION FOR TREATMENT-EMERGENT ADVERSE EVENTS (TEAE) IN OLDER (≥65 YEARS) PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) WITH >30% MARROW BLASTS IN THE PHASE 3 AZA-AML-001 STUDY

JF Seymour[1,*], H Döhner[2], RM Stone[3], D Gambini[4], D Dougherty[4], J Weaver[4], C Beach[4], H Dombret[5]
[1]Peter MacCallum Cancer Centre, East Melbourne, Australia, [2]Universitätsklinikum Ulm, Ulm, Germany, [3]Dana-Farber Cancer Institute, Boston, [4]Celgene Corporation, Summit, United States, [5]Hôpital Saint Louis, Institut Universitaire d'Hématologie, University Paris Diderot, Paris, France

Background: AML treatment (Tx) places an enormous financial burden on both payers and patients (pts). Hospitalization is the largest cost driver in AML care (Zeidan, *Crit Rev Oncol Hematol*, 2015) and AML pts report reduced quality of life when in hospital (Sekeres, *Leukemia*, 2004). The AZA-AML-001 (AZA-AML) study compared azacitidine (AZA) with conventional care regimens (CCR) in older pts with AML. As previously reported, AZA was associated with lower incidence rates (IRs) of hospitalization and total days in hospital for TEAEs per pt-year (pt-yr) of drug exposure *vs* the combined CCR arm (Dombret, *Blood*, 2015). AZA-AML had a preselection study design, allowing for comparisons

between AZA and individual CCR in groups of pts with generally comparable clinical and prognostic features at entry.
Aims: Compare IRs of hospitalization and days in hospital for TEAEs adjusted for pt-yrs of exposure within preselection groups.
Methods: Older pts with newly diagnosed AML (>30% bone marrow blasts), ECOG PS 0-2, intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L were eligible. Pre-randomization, all pts were preselected to receive the most appropriate CCR: low-dose ara-C (LDAC, 20mg SC BID x10 days (d)/28d), intensive chemotherapy (IC, cytarabine 100-200mg/m^2 IV x7d+anthracycline IV x3d induction), or best supportive care (BSC) only. Pts were then randomized to AZA (75mg/m^2x7d/28d) or to CCR and received the preselected Tx. All pts could receive BSC. Safety-evaluable pts had ≥1 dose of study drug and ≥1 post-baseline safety assessment. TEAEs were assessed for up to 28 days after the last AZA or LDAC dose, 70 days after the last IC course, or day of discontinuation for BSC pts. TEAEs were defined as new or worsening AEs during Tx. To address imbalances in duration of exposure between Tx groups, hospitalization and days in hospital for TEAEs are normalized for pt-yrs of exposure using aggregate data.
Results: In all, 471 pts were safety-evaluable (AZA n=236, CCR n=235). Most pts were preselected to LDAC (n=304; 65%). Baseline characteristics of AZA and CCR pts within preselection groups were generally comparable. Duration of exposure (pt-yrs) was longest with AZA in each preselection group (Table 1). AZA was associated with lower IRs of hospitalization and days in hospital for TEAEs *vs* other Tx. IR for number of hospitalizations was not significantly different between AZA and LDAC or AZA and IC, but was ~55% lower with AZA *vs* BSC (relative risk 0.455). Additionally, IRs for days in hospital for a TEAE were lower with AZA by 6.4 to 22.5 fewer days/pt-yr across preselection groups (Table 1).

Table 1.

Incidence rates per patient-year of treatment exposure of hospitalization and days in hospital for TEAEs

	Preselected to BSC only		Preselected to LDAC		Preselected to IC	
	BSC (n=40)	AZA (n=42)	LDAC (n=153)	AZA (n=151)	IC (n=42)	AZA (n=43)
Total exposure, pt-yrs	**9.6**	**28.1**	**82.9**	**111.7**	**14.1**	**35.1**
Patients hospitalized for a TEAE, n (%)	25 (62.5)	29 (69.0)	111 (72.5)	110 (72.8)	21 (50.0)	26 (60.5)
Total number of hospitalizations for TEAEs, n	42	56	186	226	27	60
Hospitalizations per pt-year of exposure, IR	4.38	1.99	2.24	2.02	1.91	1.71
Rate difference AZA:CCR hospitalization	-2.39		-0.22		-0.20	
Relative risk (95%CI) AZA:CCR hospitalization	0.455 (0.305, 0.679)		0.902 (0.743, 1.095)		0.893 (0.567, 1.407)	
Total number of days hospitalized for a TEAE, n	465	798	2905	3202	711	977
Days hospitalized for a TEAE per pt-year of exposure, IR	48.48	28.39	35.03	28.67	50.35	27.82
Rate difference AZA:CCR days hospitalized	-20.09		-6.36		-22.53	
Relative risk (95%CI) AZA:CCR days hospitalized	0.586 (0.522, 0.656)		0.818 (0.778, 0.861)		0.552 (0.502, 0.609)	

AZA, azacitidine; BSC, best supportive care; IC, intensive chemotherapy; IR, incidence rate; LDAC, low-dose ara-C; pt-yrs, patient-years; TEAE, treatment-emergent adverse event

Summary/Conclusions: Accounting for drug exposure when reporting safety outcomes is common in diseases with low mortality rates that require chronic Tx, but may be increasingly relevant for diseases with a high mortality rate, such as AML, particularly for drugs like AZA that are given in repeated Tx cycles. In AZA-AML, incidence rate of hospitalization for a TEAE was >50% lower with AZA *vs* BSC, suggesting that older AML patients should be offered active Tx. AZA was also associated with shorter hospital stays, as evidenced by fewer days in hospital for TEAEs with AZA *vs* LDAC, IC, and BSC.

P577

PHARMACEUTICAL TARGETING OF PYRUVATE DEHYDROGENASE KINASES IN T(8;21) ACUTE MYELOID LEUKEMIA

H Kizilkaya, K Reckzeh*
Finsen Laboratory, København, Denmark

Background: Acute myeloid leukemia (AML) constitutes a heterogeneous clonal hematological malignancy characterized by fast accumulation of immature myeloid cells that are no longer able to differentiate into fully mature blood cells. AML is the most frequent acute leukemia with more than one quarter of a million people diagnosed annually worldwide. Only moderate improvement has been achieved with standard treatment over the last 3-4 decades. Due to genetic heterogeneity and complexity of the disease with considerable variation in therapy response and high relapse rate, AML remains a disease with poor prognosis (median overall survival of 18 months). Hence, there is an urgent need to improve the existing treatment by identification of novel therapeutic targets. By comparative gene expression analysis we have identified aberrantly expressed genes in human AML patient cells as compared to their normal counterparts purified from bone marrow samples of healthy individuals. One of these genes, *pyruvate dehydrogenase kinase 1* (*PDK1*), a regulatory metabolic enzyme, has been shown to be upregulated in several subtypes of AML, and is thought to contribute to the altered energy metabolism exhibited by cancer cells known as the Warburg effect or aerobic glycolysis. Hence inhibiting the activity of PDK1 with small molecule inhibitors provides an interesting novel therapeutic strategy for the treatment of AML.
Aims: The aim of this study was to investigate how targeting of PDK1 by small molecule inhibitors dichloroacetate (DCA) and AZD7545 would affect growth and survival of t(8;21) AML in a series of *in vitro* culture experiments.
Methods: Several different methods were used in order to investigate the role of PDKs including western blot analysis as well as different functional assays to show a switch in the glycolytic acitvity.
Results: The inhibition of PDK1 with DCA was found to reverse the glycolytic phenotype of cancer cells from glycolysis toward mitochondrial respiration leading to cell death in human t(8;21) AML cells. Additionally, the combination of DCA with standard chemotherapy demonstrated a synergistic inhibitory effect. The novel PDK inhibitor AZD7545 was demonstrated to be a more potent inhibitor of PDK1 activity than DCA in t(8;21) AML. However, its ability to switch the Warburg effect is still under investigation. Furthermore in order to establish the use of DCA and AZD7545 in a preclinical setting, a mouse model mimicking human t(8;21) AML was used to determine the expression profile of PDK isoforms. Here PDK2 and PDK3 expression was identified to be predominantly important for the glycolytic phenotype. It was also possible to show that DCA and AZD7545 treatment impaired *in vitro* colony formation ability of clonogenic murine t(8;21) AML cells to a higher extent than wild-type mouse cells.
Summary/Conclusions: Overall, these results indicate that PDKs play an important role in maintaining the Warburg effect in t(8;21) AML, thus implicating that inhibition of PDKs with small molecule inhibitors might represent a novel therapeutic strategy for the treatment of AML patients.

P578

HOPX IS A HEMATOPOIETIC STEM CELL MARKER AND ITS HIGH EXPRESSION PREDICTS CHEMORESISTANCE IN *DE NOVO* ACUTE MYELOID LEUKEMIA PATIENTS

CC Lin[1,*], YC Chiu[2], HA Hou[3], WC Chou[1], HF Tien[3]
[1]Department of Laboratory Medicine, National Taiwan University Hospital, [2]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, [3]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, Taipei City, Taiwan, ROC

Background: *Homeodomain-only protein homeobox* (*HOPX*) gene encodes a homeodomain protein and functions as an adaptor protein to mediate transcriptional repression. It was shown to play a role in stemness in intestine, hair follicles, and pulmonary alveolar cells. *HOPX* was also reported as a tumor suppressor gene in lung, colon, esophagus, pancreas, uterus, and stomach cancers.However, the biological effects of HOPX in hematopoietic malignancies have not been explored.
Aims: In this study, we aim to see the clinical and biological relevance of *HOPX* expression in acute myeloid leukemia (AML).
Methods: The *HOPX* gene expression levels were extracted from the mRNA array data derived from 346 newly diagnosed AML patients in the National Taiwan University Hospital, and were analyzed for its clinical and biological relevance.
Results: The 346 patients were divided into two groups based on the median level of *HOPX* expression. Patients with higher *HOPX* expression had significantly higher incidences of mutations in *RUNX1*, *ASXL1*, *IDH2* and *DNMT3A*, but lower incidences of *NPM1* mutation and *CEBPA* double mutations. With a median follow-up of 31.2 months, patients with higher *HOPX* expression had a shorter overall survival (OS) compared with those with lower *HOPX* expression (P=0.003). In multivariate analyses, higher expression of *HOPX* still represented a poor prognostic factor for OS independent of age, WBC counts, karyotype, *FLT3*-ITD, *CEBPA* double mutations and *NPM1*, *MLL*-PTD, and *RUNX1* mutation (P=0.018). The results were recapitulated in the two independent validation AML patient cohorts. Gene set enrichment analysis (GSEA) showed enrichment of both hematopoietic stem cell (HSC) and leukemia stem cell (LSC) signatures in the AML cells with higher *HOPX* levels (P<0.0005 in HSC and P=0.004 in LSC), compatible with a role of HOPX in cell stemness. . Furthermore, the expression of six ATP-binding-cassette (ABC) transporter molecules that were related to poor prognosis and drug resistance, by pumping drugs out of AML cells, were significantly higher in the high *HOPX* group.
Summary/Conclusions: Higher expression of *HOPX* appeared to be an independent unfavorable prognostic factor in our and other AML cohorts. *HOPX* expression is highly correlated with stem cell signatures and ABC-related chemoresistance pathway. These results might at least in part explain the poor survival in AML patients with high *HOPX* expression levels.

P579

KIT MUTATIONS INCREASE THE RELAPSE RISK IN PATIENTS WITH AML WITH T(8;21) OR RUNX1-RUNX1T1 BUT NOT IN PATIENTS WITH INV(16) OR CBFB/MYH11: A SUBGROUP ANALYSIS OF CETLAM PROTOCOLS 2003 & 2012

M Pratcorona[1,*], S Brunet[1], J Esteve[2], JM Ribera[3], M Tormo[4], M Arnan[5], L Escoda[6], MP Queipo de Llano[7], O Salamero[8], D Gallardo[9], JM Martí[10], J Bargay[11], M Carricondo[1], E Bussaglia[1], M Hoyos[1], A Garrido[1], J Sierra[1], J Nomdedeu[1]
[1]Hematology, Hospital de la Santa Creu i Sant Pau, [2]Hematology, Hospital

Clínic de Barcelona, Barcelona, [3]Hematology, Hospital Germans Trias i Pujol, Badalona, [4]Hematology, Hospital Clínico de Valencia, Valencia, [5]Hematology, ICO Duran i Reynals, Hospitalet de Llobregat, [6]Hematology, ICO Joan XXIII, Tarragona, [7]Hematology, Hospital Universitario Virgen de la Victoria, Malaga, [8]Hematology, Hospital Vall d'Hebron, Barcelona, [9]Hematology, ICO Josep Trueta, Girona, [10]Hematology, Hospital Mútua de Terrassa, Terrassa, [11]Hematology, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: Patients with acute myeloid leukemia (AML) and inv(16) or t(8;21) (CBF-AML) are considered of good prognosis. In consequence, general recommendation in these patients is not to perform an allogeneic hematopoietic cell transplantation (alloHCT) in first complete response (CR). However, their relapse incidence after standard frontline chemotherapy may reach 40%. Therefore the identification of potential prognostic markers is considered of great interest in order to improve their current outcome. Among these, *KIT* mutations, identified in approximately one third of patients, have been invoked as a potential relevant prognostic factor in CBF-AML, although their clinical relevance is currently uncertain.
Aims: Analyze the prognostic impact of KIT mutations in CBF-AML, in a series of patients treated following CETLAM protocols (AML-03 and AML-12).
Methods: This study analyzed all consecutive patients with primary CBF-AML enrolled into the AML-03 and AML-12 CETLAM trials for patients up to the age of 70 years. Induction chemotherapy included idarubicin, intermediate-dose cytarabine and etoposide. Consolidation treatment consisted of repeated courses of high-dose cytarabine followed in a small fraction of patients of autologous HCT. Exon 8 KIT mutations were analyzed by PCR amplification and direct sequencing, whereas exon 17 mutations were analyzed by PCR amplification and melting curve analysis in a LightCycler.
Results: The series included 143 CBF-AML patients (73♀, 70♂), 71 with *RUNX1/RUNX1T1* and 72 with *CBFB/MYH11* rearrangements. Median age was 42 years (range: 17-71), and median WBC count 14x10^9/L (range: 1.4-243x10^9/L;). Overall, CR rate was 91%, 5-year overall survival (OS) was 75±4%, and leukemia-free survival (LFS) was 69±5%. No differences in OS or LFS were found between the two CBF-AML groups. *KIT* mutation studies were available in 101 patients with the following results: 1) *RUNX1/RUNX1T1*: 42 patients harboring (76%) wild-type KIT configuration (wt), and 13 (24%) with mutated KIT (mut); 2)*CBFB/MYH11*: 32 (70%) wt, and 14 (30%) mut. Although no differences in OS and LFS were observed between mutant and wt patients when both CBF-AML groups were analyzed together (Figure 1). In contrast, *KIT* mut had impact on outcome in the *RUNX1/RUNX1T1* subgroup: LFS was significantly better in *KIT*wt patients (5 years LFS: 79±7%, *vs* 53±16%; p=0.043) and cumulative incidence of relapse (CIR) was higher in the *KIT*mut group (5 years CIR: 12±4%, *vs* 47±15%; p=0.006). There was a trend for a worse OS in patients with *RUNX1/RUNX1T1* and *KIT*mut (5-year OS in patients with *KIT*wt was 81±6%, *vs* 50±16% in *KIT*mut patients; p=0.068); No differences in CR rate were found depending on presence or absence of *KIT* mutations in any CBF-AML subgroup. Multivariate analysis including age, WBC count, bone marrow blasts and mutational status of *KIT*, confirmed the effect of *KIT* mutations in *RUNX1/RUNX1T1* AML in terms of LFS and CIR (LFS HR=3,5; 95% CI: 1,029-11,961; CIR HR=6,2; 95% CI: 1.534-24.93), but not in OS.

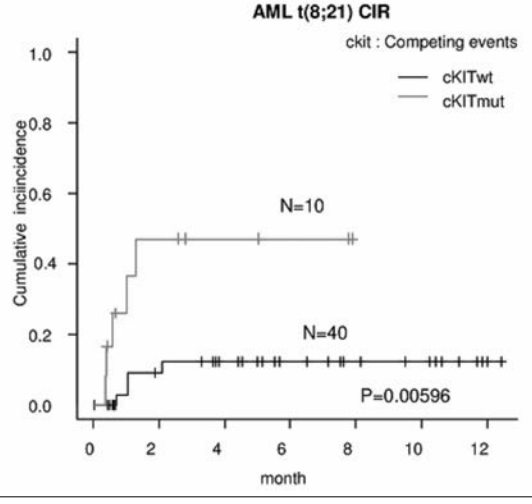

Figure 1.

Summary/Conclusions: In this study, *KIT* mutations exerted an unfavorable prognostic effect in patients within the *RUNX1-RUNXT1* AML subset, although the higher relapse risk observed in this AML subgroup did not translate into a shorter overall survival. The potential benefit of targeted therapies such as *KIT* inhibitors on relapse risk reduction deserves to be investigated in this setting. More data are needed to modify the still valid recommendation of postponing alloHCT for CBF-AML to more advanced phase of the disease.

LB580

RELATIVE BENEFIT FOR INTENSIVE *VERSUS* NON-INTENSIVE INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) USING A COMPOSITE, AGE-COMORBIDITY-CYTOGENETIC, MODEL

M Sorror[1,2,*], B Storer[1,2], M Elsawy[1], A Fathi[3], A Brunner[3], A Gerds[4], M Sekeres[4], S Mukherjee[4], B Medeiros[5], P Shami[6], E Pena[6], S Wardyn[1], J Whitten[1], P Becker[2,7], J McCune[1,2], S Lee[1,2], B Sandmaier[1,2], F Appelbaum[1,2], E Estey[2,7]
[1]Fred Hutchinson Cancer Research Center, [2]University of Washington, Seattle, [3]Massachusetts General Hospital, Boston, [4]Cleveland Clinic Taussig Cancer Institute, Cleveland, [5]Stanford University, Palo Alto, [6]University of Utah, Salt Lake City, [7]Seattle Cancer Care Alliance, Seattle, United States

Background: Induction therapy for newly diagnosed AML can be classified as "more" or "less" intensive. Currently less intensive therapies such as azacitidine or decitabine (HMA) appear to be increasing in use among patients >65 years, reflecting concerns about the ability of older patients, who often have various comorbidities, to tolerate intensive therapy. However, the issue of relative efficacy of intense *versus* non- intense therapies arises together with the question about the relative benefit/risk ratios of these options in various populations defined by age, comorbidities, and disease-related characteristics such as cytogenetic and molecular features.
Aims: Our group has designed and validated a new model combining the prognostic effects of age, comorbidity index, and cytogenetic/molecular risks (Blood 2015 126:532). Here, we used this composite model to define distinct prognostic groups and within each, compared two year mortality rates among patients with newly-diagnosed AML according to whether they received intensive or non-intensive therapy at 5 collaborating institutions. Non-intensive therapy principally included HMA or low-dose cytarabine, while intensive therapies primarily consisted of "7+3" or other similar cytotoxic induction regimens.
Methods: We retrospectively collected information regarding comorbidities, laboratory, and survival data from 1079 patients with newly diagnosed AML who received therapy at 5 institutions from 2008–2012. Median follow-up of patients still alive was 30 months.
Results: Patients were ≤49 (29%), 50-59 (25%), 60-69 (26%), and ≥70 (20%) years old. Cytogenetic-molecular risks were favorable (21%), intermediate I and II (36%), or unfavorable (43%) per European Leukemia Net classification. Induction treatments were non-intensive in 18% and intensive in 81% of patients. Using the composite risk model, 17% of patients had scores of 2-4, 37% scores 5-7, 27% scores 8-10, and 19% scores ≥11. As shown before (Blood 2015 126:532), hazard ratios (HR) for mortality increased with increasing scores. Patients with the lowest scores (2-4) almost always received intensive therapies (98%), and were therefore omitted from the comparison analysis. Table 1 shows distribution of regimen intensity per patient age groups: the proportion of patients receiving non-intensive therapy increased with increasing age. Patients with scores 5-7, 8-10, and ≥11 had statistically significantly higher survival rates when given intensive *versus* non-intensive therapies (Table 2). We also looked at outcomes specifically among patients 70-79 years old given intensive (46%) or non-intensive (54%) therapies. Intensive therapies among those older patients resulted in statistically significantly higher survival rates at 2-year (27% *versus* 11%, HR: 0.72, *P*=0.05, Figure 1).

Table 1. Regimen intensity per patient age groups.

Age, years	Total n	Intensive, %	Non-intensive, %
≤49	172	99	1
50-59	215	95	5
60-69	194	80	20
70-74	73	59	41
75-79	53	40	60
80-88	19	5	95

Table 2. Comparisons of hazard ratios (HR) and 2-year rates of survival between intensive and non-intensive first induction therapies.

Pt group	Variable	% of pts		Survival rates		HR	*P*
		Intensive, %	Non-intensive, %	Intensive, %	Non-intensive, %		
Composite scores	5-7	90	10	55	30	0.51	0.005
	8-10	83	17	36	19	0.63	0.02
	≥11	56	34	23	6	0.61	0.008

Summary/Conclusions: Intensive therapy leads to better long term survival even in older patients with significant co-morbidities. Early mortality is not increased in older patients given intensive rather than non-intensive induction therapy, likely due to improvements in supportive care over time. While we cannot exclude the effects of selection bias, our model accounted for the principal covariates associated with outcome. Absent a randomized trial comparing intensive and non- intensive therapies, our results suggest that the former should be offered to all patients up to the age of 80 regardless of their comorbidity burden. Prospective randomized studies are needed to investigate the role of non-intensive therapies in older patients in light of their comorbidity burden. Studies

of physical, cognitive, and social health might further identify groups of patients for whom non-intensive therapies could yield survival benefit.

NOVEL LEUKEMIA STEM CELL-TARGETED THERAPY FOR ACUTE MYELOID LEUKEMIA BASED ON DUAL INHIBITION OF EZH1/EZH2

I Kitabayashi*, S Fujita[1], E Takamatsu[1], D Honma[2], N Adachi[2], I Atsushi[3], K Araki[2]

[1]Division of Hematological Malignancy, National Cancer Center Research Institute, [2]Oncology Research Laboratories, Daiichi Sankyo Co., Ltd, [3]Department of Cellular and Molecular Medicine, 1Division of Hematological Malignancy, Tokyo, Japan

Background: Despite great progress in curing acute leukemia and malignant lymphoma, survival after relapse remains poor. The essential cause of the relapse following conventional chemotherapy is a remaining population of drug-resistant cancer stem cells (CSCs).

Aims: Thus, selective targeting of LSCs is a promising strategy for preventing relapse. The polycomb repressive complex 1 (PRC1) and 2 (PRC2) regulate ubiquitination of histone H2A at lysine 112 (H2AK112) and trimethylation of histone H3 at lysine 27 (H3K27), respectively. We report here that RING1A/B and EZH1/2, which are catalytic subunits of PRC1 and PRC2, are essential for maintenance of CSCs.

Results: We report here that RING1A/B and EZH1/2, which are catalytic subunits of PRC1 and PRC2, are essential for maintenance of CSCs. Using Ezh1-null, Ezh2-conditional and their double knock-out mice, we examined the effects of genetic deletion of EZH1/2 on AML. and found that double deletion of Ezh1/2 induced cell differentiation and apoptosis more severely than single deletions *in vitro* in all subtypes of AML. In AML mice models, deletion of Ezh1/2 induced differentiation of AML cells and complete remission of AML, which was not achieved by single deletion of Ezh1 or Ezh2. Interestingly, the number of CSCs, especially quiescent CSCs, dramatically reduced after deletion of both Ezh1 and Ezh2. However, such strong effects were not observed after deletion of either Ezh1 or Ezh2. We have developed potent and specific inhibitors against both EZH1 and EZH2, and found that the EZH1/2 dual inhibitor induced cell differentiation and apoptosis in most subtypes of AML tested *in vitro*, but a selective EZH2 inhibitor did not affect the growth and survival of AML cells. Oral administration of the EZH1/2 dual inhibitor selectively reduced the number of CSCs and prolonged the survival of the AML mice. Moreover, combination of the EZH1/2 dual inhibitor and Ara-C prolonged survival more dramatically. The dual inhibitor was also effective on treatment of malignant lymphomas in xenograft models.

Summary/Conclusions: Taken together, these results strongly suggest that dual inhibition of EZH1 and EZH2 is a promising therapeutic strategy to eradicate CSCs in a wide range of AMLs. Based on these results we have initiated Phase I clinical trial of the dual inhibitor in malignant lymphoma and we are preparing for AML.

LB582

IMGN632: A NOVEL ANTIBODY-DRUG CONJUGATE (ADC) OF A CD123-TARGETING ANTIBODY WITH A POTENT DNA-ALKYLATOR IS HIGHLY ACTIVE IN PRECLINICAL MODELS OF AML WITH POOR PROGNOSIS

Y Kovtun*, G Jones, L Harvey, L Rui, C Audette, F Liu, C Bai, A Wilhelm, NC Yoder, S Adams, VS Goldmacher, R Chari, T Chittenden
ImmunoGen., Inc., Waltham, United States

Background: Targeted delivery of cytotoxic molecules by ADCs recognizing cancer-specific antigens is a promising therapeutic approach. CD123, the IL-3 receptor alpha-subunit, is an attractive cancer target implicated in AML cell survival and proliferation. CD123 is universally expressed on AML blasts, is differentially expressed on AML stem cells relative to normal hematopoietic cells, and is associated with aggressive disease. Here, we report the preclinical evaluation of IMGN632, a novel conjugate of a humanized anti-CD123 antibody with a payload that alkylates DNA without cross-linking.

Aims: Evaluate the activity of IMGN632 in preclinical AML models

Methods: Anti-CD123 antibodies were generated in mice by immunization with a cell line expressing human CD123. The number of CD123 antigens per cell, MDR activity, cell cycle profile and markers of cell death were assessed by flow cytometry on AML cell lines and primary cells from AML patients. Cytotoxicity of the ADC was evaluated on AML cell lines after continuous exposure up to 7 days, and on primary AML patient samples by colony formation after 1-day exposure. Antitumor activity *in vivo* was assessed in immuno-deficient mice bearing human AML xenografts.

Results: We generated a high-affinity anti-CD123 antibody that blocks IL-3-dependent proliferation of AML cells more effectively than previously reported antibodies, and binds to a distinct epitope on the CD123 extracellular domain. The antibody was humanized and engineered so that two cysteine residues were incorporated into its constant region. The payload, an indolino-benzodiazepine dimer containing a mono-imine, was attached to the cysteines via a peptide linker, yielding the conjugate, IMGN632, with two payload molecules per antibody. Following internalization of IMGN632 into CD123 expressing cells the highly cytotoxic payload is released intracellularly. The payload alkylates DNA leading to cell cycle arrest and apoptosis-mediated cell death. IMGN632 was effective at killing twelve human AML cell lines expressing CD123 levels comparable to those of AML patients and carrying one or more known poor prognosis markers for AML (FLT3-ITD, EVI1 overexpression, P53 mutation or high MDR), generating IC_{50} values between 0.5 and 120 pM (median 3 pM). IMGN632 was inactive in CD123-negative cell lines at these concentrations. Anti-leukemic activity of IMGN632 and gemtuzumab ozogamicin (GO), the latter once approved for the treatment of relapsed/refractory AML, were compared *in vitro* in primary AML patient samples (n=15), including four from relapsed/refractory AML patients and seven with strong MDR activity. GO demonstrated variable activity killing 90 percent of AML cells at concentrations between 30 and 30,000 pM (median 1,000 pM). In contrast, IMGN632 was highly active in all samples killing at 100-fold lower concentrations, IC_{90} from 3 to 46 pM (median 14 pM). A non-targeted control ADC was inactive at 1,000 pM. *In vivo*, a single 70 mcg/kg IMGN632 dose resulted in durable complete responses in 5/6 mice bearing MV4-11 subcutaneous xenografts (FLT3-ITD AML model). Likewise, a single 240 mcg/kg IMGN632 dose reduced tumor burden in 6/6 mice bearing Kasumi-3 disseminated xenografts (AML line with P53 mutation and MDR overexpression). Corresponding payload-matched doses of a non-targeted ADC were inactive. IMGN632 was well tolerated at these doses.

Summary/Conclusions: IMGN632 exhibits potent *in vitro* and *in vivo* activity against AML cell lines and patient samples, including those with poor prognostic markers. These findings support advancing IMGN632 into clinical trials.

Genomic complexity in CLL

LONGITUDINAL EVALUATION OF T-CELLS IN CLINICAL MONOCLONAL B-CELL LYMPHOCYTOSIS (MBL)

SA Parikh[1,*], AG Ramsay[2], J Boysen[1], C Lesnick[1], W Ding[1], K Medina[3], N Ioannou[2], DF Jelinek[4], SL Slager[5], NE Kay[1], TD Shanafelt[1]
[1]Hematology, Mayo Clinic, Rochester, United States, [2]King's College, London, United Kingdom, [3]Immunology, Mayo Clinic, Rochester, [4]Immunology, Mayo Clinic, Scottsdale, [5]Health Sciences and Research, Mayo Clinic, Rochester, United States

Background: Patients with chronic lymphocytic leukemia (CLL) have significant abnormalities in the circulating T-cell compartment – including an increase in the circulating CD8+ T-cells (particularly of the exhausted phenotype), dysregulated cytokine production, and defective immunological synapse formation with antigen-presenting cells. It is not known if these defects are also present in individuals with clinical MBL, a precursor condition to CLL.
Aims: We sought to perform a comprehensive and longitudinal analysis of circulating T-cells in individuals with clinical MBL.
Methods: Using peripheral blood mononuclear cells of individuals with MBL stored in the Mayo Clinic Tissue Bank, we performed 8-color flow cytometry to comprehensively evaluate T-cell subsets (CD4+ and CD8+ naïve, effector, effector memory and central memory cells). We performed these analyses at the time of MBL diagnosis and at a second time point (median of 48 months later) in 18 individuals with MBL. We also evaluated the immunological T-cell synapse at these two time points. We compared these results to age-matched healthy adults (n=5) using the Kruskal-Wallis test. The Mayo Clinic IRB approved this study.
Results: *Analyses at MBL diagnosis:* No difference in the absolute CD4+ count or major CD4+ subsets were observed between controls and individuals with MBL at ascertainment. In contrast, the absolute CD8+ count was significantly higher in individuals with MBL relative to controls (median $0.5x10^9$/L *vs* $0.2x10^9$/L; p=0.03), mostly due to higher CD8+ effector memory cells. No difference in naïve, effector and central memory CD8+ T-cells were observed at ascertainment. *Sequential Studies :* After a median follow-up of 48 months, 9 individuals experienced an expansion of the B-cell clone (Group 1, median absolute lymphocyte count [ALC] increased from $7.5x10^9$/L to $39.0x10^9$/L at time point 2). In the remaining 9 individuals there was no expansion of the B-cell clone (Group 2, median ALC was $7.3x10^9$/L at time-point 1 and $8.7x10^9$/L at time-point 2). Among individuals in Group 1 who had expansion of the B-cell clone, a statistically significant increase in absolute CD4+ central memory, CD4+ effector memory, all CD8+ T-cell subsets (naïve, effector, effector memory and central memory), and exhausted T-cells (CD8+PD1+) was observed at time-point 2. In contrast, among the 9 MBL individuals in Group 2 who had no expansion of the B-cell clone, there were no significant differences in the distribution of CD4+ and CD8+ T-cell subsets at time point 2 compared to MBL diagnosis. We next analyzed differences in T-cell subsets at the time of MBL diagnosis between individuals in Group 1 and 2. The absolute CD8+PD1+ count was significantly higher at MBL ascertainment among individuals in Group 1 compared to those in Group 2 ($0.08x10^9$/L *vs* $0.02x10^9$/L, p=0.01); suggesting that individuals with a higher proportion of exhausted T-cells at diagnosis are more likely to experience expansion of the B-cell clone. *Immunological T-cell Synapse Studies:* As shown in Figure 1a, immunological T-cell synapse function was significantly worse in individuals with MBL compared to age-matched healthy controls. The synapse function also got progressively worse as the B-cell clone expanded among individuals in Group 1 (Figure 1b). In contrast, there was no worsening of synapse function in individuals in Group 2 (Figure 1c), suggesting that the decline in the function of T-cells was directly proportional to an increase in the size of B-cell clone.

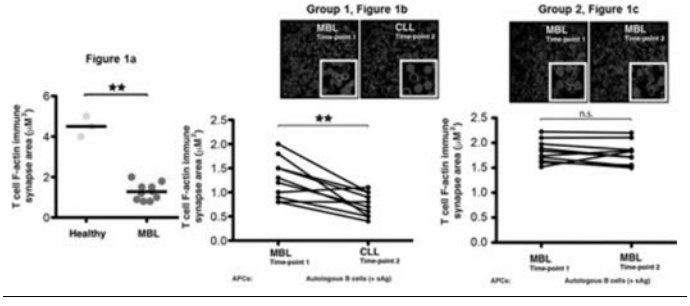

Figure 1.

Summary/Conclusions: Consistent with CLL, there is an expansion of CD8+ T-cells in MBL individuals at the time of ascertainment. MBL individuals who have a higher proportion of exhausted T-cells at diagnosis are more likely to develop an expansion of the B-cell clone over time. Finally, for the first time we demonstrate that T-cells from MBL exhibit impaired immune synapse formation and this functional defect worsens as the size of the B cell clone expands.

P581

COPY NUMBER ANALYSIS OF THE BIRC3 GENE BY DROPLET DIGITAL PCR IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH 11Q DELETION

S Raponi[1,*], I Del Giudice[1], C Ilari[1], L Cafforio[1], A Piciocchi[2], M Marinelli[1], M Messina[1], FR Mauro[1], GM Rigolin[3], F Rossi[4], M Dal Bo[4], A Cuneo[3], G Gaidano[5], V Gattei[4], A Guarini[1], R Foà[1]
[1]Cellular Biotechnologies and Haematology, Sapienza University of Rome, [2]Gimema Data Center, Gimema Foundation, Rome, [3]Azienda Ospedaliero-Universitaria Arcispedale S.Anna, University of Ferrara, Ferrara, [4]Clinical and Experimental Onco-Hematology, Centro di Riferimento Oncologico, Istituto di Ricovero e Cura a Carattere Scientifico, Aviano, [5]Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: Chronic lymphocytic leukemia (CLL) with 11q deletion (11q-) has been associated to a poor prognosis, but the clinical course of patients carrying this lesion is variable. The minimal deleted region (MDR) includes *ATM* and can also include *BIRC3*, a gene often deleted or mutated in advanced/chemorefractory CLL. The prognostic implications of *BIRC3* disruption in addition to *ATM* deletion are not well defined. We have previously conducted a study on *BIRC3* gene in 55 untreated 11q- CLL patients using Cytoscan HD array (Affymetrix) for copy number aberration (CNA) analysis. *BIRC3*, rarely mutated, was deleted in 82% of cases and the biallelic lesion (D+M) was associated with a marked hyperleukocytosis at diagnosis and immediate need of treatment.
Aims: In order to expand these preliminary observations, the study was extended to an additional cohort of 43 11q- CLL patients using the innovative droplet digital PCR (ddPCR) technique for *BIRC3* CNA.
Methods: Genomic DNA was extracted from peripheral blood samples of 43 untreated 11q- CLL. *BIRC3* CNA was performed utilizing the QX200™ Droplet Digital™ PCR System (Bio-Rad) that represents a useful tool to screen known lesions with high accuracy and to provide an absolute quantification of a given target locus relatively to a reference locus. Data were analyzed using the QuantaSoft software and CN value was computed by the ratio between the FAM-target (*BIRC3*) and the HEX-reference (*KBTBD*, centromeric probe on chr 11) molecule concentrations, times to the number of copies of reference species in the genome (*i.e.* [*BIRC3*]/[*KTBD*]*2). By a serial dilution experiment of a CLL case with 95% 11q- by FISH and by preliminary tests on CLL with different types and amounts of FISH lesions, ddPCR proved capable of identifying a deletion when present in at least 10% of CLL cells and to confirm FISH results in 100% of cases. *BIRC3* mutations (exons 6-9) were evaluated by Sanger sequencing. Time-to-first treatment (TFT) was calculated from the date of diagnosis to the date of first therapy or last follow-up.
Results: Given the comparable biological and clinical features of both cohorts, as well as the superimposable TFT (median TFT: 12.3 *vs* 12 months; p=0.36), the 98 11q- CLL patients were pooled together. Their baseline characteristics are reported in Table 1. All patients showed 11q- by FISH (median 70.5%, range 10-99% of nuclei). *BIRC3* was included in the deleted region in 74/98 cases (75.5%) and was mutated in 7/97 (7.2%), being always deleted on the other allele (D+M). After a median follow-up of 70.5 months (range 7.4-235.9), 77/91 evaluable patients have undergone treatment (median TFT 15.6 months, range 0.2-235.9). *BIRC3* deleted cases showed a TFT not significantly different from that of WT cases. Conversely, *BIRC3* D+M lesions was associated with a shorter TFT compared to that of *BIRC3* deleted/WT cases (median TFT 2.3 *vs* 16.3 months, p<0.0001). Notably, *BIRC3* D+M cases had a marked hyperleukocytosis at diagnosis significantly different from *BIRC3* deleted/WT cases (p<0.0001). Finally, 6/7 cases with *BIRC3* D+M required treatment soon after diagnosis.

Table 1. Clinical and biological characteristics of 98 11q- CLL patients.

Gender (M/F)	73/25
Age (range)	61.5 (38-83)
WBCx10^9/L (range)	41.7 (7-302.8)
Stage A/B/C/NA	43/36/9/10
IGHV UM/M	67/31
FISH: 11q- only	42
11q- with 17p-	1
11q- with +12	6
11q- with 13q-	49
BIRC3 mutation*	7
NOTCH1 mutation*	9
SF3B1 mutation*	8
TP53 mutation*	2

*All mutually exclusive with only 1 case harboring both *SF3B1* and *BIRC3* mutations.

Summary/Conclusions: Among untreated CLL with 11q-: 1) *BIRC3* deletion represents a common event (75%), whilst the mutation is rare (7%); 2) *BIRC3* deletion does not seem to influence TFT of 11q- CLL; 3) *BIRC3* D+M is strongly associated with a short TFT; 4) *BIRC3* D+M is mostly associated to an immediate need of treatment and to a marked hyperleukocytosis at diagnosis. ddPCR

represents a handy tool to screen a known CNA with a good sensitivity and accuracy, resulting in a cost-effective approach.

P582

CLONAL EVOLUTION IN CLL IS ASSOCIATED WITH AN UNMUTATED IGHV STATUS, MUTATED TP53 AND SHORTER SURVIVAL

C Haferlach*, S Jeromin, N Nadarajah, M Zenger, W Kern, T Haferlach
Munich Leukemia Laboratory, Munich, Germany

Background: CLL is a clinically heterogeneous with a course ranging from stable disease for many years to a rather rapid progression requiring treatment. During recent years several genetic parameters have been identified which are associated with progression of the disease. Clonal evolution (CE) on the genetic level is likely to correlate with clinical progression and might be used as a predictor and thus guide treatment strategies.
Aims: The aim of this study was to evaluate the frequency of clonal evolution on the cytogenetic level and its association with the *IGHV* mutation status, *TP53* mutations and clinical outcome.
Methods: 789 CLL cases were selected on the basis that chromosome banding analysis (CBA) had been performed at least at two time points. The median age at first evaluation was 72 years (range: 29-95 years). The first time point of analysis was at primary diagnosis or prior to any treatment in all patients. A total of 1902 CBA were evaluated. The median number of samples per patient was 2 (range: 2-9). The time between samples ranged from 1 months to 118 months (median 17 months). In all patients interphase FISH was performed with probes for 17p13 (*TP53*), 13q14 (D13S25, D13S319, *DLEU*), 11q22 (*ATM*), the centromeric region of chromosome 12 and t(11;14)(q13;q32) (*IGH-CCND1*). In 464 patients both *TP53* mutations and *IGHV* mutation status were evaluated. For 254 of these patients also clinical follow-up data was available. Median follow-up was 64 months and 5-year overall survival (OS) was 88.8%.
Results: At first investigation CBA revealed a normal karyotype in 134 (17%) patients. In cases with an aberrant karyotype the pattern of abnormalities was typical for CLL. CE was observed in 243/789 patients (31%). The median time to CE was 30 months (range 1.5-112 months). The most frequent abnormalities gained during CE observed in >10% of cases were gains of 2p (n=48), 8q (n=53), 13q (n=35), 17q (n=27) and losses of 6q (n=33), 8p (n=52), 11q (n=40), 13q (n=70), and 17p (n=95). In the total cohort an unmutated *IGHV* status was present in 61% of cases and was significantly more frequent in patients with CE (76.5% *vs* 59.4%, p<0.001). *TP53* mutations were detected in 15% of cases in the total cohort and were more frequent in patients in whom CE was observed (25.5% *vs* 10.2%, p<0.001). In the cohort of patients with clinical follow-up data, 70 of 87 (80.5%) patients with CE received therapy during the course of the disease, whereas in patients without CE this was the case in 112/167 (67.1%) (p=0.028). Patients in whom CE was observed had a tendency for shorter OS as compared to those without (5-year OS 84.8% *vs* 90.9%, p=0.07). While no impact of CE was observed in patients with a mutated *IGHV* status, in patients with an unmutated *IGHV* status 5-year OS was 82.8% in cases with CE compared to 92.1% to those without (p=0.05) (Figure 1).

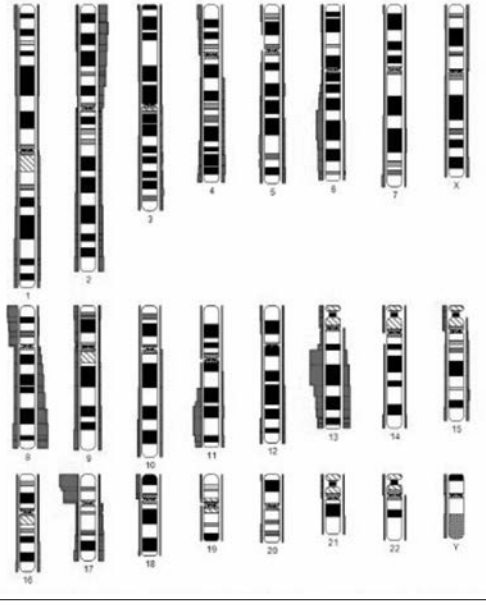

Figure 1. Pattern of chromosome abnormalities acquired during clonal evolution: gained regions are depicted in green to the right and lost regions in red to the left.

Summary/Conclusions: We observed clonal evolution in 31% of CLL patients who were analyzed during the course of their disease. Loss of 17p, 8p and 13q as well as gain of 8q and 2p were the most frequently gained chromosome abnormalities. Clonal evolution was associated with *TP53* mutations and an unmutated *IGHV* status and with inferior OS in particular in patients with an unmutated *IGHV* status. The frequency and impact of clonal evolution needs to be further evaluated in unselected patient cohorts in which chromosome banding analysis is performed on a regular basis.

EPIGENETIC REGULATION OF ROR1 IN CHRONIC LYMPHOCYTIC LEUKEMIA DEFINES PREFERABLE TARGET FOR COMBINED EPIGENETIC AND IMMUNE THERAPY

K Skorka[1,*], M Karp[1], E Zakrzewska[1], J Zaleska[1], M Zajac[1], A Karczmarczyk[1], J Purkot[1], W Tomczak[2], P Wlasiuk[1], D Matosiuk[3], K Giannopoulos[1,4]
[1]Department of Experimental Hematooncology, [2]Department of Hematooncology and Bone Marrow Transplantation, [3]Department of Synthesis and Technology of Pharmaceutical Substances, Medical University of Lublin, [4]3Department of Hematooncology, St John's Cancer Center, Lublin, Poland

Background: Definition of leukemia-associated antigens (LAA) expression represents a pivotal step towards inventing new and effective immunotherapy strategies for chronic lymphocytic leukemia (CLL). Expression of LAA could be epigenetically regulated, influencing thereby immune responses to defined LAA. In other tumors, 5-azacytydine effectively increased expression of cancer/testis antigens. Increased expression of LAA under 5'azacytidine exposure might augment immunogenicity of these antigens inducing more effectively anti-LAA cytotoxic immune response. ROR1 might be a specific neo-antigen and may serve as a target for immunotherapy. Moreover spontaneous anti-ROR1 humoral as well as a T cell responses were observed in CLL patients.
Aims: To define effect of 5'azacytidine therapy on expression of LAA and generation of ROR1-specific T-cell responses in CLL patients towards identification of preferable target for future combined epigenetic and immunotherapy approaches in CLL.
Methods: Expressions of *ROR1* and other LAA encoded by *ACTB, FMOD, PLIN2, NFXD1, BAGE, CTAG1B, GAGE1 PRM1, WT1, MAGEA1, MAGEA3* and *RPSAR* in CLL were assessed in 111 CLL patients and 29 H*Vs* using qRT-PCR. Next, the influence of 5μM 5'azacytidine in 24-hours cell cultures of mononuclear cells on the LAA expression was analyzed. Expression of genes encoding LAA were normalized using constitutive gene *GAPDH.* For functional experiments we chose ROR1 since it might represent preferable target for immunotherapy. Mixed lymphocyte peptide cell cultures followed by ELISpot assays for specific interferon gamma release were performed to determine influence of 5'azacytidine on generation of the cytotoxic ROR1-specific T-cell responses in CLL patients and H*Vs* with the expression HLA-A*0201 (as assessed by flow cytometry).
Results: We found expression of the following genes with the median 1/ΔCt of: *ROR1*=0.105, *FMOD*=0.203; *PLIN2*:=0.151; *NFXD1*=0.070; *BAGE*=0.067, *ACTB*=-0.359, *RPSAR*=0.102 and no expression of the *CTAG1B* and *GAGE1* in all CLL cases. We observed low expression of *PRM1* and *WT1* in minority of CLL patients with the median 1/ΔCt of: 0.007 and 0.056 respectively. Higher *RPSAR, FMOD, BAGE* expressions in CLL than HV (median 0.102 *vs* – 0.505, p<0.001; median 0.203 *vs* 0.060, p<0.001; median 0.067 *vs* 0.0001, p<0.001 respectively), and lower expression of *PLIN2* in CLL that HV group (median 0.151 *vs* 0.439) were found. Increased expression of *ROR1, RPSAR, FMOD* after exposure to 5'azacytidine was observed. In functional experiments we found 5'azacytidine led to effective induction of LAA-specific T-cell cytotoxic responses against peptides encoded by *ROR1.*
Summary/Conclusions: This study provides the evidence that LAA are differentially expressed and regulated in CLL. Although *RPSAR*, *FMOD*, *BAGE* showed highest expression in CLL as compared to HV, increased expression of *ROR1, RPSAR, FMOD* was observed after exposure to 5'azacytidine. Moreover, 5'azacytidine effectively augmented anti-*ROR1* cytotoxic T-cell responses. Therefore we could conclude that preferential immunotherapy could target ROR1 and its effectiveness could be augmented by the addition of 5'azacytidine to treatment.

COMPLEX KARYOTYPE AS IDENTIFIED BY CHROMOSOME BANDING ANALYSIS IS ASSOCIATED WITH SHORTER OVERALL SURVIVAL IN CLL INDEPENDENT OF TP53 ALTERATION AND IGHV MUTATION STATUS

C Haferlach*, S Jeromin, T Alpermann, W Kern, T Haferlach
Munich Leukemia Laboratory, Munich, Germany

Background: In standard CLL routine diagnostics interphase-FISH, *TP53* mutation analysis and the evaluation of the *IGHV* mutation status are performed.

Since cultivation of CLL cells was improved by stimulation of CLL cells *in vitro* with DSP30 and IL2 chromosome banding analysis (CBA) is more often performed in CLL. Rigolin *et al.* (Blood 2012) demonstrated that CBA adds prognostic information in CLL patients with "normal" karyotype as determined by interphase-FISH. Recently, Thompson *et al.* (Cancer 2015) reported that a complex karyotype is a stronger predictor than 17p deletion for an inferior outcome in relapsed or refractory CLL patients treated with ibrutinib-based regimens.

Aims: The aim of this study was to evaluate the impact of complex karyotype on overall survival (OS) in CLL patients.

Methods: The basis of this study were 1046 CLL cases evaluated at diagnosis or prior to first therapy. Median age was 67 years (range: 30-89 years). Bone marrow or blood samples were analyzed by CBA and FISH with probes for 17p13 (*TP53*), 13q14 (D13S25, D13S319, *DLEU*), 11q22 (*ATM*), the centromeric region of chromosome 12 and t(11;14)(q13;q32) (*IGH-CCND1*). Further, the *TP53* and *IGHV* mutation status was determined in all patients. Overall survival was evaluated from time of analysis to death or last follow up. For all patients follow up data was available with a median follow up of 68 months.

Results: In order to determine the impact of complex karyotype patients were categorized according to the number of chromosome abnormalities (CA) detected per case. None, 1, 2, 3, 4 and ≥5 abnormalities were observed in 228 (21.8%), 449 (42.9%), 208 (19.9%), 72 (6.9%), 36 (3.4%), and 53 (5.1%) cases, respectively. In 46 (4.4%) cases a *TP53*/17p deletion was identified by FISH and in 76 (7.3%) *TP53* mutations by sequencing. 39 patients carried both a *TP53* deletion and a *TP53* mutation, while in 963 (92.1%) no *TP53* alterations were detected. A significant association was observed between the number of CA and *TP53* alterations: 0-2 CA: 5.5%, 3 CA: 11.1%, 4 CA: 13.9%, and ≥5 CA 39.6% (p<0.001). The number of CA was also associated with an unmutated *IGHV* status (0-2 CA: 35.9%, 3 CA: 52.8%, 4 CA: 50%, and ≥5 CA 66% (p<0.001)). In the total cohort OS at 5 years differed significantly according to the number of CA (0-2 CA: 84.8%, 3 CA: 83.7%, 4 CA: 77.7%, ≥5 CA: 52.6%, p<0.001). Three different definitions for complex karyotypes were evaluated: CK3: ≥3 CA, CK4: ≥4 CA, and CK5: ≥5 CA. We tested the impact of complex karyotype on OS separately in patients with and without *TP53* alterations. In patients without a *TP53* alteration OS at 5 years was significantly lower in cases harboring a complex karyotype than in those without a complex karyotype (CK3: 80.3% *vs* 86.4%, p=0.03; CK4: 73.6% *vs* 86.4%, p=0.004; CK5: 66.4% *vs* 86.3%, p=0.001). Also in patients with *TP53* alterations a complex karyotype was associated with a negative impact on OS (OS at 5 years: CK3: 41.0% *vs* 59.6%, p=0.01; CK4: 35.7% *vs* 59.4%, p=0.01; CK5: 31.3% *vs* 59.1%, p=0.002). In multivariate Cox regression analysis an independent negative impact on OS was identified for *TP53* deletion (relative risk (RR): 3.1, p=0.001), *TP53* mutation (RR: 1.7, p=0.05), number of chromosome abnormalities (RR: 1.1 per CA, p=0.006) and unmutated *IGHV* status (RR: 2.0, p<0.001).

Summary/Conclusions: Although karyotype complexity is associated with *TP53* alterations and an unmutated *IGHV* status, the number of chromosome abnormalities as determined by chromosome banding analysis is an independent negative prognostic parameter in CLL.

P586

IMPROVING THE DIFFERENTIAL DIAGNOSIS OF CD5+ B-LYMPHOPROLIFERATIVE DISORDERS

A Rawstron[1,*], RM de Tute[1], J Shingles[1], L Gorman[1], K Turner[1], PA Evans[1], SL Barrans[1], SJ O'Connor[1], C Burton[1], RG Owen[1], P Hillmen[2]
[1]HMDS, St. James's Institute of Oncology, [2]LICAP, University of Leeds, Leeds, United Kingdom

Background: The multidisciplinary diagnosis of CD5+ B-lymphoproliferative disorders (B-LPD) can be challenging because there is significant overlap in the clinical, cellular/immunophenotypic and molecular features. There is no pathognomonic molecular abnormality in CLL: deletion of 13q14 is present in approximately half of CLL cases but is also present in more than 10% of MCL as well as other B-LPD. The presence of a CCND1/IGH in a monoclonal CD5+ B-LPD indicates a diagnosis of MCL. The MYD88 L265P mutation is a gain-of-function driver mutation present in the majority of WM/LPL and <5% of CLL cases. An immunophenotypic scoring system is often used to facilitate differential diagnosis but markers such as CD200 & ROR1 may permit a more reproducible diagnosis, particularly when considering recently identified signalling pathway abnormalities.

Aims: To compare immunophenotypic scoring with a diagnostic panel comprising CD200 and ROR1 the differential diagnosis of CD5+ B-LPD

Methods: Analysis was performed on 3082 sequential cases (1041 diagnosis, 2041 follow-up) pre-treatment or relapse). Flow cytometry (5x8-CLR tubes with CD19 & CD20 as a backbone combined with 38 markers including CD5, CD23, κ, λ, CD79b, CD43, CD200 and ROR1) and morphological evaluation was performed in all cases with immunohistochemistry in 1058/3082; molecular analyses were determined by the clinical details and immunophenotype. The final diagnosis was determined by a multidisciplinary team review of all the available data with input from haematopathologists, clinicians, and radiologists. An immunophenotypic score of 0-5 was calculated separately assigning 1 point for expression of CD5 or CD23 and 1 point for weak or no expression of CD79b or sIg or CD20.

Results: A learning set comprising 1172 cases showed ROR1 was expressed in 97.1% of CLL (639/658), 71.7% of MCL (33/46), 23.1% of HCL (6/26), 21.9% of WM/LPL/MZL (75/342), 9.5% of DLBL (4/42), and 3.4% of FCL (2/58). The markers contributing most to the differential diagnosis of CLL *vs* MCL were CD20, CD23, and CD200 (specificity 91.3%, 82.6% and 78.3% respectively). CD23 was expressed in 17.3% (8/46) MCL cases; co-expression of CD200 and CD23 was evident in 8.7% (4/46) MCL cases. The markers contributing most to the differential diagnosis of CLL *vs* WM/LPL/MZL were CD20, ROR1, and CD43 (specificity 83.0%, 78.1% and 70.5% respectively). CD43 and ROR1 were frequently expressed in MCL and so did not help to differentiate CLL *vs* MCL. Similarly CD200 was frequently expressed in WM/LPL/MZL (69.9%, 239/342) and did not contribute to the differential diagnosis of CLL *vs* WM/LPL/MZL. Overall the protein expression profiles that showed specificity for differential diagnosis of CLL *vs* other disorders were CD5, CD23, CD43, ROR1 and CD200 expression with weak CD20, CD81 and surface immunoglobulin/CD79b expression (Figure 1A). This profile was compared with a scoring system in a validation set (n=1469): cases scoring 5 included a small proportion with a CCND1/IGH translocation; cases scoring 4 had a similar incidence of CCND1/IGH and MYD88 abnormalities as cases with a score of 1-3 (Figure 1B). Cases with a fully characteristic immunophenotype had no detectable CCND1/IGH translocations; 2/66 had a MYD88 mutation & both had a CD5-negative MBL in addition to the dominant CLL-phenotype population. Other CD5+CD23+ cases had a high incidence of CCND1 or MYD88 abnormalities.

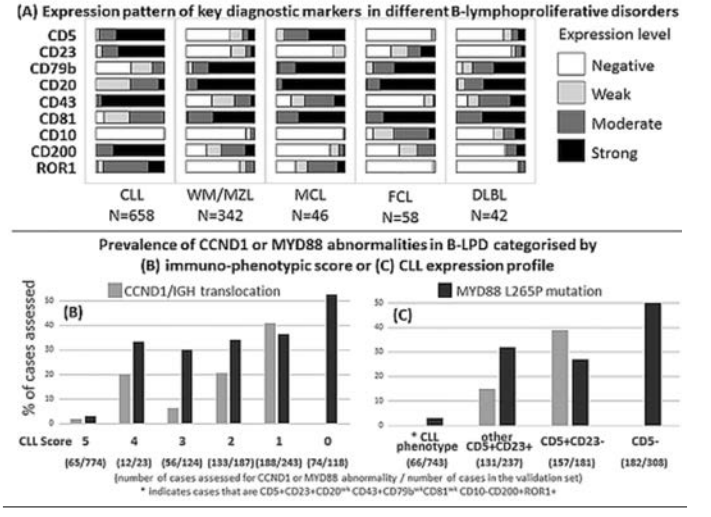

Figure 1.

Summary/Conclusions: A scoring system is suboptimal for diagnosis when additional pathway abnormalities such as MYD88 mutations are taken into account, particularly if cases with a score of 4 or 3 are included. The detection of a MYD88 mutation in a case with a characteristic CLL immunophenotype is frequently associated with the presence of an additional neoplastic non-CLL B-cell population. This study is limited by the fact that molecular testing was guided by immunophenotypic analysis and we are currently assessing sequential cases to determine the incidence CCND1/MYD88 pathway abnormalities in a larger series of cases with a homogeneous phenotype. However the results clearly demonstrate that lack of ROR1 expression in a CD5+CD23+ B-LPD is associated with a high incidence of MYD88 pathway abnormalities; this may represent a group of disorders with biological features intermediate between CLL and WM that should be characterised further.

Anna, University of Ferrara, Ferrara, Italy, [3]Department of Biomedical Informatics, Center for Computational Biology and Bioinformatics, Columbia University, New York, United States, [4]GIMEMA Data Center, GIMEMA Foundation, Rome, [5]Laboratory for Technologies of Advanced Therapies (LTTA) and Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, [6]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: Chronic lymphocytic leukemia (CLL) patients with isolated dele-

tion at chromosome 13q (13q-) and devoid of *NOTCH1*, *SF3B1*, *BIRC3, TP53* clonal mutations represent a very low risk subgroup. Cytogenetics with novel mitogens has allowed to reveal chromosomal aberrations in regions uncovered by standard fluorescence *in situ* hybridization (FISH) in CLL and to identify novel genetic subgroups with prognostic relevance beyond known gene mutations (Rigolin *et al.,* GCC 2015).

Aims: To identify in CLL patients with a very low risk genetic profile - *i.e.* 13q- or normal FISH and devoid of *NOTCH1*, *SF3B1*, *BIRC3, TP53* mutations - karyotype (KT)-defined categories using novel mitogens and subclonal *TP53* mutations with the aim of further refining the identification at diagnosis of patients who may never require treatment and with a possible normal life expectancy.

Methods: A cohort of 106 CLLs with a very low risk genetic profile, as defined above, was selected from a series of consecutive CLL patients characterized at diagnosis. FISH and cytogenetics with novel mitogens were performed as described (Bardi *et al.,* J Biomed Biotechnol 2011). The mutational screening of *NOTCH1*, *SF3B1*, *BIRC3* and *TP53* was performed by Sanger sequencing. Subclonal *TP53* mutations were identified by ultra-deep sequencing on Genome Sequencer Junior (Roche-454 Life Sciences) and a dedicated bioinformatic analysis, as described (Rossi *et al.,* Blood 2014).

Results: The characteristics of CLL with 13q- only (n=62; 58.5%) or normal FISH (n=44; 41.5%), with no clonal gene mutations, were the following: 69 males, 37 females; median age 64 years (range 27-85); *IGHV* genes: mutated 72/96 (75%), unmutated 24/96 (25%). KT with novel mitogens was evaluable in 104/106 cases (98%). Overall, a normal KT was present in 39 cases (37.5%), 13q- only in 34 (32.7%), 1 or 2 lesions (other than 13q-) in 25 (24%), ≥3 lesions in 6 (5.8%). Complex KT or additional chromosomic lesions were not associated with the *IGHV* gene mutation status (37.5% of unmutated *vs* 30% of mutated cases). In particular, CLL with 13q- only by FISH and no gene mutations showed additional karyotypic lesions in 25.8% of cases (1-2 additional lesions in 14, ≥3 lesions in 2); CLL with normal FISH and no gene mutations showed karyotypic lesions in 34% of 42 evaluable cases (1-2 lesions in 11, >3 lesions in 4). After a median follow-up of 42.5 months (range 2.0-102.0), according to KT, very low risk CLL patients with normal KT/13q- only were associated with a significantly longer overall survival (OS) (p=0.0004) than cases with additional lesions/complex KT (Figure 1A). The same stratification held true even among 13q- (p=0.005) and normal FISH CLL (p=0.03) subgroups (Figure 1B). Time-to-first treatment (TFT) was significantly longer for very-low risk CLL with normal KT/13q- than for cases with additional lesions/complex KT in the whole series (p<0.0001) and within normal FISH CLL (p<0.0001). *TP53* subclonal mutations were identified only in 3/97 cases (3%), with a minor allele frequency of 0.015-0.03. All showed normal KT/13q-; 2 cases showed mutated *IGHV*. All are alive and 2 are still untreated at the last follow-up.

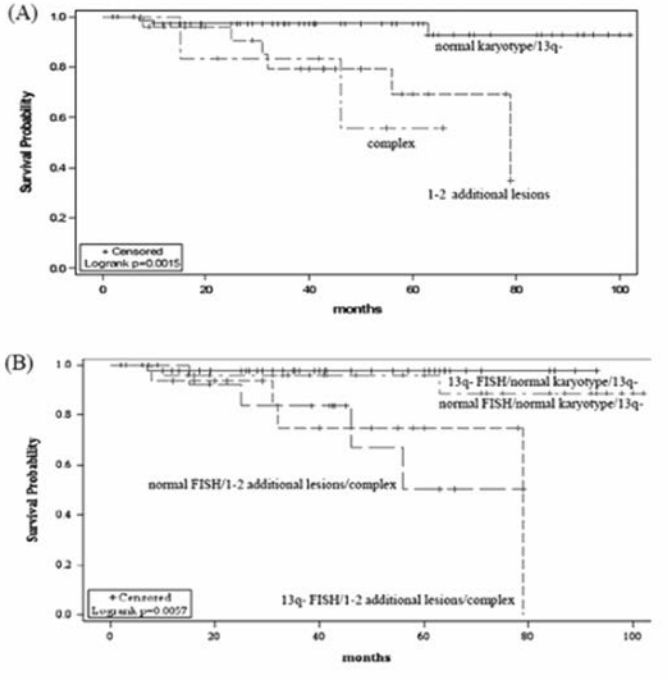

Figure 1.

Summary/Conclusions: In CLL patients belonging to a very low risk category by FISH and gene mutations, whilst *TP53* subclonal mutations are very rare and of uncertain significance, KT using novel mitogens further refines the prognostic stratification allowing to identify a subgroup of patients with excellent long-term prognosis and about 30% of cases with a worse outcome.

PRO-APOPTOTIC EFFECTS OF PRIMA-1MET CORRELATE WITH NOXA GENE INDUCTION IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

Z Jaskova[1,*], J Malcikova[1,2], J Smardova[3], Y Brychtova[1], M Doubek[1], M Trbusek[1]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, [2]Center of Molecular Medicine, Central European Institute of Technology, Masaryk University, [3]Department of Pathology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: *TP53* mutations represent the most adverse predictive and prognostic factor in chronic lymphocytic leukemia (CLL). We have previously shown that missense mutations located in central DNA-binding domain of p53 protein frequently lead to the accumulation of mutated p53 protein with presumably oncogenic properties. A small molecule involved in clinical trials, PRIMA-1^{MET}(Tocris Bioscience), has been declared to be able to change mutated p53 to its wild-type (wt) conformation with rescue of its activity.

Aims: To identify factors correlating with pro-apoptotic activity of PRIMA-1^{MET} in CLL cells.

Methods: Peripheral blood mononuclear cells from patients with CLL (proportion of leukemic cells >85%) were chosen from the *TP53* cohort characterized by the yeast functional analysis FASAY and direct sequencing. A metabolic WST-1 assay determined the viability of cells after PRIMA-1^{MET} treatment. The impact of 48h PRIMA-1^{MET} treatment on p53 protein level was analyzed by western blot (WB). The induction of pro-apoptotic p53 target genes was assessed by qRT-PCR.

Results: Initially, we assessed the effect of PRIMA-1^{MET} on viability of CLL cells. Both p53-mutated and p53-wt samples (n=12) responded by the clear concentration-dependent curve of viability within the concentration range 0.5-4μM; thus indicating that the observed PRIMA-1^{MET} effects on cell viability were p53-independent among the samples. The PARP1 protein cleavage observed in most of the tested samples (7 out of 12) confirmed apoptosis as the principal mechanism of cell death. Using 11 samples and treatment with 2μM and 4μM, we demonstrated that PRIMA-1^{MET} can readily eliminate (n=5) or partially reduce (n=4) high baseline level of mutated p53 protein. Next, we analyzed the expression of p53 target genes and detected a pronounced induction of *CDKN1A* (*p21*), *GADD45* and *PMAIP1* (*Noxa*) in all analyzed types of samples: (i) with strong accumulation of mutated-p53 protein, (ii) with null p53 protein resulting from a truncating *TP53* mutation, and (iii) in p53-wt samples. In addition, we observed a prominent inverse correlation between the final viability of CLL cells and *PMAIP1* induction after 4μM PRIMA-1^{MET} treatment (Spearman´s rho=-0.8462; p=0.0005). A similar effect was also noticeable for the viability of CLL cells and *CDKN1A* induction (Spearman´s rho=-0.6853; p=0.0139). In line with these findings, there was also a significant correlation between *PMAIP1* and *CDKN1A* inductions after 4μM PRIMA-1^{MET} treatment (Spearman´s rho=0.7413; p=0.0058).

Summary/Conclusions: In CLL cells, the PRIMA-1^{MET} is able to markedly diminish or even completely eliminate accumulated mutated p53 protein. However, all accompanying experiments suggest that the observed effects of PRIMA-1^{MET} towards apoptosis induction are in fact p53-independent in CLL cells. Currently, we addressed the question of whether other family members like the p73 protein can account for the observed effects.

PILOT STUDY TO ASSESS REAGENT AND INSTRUMENT QUALITY FOR REPRODUCIBLE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA: AN ESCCA AND ERIC HARMONISATION PROJECT

A Rawstron[*], KA Kreuzer, A Soosapilla, M Spacek, O Stehlikova, P Gambell, N McIver-Brown, K Psarra, M Arroz, R Milani, J de la Serna, CM Teresa, O Jaksic, JF Nomdedeu, C Moreno, GM Rigolin, A Cuneo, P Johansen, HE Johnsen, R Rosenquist, CU Niemann, W Kern, DA Westerman, M Trneny, SP Mulligan, M Doubek, S Pospisilova, P Hillmen, DG Oscier, M Hallek, P Ghia, E Montserrat
On behalf of the European Society for Clinical Cell Analysis (ESCCA) & European Research Initiative on CLL (ERIC), Barcelona, Spain

Background: The WHO and iwCLL diagnostic criteria for CLL rely on morphology and immunophenotype based on the co-expression of CD19/CD5/CD23 on B-cells with weak CD20 and monoclonal immunoglobulin expression. The current criteria have some limitations affecting reproducibility, particularly flexibility in marker expression with some centres using a scoring system that permits absence of CD5 or CD23. Through survey of 154 ERIC and ESCCA members involved in the diagnosis CLL, a consensus marker panel was identified, comprising CD19, CD5, CD23, CD20, Kappa and Lambda as a minimum (*i.e.* required for a diagnostic panel) with CD43, CD79b, CD81, CD10, CD200, and ROR1 also recommended for investigation. In addition, definitions for the expression pattern and performance characteristics of the proposed markers were developed that could potentially improve reproducibility of diagnosis across different centres.

Aims: To determine the feasibility of testing whether the proposed diagnostic markers meet the required performance characteristics in individual laboratories.
Methods: A gating strategy to identify the expression levels of component markers on normal peripheral blood lymphocytes was developed and distributed to participating laboratories who tested it on ten historical cases with polyclonal B-cells. The median fluorescence intensity for the relevant markers on defined positive and negative control populations were recorded and returned for central analysis where the relative signal value was calculated.
Results: Data were returned from 9 participating laboratories. The marker combinations used were different in each centre but the results, shown in Table 1, demonstrate that most centres are using appropriate reagents with acceptable instrument settings. The performance characteristics for all 6 markers were met in all 10 cases in 5/9 centres. Suboptimal results were identified for 1 or 2 markers in 3/9 centres. Suboptimal results did not necessarily relate to the reagent used and the same reagent could have different performance characteristics in different laboratories because overall results were also influenced by laboratory procedures and instrument settings.
Summary/Conclusions: Flow-cytometry laboratory performance is influenced by many factors including the clone, fluorochrome, and manufacturer of each reagent, the combination and concentration of reagents used as well as the cytometer instrument settings. Optimising and standardising each component of the process can be labour-intensive. The relatively simple global approach developed by ERIC/ESCCA to assess the CLL diagnostic panel is applicable to a variety of reagent and instrument suppliers and can easily identify potential problems or confirm acceptable performance in individual laboratories. The quality assessment of the diagnostic panel is being extended to other markers including CD43, CD200 and ROR1 with prospective evaluation as part of an ERIC project to improve the reproducibility of differential diagnosis in CLL.

The median relative signal, defined as the median fluorescence intensity (MFI) of the positive control population divided by the MFI of the negative control population, for ten cases with polyclonal B-cells from each centre (range in brackets).
A * indicates that the relative signal was below target in 1 or more of the 10 cases evaluated. Grey cell shading indicates that the result was below target in 5 or more cases.

P590

THE SYK/JAK INHIBITOR CERDULATINIB SHOWS PROMISING *IN VITRO* ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Blunt[1], R Dobson[1], M Larrayoz[1], S Wilmore[1], A Hayman[1], J Parnell[1], L Smith[1], A Davies[1], P Johnson[1], P Conley[2], A Pandey[2], J Strefford[1], M Cragg[3], F Forconi[1], F Stevenson[1], G Packham[1], G Coffey[2], A Steele[1,*]
[1]Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [2]Portola Pharmaceuticals, San Francisco, United States, [3]University of Southampton, Southampton, United Kingdom

Background: B cell receptor (BCR) kinase inhibitors such as ibrutinib and idelalisib have proved effective for the treatment of chronic lymphocytic leukaemia (CLL). However, these inhibitors appear only to suppress the disease without being curative. A number of patients have developed resistance to ibrutinib following mutation of the BTK or PLCγ2 gene, whilst other patients are unable to tolerate these drugs due to adverse events or progress whilst on therapy for unknown reasons. More recently, our group showed that microenvironmental signals such as IL-4 can partially reverse BCR-kinase inhibition by ibrutinib and idelalisib restoring αIgM induced ERK phosphorylation and calcium flux. Therefore, the development of novel drugs that are still effective once other BCR-kinases inhibitors become ineffective and/or which target signals from the tumour microenvironment is of utmost importance. Cerdulatinib inhibits both Syk (a protein pivotal to BCR signalling) and JAK3 (a protein integral for IL-4 signalling). Importantly, targeting Syk was also shown to induce apoptosis in CLL samples resistance to ibrutinib, identifying Syk inhibition as a promising strategy to treat these patients. Cerdulatinib is currently in a phase I open label dose escalation study and is currently demonstrating clinical activity in patients with relapsed/refractory B cell malignancies including CLL.
Aims: To investigate the dual Syk/Jak inhibitor, cerdulatinib, on CLL cell biology.
Methods: Twenty-four primary CLL samples were treated with cerdulatinib in the presence or absence of IL-4/CD40L or αIgM and apoptosis assessed using propidium iodide/Annexin V staining or PARP cleavage. The effect of cerdulatinib on BCR and IL-4-induced signalling were assessed by immunoblotting and flow cytometry.
Results: At plasma concentrations achievable in patients, cerdulatinib induced apoptosis of CLL cells cultured *in vitro* in a concentration, time and caspase dependent manner, with a mean IC50 of 3μM and 1μM at 48hr and 72hr respectively. Cerdulatinib preferentially induced apoptosis of samples with progressive disease (unmutated IGHV, CD49d+ or ZAP70+) compared to indolent disease (mutated IGHV, CD49d- or ZAP70-). Cerdulatinib significantly inhibited IL-4 induced phosphorylation of STAT6 and αIgM induced calcium flux and downstream signalling via phosphorylation of AKT, ERK and S6 Kinase at concentrations ≤300nM. Cerdulatinib induced similar levels of apoptosis irrespective of pro-survival signalling via IL-4/CD40L or αIgM treatment, suggesting that this drug may be able to overcome microenvironmental signals and thus target tumour cells within the lymph nodes. In addition, cerdulatinib inhibited αIgM and IL-4/CD40L induced expression of pro-survival proteins MCL1 and Bcl-XL. Next we explored the possibility of augmenting cerdulatinib induced apoptosis by simultaneous inhibition with the Bcl-2\Bcl-XL inhibitor ABT-199. *In vitro* in the presence of IL-4/CD40L, ABT-199 synergised with cerdulatinib to induce significantly greater cell death than with either agent alone. Finally we evaluated the effect of cerdulatinib on BCR-induced expression of CCL3 and CCL4 in CLL cells. Cerdulatinib significantly inhibited CCL3 and CCL4 expression at concentrations achievable in patients and to a greater extent than observed with ibrutinib alone.
Summary/Conclusions: Together these data provides the first *in vitro* support for the continued use of cerdulatinib in clinical trials for the treatment of CLL as either a single agent or in combination with other therapies such as ABT-199.

Background: Venetoclax (VEN) is an orally bioavailable BCL2 selective inhibitor. Patients (pts) with relapsed or refractory CLL or small lymphocytic lymphoma were treated in a phase 1 trial (M12-175, NCT01328626) with doses ranging from 150-1200 mg/day (Roberts, *et al.*, NEJM 2016).
Aims: Here we report the updated safety and efficacy data in the subset of CLL pts treated at the recommended phase 2 dose (RP2D) of VEN (400 mg daily), with a focus on effects on the host immune system.
Methods: 59 CLL pts were enrolled to receive VEN at the RP2D of 400mg/day. This analysis is restricted to the 57 pts with complete baseline and re-staging evaluations. Immunophenotyping studies were performed by flow cytometry on the peripheral blood at local laboratories.
Results: As of December 1, 2015, the median time on study was 19 months (range 0.5-44). Pts had a median of 3 prior therapies (range 1-11). The overall response rate was 81%; 16% achieved complete remission. The 24-month estimate for progression-free survival was 62% [95% CI=45, 75] and that for duration of response was 77% [95% CI=58, 98]. The most common treatment emergent adverse events (AEs) were upper respiratory tract infection (49%), diarrhea (47%), and neutropenia (44%). Grade ≥3 AEs occurred in 86% of pts, including 40% with neutropenia, 17.5% with infection, and 13.5% with febrile neutropenia. 19/25 pts with neutropenia were treated with GCSF; all of them responded, 2 were also dose-reduced. 8 deaths were reported [Richters transformation (n=4), complications after allogeneic stem cell transplant (n=2), small bowel obstruction, viral pneumonia (n=1 each)]. Significant reductions were seen in blood B-cell counts, however, no appreciable reductions were observed in the mean absolute counts for CD3+ T-cells, CD4+ or CD8+ T-cells, or NK cells. Similarly, no significant changes were observed in immunoglobulin levels. Only 11/57 pts experienced Grade ≥3 infection, at the rates of 14% in the first 6 months and 9% for the subsequent time on study.
Summary/Conclusions: VEN at RP2D of 400 mg/day resulted in a high response rate and durable remissions. While VEN can induce neutropenia, host T-cell numbers and immunoglobulin levels remained unchanged, and the risk of Gr ≥3 infection in this relapsed CLL population was low.

IBRUTINIB FOR RELAPSED CLL PATIENTS OLDER THAN 75 YEARS: PROVEN EFFICACY, TOXICITIES TO KNOW

AS Michallet[1,*], A Campidelly[2], H Lequeu[3], MS Dilhuydy[4], O Tournilhac[5], LM Fornecker[6], J Dupuis[7], F Cymbalista[8], S De Guibert[9], A Delmer[10], MC Bene[11], JP Vilque[12], D Ghez[13], V Leblond[14], P Feugier[15], L Ysebaert[16]
[1]hematology, Centre Léon Bérard, Lyon, [2]hematology, CHU Nancy, Nanacy, [3]hematology, CHLS, Lyon, [4]hematology, CHU Bordeaux, Bordeaux, [5]hematology, CHU Clermont Ferrand, Clermont Ferrand, [6]hematology, CHU Strasbourg, strasbourg, [7]hematology, APHP Henri Mondor, [8]hematology, APHP Avicennes, Paris, [9]hematology, CHU Rennes, Rennes, [10]hematology, CHU Reims, Reims, [11]hematology, CHU Nantes, Nantes, [12]hematology, APHP Paris, [13]hematology, IGR, [14]hematology, APHP Pitie salpétriere, Paris, [15]hematology, CHU Nancy, Nancy, [16]hematology, IUCT, Toulouse, France

Background: Ibrutinib is an option in patient with relapsed/refractory CLL. Nevertheless, the median age in the Phase I-III studies is 67 to 71 years, which does not reflect current practice.
Aims: In France, the data of the ATU (early-access program, n=428 CLL patients) could be used to analyze the safety (adverse events, AE) and efficacy of this treatment in patients older than 75 years old (n=150/428).
Methods: Analysis of efficacy and safety data in 71/150 elderly patients (70.4% male), median age 79 years (75-89 years, 39.4%>80 years) who received the Ibrutinib treatment for their CLL.
Results: At initiation of treatment, the population had frequent vascular comorbidities (hypertension 34%, venous thrombosis 10%, arteritis 7%), heart comorbidities (myocardial infarction, 10.3%, arrhythmias 13.4%, valvular disease 4%), or kidney dysfunction (31.3% with reduced creatinine clearance 30-60ml/min). As such, they required antiplatelet therapy and/or anticoagulant in 30% and 12% of cases, respectively. Baseline CLL characteristics included: advanced Binet stage (stage C 68%), deletion 17p and/or TP53 mutation 53.3%, deletion 11q 21.6%, median of 3 lines of previous treatments (range 1-9). Patients started ibrutinib at 420mg/d in all but one patient, still 55.7% of patients had a dose reduction to 280mg/d due to toxicity during the first year of follow-up, after a median of 8 weeks (range 2-52)). Standard dose was reintroduced in 10/39 pts after resolution of AE, among which 5/10 had to decrease dose from one level again. Ibrutinib was definitively stopped in 34% of pts after a median of 5 months (range 1-16), mainly for AEs (infections 5.6%, cardiac complications 7%, bleedings 11.3%, hematological toxicity), rarely for PD (5.6%). After a median follow-up of 15.1 months, overall response rate at 12 months (45 evaluable patients) was 93.4%, including 75.5% partial remission (35,6% with or 40% without lymphocytosis). Overall survival (OS) and progression-free survival (PFS) rate at 12 months were 92% and 83%, respectively. At last follow-up (median: 15.1mo), 63.4% of patients were alive on treatment, 15.5% alive without ibrutinib, and 21.1% (15/71) died from: infection (7/15), CLL progression (6/15, 3/6 had proven Richter transformation), heart disease (2/15). In statistical analysis, the only factor influencing PFS (HR=6,369; p=0,004) and duration of response (HR=7,052, P=0,017) but not OS was a previous medical history of arteritis/myocardial ischemia. As reported from clinical trials, a drug hold>7 days tended to be associated with a reduction of the duration of response, but not a dose reduction from 420 to 280mg/d. In this series, estimated median OS was 21 months. Safety profile was fairly known and manageable: grade 1-2 bleeding (19%), cardiac toxicity (7%), diarrhea (24%), myalgia/arthralgia (20%), the frequency of which decreasing over the first 6 months. On the other hand, ibrutinib was associated with a risk of hematologic AE and infection (20% of patients experienced infection of at least grade 2), irrespectively from date of assessment (3, 6 or 12 months).
Summary/Conclusions: In very elderly patients with CLL, Ibrutinib was an effective strategy requiring nevertheless an adequate management of toxicities, dose reduction being often efficient.

Background: In chronic lymphocytic leukemia (CLL), *TP53* mutation (*TP53mut*), 17p deletion (17p-) or fludarabine-refractoriness are strongly associated with resistance to chemotherapy-based treatment and a poor prognosis. The German and French CLL study groups initiated the CLL2O trial, which aimed to achieve sufficient response rates and remission duration by combining the CD52-antibody alemtuzumab with dexamethasone followed either by alemtuzumab-maintenance or allogeneic stem cell transplantation. The trial enrolled only CLL patients refractory to a fludarabine-based regimen (with or without 17p-) or with 17p- (front line or relapsed).
Aims: While incidence and prognostic value of gene mutations have been extensively evaluated in first-line CLL treatment situations, only scarce data is available from clinical trials focusing on high risk patients.
Methods: We performed targeted next generation sequencing (tNGS) of eight recurrently mutated genes (*TP53, NOTCH1, SF3B1, ATM, BIRC3, POT1, FBXW7, MYD88*) on baseline samples of 111 CLL2O patients. Statistical analyses were performed by Fisher's exact test, Kaplan-Meier estimates, and Cox proportional hazards regression with significance as $p<.05$ (two-sided).
Results: The full CLL2O cohort (n=131) comprised 17p- frontline (n=42), 17p- relapsed (n=28) and refractory (with 17p- (n=30) and without 17p- (n=31)) patients. Analyses are reported for the full cohort and for those predefined subsets of the trial. Among all 111 patients with mutation data available, *TP53* mutations were detected in 79 (71.2%), *NOTCH1* in 32 (28.8%), *SF3B1* in 27 (24.3%), *ATM* in 24 (21.6%), *BIRC3* in 7 (6.3%), *POT1* in 4 (3.6%), *FBXW7* in 3 (2.7%) patients and *MYD88* in a single (0.9%) patient. There were associations of muta-

tions with genomic aberrations, *e.g. TP53* with 17p- (p<.001), *ATM* with 11q- (p=.037), but there was no correlation between *TP53mut* and other recurrent mutations. Remarkably, 11 pretreated patients showed 2 to 4 *TP53mut*, while only a single untreated patient had two *TP53mut*. In the full trial cohort, none of the mutations had a significant impact on response, progression free survival (PFS) or overall survival (OS). Notably, in patients with 17p-, the incidence of *TP53, SF3B1 and NOTCH1* mutations was similar in treatment naïve (n=37) and pretreated (n=74) patients and the overall genomic landscape appeared not markedly different between those cohorts (Figure 1). These findings indicate that most genomic variants preexist and are not induced by fludarabine-based chemotherapy in 17p- CLL. Of note, in the 17p- frontline cohort, there was a significant association of *TP53* wild-type (hazard ratio 0.14; p=.02) and *ATMmut* status (hazard ratio 0.16; p=.04) with prolonged PFS. In contrast, within the refractory and 17p- relapsed subgroup, there was no significant association of any mutation with outcome. In the F-refractory cohort, when comparing the groups with (n=26) and without (n=21) 17p-, there was an association of *ATMmut* with absence of 17p- (p=.01), but no significant correlation to outcome.

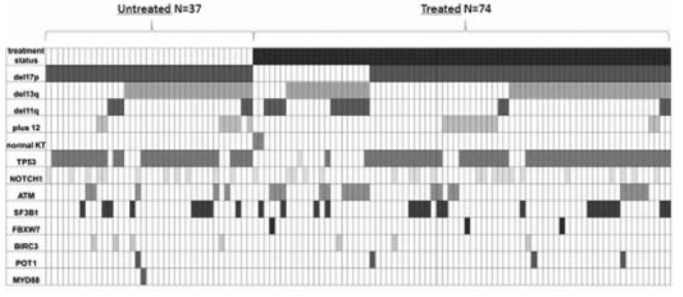

Figure 1.

Summary/Conclusions: In conclusion, within the full trial cohort none of the recurrent mutations had an impact on outcome in the CLL2O trial. Fludarabine-based treatment does not appear to increase the overall complexity of the genomic landscape of 17p- CLL, but it might increase the number of intraindividual *TP53mut* in a given tumor. *TP53* is a prognostic factor in previously untreated, but not in pretreated and refractory patients enrolled within the CLL2O trial. Of note, in the F-refractory cohort 20/21 (95,2%) patients without 17p- and with *TP53* wild-type had at least one other alteration such as 11q-, *NOTCH1mut*, *ATMmut* or *SF3B1mut.*

IDELALISIB IN COMBINATION WITH RITUXIMAB IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)/SMALL LYMPHOCYTIC LYMPHOMA (SLL): REAL-WORLD EXPERIENCE THROUGH AN EARLY ACCESS PROGRAM IN EUROPE AND AUSTRALIA

JJ Li[1], AS Yong[1], JL Justicia[1], C Smith[1], J Delgado[2,*]
[1]Gilead Sciences, Inc., Foster City, CA, United States, [2]Hospital Clinic, Barcelona, Spain

Background: Idelalisib (IDELA) is a first-in-class selective PI3Kδ inhibitor approved in EU for use in combination with rituximab (R) for patients (pts) with relapsed CLL; or as first-line CLL treatment in the presence of del(17p) or TP53 mutation (TP53m) in pts unsuitable for chemo-immunotherapy. A post-authorization, pre-national reimbursement early access program (EAP) was initiated for Australia, Belgium, Greece, Ireland, Spain and UK, for pts without other therapeutic options and who could not be included in an IDELA clinical trial. Pts with relapsed/refractory (R/R) CLL/SLL and treatment naïve (TN) CLL/SLL with del(17p)/TP53m, were eligible for the CLL/SLL cohort. IDELA data outside clinical trials and in real-world settings is limited.
Aims: This analysis was to characterize baseline demography of pts treated with IDELA+R in both TN CLL/SLL pts with del(17p)/TP53m and R/R CLL/SLL, outside of a clinical trial setting. Serious adverse events (SAE) reported are also presented.
Methods: The EAP enrolled pts from March 2015, analysis data-cut off was 15 January 2016. Available data were collected from de-identified pt registration data and SAE reports. This analysis summarizes baseline pt characteristics which were either mandatory or optional on the enrolment form. SAEs were reported whilst pts were on treatment. The proportion of missing data (unreported or unrecoverable) is also shown in the Table 1.
Results: Median follow up was 133 days (2-315). 170 pts with R/R CLL/SLL had documented prior treatment regimens (166 with specific treatment and 4 with number of lines only). Most commonly used prior therapies included anti-CD20 (85.6%), cyclophosphamide (69.3%), fludarabine (56.6%), bendamustine (43.3%) and prednisolone (40.0%). SAE data collected were consistent with previous clinical study SAE reporting with SAEs in 37/263 (14.1%) pts. SAEs included 8 (3.0%) pneumonia, 7 (2.7%) liver test elevations, 5 (1.9%) neutropenia, 5 (1.9%) pneumonitis, 4 (1.5%) skin reactions, 3 (1.1%) diarrhea and 3 (1.1%) febrile neutropenia.

*SLL enrolled in Australia only

Summary/Conclusions: This is the largest cohort reported to date for pts with CLL/SLL treated with IDELA+R, outside of clinical trials. Pts included in the EAP had similar demographic characteristics to those previously reported in clinical trials.[1] To date, available results indicate an acceptable tolerability profile of IDELA+R in the real-world setting for pts withTN CLL/SLL and 17p deletion/ TP53m and for pts with R/R CLL/SLL.

Background: *TP53* aberrations (deletions and/or mutations, *TP53*ab) in chronic lymphocytic leukemia (CLL) are associated with dismal clinical outcome and reduced life expectancy. However, mounting evidence suggests that within cases carrying *TP53*ab other cytogenetic features may also influence the clinical outcome. Alterations in chromosome 8, in particular 8p losses (affecting several regions, from 8p12 to 8p23) and 8q gains (usually involving 8q24, where *MYC* is located), are enriched in *TP53*ab patients and have been proposed as features with potential prognostic value within this aggressive group.
Aims: To assess the prevalence of 8p losses (8p-) and 8q gains (8q+) in CLL patients with *TP53ab*, characterize their clinicobiological profile and evaluate their prognostic value.

Methods: A total of 101 patients with *TP53*ab from 17 Spanish and Greek institutions were included in the study. 8p- and 8q+ were analyzed in peripheral blood samples by FISH using *LPL* (8p22) and *MYC* (8q24) probes (AbbottMolecular) in 75 and 101 cases, respectively. Clinical and cytogenetic data from patients with 8p- *vs* normal 8p (N-8p) and 8q+ *vs* normal 8q (N-8q) were compared.
Results: A total of 11/75 patients (14.7%) showed 8p- and 18/101 cases (17.8%) carried 8q+. In 6/75 patients (8%) both abnormalities were concomitant. As for the clinicobiological profile at diagnosis, 8p- and 8q+ cases displayed no differences regarding age, Hb/platelet/leucocyte values, as well as FISH detected abnormalities del(11q), del(13q) and trisomy 12 compared to cases with normal 8p (N-8p) and normal 8q (N-8q), respectively. However, cases with 8p- exhibited a higher incidence of B symptoms compared to N-8p cases (P=0.039). Interestingly, 8p- cases carried a higher number of 17p-deleted cells as well as a higher median number of chromosomal alterations detected by chromosome banding analysis (CBA) (7 *vs* 3) and, therefore, a higher frequency of complex karyotypes (CK, defined as ≥3 structural/numerical aberrations) compared to N-8p cases (P=0.001, P=0.041 and P=0.006, respectively). Similarly, cases with 8q+ also showed a higher median number of chromosomal abnormalities (6.5 *vs* 2) and higher frequency of CK compared to N-8q cases (P=0.001 and P=0.002, respectively). Ten-year survival analysis revealed a significant shorter overall survival (OS) for both 8p- and 8q+ (P=0.002 for 8p- *vs* N-8p, and P=0.007 for 8q+ *vs* N-8q). CK also had a negative impact on OS (P=0.018) (Figure 1). In multivariate analysis only CK retained independent significance (P=0.032, HR: 2.5).

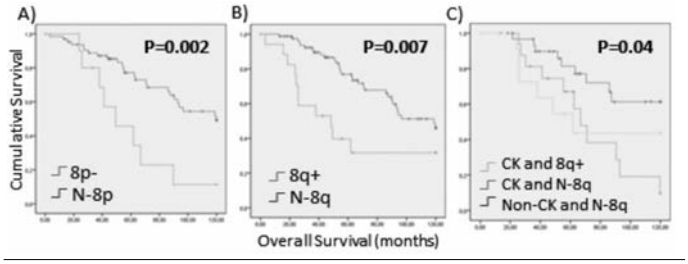

Figure 1. Kaplan Meier plots for ten-year OS in patients carrying (A) 8p-, (B) 8q+ and (C) complex karyotype with 8q+ or N-8q.

Summary/Conclusions: 1. The prevalence of 8p- and 8q+ in this cohort of CLL patients with *TP53ab* was 14.7% and 17.8% respectively. 2. The detection of chromosome 8 abnormalities (8p- and/or 8q+) by FISH in patients with CLL and *TP53*ab is associated with karyotype complexity and further deteriorates outcome. 3. Genomic complexity assessed by CBA negatively impacts on survival even amongst patients with *TP*53ab. 4. Validation in large cohorts is required to elucidate if the observed dismal OS in CLL patients with 8p- and/or 8q+ is due to chromosome 8 alterations *per se* or by the genomic instability associated with complex karyotypes.

Background: Ibrutinib (ibr) is the first-in-class, oral, once daily Bruton's tyrosine kinase inhibitor EMA-approved for adult patients with CLL with ≥1 prior therapy. Difference in outcomes with ibr may exist by prior lines of therapy (LoT). Variable overall survival (OS) after ibr discontinuation (DC) have also been reported.
Aims: To evaluate outcomes with ibr based on prior LoT, and following ibr DC in patients with CLL.
Methods: We analyzed data from two randomized phase 3 trials of ibr: PCYC-1115/16 (RESONATE-2) in patients ≥65 years with treatment naïve (TN) CLL; PCYC-1112 (RESONATE) in previously treated (PT) CLL, excluding patients with del17p for a more homogenous dataset for analysis. All patients provided informed consent. Progression-free survival (PFS) and overall response rate (ORR) were assessed by investigator.
Results: Data from 271 patients were included in this analysis. In TN *vs* PT patients, median age was 73 *vs* 66 years. PT patients had a median of 3 prior therapies including CD20 antibody (93%), purine analog (87%), or alkylating agents (93%; bendamustine 41%). Median PFS and OS were not reached (NR) for TN or PT patients, with 89-92% progression free at 2 years for patients treated with ibr in 1st- or 2nd-line (Table 1). ORR was high regardless of LoT (91% in TN, 92% in PT patients). 85% of TN patients and 61% of PT patients continue ibr treatment. Adverse event (AE) profile was similar for both groups. Patients receiving ibr in earlier LoT were less likely to DC ibr due to progressive disease (PD) (Table 1). Median OS post ibr DC is NR for patients who received ibr in 1st- or 2nd-line (n=23) *vs* 7-9 months (mo) in 3rd-line and beyond (n=34).

Table 1. Outcomes with Ibrutinib based on prior LoT including outcomes following discontinuation.

	Subgroups by Prior LoT (N=271)			
	0 (n=136)	1 (n=27)	2 (n=41)	≥3 (n=67)
Median age, years (range)	73 (65-89)	64 (30-85)	66 (46-86)	67 (44-83)
Median follow up, mo (max)	22 (32+)	30 (36+)	31 (34+)	30 (37+)
Continuing study ibr, n (%)*	116 (85)	19 (70)	28 (68)	36 (54)
24-mo PFS, %	92	89	80	69
30-mo OS, %	97	93	83	82
ORR (w/PR-L), %	91	100	93	88
CR/CRi	17	7	15	6
PR-L	3	0	2	9
DC due to, n (%)*				
PD	4 (3)	2 (7)	5 (12)	11 (16)
AEs	13 (10)	1 (4)	6 (15)	7 (10)
Deaths	2 (2)	2 (7)	1 (2)	5 (7)
Other	1 (1)	2 (7)	1 (2)	4 (6)
Median time post DC*, mo				
Follow up	9	5	9	10
OS	NR	NR	9	7
OS: DC due to AE	NR	NR	16	NR
OS: DC due to PD	NR	NR	8	6
Patients with subsequent therapy, n	4	1	6	11
Common subsequent therapy	2 FCR, 1 BR, 1 clb	1 EPOCH-R	3 R-CHOP	4 idela±R, 3 ofa

*5 patients who DCed study ibr to receive commercial ibr not included.

Summary/Conclusions: Treatment with once daily ibr led to favorable PFS and OS, and high ORR regardless of LoT in patients with CLL. Patients who received ibr in earlier LOT as 1st- or 2nd-line therapy were less likely to progress and experienced better post-ibr survival outcomes.

P597

SINGLE-AGENT IBRUTINIB *VS* STANDARD OF CARE FOR PATIENTS WITH RELAPSED/REFRACTORY (R/R) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE™ WITH THE CLLEAR DATABASE

M Doubek[1,*], P Obrtlikova[2], M Spacek[2], R Urbanova[3], J Diels[4], P Thilakaratne[4], P Musingarimi[5], F Mac Dougall[6], R Hermans[6], M Barendse[7], W Iraqi[8], L Smolej[9]
[1]Internal Medicine – Hematology and Oncology, University Hospital, Brno and Faculty of Medicine, Masaryk University, Brno, [2]Internal Medicine I - Hematology, General Faculty Hospital, Prague, [3]Hemato-oncology, University Hospital, Olomouc, Czech Republic, [4]Janssen EU HEMAR, Beerse, Belgium, [5]Janssen-Cilag, High Wycombe, [6]IMS RWE Solutions, London, United Kingdom, [7]Janssen-Cilag AB, Sollentuna, Sweden, [8]Janssen Pharmaceuticals, Paris, France, [9]Medicine IV - Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE™ trial (NCT01578707) compared ibrutinib (ibr) with ofatumumab (ofa) in patients (pts) with previously treated CLL and not eligible for purine analogue treatment. Ibr showed significantly improved progression-free survival (PFS; hazard ratio [HR]=0.22; p<0.001) and 18-month overall survival (OS; adjusted for crossover) (HR=0.35 [0.16-0.75]) (Diels, ISPOR-EU 2015).
Aims: In the absence of a head-to-head comparison of single-agent ibr with other frequently used treatments, we investigated the relative efficacy of ibr *vs* physician's choice in R/R CLL pts by comparing pt-level data from RESONATE™ with R/R pts in a real-world setting (the CLLEAR database). The CLLEAR database holds data on CLL pts from the Czech Republic, collected

from academic centers. Electronic Medical Records for 450 pts from 3 centers, collected between 2012 and 2015 were available from this database.
Methods: Pt-level data from the RESONATE™ trial (ibr, n=195; ofa, n=196) were compared with data from the CLLEAR database, adjusting for confounding factors using multivariate statistical modelling. From this database, pts who received second-line or later line treatment were identified. Longitudinal follow-up in subsequent treatment lines was available for pts in second (n=87), third (n=33), fourth (n=15), and subsequent (n=13) lines. In order to account for non-comparability of ibr pts with the CLLEAR cohort due to lack of randomization, the statistical approach of a multivariate Cox proportional hazards model was used to compare PFS and OS between treatments, including line of therapy, age, gender, disease stage (based on Binet/Rai), and ECOG performance status as covariates.
Results: Across all treatment lines, the most frequent treatment regimens used were FCR or FCR-based treatment (20.9%), alemtuzumab monotherapy (15.5%), chemotherapy+monoclonal antibodies (14.2%), rituximab monotherapy (9.5%), corticosteroid only (9%), R-CHOP or R-CHOP–based (6.1%), and BR (4.7%); the remaining percentages comprised a multitude of various other therapies, each used in less than 4% of pts. Line of therapy, age, gender, disease stage, and ECOG performance status were all independent risk factors for worse outcome of PFS and OS. Median age at treatment initiation was 67 years for both pt cohorts. Median number of prior therapies in RESONATE™ was 3, compared with 1 for CLLEAR. The observed HRs for PFS and OS of ibr *vs* physicians' choice from the CLLEAR database were 0.19 (0.13-0.27) and 0.26 (0.17-0.42). After adjustment for differences in baseline characteristics, HRs improved to 0.10 (0.06-0.16) for PFS and 0.15 (0.08-0.28) for OS. The impact of adjustment on PFS and OS was mainly driven by differences in number of prior lines of therapy. Adjusted HRs for PFS and OS of ibr *vs* FCR-based treatment in the second line were 0.07 (0.02-0.25) and 0.11 (0.02-0.57), respectively.
Summary/Conclusions: Investigation of clinical outcomes suggests that ibr administered to pts in the RESONATE™ trial was more effective than physician's choice amongst pts from a real-world cohort of Czech pts. PFS and OS for ibr is improved compared with standard therapies currently available for pts with R/R CLL. These results are consistent with a previous report from a Swedish observational study showing superiority of the ibr cohort from RESONATE™ over physicians' choice (Österborg, ASH 2015) and further support the growing evidence that ibrutinib significantly improves both PFS and OS *vs* current and prior commonly used regimens.

P598

NO IMPROVEMENT IN LONG-TERM OVERALL SURVIVAL AFTER THE INTRODUCTION OF CHEMO(IMMUNO)THERAPY FOR CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS BELONGING TO STEREOTYPED SUBSET #2

Background: Several population-based studies support the notion that overall survival (OS) in CLL has improved in recent years. Relevant to this, a turning point in the management of CLL was the introduction of chemoimmunotherapy, in particular the fludarabine-cyclophosphamide -rituximab (FCR) regimen, the first to lead to prolonged OS compared to previous chemotherapy approaches. However, certain CLL subgroups have proven refractory to chemo(immuno) therapy, the paradigmatic example being patients harboring aberrations within the *TP53* gene who display resistance to all such approaches. Aside from this, relatively little is known about the trends in OS over time among other CLL prognostic subgroups.
Aims: To investigate trends in long-term survival of CLL patients with particular biomarker profiles treated with chemo(immuno)therapy.
Methods: We evaluated parameters affecting OS within a cohort of 3503 patients treated for CLL with chemo(immuno)therapy in 15 institutions in Europe and the US. The patient distribution in the present study was as follows: males: n=2410 (69%), median age at treatment: 63.5 years; CD38 positivity: n=707/1853 (39%); del(17p): 111/1059 (11%); del(11q): 199/937, 21%; trisomy 12: 133/706, 19%; del(13q): 323/570, (57%); unmutated IGHV genes (U-CLL): n=2216 (63%); membership in stereotyped subset #2 (IGHV3-21/IGLV3-21): n=166 (5%). The latter was assessed separately due to representing an aggressive CLL subgroup, independently of IGHV gene somatic hypermutation status. Patients included in the analysis received primary treatment between May 1980 and July 2013 and were subdivided into two groups: (A) treated before 2006 (n=2092) and; (B) treated in 2006 and after (n=1411). This time-point was chosen due the following implementation of chemoimmunotherapy in clinical practice after 2005.
Results: The two groups did not differ at diagnosis with regards to gender, IGHV mutational status, stereotyped subset #2 membership or cytogenetic profile. In contrast, significant differences ($p<0.05$) were identified concerning: patient age at time of first treatment (median: 63 for group A *vs* 64.5 for group B); CD38 positivity (42% in group A *vs* 33% in group B, $p<0.0001$); OS (measured from the time of diagnosis): 9.5 years in group A *vs* 17.5 years in group B ($p<0.0001$). The superior outcome of patients treated after 2005 (group B) was evident across subgroups defined by age, gender, IGHV mutational status, CD38 expression, del(11q), trisomy 12 and del(13q) ($p<0.05$ for all comparisons). In contrast, the OS was not improved after 2005 for cases carrying del(17p) (median OS: 7 and 5.2 years in groups A and B respectively, p=0.61), which is not unexpected given the documented low efficacy of chemo(immuno)therapy amongst patients with such aberrations. Notably, a similar lack of improvement in OS (median OS: 7 and 9 years in groups A and B respectively, p=0.14) was identified for cases belonging to stereotyped subset #2, further highlighting this subset as a particularly aggressive CLL subgroup.
Summary/Conclusions: Advances in chemo(immuno)therapeutic approaches in CLL during the last decade have translated into prolonged OS in all prognostic subgroups of the present study except those carrying *TP53* abnormalities as expected, but also to those assigned to stereotyped subset #2, that are generally devoid of such gene aberrations. This latter finding, reported here for the first time, supports the clinical relevance of B cell receptor IG stereotypy in CLL and indicates the need for alternative treatment options for subset #2 patients.

P599

VENETOCLAX IS ACTIVE IN CLL PATIENTS WHO HAVE RELAPSED AFTER OR ARE REFRACTORY TO IBRUTINIB OR IDELALISIB

S Coutre[1,*], W Wierda[2], M Choi[3], MS Davids[4], BD Cheson[5], RR Furman[6], N Lamanna[7], PM Barr[8], H Eradat[9], A Halwani[10], L Heffner[11], B Chyla[12], M Zhu[12], J Potluri[12], M Verdugo[12], R Humerickhouse[12], AR Mato[13], J Jones[14]

Background: Patients (pts) with chronic lymphocytic leukemia (CLL) who relapse after or become refractory (R/R) to BCR pathway inhibitors have poor outcomes. Venetoclax (VEN) is a selective, oral BCL-2 inhibitor with significant activity in R/R CLL.
Aims: Primary endpoints are ORR by iwCLL criteria [week (w) 8, 24, then every 12w] and safety.
Methods: In this ongoing Ph 2 study, pts with CLL R/R to ibrutinib (IBR, Arm A) or idelalisib (IDE, Arm B) receive VEN 20 mg daily followed by 5-week ramp up to 400 mg daily.
Results: 54 pts were enrolled (41 A, 13 B), including 25 refractory to IBR and 6 to IDE; 12 and 6 were intolerant with CLL progression after stopping IBR and IDE, respectively; 3 in each arm had both IBR and IDE. 54% had >5 prior therapies, 83% had unmutated *IGHV*, 20% had ALC >100x10^9, 35% had del(17p),

and 24% had ≥1 node ≥10 cm. Median time on VEN was 31.9 w (0.6– 52.9) for Arm A and 23.7 w (5.4–52.9) for Arm B. 8 in Arm A discontinued VEN (4 PD; 1 each respiratory failure, multi-organ failure, death of unknown cause, consent withdrawal); 2 in Arm B (1 PD, 1 non-response). Efficacy in 48 evaluable pts is shown in the Table 1. In the refractory subsets, 14/22 Arm A pts and 3/5 Arm B pts achieved response. 8/27 pts who reached w24 were MRD-negative (10^{-4}) by flow cytometry in blood (all Arm A: 2 CR, 1 nPR, 4 PR, 1 SD).

Table 1.

Best response in evaluable* pts, n (%)	Arm An=38	Arm Bn=10
ORR	23 (61)	5 (50)
CR	3 (8)	0
PR/nPR	19 (50)/1 (3)	5 (50)/0
SD	10 (26)	4 (40)
PD	1 (3)	1 (10)
DC before assessment	4 (11)	0

**3 in each arm are not yet evaluable*

Safety was consistent with prior reports. AEs in >20% pts: neutropenia (48%), diarrhea (37%), nausea (35%), anemia (32%), fatigue (24%), hyperphosphatemia (20%). Grade 3/4 AEs >10%: neutropenia (39%), thrombocytopenia (22%), anemia (20%), leukopenia (13%), pneumonia (13%). SAEs in ≥2 pts: pneumonia (9%), febrile neutropenia (7%), increased potassium, multi-organ failure, septic shock (4% each). 2 pts had laboratory TLS without clinical sequelae.

Summary/Conclusions: In CLL pts R/R to IBR or IDE, VEN monotherapy showed promising activity, including MRD negativity at 24w, with acceptable safety. This is the first prospective study to demonstrate efficacy in this poor prognosis population. Follow-up will assess depth and duration of response.

Chronic myeloid leukemia - Biology

Background: Although tyrosine kinase inhibitors (TKIs) have significantly improved the prognosis of chronic myeloid leukemia (CML), the ability of TKIs to eradicate CML remains uncertain and patients must continue TKI therapy for indefinite periods. The *BCR-ABL1* gene is a strong driver mutation in CML pathogenesis, and there have been few reports of somatic mutational analysis in CML.
Aims: Our study objective is to identify somatic mutations in newly-diagnosed chronic-phase of CML (CML-CP) patients who were registered in Japan adult leukemia study group (JALSG) CML212 study by whole-exome sequensing (WES).
Methods: The JALSG CML212 study is a multicenter prospective randomized study to compare the cumulative achievement of CMR for adult *de novo* CML-CP (UMIN Clinical Trials Registry, UMIN000007909). Patients were randomly assigned to receive either dasatinib or nilotinib. Samples from the initial 24 patients enrolled in the study between May 2013 and Jan 2014 were analyzed. Genomic DNA was extracted from PBMCs at the time of diagnosis. As a germline control, DNA was obtained from buccal mucosal cells. Whole exome capture was accomplished by liquid phase hybridization of sonicated genomic DNA with a mean length of 150–200 bp for the bait cRNA library, which was synthesized on magnetic beads. The captured targets were subjected to massive sequencing using HiSeq 2000 sequencing system with the pair end 100 bp read option. Copy number analysis was performed using DNAcopy, in which the total number of reads covering each bait region and the allele frequency of heterozygous SNPs detected by WES were used as input data. The mean coverage of more than 95% of the target sequences was analyzed at an average depth of more than ×20. The mutations identified by WES were confirmed by Sanger sequencing and deep sequencing. Single nucleotide variants (SNVs) were extracted from WES as somatic mutations. All mutations were compared with published SNP data. Known synonymous SNPs with p values ≥0.001 compared with the valiant allele frequency (VAF) of peripheral blood leukocytes and oral mucosa by the Fisher's exact test were excluded from further analysis. Correlations between the number of mutations and clinical factors were identified by the Pearson product-moment correlation coefficient using EZR software. Gene ontology (GO) analysis was used to evaluate functional enrichment in GO terms among mutated genes detected by WES.
Results: The median age of the patients was 55 years, 75% were male, and the mean WBC count at diagnosis was 96000/μL. The median IS-*BCR-ABL1* was 57%. 8.3% of patients had additional mutations besides translocation of (9;22) that were detected by the G-band staining method. We identified 190 somatic mutations on 184 genes other than the *BCR-ABL1* fusion gene (median 8, range 1-17). Summary of mutations were shown in Figure 1. *TET2* or *TET3*, *AKT1*, and *RUNX1* were mutated in one patient each. Especially mutations in epigenetic regulators, *ASXL1*, *TET2*, *TET3*, *KDM1A* and *MSH6* were mutated in 5 patients (21%). Two patients had mutations on *ASXL1*, both were loss of function mutations and existed within exon 12. Other recurrent mutations were identified in *CLSTN2*, *COL7A1*, *CSMD2*, and *DYSF*. By GO analysis, mutated genes were mostly enriched with cell signaling and cell division pathways. DNA copy number alterations revealed that 2 out of 24 patients had uniparental disomy (UPD) in chromosomes 1p and 3q, respectively.
Summary/Conclusions: We identified mutations of *TET2*, *TET*3, *ASXL1*, *AKT*1, *RUNX*1, and *PRDM9*, besides multiple novel recurrent mutations previously reported in association with hematological malignancies. Further analyses such as the transition of these mutations by deep sequencing are required

to elucidate associations with therapeutic responses or prognosis, and functional analysis of these candidate genes in CML cell lines is required to confirm these findings.

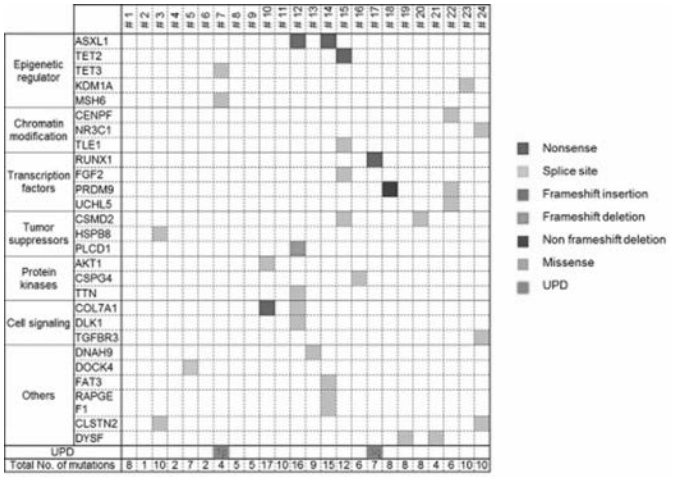

Figure 1.

P601

ROCK AS THERAPEUTICAL TARGET FOR MORGANA LOW CML

S Rocca[1,*], A Di Savino[1], C Panuzzo[2], U Familiari[3], G Saglio[2], A Morotti[2], M Brancaccio[1]

[1]Department of Molecular Biotechnology and Health Sciences, [2]Division of Internal Medicine and Hematology, Department of Clinical and Biological Sciences, [3]Division of Pathology, Department of Oncology, University of Turin, Turin, Italy

Background: Atypical chronic myeloid leukemia (aCML) is an haematological neoplasm characterized by a median overall survival of 12.4 months. The standard treatments for aCML patients are chemotherapeutic drugs. However, these treatments result inefficient in inducing remission from the pathology. Recently we demonstrated that the haploinsufficiency of Morgana, an Hsp90 co-chaperone, *in vivo* is sufficient to induce a lethal and transplantable CML-like myeloid neoplasm characterized by non recurrent cytogenetic abnormalities in the bone marrow. Morgana is able to bind to and inhibit Rho-kinases, which are emerging as key oncogenic players in haematological disorders
Aims: Identify fundamental altered pathways in aCML to uncover the biological basis of the disease and find new therapeutical targets.
Methods: The bone marrow of morgana heterozygous mice and chronic myeloid leukemia patients has been analyzed extensively by flow cytometry and immunoistochemestry. Murine and human CML bone marrow cells and *in vitro* cellular models (K562 and THP-1 cells) have been tested for sensitivity to the ROCK inhibitor Fasudil.
Results: We demonstrated that diseased morgana heterozygous mice show ROCK hyperactivation in the bone marrow and that inhibition of these kinases results in apoptosis of morgana^{low} bone marrow leukemic cells without affecting normal cells survival. Moreover, in THP-1 cells Morgana downregulation enhances ROCK activity promoting cell proliferation while ROCK inhibition significantly reduces the proliferation of these cells. Interestingly, we found that the Morgana-ROCK pathway is altered in the 16% of Philadelphia-positive CML patients where ROCK hyperactivation, cooperating with BCR-ABL signalling, leads to imatinib resistance. In this context, treatment with a ROCK inhibitor restores the efficacy of imatinib to induce apoptosis. In addition, we found Morgana downregulation and ROCK hyperactivation in the bone marrow of all aCML patients we tested.
Summary/Conclusions: Taken together these results point out Morgana as an oncosuppressor and ROCK as potential therapeutical target for Morgana^{low} CML patients.

P602

A NOVEL C-TERMINAL HSP90 INHIBITOR WITH THERAPEUTIC EFFECT IN IMATINIB RESISTANT CML

S Bhatia[1,*], D Deidrich[2], S Stein[3], F Lang[4], T Ernst[5], A Hochhaus[5], A Borkhardt[1], T Kurz[6], H Gohlke[6], F Hansen[6], J Hauer[1]

[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, [2]Institute for Biochemical Plant Physiology, Heinrich Heine University, Duesseldorf, [3]Insititute for Tumor Biology and Experimental Biology, Georg-Speyer-Haus, Frankfurt, [4]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, [5]Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, [6]Institute for Pharmaceutical and Medicinal Chemistry, Heinrich Heine University, Duesseldorf, Germany

Background: The introduction of specific BCR-ABL tyrosine kinase (TK) inhibitors, especially imatinib mesylate (Gleevec), revolutionized the clinical treatment of Chronic Myeloid Leukemia (CML). However, in many cases stable remission cannot be sustained through several escaping mechanisms, such as mutations in the ABL-kinase (*e.g.* T315I & M351T). These insights raise an urgent need to develop alternative treatment strategies. An attractive approach is targeting Heat Shock Protein 90 (Hsp90), which acts as a molecular chaperone and facilitates the folding of several oncogenic proteins including, BCR-ABL.FDA approved Hsp90 inhibitors are available and show anti tumor activity but to the best of our knowledge they all target the N terminal domain of Hsp90 and initiate heat shock response (HSR) with severe side effects (Wang & McAlpine, 2015). Thus C-terminal Hsp90 inhibition can be an attractive approach in targeting Imatinib resistant CML with low toxicity. We have identified hotspots in the C-terminal domain of Hsp90 (Ciglia *et al.*, 2014) and designed several non-peptidic inhibitors, which target Hsp90's C-terminal dimerization.
Aims: Generation and characterization of novel compounds targeting C terminal dimerization of Hsp90 *in vitro* and *in vivo*.
Methods: The specificity of selected inhibitor (DDK88) to Hsp90 was determined by Hsp90 dependent luciferase refolding assay followed by efficacy experiments using imatinib sensitive and resistant myeloid leukemic cell lines *in vitro* as well as in *in vivo* Xenograft model.
Results: In the present study, we have extensively characterized a novel and promising therapeutic compound (DDK88) for patients with Imatinib resistant CML *in vitro* and *in vivo*. DDK88 exhibits anti-proliferative and cytotoxic activity in several human myeloid leukemic cell line models (*e.g.* K562 - 5.72±0.31μM, KCL-22 - 2.74±0.52μM) and induces cell cycle arrest, early differentiation and inhibits colony formation. DDK88 disrupts Hsp90's chaperone activity to BCR-ABL protein. Hence *in vitro* application of DDK88 revealed down regulation of BCR-ABL protein expression and its downstream signaling network including, STAT5a, CRKL, AKT and mTOR proteins. Moreover, imatinib resistant CML cell lines are equally sensitive to DDK88 (*e.g.* K-562r - 6.24±0.52 μM, KCL-22r - 2.86±0.63μM) as compared to imatinib sensitive cells. In the same way, DDK88 inhibits proliferation and BCR-ABL kinase activity of 3 clinically relevant imatinib-resistant (~10 μM) BCR-ABL mutant (T315I, M351T & E255K - ~3μM) cell lines. Notably, unlike clinical inhibitors targeting N-terminal (*e.g.* AUY922), DDK88 does not induce HSR, evaluated by protein expression of HSF-1, Hsp70, Hsp40 and Hsp27. DDK88 has a therapeutic window as its inhibitory effects on healthy cord blood (CB) derived mononuclear cells (MNCs) and CD34+ cells were significantly less potent as compared to the human leukemic cell lines. Furthermore, *in-vivo* proof of concept studies demonstrate the efficacy of DDK88 at 0.5 mg/kg in a K-562-Luciferase Xenograft tumor model. DDK88 reduced tumor burden with respect to tumor weight (DDK88 0.2±0.01g *vs* vehicle 1.26±0.44g (p=0.04)). Immunoblot analysis of tumor samples derived from DDK88 treated mice revealed the absence of HSR as well as downregulation of BCR-ABL kinase activity and its associated downstream signaling pathways.
Summary/Conclusions: This study provides *in vitro* and *in vivo* characterization of a novel anti-Hsp90 compound, which is specific against its C-terminus. Hence further improvement and testing of DDK88 in pre-clinical studies can be a promising strategy to target imatinib resistant CML and to avoid HSR.

RESISTANCE IN CHRONIC MYELOID LEUKEMIA: THERAPEUTIC TARGETING OF ESCAPE VIA CSF2RB

C Becker[1,*], I Poser[1], A Wohlmann[2], J Clement[1], J Ziermann[1], K Friedrich[2], A Hochhaus[1], P La Rosée[1]

[1]Hematology/Oncology, [2]Biochemistry II, Jena University Hospital, Jena, Germany

Background: Treatment of chronic myelogenous leukemia (CML) with BCR-ABL tyrosine kinase inhibitors (TKI) achieves high rates of molecular response. However, BCR-ABL-positive leukemic stem and progenitor cells persist implying the need for lifelong treatment. Bone marrow stroma plays an important role in inhibiting apoptosis. Cytokines such as interleukin 3 (IL-3) and granulocyte/macrophage-colony stimulating factor (GM-CSF) mediate BCR-ABL-independent survival of progenitor cells via common receptor subunit CSF2RB. Disruption of the CSF2RB axis by the Janus kinase1/2-inhibitor ruxolitinib overcomes cytokine-mediated resistance *in vitro*. We previously demonstrated upregulation of CSF2RB in BCR-ABL-transformed cells as potential resistance mechanism, and now provide an indepth molecular and functional analysis.

Aims: The aim of this study was to examine the functional and biological relevance of CSF2RB upregulation in BCR-ABL positive leukemia cells in response to TKI treatment as mechanism by which IL-3 and GM-CSF induce TKI resistance.
Methods: Human M07p210 cells were used to study the functional relevance of CSF2RB-mediated rescue of TKI-treated leukemia cells by siRNA-mediated knockdown of CSF2RB. Cell proliferation and viability of BCR-ABL positive CML CD34+ progenitor cells under the influence of nilotinib/ dasatinib and ruxolitinib were analyzed *in vitro*. Expression of CSF2RB in M07p210 cells and BCR-ABL positive CML CD34+ progenitor cells in response to nilotinib and dasatinib was examined by western blot and RT-PCR. Bone marrow samples harvested at 3 months on nilotinib therapy were used to study CSF2RB regulation in CML-patients with defined levels of molecular response.
Results: In M07p210 cells and CML CD34+ progenitor cells, BCR-ABL inhibition with TKIs induces significant upregulation of CSF2RB on protein and mRNA-level. Moreover, cytokines exert distinct survival signals including STAT5 activation, despite effective BCR-ABL-inhibition in the presence of nilotinib. Furthermore, selective knockdown of CSF2RB prevents cytokine-mediated cell survival in nilotinib-treated M07p210 cells. Combination treatment of M07p210 and treatment naïve CML CD34+ progenitor cells with nilotinib/ dasatinib and ruxolitinib overcomes cytokine-mediated tyrosine kinase inhibitor resistance as demonstrated by additive growth inhibition in the presence of GM-CSF. Normal progenitors remain unaffected indicating differential activity. In colony assays with treatment naïve CML progenitors, combined application of nilotinib/ dasatinib and ruxolitinib significantly diminished granulocyte-monocyte and erythroid colony formation in the presence of rescuing cytokines. In picked progenitor colonies, mRNA-upregulation of CSF2RB was observed in 2 of 7 nilotinib-treated patient samples. Interestingly, marked upregulation of CSF2RB was also seen in 2/7 samples exposed to combined treatment. In contrast, total leukocytes from bone marrow harvested at 3 months after start of nilotinib treatment in 8 patients shows unidirectional upregulation of CSF2RB mRNA independently of the molecular response.
Summary/Conclusions: CSF2RB is upregulated in response to nilotinib and dasatinib *in vitro*, and in clinical samples derived from nilotinib treated patients. Marked individual variations of CSF2RB expression in correlation to clinical outcome can be observed in bone marrow mononuclear progenitors indicating patient specific cell intrinsic regulation of CSF2RB. In contrast, consistent CSF2RB upregulation in total bone marrow lysates confirms the bone marrow cytokine-response counteracting nilotinib treatment most likely governed by the bone marrow stroma. Efficacy and tolerability of combined BCR-ABL/ Jak1/2-inhibtion with ruxolitinib and nilotinib to target persistent stem cells is currently investigated in clinical trial NCT02253277.

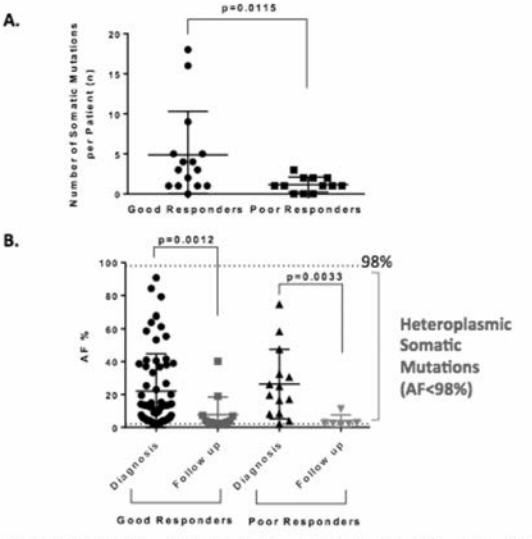
MITOCHONDRIAL DNA MUTATIONS IDENTIFY CLONAL HETEROGENEITY IN CHRONIC MYELOID LEUKAEMIA

IS Pagani[1,2,*], C Hoow Kok[1,3], J Wang[1,3], V Saunders[1], J Goyne[1], J McLean[1], MB Van der Hoek[1], S Heatley[1,3], AP Schwarer[4], TP Hughes[1,3,5,6], DL White[1,3], DM Ross[3,5,7,8]
[1]Cancer Theme, South Australian Health and Medical Research Institute (SAHMRI), Adelaide, Australia, [2]School of Medicine, University of Milan, Milan, Italy, [3]School of Medicine, University of Adelaide, Adelaide, [4]Box Hill Hospital, Melbourne, [5]Department of Haematology, SA Pathology, [6] Centre for Cancer Biology, University of South Australia, [7]Flinders University and Medical Centre, [8]Centre for Cancer Biology, University of South Australia, Adelaide, Australia

Background: Genomic instability in chronic myeloid leukaemia (CML) is reported to be associated with increased reactive oxygen species (ROS). The mitochondrial (mt) genome is susceptible to ROS-induced mutations due to oxidative stress in the mitochondrion and limited DNA repair mechanisms. MtDNA is present in multiple copies per cell: homoplasmy indicates that all mtDNA copies in a cell are identical, whereas coexistence of variant and wild type is referred to as heteroplasmy. Significant variations in treatment outcome occur despite all CML patients having the BCR-ABL1 fusion gene. We hypothesized that mtDNA mutations might reflect high mutational stress and an adverse prognosis.
Aims: To determine the landscape of somatic mtDNA mutations in CML, and to determine whether mt mutations are due to oxidative stress.
Methods: The whole mt genome was amplified in two overlapping fragments, pooled in equimolar concentrations and sent for next generation sequencing. We studied 27 CML patients at diagnosis (Dx) and follow-up (FU) after 12 months of therapy in the ALLG CML9 trial using up-front imatinib, with selective switching to nilotinib for sub-optimal molecular response. Patients were selected as good (n=15) or poor (n=12) responders based on achievement of major molecular response (BCR-ABL1^{IS} ≤0.1%) at 12 months. Mesenchymal stem cells or hair follicles were used to exclude germline polymorphisms. Comparison of technical duplicates was used to establish a 2% cut-off to distinguish mutations from background sequencing errors.
Results: No indels were found. We identified 73 somatic point mutations in 14/15 (93%) good responder patients, and 14 somatic mutations in 9/12 (75%) poor responder patients at Dx. Mutations were distributed across the mt genome with no evident hotspots. The distribution did not differ between good and poor responders, and did not show the excess of G>T transversions that is considered characteristic of ROS-induced damage. The number of somatic mutations per patient was higher in good responders (1-18 per patient; mean 4.87) than in poor responders (mean 4.87 *vs* 1.17 per patient; p=0.0115) (Figure 1A). There was no correlation between Sokal or EUTOS score and the number of mutations. All somatic mutations at Dx were heteroplasmic, with the exception of one patient carrying 10/18 homoplasmic mutations. No difference in the allele frequency (AF) of mutations was found between good (2.1% -90.8%; mean 22.1%) and poor responders (3.7%>74.6%; mean 26.4%) (Figure 1B). Most (85/87) mutations found at diagnosis reverted to homoplasmy in FU samples. Only two patients had mutations showing persistent heteroplasmy with a change in the AF. New heteroplasmic mutations were identified in FU samples in 7/15 (47%) good responder patients, and in 5/12 (42%) poor responders. The AF of mutations at FU was lower than at Dx (2.1%>40.3%, mean 6.5%;) (Fig 1B), but was higher than the estimated level of the residual CML clone (BCR-ABL^{IS} 0%>2.7%; mean 0.46%).



Mitochondrial DNA mutations are common in CML and identify clonal heterogeneity. (A) Number of somatic mutations per patient at diagnosis. Good Responders tended to have more mutations than did poor responders. **(B) Comparison of the Allele Frequency (AF) between good and poor responder patients at diagnosis and follow up.** The AF of mutations at follow-up is lower than at diagnosis.

Figure 1.

Summary/Conclusions: MtDNA mutations are common in CML, and identify clonal diversity both at diagnosis and after imatinib treatment. The pattern of mtDNA mutations was not consistent with ROS-mediated damage. The presence of mt mutations was not associated with clinical risk score and had no prognostic effect. Most mutations found at diagnosis were undetectable at follow-up, consistent with molecular response of the CML clone, but the emergence of heteroplasmy in follow-up might indicate the presence of a non-CML haematopoietic clone in some patients.

CLONAL STRUCTURES OF LEUKAEMIA STEM CELL POPULATIONS IN MYELOID BLAST PHASE CHRONIC MYELOID LEUKAEMIA

D Karamitros[1,*], H Morrison[2], R Kinstrie[2], N Goardon[1], RE Clark[3], M Copland[2], P Vyas[1]
[1]MRC, Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [2]Paul O'Gorman Leukaemia Research Centre, College of Medical, Veterinary & Life Sciences, Institute of Cancer Sciences, University of Glasgow, Glasgow, Scotland, [3]Department of Haematology, Royal Liverpool University Hospital, University of Liverpool, Liverpool, United Kingdom

Background: Chronic myeloid leukaemia (CML) is a model of the multistep processes in cancer. In myeloid malignancies initiating mutation originates in a haemopoietic stem cell (HSC) to give rise to pre-leukaemic stem cell populations. After blast transformation, multiple leukemic stem cell (LSC) populations can be identified. We have shown that CD34+LSC populations were most closely related to normal progenitor populations but had shared elements of a normal stem cell expression signature[1]. In chronic phase (CP)-CML, the leukaemia-propagating population is the HSC, and the progenitor subpopulations do not have stem cell characteristics. Studies to isolate LSC populations in BP-CML have been limited, identifying the granulocyte-macrophage progenitor subpopulation as a possible LSC source[2]. Moreover while CP-CML is dependent on BCR-ABL, the mutations and additional cytogenetic abnormalities underlying disease progression are poorly annotated.

Aims: In this study we aim to: i)Identify changes in size of immunophenotypic (IP) compartments in the progression from CP to BP-CML, ii)characterize which haemopoietic stem/progenitor cell (HSPC) subpopulations of BP-CML patients contain LSCs iii)understand the clonal structures associated with disease progression.
Methods: We have performed extensive IP analysis of 14 AP-CML, 4 CP-CML and 11 BP-CML patients and compared the various HSPCs compartments to normal bone marrow (BM) (N=3). Furthermore we purified HSPC-like populations from 5 BP-CML patient samples and performed *in vivo* xenograft studies using NSG mice with serial transplantation to identify populations with LSC potential. Finally multicolor FISH analysis was performed in 3 patient samples and in engrafted human cells from primary and secondary murine recipients.
Results: Our data conclusively demonstrate that functional LSCs are present in multiple stem/progenitors populations in myeloid BP-CML,. We have described the clonal structures in the samples of 3 patients. Sequential acquisition of 17p13 loss or of 17p13loss and isochromosome 17 was seen in patient samples. More complex clonal structures, with the presence of subclonal atypical BCR-ABL and 17p13loss were detected after transplantation in NSG mice. The monitoring of clonal structures in a patient with 2 sequential samples suggested that the clonal architecture is dynamic and can change with progression of the disease.
Summary/Conclusions: Our results demonstrate that myeloid BP-CML is a heterogeneous disorder with variable LSC populations. Further interrogation of these populations and of clonal hierarchy will identify novel therapeutic targets of LSC populations.
DK and HM are joint first authors, MC and PV are joint senior authors

ROLE OF THE AURORA KINASE A AXIS IN IMATINIB RESISTANCE OF CHRONIC MYELOID LEUKEMIA CD34+ PROGENITORS

M Mancini[1,*], S Soverini[2], F Castagnetti[1], C De Benedittis[1], G Gugliotta[1], G Rosti[1], MA Santucci[1], M Cavo[1], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine - DIMES, Institute of Hematology "L. and A. Seràgnoli", [2]Department of Experimental, Diagnostic and Specialty Medicine - DIMES, Istituto di Ematologia Seràgnoli, Bologna, Italy

Background: Aurora Kinase (AK) A has a pivotal role in chronic myeloid leukemia (CML) genomic instability. Its constitutive activation associated with the *BCR-ABL*1 TK activity promotes the progression of mitosis irrespective of the integrity of replicated DNA. Published studies have proven the therapeutic advantage of AK inhibitors in CML patients either responsive or resistant to imatinib (IM). Such AK inhibitors potential has been ascribed to their inhibitory activity on p210 TK activity.
Aims: In this study, we have focused on the specificity and mechanisms of action of AKs and Plk inhibitors in the putative LSC compartment (CD34+).
Methods: The CD34+ hematopoietic cell fraction was investigated for the phosphorylation levels of AKA and other pro-survival components of its signalling pathways: - FoxM1, a proliferation-associated transcription factor implicated in the advantage of clonal hematopoiesis over the normal counterpart, particularly in the leukemic stem cell (LSC) compartment, which is not dependent on BCR-ABL1 tyrosine kinase (TK) for proliferation and survival; - Polo-like kinase 1 (Plk1), a ser-thr kinase involved in M/G1 progression. CD34+ cells were isolated from bone marrow samples of 10 CML patients at clinical diagnosis by means of immuno-magnetic selection (miniMACS from Miltenyi Biotec). CD34+ cells from peripheral blood of healthy donors, pooled to avoid individual differences were used as normal controls. Informed consent was obtained from all the patients. RT-PCR (reverse transcriptase-polymerase chain reaction), WB (western blotting), IP/IB (immunoprecipitation and immunoblotting) were used to investigate gene expression and protein interactions.
Results: Our results proved a FoxM1 increment associated with IM resistance. An IM-resistant K562 cell line (LD50 0.37 microM *vs* 0.026 microM of parental cells) generated in our lab exhibited FoxM1 over-expression and hyper-phosphorylation contingent upon the upstream activation of AKA and Plk1. In fact, in IM-resistant K562 cells, both Plk1 inhibition by volasertib (1microM) and AKs inhibition by danusertib (1microM), activated a significant increment of apoptotic cell death compared to parental cell line. AKA, FoxM1 and Plk1 involvement in IM resistance was confirmed in mononuclear cell fraction from bone marrow samples of 3 CML patients who developed IM resistance independent from BCR-ABL1 point mutations. Interestingly, the putative BCR-ABL1+/CD34+ LSC compartment, which is neither dependent on BCR-ABL1 TK for proliferation and survival nor killed by IM and second generation inhibitors, showed a hyperphosphorylation of AKA and a consequent overexpression and hyper-activation of FoxM1 and Plk1. Moreover, clonogenic assays performed by using CD34+ progenitors from 3 CML patients at diagnosis showed that volasertib and danusertib are capable to reduce the clonogenic potential of the CD34+ compartment to a much greater extent compared to 1st and 2nd generation TKIs (see Table 1).

Table 1.

LD50	PT1	PT2	PT3
IMATINIB	0.255 M	0.374 M	0.472 M
NILOTINIB	0.197 M	0.277 M	0.324 M
DASATINIB	0.269 M	0.311 M	0.295 M
VOLASERTIB	0.112 M	0.093 M	0.162 M
DANUSERTIB	0.098 M	0.084 M	0.073 M

Summary/Conclusions: The BCR-ABL1+/CD34+ compartment provides a sanctuary for disease relapse upon drug withdrawal as well as a putative source of drug-resistance. We have identified a new signaling pathway involved both in drug resistance and in CD34+ cell survival. Our data open the route to novel therapeutic approaches worth exploring in order to overcome drug resistance. Danusertib and volasertib are in clinical trials in hematologic malignancies.

P607

PRESENCE OF SOMATIC AND GERMLINE MUTATIONS IN EPIGENETIC MODIFIERS IN CML-CP

G Nteliopoulos*, A Bazeos, G Gerrard, M Alikian, HE Foong, L Foroni, JF Apperley
Department of Medicine, Centre for Haematology, Imperial College, London, United Kingdom

Background: Chronic myeloid leukaemia (CML) originates from a single genetic aberration (BCR-ABL1); however the clinical disease is remarkably heterogeneous and the genetic mechanisms of resistance to tyrosine kinase inhibitors (TKI) are still poorly understood. Recently, we have identified consistent differences in genome-wide DNA methylation patterns in chronic phase (CP) CML patients compared to healthy controls, whireas epigenetic modifying enzymes have been found frequently mutated in other haematological neoplasms.
Aims: The aim of this study is to analyse a panel of mutations in epigenetic modifiers in CML-CP using Ion Torrent PGM next-generation sequencing. The panel design was based on gene expression analysis we generated and literature search. Potential mutations found at diagnosis may be used as novel prognostic biomarkers for TKI response.
Methods: 52 samples from untreated patients with newly diagnosed CML-CP ($CD34^+$) who started on imatinib were included in the study, classified as responders (n=26) /non-responders (n=26) based on BCR-ABL1/ABL ratio at 3 months. As constitutional non-leukaemic DNA, for non-responders we used DNA from T cells, cultured *in vitro* for 7 days, and for responders DNA from the patients in deep molecular remission (whole blood). 14 samples from healthy donors ($CD34^+$) and 5 samples from CML-BC (blast crisis) were also used. A custom panel covering the coding region of 71 epigenetic enzymes was designed.
Results: A mean depth of 273/amplicon was obtained, detecting mutations as low as 4%. After excluding "bad" variants of low quality, common SNPs with minor allele frequency (maf) >1%, variants found in healthy controls and intronic variants, we kept the non-synonymous variants predicted disease causing, deleterious and damaging by Mutation Taster, PolyPhen-2 and SIFT respectively, and found 104 variants in 46/71 of the genes. However, when constitutional DNA was used as non leukaemic control, we found that only 35 were CML-related somatic mutations, including missense, nonsense, frameshift/non-frameshift insertions and splice site variants, present in 25 genes. 26 mutations were found in non-responders (NR), 13 in responders (R). Interestingly all nonsense variants (in *ASXL1, IKZF1, DNMT3A, EP300*) and most insertions (in *ASXL1, WT1),* were found only in non-responders. Similarly, nonsense mutations in *ASXL1 and IKZF1* were found in 2 CML-BC patients. The frequency of the mutated allele for most mutations was <10%. Mutations were detected in the R and NR group in equal proportion (11/26 patients), however, the presence of ≥2 mutations was more common in NR**.** In addition, we examined the correlation of presence of mutations with gene expression, detecting a correlation in some cases, and their influence on overall survival (OS), finding an influence, especially in the non-responders, more prominent when there were ≥2 mutations. Moreover, we found 69 missense variants that were also present in the constitutional DNA, with frequency of the mutated allele ~50%, considered as germline mutations. These variants were present in 32 genes with 39 and 34 variants in NR and R respectively**,** while there was no difference in the number of R, NR that carried at least one mutation (both groups 20/26 patients)**.** Specific variants in *RUNX1, TET1, TET2* were found in ≥3 patients.
Summary/Conclusions: The mutation analysis of epigenetic modifiers in CML-CP identified the presence of somatic mutations, some of which (found only in NR) can be considered as predictive biomarkers for IM failure, and germline mutations that may predispose to CML.

Seràgnoli", University of Bologna, Bologna, Italy

Background: Assessment and monitoring of BCR-ABL1 levels by quantitative PCR (qPCR) is essential for the management of CML patients treated with TKIs. Currently, up to 30-40% of CML patients treated with TKIs can achieve a deep molecular response (DMR: BCR-ABL1 ≤0,01% IS), but only 50% maintain a stable Treatment Free Remission (TFR) after discontinuation of TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region. The number of target copies originally present in the sample can be calculated from the number of partitions in which amplification has successfully occurred. The dPCR is expected to give a better sensitivity and accuracy than qPCR in the assessment of molecular Minimal Residual Disease (MRD) in CML patients treated with TKIs.
Aims: The aim was to quantify the BCR-ABL1 transcript levels by dPCR in 116 CML patients treated with TKIs (imatinib, nilotinib or dasatinib) and achieving a major molecular response (MMR or $MR^{3.0}$) or DMR ($MR^{4.0}$, $MR^{4.5}$and $MR^{5.0}$). The results obtained by dPCR were compared with the ones obtained by qPCR.
Methods: The dPCR was performed on a QuantStudio 3D Digital PCR System (Life Technologies) by using a TaqMan-MGB probes targeting the BCR-ABL1 transcript. The absolute quantities of BCR-ABL1 transcript were expressed as number of copies/ul. Samples for dPCR testing were obtained from CML patients treated with TKIs, on time-checks planned for MRD monitoring by standard qPCR performed according to the last International Guidelines. The analysis by dPCR and qPCR were performed on 33 cases with stable $MR^{3.0}$, 37 cases with stable $MR^{4.0}$, 34 cases with stable $MR^{4.5}$, 12 cases with stable $MR^{5.0}$. Blank samples served as negative controls, while 10 healthy donors served as normal controls. Patients enrolled in the study gave informed consent.
Results: In patients with $MR^{3.0}$ the number of BCR-ABL1 copies/ul assessed by dPCR were significantly higher than those of patients with $MR^{4.0}$ (0.0002), $MR^{4.5}$ ($p<0.0001$) or $MR^{5.0}$ ($p<0.0001$). BCR-ABL1 transcript levels were detectable by dPCR also in cases (n°=43) resulted undetectable by qPCR. No linear correlation was found between the BCR-ABL1 copies/ul assessed by dPCR and the values of BCR-ABL1/ABL1% IS (R=0.196) or the absolute copy number of BCR-ABL1 transcripts assessed by qPCR (R=0.184). However, a case by case analysis revealed a linear correlation (R=0.729) only for the cases with an absolute copy number of BCR-ABL1 transcript >15 assessed by qPCR. One-way ANOVA test revealed a correlation between dPCR BCR-ABL1 levels and the $MR^{3.0}$class only. The 84% of deep responders fell under the value of 0.468 BCR-ABL1 copies/ul indicated by the ROC analysis as the value below which the patients with lower levels of MRD might be dissected (specificity=63.64%, sensitivity=84.34%; AUC=0,847).
Summary/Conclusions: The study suggests that dPCR is more accurate and sensitive than qPCR especially in the patients with DMR and currently we are conducting a systematic monitoring of MR by dPCR to evaluate its reliability. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

Background: b3a2 (e14a2) and b2a2 (e13a2) are the two major *BCR-ABL1* transcripts in CML. The prognostic relevance of the two transcript subtypes after frontline therapy with tyrosine kinase inhibitor is unclear.
Aims: We aimed to determine the impact of the two *BCR-ABL1*subtypes on outcome of CML patients following frontline imatinib therapy.
Methods: *BCR-ABL1* transcript subtype was determined in 655 newly diagnosed CML-CP patients enrolled in Taiwan CML Study from Jun-2004 to March-2014. The frequencies of transcript subtypes were 62.4% (n=409) for b3a2, 34.5% (n=226) for b2a2, 1.8% (n=12) for both b3a2 and b2a2, and 1.3% (n=8) for other rare types. The *BCR-ABL1* levels expressed as International scale (IS) were measured in a central laboratory every 3 months following frontline imatinib 400mg/d. A comparison of the molecular responses and outcome of patients between b3a2 and b2a2 transcript subtypes was made.
Results: Of the 635 patients with b3a2 and b2a2 transcripts, there was no difference in age, gender, WBC count, circulating blast percentage, platelet count, or Sokal risk score between the two subtypes. At 3 months, *BCR-ABL1* IS ≤10% was achieved in 49% of b3a2 patients compared with 42% of b2a2 type (*P*=0.114). At 6 months, 19% of b3a2 patients had *BCR-ABL1* IS >10% compared with 37% of b2a2 (*P* <0.0001). At 12 months, 35% of b3a2 type had *BCR-ABL1* IS >1% compared with 46% of b2a2 patients (*P*=0.027). Patients with b2a2 transcripts had a slower rate of decline as compared with that of b3a2 transcripts over the time from 3 months to 7 years after imatinib treatment. The cumulative incidence of MMR at 2 years in b3a2 and b2a2 patients were 55.6% and 38.2%, respectively (*P* <0.0001); at 4 years was 71.2% for b3a2 and 59.2% for b2a2 (*P* <0.0001). The cumulative incidence of $MR^{4.5}$at 4 years was 28% and 26.7% for b3a2 and b2a2, respectively (*P*=0.323); at 6 years was 42.2% for b3a2 and 41.5% for b2a2 (*P*=0.323). The median time to MMR was not different between patients carrying the two transcript types, 14.4 months for b3a2 and 15.5 months for b2a2 (*P*=0.659). The median time to $MR^{4.5}$for b3a2 was 32.6 months and 34.1 months for b2a2 patients (*P*=0.994). With a median follow-up of 49.3 months, 30 (4.7%) patients had disease progression, accelerated phase (n=13) and blast crisis (n=17; 10 myeloid and 7 lymphoid). There was no difference in the occurrence of disease progression between the two transcript subtypes (3.7% for b3a2 and 6.6% for b2a2, *P*=0.117). Lymphoid-blast phase was highly associated with b2a2 transcript (6/7) compared to b3a2 type (1/7) (*P*=0.010). The overall survival at 10 years for b3a2 and b2a2 transcripts were 94.0% and 93.9%, respectively (*P*=0.635). The progression-free survival at 10 years was 92.7% for b3a2 and 87.9% for b2a2 patients (*P*=0.089).
Summary/Conclusions: Taiwan CML Study demonstrated that patients with b2a2 transcripts had significant higher failure rates at 6 and 12 months, a lower cumulative incidence of MMR by 2 and 4 years, a higher frequency of lymphoid crisis and a trend of inferior progression-free survival as compared to those with b3a2 patients.

P610

THE INCIDENCE AND NATURAL HISTORY OF DASATINIB COMPLICATIONS IN THE TREATMENT OF CHRONIC MYELOID LEUKAEMIA

L Fox[1,*], F Putt[1], D Yeung[2], L Carne[2], R Cleary[3], K Cummins[4], S Fleming[4], C Forsyth[5], M Dixon[5], M Tatarczuch[6], O Motorna[7], W Janowski[8], M Hughes[8], A McQuillan[9], A Schwarer[10], J Devos[11], R Harrup[12], A Holmes[13], S Ratnasingam[14], KL Chan[15], B Hsu[16], K Bury[17], A Grigg[1]

Background: Dasatinib (DAS) has shown superiority over imatinib in achieving cytogenetic and molecular responses in chronic phase (CP) CML but with a different toxicity profile, which may impact on its overall benefit. Reported tox-

icities from the DASISION trial at 5 years include pleural effusions (PE) (29%), pulmonary hypertension (PHTN) (5%), and low rates of arterial ischemic events. While the literature well describes the incidence of these events, the response to therapy and the impact of subsequent dose modifications on the outcome of the toxicity have generally not been comprehensively characterised.
Aims: To review the incidence of these side-effects in a snapshot survey of Australian patients (pts) receiving DAS, either as first or subsequent line of therapy for CML-CP, with a focus on risk factors and the response of the toxicity to therapeutic changes.
Methods: Retrospective study of all eligible pts (received DAS for CML-CP and access to sufficient data) at 17 Australian institutions. Each pt's history was tracked in detail to identify any complications potentially attributable to DAS, and the treatment and outcome of these complications in response to cessation or alterations in DAS dose or schedule.
Results: 221 pts were evaluable, with a median age at DAS commencement of 53 years (range 20 – 86) and median starting dose of 100mg (20-140*)*. 51 (23%) received DAS as 1st line therapy, 133 (60%) 2nd line and 37 (17%) 3rd line. The median follow up from DAS commencement was 27 months (4 –116 months). No side effects were reported in 105 (48%) pts. Of the 116 (52%) pts with side-effects, the most common side effect was PE, observed in 53 (24%) pts with a median age of 65 years (41-86 years) and with median time to onset of 11 months (0.5-59 months). Most (40 pts, 76%) were receiving DAS as 2nd line therapy*.* DAS dose at PE onset was 100mg in 37 pts (70%), 140mg in 9 pts (17% PEs; notably 38% of pts on this dose developed PE), 70mg in 4 pts, 80mg in 2 pts and 50mg in 2 pts. The Figure 1 documents outcomes in pts with PE at 100mg dose with the key findings being a very high risk of recurrence in the absence of dose reduction and a substantial risk despite dose modifications. Evaluation of the CML status in these patients 6 months after changes in DAS dose and schedule is currently underway. Additional management of PE included diuretics (79%), thoracocentesis (43%), and steroids (47%). Only 1 of 7 pts given maintenance low dose steroids developed recurrence. Other side-effects included Grade 3-4 haemorrhage in 8 pts (4%), 3 of whom had platelets <50 $x10^9$/L and fatal intracerebral haemorrhage in a pt with a normal count. Ten (5%) pts had elevated pulmonary artery pressures meeting criteria for PHTN (RVSP >36mmHg) [median DAS dose 100mg (100-140)]; all described dyspnoea, although notably 8 had either concurrent PE or developed PE within 6 months. Of 5 PHTN pts with available follow up data, RVSP normalised in 4 post DAS cessation. The two episodes of peripheral vascular disease requiring intervention occurred in pts previously treated with nilotininb. There were no atypical infections apart from one pt with an empyema. Two pts had benign cervical lymphadenopathy. There were no deaths clearly attributable to DAS. Side-effects led to permanent DAS cessation in 51 pts (23%).

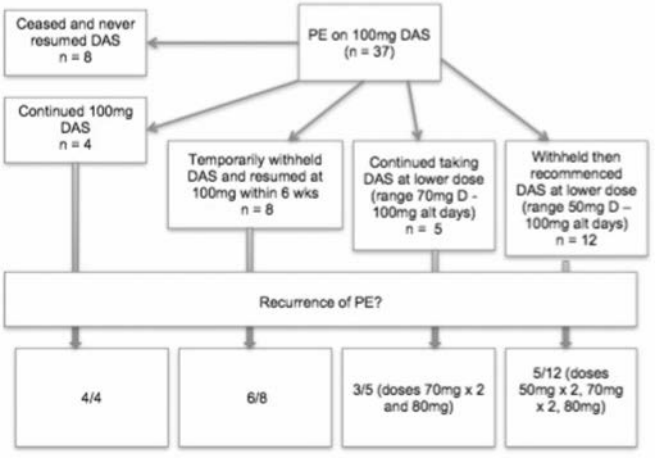

Figure 1.

Summary/Conclusions: The incidence of common DAS side effects (PE, PHTN) were similar to those seen in the DASISION study. Other side-effects were uncommon. Age and dose were risk factors for PE. In pts with PE on 100mg, recurrence was very high in the absence of dose reduction, and was still high despite reduction but appeared to be reduced by maintenance low dose steroids. These findings support the results of Porrini (ASH 2011) who found DAS at lower doses is effective in the elderly. With dosing appropriate for age, possibly supported by titration according to DAS levels and molecular response, severe side effects of DAS requiring permanent drug cessation are likely to be rare.

P611

THE HOCT1/ABCB1 DIPLOTYPE IS ASSOCIATED WITH COMPLETE CYTOGENETIC RESPONSE AND TOLERABILITY TO IMATINIB IN PATIENTS AFFECTED BY CHRONIC MYELOID LEUKEMIA

S Galimberti[1,*], L Galeotti[2], F Ceccherini[2], D Domingo[2], M Laurino[2], C Baratè[1], F Ricci[1], S Grassi[1], F Guerrini[1], C Fava[3], A D'Avolio[4], G Cervetti[1], G Fontanelli[1], G Saglio[5], F Cornolti[6], M Petrini[7], E Arrigoni[8], A Di Paolo[8]
[1]Clinical and experimental Medicine, UO Hematology University of Pisa, Pisa, [2]Phymtech Srl, Navacchio (PI), [3]Department of Biological and Clinical Sciences, [4]Laboratory of Clinical Pharmacology and Pharmacogenetics, Department of Medical Sciences, Unit of Infectious Diseases, University of Turin, [5]Hematology Ospedale Mauriziano, University of Turin, Turin, [6]Physics, University of Pisa, [7]Clinical and experimental Medicine, University of Pisa, [8]Clinical and experimental Medicine, section of Pharmacology, University of Pisa, Pisa, Italy

Background: Drug transporters, such as hOCT1 (SLC22A1) and ABC members (ABCB1, ABCG2), have been already shown to play a role in both intracellular and systemic plasma concentrations of imatinib. In particular, our group showed that the hOCT1 c.480C>G polymorphism conditions higher rates of adverse events and shorter EFS. Analogously, the ABCB1 polymorphisms have been related to a worse prognosis, but the item is still debated.
Aims: Here we address imatinib pharmacodynamics through a mathematical analysis based on patient's pharmacogenetic data and gender. All analyses were conducted in the context of the TIKlet protocol (ClinicalTrials.gov code: NCT01860456).
Methods: Fifty-three CML patients receiving imatinib, 30 males and 23 females, were enrolled at the Hematology Unit of Pisa and at the Department of Internal Medicine of Orbassano (TO), Italy. The following polymorphisms were assessed: rs72552763 [MI420I], rs12208357 [c.181C>T] and rs683369 [c.480C>G] (hOCT1), rs1128503 [c.1236C>T], rs2032582 [c.2677G>T/A] and rs1045642 [c.3435C>T] (ABCB1), rs4149117 [c.334G>T] (SLCO1B3). Patients were grouped according to the absence (wild-type) or the presence (heterozygous or polymorphic homozygous) of at least one polymorphic allele.
Results: We found that the complete cytogenetic response was in strong relationship with combinations of hOCT1 [c.480C>G] and ABCB1 [c.3435C>T] polymorphisms. Indeed, genotypes identical for both loci (*i.e.*, wild/wild or polymorphic/polymorphic) exhibited a longer time to CCyR than those with mixed types (wild/polymorphic or polymorphic/wild), p-value=0.013. Since the drug tolerability has a strong incidence on the discontinuation of the therapy, we studied also whether the onset of toxicities was related to any of the considered variables. Interestingly, the same combinations of hOCT1 [c.480C>G] and ABCB1 [c.3435C>T] polymorphisms found related to efficacy were found associated with the maximum grade of toxicity as well, p-value=0.022. In particular, patients with mixed hOCT1 c.480C>G and ABCB1 c.3435C>T genotypes displayed higher levels of toxicity. As ancillary investigation we studied also the time to the onset of the main toxic effects and we found that the time of manifestation of the cramp toxicity was shorter in females than in males (5.3 *vs* 22.6 months) and the time to manifestation of the edema toxicity was associated with a combination between gender and ABCB1 c.3435C>T (2.5 *vs* 16.4 months).
Summary/Conclusions: To the best of our knowledge this study sheds a first light on the possible role of the combination between hOCT1 [c.480C>G] and [ABCB1 c.3435C>T] polymorphisms as predictor of both efficacy and toxicity of the imatinib treatment.

P612

REAL-LIFE COMPARISON OF DASATINIB AND NILOTINIB AS SECOND-LINE THERAPY AFTER IMATINIB FAILURE FOR CHRONIC PHASE CML

Background: Use of 2nd generation tyrosine kinase inhibitors (2G-TKIs) dasatinib (DAS) and nilotinib (NIL) in chronic phase (CP) chronic myeloid leukemia (CML) patients failing imatinib (IM) result in around 50% of sustained cytogenetic response. However, it's unclear if there's a significant difference in efficacy of the two 2G-TKIs, especially in the long-term.
Aims: To compare efficacy of DAS and NIL in CP-CML patients after IM resistance or intolerance.
Methods: We retrospectively analysed 163 CP-CML patients resistant or intolerant to IM that received either DAS (n=95) or NIL (n=68) as second-line therapy.

We compared the characteristics of the two groups at the time of CML diagnosis and at the time of IM failure, including the cause of switch to 2G-TKI, duration of IM therapy, IM dose escalation and Hammersmith score to predict the probability of response to 2G-TKIs. Cytogenetic and molecular responses were evaluated according to the ELN recommendations. Time to treatment failure (TTF) was calculated from the start of 2G-TKI to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, treatment discontinuation for primary or secondary resistance or intolerance. Progression free survival (PFS) was calculated from the start of 2G-TKI to ABP or death. Overall survival (OS) was calculated from the start of 2G-TKI to death.

Results: Considering CML characteristic at diagnosis, the DAS and NIL cohorts were comparable for age, sex and risk score (Sokal and EUTOS). Median duration of IM therapy was similar (DAS 19 months, NIL 14 months), but 27/95 patients (28%) had IM dose escalation before DAS compared to only 9/68 (13%) before NIL (p=0.03). There was a higher rate of switch to DAS than to NIL for secondary resistance (26/95, 27% *vs* 7/68, 10%; p=0.01) while more patients changed from IM to NIL due to intolerance (31/68, 46%, *vs* 21/95, 22% for DAS; p=0.002). Rates of primary resistance did not differ (47/95, 49% for DAS *vs* 28/68, 41% for NIL; p=0.37), as other causes of switch (1/95, 1% for DAS *vs* 2/68, 3% for NIL; p=0.77). Hammersmith score was almost identical in the two groups. Complete cytogenetic response (CCyR) was attained in 53/73 (73%) patients not in CCyR at the time of DAS start, compared to 31/48 (65%) patients not in CCyR at the time of NIL start (p=0.46). Mean time to attain CCyR was similar (7.1 months for DAS and 5.3 months for NIL; p=0.30). Major molecular response (MMR) was achieved in 55/89 (65%) patients not in MMR at the time of DAS start and in 39/61 (65%) patients not in MMR at the time of NIL start (p=0.82). Again, mean time to MMR was not different in the DAS e NIL cohorts (12.4 *vs* 8.5 months; p=0.14). With a median follow-up of 44 months (range 1–124), 5-year TTF was similar for DAS (65%, 95%CI 52-75%) and NIL (61%, 95%CI 43-74%; p=0.40) [Figure 1a]. Thirty-two of 95 patients (34%) stopped DAS due to toxicity (19/32, 59%), resistance (11/32, 31%) or other causes (3/32, 10%); 22/68 patients (32%) interrupted NIL for toxicity (11/22, 50%), resistance (8/22, 36%) or other causes (3/22, 14%), Probability of survival and progression were almost identical, with a 5-year PFS of 84% (95%CI 68-89%) for DAS and 92% (95%CI 79-97%) for NIL (p=0.27) [Figure 1b] and a 5-year OS of 89% (95%CI 78-95%) and 96% (95%CI 85-99%) (p=0.31), respectively.

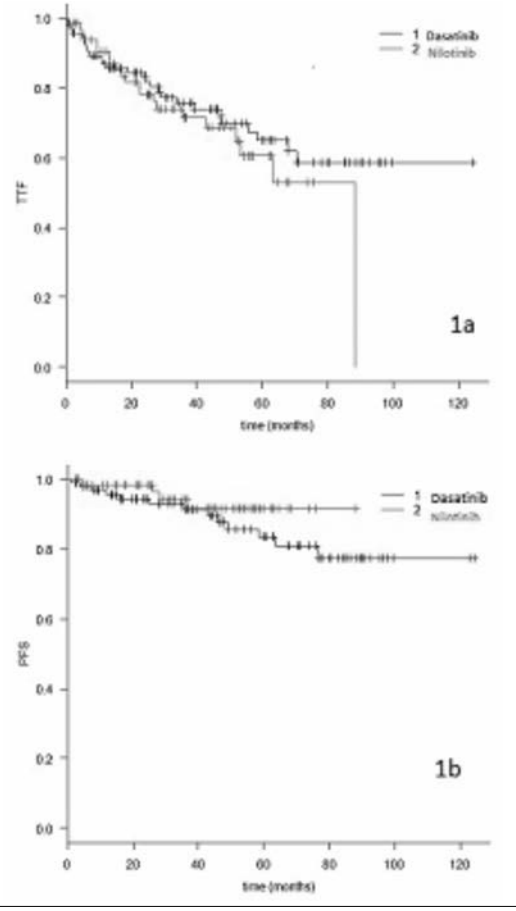

Figure 1.

Summary/Conclusions: With the limits of a retrospective analysis, our data suggest similar efficacy of DAS and NIL after IM failure in CP-CML, with high rates of cytogenetic and molecular responses and excellent long-term survival.

P613

FACTORS THAT INFLUENCE PATIENT WILLINGNESS TO ATTEMPT TREATMENT-FREE REMISSION IN CHRONIC MYELOID LEUKAEMIA

D Ross[1,*], L Villemagne-Sanchez[2], K Hall[1], K Gough[2], Y Kashima[2], C O'Callaghan[2], J Seymour[3], P Schofield[4]
[1]Haematology, SA Pathology, Adelaide, [2]Psychology, University of Melbourne, [3]Haematology, Peter MacCallum Cancer Centre, [4]Psychology, Swinburne University, Melbourne, Australia

Background: Most patients (pts) with chronic myeloid leukaemia (CML) on long-term tyrosine kinase inhibitor (TKI) treatment will achieve a deep molecular response (commonly defined as MR4.0; BCR-ABL ≤0.01%). Around half of these pts would remain in treatment-free remission (TFR) if their TKI were stopped after several years of stable MR4.0 or better. TFR is increasingly becoming a goal of treatment, yet little has been reported about pt perceptions of TFR.

Aims: To examine factors that influence expressed willingness to attempt TFR.

Methods: We developed a survey incorporating CML-specific factors (disease history, treatment toxicity, adherence) and questions relating to perceived susceptibility to relapse and consequences of relapse, benefits of and barriers to attempting TFR. Verbatim responses to an open-ended question regarding willingness to attempt TFR were grouped into themes. The survey incorporated two validated inventories: the Morisky Medication Adherence scale and the MDAnderson Symptom Inventory for CML TKI toxicity. CML pts in MR4.0 were eligible if they were taking any approved TKI. Pts were recruited from around Australia after receiving an invitation letter explaining the survey.

Results: There were 87 eligible respondents (Table 1). 82% of pts (95% CI 73-90%) indicated that they would be willing to cease TKI under close medical supervision if their doctor (Dr) thought it appropriate. On a scale of 0-100 (where 100 is extreme willingness) the median score was 69. No demographic or CML-related (disease duration, TKI) variable in the survey was significantly associated with the outcome variable. On average, respondents rated their TKI toxicity severity as 2.3 (SD: 1.7; Range: 0-7) on a 0-10 scale, (where 10 is very severe). This was positively correlated (r=0.76; p<0.01) with interference of TKI toxicity in daily life (mean 2.66). Increasing age was positively correlated with TKI toxicity severity (r=0.34; p<0.05), but not with interference of toxicity. Neither measure of TKI toxicity was significantly associated with willingness to stop TKI treatment. Stated treatment adherence was moderate (mean score 6.9/10 [SD: 1.1; Range: 3.5-8]). Adherence was positively correlated with age (r=0.27; p<0.05), but not with willingness to attempt TFR. Qualitative responses were related to willingness (59%); reluctance (34%); and ambivalence or conditional willingness (38%) to attempt TFR. The most frequently cited reasons to stop TKI included: TKI toxicity, actual (n=21) or potential (n=5); and confidence in the Dr (n=11) or molecular response (n=8). The leading reason not to stop was fear of disease progression or TKI resistance (n=7). Some patients believed that age or comorbidities made them unsuitable to attempt TFR; that TKI treatment was essential to prevent relapse or death; or cited negative experiences of friends stopping chemotherapy for other cancers. Conditional willingness was most often related to availability of medical supervision and testing (n=14) and probability of maintaining TFR (n=7).

Table 1. Patient characteristics.

Mean age (years)	56
Male:Female	38:49
Median BCR-ABL%	0
Current undetectable BCR-ABL	34
Current TKI	
Imatinib	56%
Nilotinib	26%
Dasatinib	17%
Ponatinib	1%
Median years since CML diagnosis	6
Median years on current TKI	3
Median MDASI-CML symptom score*	29

*0=no symptoms; 200=worst possible

Summary/Conclusions: Most respondents (82%) would be willing to stop their TKI with the support and supervision of their Dr. Although TKI toxicity was the commonest reason to attempt TFR, there was no correlation between symptom severity and willingness to stop TKI. This might indicate that even mild TKI toxicity is sufficient motivation for pts to attempt TFR. Potential future toxicity was also relevant to some patients. Reluctance to stop TKI was often associated with needs for additional information or misunderstanding of the current data. Understanding pt motivations and concerns is important if TFR is to be incorporated into the routine treatment pathway for CML.

P614

GENETIC VARIABILITY OF OXIDATIVE STRESS AND DNA REPAIR GENES POTENTIAL PROGNOSTIC AND THERAPEUTIC BIOMARKERS IN CHRONIC MYELOID LEUKEMIA

AC Gonçalves[1,2,3,*], R Alves[1,2,3], P Couceiro[2], P Rodrigues-Santos[2,4], P Freitas-Tavares[5], A Pereira[3,6], L Ribeiro[5], L Mota-Vieira[7,8,9], JM Nascimento Costa[10,11], AB Sarmento-Ribeiro[1,2,3,5]

Background: Oxidative stress (OS), resulting from an imbalance between Reactive Oxygen Species (ROS) production and antioxidant defenses, contributes to cell damage, apoptosis and ineffective hematopoiesis. Chronic myeloid leukemia (CML) is a clonal neoplastic disease associated with the reciprocal translocation t(9;22), encoding the *BCR-ABL1* oncogene. BCR-ABL protein induces, among other mechanisms, production of reactive oxygen species (ROS) by activation of the PI3K pathway, increase glucose metabolism and mitochondrial dysfunction. The antioxidant enzymes superoxide dismutases (SOD) and catalase (CAT), as well as DNA repair enzymes, such as OGG1, are important cell defense components against OS. Polymorphisms in genes that codify these enzymes may contribute to differences in susceptibility of individuals to oxidative damage, since it can lead to reduced protection against OS, influencing CML development and therapeutic response.
Aims: In the present study we investigate the influence of polymorphisms in genes related with oxidative stress (*CAT, GPX1, MPO, SOD1*, and *SOD2*) and DNA repair (*OGG1, NEIL1*, and *XRCC1*), and in the transcription factor *NFE2L2*, as a prognostic risk marker in CML patients [namely the impact in overall survival and tyrosine kinase inhibitors (TKIs) response]. Moreover, we also analyzed their participation in the development of mutations in *BCR-ABL1* gene.
Methods: This study enrolled 75 patients diagnosed with CML. The genetic polymorphisms of *CAT* (rs1001179), *GPX1* (rs1050450), *MPO* (rs2333227), *SOD1* (rs2070424), *SOD2* (rs4880), *OGG1* (rs1052133), *NEIL1* (rs5745920), *XRCC1* (rs1799782), and *NFE2L2* (rs13001694), were assessed by RFLP-PCR and Tetra-primer-ARMS-PCR. The oxidative stress (reactive oxygen species/total antioxidant status ratio) and DNA damage (8-hydroxy-2'-deoxyguanosine) were measured using commercial kits. The statistical analysis was carried out by variance analysis, $\chi 2$ test and Fisher exact test ($p<0.05$).
Results: Our results show that *SOD2* CC genotype influence the mutation status of *BCR-ABL1* gene (odds ratio 9.25x, I.C.95% 1.24-18.82; $p=0,007$), being the CC genotype also associated with higher oxidative stress levels. On the other hand, patients with *MPO* GG and AG genotypes have a high rate of suboptimal response to TKIs (odds ratio 4.92x, I.C.95% 1.24-9.10; $p=0,043$), and these genotypes were also associated with higher oxidative stress levels. Moreover, the overall survival of CML patients can be influenced by *NEIL1* [CML patients with CT genotype had lower survival (166±5 months) than patients with CC and TT genotypes (204±6 months; $p=0.041$)] and *NFE2L2* [CML patients with TT genotype had lower survival (88±7 months) than patients with CT and TT genotypes (216±8 months; $p=0.003$)].
Summary/Conclusions: Our results show that genetic polymorphisms in oxidative stress and DNA repair related genes modulate oxidative stress and DNA damage levels in CML patients. Moreover, these polymorphisms influence the prognosis of CML patients, their response to TKI treatment and the development of *BCR-ABL1* mutations, which suggest their potential as new prognostic and therapeutic biomarkers.

LANDMARK ANALYSES IN THE PIVOTAL PONATINIB PACE TRIAL: IMPACT OF EARLY RESPONSES ON 3-YEAR OUTCOMES IN HEAVILY PRETREATED CP-CML PATIENTS

M Mueller[1,*], M Baccarani[2], MW Deininger[3], F Guilhot[4], A Hochhaus[5], TP Hughes[6], NP Shah[7], M Talpaz[8], S Lustgarten[9], VM Rivera[9], T Clackson[9], FG Haluska[9], JE Cortes[10]

[1]Universitätsmedizin Mannheim, Mannheim, Germany, [2]S. Orsola-Malpighi University Hospital, Bologna, Italy, [3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, United States, [4]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [5]Jena University Hospital, Jena, Germany, [6]South Australian Health and Medical Research Institute and University of Adelaide, Adelaide, Australia, [7]University of California San Francisco, San Francisco, CA, [8]Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI, [9]ARIAD Pharmaceuticals, Inc., Cambridge, MA, [10]The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Ponatinib is a potent oral tyrosine kinase inhibitor (TKI) active against native and mutant forms of BCR-ABL1. It is approved for patients with refractory CML or Ph+ALL, or with the T315I mutation. Responses at early landmark time points have been correlated with positive long-term outcomes in patients treated with other TKIs in the first- and second-line settings.
Aims: Landmark analyses are limited for populations treated with multiple prior TKIs. Here, we evaluate the impact of achieving early landmark responses with ponatinib on 3-year outcomes in heavily pretreated patients in the ongoing Phase 2 PACE trial (NCT01207440).
Methods: Molecular responses (International Scale; BCR-ABL ≤0.1% [major molecular response (MMR)], >0.1–1%, >1%–10% and >10%) and cytogenetic responses (Ph+ metaphases ≤35% [major cytogenetic response (MCyR)]) at 3, 6 and 12 months and their association with outcomes at 3 years past landmark were examined in a post hoc analysis of heavily pretreated patients with chronic-phase (CP)-CML (n=267). *P* values were calculated using the log-rank test. Data cutoff date was 3 August, 2015. All patients gave informed consent.
Results: Median time from diagnosis was 7 years (range 0.5-27) and median age was 60 years (range 18-94); 61% of patients had received ≥3 prior TKIs. At 3, 6, and 12 months, 48%, 62% and 71% of patients, respectively, achieved MCyR, and 14%, 29% and 39%, respectively, achieved MMR, among patients evaluable at each landmark. Greater reductions in BCR-ABL1 transcript levels at most landmark time points were associated with improved PFS and OS at 3 years (Table 1), as was MCyR. Deeper responses at all landmark time points were also associated with the achievement of MR4.5 over time.

Table 1. Estimated PFS and OS at 3 years past landmark by BCR-ABL1 level.

Landmark/Response		n	PFS	*p-value	n	OS	*p-value
3 mo	BCR-ABL1 ≤0.1%	32	97%	—	33	97%	—
	BCR-ABL1 >0.1–1%	47	70%	.39	48	85%	.60
	BCR-ABL1 >1%–10%	51	61%	.0080	55	81%	.13

*Calculated across the entire post-landmark timespan and unadjusted for multiple comparisons

Summary/Conclusions: Deep, early reductions in BCR-ABL1 transcripts were positively associated with long-term survival in this refractory population. These data support the prognostic value of achieving early landmark cytogenetic and molecular responses with ponatinib in heavily pretreated patients.

P616

BCR-ABL1 TRANSCRIPT LEVEL ON DAY+28 CAN PREDICT EARLY MOLECULAR RESPONSE AT 3 MONTHS AND MAJOR MOLECULAR RESPONSE AT 12 MONTHS IN CHRONIC MYELOID LEUKEMIA PATIENTS WHO TREATED WITH FRONTLINE DASATINIB

Medicine, Hemato-Oncology, Sungkyunkwan University, Kangbuk Samsung Hospital, Seoul, [8]Internal medicine, Dong-A University Hospital, Busan, [9]Hematology, The Catholic University of Korea, St. Vincent's Hospital, Suwon, [10]Internal medicine, Hallym University Hospital, [11]Hematology, Ehwa Womans University Hospital, Seoul, [12]Internal medicine, Hanyang University Guri Hospital, Guri, [13]Hematology, The Catholic University of Korea, Seoul St. Mary's Hospital, Leukemia Research Institute, Seoul, Korea, Republic Of

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 month is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensityduring first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel, oral tyrosine kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

Aims: We evaluated the possibility of the VEMR at I month predicting outcomes in newly diagnosed CP-CML patients treated with dasatinib.
Methods: In this multi-center, observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100 mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24, 36 month, time to and duration of MMR and CMR, bcr-abl kinetics by digital PCR, and safety were tested. A receiver operating characteristic (ROC) curve from molecular data on Day+28 was calculated to predict EMR and MMR at specific timepoints.
Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 17 months (0.9-27.2 months), 92 (90.1%) out of 102 patients were still on dasatinib treatment and 10 patients discontinued due to disease progression or treatment failure in 3 patients or adverse events in 4 patients or other causes. The cumulative MMR at 12 months was 65.2%. The cut-off value of BCR-ABL1 transcript on Day+28 calculated by ROC curve was 40%. Among 92 patients who have available molecular data of both D+28 and 12 months, fifty nine (64.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. In 59 patients who had VEMR, 50 (84.7%) patients achieved MMR at 12 months. However, only 30.3 (10 out of 33 patients) % of patients with no VEMR achieved MMR at 12 month. More detailed data will be updated at presentation.
Summary/Conclusions: Our study shows that VEMR at I month can be an important predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

P617

THE IMPACT OF EARLY MOLECULAR RESPONSE ON LONG-TERM OUTCOMES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) TREATED WITH DASATINIB OR IMATINIB FROM THE DASISION TRIAL

F Stegelmann[1,*], NP Shah[2], G Saglio[3], A Hochhaus[4], R Bilmes[5], L Li[5], JE Cortes[6]
[1]Universitätsklinikum Ulm, Ulm, Germany, [2]UCSF School of Medicine, San Francisco, United States, [3]University of Turin, Turin, Italy, [4]Universitätsklinikum Jena, Jena, Germany, [5]Bristol-Myers Squibb, Princeton, United States, [6]University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: An exploratory, landmark analysis of the randomized phase 3 DASISION trial (NCT NCT00481247) demonstrated improved long-term outcomes (progression-free survival [PFS] and overall survival [OS]) in newly diagnosed CML-CP patients treated with dasatinib or imatinib who achieved *BCR-ABL1* ≤10% *vs* >10% at 3 months. The early molecular milestone of *BCR-ABL1* ≤10% at 3 months was achieved by a higher proportion of patients on dasatinib (84%) compared with imatinib (64%).
Aims: To evaluate the effect of EURO (Hasford) risk score on the achievement of *BCR-ABL1* ≤10% at 3 months and to evaluate long-term efficacy (PFS, OS, major molecular response [MMR], and $MR^{4.5}$) in treatment-naïve CML-CP patients from DASISION. A multivariate analysis was performed to explore the relationship between the survival of a patient and several explanatory variables including treatment, gender, ECOG performance status, race, age, smoking status, and geographical region.
Methods: In DASISION, patients received dasatinib 100 mg once daily (n=259) or imatinib 400 mg once daily (n=260). *BCR-ABL1* transcript levels were measured on the International Scale. Patients with a EURO score ≤780 were considered low risk, >780 to ≤1480 intermediate risk, and >1480 high risk.
Results: Most patients in DASISION were at intermediate risk according to EURO score (124 [48%] on dasatinib and 123 [47%] on imatinib); 86 patients on dasatinib and 87 patients on imatinib (33% each arm) were at low risk, and 49 patients on dasatinib and 50 patients on imatinib (19% each arm) were at high risk. A higher percentage of patients in the dasatinib arm achieved *BCR-ABL1* ≤10% at 3 months *vs* the imatinib arm in all risk groups (low: 91% *vs* 73%; intermediate: 80% *vs* 66%; high: 83% *vs* 44%). The largest difference was observed between those at high risk: 17% of high-risk patients on dasatinib did not achieve *BCR-ABL1* ≤10% at 3 months *vs* 56% on imatinib. Within each EURO risk score group, a higher proportion of patients on dasatinib *vs* imatinib had *BCR-ABL1* ≤1% at 3 months (low: 56%, 95% confidence interval [45-68%] *vs* 20% [12-30%]; intermediate: 48% [38-57%] *vs* 12% [7-20%]; high: 33% [20-48%] *vs* 5% [1-16%]). Five-year PFS, OS, MMR, and $MR^{4.5}$ rates were higher for patients with *BCR-ABL1* ≤10% *vs* >10% at 3 months in all risk groups (Table 1). Based on multivariate analysis of OS at 5 years, women were found to be at a lower risk of death than men (hazard ratio: 0.38, 95% confidence interval: 0.19, 0.75). No association was found between survival and other explanatory variables.
Summary/Conclusions: In all EURO risk score groups, a higher percentage of patients on dasatinib achieved *BCR-ABL1* ≤10% at 3 months than patients on imatinib, with the most striking difference in high-risk patients. The proportion of patients achieving *BCR-ABL1* ≤1% at 3 months was higher with dasatinib *vs* imatinib, and the 95% confidence intervals for the two treatment arms did not overlap. Long-term outcomes were superior for patients with *BCR-ABL1* ≤10% at 3 months across all risk groups. These analyses suggest that dasatinib should continue to be considered as a first-line therapy for CML-CP patients, irrespective of EURO risk score.

Table 1.

		DASATINIB		IMATINIB	
		BCR-ABL1 at 3 months			
Risk category	5-year rates, % (95% confidence interval)	≤ 10%	> 10%	≤ 10%	> 10%
Low risk	PFS	94 (86-98)	86 (42-100)	95 (86-99)	91 (71-99)
Low risk	OS	97 (90-100)	86 (42-100)	97 (89-100)	100 (85-100)
Low risk	MMR	94 (86-98)	71 (29-96)	82 (70-91)	41 (21-64)
Low risk	$MR^{4.5}$	61 (48-72)	14 (<1-58)	53 (40-66)	23 (8-45)
Intermediate/ high risk	PFS	91 (85-96)	80 (61-92)	93 (85-97)	79 (67-89)
Intermediate/ high risk	OS	95 (90-98)	87 (69-96)	96 (90-99)	86 (75-93)
Intermediate/ high risk	MMR	84 (76-90)	30 (15-49)	80 (70-87)	41 (29-54)
Intermediate/ high risk	$MR^{4.5}$	50 (41-59)	3 (<1-17)	45 (34-55)	8 (3-18)

Med. Klinik, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany, [13]NMDTI, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, [14]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, United States, [15]SA Pathology, Adelaide, Australia, [16]Novartis Pharma AG, Basel, Switzerland, [17]Novartis Pharmaceuticals Corporation, East Hanover, [18]Novartis Institute for Biomedical Research, Cambridge, United States, [19]Abteilung Hämatologie/Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: Proof of concept for TFR in CML-CP was demonstrated in the STIM trial, which enrolled pts with sustained deep molecular response (MR) on long-term imatinib (IM; median duration of 59 mo); ≈ 40% of pts enrolled in STIM maintained TFR (no loss of deep MR) after stopping IM. Similar results were observed in subsequent tyrosine kinase inhibitor (TKI) TFR studies, although differences in design (eg, pt population, monitoring requirements, criteria for reinitiation of therapy) preclude direct comparison of results across studies. Several studies have shown an association between maintaining TFR and longer TKI treatment duration.
Aims: To present results from the single-arm phase 2 ENESTfreedom study (NCT01784068) evaluating the ability to stop NIL and maintain TFR in pts who achieved a sustained deep MR on frontline NIL.
Methods: Eligible pts had CML-CP, typical b2a2 and/or b3a2 *BCR-ABL1* transcripts, and ≥ 2 y frontline NIL, and had achieved $MR^{4.5}$ (*BCR-ABL1* ≤ 0.0032% on the International Scale [IS]) on treatment. All pts provided informed consent. On study, pts continued NIL for 1 y (consolidation phase; RQ-PCR assessments every 12 wk); pts meeting response criteria during the consolidation phase (no assessment worse than MR^4 [*BCR-ABL1*^{IS}≤ 0.01%], ≤ 2 assessments between MR^4 and $MR^{4.5}$, and $MR^{4.5}$ in the last assessment) were eligible to stop NIL (TFR phase; RQ-PCR assessments every 4 wk for the first 48 wk). NIL reinitiation (ReRx phase) was triggered by loss of major MR (MMR [*BCR-ABL1*^{IS} ≤ 0.1%]). This analysis was conducted when all pts who entered the TFR phase had completed 48 wk of TFR, entered the ReRx phase, or discontinued from the study (data cutoff, 30 Nov 2015).
Results: A total of 215 pts were enrolled and entered the consolidation phase; 190 of these pts stopped NIL and entered the TFR phase. Median age at enrollment was 55 y, and median NIL duration prior to TFR was 43 mo (range, 33-89 mo). At wk 48 of the TFR phase, 51.6% (95% CI, 44.2-58.9%) of 190 pts remained in MMR without reinitiation of treatment (primary endpoint), and 47.4% (95% CI, 40.1-54.7%) were in $MR^{4.5}$ without reinitiation of treatment. A total of 86 pts lost MMR and reinitiated NIL. Of these 86 pts, 85 pts regained MMR, and 76 pts regained $MR^{4.5}$(1 pt discontinued from the study without regaining MMR [pt decision] 7.1 wk after entering the ReRx phase). The median time to regain MMR was 7.9 wk. No new safety signals were observed with NIL treatment. Fewer pts developed adverse events (AEs) in the TFR phase (65.8%) *vs* the consolidation phase (83.2%). Myalgia has been reported as part of an IM withdrawal syndrome in prior studies. Here, in the first 48 wk of the TFR phase, 47 pts (24.7%; grade 3/4 in 1.1%) stopping NIL reported AEs

in the musculoskeletal pain grouping (defined as musculoskeletal pain, myalgia, pain in extremity, arthralgia, bone pain, and/or spinal pain), of whom 32 had no previous such events. Most of these events occurred early in the TFR phase (39 pts had an event within the first 24 wk; median duration, 24.0 wk).
Summary/Conclusions: In ENESTfreedom, over 50% of pts remained in TFR 48 wk after stopping NIL, a clinically meaningful rate for pts with a relatively short duration of NIL therapy (≈ 3.6 y). Among pts who did not remain in TFR, all who remained on study regained MMR, and most regained $MR^{4.5}$ with NIL reinitiation.

Myelodysplastic syndromes - Clinical 2

IMPACT OF AZACITIDINE THERAPY ON OVERALL SURVIVAL OF NEWLY DIAGNOSED PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROMES: A POST HOC ANALYSIS OF THE ERASME STUDY

R García[1,*], M Arnan[2], M Tormo[3], M Calbacho[4], R Coll [5], T Bernal[6], F Ramos[7], I Marchante[8], JM Bastida[9], M Albors[10], N Somolinos[11], A Lemes[12], M Castellanos[13], M Navarro[14], S López[15], D Valcárcel[16]
[1]Hospital Clínico Virgen de la Victoria, Málaga, [2]Hospital Duran y Reynals, Institut Català d'Oncologia, Hospitalet de Llobregat, Barcelona, [3]Hospital Clínico Universitario de Valencia, Valencia, [4]Hospital Ramon y Cajal, Madrid, [5]ICO Girona, Girona, [6]Hospital Universitario Central de Asturias, Oviedo, [7]Hospital Universitario de León, León, [8]Hospital Puerta del Mar, Cádiz, [9]Hospital Universitario de Salamanca, Salamanca, [10]Complexo Hospitalario Universitario de Ourense, Ourense, [11]Hospital Universitario de Getafe, Madrid, [12]Hospital Universitario de Gran Canarias Dr. Negrín, Las Palmas de Gran Canarias, [13]Hospital Clínico Universitario de Valladolid, Valladolid, [14]Celgene MAFF, [15]Celgene Ops, Madrid, [16]Hospital Vall d'Hebrón, Barcelona, Spain

Background: Treatment of myelodysplastic syndromes (MDS) has undergone a sweeping change in recent years following the emergence of demethylating agents such as azacitidine (AZA). However, recently published data establish a clear need for population-based studies to confirm the findings of clinical trials in the real-life setting.
Aims: To evaluate the use and outcomes of AZA in higher-risk MDS (HR MDS; International Prognostic Scoring System [IPSS] Int-2/High-risk) patients (pts) in a real-life setting.
Methods: The ERASME study is an observational, prospective study of pts with MDS (WHO 2008 classification). This sub-analysis included only HR MDS pts who had been chosen for one of the following management therapies at time of diagnosis: active therapy with AZA or allogeneic hematopoietic cell transplant preceded by AZA (AZA-HCT). The presence of therapy-related MDS and cytogenetic abnormalities was taken into consideration. Overall survival (OS) of these pts was compared against best supportive care using the Kaplan-Meier and time-dependent methods.
Results: A total of 150 pts with HR MDS were recruited between January 2013 and August 2015. 113 pts (median age 73.0 years [yrs; interquartile range 66.0-77.0]; 52% male) were treated with AZA and 37 pts (median age 81.0 yrs [75.0-85.0]; 57% male) with best supportive care (considered only for survival analysis). Therapy-related MDS was detected in 19% of cases. IPSS score was Int-2 in 51% of pts and High-risk in 49%. Prognostic cytogenetics was classified as good in 35% of pts, intermediate in 4%, poor in 22%, and very poor in 27% (14% were unclassified due to missing metaphase data). The first therapy administered was AZA for 84 (74%) pts and AZA-HCT for 29 (26%) pts. The main reasons for treatment strategy selection were risk classification (99%), age (80%), symptomatology (58%), and comorbidities (52%). The median number of AZA cycles was 4.0 (1.0-7.0), with 41 pts (36%) receiving ≥6 cycles. Most pts were treated on a 7-day regimen (n=91 [81%]; missing=14%) and a dose of 75 mg/m^2 (n=71 [63%]; missing=2%). The most common adverse events (AEs) were asthenia in 20 pts, pyrexia in 18, constipation in 14, febrile neutropenia in 12, and neutropenia in 10. AEs led to dose reductions in only 8% of cases. Overall, median OS for pts treated with AZA on the 7-day regimen at the 75 mg dose *vs* pts treated with other regimens was 19.4 months (mos; 12.8-23.2) *vs* 14.9 mos (11.8-18.6) (*P*=not significant [ns]), respectively. Observed OS in pts treated for ≥6 cycles *vs* those treated for <6 cycles was 20.3 mos (14.2-23.2) *vs* 14.9 mos (6.6-not reached [NR]) (*P*=0.05). OS in pts who did not have comorbidities *vs* those who did was 20.3 (7.4-NR) *vs* 16.6 (12.8-22.2) (*P*=ns). At last study follow-up (36 months), 53 pts (47%) had died after a median of 7.4 mos (4.2-13.7): 39 (46%) and 14 (48%) pts on AZA and AZA-HCT, respectively. Median OS in HR MDS pts treated with AZA was higher than in HR MDS pts receiving supportive care: 16.6 mos (13.1–21.7) *vs* 8.4 mos (5.7-13.0) (*P* <0.01). Median time-dependent OS was also higher with AZA than with supportive care: 14.8 mos (12.8-18.7) *vs* 5.0 mos (2.5-11.6) (*P* <0.01).
Summary/Conclusions: The findings from this post hoc subanalysis of the prospective population-based study show that treatment with AZA prolongs OS in pts with HR MDS in a real-life setting when compared with supportive care. The results support the hypothesis that OS could be compromised with significantly more baseline comorbidities or reduced total dose recommended of AZA.

P619

IMPACT OF BONE MARROW FIBROSIS IN RESPONSE TO AZACITIDINE IN 94 PATIENTS WITH MYELODISPLASTIC SYNDROMES (MDS), CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) AND ACUTE MYELOID LEUKEMIA

G Reda[1,*], M Riva[2], R Cassin[1], B Fattizzo[1], M Deodato[2], A Freyrie[1], A Molteni[2], R Cairoli[2], A Cortelezzi[1]
[1]Haematology Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, [2]Division of Haematology, Niguarda Hospital, Milan, Italy

Background: Azacitidine (AZA) is effective in high risk MDS, CMML-2 and low blast count AML patients not suitable for more intensive treatment. Factors that may influence response to AZA are still under investigation. Bone marrow fibrosis is a potentially negative prognostic marker on overall survival (OS), but its clinical significance in this setting of patients remains to be clarified.
Aims: To evaluate efficacy and clinical predictors of OS and overall response rate (ORR) to AZA in a real life patient cohort.
Methods: We retrospectively evaluated 94 consecutive patients treated at two Institutions from June 2009 till February 2016 with AZA subcutaneously (5+2+2 schedule) every 28 days, outside clinical trials. We analyzed data from routine laboratory analysis, bone marrow histology, morphology and cytogenetics at diagnosis. Statistical analysis was performed using Student' t test for continuous variables, and chi-square test for categorical ones. OS was measured from the starting of AZA treatment. Median age at diagnosis was 72.5 years (range 39-90); male to female ratio was 1.7 (58/34). The initial diagnosis according to WHO 2008 classification were low blast count AML in 15 cases (15.9%), AREB2 in 40 (42.6%), AREB1 in 25 (26.6%) CMML in 5 (5%) and RCUD/RCMD/MDS NOS in 9 (10%). The International Prognostic Scoring System (IPSS) risk for all MDS patients was int-2 (N=60) or high (N=20) at the onset of AZA therapy. Median number of cycles administered was 7 (range 1-44).
Results: Seventy-nine patients (84%) receiving ≥4 cycles of therapy were available for response evaluation according to International Working Group 2006 criteria. After a median of 6 cycles (4-13), ORR was 47.8% (CR 23.1%, PR 14.1% and SD with hematologic improvement 10.3%), SD was 23.1%, and PD 29.5%. Median OS from the beginning of therapy was 19.9 months (range 4-75 months). AREB-1 and AREB-2 presented a lower OS (11.4 and 19 months) than AML (22 months) and CMML/RCUD/RCMD/MDS NAS (42 months). As expected, a statistically significant difference in median OS was observed between int-2 and high risk (31 *versus* 15 months respectively, p<0.005). In univariate analysis monocytosis, severe neutropenia, peripheral and marrow blasts percentage, and bone marrow cellularity did not influenced ORR. IPSS cytogenetic risk category (43 favourable, 10 intermediate, 41 poor) did not influence ORR, but it had an impact on OS that is significantly lower in poor than in intermediate risk (median OS 12 *vs* 26 months, p=0.05). OS in low risk cytogenetic category was 31 months. As regards the grade of marrow fibrosis, patients with MF-0 had significantly lower PD rate than those with any grade of fibrosis (25% *vs* 52%, p=0.01). Moreover, ORR was higher in patients with MF-0 *versus* the others (48% *vs* 40%), although not significantly (Figure 1). In our study, patients with any grade of fibrosis had worse median OS then patients with no fibrosis (15 months *vs* 26 months).

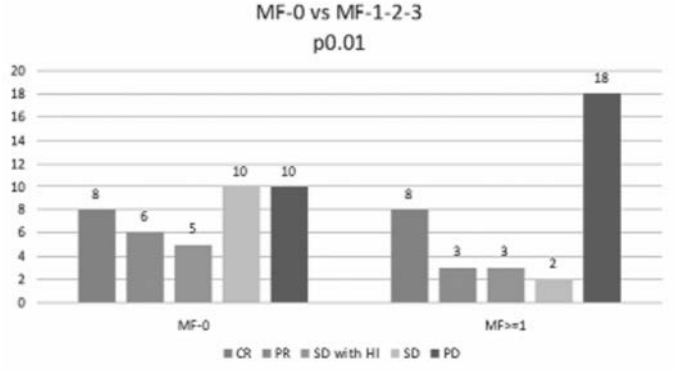

Figure 1.

Summary/Conclusions: Our results confirm effectiveness of AZA in patients with high risk MDS and AML with low marrow blast counts. To the best of our knowledge, this is the first report showing that bone marrow fibrosis negatively impacts response to AZA therapy. Further studies are needed to clarify the clinical significance of marrow fibrosis and its impact on OS and ORR among patients treated with hypomethylating agents.

P620

AGE DISTRIBUTION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) IN GERMANY AND THEIR PROGNOSIS ACCORDING TO THE INTERNATIONAL PROGNOSTIC SCORING SYSTEM (IPSS): DATA FROM THE REGULAR CARE MDS REGISTRY

HT Steinmetz[1,*], I Böttger[1], R Wahdat[1], B Haastert[2], B Lathan[3], A Sauer[4], U Germing[5], S Schmitz[1]
[1]Onkologie Köln, Outpatient Clinic for Hematology and Oncology, Cologne, [2]mediStatistica, Neuenrade, [3]Outpatient Clinic for Hematology and Oncology, Dortmund, [4]Outpatient Clinic for Hematology and Oncology, Cologne, [5]Hematology and Oncology, University Clinic, Düsseldorf, Germany

Background: The IPSS and the revised-IPSS were generated with data from 816 and 7,019 patients (pts) of academic centers with a median age of 69 and 71 years (y), respectively. The IPSS should be applied to all MDS-pts to assess prognosis and define the optimal therapeutic strategy.
Aims: The aim of the current evaluation of the regular care MDS-registry was to describe the age distribution of MDS in regular care and the meaning of the IPSS in various classes of age.
Methods: Pts were eligible if a bone marrow (BM) biopsy was performed and pts have given written informed consent. Basic data and the quarterly course of the disease were documented in an online registry. Statistical analysis: Depending on the distributions of each variable frequency tables, means (SD), medians were calculated overall and stratified by age classes. Corresponding overall tests were performed (Chisquare, Kruskal-Wallis). Furthermore, survival was estimated by IPSS and age stratified Kaplan-Meier curves and compared using a bivariate Cox regression model.
Results: Between July 2009 and March 2015 (69 months) 1689 pts from 85 institutions mainly outpatient practices, were recruited and eligible. Median age of 681 (40.3%) women and 1008 (59.7%) men were 74.8y (min-max: 26.5-94.2). The duration of observation, frequencies of IPSS, need for transfusions (Tx) prior to diagnosis (d), comorbidities and the Charlson comorbidity index (CCI) are given in the Table 1. Higher age and IPSS risk were significantly associated with the risk of death (Figure 1).

Table 1. Age distribution and MDS parameter.

Item	All	- 69y	70-74y	75-79y	80y +	p value

Missing values: [a]520, [b]142, [c]789 pts without CIRS-relevant comorbidity.

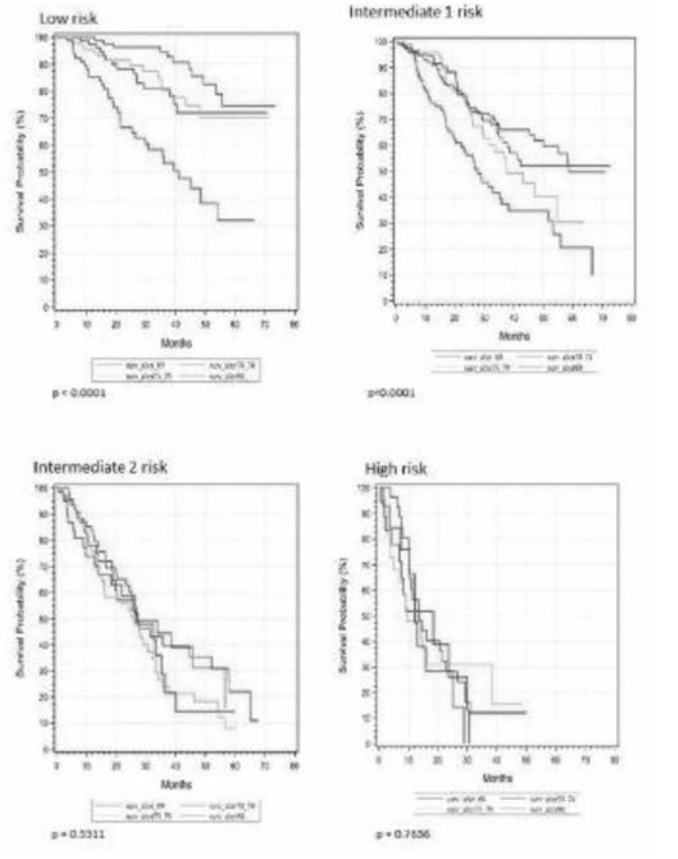

Figure 1. Survival stratified in IPSS and age (classified <=69, 70-74, 75-79, >=80).

Summary/Conclusions: The median age of MDS pts in the German regular care registry is higher than that of the cohorts, who generated the IPSS. Further analysis will clarify the impact of the enhanced rate of comorbidities and need for transfusion in the 80y+ cohort related to the survival in the low and Int-1 IPSS subgroups.
The MDS-registry is supported by an unrestricted grant from Celgene and Novartis.

VALIDATION OF PROGNOSTIC SCORING SYSTEMS FOR MYELODYSPLASTIC SYNDROMES IN THE SWEDISH MDS-REGISTER

D Moreno Berggren[1,*], Y Folkvaljon[2], M Engvall[3], J Sundberg[1], S Lehman[1], M Lambe[24], P Antunovic[5], H Garelius[6], E Hellström-Lindberg[7], M Jädersten[7], F Lorenz[8], L Nilsson[9], E Ejerblad[1]
[1]Department of Medical Science, Section of Hematology, Uppsala University, [2]Regional Cancer Center, Uppsala/Örebro, Uppsala University Hospital, [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, [4]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, [5]Department of Hematology, Linköping University Hospital, Linköping, [6]Section for Haematology and Coagulation, Department of Medicine, Sahlgrenska University Hospital, Gothenburg, [7]Center for Hematology and Regenerative Medicine, Karolinska University Hospital, Stockholm, [8]Department of Medical Biosciences, Umeå University, Umeå, [9]Department of Medicine, Skåne University Hospital, Lund, Sweden

Background: Since the survival in patients diagnosed with MDS varies from months to decades, prognostic models are important tools for estimating prognosis and making therapy-related decisions. Several scoring systems for risk stratification have been developed including the International Prognostic Scoring System (IPSS), the Revised IPSS (IPSS-R) and the World Health Organization (WHO) Classification-based Prognostic Scoring System (WPSS). The nationwide Swedish MDS-register was started in 2009 and includes newly diagnosed patients with Myelodysplastic syndrome (MDS) and disorders with combined features of myelodysplastic and myeloproliferative neoplasms (MDS/MPN). All hospitals in Sweden diagnosing these patients report to the MDS-register, including university hospitals, county and local hospitals. The completeness against the compulsory Swedish Cancer Register was 95% for the period under study (2009-2013).
Aims: The aim of this study was to validate and compare IPSS, IPSS-R and WPSS in a nationwide population-based setting. Furthermore, we present data on incidence, clinical characteristics at diagnosis and clinical outcomes such as overall survival and AML-transformation.
Methods: All patients aged 16 years or older diagnosed with MDS 2009-2013 and reported to the MDS-register were included (n=1334). Patients with MDS/MPN were excluded (n=291). Data included date of diagnosis, age, gender, WHO-diagnosis, laboratory parameters, transfusions-dependency, diagnostic procedures including information on bone marrow morphology and cytogenetics and information on previous treatment with chemotherapy or irradiation. By means of record linkage, information was obtained from the Swedish Cause of Death Register and the Swedish AML-register up to December 31, 2014 to calculate overall survival (OS) and transformation to AML.
Overall and AML-free survival was assessed using the Kaplan-Meier method. Prognostic scores were calculated for IPSS, IPSS-R and WPSS, respectively. The prognostic methods were evaluated using Harrell's concordance (C) index. The indices were internally validated by bootstrapping with 1000 samples.
Results: The crude yearly incidence of MDS was 3.5 per 100.000 persons. Median age at diagnosis was 76 years and 58% of the patients were male. At time of diagnosis, 49% of patients were dependent on red blood cell transfusions. The median OS for the whole population was 2.7 years and time to 25% AML-transformation was 3.8 years. For 848 (64%) patients data were complete, enabling risk score assessment for all three systems. The major part of missing data was attributed to that karyotyping was not performed, mainly in the older population. Compared to previous register-based studies we found that a larger proportion of patients had higher risk disease. Risk category in the different scoring systems, OS and time to 25% AML-transformation are presented in Table 1. Comparisons between the scoring systems show that all three had good prognostic power. However, IPSS-R and WPSS had significantly better prognostic properties compared to IPSS.

Table 1. Clinical outcome and discriminative power on the WPSS, IPSS and IPSS-R based risk categories.

	Total, N (%)	Overall survival		AML-risk	
	848 (100)	Median	C-index +	AML 25% *	C-index +
WPSS			0.72		0.79
Very low risk	108 (13)	NR		-	
Low risk	205 (24)	65.6		NR	
Intermediate risk	157 (19)	36.0		NR	
High risk	246 (29)	19.9		16.3	
Very high risk	132 (16)	9.8		9.7	
IPSS			0.71		0.78
Low risk	254 (30)	67.2		NR	
Interm. risk I	320 (38)	31.3		42.4	
Interm. risk II	202 (24)	13.5		13.3	
High risk	72 (8)	10.8		7.4	
IPSS-R			0.73		0.79
Very low risk	113 (13)	NR		NR	
Low risk	280 (33)	57.7		NR	
Interm. risk	168 (20)	30.2		31.7	
High risk	138 (16)	17.1		15.9	
Very high risk	149 (18)	9.5		9.0	

* Number of months after diagnosis when 25% of patients had developed AML.
+ The C-index measures the discriminative power of a score, ranging between 0.5 (no discriminative power) and 1 (perfect discrimination).
NR = Not reached

Summary/Conclusions: To our knowledge, this is the first nationwide population based validation of IPSS, IPSS-R and WPSS. While our findings confirm the prognostic power of all three systems, IPSS-R and WPSS appear to be slightly more powerful tools for prognostication than IPSS.

P622

EXPRESSION OF TUBB GENE IN MYELODYSPLASTIC SYNDROME WITH OR WITHOUT EVOLUTION TO LEUKEMIA

Y Ma[1,*], B Chen[1], X Xu[2], G Lin[2]
[1]Hematology, [2]Huashan hospital, Fudan University, Shanghai, China

Background: Myelodysplastic syndromes (MDS) are a heterogenous group of clonal hematopoietic stem cell disorders characterized by increased risk of leukemic transformation.Patients evolving into leukemia respond poorly to chemotherapy and die within a short time. Hence, it is very important to find detectable marker to predict the probability of leukemic transformation once MDS has been diagnosed. In our previous study, we establish a nested case-control study cohort in 435 MDS patients. With whole-genome expression chip, we analyzed the different gene expression profile of paired MDS patients. A subset of 6 genes was found to distinguish the leukemia group (MDS patients with evolution to leukemia) and control group (MDS patients without evolution to leukemia). These 6 genes were TUBB, PSMD1, SLC7A5, ATG3, TUBB2C and TIMM10.
Aims: Based on our previous study on feature genes related to leukemic evolution of myelodysplastic syndrome (MDS), we investigated the differential expression of TUBB gene in MDS patients with leukemic evolution and that without evolution. Also, we studied the effect of down-regulation of TUBB gene on SKM-1 cell line.
Methods: Based on our nested case-control study cohort of MDS patients, we chose paired patients in 1:1 ratio, according to age, gender, WHO subtype, IPSS cytogenetic subgroup and follow-up period (≥1 year). We examined TUBB gene expression changes in paired patients from case group (with evolution) and control group (without evolution), using quantitative real time PCR. We used small interfering RNA to down-regulateTUBB gene expression in SKM-1 cell line. The effect of TUBB-siRNA on the growth rate,colony formation percentage and the ultrastructure of SKM-1 were tested by CCk-8 kit, flow cytometry, soft agar and transmission electron microscope, respectively.
Results: We chose 11 patients in each group of our MDS nested case-control study cohort excluding patients underwent gene expression microarray test. TUBB gene expression of MDS patients in case group were significantly higher than that in control group (P<0.01).Satisfactory transfection efficiency (>80%) could be obtained withlipofectamine. Real time PCR showed the down-regulated expression of TUBB after transfection (P<0.05). Growth inhibition of SKM-1 cell was obvious 24 hours after TUBB-siRNA transfection (P<0.05). The cell-cycle analysis by flowcytometershowed the percentage of SKM-1 before transfection in S phase was higher than that after transfection. Colony formation percentage of SKM-1 was inhibited obviously with TUBB-siRNA transfection (P<0.01). The ultrastructure of SKM-1 cell after transfection exhibit several features, such as vacuole in cytoplasm and nuclear fragmentation (Figure 1).

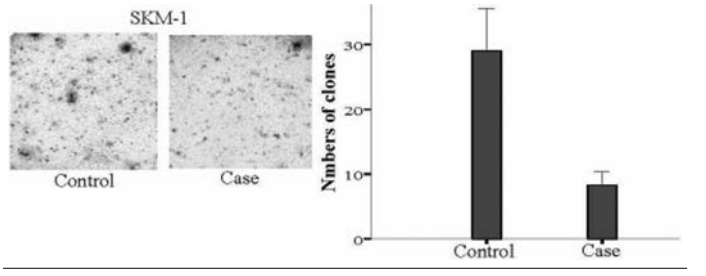

Figure 1.

Summary/Conclusions: TUBB gene expression was significantly higher in case group than that in control group of our MDS nested case-control study cohort. Growth and colony formation inhibition are the result of siRNA against TUBB.Our results indicate that TUBB gene may play a role in evolution of MDS into acute leukemia.

HIDDEN MDS: A PROSPECTIVE STUDY TO CONFIRM OR EXCLUDE MDS IN PATIENTS WITH ANEMIA OF UNCERTAIN ETIOLOGY

JM Bastida Bermejo[1,*], O Lopez-Godino[2], AI Vicente-Sanchez[3], S Bonanad[3], B Xicoy[4], JM Hernandez-Sanchez[5], E Such[6], R Benito[5], JC Caballero[1], F Lopez-Cadenas[1], M Arnao-Herraiz[3], I Llopis-Calatayud[3], J Cervera[6], G Sanz[6], M del Cañizo-Roldan[1], M Diez-Campelo[1]
[1]Hematologia, Hospital Universitario Salamanca, Salamanca, [2]Hematologia, Hospital Universitario Morales Meseguer, Murcia, [3]Hematologia, Hospital de la Ribera, Valencia, [4]Hematologia, Hospital Germans Trias i Pujol, Badalona, [5]Hematologia, Instituto de Investigacion Biomedica de Salamanca, IBMCC,

Centro de Investigacion del Cancer, Universidad de Salamanca-CSIC, Salamanca, [6]Servicio de Hematología, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: Anemia is one of the most frequent abnormalities detected in hemograms and it can be the first sign of MDS, especially in the elderly patients. Diagnosis of MDS when anemia is the only abnormality can be complicated, so the diagnosis is delayed until the degree of anemia becomes severe (transfusion dependency) and/or other cytopenias/blasts appears.
Aims: To evaluate the impact of systematically review of all hemograms performed in a hematology department-lab selecting those with anemia and/or macrocytosis of undetermined significance. In these hemograms selected we performed a study trying to identify the underlying disease causing anemia.
Methods: We performed a prospective study within 4 months (Dec/12-Mar/13) in 3 hematology labs in Spain. Algorithm approach consisted of four steps (Figure 1). NGS analysis was performed on a MiSeq platform (Illumina) and IonReporter (Life Technologies) in MDS patients. Target-capture sequencing was performed across genes previously related to MDS. The statistical analysis was implemented using SPSS v21.0.
Results: From 290 hemograms candidates to MDS screening, 139 final diagnoses have been made (48%) (Figure 1). The main causes of anemia were iron deficiency (n=59) and megaloblastic anemia (n=39). A MDS was diagnosed in 14/25 hematological malignancies (56%). Regarding those MDS patients (Table 1) median age was 79 years (58-91); 12/14 patients had anemia [Hb=10,7g/dl] such as isolated cytopenias. All patients had macrocytosis (mean MCV=104fL). Most of patients (n=10) were low-risk MDS (IPSS-R≤3.5) and were treated according to guidelines. Table 1: Baseline characteristics of MDS cohort.

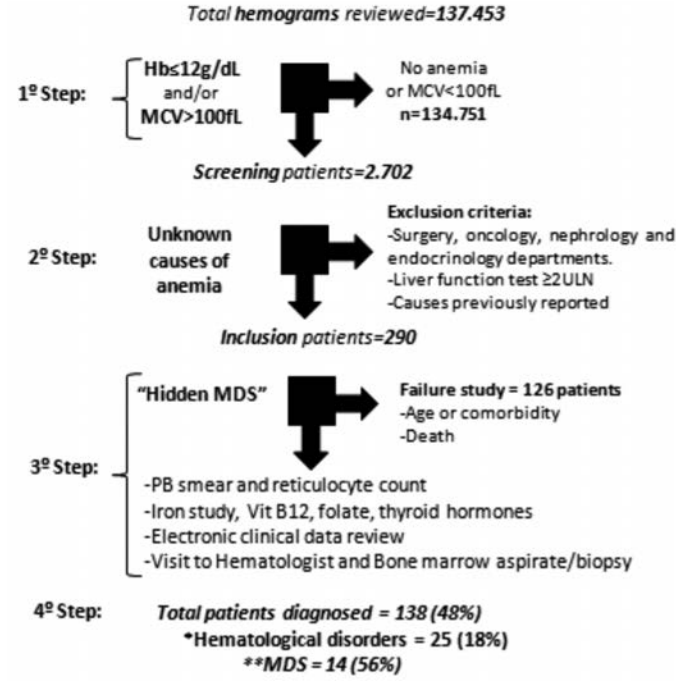

Figure 1.

Table 1.

Id	Age/Sex	WHO 2008	Hb (g/dl)	MCV (fL)	Platelets count (x10^9/L)	ANC (x10^9/L)	Cytog.	IPSS-R	Treatment	OS (Months)	Gene mutated
1	58/M	RCMD	8,5	112	379	2,3	N	2	Stimulating Ag.Chelation	28	*SF3B1*
2	71/M	MDS NOS	10	107	125	2,4	+8	2	Blood cells Transfussion	36	*WASF3*
3	81/M	RCMD	10,7	119	343	3,9	N	1	Stimulating Ag.Chelation	36	Any
4	79/M	RAEB-1	7,4	106	20	7,8	N	5,5	Blood cells Transfussion	10	*ZRSR2*
5	82/F	RAEB-1	6,8	102	424	2,8	del(5q)	4,5	Blood cells Transfussion	17	*TP53*
6	85/F	RCMD	10,3	104	227	2,2	N	1	Stimulating agents	30	*SF3B1*
7	91/F	RAEB-2	10,7	99	98	0,9	ND	ND	Blood cells Transfussion	3	No analyzed
8	84/F	RAEB-1	10,1	100	136	1	del(5q)	3	Stimulating Ag. IMiDs	28	*TET2*
9	85/M	RCUD	11,4	99	182	3	N	1	No	31	*SF3B1*
10	77/M	RCMD	11,7	100	262	3,5	N	1	No	31	*SF3B1, JAK2*
11	74/F	RARS	11,1	106	350	3,4	N	1	Stimulating agents	30	*SF3B1, DNMT3*
12	60/M	RCUD	12	111	307	1,7	N	1	No	30	*TET2*
13	76/M	RAEB-2	10,9	102	183	1,1	Complex	7	Hypometh. agents	5	*TP53*
14	81/F	RCUD	10,8	101	319	2	N	1	No	31	*SF3B1, DNMT3*

The K700E mutation in *SF3B1* was the most frequent (n=6) and was highly correlated to ring sideroblasts in bone marrow (100% of patients). The median follow-up MDS patients were 30 months [28-36]. KM estimated 3-year OS was 71%. Regarding impact on survival of mutational status, *TP53* and *ZRSR2* mutations were associated to poor prognostic and all these patients had died as compared to the presence of other mutations (*SF3B1* or *TET2*) where all patients are still alive (p=0.001).

Summary/Conclusions: This prospective approach is a reasonable screening procedure in the hematological laboratories and will probably allow us to diagnose early the more relevant causes of anemia, including MDS, and providing the appropiate intervention for the patients.
Celgene supported this study.

MANAGEMENT OF IRON OVERLOAD WITH DEFERASIROX IN VARIOUS HEMATOLOGICAL MALIGNANCIES – REAL WORLD EXPERIENCES FROM THE GERMAN NON-INTERVENTIONAL STUDY EXSEPT

F Nolte[1,2,*], C Schumann[1], H Nückel[3], B Schmidt[4], H Hebart[5], O Rubanov[6], R Kühn[7], S Kreil[1,8], G Metzgeroth[1,8], C Johr[9], S Albrecht[9], W Hofmann[1,8]
[1]Medical Faculty Mannheim of the University of Heidelberg, Mannheim, [2]Internal Medicine, Hematology and Oncology, St. Hedwig Hospital, Berlin, [3]Office-based Hematology/Oncology specialist, Office-based Hematology/Oncology, Bochum, [4]Office-based Hematology/Oncology, Munich, [5]Internal Medicine, Stauferklinikum Schwaebisch Gmuend, Mutlangen, [6]Office-based Hematology/Oncology, Hameln, [7]Office-based Hematology/Oncology, Oldenburg, [8]Hematology and Oncology, University Hospital Mannheim, Mannheim, [9]Novartis, Nuremberg, Germany

Background: Iron overload (IO) resulting from chronic transfusion therapy is common in patients with various hematological disorders and may finally result in organ failure. Deferasirox is approved for the treatment of iron overload in patients with transfusion dependence.
Aims: The aim of the study was to evaluate the pattern of use of deferasirox in the daily routine setting.
Methods: Overall, 420 patients (pts) receiving deferasirox were analyzed across 107 German office- and hospital-based hematology centers: 280 with myelodysplastic syndrome (67%), 53 with myeloproliferative disorders (13%), 18 with AML (4%) and 69 with other acquired and inherited anemias (16%). The study was conducted during 2010-2014 with an ongoing 2-year follow-up period until the end of 2016. Serum ferritin, liver function parameters, dosing and adverse events were recorded at baseline and at month 1, 3, 6, 12, 18 and 24 following initiation of deferasirox therapy. Deferasirox was administered according to the summary of product characteristics and pts with at least 1 follow-up visit were eligible for analysis.
Results: Of a total of 420 pts, 243 were male (58%) and 177 female (42%) with a median age of 74 yrs., (range 2-93 yrs.). Mean time from first diagnosis of the hematological malignancy and transfusion therapy to initiation of IO therapy was 3.4 yrs. and 1.8 yrs. respectively. 227 pts (54%) showed a moderate need for blood transfusions (2-4 units/month) and 107 pts (25%) a mild need for blood transfusion (<2 units/month) at baseline. Deferasirox effectively reduced mean iron burden as measured by serum ferritin from 2230 µg/L (±1279 µg/L) at baseline to 1786 µg/L (±1390 µg/L) at 24 months, respectively. As expected, mean creatinine clearance decreased from 91 mL/min to 80 mL/min within the first 3 months and remained stable until the end of observation. Median daily dose of deferasirox at time of initiation was 17 mg/kg (range 2-30 mg/kg); dose adjustments were required in 162 pts (39%). Adverse events (AE) were reported in 364 pts (87%). The most common AEs were gastrointestinal disorders (29%), a decrease in renal creatinine clearance (22%) and an increase in blood creatinine (18%), presented as proportion of pts suffering from the AE.
Summary/Conclusions: These findings indicate that chelation therapy with deferasirox is feasible in treated patients with the capability to reduce iron burden. The safety profile shows no unexpected toxicities. The results of this interim analysis will further contribute to understand the management of IO therapy with deferasirox in the routine setting.

P625

CLASSIFICATION OF MYELODYSPLASTIC SYNDROMES (MDS) IN DAILY PRACTICE: A POPULATION-BASED STUDY AMONG 8912 PATIENTS DIAGNOSED IN THE NETHERLANDS FROM 2001 TO 2014

A Dinmohamed[1,2,3,*], O Visser[4], M Jongen-Lavrencic[3], A van de Loosdrecht[5]
[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Public Health, Erasmus University Medical Center, [3]Hematology, Erasmus MC Cancer Institute, Rotterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Specific morphological features in the bone marrow (BM)—eg, type and degree of dysplasia, as well as myeloblasts—constitutes a diagnostic hallmark of MDS. Careful assessment and subsequent documentation of these features are necessary to facilitate an accurate classification of MDS according to the World Health Organization (WHO) classification that was initially published in 2001 and updated in 2008.
Aims: In this population-based study, we sought to assess the implementation of the WHO classification of MDS in daily practice in the Netherlands according to time and health care region.
Methods: We selected all adult (≥18 years) MDS patients diagnosed between

2001-2014 (N=8912; median age, 75 years; 59% males and 19% previous malignancy) from the nationwide Netherlands Cancer Registry (NCR). All MDS subtypes were recorded in the NCR according to the International Classification of Diseases for Oncology Third Edition (ICD-O-3) that follows the WHO classification of MDS and includes: refractory cytopenia with unilineage dysplasia (RCUD), refractory anemia (RA) with ring sideroblasts (RARS), MDS with isolated del(5q), refractory cytopenia with multilineage dysplasia (RCMD), RA with excess blasts (RAEB) and MDS not otherwise specified (MDS NOS). The ICD-O-3 does not have separate codes for RAEB-1 or 2. Univariable and multivariable logistic regression models were constructed to identify variables associated with the diagnosis of MDS NOS. These variables included age at, and year of, diagnosis, sex, previous malignancy, as well as hospital type (non-academic *v* academic) and health care region of diagnosis (8 regions in total).

Results: The proportion of MDS NOS decreased from 58% in 2001 to 13% in 2014 (Figure 1A). There was regional variation noted in the distribution of MDS NOS (average in 2001-2014, 43%; range 30%>50%; *P*<0.001), which eventually leveled off with time (average in 2014, 13%; range 8%>24%; *P*=0.385; Figure 1B). Following multivariable logistic regression analysis with adjustment for variables with *P*<0.20 in univariable analysis, age per 10 year increase (odds ratio [OR], 1.18; *P*<0.001) was associated with having a MDS NOS diagnosis, whereas year of diagnosis per 1 year increase (OR, 0.87; *P*<0.001) and diagnosis in particular health care regions were associated with a lower odds of MDS NOS.

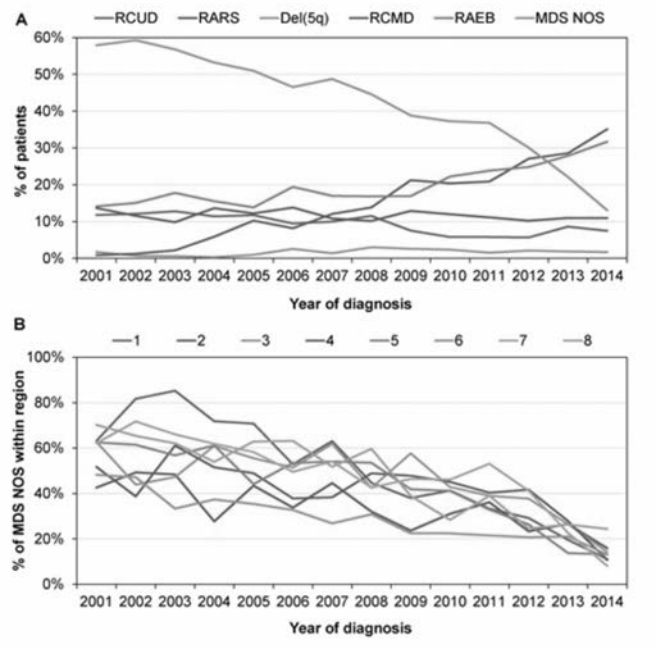

Figure 1.

Summary/Conclusions: These encouraging population-based results indicate that the classification of MDS improved markedly over time across all health care regions in the Netherlands. The reason behind this improvement may be twofold. First, clinicians, cytomorphologists and pathologists became increasingly aware with the WHO classification of MDS. This is mainly due to efforts by HOVON to create awareness for MDS by education and the design of MDS-specific clinical trials, especially since 2008. Secondly, the registration of MDS subtypes by registrars of the NCR improved due to better training in recognizing MDS subtypes in the medical records. Nevertheless, advance age is still associated with the diagnosis of MDS NOS. It is anticipated that specific morphological features in the BM will remain central for the classification of MDS in the upcoming revision of the WHO classification that will be expected in 2016. Therefore, careful analysis and proper documentation of morphological findings remain crucial to facilitate an accurate classification of MDS, which, in turn, is needed to accurately inform patients about their MDS. Well-established population-based registries are useful instruments to evaluate guideline adherence and registration practice.

P626

LEVELS OF TRANSFUSION BURDEN AND ASSOCIATED COSTS FOR PATIENTS WITH TRANSFUSION-DEPENDENT MYELODYSPLASTIC SYNDROMES

AE DeZern[1,*], G Binder[2], S Rizvi[2], FA Corvino[3], SR Arikian[3], A Surinach[3], J Lee[3], BD Smith[1]
[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [2]Celgene Corporation, Summit, NJ, [3]Genesis Research, Hoboken, NJ, United States

Background: For patients (pts) with myelodysplastic syndromes (MDS), dependence upon red blood cell (RBC) transfusions has been long demonstrated to be a risk factor for progression-free survival. Recent studies have suggested that higher levels of transfusion burden are associated with worse prognosis (Chan LSA, *et al.* Leuk Lymphoma 2014;55:10:2296-2300; Pereira A, *et al*. Am J Hematol 2010;86:245-250). The increasing prognostic risk associated with more frequent transfusions poses the question of whether costs also vary with transfusion frequency.

Aims: To assess the costs associated with different levels of transfusion burden among pts with transfusion-dependent (TD) lower-risk MDS, from a US perspective based on claims data.

Methods: Pts were identified from a large US claims database (2008–2013) by ICD-9 codes for MDS, with the first such code determining the index date. Pts with ≥12 months pre- and ≥6 months post-index data were included if they met the criteria of TD post-index, defined as 2 consecutive 8-week periods each with ≥1 transfusion episode and no interim 56-day period without a transfusion. Pts with ICD-9 codes for high-grade MDS or acute myeloid leukemia at diagnosis or stem cell transplant anytime were excluded. Transfusion burden was measured as average days between RBC transfusions during the TD period. Pts were followed until they no longer met TD criteria or end of data. Total costs of care (medical and pharmacy) were evaluated in 2015 US dollars from a payer's perspective, based on paid claims for initial TD periods and averaged to determine monthly cost levels.

Results: 2,645 TD MDS pts met the inclusion criteria; 59% were male and 51% were ≥75 years old. 1,854 (70%) pts averaged ≤28 days between RBC transfusions during the TD period. When patients were categorized by the average time between transfusions, those transfused every 2–3 weeks comprised the largest group (23%) (Figure 1). The principal differences in baseline characteristics for TD pts transfused ≤28 days apart *vs* TD pts with less frequent transfusions were sex (60.7% female *vs* 53.6% male), age (median 74 years *vs* 78 years) and prevalence of thrombocytopenia (25.9% *vs* 16.8%). Average monthly total cost of care per pt was 53% higher for TD pts transfused ≤28 days apart *vs* TD pts with less frequent transfusions ($19,497 *vs* $12,717). Within the former group, costs were 58% higher among pts who transfused ≤14 days apart compared with those who transfused every 15–28 days ($25,268 *vs* $16,033). Inpatient services and pharmacy represented 45% and 8% of total monthly TD costs, respectively.

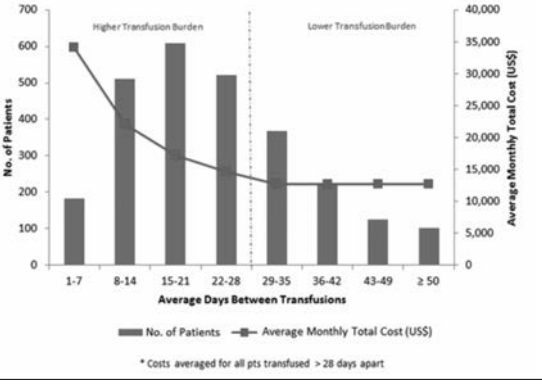

Figure 1. Average time between transfusions during TD period, and associated average total monthly cost/patient*.

Summary/Conclusions: The average time between transfusions is heterogeneous among TD MDS pts, with 27% having ≤14 days between transfusions and similar percentages transfused every 2-3 or 3-4 weeks. Pts with more frequent transfusions had higher average monthly total costs. This suggests that TD pts with higher transfusion burden face greater economic challenges as well as the established clinical challenges.

P627

THE INCORPORATION OF COMORBIDITIES IN THE PROGNOSTICATION OF PATIENTS WITH LOWER-RISK MDS

T Knight Asorey*, J Falantes, FJ Márquez Malaver, C Calderón-Cabrera, R Bernal, R Morales, I Espigado, J Pérez-Simón
Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Patients (pts) with Lower-risk Myelodysplastic syndromes (LR-MDS) defined by having Low or Intermediate-1 IPSS score show a wide prognostic heterogeneity. In addition to age, the presence of comorbidities defined as other chronic advanced medical diseases, can impact on survival in MDS. However, the prognostic significance has not been evaluated specifically in the group of LR-MDS pts.

Aims: To evaluate extra-hematological comorbidities together with classic hematological parameters in a series of pts with LR disease by IPSS and non-unfavorable cytogenetic categories by IPSS-R.

Methods: 232 pts with LR-MDS were retrospectively analyzed between 2000 and 2015. Only pts who received best supportive care with blood transfusion, erythropoietic stimulating agents and/or just observation if no symptomatic cytopenias were included. Non-leukemic death (NLD) was analyzed according to the following variables: age, hematological parameters, IPSS and the MDS-comorbidity index (MDS-CI. Della Porta MG, *et al. Haematol.* 2011)
Results: Clinical and baseline characteristics are shown in Table 1. At last follow-up, 148 pts (64%) had died and 33 pts (14%) progressed to acute myeloid leukemia. Diabetes requiring treatment and cardiac disease were the most frequent comorbidities (30% and 29% respectively). Prevalence of comorbidities was higher in the group of pts aged >65 years (63.3% *vs* 38.4%; *P*=0.04) as well as the number of pts with more than one comorbidity (30.2% *vs* 9.6%; *P*<0.001). After a median follow-up of 60 months (range, 48-71), median OS for the whole series was 36 months (range, 30-41). In univariate analysis, the following variables significantly influenced on outcome (P<0.05): IPSS (low *vs* int-1), Hb <10 g/dL, platelet <50x10e^9/L, BM blasts 5-9%, transfusion dependence (TD), diabetes requiring treatment, cardiac, severe pulmonary and severe to moderate hepatic disease as defined by MDS-CI. Table 2 shows multivariate analysis. Age did not influence on survival. According to these data, an assigned weight was applied to each parameter with prognostic impact for OS. As shown in Figure 1, three sets of patients were categorized into different risk groups with significantly different risk of NLD (P<0.001): group 1 (pts with score 0-2; Low-risk group, n=110, 47.5%), group 2 (score 3-4; intermediate risk group, n=94, 40.5%) and group 3 (score 5-6; high risk, n=28, 12%). At last follow-up, 51 out of 110 (46.4%) patients in the low risk group and 69 out of 94 (73.4%) in the intermediate risk group had died from other causes non-leukemia related.

Table 1.

Table 2.

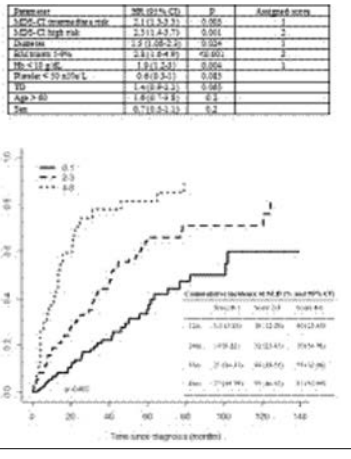

Figure 1.

Summary/Conclusions: This integrated score (clinical and comorbidity) stratifies patients in 3 groups with significant different risk of NLD. Diabetes and cardiac diseases are the most prevalent comorbidities. Interestingly, age, when considered together with clinical parameters and comorbidities, did not influence on outcome. In summary, this study confirms the importance of comorbidities at diagnosis, together with other well-known hematological parameters in pts with LR-MDS and may help to proper define therapeutic strategies in this set of pts.

Bone marrow failure syndromes incl. PNH - Biology

STROMAL MICROENVIRONMENT COMPONENTS DAMAGE IN PATIENTS WITH GRAFT FAILURE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELLS TRANSPLANTATION

N Petinati[1,*], L Kuzmina[2], N Sats[1], N Drzie[1], N Risinskaya[3], A Sudarikov[3], V Vasilieva[2], M Drokov[2], E Michaylzova[2], E Parovichnikova[2], V Savchenko[2]
[1]Physiology of hematopoiesis lab., [2]Bone marrow transplantation, [3]Molecular Hematology, NATIONAL RESEARCH CENTER FOR HEMATOLOGY, Moscow, Russian Federation

Background: Graft failure following allogeneic hematopoietic cell transplantation (alloHSCT) may result from rejection by recipient T cell. The changes of stromal microenvironment (SM) in patients with graft failure were not described. It was demonstrated that multipotent mesenchymal stromal cells (MSC), the element of SM, are impaired by allogeneic lymphocytes. It was assumed that SM in patients with graft failure could be altered.
Aims: The aim of the study was to analyze SM in patients with graft failure and long-term bone marrow (BM) aplasia.
Methods: A randomized clinical trial (ClinicalTrials.gov NCT01941394) for acute graft-*versus* host disease prevention with MSCs has been on-going at the National Research Center for Hematology. BM MSCs have been developed individually for each patient from its own donor of HSC. Three patients with AML and graft failure after alloHSCT (1 from unrelated and 2 from related partially compatible donors) were observed. In an attempt to restore the SM donor MSCs were injected under local anesthesia in the iliac crest after obtaining informed consent from the patient. The cells were injected into the bone tissue in small portions 100-200 mkl through 2 skin punctures, and multiple periosteal punctures. In 2 patients bone marrow punctures were performed 5 and 3 months after the donors' MSCs implantation. It was withdrawn by 2-3 ml of bone marrow from 4 independent punctures from iliac crest of each patient. Colony-forming units fibroblast (CFU-F) from these BM samples were analyzed and MSCs were isolated and cultured by standard method.
Results: In 2 patients 2 weeks after MSCs administration their own hematopoiesis recovered. Analysis of BM MSCs in 5 months after donor MSCs implantation revealed significant decrease in cumulative MSCs production for 3 passages (1.2±0.2x10^6) compared with all AML patients after alloHSCT (4.2±0.6x10^6) and healthy donors (8.0±2.1x10^6). The efficiency of cloning, showing the number of MSCs with proliferative ability in the population, was also significantly decreased (0.101±0.014) compared with donors (0.34±0.07). In one patient leukocyte count reached 10^9/L only in 9 months after donor MSCs implantation. Analysis of BM samples from this patient after MSCs implantation revealed decrease of bone marrow cellularity (Table 1) per ml *versus* 16.7±0.7x10^6 in donors. Cumulative MSCs production in this patient was very low (Table 1) Cloning efficiency was also significantly lower than donors. Gradually, the total cell production increased and 3 months after the start was 2 times higher than the original and CFU-F concentration in the BM also began to recover. In 3 and 5 months after MSCs implantation donor MSCs were found in the bone marrow of 2 patients.

Table 1. Analysis of BM samples of one patient.

Days after MSCs implantation	Number of leukocytes per mkl	Number of BM cells/ml, x10^6	Cumulative MSC production for 4 passaged, x10^6	CFU-F per 10^6 BM cells	Efficiency of cloning
77	100	1±0.16	0.73±0.2		
99	700	2.76±1.02	1.19±0.34	8.0	
171	700	2.32±0.21	1.56±0.38	40.8±15.7	0.25±0.08

Summary/Conclusions: Thus it is possible that graft failure in patients after alloHSCT is not only connected with the immune response, but with severe damage of bone marrow stromal cells, which may partly be restored after administration of the donor MSCs.

P629

SPONTANEOUS REMISSION IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA - RETURN TO HEALTH OR TRANSITION INTO MALIGNANCY?

ES Kairemo[1,*], AE Armstrong[2], H Jarva[1,3], S Meri[1,3]
[1]Department of Bacteriology and Immunology, University of Helsinki, [2]Coagulation Disorder Unit, Helsinki University Central Hospital Comprehensive Cancer Center, [3]Helsinki University Hospital Laboratory (HUSLAB), Helsinki, Finland

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired syndrome characterized by intravascular hemolysis, thrombosis and bone marrow failure. The disease is caused by a mutation on the *PIG-A* gene that leads to

a lack of glycosylphosphatidylinositol (GPI) -anchored complement regulatory molecules CD55 and CD59 from the surface of a clonal lineage of blood cells. The diagnosis of PNH is made by analyzing GPI-anchored molecules on blood cells by flow cytometry. The disease course is often unpredictable and the therapeutic options are limited. While in previous studies spontaneous remissions have been reported to occur in up to 15-30% of cases, there are no detailed case reports published of these patients. In particular, it would be important to distinguish true remissions from other developing disorders, especially from malignancy.

Aims: Because of the variable clinical course of PNH we wanted to explore whether true spontaneous remissions occur in PNH in the Finnish patient material. A nation-wide study of all patients in Finland since 1995 and an extended follow-up time (up to 20 years) have allowed a detailed analysis of the course of the disease in our patients.

Methods: In a nation-wide project we collected patients from all Health Care Districts in Finland. The sources of information included the Helsinki University Central Hospital Laboratory (HUSLAB) databases, flow cytometry analysis of red blood cells (RBC) and leukocytes, patients' medical records and a patient questionnaire. The patients were evaluated until September 2015. An ethical permission for the study was given by the co-ordinating ethical committee at the Helsinki University Hospital Health Care District. A research permission was also obtained from the National Institute of Health and Welfare (Helsinki, Finland) and the patients gave written informed consents for the study.

Results: In a cohort of 106 Finnish patients with a PNH clone we found six cases where the clone disappeared or clearly diminished (to a level equal or below 1.5%). Two of the six patients subsequently developed leukemia (acute myeloid leukemia and chronic myelomonocytic leukemia) while the other four are in clinical remission. The median time from the diagnosis until the remission was 12.5 years (range 6-15 years). For the two patients who developed leukemia the diagnosis was made 26 years and 12 years respectively after the initial PNH diagnosis. For one of the patients the CD59-deficient cell clone disappeared three years earlier and for the other one in the same year leukemia was diagnosed. For all patients the median CD59-deficient RBC clone size was 64% at highest (range 30-91%). Four of the patients had classic PNH with signs of hemolysis. All of the patients had underlying aplastic anemia.

Summary/Conclusions: According to our data spontaneous remissions are not as frequent as previously described and the disappearance of the PNH cell clone may have dramatically different outcomes. Nevertheless, true remissions occur, but the patients need to be carefully followed up for a potential emergence of malignancy. The remission may have an immunological background. In our cases immunosupressive treatment may have affected the PNH cell clone or the cell clone could have lost its growth advantage after repopulation of the bone marrow. Spontaneous remissions provide an interesting topic for further studies, which could bring along a better understanding of the natural history of PNH.

P630

UNAFFECTED MYELOID DIFFERENTIATION OF IPS CELLS DERIVED FORM A CYCLIC NEUTROPENIA (CYN) PATIENT WITH ELANE MUTATION

A Zahabi[1,*], T Morishima[1], R Bernhardt[1], K Welte[2], J Skokowa[1]
[1]Department of Hematology, Oncology, Immunology, Rheumatology and Pulmonology, [2]University Hospital Tübingen, Germany, Tübingen, Germany

Background: Cyclic neutropenia (CyN) is a hematologic disorder in which blood cell counts particularly granulocytic neutrophils, monocytes, platelets, and reticulocyte numbers show cycles at appr. 21 day intervals. The majority of CyN patients (ca 90%) harbor inherited mutations in the ELANE gene. Intriguingly, same *ELANE* mutations are present in two different bone marrow failure syndromes: congenital as well as in cyclic neutropenias. It is unclear how mutation in the same gene cause congenital (CN) or cyclic neutropenia (CyN). The pathomechanism of cycling hematopoiesis downstream of *ELANE* mutations is also unclear. Recent studies using inducible pluripotent stem cells (iPSCs) derived from severe congenital neutropenia (CN) patients harbouring ELANE mutations demonstrated markedly diminished granulocytic differentiation of these cells *in vitro* (Nayak RC, *et al.* JCI 2015; Hiramoto T, *et al.* PNAS 2013). Interestingly, correction of *ELANE* gene mutation in iPSCs from a CN patient using CRISPR/Cas9 technology restored defective granulopoiesis, suggesting the monogenic origin of the *ELANE* mutation caused congenital neutropenia (Nayak RC, *et al.* JCI 2015). These data suggest that additional gene mutations or epigenetic defects in combination with mutated *ELANE* might be responsible for the pathogenesis of cyclic neutropenia.

Aims: In the present study we evaluated the *in vitro* myeloid differentiation of iPSCs derived from the CyN patient harboring sporadic heterozygous *ELANE* mutation (c.761C>G p.W241L), in comparison to iPSCs derived from healthy individuals.

Methods: We used embryoid-body (EB)-based protocol of granulocytic differentiation from iPSCs described by N. Lachmann *et al.* (Stem Cell Reports 2015).

Results: we found that myeloid differentiation of iPSCs derived from CyN patient, was comparable to that of healthy individual iPSCs, as revealed by the analysis of the percentage and absolute numbers of $CD45^+/CD11b^+$, $CD45^+/CD16^+$ and $CD45^+/CD15^+$ cells as well as by the examinations of the cell morphology on cytospin preparations.

Summary/Conclusions: These data suggest that the *in vitro* hematopoiesis in CyN is normal as judged by iPSC technology and that *in vivo* additional humoral or bone marrow niche components might influence myeloid cell cycling in CyN.

P631

OUTCOME OF ADOLESCENT AND YOUNG ADULTS WITH ACQUIRED APLASTIC ANEMIA TREATED WITH IMMUNOSUPPRESSIVE THERAPY IN COMPARISON WITH CHILDREN AND OLDER ADULTS

A Cabannes-Hamy[1,*], N Boissel[1], R Peffault De La Tour[2], E Lengliné[3], T Leblanc[4], E Raffoux[3], M Robin[2], A Xhaard[2], A Baruchel[4], G Socié[2], N Dhédin[1]
[1]Adolecent and Young adult Hematology, [2]Bone Marrow Transplantation Hematology, [3]Adult Hematology, Saint Louis Hospital, [4]Pediatric Hematology, Robert Debré Hospital, PARIS, France

Background: Acquired aplastic anemia (AA) is a rare hematological disorder with a peak of incidence in the Adolescent and Young Adult (AYA) population. Younger age has been associated with better response after immunosuppressive therapy with anti-thymoglobulin and cyclosporine (ATG-CSA), as well as better survival. However, no study focused on the specific outcome of AYA patients so far.

Aims: This retrospective study assessed the impact of age on outcome of AA after ATG-CSA by comparing AYA with younger and older patients.

Methods: We retrospectively analyzed a cohort of AA patients treated frontline by the association of ATG (rabbit or horse) and CSA in Saint-Louis Hospital between January 2000 and June 2013. Patients were divided into three age groups: children (<15 years), AYA (15-25 years) and adults (>25 years). Eighty-four consecutive patients were included (29 children, 32 AYA and 23 adults). Children presented more frequently with very severe AA (55% *versus* 22% in AYA and 22% in adults, p=0.023). Time from diagnosis to ATG was longer in adults (69 days *versus* 26 in children and 28 in AYA, p=0.007). Children were more frequently treated with rabbit-ATG (86% *versus* 59% in AYA and 52% in adults, p=0.004). Patients were similarly transfused before ATG in the 3 groups. Rates of transplantation after failure/relapse were similar in these subgroups. Complete response (CR) was defined as a neutrophil count >1 G/L, a platelet count >100 G/L and a haemoglobin level >10 g/dl, according to the National Institutes of Health (NIH) criteria. Partial response (PR) was defined as transfusion independence with a neutrophil count >0.5 G/L, but not meeting the blood count criteria for CR.

Results: The overall response rate at 6 months was 48% in children, 69% in AYA and 30% in adults, and 76%, 78% and 49% respectively at 5 years. In multivariate analysis, along with the use of horse ATG (OR=3.398, p=0.045), age remained associated with better response rate. Thus, in comparison with AYA patients, the 6-month response rate was lower in adults (OR=0.179, p=0.008) and similar in children (OR=0.609 p=0.386). The 5-year relapse rate was 20.7%, with no impact of age. The only relapse risk factor identified was higher baseline lymphocytes count (OR=1.939, p=0.011). Twenty seven patients (12 children, 6 AYA and 9 adults) underwent allogeneic hematopoietic stem cell transplantation (HSCT), 4 from an HLA-identical sibling donor (adults over 40 years), 18 from an unrelated donor and 5 from cord blood. They were referred to HSCT after failure (16), relapse (8) or clonal evolution (3). With a median follow-up of 5.4 years, the 5-year overall survival (OS) was 86.5%. After censoring at the time of HSCT, the 5-year OS was 95.9%. Eleven patients died, all in failure/relapse after ATG-CSA, including 8 after HSCT (5 from infection, 2 from GVHD and 1 from graft failure). Adults over 25 years had shorter survival than AYA (HR=4.984, p=0.049) and showed a trend toward worse survival than children (HR=3.311, p=0.092). However, in multivariate analysis, younger age did not impact OS. The predictive factors associated with improved survival were a lower baseline lymphocytes count (HR=4.696, p=0.015), a lower baseline neutrophils count (HR=4.735, p=0.045), a higher baseline reticulocytes count (HR=0.897, p=0.023) and a shorter time from diagnosis to ATG (HR=7.341, p=0.001) (these 4 factors analyzed as continuous variables), as well as a better 6-month response rate (HR=0.008, p=0.015).

Summary/Conclusions: Response rate of AYA population treated with ATG-CSA for AA is similar to children's and better than adult's one. However, younger age has no influence on OS or relapse.

P632

A PHASE 1 SINGLE-ASCENDING-DOSE CLINICAL STUDY OF RA101495, A SUBCUTANEOUSLY ADMINISTERED SYNTHETIC MACROCYCLIC PEPTIDE INHIBITOR OF COMPLEMENT C5 FOR TREATMENT OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

JM Johnston[1,*], A Ricardo[1], M Arata[1], J Lickliter[2], SJ DeMarco[1], R Fahrner[1], RP Hammer[1], B Newstat[1], D Roychowdhury[1], S Tobe[1], D Winslow[1], D Treco[1]
[1]Ra Pharmaceuticals, Cambridge, United States, [2]Nucleus Network, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, acquired, clonal hematopoietic stem cell disorder caused by a deficiency in glycosylphosphatidylinositol (GPI)-linked proteins on cell surfaces. Patients with mutations

in the phosphatidylinositol glycan class A gene are unable to produce functional, protective, GPI-linked proteins, resulting in the accumulation of specific complement proteins on the surface of red blood cells (RBCs) and subsequent RBC lysis by the membrane attack complex (MAC). Inhibition of complement activation at the level of complement C5 is a clinically validated approach for the treatment of PNH. RA101495, a synthetic macrocyclic peptide, binds to C5 at a unique site not targeted by currently available therapies, and allosterically inhibits C5 cleavage into C5a and C5b, preventing production of a key component of the MAC. RA101495 also inhibits the assembly of MAC by blocking the interaction between C5b and C6.

Aims: A Phase 1 single-ascending-dose clinical pharmacology study in healthy human volunteers designed to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of RA101495 following subcutaneous (SC) injection.

Methods: The study was randomized, double-blinded, and placebo (PBO)-controlled with 4 SC single-ascending-dose cohorts housed in a clinical pharmacology unit for 3 days. After obtaining written informed consent, all subjects received 1 dose of RA101495 on Day 1. Four subjects (2 RA101495 and 2 PBO) were administered the lowest dose level (0.05 mg/kg) and 6 subjects per cohort (4 RA101495 and 2 PBO) were sequentially administered the 3 higher dose levels (0.1, 0.2, and 0.4 mg/kg). Safety was assessed by intensive clinical monitoring, and frequent blood samples were obtained for determination of RA101495 concentrations by liquid chromatography/high resolution mass spectroscopy and ability to inhibit complement-mediated RBC lysis in an *ex vivo* antibody-sensitized sheep erythrocyte hemolysis assay. All subjects received prophylaxis for N. meningitides infection with ciprofloxacin and, for the highest dose, vaccination as well.

Results: A total of 22 subjects were enrolled into the study (14 RA101495 and 8 PBO). Plasma concentrations of a single SC injection showed linear dose-dependent exposure across all dose levels. Preliminary results show that at the maximum plasma concentration, the percent inhibition of hemolysis compared to baseline reached ≥90% for the 0.1, 0.2, and 0.4 mg/kg dose cohorts and 60% for the lowest dose (0.05 mg/kg) cohort. Suppression of hemolysis of up to 4 days (further time points are being analyzed) was observed for the 0.1, 0.2, and 0.4 mg/kg dose ohorts. Notably, a single injection of 0.4 mg/kg resulted in ≥90% suppression of hemolysis for at least 4 days. The only safety finding noted was mild cutaneous injection site erythema in 3 of 6 subjects on the highest dose (data are still blinded); there was no associated pain, tenderness, swelling, or induration and all events resolved rapidly following dosing.

Summary/Conclusions: RA101495 is a novel synthetic macrocyclic peptide inhibitor of C5-mediated hemolysis that is being developed as an alternative to intravenous monoclonal antibody therapy for the treatment of PNH. RA101495, currently being investigated for daily at-home SC self-administration, shows a rapid onset of activity, and appears to be safe and well tolerated. These preliminary data suggest low daily doses will achieve steady-state levels suitable for ≥90% suppression of hemolysis, and that once-weekly dosing should be achievable.

P633

THE PRESENCE OF A PNH CLONE INFLUENCES THE KINETICS OF RESPONSE TO IMMUNOSUPPRESSIVE THERAPY (IST) IN APLASTIC ANEMIA (AA) PATIENTS.

E Nevill[1,*], B Dalal[2], S Narayanan[1], H Donna[1], M Power[1], D Sanford[1], D Forrest[1], S Nantel[1], M Barnett[1], Y Abou Mourad[1], A Gerrie[1], K Song[1], C Toze[1], R Broady[1], H Sutherland[1], T Nevill[1]
[1]Division of Hematology, Leukemia/BMT Program of BC, [2]Division of Hematopathology, Vancouver General Hospital, Vancouver, Canada

Background: Immunosuppressive therapy (IST) is effective in improving the hematologic cytopenias in 65-75% of patients (pts) with aplastic anemia (Young NS, *Blood*, 2006). A clone of hematopoietic cells deficient in glycosylphosphatidylinsoitol membrane protein anchors - a PNH clone - can be seen in ~50% of AA (pts) (Socie G, *Sem Hematol*, 2000). The presence of a PNH clone in AA may predict for a favourable response to IST (Sugimori, *Blood*, 2006) although this remains controversial (Scheinberg, *Br J Haemtol*, 2009). The development of high-resolution PNH flow cytometric testing may be a mitigating factor explaining interstudy variability.

Aims: To determine whether the presence or the size of a PNH clone in AA pts affects the rate or degree of response to standard IST at a regional/provinical referral centre.

Methods: A retrospective chart and computer data base review was performed on all AA pts >age 16 years (yrs) referred to Vancouver General Hospital (VGH) between January 2008 and October 2015 for treatment with IST. Bone marrow pathology was centrally reviewed and all pts had metaphase cytogenetic analysis performed to exclude a clonal abnormality. PNH flow cytometry was done at VGH on the red cells, granulocytes and monocytes of all pts using an antibody panel that included FLAER, CD55 and/or CD59. IST was uniform during the study period and consisted of Cyclosporine (CSA) 2.5 mg/kg p.o. b.i.d., ATGAM 40 mg/kg/d IVx4 and IV Methylprednisolone 1 mg/kg/dx10 with a 10-day taper. CSA doses were adjusted to maintain whole blood trough CSA levels of 200-300 ug/L for a 12-month period followed by tapering based uoon hematologic tolerance. Severity of AA and criteria for response to IST were as previously published (Marsh J, *Br J Haematol*, 2009). Statistical comparisons were performed using the Fisher's exact test and differences in group medians were assessed with the Mann Whitney U test.

Results: During the 8-year study period, 57 pts with AA received IST at VGH; 2 pts died within 2 weeks of commencing treatment and 55 pts were evaluable for response. There were 28 males (M) and 27 females (F) with median age of 56 yrs (range 17-74). AA was very severe in 7 pts, severe in 28 pts and non-severe in 20 pts. Response to IST was seen in 39 pts (70.1%) - partial response (PR) in 26 pts (47.3%) and complete response (CR) in 13 pts (23.6%). Ten pts received a second cycle of ATGAM or rabbit ATG (Thymoglobulin), 3 pts for recurrent AA following CSA taper (all responded) and 7 pts for initial non-response (no responses at 12 mos). A PNH clone was found at diagnsois in 29 pts (52.7%; PNH+) with median clone size 0.9% (range 0.1% - 87%). M/F ratio was 0.7 in PNH+ pts and 1.6 in pts without a PNH clone (PNH-) (p=0.18). Median age was similar in the PNH+ (51 yrs) and PNH- (57 yrs) groups (p=0.49) but was significantly younger in PNH+ pts with clone size >1%, n=14 (33.5 yrs; p=0.04). Rate and degree of response to IST was similar in PNH+ pts (65.5%; 20.7% CR) and PNH- pts (76.9%; 26.9% CR) (p=0.38) and the size of the PNH clone did not influence the response rate. Kinetics of response to IST did differ notably between PNH+ and PNH- pts (Table 1).

Table 1.

	3 mos	6 mos	12 mos	24 mos
PNH+ (n=29)	51.7%	62.1%	65.5%	65.5%
PNH- (n=26)	42.3%	53.8%	53.8%	76.9%

All of the PNH+ responders achieved ≥PR by 12 months while 6/20 of the PNH- pts reached PR/CR between 12 and 24 mos (p=0.02). On serial testing, PNH clone size increased >10% in 3 pts (10%) and decreased by >10% in 2 pts (7%). Five pts in the PNH- group (19%) developed a persistent PNH clone on follow-up. With a median follow-up of 44 mos, 49 of 55 evaluable pts remain alive; 4 PNH+ pts and 2 PNH- pts have died.

Summary/Conclusions: IST is associated with a 70% response rate in AA pts. The presence of a PNH clone and the size of a PNH clone does not predict the degree or rate of response to IST. However, the kinetics of response differs between PNH+ and PNH- pts. PNH- pts may take longer to achieve response criteria with 20-25% of pts responding during the seond year of IST.

A CLINICAL SIGNIFICANCE AND TIME-DEPENDENT CHANGE OF PNH CLONE SIZE IN PATIENTS WITH BONE BARROW FAILURE SYNDROME: JAPANESE MULTI-CENTRE PROSPECTIVE STUDY

Y Shirasugi[1,2,*], C Sugimori[2,3], H Noji[2,4], T Shichishima[2,4,5], N Obara[2,6], S Chiba[2,6], H Ninomiya[2,7], Y Nakamura[1,2], K Ando[1,2], Y Yonemura[2,8], T Kawaguchi[2,9], K Hosokawa[2,10], Y Ueda[2,11], JI Nishimura[2,12], Y Kanakura[2,12], S Nakao[2,13]
[1]Hematology and Oncology, Tokai University School of Medicine, Isehara, [2]Japan PNH Study Group, Tokyo, [3]Hematology, Ishikawa Prefectural Central Hospital, Kanazawa, [4]Cardiology and Hematology, Fukushima Medical University, [5]Fukushima Research Institute of Environment and Medicine, Fukushima, [6]Hematology, [7]Medical Sciences, University of Tsukuba, Tsukuba, [8]Transfusion Medicine and Cell Therapy, Kumamoto University Hospital, [9]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan, [10]Hematology Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, United States, [11]Hematology and Oncology, Osaka University Graduate School of Medicine, [12]Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, [13]Cellular Transplantation Biology, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: In patients with bone marrow failure (BMF) syndromes, including aplastic anemia (AA) or low-risk types of myelodysplastic syndrome (MDS), a small population of GPI-AP-deficient blood cells (PNH-type cells) is often detectable through high-resolution flow cytometry. Some studies have shown that BMF patients with PNH-type cells have a favorable response to immunosuppressive therapy (IST), compared to BMF patients lacking PNH-type cells.

Aims: We conducted a multi-centre prospective observational investigation in Japan, the OPTIMA study, to determine the clinical significance and time dependent change of PNH clone size in BMF patients.

Methods: From July 2011, we recruited patients who were diagnosed with BMF syndromes. The primary endpoint was to determine the prevalence of increased PNH-type cells in BMF syndromes and to clarify the clinical significance of the presence and quantitative changes of these cells with regard to clinical features. Six university laboratories across Japan were assigned as regional analyzing centres and the percentage of PNH-type cells was measured by high-resolution flow cytometry, originally established in Kanazawa University. Cross validations were conducted twice per year at each regional centre to minimize inter-laboratory variations in detection sensitivities, cutoff values, and other variables. The liquid FLAER method (≥0.003%) and cocktail method (≥0.005%) with CD55 and CD59 antibodies were used for the detection of PNH-type granulocytes and erythrocytes.

Results: Between July 2011 and July 2015, 2411 patients were enrolled in the

study, and we analyzed 2299 patients who were eligible for this interim analysis. Based on high-resolution flow cytometry, 784 (34.1%) patients had ≥0.005% PNH-type erythrocytes and ≥0.003% PNH-type granulocytes; for each disease subset PNH-type cells were found in 73/73 (100%) patients with PNH, 377/716 (52.7%) with AA, 110/622 (17.7%) with MDS, 182/655 (27.8%) with undiagnosed BMF, and 42/233 (18%) with suspected PNH. Overall, 186 (8.1%) patients had ≥1% of both PNH-type erythrocytes and granulocytes: 69 (94.5%) patients with PNH, 69 (9.6%) with AA, 22 (3.5%) with MDS, 10 (1.5%) with undiagnosed BMF syndromes and 16 (6.9%) with suspected PNH. With regard to the WHO classification of MDS subtypes, 20.1% (58/288) of patients with RCMD, 17.5% (28/160) with RCUD, and 40% (2/5) with del (5q) MDS possessed PNH-type cells; no patients with RARS (n=27) or RAEB (n=63) had PNH-type cells. At 3-year follow-up, a total of 86 (3.7%) patients were able to be evaluated for time-dependent changes of PNH-type cells. Seventy-six of the 86 (11 with PNH, 48 with AA, 11 with MDS, 4 with undiagnosed BMF syndromes, and 2 with suspected PNH) patients had PNH-type cells at enrollment. In four of the 76 patients, PNH-type cells became undetectable at 3-years; 3 of the 4 patients had AA and the other had MDS; all but one AA patient received IST and achieved partial or complete response to the treatment. PNH-type cells were not detected at 3 years in 10 patients who did not show PNH type cells at enrollment.

Summary/Conclusions: PNH-type cells were detected in 52.7% of patients with AA and 17.7% of patients with low-risk types of MDS, but were not detected in any of RARS and RAEB patients. The results of the nation-wide study confirmed our previous finding that the presence of increased PNH-type cells represents a benign nature of bone marrow failure.

P635

HLA-HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION: A VALID ALTERNATIVE OPTION FOR PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

F Chen*, D Wu, X Tang, M Miao, C Fu, H Qiu, S Xue, X Ma, Z Jin
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: In the era of Eculizumab, indentifying patients with PNH who may benefit from allogeneic stem cell transplantation(SCT) is challenging, especially for those who have no HLA-matched donors. Several recent studies have shown that HLA-haploidentical SCT for patients with hematological malignancy can achieved comparable outcomes with HLA-identical sibling transplantation. There are very few reports on the use of HLA-haploidentical SCT for PNH.

Aims: The aim of the present study was to assess the long-term clinical outcome of HLA-haploidentical SCT in patients with PNH.

Methods: Total of 12 PNH patients received HLA-haploidentical SCT between Oct 2010 and Oct 2015 at our institution. The patients were aged 8 to 54(median 22.5 years). The median interval from the diagnosis to transplantation was 5 months (range 2-180). Of the 12 HLA-haploidentical donors, 6 were siblings, 2 fathers, 2 mothers, 1 son and 1 daughter. 11 patients received myeloablative conditioning regimen consisting of busulfan, cyclophosphamide and ATG (antithymocyte globulin), 1 patient who underwent salvage HLA-haploidentical SCT after the graft failure of double umbilical cord blood transplantation received conditioning including reduced-intensity total body irradiation, cyclophosphomide and ATG. G-CSF-mobilized bone marrow and peripheral blood stem cells were transplanted as graft. Prophylaxis for graft-*versus*-host disease(GVHD) consisted of cyclosporine or tacrolimus+mycophenolate mofetil+short-term methotrexate.

Results: All 12 patients were engrafted successfully. The median time of neutrophils (ANC) reached to 0.5×10^9/L and platelets (PLT) reached to 20×10^9/L were 12 (range 11-26) days and 15 (range 11-120) days, respectively. 2 patients developed grade II acute GVHD, 2 patients developed limited chronic GVHD. After a median follow-up time of 16.5 (range 2.0-40.0) months, the 3-year OS probability was 77.8±13.9%. 2 patients died of treatment-related mortality, including severe pulmonary infection (n=1) and transplant-associated thrombotic microangiopathy (n=1),respectively. No patients were documented to have a recurrence of PNH clone after SCT.

Summary/Conclusions: This study showed that long-term outcomes of HLA-haploidentical SCT in patients with PNH were comparable to that of HLA-matched donor SCT (the 3-year OS probability was 80.5±10.2%, P=0.02) at our institution. HLA- haploidentical SCT should be considered as a valid alternative therapeutic option for PNH patients without HLA-matched donors.

P636

GENE MUTATIONS IN INHERITED BONE MARROW FAILURE SYNDROME REVEALED BY NEXT GENERATION SEQUENCING: COMPARISON WITH CHROMOSOME BREAKAGE TEST

DS Lee[1], SN Park[2,*], KO Im[2], JA Kim[1], HS Park[1], SM Hwang[3]
[1]Dept of Laboratory Medicine, [2]department of tumor cell biology, Seoul National University College of Medicine, Seoul, [3]Dept of Laboratory Medicine, Seoul National University College of Medicine, Bundang, Korea, Republic Of

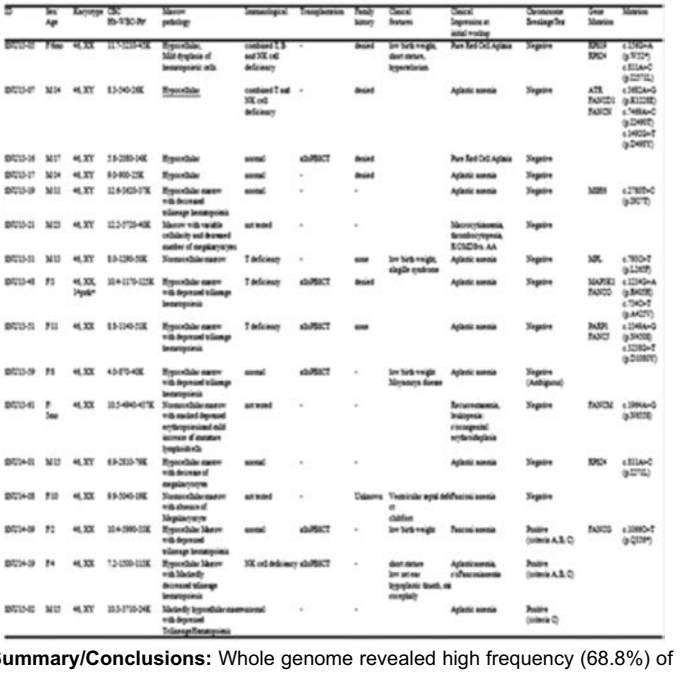
Background: Inherited bone marrow failure syndrome (IBMFS) is characterized by cytopenias, congenital physical abnormalities, and predisposition to malignancy. Fanconi Anemia (FA) is the most frequent cause among IBMFS and chromosome breakage test is routinely performed to diagnose FA, while gene tests for FA is not easily accessible due to large sized and multiple involved genes. We performed whole genome sequencing and compared the gene mutation with the results of chromosome breakage test.

Aims: The aim of our study was 1) to investigate the incidence of FA showing positive results for CBT among patients diagnosed with AA, and 2) to investigate the frequency of the gene mutations which are related to IBMFS in patients with AA. We collected the DNA of 16 patients who were suspected for the diagnosis of IBMFS and performed whole genome sequencing. For specimen in whom we could not acquire consent for genetic testing and research, we retrospectively rescored the results of CBT according to 3 different diagnostic criteria for FA.

Methods: In 16 patients with childhood Aplastic Anemia(AA), whole genome sequencing was performed in context with chromosome breakage test with mitomycin C and diepoxybutane. Additionally, the results of 67 consecutive chromosome breakage tests from 57 patients under suspicion of FA were retrospectively rescored based on widely used 3 different scoring systems and compared the concordance rate among the results of 3 different scoring systems.

Results: Mutation variants related with IBMFS were detected in 68.8% (11/16 patients); RPS19 and RPS24 in 2 patient, BLM in 2 patient and FA genes (FANCA, FANCD1, FANCG, FANCJ, FANCM, FANCN, FANCO) in 9 patients. Inherited predisposition to myeloid leukemia related genes (MSH6, ATR, MPL) were detected in 18.7% (3/16 patients). Coexisting somatic mutations of oncogene (MAP3K1) was detected in 1 patients among 9 patients with FANC mutation (11.1%, 1/9 FA patients). Among 9 patients with FA gene mutations, 2 patients showed positive results for chromosome breakage test and the other 7 patients showed negative results for chromosome breakage test. Concordance rate among 3 different scoring systems for chromosome breakage test was 91.2% (52/57 patients) (Table 1).

Table 1.



Summary/Conclusions: Whole genome revealed high frequency (68.8%) of IBMFS related genes in childhood aplastic anemia, suggesting that molecular testing is requisite for diagnosis of IBMFS. Considering that chromosome breakage test detected only 22.2% of FA patients who were confirmed by molecular test and significant portion of patients who showed positive chromosome breakage test did not harbor FA gene mutation, significance of chromosome breakage test for FA must be reconsidered.

P637

PROSPECTIVE STUDY ON THE USE OF PEGFILGRASTIM IN CHILDREN WITH SEVERE CONGENITAL NEUTROPENIA

F Fioredda[1,*], T Lanza[1], F Gallicola[1], M Lanciotti[1], E Mastrodicasa[2], S Signa[1], S Zanardi[3], M Calvillo[1], C Dufour[1]
[1]Haematology Unit, IRCCS Istituto Giannina Gaslini, Genova, [2]Pediatric Oncology Haematology Unit, S Maria della Misericordia Hospital, Perugia, [3]Biostatistic and Epidemiology Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Granulocyte-ColonyStimulating Factor (G-CSF), has radically changed the prognosis of Severe Congenital Neutropenia (SCN) patients who are at risk of lethal infections.The compliance to daily subcutaneous injections

is sometime scarce thus affecting the efficacy of treatment.The peghilated form of filgrastim (PEG) due to its long half-life should enable the frequency of injections.
Aims: To describe the efficacy, safety and PK profile of PEG in children affected with SCN.
Methods: SCN pediatric patients treated with G-CSF scarcely compliant to daily injections, were considered eligible to the study**.** After 72 hours wash out, PEG was administered at starting dose of 100 g/kg at an interval not shorter than 4 days; subsequent injections aimed to mantain median absolute neutrophil count (ANC) between 1000-5000/cmm and to control infections. Bone marrow morphology, cytogenetics, G-CSFR mutation analysis, abdomen ultrasound scan, and bone density assessment by dual energy X-ray absorptiometry (DEXA) were performed at baseline and then yearly. Blood count, biochemical parameters, serum concentration of pegfilgrastim (ELISA,Quantikine HS, R and D System, Inc, MN) were frequently evaluated within the first six months and afterward 3-4 times/year. Evaluation of QoL up by Short Form Health Survey questionnaire (SF-36) was performed at the beginning and at the end of the follow-up. Infectious load was calculated by infectious ratio (IR) which considers the number of documented infections over the period at risk/patient, normalized by 1000.
Results: From July 2006 to Oct 2015, 5 SCN patients (3males) diagnosed at a median age of 2 months (0-18) entered in the study. Four patients were ELANE and one HAX-1 mutated. G-CSF was given for a median of 36 months (0,23-89) and at a median dose of 7.5g/kg (5-25 g/day) before PEG. Median age at enrollment was 50 months (7-110) and median duration of PEG was 46 months (7-111). The median PEG dose was 60g/kg (50-100) given every 7-12 days. ANC rose from a median of 1000/cmm in G-CSF to 1515/cmm in PEG (p=ns). IR dropped from 9.5 in G-CSF to 5.5 in PEG (p=ns).Otitis, otomastoditis and skin abscesses were the most frequent type of infections seen during PEG.When PEG was given every 7-8 *vs* every 9-12 days ANC significantly increased (1283/cmm) over G-CSF phase (670/cmm; p=0.002). Also IR further declined with the more frequent PEG schedule (IR 6 *vs* 3.5; p=ns). The QoL questionnaire showed a marked overall improvement (100%) particularly in physical and mental performances and a relevant reduction of physical pain.PEG was never interrupted because of side effects.Biochemical parameters remained in the normal ranges, spleen size did not increase and in one patient osteoporosis developed. In the same patient a mutation of G-CSF receptor appeared after 4 years of PEG then disappeared. Peak serum concentration of PEG was achieved after 72 hr from administration, levels then declined to those of the washout phase (Pre-PEG) on day 7.
Summary/Conclusions: PEG was able to rise neutrophils and to protect patient toward severe infections enabling a better quality of life withoutside effects. PK data are probably in keeping with low risk of overexposure. Larger study and longer follow up are needed to confirm these findings.

Novel targets for MM

P638

IKAROS PROTEIN EXPRESSION IN BONE MARROW B AND T CELLS RATHER THAN MYELOMA CELLS PREDICTS OUTCOME AFTER LENALIDOMIDE-DEXAMETHASONE THERAPY

A Bolomsky[1,*], E Müldür[1], V Fritz[1], D Heintel[1], M Wilheim[2], N Zojer[1], W Hübl[2], H Ludwig[1]
[1]Wilhelminen Cancer Research Institute, Department of Internal Medicine I, Wilhelminenspital, [2]Department of Laboratory Medicine, Wilhelminenspital, Vienna, Austria

Background: The identification of cereblon, ikaros and aiolos as central partners and targets of immunomodulatory drugs (IMiDs) represents a milestone in our understanding of the mechanisms of actions of these agents. However, although we and others noted a significant association between the expression of these molecules and response or survival, methods for a valid stratification of patients to IMiD-based therapies are still missing.
Aims: In the current study, we analysed IKAROS protein expression by using multicolour flow cytometry in myeloma cells as well as distinct cell subsets of the bone marrow microenvironment for its potential as predictive and/or prognostic marker for IMiD-based therapies.
Methods: IKAROS protein levels were analysed in stored BM samples of 16 MM patients before initiation of treatment with lenalidomide-dexamethasone. Cells were thawed, restored overnight and stained for CD3/CD38/CD45/CD56/CD138/HLA-DR or CD3/CD4/CD8/CD14/CD19/CD34/CD45. Intracellular staining of IKAROS (or the corresponding isotype control) was performed according to the BD Transcription Factor Buffer Set protocol. Live/dead cells were discriminated using BD Fixable Viability Stain 520. Analyses were performed on a FACS Canto II.
Results: IKAROS protein expression was detected in all cell subtypes analysed, including MM cells, B-lymphocytes, T-lymphocyte subsets (CD3+CD4+, CD3+CD8+, CD3+CD4+CD8+, CD3+CD4-CD8-), NK cells, monocytes and CD34+ cells. No association was observed between IKAROS protein levels and response. However, we detected a significant correlation of IKAROS protein levels and overall survival (OS) for the percentage of IKAROS positive B-lymphocytes (R=0.61, P=0.012) and CD3+CD8+ T cells (R=0.50, P=0.047). Similarly, IKAROS median fluorescence intensities (MFI) of CD3+ T lymphocytes (R=0.55, P=0.027), CD3+CD8+ T cells (R=0.53, P=0.035) as well as monocytes (R=0.55, P=0.029) significantly correlated with OS. No association was found between OS and the percentage of IKAROS positive MM cells (R=0.10 P=0.70) or MFI of MM cells (R=0.12, P=0.65). Univariate Cox regression analysis confirmed the association with survival for the percentage of IKAROS positive B-lymphocytes (P=0.014) and the MFI of CD3+ (P=0.029) and CD3+CD8+ (P=0.05) T lymphocytes as well as monocytes (P=0.017). When we stratified patients according to high or low IKAROS expression (cutoff=mean) in distinct cell subtypes we were able to define different prognostic subgroups. In particular, a higher percentage of IKAROS positive cells were associated with better outcome for B-lymphocytes (median OS 82.3 *vs* 33.6 months, P=0.01) and CD3+CD8+ T lymphocytes (median OS 82.3 *vs* 31.8 months, P=0.05). Again, no association was observed between the percentage of IKAROS positive MM cells and OS (median OS 35.6 *vs* 45.3 months, P=0.43).
Summary/Conclusions: In conclusion, our results demonstrate a significant association between IKAROS protein levels in bone marrow CD3+CD8+ T lymphocytes, B-cells and monocytes with overall survival. In contrast, no association was noted between IKAROS expression in myeloma cells and OS. This suggests that the activity of IMiDs is mainly mediated via IKAROS expression in bone marrow immune cells, which therefore could serve as prognostic marker for patients assigned to IMiD containing regimens. Based on these initial results, prospective analysis of IKAROS protein expression in an enlarged patient cohort is in progress.

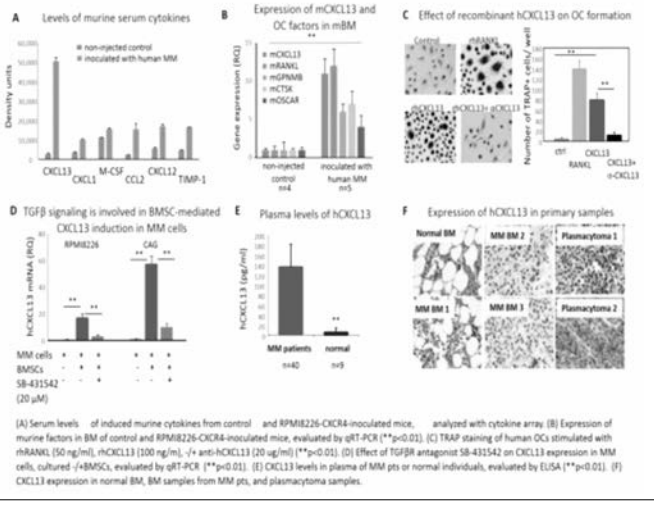
P639

CXCL13 CHEMOKINE – A NOVEL TARGET IN MULTIPLE MYELOMA MICROENVIRONMENT

K Beider[1,*], V Voevoda[1], H Bitner[1], E Rosenberg[1], O Ostrovsky[1], E Ribakovsky[1], M Leiba[1], A Shimoni[1], M Koren-Michowitz[1], M Abraham[2], A Peled[2], A Nagler[1]
[1]Bone Marrow Transplantation, Sheba Medical Center, Ramat-Gan, [2]Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, Israel

Background: Chemokine and cytokine network plays an important role in multiple myeloma (MM) pathogenesis. Studying the underlying mechanisms may help to identify new therapeutic targets to treat MM. Here we reveal B-cell chemo-attractant CXCL13 (BCA-1) being novel factor expressed in the tumor microenvironment of MM, supporting osteoclastogenesis and being associated with extramedullary progression.
Aims: To characterize the expression of CXCL13 and define its functional sequel in the MM milieu.

Methods: We utilized our recently established *in vivo* xenograft model of BM-disseminated human myeloma (using engineered CXCR4-expressing RPMI8226 cells), as well as analysis of MM cell lines, stromal components and primary samples from patients (pts) with MM.
Results: Evaluation of the cytokines in sera of MM-inoculated mice in comparison to control mice detected increased levels of the CXCL13 chemokine being the highest factor among the broad panel analyzed. Elevated mCXCL13 was also detected in bone marrow (BM) samples from the MM-bearing mice, and correlated with induced expression of murine factors associated with osteoclast (OC) activation (RANKL, NFATc, GPNMB, CTSK, OSCAR). IHC analysis of MM-occupied murine BM revealed myeloid cells being the main source of increased mCXCL13, while human RPMI8226 cells in murine BM milieu also expressed detectable levels of hCXCL13. In addition, hCXCL13 mRNA was found to be expressed by MM cell lines (n=8), BM stromal cell lines and peripheral-blood generated Mϕ. Strong induction of CXCL13 expression in both MM and stromal cells was detected upon their co-culture. Furthermore, CXCL13 expression in BMSCs and Mϕ was significantly induced following RANKL treatment; in turn, addition of CXCL13 up-regulated RANKL levels, demonstrating a positive regulation loop between CXCL13 and RANKL. Functional tests revealed the ability of CXCL13 to induce *in vitro* formation of TRAP+ OCs, while CXCL13 neutralizing antibodies blocked this effect. Furthermore, CXCL13 neutralization markedly decreased RANKL expression in BMSCs. Of note, CXCR5, cognate CXCL13 receptor, was expressed predominantly by stromal and myeloid cells, suggesting the paracrine effects of MM-generated CXCL13. Mechanistically, we found that TGFβ signaling was involved in CXCL13 induction in both MM and stromal cells. Addition of TGFβ receptor kinase inhibitor SB-431542 interfered with the activation triggered by the interaction between MM cells and stromal components and prevented the increase in CXCL13 expression. Finally, we evaluated the presence of hCXCL13 in primary MM samples. CXCL13 transcript was detected in BM aspirates from MM pts (n=20), its expression was significantly upregulated upon co-culture with BM stromal cells and correlated with expression of osteoclastogenic factors, including RANKL and MT1-MMP, an important component of OC fusion machinery. In addition, plasma level of CXCL13 was significantly higher in MM pts (n=44) (148 pg/ml±136) in comparison to normal individuals (n=9) (19 pg/ml±7.6) (p<0.001). Furthermore, IHC analysis of BM biopsies from MM pts (n=7) and plasmacytoma samples (n=6) demonstrated the expression of CXCL13 in malignant plasma cells. Importantly, CXCL13 showed markedly increased expression within plasmacytoma tissues, suggesting that elevated CXCL13 levels may be associated with extramedullary disease (Figure 1).



(A) Serum levels of induced murine cytokines from control and RPMI8226-CXCR4-inoculated mice, analyzed with cytokine array. (B) Expression of murine factors in BM of control and RPMI8226-CXCR4-inoculated mice, evaluated by qRT-PCR (**p<0.01). (C) TRAP staining of human OCs stimulated with rhRANKL (50 ng/ml), rhCXCL13 (100 ng/ml), -/+ anti-hCXCL13 (20 ug/ml) (**p<0.01). (D) Effect of TGFβR antagonist SB-431542 on CXCL13 expression in MM cells, cultured -/+BMSCs, evaluated by qRT-PCR (**p<0.01). (E) CXCL13 levels in plasma of MM pts or normal individuals, evaluated by ELISA (**p<0.01). (F) CXCL13 expression in normal BM, BM samples from MM pts, and plasmacytoma samples.

Figure 1.

Summary/Conclusions: Altogether, our data define a previously unrecognized role of CXCL13 in MM, unravel its involvement in the osteoclastogenic process and suggest CXCL13 as potential novel target for the diagnosis and treatment of MM.

P640

MESENCHYMAL STEM CELLS (MSC) PROMOTES TUMOR MICROENVIRONMENT TRANSFORMATION DRIVING GRANULOCYTE-LIKE MYELOID DERIVED SUPPRESSOR CELLS (G-MDSC) ACTIVATION IN SMOLDERING AND MULTIPLE MYELOMA PATIENTS

C Giallongo[1], D Tibullo[1,*], NL Parrinello[1], P La Cava[1], G Camiolo[1], G D'Amante[1], N Caporarello[2], C Conticello[1], CD Anfuso[2], A Romano[1], F Di Raimondo[1]
[1]Division of Hematology, azienda ospedaliera universitaria policlinico vittorio emanuele, [2]Dept. of Biomedical and Biotechnological Sciences, School of Medicine, University of Catania, Catania, Italy

Background: A well-recognized feature of multiple myeloma (MM) is the intimate relationship between plasma cells (PC) and BM microenvironment, which is mainly composed of mesenchymal stromal cells (MSC), endothelial cells, immune cells and extracellular matrix. Granulocytic-Myeloid-derived suppressor cells (G-MDSC) accumulate in the tumor microenvironment during tumor development. MDSC promote tumor growth and invasion, immunosuppression and host immune evasion by suppressing lymphocyte activation and antigen recognition. Even though it has been demonstrated that G-MDSC are increased in MM microenvironment, the role of MSC in promoting immunosuppressive microenvironment through activation of G-MDSC remains unexplored.
Aims: Analyzing MSC from MGUS, Smoldering myeloma (SMM) and MM patients in promoting tumor microenvironment transformation.
Methods: Human peripheral blood mononucleated cells (PBMC) isolated from healthy subjects (HS) were cultured alone, with HS- (n=8), MGUS- (n=6), SMM- (n=4) or MM-MSC (n=12, 8 patients at diagnosis and 4 relapsed) at 1:100 ratio. After one week, PBMC were collected. G-MDSC were isolated using anti-CD66b magnetic microbeads and the phenotype (CD11b+CD33+CD14-HLADR-) was confirmed by cytofluorimetric analysis. Immunosuppression was analyzed after incubation with autologous T cells CFSE+ stimulated by phytohaemagglutinin (PHA-P).
Results: G-MDSC educated by SMM- and MM-MSC co-cultures (MSCed-G-MDSC) exhibited suppressive effect with a reduction of T cell proliferation (p<0.001) compared to G-MDSC control (isolated from PBMC cultured in medium alone). Notably, neither MDSC control nor HS- or MGUS-MSCed-G-MDSC showed suppressive ability. Before incubation with T cells, the expression of immunomodulatory factors was investigated by real-time PCR in SMM- and MM-MSCed-G-MDSC compared to MGUS-MSCed-G-MDSC. SMM- and MM-MSCed-G-MDSC up-regulated Arg1 (56.4±18.2 and 24.9±13, p<0.001), NOS2 (82±35 and 21±18, p<0.001), TNFα (10±3 and 45.7±28.8, p<0.05) and CEBPA (90±23 and 65±19, p<0.001), a transcription factor promoting suppressive phenotype. Adding Bortezomib (5 nM) to co-culture of SMM- and MM-MSC with PBMC, isolated G-MDSC lost immunosuppressive ability. Analysis of MM-MSC from 4 patients revaluated after 3 bortezomib-based therapy followed by autologous stem cell transplantation showed that their immunological dysfunction was reverted after therapy. Since it has been reported that neutrophils can acquire monocytic characteristics in response to inflammatory signals, G-MDSC control and MSCed-G-MDSC were plated onto dentine disks (DDs) for 3 days. A significant digestive activity was observed only in DDs with MM-MSCed-G-MDSC (p=0.002) and was lost by MM-MSCed-G-MDSC isolated from co-culture with Bortezomib. Moreover, compared to MGUS-MSCed-G-MDSC, SMM- and MM-MSCed-G-MDSC up-regulated PROK2 expression (5.2±1.2 and 7.6±2, p<0.05), a chemotactic and pro-angiogenic factor. Investigating effect on angiogenesis *in vitro*, MM-MSCed-G-MDSC induced tube formation. On the contrary, this effect was not observed in the condition with MM-MSCed-G-MDSC isolated from co-culture with Bortezomib.
Summary/Conclusions: MSC from SMM and MM but not MGUS patients are able to activate G-MDSC favoring indirectly transformation of microenvironment in a "tumor" milieu with consequent immune escape and PC growth and survival. Their immunological dysfunction can be reverted by bortezomib exposure.

P641

TARGETING OF BMI-1 WITH PTC-209 AFFECTS MYELOMA CELL GROWTH & SURVIVAL AND IMPAIRS THE TUMOUR MICROENVIRONMENT

A Bolomsky[1,*], K Schlangen[2], W Schreiner[2], N Zojer[1], H Ludwig[1]
[1]Wilhelminen Cancer Research Institute, Department of Internal Medicine I, Wilhelminenspital, [2]Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Vienna, Austria

Background: The polycomb complex protein BMI-1 was previously reported to be overexpressed in multiple myeloma (MM) and silencing of BMI-1 was shown to impair the proliferation and survival of MM cells. However, therapeutic agents specifically targeting BMI-1 are not available so far.
Aims: Here we investigated PTC-209, a novel transcriptional repressor of BMI-1, for its activity in MM.
Methods: *BMI-1* expression was analysed by using publically available gene expression (GEP) data. The anti-MM activity of PTC-209 was examined by viability testing, cell cycle analysis, annexin V and 7-AAD staining, quantification of cleaved PARP, JC-1 as well as colony formation assays. Gene and protein expression was studied by quantitative PCR and flow cytometry, respectively. The impact of PTC-209 on osteoclast, osteoblast and tube formation was analysed *in vitro* by using cell type specific differentiation assays.
Results: Overexpression of *BMI-1* in MGUS, SMM and MM patients was confirmed by using publically available GEP-datasets. Of note, *BMI-1* expression was further increased at relapse which translated into significantly shorter overall survival in relapsed/refractory patients treated with bortezomib or dexamethasone (median OS 22.2 months *vs* 13.7 months, *P*=0.003).
Treatment with PTC-209 induced downregulation of BMI-1 protein levels and significantly impaired viability of all HMCLs analysed with IC50 values <2 μM in 6 of 8 MM cell lines (range: 0.21-5.68 μM). Mechanistically, PTC-209 led to an accumulation of MM cells in the G1 phase of the cell cycle and induced apoptosis. The latter was confirmed by annexin V/7-AAD staining, detection of cleaved PARP and depolarization of the mitochondrial membrane. These alterations were

observed in conjunction with the deregulation of central myeloma genes, such as downregulation of *CCND1* (up to 0.67±0.04 fold reduction, *P*<0.001), *MYC* (up to 0.50±0.07 fold reduction, *P*<0.001) as well as upregulation of p21 (up to 3.4±0.4 fold increase, *P*<0.001), p27 (up to 2.1±0.6 fold increase, *P*=0.03) and *NOXA* (up to 3.6±1.2 fold increase, *P*=0.009). In addition, PTC-209 significantly reduced the number and size of colonies formed by myeloma cells in colony formation assays (OPM-2: 215±50 *vs* 105±12 colonies with PTC-209 at 1 μM, *P*=0.005; KMS-12-BM: 59±12 *vs* 17±3, *P*<0.001). PTC-209 likewise decreased the survival propagating effects of IGF-1 and IL-6. In co-culture with BMSCs, PTC-209 was found to uphold its anti-MM activity and enhanced the activity of pomalidomide and carfilzomib. Additive and synergistic drug activities of PTC-209 and pomalidomide/carfilzomib were confirmed in six MM cell lines. Analysing the impact of PTC-209 on cells of the myeloma microenvironment demonstrated a significant reduction of *in vitro* osteoclast and tube formation. No signs of TRAP-positive osteoclasts as well as a significantly decrease of total tube length (*P*=0.005) were observed with PTC-209 at 1 μM. Unfortunately, PTC-209 displayed a likewise negative impact on the formation of osteoblasts (68±4% reduction in alkaline phosphatase activity with PTC209 at 1 μM, *P*<0.001). However, this was associated with a significant induction of DKK1 expression upon PTC-209 treatment and concurrent treatment with an anti-DKK1 antibody was found to overcome (43±6% *vs* 21±12% decrease in ALP activity, *P*=0.02), at least in part, the osteoblast inhibitory properties of PTC-209.

Summary/Conclusions: In conclusion, we confirmed overexpression of BMI-1 in MM highlighting its role as attractive drug-target and reveal therapeutic targeting of BMI-1 by PTC-209 as a promising novel therapeutic intervention for MM.

P642

LENALIDOMIDE MAINTENANCE COUNTERACTS PD-1 ELEVATION ON LYMPHOCYTES IN MYELOMA PATIENTS

S L Danhof*, M Schreder, L Rasche, S Strifler, S Knop, T Gogishvili, H Einsele[1], M Hudecek
University Hospital Würzburg, Würzburg, Germany

Background: Lenalidomide (Len) has become an integral component of multiple myeloma (MM) therapy with its tumoricidal and immunomodulatory effects, the latter being of particular interest in continuous treatment. However, the precise mode of action and the consequences of Len on lymphocyte subset composition and function are still incompletely understood.

Aims: Here, we analyzed the composition and PD-1 expression of lymphocytes from MM patients undergoing Len maintenance (LenMT) and compared those to the respective parameters in control groups of MM patients (at primary diagnosis/PDX, at relapse/RD or in complete remission/CR; according to IMWG criteria) and healthy donors.

Methods: We performed multi-parameter FACS analysis on peripheral blood (PB) of 71 MM patients to identify CD4+ and CD8+ naïve (45RA+62L+), central (45RO+62L+) and effector (45RO+62L-) memory T cells, B cells (CD19+), NK cells (CD3-CD56+), NKT cells (CD3+CD56+) and γ/δ T cells (γ/δ TCR+) and their PD-1 surface expression. Corresponding bone marrow (BM) samples from the same individuals were equally analyzed for lymphocytic PD-1 surface expression when available (n=15). Analysis was performed in the following subgroups of patients: at PDX (15), at RD (12), in sustained CR without recent anti-MM therapy (18) and during LenMT (20). The fifth subgroup comprised patients without exposure to Len and a disease burden that was comparable to the cohort of patients during LenMT who were not in CR (6). All patients provided written informed consent according to the local regulatory boards.

Results: At PDX, absolute numbers of lymphocytes were found within the normal ranges for T, B and NK cells, while the administration of LenMT significantly reduced CD3+ T cells counts. This was predominantly due to a loss of CD4+ naïve T cells (p=0.004), whereas CD8+ naïve T cells and the entire central and effector memory T cell compartments were largely preserved. B cell counts were highest in the CR group, with an approximately fourfold increase in regard to the LenMT group. Absolute numbers of NK cells were significantly higher in patients undergoing LenMT as compared to all other previously treated MM patients. Analyzing PD-1 surface expression, we found highest levels on CD3+ T cells, no matter whether the lymphocytes were of BM or PB origin. We further observed increased PD-1 expression on all PB lymphocytes from patients with active MM disease (PDX, RD), whereas optimal disease control (CR) brought PD-1 expression down to ranges observed in healthy donors. Similarly, the LenMT cohort displayed lower PD-1 levels than patients with active disease, which was most pronounced for CD8+ T cells. In order to rule out the influence of disease burden on PD-1 levels, we compared patient cohorts with equivalent residual BM and serological disease burden with and without exposure to Len and found a significant reduction of PD-1 surface expression on CD8+ T cells during LenMT (p=0.038). Longitudinal data of PD-1 levels before, during and after LenMT further confirmed this observation.

Summary/Conclusions: Our data show that LenMT modulates lymphocyte subset composition in MM patients, underlining its potent immunomodulatory capacity. Furthermore, this first *in vivo* observation of low PD-1 expression levels associated with LenMT suggests a potential for combined use of Len with novel therapeutic approaches, such as chimeric antigen receptor modified T cells or bispecific T cell engaging antibodies. Whether additional checkpoint blockade might further enhance anti-MM efficacy of Len by decoupling the PD-1/PD-L1 axis will have to be studied in future clinical trials.

P643

CIRCULATING SERUM MIRNA PROFILE IN AL AMYLOIDOSIS

E Kryukova[1,2], L Brozova[3], L Besse[4], K Growkova[1,2,5], L Sedlarikova[6], J Nekvindova[7], J Filipova[1,2,5], Z Kufova[1,2,6], T Sevcikova[1,2,5], L Zahradova[1], J Jarkovsky[3], S Sevcikova[6], F Kryukov[1,2,*], R Hajek[1,2,6]
[1]Blood Cancer Research Group, Department of Haematooncology, Faculty Hospital Ostrava, [2]Faculty of Medicine, University of Ostrava, Ostrava, [3]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [4]Department of Hematology/Oncology, Cantonal Hospital St. Gallen, St Gallen, Switzerland, [5]Department of Biology and Ecology, Faculty of Science, University of Ostrava, Ostrava, [6]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, [7]Institute of Clinical Biochemistry and Diagnostics, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Circulating serum microRNAs (miRNAs) are emerging biomarkers in cancer as well as a minimally invasive diagnostic solution due to their high stability and association with the disease. Previously, circulating miRNAs with diagnostic and prognostic potential in a broad range of monoclonal gammopathies have been described. Nevertheless, circulating miRNAs profile in immunoglobulin light chain amyloidosis (ALA) is still not elucidated. ALA is a plasma cell dyscrasia characterized by deposition of amyloid fibrils in various organs and tissues, derived from monoclonal immunoglobulin light chains (LC), leading to organ dysfunction.

Aims: To reveal ALA specific profile of circulating miRNAs

Methods: MiRNAs profiling using TaqMan Low Density Arrays was used to find differently expressed miRNAs between 15 ALA, 6 MGUS, 10 MM patients and 11 healthy donors (HD). Data normalization was performed using geometric mean of three most stably expressed miRNAs (miR-126, miR-24, miR-484). Kruskal-Wallis and Mann-Whitney U test were used to define significance. Receiver operating characteristic (ROC) analysis of chosen miRNAs was performed to describe their predictive potential.

Results: In general, 50 miRNAs were differentially expressed in ALA compared to MM, MGUS and HD (p<0.05) and 12 of them have met significance criteria after Bonferroni correction (p<0.0004). Based on high specificity and sensitivity values (≥80%), five miRNAs were defined to have prognostic value: miR-21, miR-25, miR-328, miR-451, miR-134 (Figure 1). Additionally, in ALA samples, four following miRNAs were detected as significantly overrepresented compared to the rest of tested cohorts: miR-134 (sensitivity 93.3% and specificity 81.5%, p=0.0005), miR-133a (sensitivity 73.3% and specificity 74.5%, p=0.0052), miR-342 (sensitivity 100% and specificity 59.3%, p=0.0001) and let-7b (sensitivity 66.7% and specificity 77.8%, p=0.0044) (Figure 1). We suppose that these overrepresented miRNAs could have a biological relevance in ALA pathobiology. Serum miR-134 and miR-133a were described as markers of acute coronary syndrome (Gacoń *et al.*, 2015); let-7b was found to be serum marker for primary IgA nephropathy (Serino *et al.*, 2015), while serum miR-342 was described as a biomarker for the diagnosis of Alzheimer's disease (Tan *et al.*, 2014). It is postulated that extracellular amyloid beta (Aβ) deposits are the fundamental cause of this disease. This finding raises the intriguing possibility that all amyloid diseases, irrespective of the nature of the amyloid forming protein, share common biomarkers.

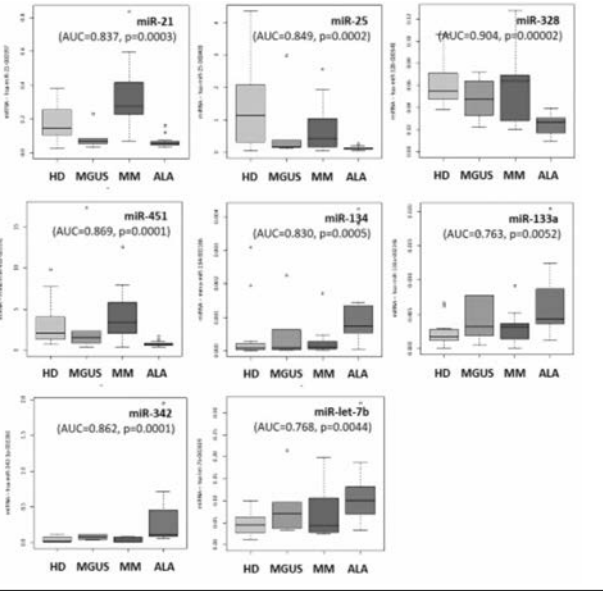


Figure 1.

Summary/Conclusions: This study identified five serum miRNAs with a potential to distinguish ALA patients from MM, MGUS and healthy donors with high sensitivity and specificity. Moreover, we described increased level of miR-134, miR-133a and let-7b that could serve as biomarkers of end-organ damage in ALA patients. Level of serum miR-342 can be suggested as a potential amyloid-specific biomarker and needs to be validated on the other amyloid diseases.

PRECLINICAL EVALUATION OF ABBV-838, A FIRST-IN-CLASS ANTI-CS1 ANTIBODY-DRUG CONJUGATE FOR THE TREATMENT OF MULTIPLE MYELOMA

K Gish[1,*], H Kim[1], R Power[1], M Fox[1], J Hickson[2], T McGonigal[2], D Chao[1], M Sho[1], H Singh[1], E Tarcsa[3], W Gao[2], L Loberg[2], C Allan[1], C Becker[2], R Duffy[1], R Nath[1], D Afar[1]
[1]AbbVie Biotherapeutics, Redwood City, [2]AbbVie, North Chicago, [3]AbbVie Bioresearch Center, Worcester, United States

Background: ABBV-838 is an antibody-drug conjugate (ADC) directed against CS1 (SLAMF7/CD319), a cell-surface glycoprotein that is expressed with high levels and prevalence on multiple myeloma (MM) cells, with normal expression limited to leukocyte subsets (including plasma cells, NK cells, and activated monocytes). This ADC uses monomethyl auristatin E (MMAE) with a cathepsin-cleavable linker, and it binds to a unique epitope on CS1.
Aims: We evaluated the preclinical anti-tumor activity and toxicology of ABBV 838, with a goal to enable Phase 1 clinical development of this novel anti-CS1 ADC.
Methods: Tumor efficacy studies of ABBV-838 monotherapy and in combination with standard-of-care agents were conducted in mouse xenograft models. Tolerability studies were conducted in rodents and non-human primates (NHP), and the IND-enabling toxicology studies were conducted in NHP.
Results: ABBV-838 showed significant antitumor activity and induced complete tumor regressions in mouse models using human myeloma xenografts, including disseminated bone marrow models (OPM-2 and LP-1). Enhanced efficacy was observed when a sub-optimal dose of ABBV-838 was combined with standard-of-care agents such as bortezomib and pomalidomide. Tumor regressions were also observed in xenograft-bearing mice that were pretreated for two weeks with bortezomib, then switched to treatment with ABBV-838 alone, or pomalidomide plus ABBV-838. To optimize efficacy and to minimize safety issues, an additional process step was used to isolate ABBV-838 product containing primarily two MMAE molecules per antibody (identified as E2). Efficacy and tolerability studies were conducted to compare different drug-to-antibody ratios (DAR) and distributions of loading; the greatest therapeutic index (maximum tolerated dose/minimum effective dose) observed in non-clinical studies was achieved with E2-enriched ADC. In a GLP-compliant toxicology study, primary toxicities of ABBV-838 were typical of other MMAE-based ADCs and consisted of bone marrow toxicity and lymphocyte decreases in lymphoid tissues, and were mostly resolved or consistent with a regenerative response at the end of a 3-week recovery period. A single-dose no-observed-adverse-effect level (NOAEL) was established in cynomolgus monkey at 12 mg/kg (1340 µg/m² of conjugated MMAE), which is the equivalent conjugated MMAE dose for the single-dose max non-lethal dose of 6 mg/kg as published for brentuximab vedotin (Figure 1).

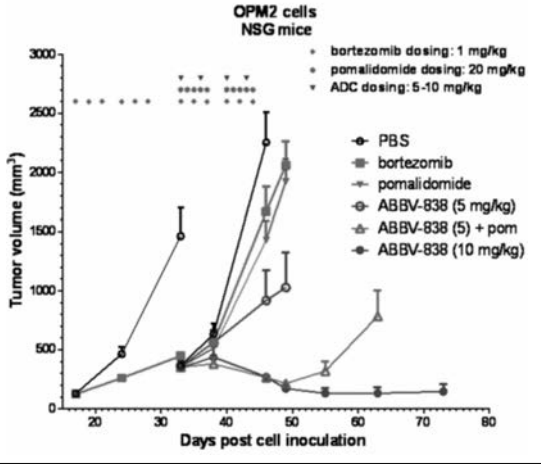

Figure 1.

Summary/Conclusions: Targeting myeloma cells via the CS1 protein with ABBV-838 results in potent preclinical anti-tumor activity as a monotherapy, and in combination with multiple approved therapies, with complete tumor regressions against multiple xenograft models of myeloma. ABBV-838 is currently being investigated in a Phase 1 first-in-human safety study.
Disclosures: All authors are employees of AbbVie. The design, study conduct, and financial support for this research were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication.

P645

SOLUBLE BCMA BINDS ITS LIGAND BAFF AND PREVENTS NORMAL ANTIBODY PRODUCTION IN MULTIPLE MYELOMA PATIENTS

J Berenson[*], E Sanchez, M Li, G Tang, C Wang, H Chen
Institute for Myeloma & Bone Cancer Research, West Hollywood, United States

Background: A hallmark of multiple myeloma (MM) is the low levels of uninvolved immunoglobulin (Ig) levels. B-cell maturation antigen (BCMA) is a receptor expressed in mature non-malignant and malignant B lymphocytes, including plasma cells. We previously demonstrated that BCMA is present in the serum of MM patients and that its levels predict overall survival (Sanchez *et al.* Br J Haematol 2012).
Aims: We hypothesized that soluble BCMA binds BAFF, preventing normal plasma cell development and antibody production in MM patients.
Methods: BCMA-Fc and control Ig were obtained (R&D Systems). Human BCMA and mouse BAFF, IgG, IgA and IgM were measured with ELISA (R&D Systems & Bethyl). Human IgA and IgG levels were determined using nephelometry (Immage 800, Beckman Coulter). Hevylite Assays (Binding Site) were used to quantify the levels of heavy0light chain isoform pairs.
Results: hBCMA-mBAFF complexes were detected with an ELISA at high levels in plasma of SCID mice with human MM xenografts; these mice showed reduced levels of free BAFF. rhBCMA or control Ig-Fc (100 µg) was injected into immune competent C57 Bl or Balb/c mice, and resulted in decreases in IgA, IgG and IgA levels. Decreases in IgA levels were observed when compared to baseline levels on days 4 and 6 (P=0.0031 and P=0.0064, respectively),, and the controls (P=0.0087 and P=0.0221). Mouse IgG levels also showed a reduction compared to baseline (P=0.0023), the Ig-Fc (P=0.0014) and the control (P=0.0129). IgM levels showed similar decreases when compared to the untreated (P=0.0001) and Ig-Fc (P=0.0088) groups. MM patients' serum containBCMA-BAFF complexes, and showed reduced free BAFF levels compared to controls (P=0.0004). Raji B-cells were then incubated with serum from a healthy subject (0.02 µg/ml BCMA) of a MM patient with serum containing high levels of BCMA (0.75 µg/ml) or low levels of BCMA (0.02 µg/ml) or rhBCMA-Fc (3.0 µg/ml) in the presence of rhBAFF (500 ng/ml). Serum from the MM patient with high BCMA and rhBCMA decreased rhBAFF binding by 71% (from 96.8 to 25.6%) and 74% (from 96.8 to 22.9%), respectively, whereas serum from the healthy subject and MM patient with low BCMA did not affect BAFF binding. Using antoher human B-cell line (TB94), serum containing high BCMA and rhBCMA decreased rhBAFF detection on these cells from 94% to 62.1% and from 98.6% to 48.7%, respectively. Given the reduction in BAFF binding to B-cells and reduction in serum free BAFF levels in MM patients, we determined whether the relationship of serum BCMA levels to uninvloved Ig levels in MM pts. Serum BCMA levels inversely correlated with uninvolved IgG in IgA MM (n=134) and uninvolved IgA in IgG MM (n=313, P <0.0001). Using Hevylite Assay, similar results were observed in BCMA levels compared to uninvolved IgG isoforms in both pts with involved IgG lambda (n=62, P=0.0006) and IgG kappa (n=117, P <0.0001).
Summary/Conclusions: We demonstrate BCMA-BAFF complexes in MM xenografts resulting in reduced BAFF levels, and administration of rhBCMA to normal mice leads to marked reductions in antibody levels. We also show these complexes in MM patients, resulting in reduced serum free BAFF levels which prevent this ligand from binding B-cells. As a consequence, serum BCMA levels inversely correlate with uninvolved Ig levels in MM pts. Thus, the lack of normal antibody production in MM pts results in part from corculating BCMA binding its ligands, preventing production of normal antibody-producing cells.

DIFFERENTIAL EFFECTS OF ELOTUZUMAB (ANTI-SLAMF7) AND ANTI-CD38 MONOCLONAL ANTIBODIES IN PRECLINICAL MODELS

N Bezman[1,*], A Kearney[1], P PVK[1], A Jhatakia[1], T Brender[1], M Maurer[1], K Henning[1], T Pazina[2], K Campbell[2], A Cohen[3], R Graziano[1], M Robbins[1]
[1]Bristol-Myers Squibb, Princeton, [2]Fox Chase Cancer Center, [3]University of Pennsylvania, Philadelphia, United States

Background: Monoclonal antibodies (mAbs) have recently presented a new treatment paradigm for patients with multiple myeloma (MM). Two such approaches, anti-SLAMF7 antibody (elotuzumab) and anti-CD38 antibodies (daratumumab and SAR650984), were primarily developed based on the rationale of high expression of target protein on myeloma cells. Expression of these protein targets (SLAMF7 and CD38), however, is not limited to tumor cells and is also found on cells of the innate and adaptive immune systems. Non-tumor-targeted effects mediated by these mAbs may not only contribute to the overall anti-tumor response, but may also provide the rationale for new combination regimens.
Aims: To further define the mechanism of action of elotuzumab and anti-CD38 mAbs on immune cell subsets.

Methods: The effect of elotuzumab and anti-CD38 mAbs on antibody-dependent cell-mediated cytotoxicity (ADCC), complement-dependent cytotoxicity, and natural killer (NK) and T-cell activation was assessed. Surrogate antibodies of daratumumab (daratumumab-s) and SAR650984 (SAR650984-s) were generated on the basis of protein sequences, as published in their corresponding patent families, and were expressed as recombinant hIgG1 for in-vitro studies with human cells or mIgG2a for in-vivo mouse tumor studies. Mutant versions of mAbs that eliminated Fc:FcγR binding were also generated to assess the contribution of FcR binding for mAb efficacy in preclinical models.
Results: SLAMF7 and CD38 were highly expressed on myeloma cells. *In vitro*, elotuzumab and anti-CD38 mAbs were equally potent in inducing ADCC of MM1S cells, whereas only daratumumab-s was able to fix complement. SLAMF7 and CD38 were also highly expressed on human NK cells. In a co-culture of myeloma cells and NK cells, elotuzumab induced more pronounced NK-cell activation than did daratumumab-s. SLAMF7 and CD38 were differentially expressed on T-cell subsets: SLAMF7 expression was highest on $CD8^+$T cells and memory subsets, whereas CD38 expression was highest on naïve cells. While both SLAMF7 and CD38 levels were induced following anti-CD3 stimulation, neither elotuzumab nor anti-CD38 mAbs mediated ADCC towards activated T cells. Elotuzumab and anti-CD38 mAbs, however, led to inhibition of cytokine production by naïve T cells isolated from healthy donors, and these effects were reversed in the presence of lenalidomide. Ongoing studies are characterizing the effects of elotuzumab and anti-CD38 mAbs on T cells from bone marrow aspirates from patients with MM.
Summary/Conclusions: Elotuzumab enhanced activation of NK cells *in vitro*, whereas anti-CD38 mAbs were cytolytic against NK cells. Engagement of both targets on myeloma cells led to similar augmentation of ADCC. SLAMF7 and CD38 engagement on T cells may also have non-overlapping effects based on the differential expression of these proteins between naïve and memory subsets, which may inform the rationale for future clinical use.

NRF2 ACTIVITY IN BONE MARROW MESENCHYMAL STROMAL CELL PROTECTS MULTIPLE MYELOMA FROM CARFILZOMIB AND BORTEZOMIB INDUCED CELL DEATH

Y Sun[1,*], L Zaitseva[1], K Bowles[1,2], S Rushworth[1]
[1]Department of Molecular Haematology, Norwich Medical school, University of East Anglia, [2]Department of Haematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: Bone marrow mesenchymal stromal cells (BM-MSC) interact with multiple myeloma (MM) cells and modify their viability and drug sensitivity. Recent studies identify various oncogenic pathways which are involved in modulating the BM-MSC/MM cell microenvironment. The transcription factor NRF2 is a key regulator for the maintenance of intra-cellular redox homeostasis and is negatively regulated by proteasome degradation through its inhibitor KEAP1. NRF2 pathways have been shown to contribute to the malignant phenotypes of several cancers through effects on proliferation and drug sensitivity.
Aims: To determine if NRF2 signalling in BM-MSCs affects the redox homeostasis of MM and promotes survival and resistance to proteasome inhibitors.
Methods: Primary human MM and BM-MSC cells were obtained under UK ethical approval (LREC ref 07/H0310/146). Transwell co-culture system was used to characterize the MM-BMSC interactions. NRF2 protein expression and its target genes were examined by Western blotting and qRT-PCR. CellTiter-Glo luminescent cell viability assay and apoptosis assay (PI/ Annexin V staining by flow cytometry) were performed. Lentiviral mediated shRNA knockdown (KD) of NRF2 in the BM-MSC.
Results: To study the cell-cell communications between BM-MSC and MM cells we established a co-culture system using primary MM derived from patients BM and the equivalent stromal cells. We also used MM cell lines. NRF2 was found to be highly expressed in primary BM-MSC derived from patients with MM. We found that both bortezomib and carfilzomib further increased NRF2 activity in both primary MM cells and BM-MSC. In addition treatment with proteasome inhibitors enhanced NRF2 target gene expression as measured by qRT-PCR and Western blotting. We showed that BM-MSC protect MM from bortezomib and carfilzomib induced cell death. Next we knocked down NRF2 (NRF2-KD) in both MM and BM-MSC and then performed a co-culture with and without bortezomib and carfilzomib. We found that BM-MSC derived NRF2 was essential for MM protection from bortezomib and carfilzomib induced cell death in-vitro.
Summary/Conclusions: NRF2 driven cytoprotective responses are activated in BM-MSC and MM by bortezomib and carfilzomib. Furthermore, NRF2-KD in BM-MSC reverses MM resistance to bortezomib and carfilzomib. This highlights the importance of NRF2 in regulating MM drug resistance within the bone marrow microenvironment through independent actions in both the tumour and the non-malignant stromal cells which support it.

Innovative therapies for MM 3

P648

PHASE 1B STUDY OF AN ALTERNATIVE LIQUID FORMULATION OF ACY-1215 (RICOLINOSTAT) IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED-AND-REFRACTORY MULTIPLE MYELOMA

S Madan[1,*], D Atanackovic[2], J Supko[3], D Tamang[4], SS Jones[4], C Wheeler[4], NS Trede[4], L Anderson[5]
[1]University of Texas Health Science Center, San Antonio, [2]Huntsman Cancer Institute at University of Utah, Salt Lake City, [3]Massachusetts General Hospital, [4]Acetylon Pharmaceuticals Inc., Boston, [5]University of Texas Southwestern Medical Center, Dallas, United States

Background: Ricolinostat (ACY-1215), a liquid, selective HDAC6 inhibitor, potently synergizes with bortezomib (Btz), lenalidomide (Len) and pomalidomide (Pom) in models of multiple myeloma (MM) (Quayle Blood 2013). Pan-HDAC inhibitors are active in MM in combination with Btz and Len, but toxicities (thrombocytopenia, fatigue, and GI events) limit dosing exposure. By contrast, ricolinostat is well tolerated in clinical studies as monotherapy (Raje Blood 2012) and in combination with Btz/dexamethasone (Dex) (Vogl, Blood 2015), Len/Dex (Yee, Blood 2015) and Pom/Dex (Raje, Blood 2015) and acts synergistically even in refractory patients. ACE-MM-104 is a dose-escalation study of an alternative liquid formulation (ALF) of ricolinostat at a concentration of 10 mg/mL in combination with Pom/Dex in patients with relapsed or relapsed-and-refractory MM (RRMM). This formulation has an improved excipient profile over earlier formulations.
Aims: Determine safety, tolerability and preliminary efficacy of ricolinostat ALF in combination with Pom/Dex.
Methods: Dose escalation of ricolinostat ALF was in combination with Pom (4 mg) for 21/28 day cycle and weekly Dex (40 mg). Patients (pts) had measurable disease, ≥2 prior therapies including ≥2 cycles of Len and proteasome inhibitor and relapsed or RRMM. Adequate bone marrow, hepatic and renal function were required. Pts with non-secretory MM, prior Pom or HDAC inhibitor therapy were excluded. Blood samples were obtained for PK and pharmacodynamics (PD) assessment of acetylated tubulin and histones. Starting dose of 120 mg BID was based on preclinical data and experience with ricolinostat in either 20 or 12 mg/mL formulations currently used in clinical trials. Median age was 64 years and median number of prior regimens was 2 (1-4). Ten pts were refractory to prior therapies (8 to Dex, 6 to Btz, 6 to Len, and 2 to both BTz and Len).
Results: Dose escalation comprised 16 pts. No DLTs were observed in the first 4 pts dosed at 120 mg ricolinostat BID. Emerging data with the 12 mg/mL formulation suggested that BID dosing was less well tolerated. Therefore, subsequent pts were dosed on a QD schedule: 4 at 120 mg, and 8 at 180 mg. Toxicities were mostly low grade and treatment was tolerated at QD dosing of 21/28 day cycles. Common toxicities of safety-evaluable pts (n=15) included fatigue (60%), URI, pruritus, dyspnea, dizziness (27% each), diarrhea, constipation, nausea (20% each). Grade 3/4 related toxicities included neutropenia (5 pts, 33%), anemia (27%), febrile neutropenia and neutropenia (20%). Few TEAEs were attributed to study drug. One DLT (neutropenia) was observed at 180 mg QD. Cohort expansion to 6 pts showed no further DLT. PK/PD demonstrates selective inhibition of HDAC6 *vs* HDAC1,2,3 at therapeutic doses. PK shows 120 mg of ricolinostat ALF and 160 mg in the 12 or 20 mg/mL formulations achieved equivalent exposure which did not increase with increased dosing. Hence, the 180 mg QD schedule was declared the highest dose level tested. There was no evidence of ricolinostat accumulation or drug-drug interaction with Pom. With a median F/U of 7 cycles for the 11 response-evaluable patients there were 6 ≥PR and DCR was 82%.
Summary/Conclusions: Ricolinostat ALF is well-tolerated in combination with Pom/Dex at doses up to 180 mg QD without major toxicities. This formulation of ricolinostat is used in ongoing clinical studies in combination with paclitaxel and abraxane to treat solid tumors.

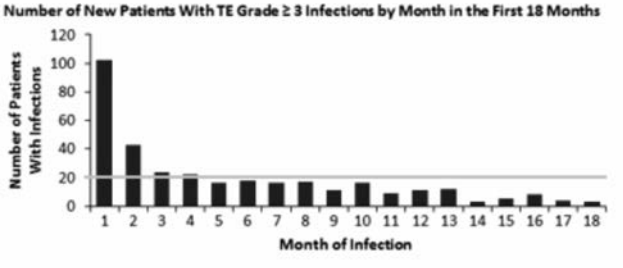
[1]Hospices Civils de Lyon, Lyon, [2]CHU Bordeaux, Bordeaux, France, [3]National and Kapodistrian University of Athens, Athens, Greece, [4]Cross Cancer Institute, Edmonton, AB, Canada, [5]Mayo Clinic Cancer Center, Rochester, MN, United States, [6]Wilhelminen Hospital, Wilhelminen Cancer Research Institute, Vienna, Austria, [7]Centre Hospitalier, Périgueux, France, [8]AZ Sint-Jan AV Brugge, Brugge, Belgium, [9]Blood Disease Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Tianjin, China, [10]Seràgnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [11]Universitair Zieken-

huis Antwerpen, Edegem, Belgium, [12]Hospital 12 de Octubre, Madrid, Spain, [13]Centre Hospitalier Yves Le Foll, Saint-Brieuc, France, [14]Gachon University Gil Hospital, Incheon, Korea, Republic Of, [15]Service des Maladies du Sang, Hôpital Claude Huriez, Lille, [16]Quinten, Paris, France, [17]Celgene International Sàrl, Boudry, Switzerland, [18]YGM Consult, Quinten, Paris, France

Background: Patients (pts) with multiple myeloma (MM) have an increased risk of infections due to toxicities of therapy, immunosuppression by the underlying disease, comorbidities, and old age (Nucci & Anaissie, *Clin Infect Dis*, 2009). Furthermore, MM demonstrates a low immune response to prophylactic vaccination and to both viral and bacterial infections, highlighting the need for preventative or early treatment measures (Karlsson *et al., Clin Vaccine Immunol*, 2011; Blimark *et al., Haematologica*, 2015). The pivotal, phase 3 FIRST trial compared lenalidomide plus low-dose dexamethasone (Rd) to melphalan, prednisone, and thalidomide (MPT) in transplant-ineligible pts with newly diagnosed MM (NDMM).
Aims: To identify factors predictive of infections in the first 4 months of the FIRST trial and develop an infection risk scoring system.
Methods: In the FIRST trial, pts were randomized 1:1:1 to receive Rd until disease progression (Rd continuous), Rd for 18 cycles (Rd18), or MPT. For this analysis, data from the Rd continuous and Rd18 arms were pooled. Demographics, medical history, and baseline characteristics including co-medications were analyzed to identify risk factors of treatment emergent (TE) grade ≥3 infection during the first 4 months. Pts with both progression-free survival ≤4 months and no TE grade ≥3 infection within the first 4 months were excluded. A subgroup discovery algorithm was used to identify univariate prognostic factors associated to high or low risk of infection. The most clinically and biologically relevant variables were used in a multivariate logistic regression model with an iterative variable selection process. Pts with missing data on at least one input variable were excluded from the model (n=9). From the resulting predictive model, a scoring system was developed by allocating -2 to 2 points to factors of low or high risk based on their influence in the model. The cumulative score classified pts into high (2 to 5 points) or low (-3 to 1 points) infection risk groups.
Results: Of the 1623 pts enrolled in the FIRST trial, 340 pts had TE grade ≥3 infections, and 56.2% of these 340 pts had their first infection in the first 4 months (Figure 1A). Risk of infection was similar regardless of therapeutic arm (*P*=.53). Risk factors were assessed in 1378 pts and the final model retained 4 variables: (Eastern Cooperative Oncology Group [ECOG] performance status, serum β2-microglobulin [Sβ2M], lactate dehydrogenase [LDH], and hemoglobin) that independently associate with TE grade ≥3 infections occurring in the first 4 months (Figure 1B). The high- and low-risk groups defined by the scoring system were associated with significantly different rate of TE grade ≥3 infections during the first 4 months (24% and 7%, respectively).



B Multivariate Logistic Regression Model for TE Grade ≥ 3 Infection Within the First 4 Months

Model	Pr(>|z|)	Points	Infection Risk
Sβ2M ≤ 3 mg/L	0.02135	−2	Lower
ECOG = 0	0.06231	−1	Lower
Hemoglobin ≤ 11 g/dL	0.07660	1	Higher
ECOG ≥ 2	0.01583	1	Higher
LDH ≥ 200 U/L	0.00299	1	Higher
Sβ2M ≥ 6 mg/L	3.09E-06	2	Higher

Figure 1.

Summary/Conclusions: The risk scoring system described here can identify pts at risk for infections during the first 4 months of treatment and may be used to implement risk-adapted strategies for the treatment or prevention of infections.

P650

OUTCOME OF MYELOMA PATIENTS WITH DELETION 17P – IMPACT OF BASELINE CHARACTERISTICS, TREATMENT AND ADDITIONAL CHROMOSOMAL CHANGES

M Merz[1,*], T Hielscher[2], A Seckinger[1], D Hose[1], E Mai[1], M Raab[1], H Goldschmidt[1], A Jauch[1], J Hillengass[1]
[1]University Hospital of Heidelberg, [2]German Cancer Research Center, Heidelberg, Germany

Background: Deletion 17p13, del(17p), is associated with poor outcome in patients with multiple myeloma (MM) but some patients show long-term survival.
Aims: With the current study we intended to identify prognostic factors for survival in patients with del(17p). Analyzed factors included baseline characteristics, treatment modalities and additional chromosomal aberrations.
Methods: Between 05/2002 and 10/2015 total of 4906 interphase FISH (iFISH) studies have been performed in patients with plasma cell diseases at the University Hospital of Heidelberg, Germany. We identified 110 patients with del(17p) in newly diagnosed, symptomatic MM according to CRAB criteria of the International Myeloma Working Group. FISH was performed on CD138-purified plasma cells using probes for: 1q21, 5p15, 5q35, 8p21, 9q34, 11q23, 13q14.3, 15q22, 17p13 and 19q13, translocations t(11;14), t(4;14) and t(14;16). Hyperdiploidy (HD) was assessed by the score of Wuilleme *et al.* (gains of at least two of the chromosomes 5, 9 and 15). Survival times were estimated with the Kaplan-Meier method and compared using log-rank test. Multivariable Cox regression analysis was performed to assess impact of baseline characteristics, treatment modalities and additional cytogenetic abnormalities on outcome.
Results: Age >65 years (n=42, 38%) was associated with adverse outcome (PFS: 13 *vs* 26 months, p=0.001; OS: 21 *vs* 56 months, p<0.001) as well as higher ISS score (ISS I/II/III PFS: 35/ 20/ 16 months, p=0.02; OS: 72/ 71/ 27 months, p=0.004) and elevated baseline LDH (PFS: 14 *vs* 26 months, p<0.001; OS: 18 *vs* 53 months, p=0.001). Patients with subclonal (10-60% of plasma cells, n=47, 42.7%) del(17p) had longer PFS than patients with del(17p) in a major >60% of plasma cells (26 *vs* 19 months, p=0.03). Additional gain of 1q21 (n=41, 37.3%) was associated with shorter PFS (17 *vs* 25 months, p=0.01, Figure 1A). Hyperdiploidy (n=36, 37.9%) did not ameliorate impact of del (17p) (Figure 1B), but gain 19q13 (n=41, 37.6%) predicted longer PFS (30 *vs* 18 months, p=0.01) and OS (50 *vs* 29 months, p=0.01, Figure 1C). Multivariate analysis in transplant eligible patients (≤65 years, n=68, 61.8%) revealed better survival for patients treated with upfront autologous transplantation (hazard ratio, [95% confidence interval]: 0.15 [0.04, 0.58], p=0.006) and a trend for better survival for bortezomib induction therapy (0.35 [0.11, 1.08], p=0.07). Application of maintenance therapy was associated with better survival in transplant-eligible patients (0.3 [0.09, 0.99], p=0.05).

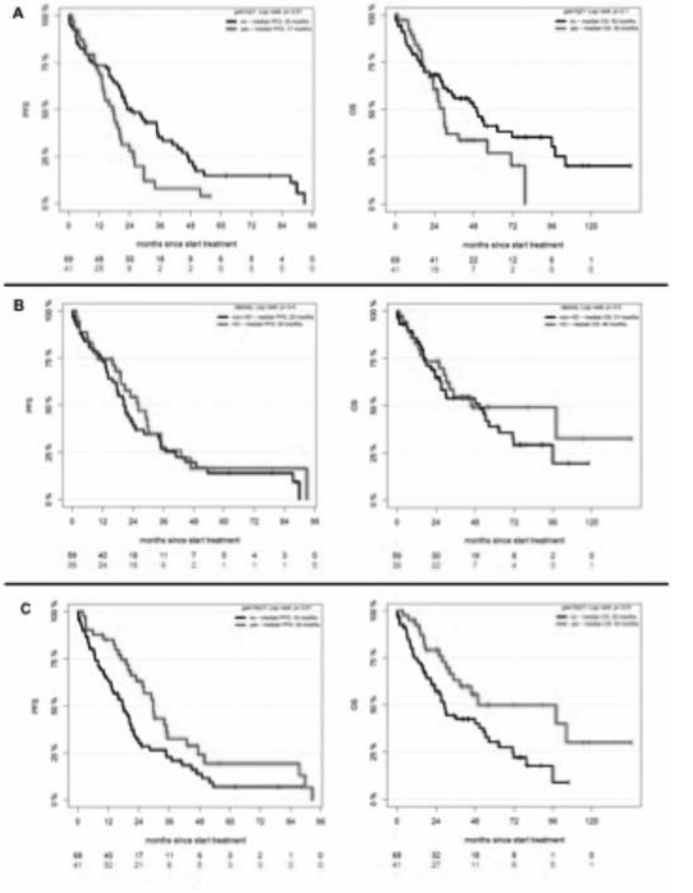


Figure 1.

Summary/Conclusions: We demonstrate heterogeneous outcome of patients with del(17p) according to baseline characteristics and treatment. 19q13 should be included in routine FISH panel, since gains were associated with better survival. Bortezomib-based induction therapy followed by autologous stem cell transplantation and maintenance therapy might be the best treatment option for patients with del(17p).

P651

CIRCULATING TUMOR DNA IN MULTIPLE MYELOMA

E Holth Rustad[1,*], E Coward[1], E Ranheim Skytøen[1], K Misund[1], T Holien[1], T Standal[1], HY Dai[2], A Sundan[1], A Waage[3]
[1]Center for Myeloma Research, Norwegian University of Science and Technology, [2]Department of Pathology and Medical Genetics, St. Olav's University Hospital, [3]Department of Hematology, St. Olavs University Hospital, Trondheim, Norway

Background: For decades, diagnosis and therapy for multiple myeloma has been guided by sequential measurements of monoclonal immunoglobulin (M-protein) as a marker for total tumor mass. However, the increasing availability of mutation specific drugs and insight into the complex genetic architecture of cancer raises a need for disease monitoring at the clonal and mutational levels. Circulating tumor DNA (ctDNA) has shown promise to this end in solid tumors, but its biology and dynamics over time are poorly understood and only preliminary reports are available for myeloma.
Aims: To evaluate the properties of ctDNA as a tumor marker in myeloma by comparison with M-protein levels and sequential whole exome sequencing (WES) of bone marrow plasma cells.
Methods: We measured ctDNA levels in stored Serum (n=278), EDTA-plasma (n=8) and citrate-plasma (n=2) samples from 22 patients by digital droplet (dd) PCR. Target mutations for each patient had been previously identified by WES or PCR of bone marrow plasma cells and were mainly in the NRAS, KRAS and BRAF genes. Blood samples were processed and frozen at -80° C within 1.5 hours of acquisition and then stored for a median of 5 years (range 0-23) before DNA isolation. Fragment length analysis by Bioanalyzer 2100 (Agilent technologies) was performed to ensure sample quality. DdPCR was performed using the QX100/200-system with Prime PCR mutation detection assays according to manufacturer's instructions (BioRad). Samples were called mutation-positive if they contained more than 1 single-positive mutant droplet, yielding a specificity of 98.4% based on control experiments.
Results: There was no correlation between sample storage time and the quantity of amplifiable DNA, and fragment length analysis revealed the presence of circulating DNA in 30 representative samples. Mutation levels in 6 time-matched serum and EDTA-plasma samples were similar. Taken together, these observations validate our material. Known tumor mutations were detected by ddPCR of ctDNA in all 14 patients analyzed at diagnosis and in 11/12 patients with relapsed disease. Compared with the average 55% sensitivity in early stage solid tumors by similar methods, newly diagnosed myeloma behaves like an advanced solid tumor with regards to ctDNA. Mutated allele frequency measured by WES of bone marrow plasma cells correlated with the level of ctDNA at the same time (Spearman´s rho=0.507, p=0.003). Furthermore, we detected two mutations in ctDNA that were not present in time-matched bone marrow aspirates, indicating that a single bone marrow aspirate may not be representative with respect to the heterogeneity of the tumor. We found a striking co-variation between ctDNA and M-protein for periods up to seven years in 9 out of 11 patients where sequential samples were available. In many cases, ctDNA reacted more rapidly to changes in tumor mass compared to M-protein although this could not be systematically assessed in a retrospective material. Peak mutation levels in ctDNA started out low at diagnosis and gradually increased with each relapse in 7 out of 9 patients. This observation was particular evident in three patients where ctDNA levels increased to around 400 times diagnostic levels at the end of the disease course as illustrated by patient 292 (Figure 1). Interestingly, in this patient we also observed increasing levels of ctDNA immediately following the initiation of effective chemotherapy, including a previously undetectable IRF4 mutation.

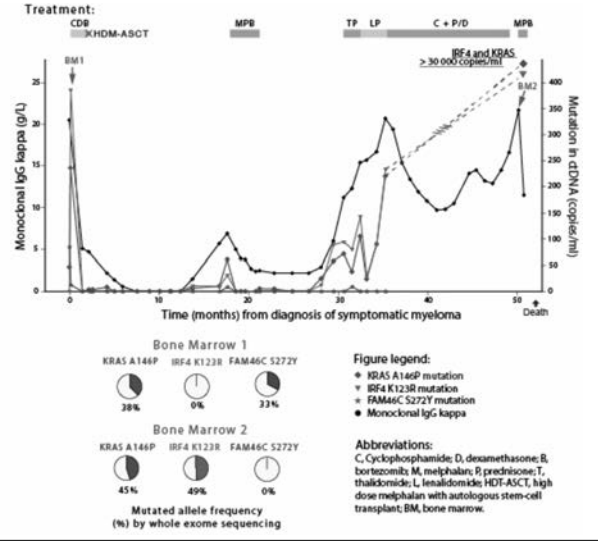

Figure 1. Co-variation of serum mutations and M-protein in patient 292.

Summary/Conclusions: We show that ctDNA is a marker for tumor mass in myeloma, as evidenced by the co-variation with M-protein. The good performance of ctDNA in this study, despite long storage time and sub-optimal samples (serum rather than EDTA-plasma), adds to its robustness as a tumor marker. Our data suggest that myeloma is particularly suited for using ctDNA to access the tumor genome, as tumor mutations can be detected in almost all patients. Increased ctDNA-levels immediately following the initiation of effective therapy may be exploited for very early evaluation of treatment response and to increase the sensitivity of ctDNA analysis.

Background: Single-agent ibrutinib, a once-daily oral inhibitor of Bruton's tyrosine kinase (BTK), demonstrated durable responses in previously treated patients (pts) with WM (Treon, *N Engl J Med.* 2015), leading to its FDA and EU approval in WM. *MYD88 L265P* is a commonly identified mutation in pts with WM; the resulting mutated protein signals through interleukin-1 receptor-associated kinase 1 and BTK, leading to constitutive activation of the NF-κB pathway (Yang, *Blood.* 2013). Ibrutinib attenuates the MYD88-BTK interaction, thus blocking BTK-dependent downstream signaling and inducing apoptosis of WM cells (Treon, *N Engl J Med.* 2012).
Aims: To evaluate the efficacy and safety of single-agent ibrutinib in WM pts considered refractory to their last rituximab-containing therapy (defined as relapse at <12 months or failure to achieve at least a minor response).
Methods: After informed consent, pts with confirmed diagnosis of WM, symptomatic disease requiring treatment (Kyle, 2003), refractory to rituximab, hemoglobin ≥8 g/dL, IgM ≥0.5g/dL, platelets ≥50,000 cells/mm^3, absolute neutrophil count ≥750 cells/mm^3, adequate hepatic function, and ECOG ≤2 received oral ibrutinib 420 mg daily until progression or unacceptable toxicity. Pts with central nervous system involvement, clinically significant cardiovascular disease, known bleeding disorder, treatment for WM ≤30 days prior to first dose were excluded. Primary endpoints were PFS, ORR, hemoglobin improvement, and OS.
Results: Baseline characteristics are shown in the Table 1 (N=31). Common reasons for treatment initiation were fatigue unrelieved by rest (74%), constitutional symptoms (42%), anemia (42%), and lymphadenopathy (23%); 4 pts started therapy due to peripheral neuropathy. Most recent therapies included monotherapy (32%), combination therapy without antibody (29%), and combination therapy with antibody (39%). At a median follow-up of 12.7 months, ORR was 84%, with a major response rate (MRR; defined as ≥PR) of 68%, and the estimated 1-year PFS rate was 93%. Initial analysis of 23 baseline samples identified MYD88^{MUT}/CXCR4^{WT} in 16 pts and MYD88^{MUT}/CXCR4^{WHIM} in 6 pts. The ORR and MRR were 88% *vs* 83% and 75% *vs* 83%, respectively. One of the 23 pts had MYD88^{WT}/CXCR4^{WT} and achieved a best response of stable disease. Four of 5 pts were able to discontinue required plasmapheresis for disease control at the end of cycle 1. Baseline median hemoglobin of 10.3 g/dL increased to 11.4 g/dL after 1 cycle and reached 12.8 g/dL at Week 49. Median IgM of 3830 mg/dL declined by >50% after 1 cycle, with continued improvement over time (median 920 mg/dL at Week 49). Any-grade adverse events (AEs; >15%) included diarrhea (42%); upper respiratory tract infections, hypertension, increased tendency to bruise (23% each); nausea, thrombocytopenia, neutropenia (19% each); and pyrexia, arthralgia, back pain (16% each). Common grade ≥3 AEs included neutropenia (13%), hypertension (10%), anemia and diarrhea (6%

each). All pts with Grade ≥3 cytopenias had received at least 4 prior therapies. Serious AEs occurred in 9 (29%) pts. Four (13%) pts had dose reductions. Four pts discontinued ibrutinib—2 pts due to progressive disease and 2 due to an AE (gastrointestinal AL amyloidosis and diarrhea*)*. Overall, 87% continue on ibrutinib, with no events of IgM flare, atrial fibrillation or major bleeding (Figure 1).

Table 1. Baseline characteristics.

	N=31
Median age, years (range)	67 (47-90)
Age ≥ 70 years, n (%)	11 (35)
ECOG, n (%)	
0-1	25 (81)
2	6 (19)
IPSSWM, n (%)	
Low	7 (23)
Intermediate	11 (35)
High	13 (42)
Median serum IgM, mg/dL (range)	3830 (740-10700)
Median β2-microglobulin, mg/L (range)	3.6 (1.7-24)
Median hemoglobin levels, g/dL (range)	10.3 (6.4-14.6)
Median platelet count, 10^9/L (range)	218 (51-896)
Median absolute neutrophil count, 10^9/L (range)	2.9 (0.7-15.4)
Median number of prior therapies (range)	4 (1-8)
Types of prior therapy (> 50%) , n (%)	
Rituximab	31 (100)
Corticosteroid	25 (81)
Alkylating agent	25 (81)
Prior autologous stem cell transplant, n (%)	2 (6)

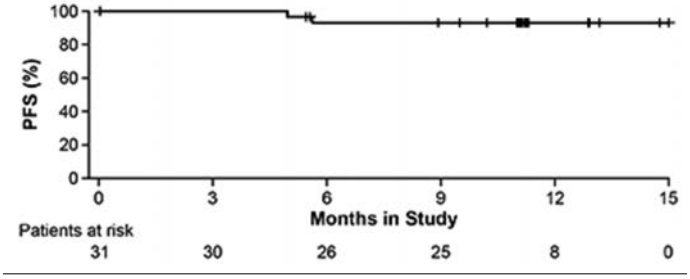

Figure 1. Kaplan-Meier analysis of PFS (all treated patients).

Summary/Conclusions: Single-agent ibrutinib is highly active in this heavily pretreated rituximab-refractory WM population, with a high ORR and manageable safety profile consistent with previous studies.

P653

POMALIDOMIDE, BORTEZOMIB, AND LOW-DOSE DEXAMETHASONE IN PROTEASOME INHIBITOR–EXPOSED AND LENALIDOMIDE-REFRACTORY MYELOMA: RESULTS OF A MULTICENTER, DOSE-ESCALATION, PHASE 1 TRIAL (MM-005)

PG Richardson[1,*], CC Hofmeister[2], NS Raje[3], DS Siegel[4], S Lonial[5], J Laubach[1], YA Efebera[2], DH Vesole[4], AK Nooka[5], J Rosenblatt[6], MH Zaki[7], A Bensmaine[7], J Herring[7], Y Li[7], S Shah[7], MS Chen[7], KC Anderson[1]
[1]Jerome Lipper Multiple Myeloma Center, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, [2]Department of Internal Medicine, Division of Hematology, The Ohio State University, Columbus, OH, [3]Massachusetts General Hospital, Boston, MA, [4]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [5]Division of BMT, Emory University, Winship Cancer Institute-Hematology and Medical Oncology, Atlanta, GA, [6]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [7]Celgene Corporation, Summit, NJ, United States

Background: The combination of an immunomodulatory drug with the proteasome inhibitor (PI) bortezomib (BORT) and low-dose dexamethasone (LoDEX) has demonstrated preclinical synergy and considerable clinical activity in relapsed and refractory multiple myeloma (RRMM) (Mitsiades *et al., Blood*, 2002;99:4525-30; Richardson *et al., Blood*, 2014;123:1461-9). Treatment (Tx) with pomalidomide (POM)+LoDEX has been shown to delay disease progression and extend survival in patients (pts) with myeloma previously treated with lenalidomide (LEN) and BORT (Richardson *et al., Blood*, 2014;123:1826-32; San Miguel *et al., Lancet Oncol*, 2013;14:1055-66). Preliminary results of MM-005 showed that POM+BORT+LoDEX (PVd) was effective and well tolerated in LEN-refractory and BORT-exposed pts. Previously, subcutaneous (SC) BORT demonstrated non-inferiority to intravenous (IV) BORT and an improved safety profile in pts with RRMM (Moreau *et al., Lancet Oncol,* 2011;12:431-40). Thus, MM-005 included a cohort that received PVd with SC BORT.
Aims: To identify the optimal dose of PVd for a phase 3 trial in pts with RRMM, to assess the efficacy and safety of PVd, and to evaluate SC administration of BORT within the PVd regimen.
Methods: Pts must have provided informed consent and received 1-4 lines of prior Tx, with ≥2 consecutive cycles of LEN plus a PI. Pts had to be PI exposed and refractory to LEN but not to BORT. A 3+3 design with 21-day cycles was used to determine the maximum tolerated dose (MTD). In cycles 1-8, dose-escalation cohorts received POM (1-4 mg/day on days 1-14), IV or SC BORT (1-1.3 mg/m^2 on days 1, 4, 8, and 11), and LoDEX (20 mg/day, or 10 mg/day for pts aged >75 years, on days 1, 2, 4, 5, 8, 9, 11, and 12) until progressive disease (PD) or unacceptable adverse event (AE). After cycle 8, BORT was given on days 1 and 8, and LoDEX was given on days 1, 2, 8, and 9. The primary endpoint was MTD.
Results: Of the 34 pts enrolled, 59% were male, and median age was 58.5 years (range, 36-76 years). The median number of prior anti-myeloma Tx lines was 2 (range, 1-4). All pts were refractory to LEN, and all were exposed to prior PI (97% received prior BORT and 6% received prior ixazomib). All pts discontinued Tx, mostly due to PD (n=23) but none due to Tx-related AEs. No dose-limiting toxicities were reported in the dose-escalation cohorts or at the maximum planned dose (MPD) of POM 4 mg, BORT 1.3 mg/m^2, and LoDEX 20 mg (10 mg for pts aged >75 years). The median number of Tx cycles received was 9 (range, 2-36) for all pts and, in the MPD cohorts, was 11 (range, 2-19) with IV BORT (n=10) *vs* 8 (range, 3-15) with SC BORT (n=12). The overall response rate (≥partial response [PR]) for all pts was 65% (n=22), with 2 complete responses (CRs), 1 stringent CR, 11 very good PRs, and 8 PRs; median duration of response was 7.4 months. All pts achieved at least stable disease. In the MPD cohorts, grade 3/4 AEs were more frequent with IV BORT *vs* SC BORT (90% *vs* 75%), including neutropenia (80% *vs* 25%), thrombocytopenia (40% *vs* 17%), and pneumonia (30% *vs* 8%). There were no reports of grade 3/4 peripheral neuropathy (PN) or deep vein thrombosis (DVT).
Summary/Conclusions: PVd was highly effective in pts with LEN-refractory and PI-exposed myeloma. PVd was well tolerated, with no grade 3/4 PN or DVT and no Tx discontinuation due to Tx-related AE. AEs were generally less frequent with SC *vs* IV BORT. Thus, the favorable tolerability and efficacy of PVd, a potential new therapeutic option in pts with RRMM, is being further evaluated in a large phase 3 trial (MM-007).

P654

PROSPECTIVE COMORBIDITY AND FUNCTIONAL GERIATRIC ASSESSMENT (CF-GA) IN MULTIPLE MYELOMA (MM) PATIENTS (PTS): RESULTS FROM A MULTICENTER GERMAN STUDY GROUP MM (DSMM) TRIAL

SM Dold[1,*], A Zober[1], M Pantic[1], J Duyster[1], R Wäsch[1], M Engelhardt[1], M Schumacher[2], G Ihorst[3], C Langer[4], LO Mügge[5], W Pönisch[6], S Knop[7]
[1]Hematology & Oncology, [2]Institute of Medical Biometry and Medical Informatics, [3]Clinical Trials Unit, University of Freiburg Medical Center, Freiburg, [4]Hematology, Oncology & Rheumatology, University of Ulm Medical Center, Ulm, [5]Hematology & Oncology, University of Jena Medical Center, Jena, [6]Hematology & Oncology, University of Leipzig Medical Center, Leipzig, [7]Hematology & Oncology, University of Würzburg Medical Center, Würzburg, Germany

Background: Cancer pts present with a highly heterogeneous health status and today treatment choices are numerous. Therefore, careful assessment of individuals' condition is relevant. Moreover, in order to define best tolerable treatment options, novel metrics for non-disease variables are needed. Albeit impairment in the Karnofsky Performance Status (KPS), Activities of Daily Living (IADL or ADL) and quality of life (QoL) are predictive for outcome in cancer pts, the prognostic variables within a defined and prospectively assessed battery of established functional tests have rarely been meticulously assessed in MM.
Aims: Our aim is to establish a prospective comorbidity and functional geriatric assessment (CF-GA) to more objectively rate fitness and pts' biological age, rather than the chronological age alone in MM. We assessed a battery of defined tests in German DSMM study centers in newly diagnosed (ND) MM pts.
Methods: This trial of DSMM centers performed a thorough, prospective comorbidity and functional geriatric assessment (CF-GA) in consecutive ND MM pts. This GA was performed prior to initiation of anti-myeloma treatment and reflected pts' baseline health status. The CF-GA included the IADL, ADL, Timed Up and Go Test (TUGT), malnutrition, pain, rating of fitness, SF12-QoL and geriatric depression scale (GDS). Moreover, established comorbidity (CM) scores, namely: ß2MG/eGFR (EJH 2009;83:519-27), Kaplan Feinstein (KF), Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), Charlson Comorbidity Index (CCI), initial-Myeloma Comorbidity Index (I-MCI) and revised-MCI (R-MCI) were assessed. The CF-GA was performed as a screening tool to assess pt fitness as well as to predict survival and toxicities. The trial protocol was approved by the ethics committees of the Freiburg University. All patients provided written informed consent and all procedures were conducted in accordance with the Declaration of Helsinki, the International Conference on Harmonization and Guidelines for Good Clinical Practice.
Results: Characteristics of a total of 238 pts, currently included in this CF-GA, were typical for tertiary centers with a median age of 62 years (27-84) and 94% with symptomatic disease: the median hemoglobin was 11.0g/dl (5-17), eGFR 72ml/min/1.73qm (7-163), ß2-MG 3.8mg/l (0.8-38.4) and BM infiltration 40% (0-95). The baseline frailty assessment revealed a median KPS of 80% (30-100) and physicians'- and patients'-scored fitness was rated with 3 (1-6). Median functional results for the IADL were 8 (1-8), for the ADL 5 (2-6), for pain 2

(0-10), for malnutrition 4 (0-14) and for cognitive deficiency via Mini Mental State Examination (MMSE) 28 (15-30). The median GDS was 2 (0-13) and TUGT 10 (4-80). Median CM scores were substantially different with an I-MCI of 1 (0-3), ß2MG/eGFR of 1 (0-2), KF of 1 (0-3), CCI of 2 (0-8), HCT-CI of 2 (0-8) and R-MCI of 4 (0-9). In age subgroups >60 and >70 years, mean R-MCI and IMWG did increase the most and much lesser with HCT-CI and KF use, confirming the latter's lesser usefulness in MM (Figure 1). According to our current results in 238 pts, highly relevant CF-GA-tools in MM are the TUGT, R-MCI and IMWG score. Since any CF-GA is time-consuming, we have created a web account that allows easy and prompt assessment of the R-MCI (https://myelomacomorbidityindex.org) within 1-2 minutes.

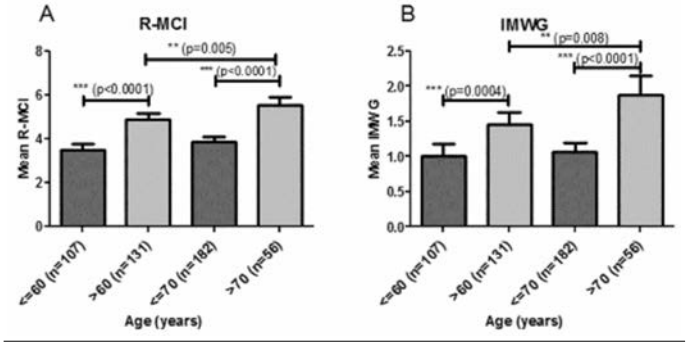

Figure 1. Mean results in different comorbidity indices in age groups.

Summary/Conclusions: To the best of our knowledge, this is the first prospective multicenter GA that accumulates most valuable MM-specific disease risks, frailty tests and comorbidity scores. Our current results in 238 pts showed that the most relevant and compromised parameter in MM are: KPS, renal function, osteolyses, pain, malnutrition, TUGT, frailty, ADL and fitness, whereas lung function, MMSE, GDS, ADL seem less informative nor substantially impaired. As combined CM test, most discriminative are the R-MCI and IMWG that reveal intermediate and unfit pts and increase with age, whereas almost all pts via HCT-CI and KF appeared fit. Most predictive CF-GA tools should be included in future clinical trials.

P655

IMPACT OF CYTOGENETIC RISK ON PFS2 OF PATIENTS TREATED WITH DIFFERENT THERAPY SEQUENCES: RESULTS OF A POST-HOC ANALYSIS

M Offidani[1,*], L Corvatta[1], S Bringhen[2], S Gentili[1], R Troia[2], L Maracci[1], A Larocca[2], A Palumbo[2], P Leoni[1]
[1]Clinica di Ematologia AOU Ospedali Riuniti di Ancona, Ancona, [2]Myeloma Unit, Division of Hematology, University of Torino, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Torino, Italy

Background: Pending the availability of second generation new drugs in clinical practice, currently patients with MM who relapse after induction therapy can be treated with bortezomib or lenalidomide-based combinations besides up front therapy. However, the impact of the different therapy sequences induction-first salvage therapy on PFS2 is not well known and even less it has been defined which is the most appropriate therapy sequence according to cytogenetic risk at diagnosis.
Aims: To analyze the impact on PFS2 of the therapeutic sequence induction-first salvage therapy in patients who were enrolled up front in 2 prospective trials (VMP *vs* VMPT-VT, MPR *vs* Mel-200) stratified according to cytogenetic risk by FISH.
Methods: Among patients included in the above prospective trials, 366/523 (70%) had available FISH analysis at diagnosis. One hundred and eight patients (29.5%) were classified at high cytogenetic risk (HR), defined by the presence of t(4;14) and/or del17p, whereas all the remaining 258 patients were considered as having a standard risk (SR). Overall, 45 patients (12%) were retreated with the same agent used up front (R-group), 94 (26%) received bortezomib as induction and lenalidomide at first relapse (B-L group), 159 (43.5%) received lenalidomide up-front followed by bortezomib at first relapse (L-B group) and 68 patients (18.5%) underwent bortezomib up-front followed by chemotherapy or thalidomide (B-suboptimal group).
Results: Both in HR (PFS2=22 months) and in SR group (PFS2=28 months), B-suboptimal sequence resulted in a significantly shorter PFS2 compared with all others treatment groups. Among patients receiving B-L sequence, HR patients had a PFS2 comparable with that of SR group (PFS2=42 *vs* 58 months; p=0.138). On the contrary, in the group treated with L-B sequence, adverse cytogenetics resulted in a significant shorter PFS2 if compared with SR group (PFS2=39 *vs* 48 months; p=0.061). Similar findings were observed in the R-group in which PFS2 of HR and SR patients was 39 and 64 months, respectively (p=0.008). Considering HR patients, no significant difference in term of PFS2 was seen between R-group and B-L group whereas PFS2 of L-B group resulted significantly shorter compared both with R-group (p=0.029) and B-L group (p=0.043).
Summary/Conclusions: The choice of appropriate therapy up-front and in first relapse is of utmost importance to maximize PFS2 in patients with MM. Cytogenetic risk should be take into account in this regard since outcome of patients with standard cytogenetic risk features seems to be not affected by therapy sequences whereas, patients with high-risk features, had a better outcome only if Bortezomib was used upfront.

Background: For patients (pts) with multiple myeloma (MM), older age and the presence of comorbidities have been associated with a poorer prognosis. A frailty scale was recently described that categorized pts with MM as fit, intermediate, or frail based on age, comorbidities, and physical and cognitive functioning (Palumbo *et al., Blood*, 2015). The frailty score was a predictor of death and toxicity. The pivotal phase 3 FIRST trial showed that treatment with lenalidomide plus low-dose dexamethasone (Rd) until disease progression (Rd continuous) prolonged progression-free survival (PFS) and overall survival (OS) *vs* melphalan, prednisone, and thalidomide (MPT) in transplant-ineligible pts with newly diagnosed MM (NDMM).
Aims: To examine the outcomes in pts in FIRST based on frailty score severity.
Methods: Pts in the FIRST trial provided informed written consent and were randomized to receive Rd continuous, Rd for 18 cycles (Rd18), or MPT. An algorithm based on the previously described frailty scale was used to categorize pts into 3 severity groups: fit, intermediate, and frail. Baseline pt characteristics included in the algorithm were age, Charlson Comorbidity Index score, and self-care and usual activities from the EQ-5D questionnaire (as proxies for the Activities of Daily Living and Instrumental Activities of Daily Living scales). Pts missing data on ≥1 variable were excluded (n=106). This analysis evaluated PFS and OS outcomes between treatment arms within each severity group using a data cutoff of March 3, 2014.

A

Breakdown of Severity Groups by Treatment Arm			
Severity Group	Rd Continuous (n = 506)	Rd18 (n = 504)	MPT (n = 507)
Frail, %	56.3	50.6	54.0
Intermediate, %	26.5	33.9	28.2
Fit, %	17.2	15.5	17.8

B

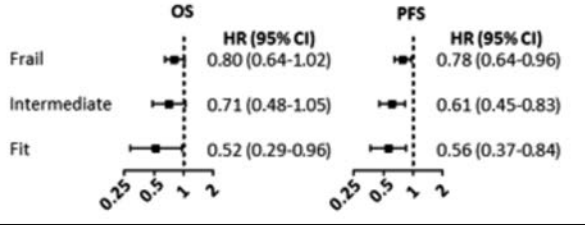

Figure 1.

Results: Of 1623 total pts, 1517 were included in the analysis, and the majority of these pts were frail compared with fit or intermediate (54% *vs* 17% *vs* 30%, respectively). Breakdowns based on severity group were similar across treatment arms (Figure 1A). Compared with fit or intermediate pts, frail pts were older and had higher Eastern Cooperative Oncology Group performance status scores, higher International Staging System (ISS) stage, higher lactate dehydrogenase levels, and worse renal function. OS was improved in fit *vs* frail pts (hazard ratio [HR], 0.42; *P* <.0001) and intermediate *vs* frail pts (HR, 0.62; *P* <.0001). Treatment with Rd continuous prolonged PFS and OS compared with

MPT for all severity groups (Figure 1B). Rd continuous reduced the risk of progression or death *vs* MPT by 44%, 39%, and 22% in fit, intermediate, and frail groups, respectively. Fit pts had a lower risk of grade 3 or higher (grade 3+) non-hematologic adverse events (AEs) compared with frail pts (HR, 0.77; *P*=.0021). The risk of grade 3+ hematologic AEs was similar for all levels of frailty. Pts treated with Rd continuous had a similar risk of grade 3+ non-hematologic AEs compared with those treated with MPT for all severity groups. The risk of grade 3+ hematologic AEs was lower with Rd continuous than with MPT in the fit, intermediate, and frail groups. Pts within each severity group were further divided based on ISS stage: fit pts were subdivided into stage I *vs* II/III and intermediate and frail pts into stage I/II *vs* III. Combining ISS stage with frailty classification further improved prognostic assessment of pts within each severity group for both PFS and OS.

Summary/Conclusions: This analysis of the FIRST trial population supports the use of the frailty scale for predicting risk of death in pts with NDMM. PFS and OS benefits were seen with Rd continuous *vs* MPT across all levels of frailty, with the greatest benefits seen in fit pts. These data support the use of continuous therapy with Rd as a standard of care for pts with transplant-ineligible NDMM.

Innovative therapies for MM 4

P657

PROSPECTIVE EVALUATION OF GERIATRIC ASSESSMENT TOOLS IN REAL-WORLD, UNSELECTED, ELDERLY PATIENTS WITH SYMPTOMATIC MYELOMA

MA Dimopoulos[1], M Gavriatopoulou[1], M Roussou[1], D Fotiou[1], D Ziogas[1], M Migkou[1], I Panagiotidis[1], S Orfanopoulos[1], U Koloventzou[1], V Babali[1], E Kafantari[1], S Giannouli[1], E Eleutherakis-Papaiakovou[1], K Konstantopoulos[2], P Tsirigotis[2], E Terpos[1], E Kastritis[1,*]

[1]Department of Clinical Therapeutics, [2]National and Kapodistrian University of Athens School of Medicine, Athens, Greece

Background: Geriatric assessment (GA) collects data related to the medical, psychosocial and functional capabilities of the elderly patients, and provides tools for treatment and care decisions. Based on data from patients who participated in clinical trials, a "Frailty score" was developed by the IMWG, by using a simplified GA with 3 tools (Katz Activity of Daily Living (ADL), the Lawton Instrumental Activity of Daily Living (IADL) and the Charlson Comorbidity Index (CCI)) (Palumbo *et al.,* Blood 2015).

Aims: To prospectively evaluate different GA tools and comorbidity indices in consecutive, unselected, "Real-World", patients >65 years.

Methods: The following tools were used: G8 geriatric assessment screening tool (G8-GAS), VES-13, GDS, Katz ADL, Lawton IADL, MMSE, KPS (%), ECOG PS, number of falls in the past 1 & 6 months, lower-extremity function and disability in elderly tool, nutritional assessment tools (DETERMINE and Mini Nutritional Assessment), social support score, cognition evaluation tools (MMSE), Geriatric Depression Scale and comorbidity indices (CCI, CIRS-G, ACE-27 tool).

Results: Since January 2012, 144 consecutive patients >65 years diagnosed with symptomatic MM in the Department of Clinical Therapeutics, University of Athens, had a GA. The median age was 76 years (range 66-92); 55% were males; 26% had ISS-1, 24% ISS-2 and 50% ISS-3 and 19% (of 121 with available) had high risk cytogenetics (del17p or t(4;14)) while 22% had eGFR<30 ml/min/1.73 m^2. Treatment was IMiDs-based in 47% (thalidomide in 13% and lenalidomide in 34%) and proteasome inhibitor-based in 53%. PR or better was achieved by 78% of evaluable patients. Two year overall survival (OS) was 71%. Advanced age was associated with shorter OS and risk of early death (<3 months) (early death rates were 3%, 8% and 20% for patients ≤70 *vs* 71-80 *vs* >80 years). ISS stage was associated with OS (p=0.004) but not high risk cytogenetics (p=0.714) or different types of primary therapy (p=0.593).
Per the IMWG "frailty score", 29% were fit, 17% intermediately fit and 54% frail with 2-year OS of 77%, 81% and 62% respectively. The distribution in frailty scores was different than that of patients in the IMWG cohort (39%, 31% & 30%), probably because our patients were unselected and older. Several different GA tools showed prognostic significance in univariate analysis, such as the number of falls in the past 6 months (p=0.002), lower extremity function (p=0.014), mini nutritional assessment (p=0.014), G8-GAS (p<0.001), KPS <50% (p<0.001), ECOG PS >2 (p=0.04) and MMSE (p=0.024). There was an association of early death with KPS ≤50% (p=0.003), ECOG PS >2 (p=0.05), Geriatric depression score (p=0.018) and G8-GAS score (p=0.015). IMWG "frailty score" was not associated with early death. In multivariate analysis, which included ISS and age, the number of falls in the past 6 months (HR: 4.7, p=0.007) and the score of the G8-GAS tool (HR: 4.7, p=0.004) were independent factors for survival. Addition of cytogenetics did not improve the multivariate model. IMWG "frailty score" in a multivariate analysis, which included ISS stage, did not have independent statistical significance for OS.

Summary/Conclusions: In elderly myeloma patients, GA with G8-GAS tool provides prognostic information related to the risk of early death and overall survival, independently from disease characteristics and the treatment type. GA can be simple and provides a strong tool which may be useful for prognostication and treatment decisions in elderly patients.

Background: The introduction of new treatment modalities have changed significantly the perspective of multiple myeloma (MM) patients. The factors that

are associated with inferior treatment response and possible drug-resistance are currently in the focus of investigation.

Aims: The aim of the study was to analyze the prognostic significance of CRBN expression in MM patients ineligible for autologous stem cell transplantation (ASCT).

Methods: The study included 92 newly diagnosed MM patients (median age 67 years, range 35-80 years; 44 male/48 female) with following distribution: IgG myeloma had 55 patients (59.8%), IgA 18 (19.6%), light chains 16 (17.4%), and IgD 2 patients (2.2%). Advanced III clinical stage (CS, Durie&Salmon) had 68 patients (73.9%), II 18 (19.6%), and 6 (6.5%) had symptomatic I CS. Of 92 patients, 24 (26.1%) had ISS score 1, 28 (30.4%) ISS 2 and 40 (43.5%) ISS 3. Elevated LDH level was present in 18/92 patients (19.6%). High risk chromosomal abnormalities (CA, iFISH): t(4; 14), del(17p), were detected in 14 patients (15.2%). Renal impairment existed in 16 patients (17.4%). The CRBN expression was analyzed on the samples of bone marrow aspirate by RT-PCR method. All patients were treated with novel agents within three-drug combinations with alkylating agents (melphalan or cyclophosphamide) and corticosteroids (dexamethasone or prednisolone). Thalidomide based combinations were applied in 77 patients (83.7%) while 15 patients (16.3%) were treated with bortezomib based combinations. The patients were ASCT ineligible due to the age, high comorbidity index, progressive disease or personal attitude.

Results: Overall treatment response (CR/VGPR/PR/MR) was achieved in 77 patients (83.7%). Median CRBN expression for patients with CR, VGPR, PR, MR and PD, in the group treated with thalidomide- or bortezomib based combinations, was 3.13, 2.65, 2.08, 1.85 and 0.97 respectively; and 2.63, 3.00, 3.04, and 1.35, respectively. Treatment response correlated with high CRBN expression (p=0.011), mainly in the group treated with thalidomide based combinations (p=0.013), while in the group treated with bortezomib based combinations such correlation was not found (p=0.665). The most discriminative cut-off value of CRBN expression selected by the ROC analysis was 1.39 (sensitivity 41% and specificity 81.8%, AUC value 0.643, 95% CI 0.502–0.785, p=0.05). Low CRBN expression (≤1.39) had 22/92 patients (23.9%), 19/77 of thalidomide group (24.7%), and 3/15 (20%) of bortezomib group. The presence of high risk CA wasn't associated with lower CRBN expression (p=0.35). Patients with low CRBN expression (≤1.39), treated with thalidomide based combinations, had significantly shorter progression free survival (PFS) compared to patients with high CRBN expression (median of PFS 22 months *vs* median not reached, Log Rank=5.70, p=0.017). In this group, low CRBN expression wasn't associated with inferior OS (Log Rank=2.93, p=0.087). Regarding bortezomib treated patients, there wasn't observed impact of CRBN expression neither on PFS (Log Rank=0.063, p=0.80), nor on OS (Log Rank=0.036, p=0.85). Among significant variables (ISS, LDH, CA, and CRBN), Cox regression analysis has confirmed that low CRBN expression has the most significant prognostic influence on PFS (HR, 3.5; 1.40-8.77; p=0.008) in patients treated with thalidomide based combinations.

Summary/Conclusions: Indicating possible suboptimal treatment outcome, the level of CRBN expression may represent additional prognostic tool in personalized treatment approach to individual myeloma patient.

Background: Subcutaneous (SC) delivery of bortezomib (BTZ) has been shown non-inferior to intravenous (IV) delivery in terms of efficacy while offering improved safety (Moreau, *et al.* Lancet Oncol 2011;12:431-40). The phase 3 ENDEAVOR study demonstrated a significant improvement in progression-free survival (PFS) for carfilzomib and dexamethasone (Kd) *vs* IV/SC BTZ and dexamethasone (Vd) in patients with relapsed or refractory multiple myeloma (RRMM) (Dimopoulos, *et al.* Lancet Oncol 2016;17:27-38). Currently, most BTZ use in MM is SC, and most relapsed MM patients had prior exposure to BTZ.

Aims: We present results of a subset analysis of the efficacy and safety of Kd *vs* SC Vd in the ENDEAVOR study consistent with current standard of care; the effect of prior exposure to BTZ was also investigated.

Methods: After providing informed consent, patients with RRMM (1-3 lines of therapy) were randomized 1:1 to Kd or Vd. The analysis compared Kd patients who had selected SC BTZ delivery pre-randomization if randomized to Vd arm with Vd patients who used SC BTZ. Kd arm received carfilzomib (30-min IV infusion) on days 1, 2, 8, 9, 15, and 16 (20 mg/m^2 on days 1 and 2 of cycle 1; 56 mg/m^2 thereafter) and dexamethasone (d) 20 mg on days 1, 2, 8, 9, 15, 16, 22, and 23 of a 28-day cycle. Vd arm received BTZ 1.3 mg/m^2 on days 1, 4, 8 and 11 and d (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 of a 21-day cycle. The primary endpoint was PFS. Secondary endpoints included overall survival (OS), overall response rate (ORR), rate of grade ≥2 peripheral neuropathy (PN), and safety.

Results: A total of 929 patients were randomized to Kd (n=464) or Vd (n=465); of these, 360 Vd patients received SC BTZ. Among 464 Kd patients, 356 patients selected SC route of BTZ administration if randomized to Vd arm. Median PFS has not been reached for Kd but was 9.5 months (mo) for Vd patients treated with SC BTZ (hazard ratio [HR]: 0.58; 95% confidence interval [CI], 0.46–0.72). Median PFS for Kd *vs* SC Vd was 13.4 mo *vs* 8.4 mo for patients with prior BTZ exposure (HR: 0.66; 95% CI, 0.50–0.87). Median OS has not been reached for Kd but was 24.3 mo for SC Vd (HR: 0.75; CI, 0.53–1.08). ORR was 76.1% (Kd) *vs* 64.4% (SC Vd), and 70.4% (Kd) *vs* 62.1% (SC Vd) for patients with prior BTZ use. Grade ≥2 PN rates were 6.5% (Kd) *vs* 33.3% (SC Vd), and 6.2% (Kd) *vs* 29.1% (SC Vd) for patients with prior BTZ. Grade ≥3 adverse events (AEs) were 74.4% (Kd) *vs* 67.5% (SC Vd), and 71.8% (Kd) *vs* 64.5% (SC Vd) for patients with prior BTZ. Results are shown in Table 1. Figure 1 shows Kaplan–Meier PFS curves.

Table 1. Outcomes

			Prior BTZ	
	Kd (n=356)	SC Vd (n=360)	Kd (n=196)	SC Vd (n=203)
Median PFS, mo	Not reached	9.5	13.4	8.4
HR for Kd *vs* SC Vd (95% CI)	0.58 (0.46–0.72)		0.66 (0.50–0.87)	
ORR, % (95% CI)	76.1 (71.3–80.4)	64.4 (59.3–69.4)	70.4 (63.5–76.7)	62.1 (55.0–68.8)
Grade ≥2 PN rate, %	6.5	33.3	6.2	29.1
Odds ratio (95% CI)	0.139 (0.09–0.22)		0.160 (0.08–0.31)	
Grade ≥3 AEs[a], %	74.4	67.5	71.8	64.5

[a]*Safety population was 355 (Kd) and 360 (SC Vd), and 195 (Kd) and 203 (SC Vd) in the prior BTZ group.*

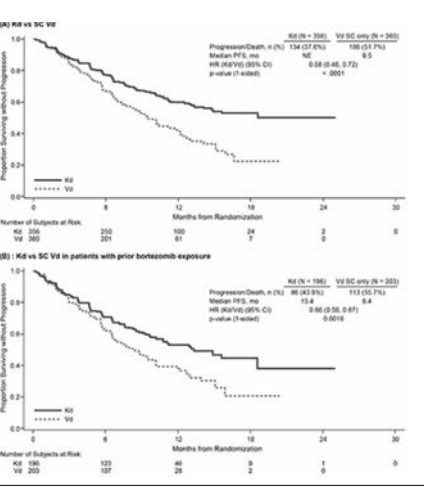

Figure 1. Kaplan-Meier PFS curves.

Summary/Conclusions: Treatment with Kd led to prolonged progression-free survival *vs* Vd patients who were administered SC BTZ. The use of Kd also led to higher response rates, a trend for prolonged OS, and lower rate of grade ≥2 PN *vs* SC Vd. In patients with prior BTZ exposure, Kd treatment resulted in longer PFS, greater ORR, and decreased PN *vs* SC Vd. These results suggest that Kd has a favorable benefit-risk profile and delivers superior efficacy and improved clinical outcomes compared with SC Vd for RRMM regardless of prior BTZ treatment.

Background: In the double-blind, placebo-controlled, phase 3 TOURMALINE-MM1 study (NCT01564537) in 722 patients with relapsed/refractory multiple myeloma (RRMM) following at least one prior therapy, IRd was associated with a significant improvement in PFS *vs* placebo-Rd (HR 0.742, p=0.012), together with limited additional toxicity (Moreau *et al.,* ASH 2015). Data from this study led to approval by the US FDA of ixazomib, in combination with Rd, in this setting.
Aims: Despite recent advances in treatment, no quality-of-life (QoL) data are available from double-blind, randomized, placebo-controlled studies in RRMM. A secondary endpoint of TOURMALINE-MM1 was to assess patient-reported QoL using the EORTC Quality of Life Questionnaire (EORTC QLQ-C30) and MM-specific MY-20 module.
Methods: Patients with RRMM were randomized 1:1 to receive IRd or placebo-Rd (ixazomib 4 mg or matching placebo on days 1, 8, and 15, plus lenalidomide 25 mg on days 1–21 and dexamethasone 40 mg on days 1, 8, 15, and 22, in 28-day cycles) until disease progression or unacceptable toxicity. Patients completed the EORTC QLQ-C30 and MY-20 questionnaires at screening, the start of cycles 1 and 2 and every other cycle, the end of treatment, and every 4 weeks until progression.
Results: Over a median follow-up of 23 months, QoL was maintained from baseline with both treatment regimens. Mean EORTC QLQ-C30 global health status scores for the intent-to-treat population were similar for the IRd *vs* placebo-Rd arms, suggesting the addition of ixazomib did not impact QoL (Figure 1). For the EORTC QLQ-C30 functioning scales, linear mixed model analysis of least squares (LS) mean change from baseline showed similar results over time for the IRd and placebo-Rd arms: 0.4 *vs* -1.3 for physical, -1.3 *vs* -3.0 for role, 1.0 *vs* -1.6 for emotional (p<0.05), -3.5 *vs* -5.7 for social, and -4.2 *vs* -4.6 for cognitive functioning scales (higher values indicate better functioning). For the physical, emotional, and social scales, significantly higher mean scores (p<0.05) were seen in the IRd *vs* placebo-Rd arm at several time points, suggesting better QoL with IRd. In line with the limited additional toxicity seen with IRd *vs* placebo-Rd (74%/47% *vs* 69%/49% of pts had grade ≥3 adverse events [AEs]/serious AEs), EORTC QLQ-C30 symptom scale scores were similar for IRd *vs* placebo-Rd, LS mean change from baseline was 1.8 *vs* 4.2 for appetite loss, 3.5 *vs* 5.1 for constipation, 14.5 *vs* 10.4 (p<0.05) for diarrhea, 1.0 *vs* 2.0 for dyspnea, -0.3 *vs* 0.9 for financial difficulties, 0.4 *vs* 2.4 for fatigue,1.1 *vs* 0.5 for insomnia, 1.6 *vs* 0.6 for nausea/vomiting, and -2.8 *vs* -2.3 for pain scales (lower scores indicate lower symptom burden). Diarrhea (which was mostly grade ≤2) did not appear to impact patient perception of overall QoL. Consistent results were also seen with the MY-20 measure: LS mean change from baseline in the IRd *vs* placebo-Rd arms was -3.3 *vs* -4.3 for body image, 8.1 *vs* 4.9 for future perspective (p<0.05) (higher scores indicate better QoL), -5.8 *vs* -5.5 for disease symptoms, and 3.8 *vs* 3.4 for side effects of treatment (lower scores indicate lower symptom burden). Post-hoc analyses showed that, in both arms, changes in global health status and several functioning and symptom scores were significantly correlated with response to treatment.
Summary/Conclusions: In the double-blind, placebo-controlled, phase 3 TOURMALINE-MM1 study in patients with RRMM, patient-reported QoL was maintained with the addition of ixazomib to Rd, which also provided a significant clinical benefit, thus improving patient outcome.

WEEKLY CARFILZOMIB WITH DEXAMETHASONE FOR PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS FROM THE PHASE 1/2 STUDY CHAMPION-1 (NCT01677858)

Background: Carfilzomib, an irreversible proteasome inhibitor, is approved as a single agent and in combination with dexamethasone in the United States (US) for the treatment of relapsed/refractory and relapsed multiple myeloma (MM), respectively and in the US and Europe in combination with lenalidomide (LEN)/dexamethasone for the treatment of relapsed MM. The approved dose/schedule of carfilzomib is a twice-weekly, 10-min intravenous (IV) infusion on days 1, 2, 8, 9, 15, and 16 of a 28-day cycle (starting dose: 20mg/m^2 [cycle 1: days 1 and 2], escalating to 27mg/m^2 thereafter).
Aims: A phase 1/2 study (CHAMPION-1; NCT01677858) to determine the maximum tolerated dose (MTD) of carfilzomib (phase 1), the overall response rate (ORR [≥partial response]) (phase 2) and safety of once-weekly carfilzomib with dexamethasone (Cd) in patients with relapsed or refractory MM.
Methods: Patients with relapsed or refractory MM (1-3 prior lines of therapy) received carfilzomib (30-min IV infusion) on days 1, 8, and 15 every 28 days. Phase 1: patients received carfilzomib 20mg/m^2 on day 1 of cycle 1 followed by 45, 56, 70, or 88 mg/m^2 beginning day 8 of cycle 1 in successive dose-level cohorts until the MTD was reached (using a standard 3+3 dose-escalation scheme). All patients received dexamethasone 40mg (IV or oral) days 1, 8, 15, and 22 (cycles 1-8); dexamethasone was omitted on day 22 cycles ≥9. Phase 2: patients received carfilzomib 20mg/m^2 on cycle 1, day 1, escalating to the MTD for subsequent doses. Dexamethasone was given as previously. Cd was administered until unacceptable toxicity or disease progression. Blood samples were collected for pharmacokinetic and pharmacodynamic analyses.
Results: Patients with relapsed or refractory MM (1-3 prior lines of therapy) received carfilzomib (30-min IV infusion) on days 1, 8, and 15 every 28 days. Phase 1: patients received carfilzomib 20mg/m^2 on day 1 of cycle 1 followed by 45, 56, 70, or 88 mg/m^2 beginning day 8 of cycle 1 in successive dose-level cohorts until the MTD was reached (using a standard 3+3 dose-escalation scheme). All patients received dexamethasone 40mg (IV or oral) days 1, 8, 15, and 22 (cycles 1-8); dexamethasone was omitted on day 22 cycles ≥9. Phase 2: patients received carfilzomib 20mg/m^2 on cycle 1, day 1, escalating to the MTD for subsequent doses. Dexamethasone was given as previously. Cd was administered until unacceptable toxicity or disease progression. Blood samples were collected for pharmacokinetic and pharmacodynamic analyses (Table 1).

Table 1. Adverse events in any grade occurring in ≥20% of patients and grade ≥3 adverse events occurring in ≥5% of patients treated at the carfilzomib MTD.

Adverse event, n (%)	Patients (n=104)	
	Any grade	Grade ≥3
Fatigue	55 (53)	11 (11)
Nausea	38 (37)	1 (1)
Insomnia	33 (32)	2 (2)
Headache	32 (31)	3 (3)
Diarrhea	32 (31)	4 (4)
Upper respiratory tract infection	31 (30)	1 (1)
Anemia	29 (28)	6 (6)
Cough	29 (28)	1 (1)
Dyspnea	28 (27)	5 (5)
Pyrexia	26 (25)	0
Thrombocytopenia	23 (22)	6 (6)
Peripheral edema	22 (21)	0
Back pain	18 (17)	5 (5)
Hypertension	14 (13)	7 (7)
Asthenia	11 (11)	5 (5)
Pneumonia	8 (8)	6 (6)
Acute kidney injury	7 (7)	6 (6)
Chronic obstructive pulmonary disease	5 (5)	5 (5)

Summary/Conclusions: Once-weekly carfilzomib (70 mg/m^2) with dexamethasone for patients with relapsed or refractory MM has an acceptable safety and tolerability profile with promising efficacy. The dose and schedule of carfilzomib used in this study (20/70mg/m^2) is currently being compared with the regulatory-approved carfilzomib dose and schedule (20/27mg/m^2 twice-weekly) in an ongoing phase 3, superiority study (ARROW; NCT02412878).

Background: Over the past decade, numerous drug therapies have emerged for the treatment (Tx) of multiple myeloma (MM). However, eventually all patients (pts) relapse or progress with heterogeneous clinical pattern (Alegre *et al., Haematologica*, 2002). According to the International Myeloma Workshop Consensus Panel (IMWCP; Rajkumar *et al., Blood,* 2011), salvage Tx for MM relapse should begin at symptomatic clinical relapse (clinR) and earlier at asymptomatic biological relapse (BR) when paraprotein increases significantly. In the case of asymptomatic BR/progression, rescue Tx could be delayed in a subset of pts (Fernández de Larrea *et al., Bone Marrow Transplant,* 2014), particularly in low-risk pts with stable M-protein and hemoglobin. Progressive increases of M-spike in blood and/or urine could lead to rescue Tx, even in the absence of clinical symptoms, to avoid complications (*e.g.*, renal failure, plasmacytomas, or hypercalcemia).
Aims: This Spanish observational prospective Registry aims to describe MM relapse patterns, comparing the impact in terms of time to progression (TTP) on Tx decisions (starting Tx at BR [TxBR] *vs* delaying Tx until clinR progression [TxClinR]).
Methods: Adult pts with MM who received 1 or 2 lines of Tx and had achieved ≥partial response (PR) to the last Tx and were in (or prior to) BR according to the IMWCP(Rajkumar *et al., Blood,* 2011)were included. 41 Spanish sites are participating, with 410 pts registered. Data recorded included, among others, demographic, relapse clinical characteristics, TTP, and time from BR to clinR (TTP-ClinR). All pts provided their informed written consent.

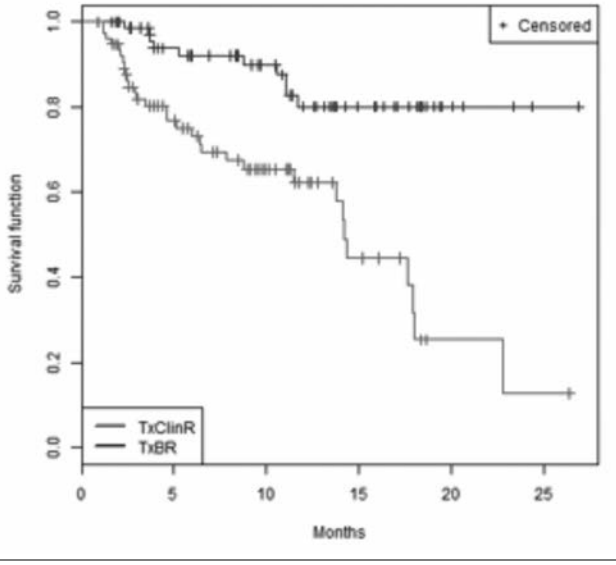

Figure 1. Time from biological relapse to clinical relapse, months.

Results: The cohort evaluated 184 pts (97 male/87 female; mean age of 68.7 years [SD, 10.7]). Heavy chain isotypes were IgG κ (39.0%), IgG λ (23.6%), IgA κ (14.3%), IgA λ (9.9%), IgM λ (1.1%) and IgD λ (0.5%). Prognostic stage at diagnosis according to the ISS was II (28.0%), I (26.9%), and III (24.7%). 47.8% of pts had received autologous stem cell transplant. In 49 pts with available cytogenetic data, 31 (63.3%) were standard-risk and 18 (36.7%) were high-risk. First-line Tx was based mostly on bortezomib (74.4%). After first-line Tx, pts achieved stringent complete response (17.9%), complete response (27.4%), very good partial response (29.6%), or PR (25.1%). Median follow-up was 8.5 months. After BR, 100 pts (55.2%) started Tx (lenalidomide, 68.4%; bortezomib, 28.9%) at BR (65% with significant paraprotein relapse), while Tx was delayed until clinR in 81 (44.8%) pts. Overall median time to progression from BR to clinR (the primary objective) was 22.8 months (95% CI, 17.7-not estimable [NE]). A statistically significant difference was found between Tx groups, median TTP-ClinR was 14.2 months (95% CI, 11.5-18.0) for TxClinR pts and NE for TxBR pts (*P* <.0001; Figure 1). Additional details regarding pattern of BR will be presented.
Summary/Conclusions: Although longer follow-up is needed, in this updated preliminary cohort of pts with MM BR, we found that starting Tx at BR delays the time to clinical relapse, suggesting that pts may benefit from early Tx after first or second relapse.

Background: Single-agent carfilzomib has demonstrated activity in patients with relapsed and refractory multiple myeloma with high-risk cytogenetic abnormalities. In the phase 3 study (NCT01080391; N=792 patients) carfilzomib, lenalidomide and dexamethasone (KRd) significantly improved progression-free survival (PFS) *versus* lenalidomide and dexamethasone (Rd) in patients with relapsed multiple myeloma (RMM).
Aims: A pre-planned subgroup analysis of the efficacy and safety of KRd *versus* Rd according to patients' baseline cytogenetic risk status.
Methods: Adult patients with RMM who had received 1-3 prior lines of therapy were randomized (1:1) to receive KRd or Rd in 28-day cycles. Patients in the KRd arm received carfilzomib as a 10-minute IV infusion on days 1, 2, 8, 9, 15, and 16 (cycle 1, 20mg/m^2 on days 1 and 2; escalated to target 27mg/m^2 thereafter) during cycles 1-12. For cycles 13-18, carfilzomib was omitted on days 8 and 9 and discontinued after 18 cycles. Lenalidomide 25mg was administered days 1-21 and dexamethasone 40mg days 1, 8, 15, and 22. The primary end point was PFS; secondary end points included overall survival, overall response rate (ORR), duration of response (DOR), health-related quality of life and safety. The high-risk group was defined as patients with the genetic subtype t(4;14) or t(14;16) or deletion 17p in ≥60% of plasma cells (as assessed using fluorescence *in situ* hybridization). The standard-risk group consisted of all other patients with known baseline cytogenetics.
Results: A total of 396 patients were randomized to each arm. For patients with known baseline cytogenetics, risk status was similar across treatment arms (high-risk: KRd, 24.6%; Rd, 23.4%; standard-risk: KRd, 75.4%; Rd, 76.6%). Efficacy outcomes by cytogenetic risk status are presented in the Table 1. In the high-risk group (n=100), median PFS was 23.1 months (95% confidence interval [CI]: 12.5–24.2) for KRd *vs* 13.9 months (95% CI: 9.5–16.7) for Rd (hazard ratio [HR]:

0.639; 95% CI: 0.369–1.106). In the standard-risk group (n=317), median PFS was 29.6 months (95% CI: 24.1–not estimable) and 19.5 months (95% CI: 14.8–26.0), respectively (HR: 0.657; 95% CI: 0.480–0.901). In the high-risk group, ORRs were 79.2% (KRd) *vs* 59.6% (Rd) and in the standard-risk group, 91.2% (KRd) *vs* 73.5% (Rd). In the high-risk group, rates of grade ≥3 adverse events were 89.1% (KRd) *vs* 78.4% (Rd) and in the standard-risk group 85.6% (KRd) *vs* 84.5% (Rd).

Table 1. Efficacy outcomes and AEs of interest by baseline cytogenetic risk status.

Outcome	High-Risk		Standard-Risk	
	KRd (n=48)	Rd (n=52)	KRd (n=147)	Rd (n=170)
Median PFS, months	23.1	13.9	29.6	19.5
HR for KRd vs Rd (95% CI)	0.639 (0.369–1.106)		0.657 (0.480–0.901)	
Best overall response, n (%)				
Stringent complete response	8 (16.7)	2 (3.8)	22 (15.0)	6 (3.5)
Complete response	6 (12.5)	1 (1.9)	34 (23.1)	5 (2.9)
Very good partial response	15 (31.3)	11 (21.2)	55 (37.4)	66 (38.8)
Partial response	9 (18.8)	17 (32.7)	23 (15.6)	48 (28.2)
Minimal response	3 (6.3)	4 (7.7)	4 (2.7)	15 (8.8)
Stable disease	0	6 (11.5)	3 (2.0)	15 (8.8)
Progressive disease	2 (4.2)	6 (11.5)	2 (1.4)	2 (1.2)
Not evaluable	5 (10.4)	5 (9.6)	4 (2.7)	13 (7.6)
ORR, % (95% CI)	79.2 (65.0–89.5)	59.6 (45.1–73.0)	91.2 (85.4–95.2)	73.5 (66.2–80.0)
Median DOR, months	22.2	14.9	30.4	20.4
Grade ≥3 AEs of interest, n (%)[a]				
Dyspnea[b]	2 (4.3)	0	5 (3.4)	5 (3.0)
Hypertension[b]	1 (2.2)	0	9 (6.2)	3 (1.8)
Acute renal failure[c]	3 (6.5)	1 (2.0)	6 (4.1)	3 (1.8)
Cardiac failure[c]	0	0	8 (5.5)	4 (2.4)
Ischemic heart disease[c]	0	1 (2.0)	7 (4.8)	2 (1.2)
Peripheral neuropathy[c]	0	1 (2.0)	6 (4.1)	4 (2.4)

[a]In the high-risk group, 46 (KRd) and 51 (Rd) patients were evaluable for safety; in the standard-risk group, 146 (KRd) and 168 (Rd) patients were evaluable for safety.

[b]Preferred term.

[c]Grouped term.

AE, adverse event; CI, confidence interval; DOR, duration of response; HR, hazard ratio; KRd, carfilzomib with lenalidomide and dexamethasone; NE, not estimable; ORR, overall response rate; PFS, progression-free survival; Rd, lenalidomide and dexamethasone.

Summary/Conclusions: In patients with high-risk cytogenetics, treatment with KRd improved median PFS by 9 months *versus* Rd (median PFS of nearly 2 years *vs* 13.9 months). KRd was also associated with a 10-month improvement in median PFS *vs* Rd in patients with standard-risk cytogenetics. Treatment with KRd resulted in higher response rates, greater depth of response and a longer DOR *versus* Rd, regardless of patients' baseline cytogenetic risk status. The triplet regimen of KRd had a favorable benefit–risk profile in patients with RMM and improved outcomes in patients with high-risk disease.

Background: In ENDEAVOR (NCT01568866; N=929), carfilzomib plus dexamethasone (Cd) was superior to bortezomib/dexamethasone (Bd), with a 2-fold improvement in median PFS (18.7 *vs* 9.4 months; HR=0.53; 95% CI, 0.44, 0.65; p<.0001) in patients with RMM.

Aims: To evaluate change from baseline in left ventricular ejection function (LVEF), right ventricular (RV) function and pulmonary artery systolic pressure (PASP) via echocardiogram (ECHO) in a subset of patients from the ENDEAVOR study.

Methods: Adults with RMM (1-3 prior regimens) with a LVEF ≥40% and no evidence of New York Heart Association class III or IV symptomatic heart failure (HF), symptomatic ischemia, uncontrolled arrhythmias or recent myocardial infarction within 4 months before randomization. Patients received either carfilzomib (30-min IV infusion on days [D] 1, 2, 8, 9, 15, 16 [20 mg/m^2 on D1, 2 of cycle 1; 56 mg/m^2 thereafter]) and dexamethasone (20mg on D1, 2, 8, 9, 15, 16, 22, 23 of a 28-day cycle) or bortezomib (1.3 mg/m^2; IV or SC on D1, 4, 8, 11) and dexamethasone (20mg on D1, 2, 4, 5, 8, 9, 11, 12 of a 21-day cycle). All eligible patients were assessed at baseline and every 12 weeks on D1 of treatment cycles and at the end-of-treatment visit (using 2D transthoracic ECHO). ECHOs were centrally read. An independent cardiac events adjudication committee (CEAC) reviewed results in conjunction with adverse events (AEs) to assess clinical significance. Primary endpoint was reduction (≥10% absolute decrease from baseline in patients with LVEF ≤55% or a reduction <45% for patients with baseline LVEF >55%) or no change in LVEF (≤24 weeks from baseline).

Results: A total of 151 patients (Cd: 75; Bd: 76) were included in this substudy; 74 in each arm were evaluable for safety. More patients in the Cd arm (*versus* the Bd arm) were aged ≥75 years (21.3% *vs* 14.5%), had prior cardiac-related medical history (26.7% *vs* 14.5%) and received drugs for obstructive airway disorders (28.0% *vs* 17.1%). Patients in the Cd arm had a higher incidence of HF reported as an AE *vs* Bd (10.8% [n=8] *vs* 4.1% [n=3]), consistent with the overall safety population (8.2% *vs* 2.9%). History of cardiac disorders was associated with an elevated (not significant) risk of HF (3/8 Cd pts; 0/3 Bd pts). Patients receiving Cd had a higher incidence of hypertension (HTN) *versus* those treated with Bd (20.3% *vs* 8.1%). Twenty-three patients (15.2%) discontinued treatment due to AEs); 8 due to non-fatal cardiac-related AEs (6 Cd [2 due to LV dysfunction, and 1 each due to HF, decreased EF, pulmonary embolism, and ischemic stroke] and 2 Bd [1 each due to decreased EF and RV failure]). Only 1 patient (Bd) had significant LVEF reduction as defined within the first 24 weeks. Six patients had a significant LVEF reduction at any time during the study (Cd: 3; Bd: 3). All but 1 had resolution to normal LVEF. CEAC evaluation found 14 patients (Cd: 8; Bd: 6) had on-study CEAC-defined clinically meaningful changes in ECHOs; 11/14 (79%) did not meet the ECHO criteria for decreased LVEF. The CEAC reported more Cd patients (*vs* Vd) had evidence of HF (n=4 *vs* n=0) or pulmonary HTN (n=4 *vs* n=1) (Figure 1).

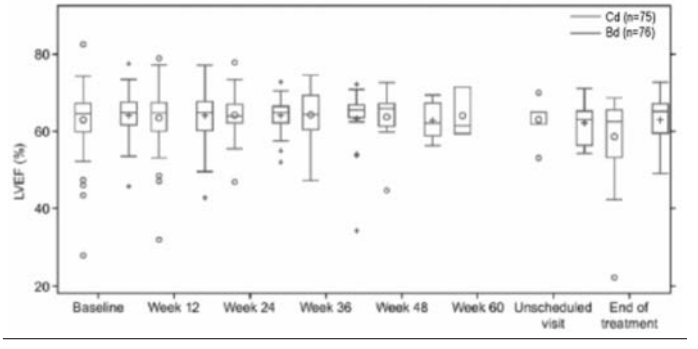

Figure 1. Left ventricular ejection fraction (LVEF) by week.

Summary/Conclusions: In the overall and cardiac substudy, HF and pulmonary HTN events occurred more frequently with Cd *vs* Vd although ECHO-detected significant decline in LVEF was low on both treatment arms and with similar frequency. The substudy found limited utility for serial screening with ECHOs to mitigate cardiac risk for unselected patients receiving carfilzomib. Alternative surveillance strategies are needed to detect early cardiotoxicity and prevent treatment interruption or discontinuation.

P665

PROGNOSTIC FACTORS IN PATIENTS WITH MULTIPLE MYELOMA AND STANDARD-RISK CYTOGENETICS

M Binder[1,*], SV Rajkumar[2], RP Ketterling[3], A Dispenzieri[2], MQ Lacy[2], MA Gertz[2], FK Buadi[2], SR Hayman[2], YL Hwa[2], SR Zeldenrust[2], JA Lust[2], SJ Russell[2], N Leung[2,4], P Kapoor[2], RS Go[2], WI Gonsalves[2], RA Kyle[2], SK Kumar[2]
[1]Department of Internal Medicine, [2]Division of Hematology, [3]Department of Laboratory Medicine and Pathology, [4]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence *in situ* hybridization (FISH) at the time of diagnosis is essential for initial risk stratification and the employment of risk-adapted treatment strategies in multiple myeloma. Despite

the absence of cytogenetic high-risk abnormalities a subset of patients does experience poor overall survival.
Aims: To identify demographic, clinical, and cytogenetic characteristics associated with poor three-year overall survival in patients with standard-risk cytogenetics.
Methods: We studied 514 patients who were diagnosed with multiple myeloma between January 2004 and December 2015 at Mayo Clinic Rochester and underwent FISH evaluation within six months of diagnosis. Patients with high-risk cytogenetics and those who were lost to follow-up within three years were excluded. High-risk cytogenetics were defined as the presence of del(17p), t(4;14), t(14;16), or t(14;20). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to five potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Multivariable-adjusted logistic regression models were used to assess the associations between the parameters of interest and three-year overall survival.
Results: The median age at diagnosis was 65 years (31-95), 316 (62%) of the patients were male. The median overall survival was 6.4 years (5.5-7.7) for the entire cohort (n=514), 9.2 years (8.3-10.4) for those who survived at least three years (n=361, 70%), and 1.2 year (1.0-1.5) for those who did not survive three years after diagnosis (n=153, 30%). The factors associated with poor three-year overall survival are summarized in Table 1.

Table 1. Factors associated with poor three-year overall survival (n=514).

Parameter	Value	OR (95% CI)	p
Age	Older than 65 years at diagnosis	2.80 (1.80-4.36)	<0.001
Plasma cells	Less than 20% in bone marrow	2.00 (1.12-3.60)	0.020
Karyotype	Hyperdiploid clone present	0.51 (0.33-0.79)	0.003

The model was adjusted for sex, β_2-microglobulin, and albumin at diagnosis.

Summary/Conclusions: Patients with multiple myeloma and standard-risk cytogenetics are a heterogeneous group. One third of the patients are experiencing less than three years of overall survival after diagnosis. Advanced age, extent of bone marrow involvement, and specific clonal abnormalities were associated with poor three-year overall survival. These findings emphasize the importance of further risk stratification and the need for reliable predictors of poor clinical outcomes in this patient population.

Myeloproliferative neoplasms - Clinical 2

Background: A distinct subcategory of the WHO 2008 classification of myeloid neoplasms comprises myeloid/lymphoid neoplasms with eosinophilia (MLN-eo) and rearrangements of PDGFRA, PDGFRB or FGFR1. Patients with PDGFRA or PDGFRB fusion genes are exquisitely sensitive to imatinib.
Aims: We sought to evaluate the clinical characteristics and long-term outcome on imatinib in MLN-eo patients (pts) with PDGFRB fusion genes.
Methods: Within the "German Registry on Disorders of Eosinophils and Mast Cells" 22 MLN-eo pts with PDGFRB fusion genese were retrospectively analysed.
Results: Fifteen different fusion genes were identified; three partner genes were recurrent (ETV6, n=5; CDCC88C, n=3; H4, n=2). Median age was 49 years (range 20-80) with a striking male predominance (20/22, 91%). Significant eosinophilia ≥0.5x10^9/l and ≥1.5x10^9/l was present in 15/19 (79%) and 11/19 (58%) pts, respectively, monocytosis >1.0x10^9/l (median 0.5x10^9/l, range 0-89) was seen in 5/15 pts (33%). Splenomegaly was observed in 12/15 (80%) pts, organ involvement in 5/22 (23%) pts including cytologically or histologically confirmed infiltration of pleura (n=2), central nervous system (n=1), endo-/myocard (n=1), liver (n=1) and skin (n=1). Five pts were initially diagnosed in blast phase (BP): myeloid BP (n=1), extramedullary myeloid sarcoma (n=1), T-cell lymphoblastic lymphoma (n=2) and B-cell acute lymphoblastic leukemia (n=1). Four pts (chronic phase, CP, n=2; BP, n=2) presented with a complex karyotype. All 17 CP pts were treated with imatinib (400mg/d, n=12, 71%; 100 mg/d, n=5, 29%) and achieved complete hematologic remission (CHR); no primary resistance was observed. Complete cytogenetic remission was achieved in 10/11 (91%) evaluated pts after median 11 months (range 3-34) and complete molecular remission (CMR), as detected by negative nested RT-PCR, in 10/12 pts (83%) after median 23 months (range 8-110). Imatinib was reduced from 400 mg/d to 100mg/d in 7/12 pts and to 3x100mg/week in two pts. After a median treatment of 7 years (range 0-11), 15/17 pts are alive. One CP patient with a complex karyotype achieved a CHR for 13 months but no cytogenetic remission and died due to progressive disease. The second CP patient died because of comorbidity while in CHR. One patient in BP with secondary T-cell lymphoma received intensive chemotherapy followed by imatinib and died due to comorbidity at month 27, while the second patient is alive on imatinib monotherapy 97 months after diagnosis. Three pts (complex karyotype, n=2) received an allogeneic stem cell transplantation (SCT) after intensive chemotherapy or a short course of imatinib median 3 months (range 1-7) after diagnosis. Two pts were re-exposed to imatinib because of residual disease. Two pts are alive 3 and 42 months after SCT, respectively. The third patient died due to progressive leptomeningeal involvement while in CHR on imatinib 9 months after SCT. Overall, 4/22 pts (18%) have died (BP, n=2; CP, n=2) due to comorbidity while in remission (n=2) or progressive disease (n=2). Of note, 3 of these 4 pts had an additional complex karyotype at diagnosis.
Summary/Conclusions: We here confirm known and report several new clinical and genetic characteristics in pts with MLN-eo and PDGFRB fusion genes: i) significant male predominance, ii) significant eosinophilia is not present in all pts (in contrast to FIP1L1-PDGFRA, but similar to FGFR1 fusion genes), iii)

except splenomegaly, organ involvement/dysfunction is rather uncommon, iv) pts can present in BP of myeloid or lymphoid origin, v) an additional complex karyotype may be associated with adverse prognosis, vi) in CP, no primary resistance to imatinib was observed and vii) pts can be treated with imatinib 100mg/d.

THROMBOTIC RISK IN IDIOPATHIC ERYTHROCYTOSIS IS LOWER THAN IN POLYCYTHEMIA VERA BUT HIGHER THAN IN GENERAL POPULATION

ML Randi[1,*], M Ruggeri[2], I Bertozzi[1], I Nichele[2], G Biagetti[1], E Cosi[1], F Fabris[1]
[1]Dept of Medicine - DIMED, University of Padua, Padova, [2]Hematology, San Bortolo Hospital, Vicenza, Italy

Background: Absolute erythrocytosis is a relatively rare finding in the clinical practice, characterized by persistently raised hemoglobin (Hb) and hematocrit (Ht) levels. The most extensively studied form of absolute erythrocytosis is Polycythemia Vera (PV), a primary neoplastic disease characterized by the presence of JAK2 mutations, risk of vascular complications and of evolution in myelofibrosis or acute leukemia. Secondary erythrocytosis are represented by rare congenital diseases (due to EPO-receptor or oxygen sensing pathway genes mutation), acquired forms, [erythropoietin (EPO)-mediated] or idiopathic erythrocytosis (IE) an absolute and isolated polyglobulia, without any definite cause, not JAK2 mutations, not EPO-mediated. These patients are rarely observed in clinical practice, thus few is known regarding their clinical characteristics, natural history and best management.
Aims: In this work, we report clinical features of a large cohort of patients with IE focusing on their thrombotic risk compared with a cohort of patients with PV.
Methods: We report 145 patients with IE (not carrying any JAK2 mutation nor affected by congenital/familial or secondary erythrocytosis) studied between 1980 and 2015 in two centers of Venetian region Italy. As controls we used 145 patients with PV all carrying JAK2 mutations, diagnosed in the same period and matched for Ht values. All patients were treated with phlebotomies, to maintain Ht below 45%. In all these patients, we collected disease-relevant parameters, including blood count at diagnosis and major events during follow-up. Statistical analysis was performed by using the Mann-Whitney test, the $\chi 2$ test or Fisher's exact test and the Kaplan-Meier method.
Results: Results are summarized in the following Table 1.

Table 1.

	IE	PV	p
Patients, n	145	145	-
Males, n (%)	127 (87.6)	83 (57.2)	<0.001
Median age at diagnosis, years (Percentile range, 5th to 95th)	56.5 (21.2-75.8)	61.7 (30.3-81.9)	0.006
Median Follow up, years (Percentile range, 5th to 95th)	6.6 (0.3-23.2)	7.4 (0.3-22.1)	n.s.
Median WBC, x10^9/L (Percentile range, 5th to 95th)	7.2 (5-11.9)	8.7 (5.7-17.3)	<0.001
Median Hb, g/L (Percentile range, 5th to 95th)	179 (164-195)	175 (149-213)	0.03
Median Ht, % (Percentile range, 5th to 95th)	52.8 (48.3-57.8)	53.1 (46.2-66.2)	n.s.
Median plts count, x10^9/L (Percentile range, 5th to 95th)	217 (132-320)	485 (209-882)	<0.001
Patients with at least a thrombosis, n (%)	21 (14.5)	39 (26.9)	0.01

During follow-up, 15 patients with IE (10.3%) and 27 with PV (18.6%) experienced at least a thrombotic complication (p=0.04), with a dramatically different Thrombosis Free survival (p=0.005). Arterial thromboses were 13 among patients with IE and 12 in patients with PV. The thrombotic incidence rate was 3% patients/year in PV and 1.5% patients/year in IE (IRR=2).
Summary/Conclusions: IE, is a poorer studied disease. The clinical picture (*i.e.* vascular complications during follow-up and final outcomes) are not fully investigated. PV, a well-studied disease, has an estimated cumulative thrombosis rate of about 4% patients/year not different than our finding in the present cohort. In this study, we demonstrate that patients with IE develop fewer thrombotic complications than patients with PV. However, IE, in spite of a stringent program of phlebotomy, absence of leukocytosis and/or thrombocytosis, maintain higher thrombosis rate (1.5% patients/year) when compared to general population (around 0.8% persons/year). The present data suggest that IE has an increased thrombotic risk even if lower than PV, showing that the rheological alteration due to high Ht play a relevant role even in the absence of a clonal disease. Moreover, taking into account that most cardiovascular complications are represented by arterial thrombosis, prophylaxis with aspirin should be considered, in absence of contraindications.

P668

AZACITIDINE IN THE TREATMENT OF PH- MYELOPROLIFERATIVE NEOPLASMS IN BLASTIC PHASE: THE EXPERIENCE OF GRUPPO LAZIALE FOR THE STUDY OF PH- SMPC

A Di Veroli[1,*], B Anaclerico[2], N Villivà[3], P Niscola[4], M Montanaro[5], G Cimino[6], MT Voso[1], M Trawinska[4], A Andriani[3], L Fianchi[7], M Breccia[8], R Latagliata[9]
[1]Hematology, University Tor Vergata, [2]Hematology, San Giovanni Hospital, [3]Hematology, Nuovo Regina Margherita Hospital, [4]Hematology, Sant'Eugenio Hospital, Rome, [5]Hematology, Belcolle Hospital, Viterbo, [6]Hematology, Polo Universitario Pontino, Latina, [7]Hematology, Catholic University of Sacred Heart, [8]Department of Cellular Biotechnologies and Hematology, University Sapienza, [9]Cellular Biotechnologies and Hematology, Policlinico Umberto I, Rome, Italy

Background: Prognosis of patients with myeloproliferative neoplasms (MPN) developing blast phase (MPN-BP) is very poor. Median overall survival (OS) of these patients is about 2-3 months and nowadays no drug can induce a durable complete response (CR) in patients who are not candidate to Bone Marrow Transplantation (BMT).
Aims: We retrospectively evaluated 27 patients (M/F 19/8, median age 62.5 years, range 30.8-80.6) with MPN-BP according to international criteria treated with azacytidine (AZA) in the last 7 years, to highlight the role of AZA in this subset. Data were obtained from database of Gruppo Laziale for the study of Ph- SMPC.
Methods: Primitive MPN diagnosis was Essential Thrombocythemia in 9 cases, Primary Myelofibrosis in 9, Polycythemia Vera in 5 and MPN-U in 4; the JAK-2 V617F mutation was present in 17/25 patients tested (68%); all but 2 patients received a previous treatment during chronic myeloproliferative phase [18 patients with Hydroxyurea (HU) alone, 1 with HU and Anagrelide, 4 with HU and Pipobroman, 1 with Melphalan followed by allo-BMT, 1 with Pipobroman alone]. Median time from diagnosis to BP evolution was 59.6 months (range 1-312). All patients were treated with 5-AZA at the dosage of 75 mg/m^2: as to the schedule, 24 patients received a 7-day schedule and 3 patients a 5-day schedule every 28 days. At the time of evolution, median WBC value was 12.8x10^6/L (range 2.2-89.5 X 10^6/L), median Hb level 9.8 g/dl (range 6.6-12.7 gr%) and median PLT value 183.5x10^6/L (range 9-846x10^6/L).
Results: Two pts were too early (only 1 cycle still performed) while 8/25 evaluable pts (32%) achieved a CR after a median time of 5 months (range 3-12) from AZA start, 2 pts (8%) had a partial response (PR), 4 pts (16%) had an hematological improvement (HI), with a 56% global response rate: the remaining 11 pts (44%) had no response (9 pts had a disease progression and 2 died early after AZA initiation from pulmonary fungal infection and respiratory failure respectively). The median OS from BP evolution of the whole cohort was 9.9 months (95% CI 7.0-12.8): the median OS of responding pts (CR+PR+HI) was 18.6 months (95% CI 8.4-28.8) compared with 4.9 months (95% CI 0.9-8.8) of resistant pts (p<0.001).
Summary/Conclusions: Our data confirm the relative efficacy and safety of AZA compared to historical controls in this group of patients with otherwise dismal prognosis, underlining the possible achievement of long-lasting responses in a sizeable portion of them.

P669

COMPARISON OF GENOMIC DNA-BASED *VS* MESSENGER RNA-BASED KIT D816V MUTATION ANALYSIS REVEALS LARGE DIFFERENCES BETWEEN BLOOD AND BONE MARROW IN SYSTEMIC MASTOCYTOSIS

T Kristensen[1,*], S Broesby-Olsen[2], H Vestergaard[3], C Bindslev-Jensen[2], MB Møller[1]
[1]Department of Pathology, [2]Department of Dermatology and Allergy Centre, [3]Department of Hematology, Odense University Hospital, Odense C, Denmark

Background: Mastocytosis is a heterogeneous group of diseases characterized by growth and accumulation of neoplastic mast cells (MCs). Mastocytosis often represents a diagnostic challenge. The vast majority of adults with mastocytosis carry the activating somatic *KIT* D816V mutation. Recent advances in *KIT* D816V mutation analysis allow detection of the mutation in peripheral blood (PB) in most patients. Mutation analysis of PB is therefore increasingly used for screening in suspected mastocytosis. A very high sensitivity is needed to produce clinical meaningful diagnostic yields in indolent SM (ISM) in both PB and bone marrow (BM) aspirate. *KIT* D816V mutation analysis may be based on genomic DNA (gDNA) or the expressed messenger RNA (mRNA). Depending on *KIT* gene expression levels of the D816V-positive cells, mRNA-based analysis is potentially more sensitive than gDNA-based analysis. However, very limited experimental evidence comparing these two approaches presently exists.
Aims: To systemically compare gDNA-based and mRNA-based *KIT* D816V mutation analysis of PB and BM aspirate in SM patients to determine the optimal technical approach.
Methods: In 82 SM patients (76 ISM (including 3 BMM and 4 SSM) and 6 SM-AHNMD), gDNA-based and mRNA-based *KIT* D816V mutation analysis of PB was performed. In 65 patients, BM aspirate was also analyzed.
A highly sensitive *KIT* D816V mutation-specific qPCR assay was used for both gDNA-based and mRNA-based analysis. Importantly, gDNA-based analysis

was performed with gDNA from 50.000 cells per reaction and mRNA-based analysis was performed with cDNA from mRNA from 50.000 cells, thus allowing non-biased comparison of the two approaches.
Results: In mRNA-based analysis, PB from 24 of the 82 patients (29%) fulfilled criteria of positivity. In gDNA-based analysis, 77 of the 82 (94%) samples tested D816V-positive, thus demonstrating a higher diagnostic yield with gDNA in PB samples (chi^2-test: P<0.001). The gDNA-based D816V-positive allele burden was significantly higher in PB samples that tested positive in the mRNA-based analysis compared to samples that tested negative in mRNA-based analysis (median allele burden 2.8% *vs* 0.051%; Mann-Whitney U-test: P<0.001). In BM aspirate, 64 of 65 samples tested D816V-positive in mRNA-based analysis, whereas all 65 samples tested positive in gDNA-based analysis (chi^2-test: P=0.32). While the diagnostic yield was thereby high in BM aspirates in both gDNA-based and mRNA-based analysis, the confidence of mRNA-based results was significantly higher than gDNA-based in samples with low mutation levels as calculated from the absolute threshold cycle (C_t) values of the qPCR analysis.
Summary/Conclusions: Previous studies performing *KIT* D816V mutation analysis of PB in ISM have reported highly different diagnostic yields. The reported differences may be explained by several factors. However, our direct comparison of mRNA-based and gDNA-based analysis indicate that the difference in mRNA-based and gDNA-based analysis is a major determinant of diagnostic yield in PB. Previous inconsistencies are therefore likely to be primarily explained by this parameter. We conclude that gDNA-based *KIT* D816V mutation analysis should always be preferred over mRNA-based in PB in ISM. In addition, mRNA-based *KIT* D816V mutation analysis may have added value in BM aspirates if gDNA-based analysis produces a borderline or weakly positive result, or test unexpectedly negative.

P670

3167 NEWLY DIAGNOSED MPN PATIENTS, A REPORT FROM THE SWEDISH MPN REGISTRY

B Andreasson[1,*], M Lindgren[2], E Ahlstrand[3], J Samuelsson[4]
[1]NU Hospital Group, Uddevalla, [2]Kalmar Hospital, Kalmar, [3]Örebro University Hospital, Örebro, [4]Karolinska Institute at Stockholm South Hospital, Stockholm, Sweden

Background: Newly diagnosed patients with Philadelphia chromosome negative myeloproliferative neoplasms (MPN) are included in the Swedish MPN Registry since 2008.
Aims: The aim was to report incidence, blood values, earlier vascular complications and planned treatment in newly diagnosed MPN patients.
Methods: From January 2008 through December 2014 a total of 3167 were registered. The diagnosing clinics report age, gender, blood values, earlier vascular complications and planned treatment. Registration of cancers is mandatory. About 95% of MPN were reported to the registry at the time of analysis.
Results: Polycythemia vera (PV) was diagnosed in 1105, essential thrombocythemia (ET) in 1285, myelofibrosis (MF) in 440 and MPN unclassified 337 patients. The annual incidence per 100,000 inhabitants for PV was 1.7, for ET 1.9, for MF 0.66 and for MPN unclassified 0.53. The median age at diagnosis was lowest for ET, 68 years, for PV was 69 years, for MF and MPN unclassified 70 years. In PV and MPN unclassified the proportion of men and women were equal, in ET there was a female predominance (58%), whereas 55% of the MF patients were male. The blood values at diagnosis are presented in Table 1.

Table 1.

	Gender female/male	Age±years	Hemoglobing/dL	Hematocrit %	WBC x10^9/L	Platelets x10^9/L	EPOU/L	JAK2 V617F/wt	Vascular complicationyes/no
PV	550/555	68±13	17.2±2.2	53±7	12.7±9.8	569±285	3.1±3.9	988/22	407/708
ET	745/540	65±16	13.8±1.5	42±5	9.7±5.3	859±337	9±20	708/400	446/825
MF	198/242	69±13	11.3±2.1	38±7	12.0±10.3	490±394	59±112	206/158	115/325
MPN uc	165/172	69±15	12.8±2.8	40±8	20.1±32.5	583±415	30±103	178/103	124/228

The prevalence of vascular complications prior to MPN diagnosis was highest for the PV, ET and MPN unclassified, 37%, 35% and 34% respectively. The MF patients had significantly lower prevalence, 26% (p<0.001 compared with PV and ET, p=0.018 compared with MPN unclassified). The time from a previous vascular event to diagnosis was not reported in the registry. The majority of complications were thromboembolic; 32% of PV patients, 30% of ET patients, 28% of MPN unclassified patients and 20% of MF patients. The corresponding frequencies for hemorrhagic events were 5%, 5%, 8% and 7%, respectively. The most frequent vascular events were of cerebral, cardiac and deep vein thrombosis/pulmonary embolism. ET patients with reported vascular complications had a significantly lower hemoglobin and hematocrit (p=0.002 and p=0.005, respectively) and higher WBC count (p=0.031), whereas the platelet concentration was comparable in patients with or without recorded complication. JAK2 V617F mutation was present in 71% of ET patients with vascular complications prior to diagnosis, compared to 60% of the patients without complications (p<0.001). Also, the PV patients with earlier reported vascular events had a significantly higher mean age, lower hemoglobin and hematocrit at diagnosis compared to patients without vascular complications (p<0.001, respectively). Myelosuppressive treatment was planned in 66.6% of the ET patients compared to about 50% of the patients with PV, MF and MPN unclassified (p<0.001, respectively). Phlebotomy treatment was planned in 82% of the PV patients. Transfusion was planned to be given to 16% and EPO to 13% of the MF patients. ASA prophylaxis was recorded for about 60% of the PV and ET patients, compared to about 30% of the MF and MPN unclassified patients.
Summary/Conclusions: ET and PV were the most common MPN entities, 40% and 35% respectively. JAK2 V617F mutation was present in 98% of PV patients and in 57-64% in the other MPN etities. Reported vascular complications prior to diagnosis were common, especially in PV, ET and MPN unclassified. The majority of events were thromboembolic.

P671

PREDICTIVE ROLE OF CIRCULATING LEUCOCYTE-PLATELET AGGREGATES FOR THROMBOEMBOLIC COMPLICATIONS IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A PROSPECTIVE STUDY

D Šefer[1,*], P Miljić[1,2], N Kraguljac-Kurtović[1], S Bižić-Radulović[1], V Čokić[3], D Marković[3], B Beleslin-Čokić[4], I Novaković[2,5], J Erić-Marinković[2,6], D Leković[1,2], J Bodrožić[1], M Gotić[1,2]
[1]Outpatient Clinics and Diagnostic Department, Clinic for Hematology,Clinical Center of Serbia, [2]Medical School, University of Belgrade, [3]Institute for Medical Research, University of Belgrade, [4]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, [5]Institute for Human Genetics, University of Belgrade, [6]Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Thrombosis represents the main complication in Philadelphia negative myeloproliferative neoplasms (Ph$^-$MPN). It is supposed that inappropriate activation of leukocytes and platelets with their mutual interaction represents an important mechanism of thrombosis tendency in these diseases. The role of circulating leukocyte-platelet (Le-Plt) aggregates as risk factor for thrombosis in Ph$^-$MPN has been investigated so far in retrospective studies which included significant proportion of patients (pts) on antiplatelet or cytoreductive therapy.
Aims: The aim of our prospective study was to investigate the predictive value of circulating neutrophyle-platelet (Neu-Plt) and monocyte-platelet (Mo-Plt) aggregates as well as soluble selectins for occurence of thromboembolic events in pts with Ph$^-$MPN.
Methods: The study included 95 consecutive pts with *de novo* Ph$^-$MPN (39 polycythemia vera, 27 essential thrombocythemia, and 29 primary myelofibrosis), diagnosed according to WHO criteria. All analysis were performed after diagnosis, and before the start of antiplatelet or cytoreductive therapy. Flow cytometric analysis of Le-Plt aggregates was performed on whole blood samples anticoagulated with EDTA/CTAD. Le-Plt aggregates were estimated as a fraction (%) of CD42b$^+$CD61$^+$ neutrophyles and monocytes. The plasma levels of E-, L-, and P-selectins were determined by enzyme immunoassay. All arterial and venous thrombotic events, except microcirculatory disturbances, were recorded during mean follow-up period of about 3.25 years after diagnosis.
Results: During the follow-up thromboembolic complications occurred in 12.6% Ph$^-$MPN pts (arterial in 9.4%, venous in 3.2%), with mean time to thromboembolic event of 39 months. The overall incidence rate of main thrombotic events in whole group of Ph$^-$MPN during the follow-up was 4.36 per 100 pts-years. The levels of Neu-Plt (26.7% *vs* 22.4%) and Mo-Plt (17.8% *vs* 12.3%) aggregates did not differ significantly between groups of pts with and without thrombosis. Using multivariate COX proportional hazard regression model, it was proved that Mo-Plt aggregates represent independent predictive factor for thrombosis development (HR=1.561, 95% CI: 1.007-2.420, p=0.046). Frequency of HTA was significantly higher in group of Ph$^-$MPN pts with thrombosis compared to those without thrombosis (p<0.05), and multivariate COX proportional hazard regression model confirmed that interaction between Mo-Plt aggregates and HTA may be additive (HR=1.975, 95%CI: 1.215-3.212, p=0.006). The level of soluble P-selectin was significantly higher in group of Ph$^-$MPN pts with thrombosis than in group of pts without thrombosis (346.89 ng/ml *vs* 286.39 ng/ml, p=0.034), but has not been proved as a predictive risk factor for occurrence of thrombosis (COX proportional hazard regression model). The levels of E- and L-selectin did not differ significantly between Ph$^-$MPN groups, according to the presence of thrombosis.
Summary/Conclusions: This is the first prospective study investigating predictive role of Le-Plt interactions on occurence of thromboembolic complication in Ph$^-$MPN. Among several investigated parameters, only increased level of Mo-Plt aggregates was shown as independent predictive risk factor for development of thromboembolic complications. Concomitant presence of HTA further strengthens predictive role of Mo-Plt aggregates. Since the reduction of thrombotic risk is a primary goal of therapy in Ph$^-$MPN, special attention should be paid to the treatment of HTA.

Emanuele", Catania, [16]Division of Hematology, Città della Salute e della Scienza Hospital, Turin, [17]Institute of Hematology "L. and A. Seràgnoli", Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Background: Response to ruxolitinib (RUX), the only JAK1/2 inhibitor commercially available for the treatment of Myelofibrosis (MF) may vary among patients (pts) and is largely unpredictable at therapy start. Due to the lack of predictors of response, pts' selection is based on clinical needs.
Aims: To evaluate the impact of pre-treatment clinical/laboratory factors, as well as RUX dose, on response to RUX in a cohort of "real-life" MF pts.
Methods: A multicenter observational study on WHO-defined MF was conducted in 11 Italian Hematology Centers. Data were extracted from an electronic database that included retrospective data on pts treated before January 2015. Response to RUX was evaluated according to IWG-MRT criteria.
Results: Between June 2011 and June 2015, 266 pts with PMF (140 pts,52.6%), or PET-MF (51,19.2%) or PPV-MF (75,28.2%) were treated with RUX in participating Centers. At diagnosis, baseline characteristics were (median): age, 64.2 y (range, 26-86); ≥65 y, 45.5%; male, 58%; hemoglobin (Hb), 11.5 g/dL (5-17.7); Hb <10 g/dL, 27.4%; PLT, 356×10^9/L (30-1110); PLT <100×10^9/L, 5.2%; spleen enlargement, 87.5% (spleen length ≥10cm: 40.6%); constitutional symptoms, 48.8%. Molecular analysis was performed on 215 pts (81%) and was positive in 90% (*JAK2*V617F), 7% (*CALR*), 1% (*MPL*W515K/L); 2% (triple negative). Karyotype was abnormal in 43 (30%) out of 145 evaluable pts (unfavorable: 9%). Median follow-up from MF diagnosis was 4 yr (0.5-29.6) and median RUX exposure was 22 mos (3-54). Overall, 92 out of 232 (39.7%) pts with spleen ≥5cm achieved a spleen response at any time during RUX therapy (Table 1).

Table 1. Patients characteristics at RUX start.

Characteristics	Spleen response (n.92)	No spleen response (n.140)	p
Male sex, no. (%)	59 (64.1%)	80 (57.1%)	*0.28*
PMF, no (%)	48 (52.2%)	72 (51.4%)	*0.91*
JAK2 V617F mutation, no (%)	74 (93.7%)	95 (88%)	*0.59*
Median age, years (range)	67 (26-86)	68 (26,3-87)	*0.30*
Median hemoglobin, g/dl (range)	12 (5,9-17,3)	10.1 (4-17,3)	***0.0007***
Median leukocyte, x10^9/l, (range)	12,3 (1,2-106,9)	9,2 (1,6-57,5)	***0.0068***
Median platelet, x10^9/l (range)	322 (15-1657)	211 (4-2513)	***0.0006***
Constitutional symptoms, no (%)	44 (47.8%)	72 (51.4%)	*0.42*
Spleen ≥ 10cm, no (%)	46 (50%)	96 (68.6%)	***0.005***
Palpable hepatomegaly, no (%)	24 (26.1%)	32 (27.4%)	*0.87*
Unfavorable karyotype, no (%)	5 (10.9%)	6 (7.3)	*0.49*
Grade 3 marrow fibrosis, no (%)	10 (13%)	27 (27%)	***0.02***
Platelet <100	6 (6.5%)	15 (10.7%)	*0.27*
Platelet >200	63 (68.5%)	76 (54.3%)	***0.03***
Age >65 yrs, no (%)	54 (58.7%)	91 (65%)	*0.33*
Transfusion dependence, no (%)	16 (20%)	41 (33.1%)	***0.04***
Previous cytoreductive therapy, no (%)	59 (64.1%)	106 (75.7%)	*0.09*
Time from MF diagnosis to RUX start (range)	1 (0.3-27.5)	2.2 (0.3-30.1)	***0.001***

At 3 and 6 mos, the response was achieved by 28.1% and 31% of evaluable pts, respectively. In univariate analysis, pre-treatment factors negatively correlating with spleen response were: transfusion dependence, platelet count ≤200x10^9/l, spleen palpable ≥10 cm below costal margin, grade 3 marrow fibrosis and interval between MF diagnosis and RUX start ≥2y. Also, the rate of spleen response significantly correlated with RUX starting dose, with 18.5%, 33.8% and 47.7% of responses observed in pts treated with 5mg BID, 15mg BID and 20mg BID, respectively (p=0.008). Also, spleen response correlated with the average RUX dose in the first 12 wks, with pts treated with doses ≥10 mg BID having better response rates (44.4% *vs* 25.4% in pts treated with ≤10 mg BID, p=0.01). Three variables remained significant in multivariate regression logistic analysis: large splenomegaly (HR:2.01, 95%CI:1.1-3.1;p=0.015), time between MF diagnosis ≥2y (HR:1.8, 95%CI:1.0-3.2;p=0.037) and median RUX dose ≤10mg BID in the first 12 wks (HR:2.29, 95%CI:1.1-4.3;p=0.02).Overall, 178 pts out of 217 symptomatic patients (82%) had a symptom response. Factors associated with worse responses were: grade 3 marrow fibrosis (p=0.035), transfusion dependency (p=0.001) and RUX titrated dose ≤10 mg BID (p=0.014). In multivariate analysis, symptom response rate correlated only with RUX titrated dose (HR:2.4, 95%CI:1.1-4.9,p=0.016). Neither spleen or symptoms response significantly correlated with survival.
Summary/Conclusions: In the real-life setting, IWG-MRT-defined spleen and symptoms response rates were observed in 40% and 70% of pts, respectively. Among pre-treatment features, large splenomegaly and a delay in treatment start ≥2 yrs from diagnosis identified pts with lower spleen response rates. Additionally, median titrated doses ≤10mg BID significantly correlated with poorer spleen and symptoms responses. Overall, these data point out the role of an early treatment in order to achieve better therapeutic results. Also, since drug-induced anemia was not significantly associated with RUX doses, the study supports the importance to start and maintain over time the maximum tolerated RUX dose.

P673

MYELOPROLIFERATIVE NEOPLASIA ASSOCIATED WITH SPLANCHNIC VEIN THROMBOSIS IS CORRELATED WITH DISTINCT CLINICAL FEATURES AND LOW JAK2 V617F ALLELE BURDEN

W Toscano[1,*], J Bryon[2], T Khaguli[1], S Jenkins[3], M Griffiths[2], D Tripathi[4], F Chen[1]
[1]Department of Haematology, University of Birmingham & Queen Elizabeth Hospital NHS Trust, Birmingham B15 2TH, [2]West Midlands Regional Genetics Laboratory, Birmingham Women's Hospital NHS Trust, Birmingham B15 2TG, [3]Department of Haematology, Russels Hall Hospital, Dudley DY1 2HQ, [4]Department of Hepatology, Queen Elizabeth Hospital NHS Trust, Birmingham B15 2TH, United Kingdom

Background: Splanchnic vein thrombosis (SVT) is strongly associated with myeloproliferative neoplasms (MPN) such as Polycythemia Vera (PV), Essential Thrombocythemia (ET), Myelofibrosis (MF). This association was established when routine molecular analysis of JAK2 V6176F mutation was introduced as a diagnostic assessment for MPN. Up to 50% of Budd-Chiari syndrome and 30% of extraepathic thrombosis are associated with the presence of JAK2 V617F mutation. However, 30% of these patients do not meet the WHO criteria for the diagnosis of PV, ET or MF.
Aims: The study aims to compare and contrast the pathophysiological and genotypic features of JAK2 V617F positive SVT patients with those meeting the standard diagnostic criteria for MPN.
Methods: We conducted a retrospective single centre study of 43 patients with JAK2 V617F positive SVT at the Queen Elizabeth Hospital NHS Trust to document the clinical and haematological features of these patients at presentation, their long-term outcome and their JAK2 mutational status and allele burden by quantitative digital droplet PCR.
Results: SVT occurred before MPN was diagnosed according to WHO criteria in 28 out of 43 patients, and in 3 patients a thrombotic event at a different site occurred before onset of MPN. Within this cohort 18 patients were females and 13 were males. The mean age at diagnosis of SVT/ thrombotic event was 35 years (range 22-67). During follow-up 10 patients developed PV (3 female, 7 males), 7 patients developed ET (3 females, 4 males), 9 patients developed U-MPN (7 females, 2 males), 5 patients did not develop a recognisable MPN at their last follow-up. The median hemoglobin at SVT diagnosis was 14.05 g/dL in females and 14.85 g/dL in males, the median WBC was 9.1x10^9/L, the median platelet count at SVT diagnosis was 266x10^9/L. These values would not have met the WHO diagnostic criteria for ET, PV or MF at diagnosis. In this study we considered JAK2 mutational burden in the range of 0-25% as low, 26-74% as intermediate and >75% as high (AM Vannucchi *et al.*). In our cohort, the median JAK2 mutational burden was in the lower range with a median allele burden of 17% (range 0.6-81%). The median JAK2 mutational burden in the patients diagnosed with SVT without developing MPN at their last follow up had a median allele burden of 14% (range 9.9-22%), which is lower than the mutational burden found in PV and PMF (26-50%) and similar to ET (0-22%).
Summary/Conclusions: JAK2 V617+ SVT constitute an early but distinct MPN subtype presenting with young age, unremarkable haematolgical parameters and low JAK2 V617F allele burden.

P674

BONE MARROW MICROVESSEL DENSITY AND PLASMA ANGIOGENIC FACTORS IN BCR-ABL1 NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A STUDY OF 90 PATIENTS WITH CLINICOPATHOLOGICAL AND MOLECULAR CORRELATIONS

D Lekovic[1,2,*], M Gotic[1,2], D Sefer[1], B Beleslin-Cokic[3], N Milic[2,4], O Mitrovic-Ajtic[5], T Suboticki[5], D Markovic[5], M Buac[5], M Diklic[5], N Colovic[1,2], J Bodrozic[1], VP Cokic[5]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical faculty, University of Belgrade, [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, [4]Institute for Medical Statistics, Belgrade, Serbia, [5]Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Increased angiogenesis in BCR-ABL1 negative myeloproliferative neoplasms (MPNs) has been recognized but its connection with clinical and molecular markers needs to be defined.
Aims: The aim of our study was to (1) asses bone marrow (BM) angiogenesis measured by microvessel density (MVD) using two different monoclonal antibodies CD34 and CD105; (2) analyze correlation of MVD with plasma angiogenic factors including vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF) and Interelukin-8 (IL-8); (3) examine the possible association of MVD with clinical, laboratory, morphological and molecular markers.
Methods: We examined serum and BM specimens from 90 patients with MPNs (30 polycythemia vera (PV), 30 primary myelofibrosis (PMF), 30 essential thrombocythemia (ET)) at the time of diagnosis. Ten age-matched patients without hematological disorder were used as controls. MVD was analysed by immunohistochemistry "hotspot" method while serum angiogenic factors VEGF, bFGF and IL-8 were tested by Elisa immunoassay. Mutation analysis of JAK2-V617F, CALR exon 9 was analyzed by DNA sequencing and allelic PCR.
Results: MVD was significantly increased (CD34=37.6±17.6; CD105=30.8±15.3) in whole MPN cohort compared to controls (CD34=19.8±12; CD105=11.7±24.4). MVD was highest in PMF (CD34=44.5±20.3; CD105=38.4±16.9) followed PV (CD34=43.2±15.8; CD105=31.7±13.4) then ET (CD34=26.6±8.9; CD105=24.7±11). Correlation between MVD and plasma angiogenic factors was found in all cases. MVD was significantly increased in patients with JAK2-V617F mutation and correlated with JAK2 mutant allele burden (CD34-MVD: ρ=0.491, p<0.001; and CD105-MVD: ρ=0.276, p=0.02) but regarding CALR mutation no significant MVD differences were detected in whole cohort. MVD analyzed by both antibodies correlated with leukocyte count, serum lactate dehydrogenase, hepatomegaly, and splenomegaly. BM fibrosis was significantly associated with CD34-MVD (p=0.002), CD105-MVD (p=0.008), IL-8 (p=0.001) and JAK2 mutant allele burden (p=0.013). JAK2 homozygote status had positive predictive value (100%) for BM fibrosis. Patients with prefibrotic PMF (CD34-MVD=39.1±13.4, CD105-MVD=37.1±14.4) had significantly higher MVD then patients with ET (CD34-MVD=26.6±8.9; CD105-MVD=24.7±11) (p<0.001).
Summary/Conclusions: This study highlights the strong correlation of MVD with plasma angiogenic factors, JAK2 mutant allele burden and BM fibrosis in MPNs. We identified specific angiogenic factors, which correlated with BM fibrosis. According to our results, we could recommend MVD to be additional histopathological marker to distinguish ET from prefibrotic PMF.

P675

ANAGRELIDE CONTROLLED RELEASE (GALE-401) SAFETY PROFILE CONSISTENTLY WELL TOLERATED IN MYELOPROLIFERATIVE NEOPLASMS PATIENTS AND HEALTHY VOLUNTEERS

S Verstovsek[1,*], M Saltzman[2], S Dakhil[3], J Lee[4], L Chance[4], P Gildden[4], A Pilgrim[5], S Flores[4], V Fernandez[4], B Nejadnik[4], G Choy[4]
[1]University of Texas, MD Anderson Cancer Center, Houston TX, [2]Innovative Medical Research of South Florida, Miami FL, [3]Cancer Center of Kansas, Wichita KS, [4]Galena Biopharma Inc., San Ramon CA, [5]BioVascular, Inc., San Diego CA, United States

Background: The most frequently reported AEs leading to treatment discontinuation with anagrelide (Agrylin®, Shire) were headache, diarrhea, edema, palpitations, and abdominal pain. Of the 942 subjects treated with anagrelide for a mean duration of approximately 65 wks, 161 (17%) were discontinued due to AEs or abnormal laboratory test results (PI, Agrylin). These effects may be attributable to anagrelide's inhibitory effects on human PDE3. Modification of the PK profile of anagrelide to reduce peak plasma levels while maintaining therapeutic blood levels may offer a means to retain platelet lowering activity while reducing potential side-effects. In the Phase 1 HV study, BIO-ANA101, 2 such novel controlled release formulations of anagrelide (CR and IR/CR) were compared with the EU marketed formulation (Xagrid®, Shire) in a single dose cross-over study at a dose of 0.5 mg. The CR formulation demonstrated C_{max}/$AUC_{0\text{-}inf}$ values that were 23%/72% of Xagrid's, respectively leading to the development program of anagrelide CR (GALE-401).
Aims: Characterize the safety profile of GALE-401 in HV and MPN subjects.
Methods: To date, 98 HV and 18 MPN subjects have been enrolled among 5 Phase 1 clinical trials (BIO-ANA101, 102, 103, 104, 105) and a Phase 2 single arm, open label pilot study (NCT02125318) of GALE-401, respectively. All studies were conducted in accordance with ICH Guidelines and GCP principles. Safety events were compared across HV *vs* MPN subjects treated with GALE-401 compared to historical Agrylin published data.
Results: In the HV studies, single and multiple doses of GALE-401 were safe and well tolerated and there were no clinically relevant changes in vital signs, ECGs, and safety laboratory parameters other than a reduction in platelet counts. The most frequent TEAEs reported included headache, pain in extremities or back, palpitations and gastrointestinal disturbances. In particular, in BIO-ANA105, with 20 subjects randomized to receive either GALE-401 or Agrylin (0.5 mg BID for 7d) after which they were washed out for a minimum of 21d and received the alternative drug product for an equal period, the overall AEs considered by the Investigator to be related to treatment were observed [GALE-401 (7 events/6 subjects) *vs* Agrylin (12 events/8 subjects)]. With the exception of GI disorders (15%, GALE-401 *vs* 10.5%, Agrylin), the incidence of TEAEs across SOCs was higher during Agrylin treatment compared to GALE-401 treatment. In the Phase 2 MPN study, subjects treated with GALE-401 exhibited fewer of the more common AEs associated with Agrylin (cardiac; general; gastrointestinal; respiratory, thoracic, and mediastinal; skin and subcutaneous tissue; nervous system) or equivalent (musculoskeletal and connective tissue) AEs associated with Agrylin. Some of the less common AEs of Agrylin were comparatively more frequent for GALE-401 (vascular; hepatobiliary; blood and lymphatic). Additionally, fewer moderate to severe (Grade 3/4) AEs and fewer AEs per patient (2.3 *vs* 3.3) were observed with GALE-401 *vs* Agrylin, respectively. Further, based on treatment discontinuation due to an AE, 5 subjects who were previously intolerant to Agrylin (because of AEs) have continued their treatment with GALE-401. Overall, 3 of these 5 subjects were on study for a longer duration [mean time on study, 106d, (47–196d)] compared to their experience with Agrylin prior to enrollment into the Phase 2 study (~7d). Two subjects (40%) have remained in the study and have been able to continue their treatment with GALE-401 for 15 and 22m, respectively. Given this information, GALE-401 seems to confer an improved overall safety profile and potentially offers patients improved tolerability compared to the licensed product.
Summary/Conclusions: Across HV and MPN subjects, GALE-401 consistently demonstrated a well-tolerated safety profile. Moreover, in a small subset of subjects enrolled in the Phase 2 MPN pilot study, some previously treated Agrylin intolerant subjects, demonstrated a continued prolonged clinical benefit with GALE-401. A randomized trial comparing Agrylin *vs* GALE-401 is needed, alternatively or together with a trial evaluating Agrylin intolerant subjects is warranted.

[1]Kyoto University, Kyoto, [2]University of Miyazaki, Miyazaki, [3]Nagasaki University, Nagasaki, [4]The University of Tokyo, Tokyo, [5]Nagoya Medical Center, Nagoya, [6]Kumamoto University, Kumamoto, [7]University of Miyazaki, Kyoto, [8]Sasebo City General Hospital, Sasebo, [9]National Cancer Center Hospital, [10]Showa University School of Medicine, Tokyo, [11]Kanazawa University, Kanazawa, [12]Tokyo Metropolitan Ohtsuka Hospital, [13]National Cancer Center Research Institute, Tokyo, Japan

Background: Adult T-cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm associated with human T-cell leukemia virus type-1 retrovirus. ATL includes a heterogeneous group of patients with regard to pathological and clinical features as well as prognosis, suggesting the presence of underlying molecular pathogenesis that can account for such heterogeneity among patients. Recently, through an integrated molecular analysis of a large cohort of ATL cases, we delineated the complete registry of genetic alterations in ATL.
Aims: We sought to analyze possible associations between these genetic/epigenetic lesions and clinical/pathological phenotypes in a large set of ATL patients, especially focusing on the impact of mutations and copy number alterations (CNAs) on clinical outcome.
Methods: We investigated a total of 361 ATL samples, including acute (n=192), lymphoma (n=66), chronic (n=89), and smoldering (n=14) subtypes, for recurrent mutations and CNAs, and assessed their impact on disease phenotypes and prognosis.
Results: Aggressive (acute and lymphoma) subtypes were characterized by a higher number of mutations and focal amplifications/deletions, hyperploid status, and CIMP phenotype, compared with indolent (chronic and smoldering) tumors. Two mutations (*TP53* and *IRF4*) and eight focal deletions involving 1p13 (*CD58*), 6p21 (*HLA-B*), 9p21 (*CDKN2A)*, 10p11 (*CCDC7*), 13q32 (*GPR183*), 16q23 (*WWOX*), 17p13 (*TP53*), and 19q13 (*CEBPA*), were more common in aggressive ATL than in indolent ATL. In contrast, showing a similar mutational distribution to those found in large granular lymphocytic leukemia, *STAT3* mutations were characteristic of indolent diseases. Next, we examined the impact of mutations and CNAs on prognosis among 215 ATL cases, for which survival data were available. Multivariate analysis revealed that disease subtype (aggressive *vs* indolent) was the most significant predictor of clinical outcome in ATL. Subsequent multivariate analysis showed that within the patients with aggressive ATL, older age (≥70 years), *CCR4* mutations, and 9p24 amplification were independently associated with an inferior outcome. Based on the number of the risk factors, patients with aggressive ATL were classified into three categories showing marked difference in 3-year overall survival (OS) (P <0.001): those with no (OS, 32%), one (18%), and two or more risk factors (0%). Among patients with indolent ATL, we found *IRF4* and *TP53* mutations, 9p24 amplification, and deletions in 9p21 and 10p11 were significantly associated with worse prognosis. Interestingly, these alterations, except for 9p24 amplification, were more frequently found in aggressive ATL. More importantly, based on these risk factors, the patients with indolent ATL can be classified into two major categories showing marked difference in clinical outcomes: patients with no risk factors (OS, 89%) and those with one or more risk factors (OS, 21%) (P <0.001, HR=16.8, 95% CI:5.4-52.5), suggesting that patients with indolent ATL harboring a genetic feature of the aggressive subtypes might represent a genetically and biologically distinct subset, which should be better treated as having an aggressive disease.
Summary/Conclusions: Through comprehensive genetic profiling, we demonstrated that the known subtypes of ATL can be further classified into molecularly distinct subsets characterized by discrete sets of genetic alterations and substantially different prognosis. Our results suggest that genetic profiling can improve the prediction of prognosis in ATL patients and better guide therapy.

P677

HNRNP K: A NOVEL ONCOGENE THAT DRIVES C-MYC-DEPENDENT LYMPHOMAS AS A POTENTIAL THERAPY TARGET

M Gallardo[1,*], MH Hornbaker[2], X Zhang[2], M McArthur[3], T Manshouri[2], J Martinez-Lopez[4], SM Post[2]
[1]Leukemia, MD Anderson Cancer Center, Houston, Spain, [2]Leukemia, [3]Veterinary Medicine & Surgery, MD Anderson Cancer Center, Houston, United States, [4]Hematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: hnRNP K is a versatile molecule that regulates numerous critical cellular process, such as transcription and translation. Recently, we demonstrated that alterations in hnRNP K expression can drive hematological malignancies. Additionally, using reverse phase protein array (RPPA) analyses, we discovered that hnRNP K overexpression correlates with increased c-Myc levels and activation of putative c-Myc targets in patients with hematological malignancies. Likewise, RT-PCR analysis revealed that *HNRNPK* is overexpressed in specific subsets of lymphoma patients. These findings could explain an alternative mechanism by which c-Myc is overexpressed in lymphoma patients without c-Myc alteration.
Aims: The aim of this work is understand the oncogenic potential of *hnRNP K* and evaluate its role in driving c-Myc-dependent lymphomas that do not harbor MYC translocations.
Methods: To directly examine the impact of hnRNP K overexpression on lymphomagenesis, we generated a transgenic mouse model that specifically overexpresses hnRNP K in the B-cell compartment (*Eμ-Hnrnpk*). Phenotypes were characterized by cytokine analyses, CBC, and flow cytometry of serum, blood, and bone marrow. Livers, lymph nodes, spleens, and thymi were measured and molecularly investigated through qRT-PCR, immunohistochemistry, and western blot analyses. Molecular mechanisms were validated using ChIP- and RIP-assays. Malignant lymphoma cells from *Eμ-Hnrnpk* mice were examined for sensitivity to bromodomain inhibitors *in vitro* and *in vivo* assays.
Results: *Eμ-Hnrnpk* mice overexpressed hnRNP K in the B-cell compartment in multiple transgenic lines resulting in a highly penetrant lymphoma phenotype marked by a significant reduction in survival, enlargement of hematopoietic tissues, and dissemination into distant organs (Figure 1A-B). *Eμ-Hnrnpk* mice also display a significant increase in immature lymphoblasts that were transplantable and reproduced the aggressive lymphomas observed in the donor mice (Figure 1C). Together, these results indicate that hnRNP K is an oncogene when overexpressed. Molecularly, we observed a direct correlation between hnRNP K overexpression and elevated c-Myc levels in tissues from transgenic mouse (Figure 1D), as well as in transfected cell lines. RIP analysis demonstrated a directly interaction and causal relationship between hnRNP K overexpression and translation of the *Myc* transcript. In addition to the hnRNP K-mediated activation of the c-Myc pathway, pro-lymphoid cytokines such as IL-9 and CXCL-1 were also elevated in the sera of *Eμ-hnRNP K* mice, resulting in the overexpression/activation of the JAK-STAT pathway. c-Myc is currently an "undruggable target." However, the discovery of small molecules that inhibit the function of Bromodomain and extra terminal (BET) family members (*e.g.* JQ1) have shown efficacy in disrupting c-Myc activities. Using JQ1 and BRD4-Protac (Arvinas®) in *in vitro* and *in vivo* studies, we demonstrate that lymphoma cells from *Eμ-Hnrnpk* mice have a significant reduction of viability *in vitro* with both compounds. Furthermore, engraftment studies using NSG mice showed that JQ1 treatment reduced the percent of engrafted cells compared to mice treated with vehicle alone.

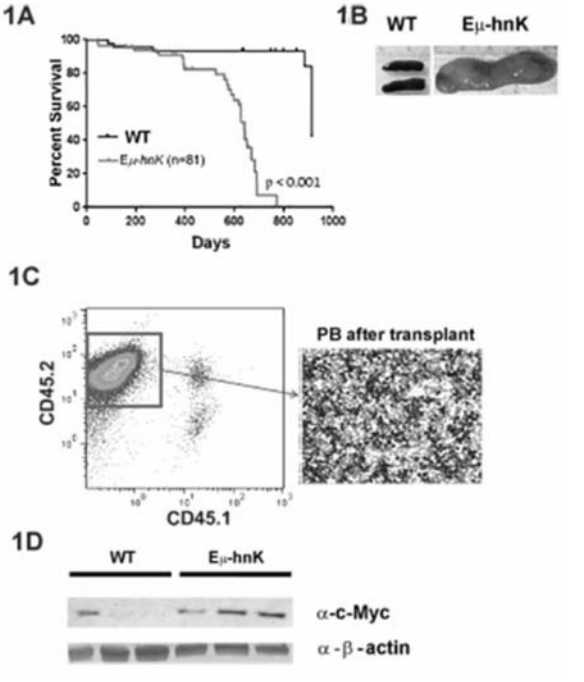

Figure 1.

Summary/Conclusions: We demonstrate for the first time that hnRNP K is a bona fide oncogene with the capacity to drive c-Myc dependent lymphomas. Given our observations that hnRNP K is overexpressed in patients lymphoma, these results suggest that hnRNP K represents a potential biomarker to select patients for target therapies that inhibit c-Myc in the absence of *MYC* translocations or gene amplifications.

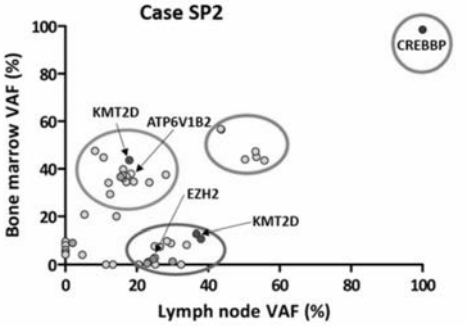
GENOMIC PROFILING REVEALS SPATIAL HETEROGENEITY IN FOLLICULAR LYMPHOMA: IMPLICATIONS FOR PRECISION MEDICINE

S Araf[1,*], J Wang[2], C Pangault[3], E Kotsiou[1], E Hoxha[1], S Iqbal[1], J Davies[1], P Johnson[4], J Gribben[1], T Graham[5], C Chelala[2], T Fest[3], J Fitzgibbon[1], J Okosun[1]
[1]Haemato-oncology, [2]Molecular Oncology, Barts Cancer Institute, London, United Kingdom, [3]Inserm U197 Laboratoire d'hematologie, CHU Rennes, Rennes, France, [4]Cancer Sciences Unit, Cancer Research UK Centre, Southampton, [5]Evolution and Cancer Laboratory, Barts Cancer Institute, London, United Kingdom

Background: Follicular lymphoma (FL) is an incurable B-cell malignancy characterised by advanced disease and a heterogeneous clinical course. Recent temporal analyses of the genetic changes in these tumours suggest that each disease episode evolves from a putative lymphoma-propagating population. These studies have relied on profiling 'single' FL biopsies over several time points, however, multi-site sampling in solid cancers has demonstrated profound intra-tumour heterogeneity. Whether such patterns are seen in FL has not been examined, with their presence likely to complicate precision medicine based initiatives of these lymphomas in the future.
Aims: To measure the extent of genetic diversity in FL by profiling spatially-separated biopsies.
Methods: Eighteen tumour samples from several tissue sources (lymph node, LN; bone marrow, BM; skin, spleen, ascites or pleural effusion) were collected from 7 FL patients (SP1-7) representing 9 distinct episodes of disease (diagnosis (5); progression (2), transformation (2)). FL B-cells and normal T-cells were enriched by fluorescence activated cell sorting (FACS) in the majority of cases. Whole exome sequencing (WES) was performed on tumour and germ-line DNA from all patients (mean coverage 142x). Somatic variants, acquired uniparental disomy (aUPD), copy number alterations (CNAs) were defined using established bioinformatics tools. Variant allele frequencies (VAFs) were used to define the clonal architecture. Validation of variants and CNAs were completed by targeted deep sequencing using the Fluidigm-Miseq platform (>1000x) and multiplex ligation-dependent probe amplification (MLPA) respectively.
Results: Amongst the 18 tumours, we identified a mean of 63 non-synonymous somatic variants (range 34-128). Together with *BCL2-IGH* translocations, mutations in *CREBBP* (7/7) and *KMT2D* (6/7) were shared and clonally represented in all spatially-related samples supporting their roles as early "drivers" of FL. Outside of these 3 aberrations, there was widespread intra-tumour heterogeneity with discordance of variants across spatially-separated sites ranging from 3% - 47%. While these site-specific or private mutations included genes recurrently mutated in FL (*TNFRSF14*, *RRAGC*, *TNFAIP3*), there was variegation in VAFs at predominantly subclonal levels, alluding to their acquisition at different evolutionary time points. In SP2, we observed differential (sub) clonal selection with the p.Y641S *EZH2* mutation preferentially expanded in the LN compared to the corresponding BM, whereas the reverse was the case with a p.R400Q *ATP6V1B2* mutation (Figure 1). This dichotomy in mutation preference suggests that the local microenvironment may impact on the fitness of a particular mutation. CNA analyses mirrored mutational patterns with both shared 16p aUPD (encompassing the locus of *CREBBP*) in 5 of 7 cases but also site-specific alterations observed in 4 of 7 cases. Overall, the extent of spatial heterogeneity was highest at histological transformation with >30% of mutations discordant across biopsies and included mutations in *TNFAIP3* (SP3) and *CCND3* (SP4).



Diagonal plots comparing the VAFs of the mutations in the lymph node (LN) and bone marrow (BM) in SP2. Green circles indicate variants that are clonal in both LN and BM compartments. Orange circle indicates variants that are clonal in the BM but subclonal in the LN. Blue circle indicates variants with higher allelic burden in the LN than in the BM.

Figure 1.

Summary/Conclusions: We demonstrate spatial genomic heterogeneity is prevalent in FL and is more pronounced at transformation. The existence and diversity of site-specific aberrations suggests that a single biopsy can capture some but not all of the clonal complexities in a patient's lymphoma at a given time-point. These spatial variations need to be considered in biomarker-led clinical studies.

SOMATIC MUTATION PROFILING FOR PROGNOSIS AND TREATMENT STRATIFICATION OF DIFFUSE LARGE B-CELL LYMPHOMA IN THE REMODL-B TRIAL

MQ Du[1,*], A Clipson[1], M Wang[1], B Sharon[2], K Pugh[3], AJ Davies[4], C Mamot[5], J Caddy[3], E Ochoa[1], MA Care[6], J Taylor[2], T Maishman[4], L Stanton[4], D Hamid[4], A McMillan[7], P Fields[8], A Jack[2], P Johnson[9]
[1]Department of Pathology, University of Cambridge, Cambridge, [2]HMDS, Leeds Cancer Centre, Leeds Teaching Hospitals NHS Trust, Leeds, [3]Southampton Clinical Trials Unit, University of Southampton, Southampton, [4]Southampton Clinical Trials Unit, University of Southampton, Southampton, United Kingdom, [5]Kantonsspital Aarau AG, Aarau, Switzerland, [6]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, Leeds, [7]Centre for Clinical Haematology, Nottingham City Hospitals NHS Trust, Nottingham, [8]Guys and St Thomas' and Kings College Hospitals, London, [9]Cancer Research UK Clinical Centre, University of Southampton, Southampton, United Kingdom

Background: Recent studies on mutation discoveries have identified an ever growing long list of potential pathogenic mutations in diffuse large B-cell lymphoma (DLBCL). There are also remarkable variations in the spectrum and frequency of somatic mutations identified among different studies with only a few genes showing mutations in >10% of cases. It is imperative to validate the incidence of the recurrent mutations and investigate their inter-relationship and potential correlation with lymphoma molecular subtype in a large cohort of well documented DLBCL, and explore their potential value in prognosis and treatment stratification. The REMoDL-B trial utilised GEP (gene expression profiling) to stratify patients with newly diagnosed DLBCL (n=1132) for the addition of bortezomib to R-CHOP, based on the hypothesis that this agent may selectively improve the outcome of ABC-DLBCL, thus providing an excellent opportunity for validation of potential genetic biomarkers.
Aims: 1) to investigate the incidence of recurrent mutations, their inter-relationship and distribution according to COO molecular subtype in the REMoDL-B trial; 2) to access the potential value of these genetic changes, together with other clinicopathological and molecular parameters, in disease prognosis and treatment stratification.
Methods: In the first phase of the study, mutation screening was performed for 19 genes involving the NF-kB pathway (*CD79A, CD79B*, *CARD11*, *TNFRSF11A*, *MYD88, TNFAIP3*, *TRAF3*), plasma cell differentiation (*PRDM1*), apoptosis regulation (*TP53*, *FAS*, *DDX3X*), antigen presentation and recognition (*B2M*, *CD58*), and histone modifiers (*CREBBP*, *EP300*, *EZH2*, *MLL2, MEF2B*, *KDM2B*). Mutation in these genes was screened in duplicate by Fluidigm multiplex-PCR and Illumina sequencing using DNA samples extracted from formalin-fixed paraffin-embedded (FFPE) diagnostic biopsies (Wang *et al.* JMD 2015). Mutation data was correlated with COO molecular subtype, which was determined by Illumina WG-DASL^{TM} GEP using RNA samples from FFPE diagnostic biopsies (Care *et al.,* PLOS ONE 2013).
Results: To date, mutation data was obtained in 240 cases of DLBCL including 121 cases of GCB-DLBCL, 72 cases of ABC-DLBCL and 47 cases of unclassified. Among the 19 genes investigated, 5 genes showed a significant difference in their mutation frequencies between ABC and GCB-DLBCL, with *CD79B* (13% in ABC, 4% in GCB, p=0.04) and *MYD88* (32% in ABC, 5% in GCB, p=7x10^{-7}) mutations significantly enriched in ABC-DLBCL, while *EZH2* (27% in GCB, 0% in ABC, p=1x10^{-6}), *MLL2* (16% in GCB, 6% in ABC, p=0.04) and *CBP* (24% in GCB, 3% in ABC, p=7x10^{-5}) mutations significantly enriched in GCB-DLBCL. In general, there was a tendency of mutual exclusion among gene mutations in the NF-kB pathway, apoptosis regulation, and to a lesser extent in histone modifiers. By grouping genes according to their molecular function, mutations in the NF-kB pathway (51% in ABC, 29% in GCB, p=0.002) were also significantly enriched in ABC-DLBCL, while mutations in histone modifiers (57% in GCB, 21% in ABC, p=1x10^{-6}) were significantly enriched in GCB-DLBCL. Interestingly, there was a significant association in the mutations between the NF-kB pathway and plasma cell differentiation programme (p=0.02).
Summary/Conclusions: The data collected so far confirm the association between mutations in individual genes or molecular pathways, and DLBCL molecular subtype. Ongoing investigations to expand both the number of cases and the list of the genes for mutation analysis are in progress.

P680

ADHESION MOLECULE JAM-C: A POTENTIAL TARGET FOR MANTLE CELL LYMPHOMA THERAPEUTICS

T Matthes[1,2,*], A Vijaya Kumar[2], C Donate[1], B Imhof[3]
[1]Clinical Pathology, [2]Haematology, University Hospital Geneva, [3]Experimental Pathology and Immunology, Geneva University, Geneva, Switzerland

Background: Junctional adhesion molecule C (JAM-C), a member of the JAM

family is expressed by endothelial cells, platelets, NK cells, B lymphocytes and some B-cell lymphoma subtypes, in particular mantle cell lymphoma (MCL). MCL constitutes 3-10% of all malignant non-Hodgkin B cell lymphomas and the median survival of patients remains only 4-5 years, despite recent drug developments. We have shown previously, that blocking JAM-C using polyclonal antibodies inhibited B cell homing to lymphoid organs and decreased lymphoma engraftment in a NOD/SCID mouse model.
Aims: Homing of malignant B-cells to bone marrow and secondary lymphoid organs is of critical importance for lymphoma spread and growth. The aim of the current work was to develop and to test monoclonal antibodies with JAM-C blocking activities for potential therapeutic use in the clinics.
Methods: Monoclonal antibodies (mAb's) were generated by classic hybridoma technology and tested for binding to JAM-C. mAb's with highest affinity were selected and tested *in vitro* and in our NOD/SCID mouse model. For *in vitro* studies, B-cells from peripheral blood of healthy donors and of lymphoma patients were activated with interleukins and CD40L, with or without mAb's, then phosphorylation of intracellular kinases, proliferation, cell cycle status and JAM-C expression were assessed. For *in vivo* studies, primary B cells and Jeko-1 cells (MCL cell line) were injected i.v. into NOD/SCID mice and homing and engraftment of cells to lymphoid organs were studied in mice treated with mAb's compared to non-treated animals.
Results: From six different mAb's generated, one mAb H225, significantly reduced proliferation of normal and malignant JAM-C pos B-cells *in vitro* by 30 and 35%, respectively. This reduction was found to be paralleled by a decrease in the phosphorylation of ERK1/2 by 20%, whereas the phosphorylation of other signaling kinases remained unchanged (Akt, JNK, p38 and STAT5). In mice injected with primary B cells incubated with mAb H225, homing to bone marrow, spleen and lymph nodes was significantly decreased by 50%, 60% and 40%, respectively. Treatment of mice with H225 for two weeks starting several days after injection of Jeko-1 cells, resulted in drastically reduced lymphoma cell numbers in spleen, liver, bone marrow and lymph nodes (decrease of 100%, 99%, 95% and 100%, respectively), compared to control mice. Lymphoma cells recovered from treated mice showed decreased proliferation kinetics (34% decrease) compared to cells from non-treated animals.
Summary/Conclusions: Our results show that mAb H225 effectively blocks homing of lymphoma B cells to supportive lymphoid organs and decreases lymphoma engraftment in bone marrow, spleen, and lymph nodes. Additionally, we show for the first time an inhibitory effect of JAM-C blocking on B cell proliferation. Targeting JAM-C could therefore constitute a new therapeutic strategy for the treatment of B cell lymphomas expressing JAM-C, in particular MCL.

P681

ATM GENE MUTATIONS REPRESENT A HALLMARK OF MANTLE CELL LYMPHOMA BUT DO NOT IMPACT PATIENTS' SURVIVAL

A Marečková[1,*], J Malcikova[1,2], N Tom[2], K Pal[2], D Salek[1], S Pospisilova[1,2], M Trbusek[1]
[1]Department of Internal Medicine-Hematology and Oncology, University Hospital Brno, [2]Center of Molecular Medicine, CEITEC, Masaryk University, Brno, Czech Republic

Background: Mantle cell lymphoma (MCL) represents 5-10% of non-Hodgkin's lymphomas and is characterized by aggressive clinical course with median survival reaching only 3-5 years. Mutations in the *TP53* tumor suppressor gene detected in approximately 20% of patients negatively influence overall survival (OS). In addition, ATM kinase, the upstream p53 activator, was described to be mutated in up to 56% of MCL patients; however, the data about clinical impact of this aberration is still limited.
Aims: To explore the *ATM* mutations frequency in our MCL patients' cohort and to assess their impact on OS.
Methods: Samples from predominantly (85%) untreated patients containing at least 5% of malignant cells according to flow cytometry were selected for NGS analysis. Amplicon-based targeted sequencing using an in-house methodology was done on MiSeq instrument (Illumina). Whole coding regions and splicing sites of *ATM* and *TP53* genes were analyzed (*ATM*: exons 4-65, *TP53*: exons 2-11). Final data was processed by CLC Genomic Workbench software. The median coverage was 4212 reads and a cut-off for the variant allele frequency (VAF) was set at 1%. Functional impact of detected variant was assessed using dbSNP, COSMIC, and HGMD mutation databases. All detected presumably pathogenic alterations were verified either by Sanger sequencing (mutations above 20% VAF) or by repeated NGS analysis (mutations under 20% VAF). The 11q and 17p loci deletions were analyzed using MLPA technology in samples containing >30% of malignant cells.
Results: Samples from 78 MCL patients were analyzed using the targeted NGS. *ATM* mutations were identified in 41/78 patients (53%). In total, 57 mutations were disclosed with 12 patients carrying two mutations and 2 patients even three *ATM* mutations. Truncating variants represented 42% of all mutations. The analysis of germline status performed in 16 patients with available DNA from remission period showed the germline origin in one case (mutation c.3939_3940del). The MLPA analysis was performed in 33/78 patients and showed *ATM* locus deletion in 16 cases (48%). A majority of *ATM*-mutated patients (70%) carried accompanying allelic deletion, while all remaining *ATM*-affected patients manifested two or three *ATM* mutations; presumably on opposite alleles. Only two patients carried isolated 11q deletion. To reliably assess a clinical impact of *ATM* mutations, the known impact of *TP53* gene aberration must have been set aside; therefore the *TP53* gene status was analyzed as well. *TP53* mutations were identified in 18/78 patients (23%). Besides that, four patients carried isolated 17p deletion. In line with presumably common ATM/p53 activity in one biological pathway, concurrent mutations in both genes were rare occurring in 3 patients. The OS analysis then unambiguously showed a negative impact of *TP53* defects but not of *ATM* mutations (P=0.02 and P=0.74, respectively) with the median OS being 81 months in *ATM*-mutated patients, 49 months in *TP53*-defective group and "not reached" in *ATM*/*TP53* wt patients.
Summary/Conclusions: Although *ATM* mutations represent the second most frequent genetic abnormality in MCL besides cyclin D1 translocation t(11;14), their impact on survival seems absent. This is in a striking contrast to *TP53* defects, which significantly deteriorate overall survival of MCL patients.

MODE OF ACTION OF DIFFERENT PI3K-INHIBITORS IN MANTLE CELL LYMPHOMA

G Hutter[*], Y Zimmermann, A Zoellner, P Irrgang, J Arnd, W Hiddemann, M Dreyling
Dept. of Medicine III, Univ. Hospital Grosshadern/LMU, Munich, Germany, Munich, Germany

Background: Mantle cell lymphoma (MCL), is a distinct lymphoma subtype with an aggressive clinical course and a median survival of 3-5 years. New emerging strategies include especially inhibitors of the B-cell receptor pathway (BTK, PI3K, Akt, mTOR) which is constitutively activated in MCL and plays a critical role in tumor growth and survival.
Aims: In the present study we investigated different PI3K-Inhibitors (Copanlisib, Pictilisib, AS-605240, duvelisib, A66, idelalisib and TGX-221) targeting different isoforms (PI3Kα/δ, PI3Kγ/α, PI3Kγ, PI3Kγ/δ, PI3Kα, PI3Kδ and PI3Kß) in MCL.
Methods: MCL cell lines (Z-138, Mino-1, Granta-519, Jeko-1, Rec-1, Maver-1) were exposed to different PI3K-Inhibitors (Copanlisib, Pictilisib, AS-605240, IPI-145, A66, idelalisib and TGX-221; 0,3125-5μM) with or without murine feeder layer (M210B4). The effect of drugs was evaluated by cell count (trypan-blue staining), cell metabolism (WST-assay or ONE-Glo^{TM} Luciferase assay for luciferized MCL cell lines), cell cycle (FACS) and apoptosis (Annexin V PE/7-AAD staining). Subsequently, combinations with other inhibitors of the PI3K/mTOR pathway were analysed. Proteome Profiler phospho-kinase antibody array as well as Western blot analyses were performed after exposure to the various PI3K inhibitors and correlated to the sensitivity of cell lines. Finally, the effects of drug combination were confirmed in primary patient samples.
Results: The most efficient PI3K inhibitor (tested at 5μM) was Copanlisib (PI3Kα/δ) with a median reduction of cell proliferation of 77% (57.5%>89.4%) followed by the dual isoform inhibitor Pictilisib (PI3Kγ/α) reaching a median reduction of cell proliferation rate of 60% (47%>72.5%). For the single PI3K isoform inhibitors AS-605240 (PI3Kγ) was the most efficient reaching a median reduction of cell proliferation of 26% (8.2%>49.7%). Comparison of single isoform inhibition to combined inhibition of the different isoforms in MCL cell lines confirmed the superiority of the combined inhibition of all four isoforms to inhibition of three by 7,2%, to two by 19,2% and to single by 33,7%. Interestingly triple combinations including targeting of the α-and γ-isoforms were almost as efficient as inhibition of all 4 isoforms. In addition reduction of cell proliferation of dual-PI3K-Inhibitors (Pictilisib and Copanlisib) were higher (60% and 77%) than combinations of single isoform inhibitors (AS-605240 and A66: 34%; A66 and idelalisib: 36%; respectively). In primary patient samples copanlisib revealed the highest cytotoxicity followed by duvelisib, idelalisib, TGX221 and A66 (80.9%; 62.5%; 48.7%; 50% and 40.5%, respectively, 5μM). The differential impact of single and multiple PI3K isoform inhibition on phospho kinases suggests that concurrent phosphorylation inhibition of p53, Akt, p70S6 Kinase, RSK1/2/3, STAT3, c-Jun, eNOS, WNK1, Pyk2 and PLCγ-1 is responsible for increased biological activity to multiple PI3K-isoform inhibition. The observation that inhibitors of different isoforms of PI3K result in different protein phosphorylation patterns supports the hypothesis that the PI3K isoforms act on different downstream signaling pathways. Additional data on the influence of microenvironment on the different PI3K-Isoform inhibitors will be presented.
Summary/Conclusions: Based on the comprehensive analysis of PI3K inhibition, inhibition of multiple isoforms of PI3K appears to be most efficient in MCL. Thereby the superiority of combined PI3K-isoform inhibition *vs* selective single isoform inhibition leads to the assumption that each PI3K-isoform regulates different downstream pathways. In addition, the modulating effect of the murine feeder layer confirms that the microenvironment plays a critical role for the mode of action of inhibitors of the B-cell receptor pathway.

Background: Recent studies have described the landscape of recurrently mutated genes in mantle cell lymphoma (MCL). However, with the exception of TP53, little is known about the clinical relevance of these mutations.
Aims: Thus, we performed deep sequencing analysis of a MCL gene panel in the prospective series of patients enrolled in the FIL-MCL0208 phase III trial (EudraCT-Number: 2009-012807-25, high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL patients).
Methods: The mutational study included a subgroup of patients with availability of tumor DNA. A specifically designed, targeted resequencing gene panel, including coding exons and splice sites (genes: ATM, BIRC3, CCND1, KMT2D, TP53, TRAF2, WHSC1, NOTCH1) was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, for comparative purposes to filter out polymorphisms, in the paired normal genomic DNA (available in 55% of cases) using a TruSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 2356x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatic pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Primary endpoint of the analysis was progression free survival (PFS) and clinical data were retrieved at the time of the first, planned, interim analysis (as of May, 2015).
Results: Out of the 300 enrolled patients, 174 were evaluable for the mutational study (median age: 57 years, range 35-66; males 75%). The MIPI was intermediate or high-risk in 39% of patients, the Ki67 ≥30% in 44%, and blastoid histology occurred in 9%. Patients not included in the study, due to unavailable tumor DNA (n=124) showed superimposable clinical features, except from a lower stage IV rate (79% *vs* 91%, p=0.003), as expected. At the first planned interim analysis, median follow-up of alive patients was 26 months. At 2-years, 79% of patients were progression free and 91% alive (Cortelazzo *et al.* EHA 2015). Overall, at least one mutation was detected in 114/174 cases (66%), including mutations of ATM in 43% of cases, WHSC1 in 16%, CCND1 in 13%, KMT2D in 12%, TP53 in 8%, NOTCH1 in 8%, BIRC3 in 5% and TRAF2 in 1%. By univariate analysis, mutations of TP53 (2y PFS 42% *vs* 83%; p<0.0001) and KMT2D (2-years PFS 69% *vs* 81%; p=0.008) associated with a significantly shorter PFS. By multivariate analysis, mutations of TP53 (HR: 5.3) and KMT2D (HR: 2) associated with an increase of the hazard of progression. By recursive partitioning analysis, three MCL subgroups were hierarchically classified (Figure 1).

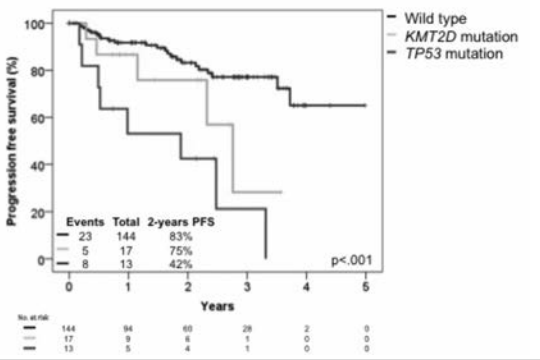

Figure 1.

The high-risk category (TP53 +/- KMT2D mutation, 7% of patients) showed a 2y PFS of 42%, the intermediate risk (KMT2D mutation without TP53 mutation, 10%) showed a 2y PFS of 75%, while the low-risk (no TP53, no KMT2D mutations, 83%) had a 2y PFS of 83%. The low number of events so far recorded prevented any analysis on overall survival.
Summary/Conclusions: Though limited by the short follow-up, our data show that: i) the combination of TP53 and KMT2D mutations predicts a shorter PFS in younger MCL patients receiving high-dose therapy; ii) intensive chemotherapy does not overcome the negative prognostic impact of TP53 mutations; and iii) KMT2D mutations may represent a novel genetic biomarker in MCL.

P684

DECIPHERING THE IMPACT OF IDELALISIB ON FOLLICULAR LYMPHOMA AND ITS IMMUNE MICROENVIRONMENT

A Matas-Céspedes[1,*], M Guerrero[1], L Magnano[2], L Grosmaire[3], A Yahiaoui[3], S Tannheimer[3], A López-Guillermo[2], P Pérez-Galán[1]

[1]Hematology-Oncology, IDIBAPS, [2]Hematology, Hospital Clínic, Barcelona, Spain, [3]Gilead Sciences, Inc., Foster City, United States

Background: The PI3K pathway is known to contribute to B-cell non-Hodgkin lymphoma (NHL) cell survival by regulation of cell cycle, apoptosis, proliferation, differentiation, homing and retention. The PI3K p110 subunit constitutes the catalytic domain of class I PI3Ks and exists as four isoforms. p110-δ isoform is primarily expressed in cells of hematopoietic origin and constitutes a key component of the BCR pathway. Idelalisib (IDELA/GS-1101/CAL-101) is a first-in-class PI3Kδ selective inhibitor that is approved for the treatment of relapsed chronic lymphocytic leukemia, follicular B-cell non-Hodgkin lymphoma (FL), and small lymphocytic lymphoma. The mechanisms of IDELA sensitivity and resistance remain to be fully elucidated.
Aims: Characterization of the cellular and molecular effects of IDELA in an *in vitro* model utilizing a primary FL coculture system with follicular dendritic cells (FDC) or M2-polarized macrophages (M2).
Methods: FL primary cells from lymph node (LN) biopsies were co-cultured (24-72h)with the FDC cell line HK or M2 generated from M-CSF activated monocytes from peripheral blood of normal donors. Viability of FL cells was assessed by flow cytometry (AnnexinV/7-AAD). B cells were isolated using CD20 magnetic beads, RNA extracted and subjected to Gene Expression Profiling (GEP). Significant pathways were identified by Gene Set Enrichment Analysis (GSEA).
Results: In the absence of accompanying cells, IDELA (100-500nM) induced a moderate cytotoxic effect in FL cells (n=10). FDC or M2 co-cultures increased FL cell viability up to 2-fold. IDELA was also able to reduce this pro-survival effect of FDC or M2, highlighting its impact on lymphoma-microenvironment interactions (Figure 1A). To characterize the molecular mechanisms of these observations, FL primary cells (n=5) were cultured either alone,with FDC or M2, and treated with 500nM IDELA for 48h. GSEA indicated that both FDC and M2 induced the transcription of genes related to B-cell receptor (BCR) and CD40 signaling pathways, together with Germinal Center program and BLIMP-targets. IDELA significantly (FDR<0.05) reduced the engagement of these transcriptional pathways. Additionally, FDC promoted the transcriptional activation in FL cells of gene sets related to angiogenesis, trans-endothelial migration, extracellular matrix (ECM) adhesion and integrin signaling. IDELA was able to counteract this gene upregulation in a subset of patients and preliminary functional experiments validated that IDELA abrogates ECM adhesion (Figure 1B) and VEGF-A secretion (Figure 1C). However, IDELA was inefficient at blocking the secretion of the macrophage attractant CCL-2, the matrix metalloproteinase MMP-2 and the pro-inflammatory cytokines IL-6 and IL-8. In FL-M2 co-culture, GSEA showed that M2 activated the transcriptional activation in FL cells of gene sets that were not sensitive to IDELA treatment, such as Toll-like receptor (TLR) and CCR5 signaling pathways. Moreover, the matrix metalloproteinase MMP-9 was highly elevated in FL-M2 co-culture and was not modulated by IDELA exposure.

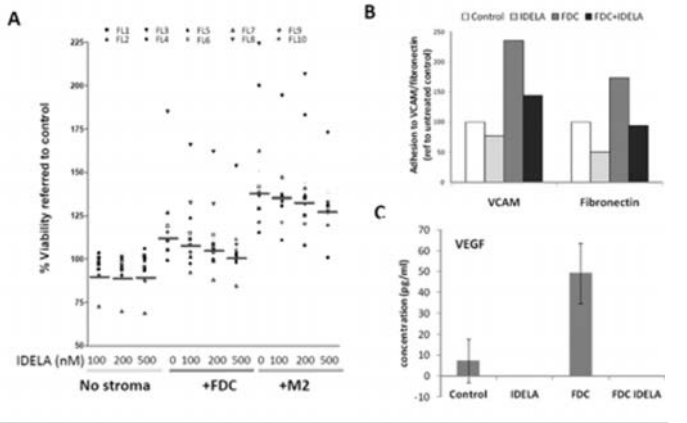

Figure 1.

Summary/Conclusions: We have characterized the impact of IDELA on FL cells and their crosstalk with two immune populations (FDC and M2 macrophages) present in the LN which are associated with poor prognosis. These results suggest that although IDELA targets several important B-cell pathways (BCR, CD40, angiogenesis, trans-endothelial migration, ECM adhesion), other pathways related to pro-inflammatory immune response and cell disseminationare not affected.

P685

MIR-34A PREVENTS LUNG INJURY IN BLEOMYCIN INDUCED PULMONARY FIBROSIS

R Bulvik[1,*], S Wallach-Dayan[1], S bulvik[2], R breuer[1]
[1]Lung Biology Laboratory, Hadassah hebrew university medical center, jerusalem, [2]Hematology department, Laniado hospital, Netanya, Israel

Background: Bleomycin is a critical component in the treatment of Hodgkins disease however its major side effect, namely lung fibrosis prevents its use in certain subgroups, especially elderly patients. Prevention of this life threatening side effect could potentially increase the cure rate in this disease. A prominent feature of fibrotic lungs is the development of inflammation leading to accumulation of abnormal myofibroblast populations resistant to death receptor-induced apoptosis. We have previously shown that this resistance is mediated by the expression of cellular FLICE-Inhibitory Protein (c-FLIP). In this work we study the regulation of c-FLIP expression by miR-34a.
Aims: To assess the critical role of miR-34a on FLIP expression during in-vivo bleomycin-induced fibrosis.
Methods: Lung fibrosis was induced using a well-established model of Bleomycin- and control saline-treated C57BL/6 and miR-34 knock-out (KO) mice. Fibrosis was measured by histological H&E semi morphological index (SMI) score, bronco-alveolar-lavage (BAL) cytological ratio and by Collagen abundance using Sircoll-collagen kit. miR-34KO and C57BL/6 myofibroblasts were isolated from day 0/14/28 and day 56 of the model. qPCR and Western blot assays were used to analyze level of miR-34A and FLIP. Furthermore, isolated myofibroblasts were transfected with miR-34 overexpression lentiviral-vector *vs* scrambled vector and levels of FLIP were measured. Apoptosis was induced in miR-34 over-expressed myofibroblasts co-cultured with T-cells and the apoptosis ratio was measured by caspase-3 cleavage and annexin-v staining.
Results: In-silico DIANA prediction tools found FLIP among the top 10th putative genes with an 85% probability to be targeted by miR-34a. in-vitro we detected an inverse correlation between RNA levels of miR-34a and FLIP in myofibroblasts isolated from Bleomycin- and saline-treated mice; saline-treated Lung-myofibroblasts isolated from day 14 express high levels of miR-34a and low levels of FLIP while Bleomycin-treated mice lung-myofibroblasts isolated from day 14 (when fibrosis severity is at its highest) show low levels of miR-34a expression and high levels of FLIP (FLIP: 0.98±0.3 *vs* 3.5±1.2 ; miR-34a: 1.03±0.1 *vs* 0.48±0.07, respectively. p<0.05). The same pattern as Bleomycin-treated myofibroblasts is seen in miR-34 KO untreated myofibroblast; low levels of miR-34a and high levels of FLIP. Restoration of MiR-34a into miR-34KO naive myofibroblasts reduced FLIP levels back to a normal state as opposed to scrambled control counterparts. Moreover, miR-34a over-expression regained myofibroblast susceptibility to apoptosis when cocultured with T-cells. In-vivo, both Bleomycin treated C57BL/6 and miR-34KO groups show high levels of FLIP and severe fibrosis on day 14 compared to healthy saline treated groups. However, while C57BL/6 Bleomycin treated mice recover from fibrosis on day 28, the miR-34KO Bleomycin treated mice continue to express high FLIP levels and persistent fibrosis.
Summary/Conclusions: miR-34a is an important regulator of FLIP expression and is effective in attenuation of Bleomycin lung fibrosis progression. Maintaining high levels of miR-34a in Hodgkins disease patients treated with Bleomycin may prevent lung fibrosis.

Indolent Non-Hodgkin lymphoma - Long-term and outcome

P686

INTERIM ANALYSIS OF POST MARKETING SURVEILLANCE OF YTTRIUM-90 IBRITUMOMAB TIUXETAN IN JAPANESE PATIENTS WITH RELAPSED OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMA OR MANTLE CELL LYMPHOMA

K Hatake[1,*], R Kanzaki[2], Y Yabuuchi[2], O Kataoka[2], S Nagai[2], Y Asaeda[2]
[1]The Cancer Institute Hospital, [2]Mundipharma K.K., Tokyo, Japan

Background: Yttrium-90 ibritumomab tiuxetan (^{90}Y-IT) is a radiolabeled anti-CD20 monoclonal antibody approved in Japan since 2008 for use in relapsed or refractory (R/R) indolent B-cell non-Hodgkin lymphoma (NHL) or mantle cell lymphoma (MCL). Here we present data from its real world use in Japanese patients (pts) after marketing authorization.
Aims: To evaluate safety and efficacy of ^{90}Y-IT in Japanese pts with R/R B-cell NHL or MCL in usual clinical settings.
Methods: This is a prospective study of consecutive clinical cases collected from 63 institutions across Japan. Pts were enrolled between Aug, 2008 and May, 2010. The data cut-off was Aug 27, 2015. Adverse events were assessed for intent-to-treat population. Efficacy was analyzed during standard observation period according to IWC 1999 and followed annually for outcomes and secondary malignancy.
Results: Safety was evaluated for 413 pts enrolled. Median age was 61 (range 31-87) with 77.2% follicular lymphoma and 12.1% MCL according to WHO classification. 97.3% of pts were performance status 0 - 1 with Ann Arbor staging I, II, III and IV ranging 10.9%, 22.5%, 35.4% and 29.8% respectively. Median number of previous treatments were 3 (range 1 - 22). Of the 409 pts who received ^{90}Y-IT, 315 received 14.8 MBq/kg (0.4 mCi/kg) and 89 received 11.1 MBq/kg (0.3 mCi/kg). Adverse drug reactions (ADRs) were reported in 373 pts (90.3%). There was no difference observed in the incidence rate of ADRs across patients demographics. The most common ADRs were hematotoxicities (88.6%): thrombocytopenia (75.5%), leukopenia (57.6%) and neutropenia (35.6%). Infection was reported in 45 cases (10.9%), with most common being herpes zoster 10 (2.4%), nasopharyngitis 6 (1.5%) and bronchitis 5 (1.2%). Secondary malignancy was reported in 13 pts, including 9 myelodysplastic syndrome and 2 acute myeloid leukemia. Of 409 pts, 59 were excluded from the efficacy analysis data set due to unavailable best response, off-label use, or ^{90}Y-IT not being administered. The overall response rate (ORR) in 354 evaluable pts was 76.8% [95% CI: 72.1 to 81.1%] and complete response (CR) rate was 47.7% [95% CI: 42.4 to 53.1%]. ORR and CR for those receiving 2 or less prior regimens were 86.0% [95% CI: 79.6 to 91.0%] and 56.1% [95% CI: 47.9 to 64.0%] respectively, while ORR and CR for those receiving more than 2 prior regimens were 69.3% [95% CI: 62.2 to 75.8%: p=0.0003] and 40.7% [95% CI: 33.7 to 48.1%: p=0.005] respectively.
Summary/Conclusions: The interim analysis of this surveillance confirms ^{90}Y-IT is a tolerable and efficacious treatment option for pts with R/R B-cell NHL or MCL in Japan, demonstrating good benefit-risk balance consistent with the currently available international and Japanese data. (NCT01448928)

P687

PATIENTS WITH FOLLICULAR LYMPHOMA (FL) SHOWING A DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) COMPONENT HAVE AN INTERMEDIATE OUTCOME BETWEEN FL AND DLBCL

L Magnano[1,*], O Balagué[2], I Dlouhy[1], J Rovira[1], K Karube[3], A Rivas[1], B Gonzalez[2], A Martinez-Trillos[1], A Martinez[2], J Delgado[1], E Gine[1], N Villamor[4], E Campo[2], A Lopez-Guillermo[1]
[1]Hematology, [2]Pathology, Hospital Clinic de Barcelona, Barcelona, Spain, [3]4Department of Pathology and Cell Biology, University of the Ryukyus, Nishihara, Japan, [4]Hematopathology Unit, Pathology Department, Hospital Clinic de Barcelona, Barcelona, Spain

Background: Whereas histologic transformation to DLBCL during the follow-up of FL determines a poor outcome, it is not clear the prognostic impact of the presence of a DLBCL component (FL/DLBCL) in the diagnostic biopsy of patients with FL.
Aims: to analyze the clinical characteristics, treatment, response, progression free survival (PFS) and overall survival (OS) of patients diagnosed with FL/DLBCL in comparison with FL or DLBCL patients.
Methods: 877 patients diagnosed either FL or DLBCL between 2002 and 2015 in a single institution were included in the study. The distribution was as follow: FL, 369 cases (161 M/208 F; median age, 59 years), DLBCL, 508 cases (274 M/234 F; median age, 65 years). The main clinical, biological features and outcome were analyzed. All biopsies of FL/DLBCL patients were reviewed in order to quantify the DLBCL component. *NOTCH1* mutations were assessed in 195 cases.
Results: 41 patients showed a DLBCL component ranging from 5% to 95% (median: 50%). Patients with FL/DLBCL showed more frequently than DLBCL

cases, ambulatory performance status, absence of B symptoms, primary nodal origin, advanced stage and low risk IPI with these features being closer to those of FL patients (p<0.01 in all cases). On the contrary, FL/DLBCL patients had an intermediate position between FL and DLBCL cases regarding bone marrow infiltration, anemia and serum LDH levels. All FL/DLBCL patients were treated as aggressive lymphoma (R-CHOP). Response and outcome of the patients according to the histology are listed in the Table 1. Of note, the proportion of primary refractoriness in FL/DLBCL patients was significantly higher than in FL and similar than that of DLBCL patients. In Figure 1, PFS and OS of the 3 groups are plotted. No significant differences were seen according to the degree of DLBCL component. In a multivariable analysis with FL patients (including FL/DLBCL, B2 microglobulin and FLIPI), FLIPI demonstrated to be significant for OS (p<0.001). *NOTCH1* were more frequently mutated in FL/DLBCL (11%) in comparison with FL (2%) or DLBCL patients (1.5%) (p=0.06).

Table 1. Response and outcome of the patients according to the histology.

Characteristics	FL (n=328) n (%)	FL/DLBCL(n=41) n (%)	DLBCL(n=508) n (%)
Response to therapy			
CR	216; 75	26; 65	343; 69
PR	58 (20)	6 (15)	40 (8)
Failure	14 (5)	8 (20)*	116 (23)
Relapse/progression	100 (31)	15 (37)	224 (44)
PFS-5 years (95% CI)	65% (59-71)	56% (40-72)	50% (45-55)
OS-5 years (95% CI)	85% (81-89)	73% (57-89)	63% (59-67)

** p<0.05 with FL.*

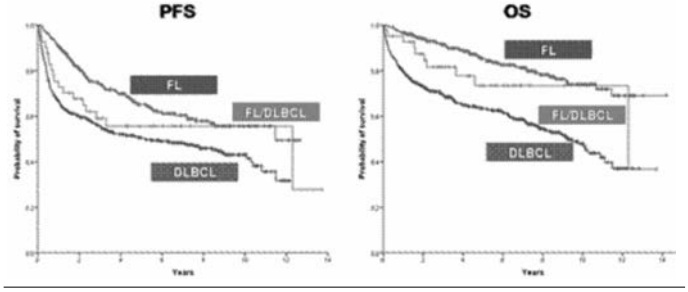

Figure 1.

Summary/Conclusions: FL patients with a component of DLBCL showed an intermediate outcome between FL and DLBCL. These patients may represent a different group of FL that warrants further biological studies.

P688

DISTINCT INCREASING TREND AND BIRTH-COHORT EFFECT OF FOLLICULAR LYMPHOMA INCIDENCE IN TAIWAN: EPIDEMIOLOGICAL ANALYSES AND IMPLICATIONS

SJ Wu[1,*], CJ Chiang[2,3], JYC Chen[2,3], WC Lo[2,3], CT Lin[1], MS Lai[2,3]
[1]National Taiwan University Hospital, [2]Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, [3]Taiwan Cancer Registry, Taipei, Taiwan, ROC

Background: Follicular lymphoma (FL) is much less prevalent in Asia than in the West. However, the recent reports have shown that the relative rate of FL among all lymphoma subtypes is increasing in Taiwan as well as in other Asian populations. Since lifestyle and environmental factors have been proposed to be associated with the risk of FL, it is of interests whether the Westernized lifestyle and environmental alternations that are increasingly affecting Taiwanese may have an important impact on this change.
Aims: The study is aimed at drawing the epidemiological pictures of FL in both Taiwan and the US and dissecting the individual factors contributing to the epidemiological differences between these two areas. The comparison of the epidemiological characteristics of FL between Taiwan and the West may help clarify the factors relevant to the development of this disease.
Methods: The relevant epidemiological data of FL during 1993-2012 for Taiwanese were obtained from the Taiwan National Cancer Registry Database, and the corresponding data of Caucasian Americans, the Surveillance, Epidemiology, and End Results (SEER) Program Research Data. Age-specific incidence rates of FL were plotted by calendar year at diagnosis and by birth-cohort for both populations. The individual effects of time-period and birth-cohort on the incidence trends were evaluated with the age-period-cohort analysis. Patients' outcomes, represented by 5-year relative survivals (RS) between 1990 and 2009, were calculated for outcome comparisons.
Results: The age-standardized incidence rate of FL for the Taiwanese was continuously increasing during the 20-year period while that for Caucasian Americans remained steady (Figure 1). The age-specific incidence rates for Taiwanese were much lower than those for Caucasian Americans for all age group. The estimations of the average annual percentage changes (AAPC) of incidences were significantly positive for all age groups in Taiwan, indicating a consistently increasing incidence trend in all age groups, whereas the AAPC for Caucasian Americans were small and without a consistent pattern. Comparisons of the age-specific incidences in representative birth cohorts demonstrated that for Caucasian Americans, there were almost no differences in the incidences between earlier and later birth cohorts; but for the Taiwanese, the incidence was higher for every later birth cohort in every given age group. With the age-period-cohort modeling approach to dissect the individual effects contributing to this distinct incidence trend, a much stronger birth-cohort effect was identified for the Taiwanese but not for Caucasian Americans. In regard of the outcomes, the 5-year RS in Taiwan and the US were both improving. However, patients' RS in Taiwan during this period were steadily 10~15% inferior to that in the US in both younger and older patients.

	1993-1997	1998-2002	2003-2007	2008-2012
TWN Male	0.338	0.455	0.692	0.911
TWN Female	0.290	0.407	0.594	0.810
US Male	3.737	3.936	4.443	3.962
US Female	3.240	3.519	3.841	3.549

Figure 1.

Summary/Conclusions: Despite the much lower incidence, there is a distinct increasing trend of FL in Taiwan; underlying this increasing trend is a strong birth-cohort effect, suggesting that changes in life style may be an important factor for the difference in incidence trend between the East and the West and providing an evidence of associations between environmental factors and the development of FL. The improved RS in both areas implies that therapeutic advances are changing the clinical course of FL, but the stable RS gap between Taiwanese and American patients indicates that the genetic background is affecting FL patients' outcomes.

P689

LONG-TERM OUTCOMES OF 131I-RITUXIMAB RADIOIMMUNOTHERAPY IN FOLLICULAR NON-HODGKIN LYMPHOMA: TEN YEAR UPDATE ON TOXICITY, TIME-TO-NEXT-TREATMENT AND SURVIVIAL OF THE PHASE II INITIAL STUDY

M Kesavan[*], JH Turner, AD McQuillan
School of Medicine and Pharmacology, University of Western Australia, Perth, Australia

Background: Follicular lymphoma (FL) is the second most common non-hodgkin lymphoma (NHL) in Western countries. The decision to treat is generally based on the disease grade and presence of GELF criteria. Standard rituximab chemotherapy regimens improved progression free survival (PFS) but have not translated into an improvement in overall survival (OS). Conventional therapy has a risk of myelotoxicity including myelodysplastic syndrome (MDS). Our phase II INITIAL clinical trial was the first to report significant efficacy of first-line ^{131}I-rituximab outpatient therapy in advanced symptomatic FL. To allay concerns regarding long-term toxicity we report the incidence and nature of both short and long-term myelotoxicity over 10 years of follow up. An update

of the TTNT and long-term survival outcomes of our INITIAL experience of front-line ^{131}I-RIT for follicular lymphoma is also reported.
Aims: We report the toxicity, time-to-next-treatment (TTNT) and survival outcomes after a decade of follow-up of the original phase II INITIAL study patient cohort treated with Iodine-131-rituximab radioimmunotherapy (^{131}I-RIT).
Methods: We reviewed the 68 patients in the original prospective phase II INITIAL study commenced April 2006. Standard eligibility criteria were applied; baseline entry myeloid function required platelets >70x10^9/L, neutrophils >1x10^9/L and hemoglobin >100g/L. All patients met GELF criteria for treatment. Therapy comprised 375mg/m^2 rituximab at weekly intervals for 4 weeks. Standard maintenance rituximab was then given. Individual dosimetry was performed using tracer 250Mbq ^{131}I-rituximab whole body SPECT/CT. A prescribed radiation absorbed dose to the whole body was fixed at 0.75Gy and each patient received an individual administered activity for therapy based upon this dose. Patients were monitored with weekly blood counts during the first 8 weeks and reviewed at regular intervals thereafter.
Results: No patient was lost to follow up. All patients were treated at the fixed radiation dose of 0.75Gy to whole body. Of 68 patients, 5 were excluded from toxicity analysis due to insufficient data. All patients were included in the OS and TTNT assessments. Median age at enrollment was 60 years (37 females and 31 males) with median follow-up of 70 months. No patient required hospital admission for management of bleeding, sepsis or any other complication. Myelotoxicity of grade 3/4 (CTCAE) during the first 8 weeks of therapy occurred in 23 patients (36%); 6 with grade 3/4 thrombocytopenia, 14 with grade 3/4 neutropenia and 3 patients with concurrent grade 3/4 thrombocytopenia and neutropenia. Grade 3/4 myelotoxicity manifested as a nadir of platelets at week 4 and of neutrophils at week 6. Resolution was essentially complete by week 8. No significant hemoglobin reduction was seen. On multivariate analysis bone marrow involvement was independently associated with development of acute thrombocytopenia (p=<0.01). No significant long-term myelotoxicity was observed. There was no instance of MDS or acute leukemia. Deauville criteria were fulfilled for complete response (CR) based on ^{18}F-FDG PET/CT at 3 months follow up in 56 patients (82%). Mean TTNT was 97 months (95 months for FLIPI 0/1, 104 months for FLIPI 2 and 83 months for FLIPI >3). Mean OS was 107 months (94 months for FLIPI 0/1, 109 months FLIPI 2 and 99 months for FLIPI >3). There was no statistically significant difference between groups for TTNT or OS. Achievement of CR at 3-month follow-up ^{18}F-FDG PET/CT was predictive of long-term survival (relative risk=0.36 in contrast to 2.8 for patients not achieving CR) (Figure 1).

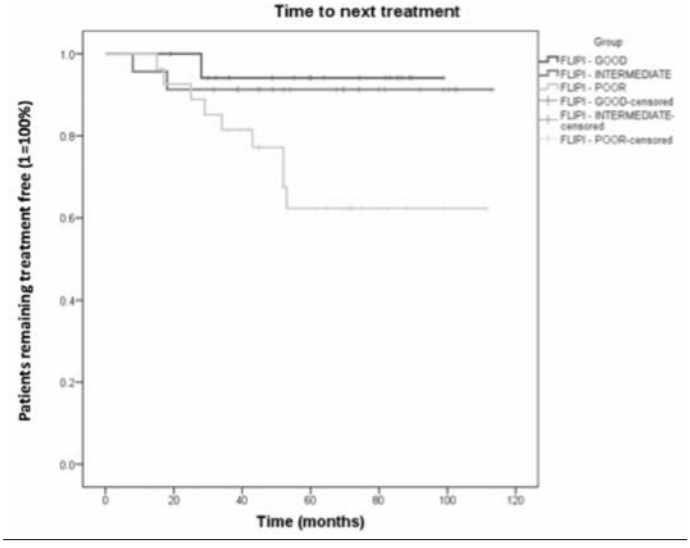

Figure 1.

Summary/Conclusions: First-line^{131}I-RIT for advanced FL is safe and effective. Long-term follow-up of ^{131}I-RIT of advanced FL demonstrates durable response without toxicity. Myelosuppression is modest and self-limited. Deauville criteria at 3-month ^{18}F-FDG PET/CT are predictive of TTNT and OS.

P690

LONG TERM OUTCOMES IN PRIMARY OCULAR ADNEXAL MUCOSA-ASSOCIATED LYMPHOID TISSUE LYMPHOMAS (POAML): A LARGE SINGLE INSTITUTE COHORT STUDY

A Desai[1,*], MG Joag[2], L Lekakis[1], D Tse[2], A Markoe[3], IS Lossos[1]
[1]Hematology/Oncology, Sylvester Comprehensive Cancer Center, University of Miami, [2]Ophthalmology, Bascom Palmer Eye Institute, University of Miami, [3]Radiation Oncology, Sylvester Comprehensive Cancer Center, University of Miami, Miami, United States

Background: POAML are rare malignant proliferations affecting the orbit, lacrimal gland, eyelids and conjunctiva, accounting for 35%– 80% of the Primary Ocular Adnexal Lymphoma (POAL) cases. We present the outcomes of the largest single institute study on 182 POAML patients followed for a medium of 63.5 (range 1-387) months.
Aims: To report natural history and identify clinical parameters associated with POAML relapses/progression.
Methods: A retrospective study of 182 patients with POAML diagnosed or treated between January 1984 and December 2015, based on the tumor registry at the University of Miami Sylvester Comprehensive Cancer Center. Information on demographics, medical history, anatomic location, International Prognostic Index (IPI), laboratory/imaging data, stage, treatment and response, details on relapse and management, progression free survival (PFS), time to progression (TTP) and overall survival (OS) was extracted. Kaplan-Meier survival curves were constructed and analyzed by the log rank test with JMP® statistical discovery software.
Results: Of the analyzed 182 patients with POAML, 145 (79.6%) presented in Ann-Arbor stage I and 30 (16.4%) in stage II-IV disease. Median age at diagnosis was 72 years (range, 7-92 years). Patients with lacrimal POAML tended to present at a younger age (median 49.5 years) compared to those with orbital (median 65 years) (p=0.002) and conjunctival POAML (median 62 years) (p=0.05). Overall, 147 of 174 (84.4%) treated patients achieved a complete response (CR) after first-line therapy. In 98 patients with stage I disease who received initial radiation therapy (RT), CR was more commonly observed in patients treated with radiation dose ≥30.6 Gy compared to patients receiving lower RT doses (p=0.04). Similarly, there was also statistically significant difference between these groups in 5 and 10-year PFS (p<0.0001), but no difference in OS. Overall, the long-term local control was achieved in 14 (70%) patients treated with RT <30.6 Gy and 69 (88%) patients treated with RT ≥30.6 Gy (p=0.04). In patients treated with RT for stage I disease 5(4.5%) developed CNS relapses with significantly higher relapses (3/5) in the group receiving <30.6 Gy (p=0.04). Among 174 patients with available follow up data, 36(20.6%) relapsed/progressed and in 147 who achieved a CR after first-line treatment, 5-year and 10-year relapse rates were 23.7% and 43.3%, respectively. Transformation to diffuse large B-cell lymphoma was diagnosed in 7 (4%) and accounted for 7/36 (19.4%) progressions/relapses, leading to death in 2 patients. Median OS for all patients was 250 months (95% CI: 222-upper limit not reached), median PFS was 134 months (95% CI: 87-198) and the median time to progression was 198 months (95% CI:109-upper limit not reached). Kaplan-Meier estimates for the FFP for all 174 patients at 1, 5, and 10 years after completion of initial treatment were 92.7% (95% CI: 87.6%-95.8%), 73.8% (95% CI: 65.8%-80.4%), and 60% (95% CI: 49%-70%), respectively. On univariate analysis, age >60 years, radiation dose, bilateral ocular involvement at presentation and advanced stage were significantly associated with shorter PFS (p=0.006, p=0.0001, p=0.002 and p=0.0001 respectively) Multivariate analysis showed that age >60 years (HR=2.44) and RT<30.6 Gy (HR=4.17) were the only factors associated with shorter PFS (p=0.01 and p=0.0003, respectively).
Summary/Conclusions: Patients with POAML have CNS relapses in 2.8% and transform to DLBCL in 4% of cases. RT at doses ≥30.6 Gy are associated with better local control; fewer local, CNS and distant relapses and longer PFS. Early stage POAML do well with localized RT for stage I disease but demonstrate long-term constant risk for relapse.

P691

EARLY TRANSFORMATION IN LOW-GRADE LYMPHOMAS AND ITS ADVERSE PROGNOSTIC SIGNIFICANCE ON SURVIVAL

LM Juárez Salcedo[1,2,*], P Griffin[2], J Sandoval-Sus[2], C Bello[2], B Shah[2], E Ayala[2], MA Kharfan-Dabaja[2], P Chervenick[2], EM Sotomayor[3], L Sokol[2], JC Chavez[2]
[1]Haematology Department, Principe de Asturias University Hospital, Alcalá de Henares, Spain, [2]Department of Malignant Hematology, Moffitt Cancer Center, Tampa, [3]Hematology/Oncology, George Washington University, Washington D.C, United States

Background: Transformed lymphoma (TL) is a very heterogeneous condition that usually represents the final stage of low grade non-Hodgkin's lymphomas (LG-NHL) progression. It is commonly associated with poor survival. Previously, we reported the prognostic impact of the Revised International Prognostic Index (R-IPI) and National Comprehensive Cancer Network-IPI scores at histologic transformation in survival (Tsao *et al.,* ASH 2013 and Griffin *et al.,* ASH 2014). Here we investigate the impact of early transformation in TL.
Aims: To determine if early transformation of LG-NHL has a prognostic impact in high-risk TL.
Methods: Patients with a biopsy proven diagnosis of TL from LG-NHL between January 2001 and December 2014 that were treated at Moffitt Cancer Center were identified using the Total Cancer Care Database. High risk TL was defined based on an R-IPI over 3 points and NCCN-IPI over 3 points. Early transformation was empirically defined as the evidence of aggressive transformation within 24 months (TT24) from LG-NHL diagnosis. Overall survival (OS) was calculated from the date of transformation, estimated by the Kaplan-Meier method (K-M), and compared using the Log-rank test. Predictors of survival were assessed using Cox proportional hazards model, and multivariate analy-

ses of significant factors were assessed by backward step elimination for variables with a p<0.05.
Results: A total of 149 patients with transformed DLBCL were identified. The median age at transformation was 58 years (range 21–89), the M/F ratio was 1.4. The most common type of LG-NHL was follicular lymphoma (75.8%). At TL, B-symptoms were present in 30%, stage III/IV in 64.4%, elevated LDH in 55.2%, serum albumin (SA) less or equal than 3,7 g/dL in 28% of patients. Forty-five percent and 44.6% had IPI score ≥3 and NCCN-IPI score ≥3, respectively. The most common treatment regimen at time of transformation was R-CHOP (61%) then by R-ICE (12.7%). The median OS was 6.4 years (95% CI, 5.48-7.49). The 5 and 10-years OS were 54% and 33% respectively. Patients with NCCN-IPI and R-IPI ≥3 were associated with poor survival (median OS of 4.2 years, p=0.024; and 3.76 years, p<0.001, respectively). SA ≤3.7 g/dL was predictive for inferior OS (3.5 y *vs* 8.6 y, p=0.04). TT24 was associated with poor outcomes (OS 3.3 *vs* 6.1 y, p=0.008) (Figure 1). Multivariate analysis showed that TT24 (HR 4.13, p=0.042), NCCN-IPI >3 (HR 3.16, p=0.075) and IPI ≥3 (HR 3.47, p=0.063)were statistically significant for shorter OS. The impact of TT24 was particularly significant in high risk TL (NCCN-IPI >3 and/or IPI ≥3) with very poor outcomes (OS 1.7 *vs* 4.4 y, p=0.038 and 1.3 *vs* 4.4 y, p <0.001; respectively).

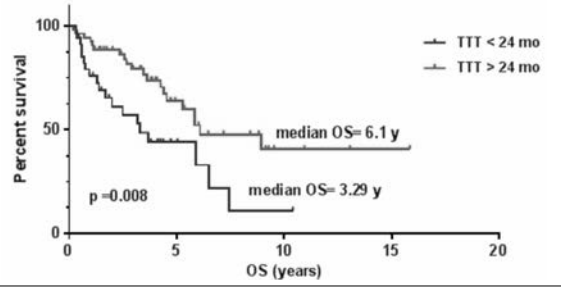

Figure 1. OS by early transformation (TTT24).

Summary/Conclusions: Early time of transformation (TT24) to a more aggressive lymphoma is predictive of shorter OS in patients with TL, especially in cases of high risk TL, defined by the R-IPI and/or NCCN-IPI scores. New strategies in prospective studies based on TT24 are warranted for patients with TL.

P692

OFATUMOMAB FOR THE TREATMENT OF EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA OF THE MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT LYMPHOMA): THE O-MA1 STUDY
B Kiesewetter[1,*], O Neuper[1], ME Mayerhoefer[2], W Dolak[3], J Lukas[4], M Raderer[1]
[1]Dept. of Medicine I/Clin. Div. of Oncology, [2]Dept. of Radiology, [3]Dept. of Medicine III/Clin. Div of Gastroenterology and Hepatology, [4]Dept. of Ophthalmology, Medical University Vienna, Vienna, Austria

Background: To date there is no defined treatment standard for Helicobacter pylori (HP)-eradication refractory, extragastric or advanced mucosa-associated lymphoid tissue lymphoma (MALT lymphoma). Immuno-/chemotherapy combinations have been successfully tested in this setting, however, due to the indolent course of this disease less toxic approaches are warranted. Rituximab-monotherapy has been tested for MALT lymphoma and has shown symptomatic activity but a relatively low rate of durable remissions. Based on data generated in other B-cell malignancies second-generation compound ofatumumab (OFA) appears to be an attractive agent for the treatment of MALT lymphoma.
Aims: The primary endpoint of this trial was to evaluate the capacity and safety of OFA to induce objective responses in patients with HP-eradication refractory or extragastric MALT lymphoma
Methods: The O-MA1 study was a single-center phase II study. In case of HP-positive MALT lymphoma a minimum of 12 months follow-up after successful HP-eradication was required. OFA monotherapy was given at four weekly doses (1000mg i.v., weeks 1,2,3,4) followed by four doses at two-month intervals, starting at week 8. Restaging was performed at weeks 12, 24 and at end of treatment. To date, the planned number of 16 patients has been included and the study is closed to recruitment.
Results: The median age at treatment start was 69 years with an absolute range of 38 to 85 years. Five of 16 patients (31%) had primary gastric MALT lymphoma while the remaining 11 (69%) presented with extragastric manifestations including lymphoma of the ocular adnexa (n=6), the lung (n=1), the bladder (n=1), the liver (n=1), the breast (n=1) and bilateral lymphoma of the parotid glands (n=1). In terms of staging 12 patients (75%) had localized lymphoma *i.e.* stage I or II according to Ann Arbor, and four patients (25%) disseminated disease *i.e.* stage IV. All patients had an ECOG performance status below two, but a total of nine patients (56%) had more than four significant comorbidities. IPI-Score was 0 - 1 in 12 patients (75%) and 2 - 3 in four patients (25%). A total of eight patients (50%) had been pretreated including five patients (31%) with prior immuno- or chemotherapy. Median time from last treatment to the first dose of OFA in pretreated patients was 8.9 months (range; 4.5-59). At the time of this analysis all patients had at least one restaging and were thus evaluable for response. Twelve of 16 patients showed an objective response for an overall response rate of 75%. The complete remission rate was 50% (8/16), while 25% had a partial remission (4/16) and 25% disease stabilization (4/16) as best response. However, one patient with gastric lymphoma and complete remission at first and second restaging had a focal gastric relapse at final assessment. This patient is currently asymptomatic and no salvage treatment has been indicated so far. The median time to best response was 3.3 months (range; 2.5-10). Tolerability of treatment was excellent with no related adverse events greater CTCAE grade I except infusion reaction grade I/II in 13/16 patients (81%) during the first OFA-application, which could be easily handled with steroids or antihistamines and did usually not reoccur in the following. However, one patient was taken off-study due to unrelated prolonged hospitalization for erysipelas but was still evaluable for response as this was after the fourth application of OFA. No relevant grade III or IV hematologic adverse events have occurred. To date at a median follow-up time of 16.2 months (range; 3.9-28.2) 14 of 16 patients have finished treatment with no further relapse or progress, while two patients are on treatment. More mature data will be presented at the meeting.
Summary/Conclusions: This is the very first study to evaluate OFA as a chemotherapy-free approach for the treatment of MALT lymphoma. With 16/16 planned patients recruited we report a response rate of 75% and a disease stabilization rate of 94%. Toxicities were negligible even in elderly patients with significant comorbidities.

P693

BENDAMUSTINE PLUS RITUXIMAB *VERSUS* R-CHOP AS FIRST-LINE TREATMENT FOR PATIENTS WITH INDOLENT NON-HODGKIN'S LYMPHOMA: EVIDENCE FROM A MULTICENTER, RETROSPECTIVE STUDY
P Mondello[1,*], N Steiner[2], W Willenbacher[2], I Wasle[2], F Zaja[3], R Zambello[4], A Visentin[4], E Mauro[5], S Ferrero[6], P Ghione[6], V Pitini[7], S Cuzzocrea[8], M Mian[9]
[1]Human Pathology, University of Messina, Messina, Italy, [2]Internal Medicine V: Hematology & Oncology, Medical University of Innsbruck, Innsbruck, Austria, [3]Hematology, DISM, AOUD S. M. Misericordia, Udine, [4]Hematology and Clinical immunology unit, University of Padova, Padova, [5]Internal Medicine, Pordenone General Hospital, Pordenone, [6]Molecular Biotechnologies and Health Sciences, University of Torino, Torino, [7]Human Patology, [8]Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Messina, [9]Hematology & CBMT, Ospedale di Bolzano, Bolzano, Italy

Background: The optimal first line treatment for advanced low-grade non-Hodgkin lymphomas (LG-NHL) is still highly debated. Recently, the StiL and the BRIGHT trials showed that the combination of rituximab and bendamustine (R-B) is non-inferior to rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) with a better toxicity profile.
Aims: Utilizing a retrospective analysis, we compared the efficacy and safety of both regimens in clinical practice.
Methods: From November 1995 to January 2014, 263 LG-NHL patients treated with either R-B or R-CHOP were retrospectively assessed in 7 European cancer centers.
Results: Ninety patients were treated with R-B and 173 with R-CHOP. Overall response rate was 94% and 92% for the R-B and the R-CHOP group, respectively. The percentage of complete response was similar for both groups (63% *vs* 66% with R-B and R-CHOP, respectively; p=0.8). R-B was better tolerated and less toxic than R-CHOP. The median follow-up was 6.8 and 5.9 years for the R-CHOP and the R-B group, respectively. Overall, no difference in progression free survival (PFS) (108 months *vs* 110 months; p=0.1) was observed in the R-B group compared to the R-CHOP cohort. However, R-B significantly prolonged PFS in FL patients (152 and 132 months in the R-B and R-CHOP group, respectively; p=0.05).
Summary/Conclusions: We confirm that the R-B regimen administered in patients with LG-NHL is an effective and less toxic therapeutic option than R-CHOP in clinical practice. In addition, we suggest R-B as the treatment of choice for FL patients due to the long-term disease control achieved.

P694

FINAL RESULTS OF IHC ANALYSIS AND PROGNOSTIC FACTORS IN POST TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS AFTER SOLID ORGAN TRANSPLANTATION
Z Nooruddin[1], Z Pan[1], L Gross[2], D Weitzenkamp[2], D Pollyea[1], J Gutman[1], W Robinson[1], C Smith [1], J Schowinsky[1], B Haverkos[1], E Purev[1], D Sherbenou[1], R Rabinovitch [1], D Ney [1], CT Jordan [1], M Kamdar[1,*]
[1]Blood Cancer and BMT, [2]Dept of Biostatistics, University of Colorado Denver, Denver, United States

Background: Post Transplant Lymphoproliferative Disorder (PTLD) represents one of the most fatal complications following solid organ transplants (SOT). A multicenter analysis in 2010 reported a 3yr overall survival (OS) of 62%. In 2014 a single institutional study reported an improved median OS of 8 years

in the rituximab era. Clinical studies have attempted to subdivide post transplant diffuse large B cell lymphomas (PT-DLBCL) into immunophenotypic subgroups with most reviews demonstrating a higher incidence of activated B-cell (ABC) subtype. Because of the rarity of PTLD, insight into disease development and progression is currently limited

Aims: Our preliminary analysis of data on 52 patients (pts) was presented at the American Society of Hematology meeting in 2015 (Abstract 1443). We hereby present our final analysis on a larger cohort of 86 pts with PTLD treated at the University of Colorado over a 25-year period.

Methods: This retrospective analysis focused on 86 adult SOT pts who were treated for PTLD at our institution between Jan 1989 to April 2015.

Results: 86 pts were evaluated. The median age at transplantation was 49.5 yrs (5-74 yrs). Median time from SOT to PTLD was 37 months (1.4-499).The most common transplanted organ included kidney (40%), liver (38%), lung (13%) and heart (9%). Grafted organ was involved with lymphoma in 25% pts. 62% were male, 36% had Stage III-IV, 60% were EBV positive, 16% had bone marrow involvement, 19% had CNS involvement and 30% had extranodal Disease. 31% pts had early PTLD (<12mnths of SOT) and 69% pts had late PTLD(>12mnths of SOT). 77% pts with early PTLD and 49% of pts with late PTLD were EBV positive. Of the 86 patients, 75 pts (87%) had monomorphic histology. Amongst monomorphic PTLD 48 pts (64%) had DLBCL, 9% had Burkitt Lymphoma, 12% had CNS lymphoma, 1% had plasmablastic lymphoma, 1% had NK/T cell lymphoma, 3% had hodgkins lymphoma and 5% had plasma cell neoplasm. 88% pts were CD20 positive, 67% had elevated LDH and 50% had an IPI >1. 85% were on >1 immunosuppressive agent (ImSx) with a median ImSx treatment (Rx) duration of 3 years. Interestingly 80% of pts with CNS lymphoma were on mycophenolate mofetil ImSx. 86% of pts with Burkitt lymphoma had undergone liver transplantation. All Pts with CNS Lymphoma were recipients of kidney transplantation. Initial Rx included reduction in ImSx in 80% pts, rituximab monotherapy in 27% pts, rituximab +chemotherapy in 31% pts and chemotherapy alone in 11%pts. 63 of 86 patients were assessable for response. 90% achieved a complete remission after first line therapy while 17% were refractory to front line therapy. 9 out of 63 pts(14%) pts relapsed. IHC staining utilizing the Hans Algorithm was applied on 32 of 48 samples with DLBCL. ABC subtype was identified in 75% (24/32 samples) and GCB (germinal center B-cell) subtype in 25% (8/32) samples. Median overall survival was 133 months (11yrs). On univariate analysis ABC DLBCL subtype (HR 0.28, 95% CI 0.085-0.970, p=0.03) was associated with improved survival. Graft organ involvement with PTLD and CNS disease showed a trend to poor survival. EBV positivity, Polymorphic PTLD and Early PTLD showed a trend toward improved survival. Rituximab containing therapy (Monotherapy or with Chemotherapy) was better than non-Rituximab therapy (HR 0.6 P=0.3). Rituximab plus Chemotherapy had worse outcomes than Rituximab monotherapy (HR 2.06) (Figure 1).

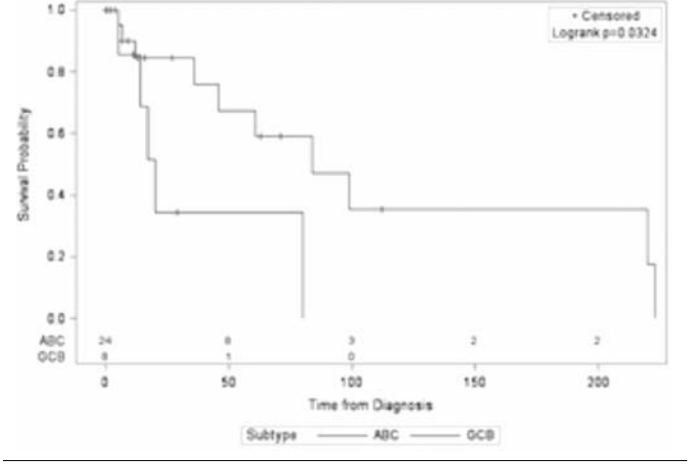

Figure 1. Product-limit survival estimates. With number of subjects at risk.

Summary/Conclusions: In this consecutive series of PTLD after SOT from a single institution over a 25 year period we noted a 3yr OS of 81% and a 5yr OS of 76%. ABC subtype was associated with improved survival whereas graft organ involvement and CNS disease was associated with a trend to poor outcomes. Rituximab based therapy was associated with improved outcomes. In one of the first ever-reported data in PT-DLBCL cases we were able to demonstrate a higher incidence and an improved survival with ABC DLBCL subtype compared to GC DLBCL. The reason for this is not fully understood and merits further evaluation in larger pt cohorts.

Aggressive Non-Hodgkin lymphoma - Clinical

IMPROVED OUTCOMES WITH HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANT IN PATIENTS WITH PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA WITH PRESERVATION OF COGNITIVE FUNCTION

S Kassam[1,*], A Costello[2], V Potter[1], P Patten[1], D Yallop[1], S Devereux[1], R Marcus[1]

[1]Haematology, [2]Neuropsychology, King's College Hospital, London, United Kingdom

Background: Outcome for patients with primary central nervous system lymphoma (PCNSL) have improved with the use of high-dose (HD) methotrexate-based (MXT) regimens but relapses are frequent. To prevent relapse, consolidation of first response is desirable, the main options being whole-brain radiotherapy (WBRT) or high-dose chemotherapy (HDC) and autologous stem cell transplant (ASCT). Our centre has favoured the latter given the high incidence of neurotoxicity with WBRT.

Aims: To retrospectively review the outcomes for patients with PCNSL treated with HDC and ASCT and report analysis of prospective neurocognitive assessments.

Methods: 63 patients were diagnosed with PCNSL between 2008 and 2015. The median age at diagnosis was 60 years (range 27-80; 37 male). 21 patients went on to receive HDT-ASCT with BCNU-thiotepa conditioning. A proportion of these patients also had prospective neurocognitive assessment. 5 cognitive domains were assessed: intellectual, memory, language, perception and executive functions. All employed tests have published, validated normative data. Raw test scores were converted into age adjusted standard scores and compared with published normative values.

Results: 49/63 patients (78%), ≤70 years and hence suitable for HDC-ASCT, were treated with HD-MXT based regimens. 23 (47%) had a response *i.e.* complete response (CR) or partial response (PR) to first-line treatment and 14/23 proceeded to HDC-ASCT. 15/26 patients who did not have a response to HD-MTX went on to receive second line treatment (6 radiotherapy, 7 chemotherapy) and, of these, 7 achieved a response (CR/PR) of whom 4 proceeded to HDC-ASCT. 9/23 patients that initially responded to HD-MXT but did not proceed to HDC-ASCT all relapsed. 5 received further treatment (2 chemotherapy and 3 radiotherapy) and of these, 3 proceeded to HDC-ASCT in second response. Overall, 21 patients received HDC-ASCT, median age 54 years (range 26-68; 15 male). Histology was DLBCL in 19, mantle cell lymphoma in 1 and ALK+ anaplastic large cell lymphoma in 1. For all 63 patients, the median follow-up is 8.3 months (0-92 months) and 36 patients (57%) have died, all except one from lymphoma. The median first remission duration is 10 months (1-71) and median overall survival (OS) 8.7 months. For the 21 patients receiving HDC-ASCT, the median follow-up is 26 months (11-92) and the median progressive free survival and OS has not been reached (Figure 1). 6/21 (29%) have relapsed; 2 with systemic lymphoma. 5 have died; 4 from lymphoma and 1 treatment-related (hepatitis E infection). 9 patients had neurocognitive assessments at baseline (pre- ASCT) and 1 year post ASCT (6 of whom had undergone baseline assessment) and 7 patients at 2 years post ASCT (3 of whom had undergone both baseline assessment and 1 year post ASCT). Intellectual, language and perceptual functions were preserved over the 2 year period. However, some patients displayed impairment in memory and executive function at baseline. While no deterioration in executive functions was demonstrated over the 2 year period, there was a suggestion of mild decline in aspects of verbal recall memory at 1 year post ASCT (paired t-tests of mean score on list learning at 1 year follow-up significantly below baseline mean score, p=0.021).

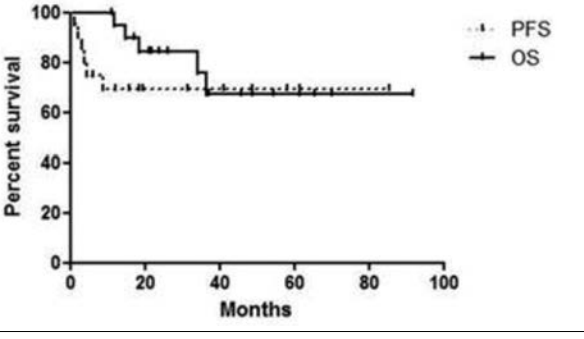

Figure 1.

Summary/Conclusions: In this unselected group of patients, the outcome for PCNSL remains poor. However, for those patients that respond to induction regimens and are fit enough to receive HDC-ASCT, prolonged disease control can be achieved with relative preservation of neurocognitive function.

P696

LENALIDOMIDE IN RELAPSED OR REFRACTORY DIFFUSE LARGE B CELL LYMPHOMA: IS IT A VALID TREATMENT OPTION?

P Mondello[1,*], N Steiner[2], W Willenbacher[2], S Ferrero[3], A Marabese[4], V Pitini[1], S Cuzzocrea[5], M Mian[4]

[1]Human Pathology, University of Messina, Messina, Italy, [2]Internal Medicine V: Hematology & Oncology, Medical University of Innsbruck, Innsbruck, Austria, [3]Molecular Biotechnologies and Health Sciences, University of Torino, Torino, [4]Hematology & CBMT, Ospedale di Bolzano, Bolzano, [5]Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Messina, Italy

Background: Diffuse large B cell lymphoma (DLBCL) is the most frequent aggressive non-Hodgkin lymphoma (NHL) in the western country. Despite its typical morphology, DLBCL is characterized by molecular heterogeneity, which can be classified by gene expression profiling (GEP) in two main subgroups based on the cell of origin, namely germinal center B cell (GCB) and activated B-cell. However, GEP is not routinely performed, which is why immunohistochemistry (IHC) is commonly used for designating these two subtypes. Because of the addiction to different oncogenic driver pathways, each subtype differs in response to drugs, leading to a distinct prognosis. In particular, the cure rate of ABC is only 40% after standard immunochemotherapy, hence novel therapeutic approaches are urgently needed. Prospective randomized studies regarding the use of lenalidomide in relapsed/refractory (R/R) DLBCL have demonstrated efficacy and feasibility of this immunomodulatory agent.
Aims: Up to now, data evaluating this drug in clinical practice are lacking. Therefore, we assessed its toxicity and efficacy in the largest R/R DLBCL real-life cohort carried out up to now.
Methods: From January 2006 to January 2015, 123 consecutive patients affected by R/R DLBCL who underwent lenalidomide monotherapy were retrospectively assessed in 3 European cancer centers.
Results: All patients received a starting dose of either 15 mg/day or 25 mg/day of lenalidomide. Response to treatment differed significantly between the two IHC subgroups: patients with non-GCB DLBCL achieved a complete remission (CR) in 32% and a partial remission (PR) in 33% compared to 0% and 3% in the GCB group (p<0.0001 and p=0.001). Toxicity was limited and reversible. The median follow-up was 4.5 years (range 2-108 months). The median duration of response was 4 months (range 1-10 months) and 15 months (5-23 months) in GCB and non-GCB DLBCL, respectively (p<0.001). Patients receiving the 25 mg daily of lenalidomide had an overall superior outcome compared to those who underwent the 15 mg regimen, namely 21% achieved a CR and 23% a PR compared to 0% and 8% (p=0.007 and 0.05). Also median duration of response varied significantly between both dosing groups (10 *vs* 4 months; p=0.03). Overall, the median progression free survival was 34 months (range 2-108 months), ranging between 37 and 30 months according to the non-GCB and GCB DLBCL group (p<0.0001) and between 24 and 34 months (p=0.002) according to the higher or lower lenalidomide dosing. However, overall survival was similar between the different subgroups (38 *vs* 41 months in non-GCB and GCB DLBCL, p=0.2; 38 *vs* 42 months in 15 and 25 mg/die, p=0.4).
Summary/Conclusions: In this real-life setting, we demonstrated that lenalidomide is a valid treatment option for R/R DLBCL with only limited and reversible toxicity. As expected, lenalidomide is more efficient in patients with non-GCB DLBCL, but responses were also observed in the other subgroup, which is why it can be considered also for GCB DLBCL. If clinically feasible, the 25mg dosing should be preferred.

P697

NONPEGHYLATED LIPOSOMAL DOXORUBICIN AS A COMPONENT OF R-CHOP IS EFFECTIVE AND SAFE IN THE TREATMENT OF A CARDIAC HIGH-RISK AND ELDERLY LYMPHOMA PATIENTS

L Rigacci[1,*], F Lancia[1], L Flenghi[2], F Angrilli[3], U Vitolo[4], ML Vigliotti[5], V Tarantino[6], A Ferrari[7], M Spina[8], G Benelli[1], S Bolis[9], G Gaidano[10], C Cox[11], PR Scalzulli[12], AM Mamusa[13], R Mazza[14], PL Zinzani[15], S Ferrari[16], G Gini[17], A Mulè[18], M Ladetto[19], N Di Renzo[20], F Zaja[21], V Zilioli[22], P Musto[23], V Zoli[24], D Marino[25], A Fabbri[26], A Guarini[27], A Carpaneto[28], F Ballerini[29], M Gotti[30], M Petrini[31], A Di Rocco[11], A Bosi[1]

Background: Doxorubicin is the most effective single agent in the treatment of non Hodgkin's lymphoma (NHL). Its use is limited for the cardiac toxicity particular in elderly patients (pts) and in pts with history of cardiac disease. Liposomal doxorubicin has been proven to reduce cordiotoxicity.
Aims: The aim of this retrospective study was to evaluate in real life in a high-risk population the use of nonpeghylated liposomal doxorubicin (NPLD) in term of efficacy and cardiac events.
Methods: 965 consecutive pts treated with R-COMP (doxorubicin was substituited with NPLD, Myocet) were collected from 32 Italian Hematologic Centers. After the evaluation of pts' records 16 were excluded, so the final analysis was conducted on 937 pts. Median age was 73 (range 26-92), the reasons for use of NPLD were: age (449 pts), cardiac disease (340 pts), uncontrolled hypertension (123 pts), other reasons (55 pts). According to clinicians evaluation 48% of pts would not have used standard doxorubicin for different situations (age, cardiomiopathy, previous use of doxorubicin, uncontrolled hypertension). 115 pts showed at diagnosis a LVFS <50% (in 108 pts this data was not reported). 5083 cycles were infused and 841 pts (90%) performed 4 or more cycles according to the therapeutical program. 462 pts (49%) were over 74 years, 66% of pts had stage III or IV, 95% were DLBCL.
Results: Overall 678 pts (72%) obtained a complete remission (CR) and 116 experienced a relapse. CR rate was not significantly different between the 52% of pts which could be able to use standard doxorubicin (76%) and the 48% of pts which would not have used doxorubicin (70%). During treatment 98 pts (11%) presented a cardiac toxic event in particular: 29 heart failure, 29 severe cardiac arrhythmia, 15 myocardial infarction, 4 atrial fibrillation, 3 cardiac arrest and 18 other mild cardiac complications. No statistical differences was reported between pts with normal FE *VS* or less tha 50% according to this cardiac toxic events. After a median period of observation of 32 months, 651 pts are alive and the overall survival (OS) was 72%. OS was significantly superior in pts considered eventually elegible to standard doxorubicin in comparison with other not elegible 79% *vs* 70% (p .001). 282 pts were death and 4 were lost to follow-up. The causes of death: 181 due to lymphoma progression, 37 due to complications other than cardiac, 15 due to cardiac complications, 12 due to second neoplasm and in 41 the cause was not known. After a median observaton period of 23 months PFS was 58%. Either in univariate or in multivariate OS and PFS were not significantly affected by age or cardiac disease.
Summary/Conclusions: In conclusion NPLD introduced in R-CHOP is effective and safe in a cardiac high-risk population and in a negatively selected group of pts. Moreover the use of this NPLD permitted that about half of our population have had the opportunity to receive the best available treatment.

P698

METHYLATION OF CELL-FREE CIRCULATING DNA IN PLASMA PREDICTS POOR OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA

LS Kristensen[1,*], JW Hansen[1], SS Kristensen[1], D Tholstrup[1], LBS Harsløf [1], OB Pedersen[2], PDN Brown[1], K Grønbæk[1]

[1]Department of Hematology, Rigshopitalet, Copenhagen N, [2]Klinisk Immunologisk Afdeling, Næstved Sygehus, Næstved, Denmark

Background: The prognostic value of aberrant DNA methylation of cell-free circulating DNA in plasma has not previously been evaluated in diffuse large B-cell lymphoma (DLBCL).
Aims: The aim of this study was to investigate if aberrant promoter DNA methylation can be detected in plasma from DLBCL patients and to evaluate this as a prognostic marker. Furthermore, we wanted to follow possible changes in methylation levels during treatment.
Methods: Seventy-four patients were enrolled in the study, of which 59 received rituximab and CHOP-like chemotherapy. Plasma samples were collected from all patients at the time of diagnosis and from 14 healthy individuals used as controls. In addition, plasma samples were collected during and after treatment for surviving patients. In total, 158 plasma samples were analyzed for DNA methylation in the promoter regions of *DAPK* (*DAPK1*), *DBC1*, *MIR34A*, and *MIR34B/C* using pyrosequencing.
Results: Aberrant methylation levels at the time of diagnosis were detected in 19, 16, 8, and 10% of the DLBCL plasma samples for *DAPK1*, *DBC1*, *MIR34A* and *MIR34B/C*, respectively. *DAPK1* methylation levels were significantly correlated with *DBC1* and *MIR34B/C* methylation levels (P<0.001). For the entire cohort five-year overall survival (OS) rates were significantly lower in the groups carrying aberrant *DAPK1* (P=0.004) and *DBC1* methylation (P=0.044), respectively. Multivariate analysis identified *DAPK1* as an independent prognostic factor for OS with a hazard ratio of 5.1 (95% CI: 1.9-13.4, P=0.001). Patients with *DAPK1* methylated cell-free circulating DNA at time of diagnosis, who became long term survivors, lost the aberrant methylation almost immediately after treatment initiation. Conversely, patients that regained or maintained aberrant *DAPK1* methylation died soon thereafter.
Summary/Conclusions: Aberrant promoter methylation of cell-free circulating DNA can be detected in plasma from DLBCL patients, and *DAPK1* methylation is an independent prognostic marker that may also be used to assess treatment response.

P699

REAL-WORLD EXPERIENCE OF IBRUTINIB IN >700 PATIENTS WITH MANTLE-CELL LYMPHOMA: DATA FROM A GLOBAL NAMED PATIENT PROGRAM

S Rule[1,*], J Diels[2], N Healy[3], W Iraqi[4], J Aschan[5], M Wildgust[6]
[1]Derriford Hospital, Plymouth, United Kingdom, [2]Janssen EU HEMAR Statistics & Modeling, Beerse, Belgium, [3]Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, [4]Janssen Pharmaceuticals, Paris, France, [5]Janssen-Cilag EMEA Medical Affairs, Sollentuna, Sweden, [6]Janssen Research & Development, Raritan, United States

Background: A global named patient program (NPP) was opened in numerous countries worldwide in order to allow access to ibrutinib for eligible patients with relapsed/refractory mantle-cell lymphoma (MCL) prior to approval in those countries. This program provides real-world data on estimated outcomes with ibrutinib across a large, global MCL population.
Aims: To use real-world data from the ibrutinib MCL NPP to investigate whether treatment benefits reported in randomized clinical trials are reflected in outcomes observed in clinical practice.
Methods: In an analysis of ibrutinib ordering/reordering, we estimated patient time on treatment, in order to provide a conservative approximation of progression-free survival (PFS) using Kaplan-Meier analysis and Cox proportional hazard regression. Reordering data were censored at the date of last ibrutinib supply or resupply (ibrutinib was resupplied every 1-3 months depending on stage of the NPP). Patients transferring to commercial ibrutinib after approval were censored at the time of NPP closure in their country.
Results: In total, 715 patients with MCL from 26 countries enrolled in the NPP were included in this analysis; median age was 70 years, and 76.1% were male. After 12 months, 52.3% (95% CI, 43.5-60.4%) of the global population remained on treatment. This estimate is similar to the 12-month time on treatment (57.6% [95% CI, 48.9-65.3%]) and PFS (58.0% [95% CI, 49.3-65.7%]) rates observed in the phase 3 RAY (MCL3001) study of ibrutinib for relapsed/refractory MCL (inclusion criteria were similar for the MCL NPP and RAY). Moreover, Kaplan-Meier curves for time on treatment for the global MCL NPP population and the RAYstudy population were not statistically different (Figure 1; MCL NPP *versus* RAY: HR, 1.14 [95% CI, 0.83-1.54]). Limited baseline demographic information collected at NPP enrollment allowed an exploration of time on treatment via multivariate analysis (Figure 2).

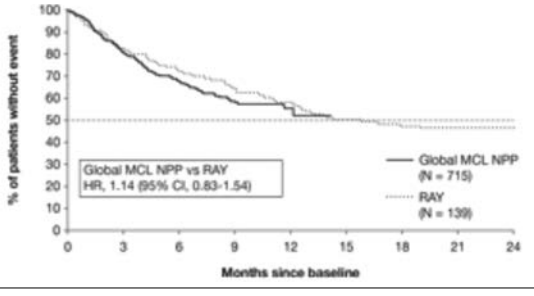

Figure 1. Time on treatment for Global MCL NPP population versus RAY.

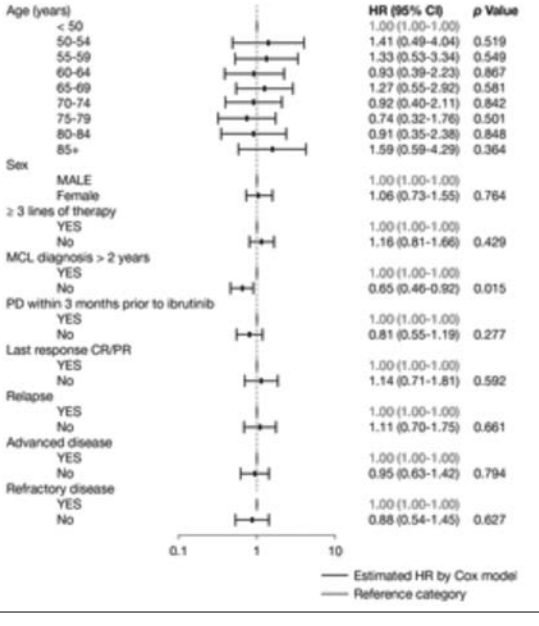

Figure 2. Multivariate analysis of time on treatment.

Timing of MCL diagnosis was the only independently significant variable in the multivariate analysis, with time on treatment being longer in patients diagnosed with MCL within the last 2 years. Of note, in this analysis, neither refractory disease (defined as no response to prior therapy [ie, stable disease or progression]), advanced disease (involvement of the bone marrow, extranodal sites, or both), relapsed disease, nor prior response with the previous therapy additionally impacted time on treatment. In total, 168 patients (23.5%) discontinued treatment during the observation period, the most common reasons being death (10.8%), disease progression (7.3%), and AEs (1.3%).
Summary/Conclusions: Although NPP data are based on physician declarations and are unmonitored, this analysis provides a real-world estimate of time on treatment, which can be considered a conservative proxy for PFS. The estimates, determined from a large, global MCL population, were similar to those for the RAY study, which suggests that results observed in MCL clinical trials with ibrutinib are reproducible in clinical practice.

P700

A SPECIFIC SIGNATURE IN LYMPH NODE BIOPSIES OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PREDICTS CENTRAL NERVOUS SYSTEM (CNS) INVOLVEMENT

I Dlouhy[1,*], D Martín-García[2], P Pérez-Galán[2], O Balague[3], L Magnano[1], J Rovira[1], M Díaz-Beyá[1], K Karube[4], A Enjuanes[2], M Pinyol[2], E Giné[1], J Delgado[1], E Campo[2], A López-Guillermo[1]
[1]Hematology, Hospital Clinic, [2]IDIBAPS, [3]Pathology, Hospital Clinic, Barcelona, Spain, [4]Pathology and Cell Biology, Graduate School of Medicine and Faculty of Medicine, University of the Ryukyus, Okinawa, Japan

Background: The infiltration of immunoprivileged sites, including the central nervous system, either at diagnosis or at relapse, confers an ominous outcome to the patients with DLBCL. A specific gene expression profiling (GEP) has been identified for primary CNS lymphomas (pCNSL). Similarly, GEP studies could help in selecting DLBCL patients with high risk for CNS infiltration.
Aims: To identify a GEP "CNS signature" in the lymph nodes of patients with DLBCL that can predict CNS involvement.
Methods: GEP analysis (Affymetrix HG-U219) was performed in 11 cases of DLBCL patients with CNS infiltration (3 cases at diagnosis and 8 during the follow up). The control group consisted of 27 DLBCL, not otherwise specified, without extranodal involvement, that showed no CNS infiltration during follow up. No case of transformed or immunodeficiency -related DLBCL was included in the control group. Lymph node samples at diagnosis were used in both groups. Differential gene expression between the two subgroups was analyzed using the Limma package (bioconductor.org, R version 3.2.0), and biological pathways assignment was performed by Gene set enrichment analysis (GSEA) using custom gene sets related to B cell biology, canonical pathways (C2CP) and transcription factor (C3TFT) public databases.
Results: Our analysis (log fold change >1,5 and P<0.05) identified 25 upregulated genes in the CNS group (Figure 1), including SRRM2, SRSF5 and TRA2A (involved in splicing), EVL (cell motility), MKI67 and TRIB2 (associated with brain metastasis in other cancers) and BCL6 (associated with pCNSL); and 11 downregulated genes, including LSP1 (implicated in transendothelial migration of leukocytes). Pathway analysis with GSEA (False discovery rate (FDR) <0.05 and Normalized enrichment score (NES) >1.8) revealed that the CNS group showed an overrepresentation of signaling pathways related to: 1) extracellular matrix molecules, migration (FAK) and adhesion-related pathways (integrins), 2) angiogenesis, 3) cell proliferation (E2F) and 4) NOTCH (Table 1). Immunohistochemistry analyses to validate these findings are ongoing.

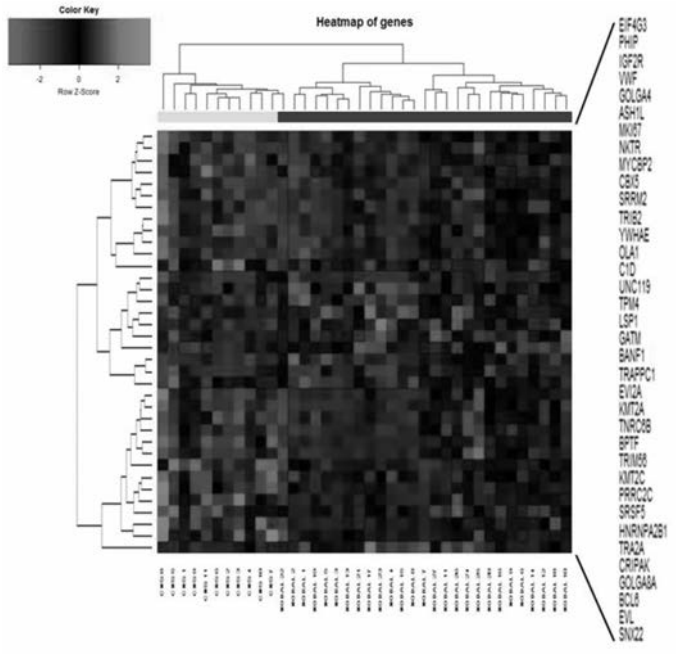

Figure 1.

Summary/Conclusions: The CNS signature identified in our study at diagnosis could represent a specific feature of DLBCL patients with high risk for CNS involvement. If confirmed, these findings could better guide initial treatment of these patients to improve their outcome.

P701

DIFFUSE LARGE B-CELL LYMPHOMA IN THE RITUXIMAB ERA: REAL LIFE ANALYSIS OF PATIENTS WITH REFRACTORY DISEASE OR RELAPSE

B Arboe*, JS Gørløv, P Brown
Department of Hematology, Copenhagen Uiversity Hospital, Rigshospitalet, Copenhagen, Denmark

Background: The addition of Rituximab as part of first line treatment for diffuse large B- cell lymphoma (DLBCL) has improved outcome. However, in the case of refractory disease or relapse, high dose chemotherapy with autologous stem cell transplant (ASCT) is regarded the only curative option.
Aims: To analyze treatment and outcome for patients with DLBCL with primary refractory or relapsed disease in the Rituximab Era.
Methods: Patients diagnosed with *de novo* DLBCL in the period 2000-2013 were identified in the Danish National Lymphoma Registry. Patients not responding to first line treatment or who subsequent developed relapse were included. Patients with primary CNS lymphoma were excluded. Survival analysis was performed according to the Kaplan Meier method and compared by log-rank tests. Survival time was measured from date of relapse to death or censored at the time of analysis.
Results: A total of 5203 patients were diagnosed with DLBCL in the study period. Median age was 68 years, and 56% were male. In 4842 patients a first line treatment was started. 3295 patients were treated with Rituximab containing treatment. 2852 (86%) achieved partial remission or better after first line therapy, however 443 (14%) had primary refractory disease, and 446 (14%) patients developed relapse (CNS involvement n=90, other lymphoma subtype n=68). The median overall survival was 8.8 years. Of the 731 patients with either primary refractory or relapsed disease, 330 received a second line treatment; 242 received salvage therapy, of these 89 patients completed ASCT. After 2 years, 46 patients receiving ASCT were still alive. Intention to treat analyses reveals significantly better outcome for patients with relapsed diseased treated with salvage strategy compared to those treated with palliative strategy (p=0.03). However, no difference was seen for the patients with primary refractory disease (p=0.3), Figure 1. As expected, patients with primary refractory disease not receiving ASCT had a dismal survival compared to patients with later relapse (p=0.003), but no significant difference was found in the group receiving ASCT. For the 1547 patients not treated with Rituximab, 1143 (73%) achieved partial remission or better, however 404 (27%) had primary refractory disease, and 344 (22%) developed relapse (CNS involvement n=37, other lymphoma subtype n=32). The median overall survival was 2.3 years. Of the 681 patients with primary refractory or relapsed disease, a total of 150 patients received second line treatment, 113 patients received salvage therapy and of them 37 patients also received ASCT. After 2 years, 28 patients receiving ASCT were still alive. Of the patients not receiving ASCT, 41 patients were still alive after 2 years. In both groups, patients with primary refractory disease had dismal survival compared to patients with later relapse (p=0.007 *vs* p=0.03).

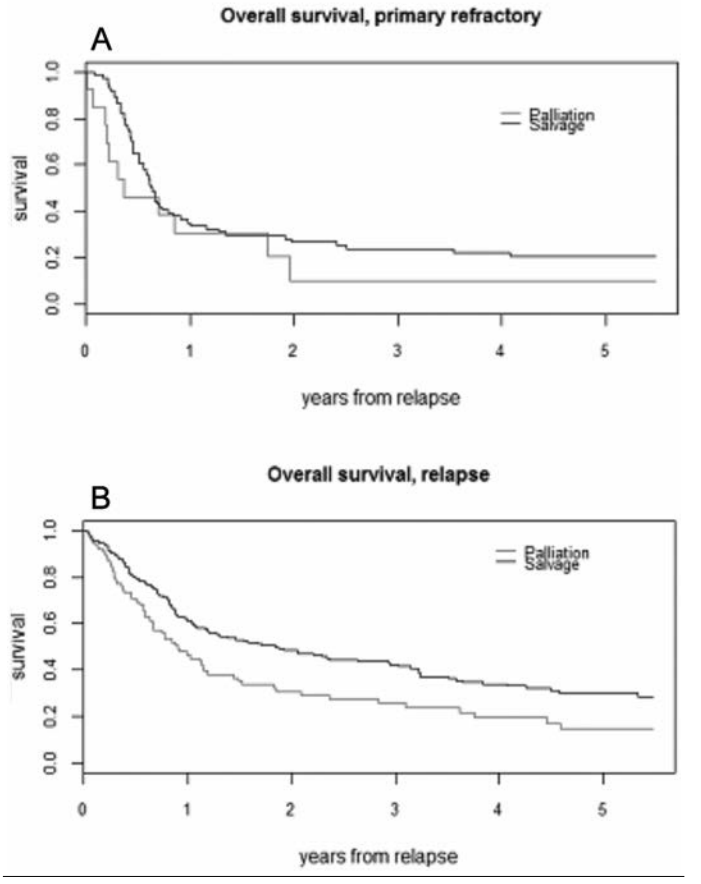

Figure 1. Survival for patients with primary refractory disease (A) and relapsed disease (B) based on intention to treat analyses.

Summary/Conclusions: The addition of Rituximab has significantly improved outcome after first line treatment for DLBCL, and the incidence of relapse has decreased. In the relapse setting, salvage with ASCT has been the standard second line treatment for DLBCL for over 20 years, but only 38% of the patients treated with salvage strategy did actually receive ASCT. Intention to treat analyses show, that patients intended to receive ASCT have significantly better outcome, but patients not being eligible for ASCT actually had a 2 year survival of 31%. This shows that patients with relapse of DLBCL do have a chance to survive although not being eligible for ASCT.

tology, Nihon University School of Medicine, Tokyo, [21]Internal Medicine, Sasebo City General Hospital, Sasebo, [22]Hematology and Oncology, Nagoya University Graduate School of Medicine, Nagoya, [23]Hematology, Tokyo Medical and Dental University, Tokyo, [24]Hematology/Immunology, Fujisawa City Hospital, Fujisawa, [25]Pathology Project for Molecular Targets, Cancer Institute Japanese Foundation for Cancer Research, Tokyo, Japan

Background: The central nervous system (CNS) is a sanctuary for lymphoma cells. Once CNS involvement in lymphoma occurs, it is almost fatal. CNS involvement is thought to be a rare but important complication in the lymphoma's clinical course. We previously demonstrated that the involvement of the breast, adrenal gland, and/or bone was an independent risk factor for CNS involvement based on clinical data in 1,221 patients with diffuse large B-cell lymphoma (DLBCL) treated with R-CHOP (Cancer Sci 2012). Afterward, several groups proposed a new prognostic model consisting of 6 factors, including the 5 risk factors in the International Prognostic Index, and involvement of kidney/adrenal gland, predicting the risk of secondary CNS involvement (Schmitz N, *et al.* 2013, Savage KJ, *et al.* 2014, and El-Galaly, *et al.* 2015).
Aims: To validate the usefulness of this prognostic index using our previously fixed data in DLBCL patients who did not receive any CNS prophylaxis.
Methods: Clinical data of untreated, *de novo* DLBCL patients were collected in 2010 from 47 institutions in Japan. Included patients had been treated with R-CHOP therapy as the primary treatment between 2003 and 2006. Clinical data collected were the presence or absence of 26 extranodal sites including the kidney and adrenal gland, along with factors including age, sex, clinical stage, serum lactate dehydrogenase (LDH) level, performance status (PS), bulky mass, and B symptoms. Patients who received any CNS prophylaxis were excluded. Patients with primary CNS involvement or with distinct forms of DLBCL, such as intravascular lymphoma, primary effusion lymphoma, and primary mediastinal large Bcell lymphoma were also excluded.
Results: A total of 1,220 CD20-positive DLBCL patients with complete information related to risk factors were available (data from 1 patient was withdrawn due to an error in one of the items mentioned). Patient characteristics were as follows: 62% were aged >60 years, 55% had elevated LDH, 46% had advanced stage disease, 21% had PS >1, 20% had >1 extranodal sites, and 4% (n=51) had kidney/adrenal involvement. With a median follow-up of 48 months in living patients, 82 (6.7%) cases of CNS involvements were observed. More than half of the CNS involvement was the parenchymal type (53.7%), followed by the leptomeningeal type (31.7%) and both (14.6%). Systemic (except for CNS) lymphoma status at CNS involvement was as follows: 38 (46%) patients were in the first complete remission (CR), 8 (10%) patients were in the second or more CR, and 36 (44%) patients were in non-CR. The median time interval between the initiation of therapy and CNS involvement was 9 months. In the 51 patients with kidney/adrenal involvement, 9 (18%) developed CNS involvement. According to sum of the above-mentioned 6 factors, patients were categorized into 3 CNS-risk categories of 0-1 (n=483, 40%), 2-3 (n=504, 41%), and 4-6 (n=233, 19%), which represented low-, intermediate-, and high-risk groups, respectively. The cumulative incidence of CNS involvement at 2 years was 1.4% for low-risk, 5.9% for intermediate-risk, and 12.9% for high-risk patients, respectively (Figure 1).

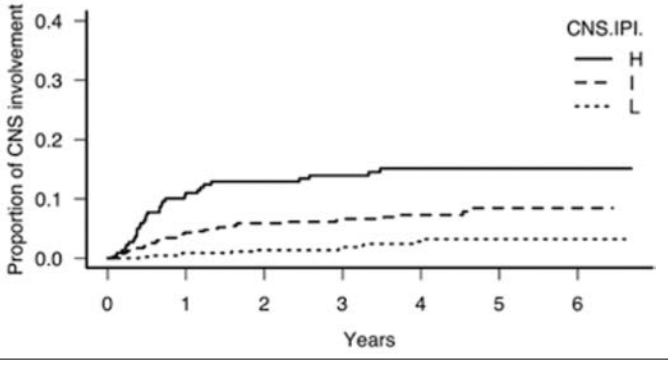

Figure 1. Cumulative risk of CNS involvement according to CNS-IPI.

Summary/Conclusions: The prognostic model for CNS involvement (CNS-IPI) was useful in a DLBCL patient cohort treated with R-CHOP and without any CNS prophylaxis.

P703

BETTER PROGNOSTICATIONS WITH INTERIM PET/CT RESPONSES BASED ON METABOLIC TUMOR VOLUME COMPARED TO VISUAL AND SUV-BASED ASSESSMENTS IN THE PATIENTS WITH DLBCL WITH EXTRANODAL INVOLVEMENTS

JH Moon[1,*], YJ Lee[1], JY Kim[1], SW Park[2], YR Do[3], SS Lee[4], HJ Kim[4], JJ Lee[4], DH Yang[4]
[1]Hematology/Oncology, Kyungpook National University Hospital, Deagu, [2]Hematology/Oncology, Busan National University Hospital, Pusan, [3]Hematology/Oncology, Keimyung University Dongsan Medical Center, Deagu, [4]Hematology/Oncology, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of

Background: [18]F-FDG PET is currently used in diffuse large B-cell lymphoma (DLBCL) for staging and evaluation of therapeutic efficacy at various time points. Nevertheless, the predictive value of interim PET/CT (iPET/CT) has not been consistent throughout the studies. Particularly, iPET/CT assessment in patients with multifocal, non-contiguous involvement at extranodal (EN) sites may result in a false determination of prognosis due to tracer uptake of inflammatory or physiologic anatomic sites.
Aims: The purpose of this study is to investigate the predictive accuracy of iPET/CT response based on visual, quantitative SUV-based and MTV-based assessment in patients with DLBCL and EN involvements.
Methods: iPET/CT responses for 163 patients with newly diagnosed DLBCL and EN involvements were investigated retrospectively. iPET/CT responses were based on the visual, SUV-based and MTV-based assessments. The assessment of PET/CT was performed at the time of diagnosis, at the third or fourth cycles and at the completion of R-CHOP. For visual assessment, the five-point scale (5-PS) based on the Deauville criteria was used and graded as negative (grade 1-3) or positive (grade 4-5) by comparison with initial PET/CT scan. Second, the quantitative analysis of [18]F-FDG uptake changes was based on the percentage of SUVmax reduction (ΔSUVmax) and the rates of reduction in the metabolic tumor volume (ΔMTV2.5) between initial and interim PET/CT scans. The cutoff point of ΔSUVmax was 65.7% and that of ΔMTV2.5 was 99.3% based on previous reports.
Results: Median age was 61 years (range 18-83 years) and 88 patients (54.0%) in advanced disease (III/IV). Patients were classified according to the IPI risk with 95 patients (58.3%) being classified as low or low-intermediate and 68 patients (41.7%) as high-intermediate or high risk. Number of extranodal site(s) were 1 site in 102 patients (62.6%), 2 sites in 39 (23.9), 3 sites in 18 (11.0), and 4 sites in 4 (2.5%). iPET/CT responses based on visual analysis were classified into grade 1-3 in 99 patients (60.7%) and grade 4-5 in 64 (39.3%), and based on SUV-based, classified into higher the cutoff of ΔSUVmax (>65.7%) in 140 patients (85.9%) and lower (<65.7%) in 23 patients (14.1%), respectively. Among the patients with MTV2.5 data (n=110), higher ΔMTV2.5 (>99.3%) was observed in 81 patients (73.6%) and lower ΔMTV2.5 (<99.3%) in 29 (26.4%). On visual assessment, iPET/CT-positive patients had no difference of relapse rates (28.3±5.4%) compared to those of iPET/CT-negative patients (23.1±4.5%) (p=0.419). Among the patients with 5-PS grade 4-5, higher the optimal cutoff of ΔSUVmax (>67.5%) and ΔMTV2.5 (>67.5%) were achieved in 46 patients (71.9%) and 18 (22.2%). The 5-year overall survival (OS) rates and progression free survival (PFS) rates were 75.6±3.8% *vs* 60.6±11.7% (p=0.056), and 77.9±3.7% *vs* 55.9±12.1% (p=0.007) depending on the cutoff of ΔSUVmax, respectively. Based on the cutoff of ΔMTV2.5, the 5-year OS rates were 77.1±4.8% and 61.9±9.1% (p=0.046), and the 5-year PFS rates were 80.2±4.6% and 64.4±9.0% (p=0.020). In the multivariate analysis, age at diagnosis, ECOG PS 2-4, EN involvement >1 site, and lower ΔMTV2.5 (<99.3%) were unfavorable factors for predicting PFS and OS.
Summary/Conclusions: The MTV2.5-based assessments in iPET/CT could have significant potential as a prognostic predictor of PFS and OS than visual assessment or SUVmax reduction in patients with EN involvements. However, the visual assessments have the limitations to predict long-term outcomes with high false positive rates at EN involvements. The quantitative SUV-based assessments in iPET/CT were significant prognostic predictor of PFS and OS, especially in the patients with 1 EN site involvement. However, the visual assessments have the limitations to predict long-term outcomes with high false positive rates at EN involvements.

P704

DETECTION OF BONE MARROW INVOLVEMENT OF DLBCL - COMPARISON OF PET-CT AND BONE MARROW BIOPSY

Y Nakajima[1,*], S Fujisawa[2], A Matsumura[1], T Ando[2], M Itabashi[2], S Koyama[2], Y Ishii[2], H Takahashi[1], W Yamamoto[2], T Miyazaki[1], T Tachibana[1], K Motohashi[2], M Hagihara[1], K Matsumoto[2], N Tomita[1], H Nakajima[1]
[1]Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Department of hematology, Yokohama City University Medical Center, Yokohama, Japan

Background: In malignant lymphoma, bone marrow involvement is considered as clinical stage IV, which adversely affects International Prognostic Index. Detecting bone marrow lesion is therefore important in staging of malignant lymphoma. Bone marrow biopsy (BMB) has been a classical method to detect bone marrow infiltration. Recently, positron emission tomography combined with computed tomography (PET-CT) became a routine tool in staging of malignant lymphoma. Especially, in diffuse large B cell lymphoma (DLBCL), PET-CT shows high sensitivity of detecting viable nodal and extra-nodal lesions.
Aims: The aim of this retrospective study is to evaluate the diagnostic accuracy of PET-CT in detecting bone marrow infiltration in patients with newly diagnosed DLBCL.

Methods: We collected data from all patients who were newly diagnosed with DLBCL from January 2005 to October 2015 at Yokohama City University Hospital, and Yokohama City University Medical Center. Patients with DLBCL who underwent both PET-CT and BMB prior to the initiation of treatments were finally included in the analysis. Bone marrow biopsy: Results of unilateral BMB of posterior iliac crest were collected from written reports. BMB specimens were evaluated by hemato-pathologists of each institution. The presence of lymphoma cells in the bone marrow was based on morphological and immunohistochemical findings. PET-CT analysis: Written reports were used to collect PET-CT data. Interpretation of images was made by radiologists of each institution where PET-CT scans were performed. Bone marrow involvement in PET-CT was defined as greater intensity of FDG uptake in the bone marrow than those in liver. This study was approved by the Internal Review Board of Yokohama City University Graduate School of Medicine.
Results: In total, 430 patients were newly diagnosed with DLBCL from January 2005 to October 2015. Of 430 patients, 254 underwent both PET-CT and BMB before treatment who were evaluated in the further analysis. Median age at diagnosis was 68 years (range: 21-93). Four patients were diagnosed with intravascular lymphoma, and 4 with primary mediastinal large B cell lymphoma. All other patients were diagnosed with DLBCL, not otherwise specified (NOS). Bone marrow FDG uptake was elevated according to the defined criteria in 23 patients (9%), while the infiltration of lymphoma cells in the bone marrow was detected by BMB in 26 patients (10%). Of 23 patients with elevated PET uptake in the bone marrow, 6 (32%) patients were diagnosed as negative for bone marrow infiltration by BMB. Among the 6 patients who were positive for PET-CT and negative for BMB, the pattern of FDG uptake in the bone marrow was focal in 3, diffuse in 1, and unknown in 2 (Figure 1). The patient with diffusely increased bone marrow FDG uptake had chronic myelogenous leukemia prior to diagnosis of DLBCL. Among the 26 patients positive for BMB, bone marrow FDG uptake was increased in 17 (65%). The remaining 9 BMB positive patients were negative for PET-CT. Of 17 patients positive for both BMB and PET-CT, the pattern of FDG uptake in the bone marrow was diffuse in 8, focal in 5, and unknown in 4.

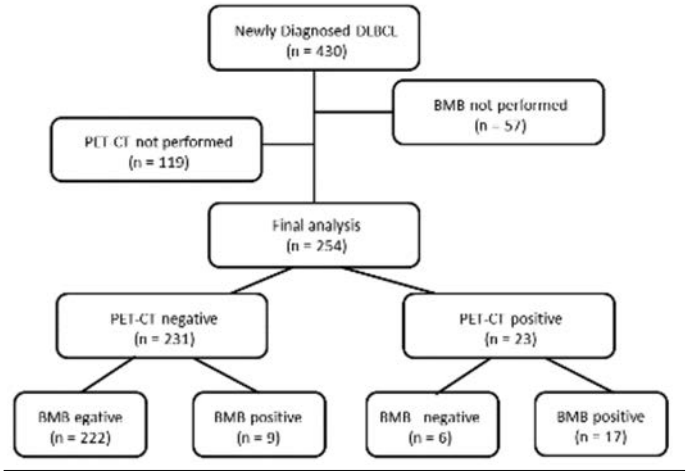

Figure 1. Study flow diagram, and comparison between PET-CT and bone marrow biopsy in detection of bone marrow involvement.

Summary/Conclusions: In conclusion, our study revealed that significant number of patients showed discrepancy between the results of PET-CT and BMB in detecting bone marrow involvement of lymphoma cell. Although PET-CT is highly sensitive tool for detecting viable lymphoma cells and is commonly used for staging in routine practice, our data indicated that PET-CT still cannot replace BMB for identifying lymphoma cells in the bone marrow.

Background: The high-risk of relapse in patients (pts) with diffuse large B-cell lymphoma (DLBCL) who achieved a complete response (CR) to first-line rituximab-based chemotherapy (R-chemo) highlights the need for effective treatments to improve outcomes.
Aims: The phase 3 PILLAR-2 (NCT00790036) study aimed to reduce DLBCL relapse after 1 year of adjuvant everolimus (EVE) treatment to poor-risk patients (International Prognostic Index [IPI] ≥3) who had achieved a CR with R-chemo.
Methods: Pts with histologically confirmed stage III/IV poor-risk (IPI ≥3) DLBLC who had a PET/CT-confirmed CR to first-line R-chemo were randomized 1:1 to EVE 10 mg/day or placebo (PBO) for 1 year or until disease relapse, unacceptable toxicity, or death. The primary endpoint was disease-free survival (DFS) by local assessment using revised IWRC. Secondary endpoints were overall survival (OS), lymphoma-specific survival (LSS), and safety.
Results: Enrolled pts (N=742) were randomly assigned to EVE (n=372) or PBO (n=370). Among randomized pts, 48% in the EVE arm and 67% in the PBO arm completed study treatment per protocol. The main reasons for discontinuation were AEs (EVE, 30%; PBO, 12%) and relapsed disease (EVE, 7%; PBO, 13%). Median follow-up was 50.4 months (range, 24.0–76.9 months). Overall, 47% of pts were ≥65 years, 50% were men, and 42% had an IPI of 4+5. In the primary analysis DFS was not significantly different between EVE and PBO (Log-rank p=0.276). The 2-year DFS rates (95% CI) were 78% (73-82%) with EVE and 77% (72-81%) with PBO. The 2-year OS rates were 91% with EVE and 88% with PBO (Hazard Ratio [HR], 0.75; 95% CI: 0.51-1.10). Results of exploratory subgroup analyses showed a trend favoring EVE over PBO for both DFS and OS in pts with IPI 4+5, in males, and in pts <65 years of age (Table 1). There was also a trend favoring EVE over PBO for LSS (Table 1). Common grade 3/4 AEs with >3% difference for EVE *vs* PBO included neutropenia, stomatitis, CD4 lymphocytes decreased, lymphopenia and anemia. During study treatment, 5 pts in the EVE arm and 2 pts in the PBO arm died.

Table 1.

	Number of patients EVE/PBO	EVE vs PBO HR (95% CI)
DFS*		
Overall (N = 742)	372/370	0.92 (0.69–1.22)†
IPI 4+5 (n = 313)	148/165	0.65 (0.42–1.01)
Male (n = 372)	168/204	0.68 (0.45–1.05)
Age <65 years (n = 393)	192/201	0.79 (0.52-1.21)
OS*		
Overall (N = 742)	372/370	0.75 (0.51–1.10)
IPI 4+5 (n = 313)	148/165	0.63 (0.37–1.07)
Male (n = 372)	168/204	0.55 (0.32–0.94)
Age <65 years (n = 393)	192/201	0.62 (0.34–1.13)
LSS* (N = 742)	372/370	0.64 (0.39–1.04)

* Median duration not estimable. †Log-Rank p = 0.276.

Summary/Conclusions: Adjuvant EVE for 1 year did not improve DFS in poor-risk pts with DLBCL who achieved a CR after R-chemo. Trends favoring adjuvant EVE for DFS and OS in selected pt subgroups and for LSS in the overall population suggest that EVE may provide anti-lymphoma activity in poor-risk DLBCL that warrants further investigation.

Stem cell transplantation - Clinical 3

P705

EFFICACY OF BONE MARROW DERIVED MSC FOR STEROID REFRACTORY ACUTE GVHD IS RELATED TO THE AGE OF THE MSC DONOR

L Van Der Wagen[1,*], K Westinga[2], M van Gelder[2], R Admiraal[3], G Huls [4], S Zeerleder[5], J Janssen[6], A Broers[7], W van der Velden[8], R van Marwijk Kooy[9], JJ Boelens[3], I Slaper-Cortenbach[2], J Kuball[1]
[1]Hematology, [2]Department of Clinical Pharmacy - Cell Therapy Facility, [3]Paediatrics - Blood and Marrow Transplantation Program, University Medical Center Utrecht, Utrecht, [4]Hematology, University Medical Center Groningen, Groningen, [5]Hematology, Academic Medical Center Amsterdam, [6]Hematology, VU Medical Center Amsterdam, Amsterdam, [7]Hematology, Erasmus Medical Center, Rotterdam, [8]Hematology, Radboud Medical Center, Nijmegen, [9]Department of Internal Medicine, Isala klinieken, Zwolle, Netherlands

Background: Acute graft *versus* host disease (aGVHD) remains a life-threatening complication and substantially reduces efficacy of allo-HSCT. In particular, the outcome of patients with severe steroid-refractory aGVHD continues to be poor. Administration of Mesenchymal Stromal Cells (MSC) has been reported by others and us as an interesting treatment option. However, variability in products and the inability to link surrogate markers of the product to clinical efficacy could prove to be a major threat in daily clinical practice.
Aims: Evaluate the impact of MSC donors as well as donor properties such as age on the outcomes clinical response and overall survival.
Methods: We evaluated the impact of individual donors as well as donor properties such as age on clinical response in a cohort of 102 patients with grade II-IV steroid refractory aGVHD treated with bone marrow derived MSC from third party non-HLA matched donors. Primary outcome measures were one year overall survival (OS) and response of GVHD. Cox proportial hazards models, competing risk analyses (Gray's test) and Kaplan Meier estimates were used for analyzing response and OS respectively.
Results: 102 patients received in total 299 MSC infusions derived from 10 different BM donors. Median number of infusions was 3 (range 1-4). 75,5% of patients received all MSC infusions from the same donor, 20,6% with MSC from 2 donors and 3,9% with MSC from 3 different donors. Two donors were used to treat 28,4% and 43,1% of patients respectively. When testing impact on one year OS of an individual product no differences between patients treated with either the 2 main contributing donors or the patients treated with the 'other' MSC donors could be observed. However, when donor age was used to cluster cohorts (donor age <and >10 years) differences were observed (Figure 1) with a survival benefit for patients treated with young donors. Competing risk analysis also revealed a significant benefit for patients only treated with young donors. Furthermore in multivariate analysis, MSC donor age remained predictive for OS (HR 2,00, p-value 0,025).

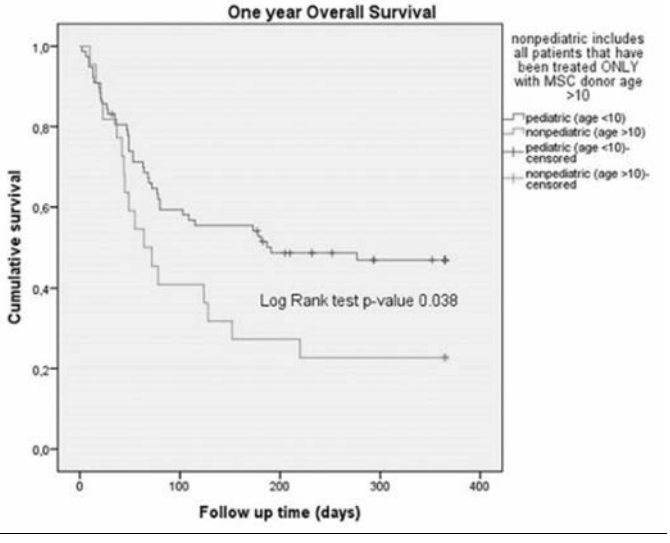

Figure 1. One year overall survival estimation by means of Kaplan Meier depending on age of MSC donor used.

Summary/Conclusions: In our cohort of 102 patients with steroid refractory acute GVHD that were treated with MSC we observed differences in both achieving complete resolution of GVHD symptoms as in OS. Patients only treated with MSC derived from very young bone marrow donors (<10 years old) had significantly better resolution of GVHD symptoms as well as an improved OS. These findings may have implications for both future as well as currently ongoing clinical trials with MSC.

P706

CHRONIC GRAFT-*VERSUS*-HOST-DISEASE AND B-CELL RECONSTITUTION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN

V Wiegering[1,*], K Haas[2], M Frietsch[3], W Matthias[1], PG Schlegel[1], M Eyrich[1]
[1]Pediatric stem cell transplant program, University Children's Hospital, [2]Department of Biometry, University Medical Center, [3]stem cell laboratory, University Children's Hospital, Wuerzburg, Germany

Background: Hematopoetic stem cell transplantation (HSCT) is an established therapy for many pediatric hematological diseases. Besides relapse, chronic GvHD (cGvHD) is the most important determinant of posttransplant morbidity and mortality. Although the precise mechanisms underlying cGvHD are not completely understood so far, convincing evidence suggests an important contribution of B-cells in cGvHD pathophysiology. Multiple studies in adult cGvHD patients have described altered patterns of B-cell reconstitution.
Aims: Since data on B-cell reconstitution and cGvHD in children, who generally show different kinetics of immune reconstitution than adults, are lacking so far, we wanted to investigate this relationship in a purely pediatric cohort of alloHSCT recipients.
Methods: First, in a retrospective cohort of 104 pediatric alloHSCT recipients transplanted between 2005 and 2013, we analyzed 2151 flow cytometric immune profiles. To identify differences in lymphocyte distribution in children with and without GvHD over time we applied hierarchial linear analysis. Second, in a prospective cohort of 74 children, we investigated more closely the distribution of B-cell subsets, cytokine production in B- and T-cells, serum cytokine levels including BAFF, autoantibody production and apoptosis resistance of peripheral B-cells.
Results: In the first retrospective cohort, median age was 8.9±7.0 years. Incidence of cGvHD was 15%, median time to onset was 132±198days. In a univariate analysis, risk factors for cGvHD were: a history of previous aGvHD, radiation-based conditioning and a donor-host sex mismatch. As expected, relapse rate was significantly lower in cGvHD patients. Hierarchial linear analysis showed that children later experiencing cGvHD had elevated T-cell frequencies during the first 180 days (63±17 *vs* 45±23% $CD3^+$ in children with *vs* without cGvHD, resp.). In contrast, B-cells were significantly lower in cGvHD children once cGvHD had occurred. Interestingly, reconstitution of naïve T-cells was delayed but not abrogated in children with cGvHD, reaching a mean of 44±17% of naïve T-cells in the CD4+ compartment after 2 years postHSCT (compared to 58±15% in children without GvHD). A more detailed analysis of B-cell subsets in the prospective cohort revealed that the lower number of B-cells in cGvHD children were due to a defect in naïve B-cell regeneration. Memory and $CD24^{++}CD38^{++}$ transitional B cells were expanded. We detected autoantibodies (mainly ANAs) in 88% of cGvhD children, compared to 13% in children without cGvHD. In approx. 50% of cGvHD children these autoantibodies became negative after 2 years postHSCT. Apoptosis resistance is a mechanism also operational in pediatric cGvHD, as B-cells from cGvHD children showed reduced rates of apoptosis after 48h in culture, a phenomenon that could be induced by exogenous BAFF in a dose dependent way. In contrast to what has been reported in adults, serum BAFF levels were not elevated continuously during cGvHD, but progressively declined over time. A detailed analysis of bone marrow B-cell precursor subsets has been performed, which is currently under biometrical evaluation.
Summary/Conclusions: Our data represent the first large and comprehensive data set on B-cell reconstitution and cGvHD in a purely pediatric cohort. We confirm patterns of B-cell dysbalance which have been described in adult cGvHD patients before. However, other features such as the preserved thymic reconstitution despite cGvHD and the rapid decline of BAFF and autoantibodies are in contrast to previous reports. Thus, the higher regenerative capacity of children seems to have a significant impact on the disturbed B-cell homeostasis in cGvHD.

P707

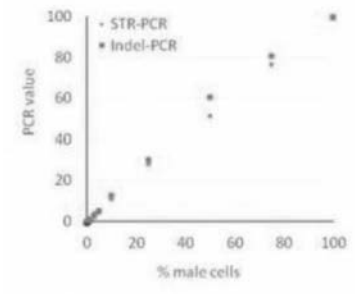
A NOVEL QUANTITATIVE PCR APPROACH TARGETING INSERTION/DELETION POLYMORPHISMS (INDEL-PCR) FOR CHIMERISM QUANTIFICATION: FINALLY HIGH SENSITIVITY AND QUANTIFICATION CAPACITY TOGETHER

A Navarro-Bailón[1,*], C Martínez-Laperche[1], D Carbonell[1], E Buces[1], M González-Rivera[2], M Bastos[1], P Balsalobre[12], M Kwon[1], D Serrano[1], J Anguita[1], J Gayoso[1], JL Díez-Martín[1], I Buño[1]
[1]Haematology, Hospital General Universitario Gregorio Marañón, [2]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Background: Post-hematopoietic stem cell transplantation (SCT) chimerism monitoring is important to assess engraftment, anticipate relapse and provide information on the development of graft *versus* host disease, facilitating therapeutic intervention.
Aims: The aim of this study was to test the technical efficacy and clinical utility of a novel quantitative PCR approach targeting insertion/deletion polymorphisms (indel-PCR).
Methods: This study included 157 samples (81 bone marrow, 60 peripheral blood (PB), 11 T-cells, 2 myeloid cells, 2 CD34-cells, 1 NK-cells purified using immunomagnetic technology) of 24 patients who underwent SCT for haemato-

logical malignancies. Additionally, 2 sets of 11 artificial mixtures were created using PB leukocytes of two healthy subjects (a male and a female) with known percentages of male leukocytes (putative recipient): 100, 75, 50, 25, 10, 5, 3, 1, 0.1, 0.01, 0. Chimerism analysis was performed by the gold-standard STR-PCR (AmpFISTR SGM Plus®, Life Technologies, USA) and by indel-PCR (Mentype® DIPscreen, Mentype® DIPquant, Biotype, Germany). Concordance between both methods was calculated with SPSS using intraclass correlation coefficient.

Results: The number of informative loci identified with indel-PCR (>3/patient) was higher than with STR-PCR for all patients. Concordance between both methods for the 157 patient samples and 11 artificial mixtures was "very good" (intraclass correlation coefficient=0.96). Of note, analysis of artificial mixtures provides evidence of significantly (≥2 logs) higher sensitivity by indel-PCR (0.01%) than by STR-PCR (1%, Figure 1). Moreover, indel-PCR shows unprecedented quantification capacity (Figure 1). Out of the 168 samples analyzed, 32 were positive and 15 negative by both methods, while 121 were positive only by indel-PCR (95% with <1% recipient). Clinical outcome and chimerism dynamics of 24 patients are described in Figure 1, data of 4 of them were censored (engraftment failure, disease progression, insufficient number of samples). All the samples presented complete donor chimerism by STR-PCR. Of the 9 patients who showed stable or decreasing percentage of recipient cells, only one (11%) presented extramedulary relapse. Of the 11 patients who presented increasing percentage of recipient cells in one determination, relapse occurred in 5 patients (45%, 3/6 patients who did not have further determinations, 2/4 who showed stable or decreasing recipient cell percentage, and 0/1 patient who presented increasing recipient cells in subsequent determinations).



% male cells	STR-PCR	Indel-PCR
100	100	100
75	76.85	80.9
50	51.75	60.9
25	28.51	30.6
10	11.25	13
5	5.25	5.5
3	4.20	2.9
1	1.82	0.8
0.1	0	0.1
0.01	0	0.02
0	0	0

Figure 1. Analysis or artificial mixtures.

Summary/Conclusions: This novel indel-PCR is a simple and accurate technique that, in comparison with the current gold standard STR-PCR, shows very good concordance and provides higher rates of informative loci per patient, as well as unprecedented combined sensitivity and quantification capacity. Such features allow minutely monitoring chimerism dynamics and might improve clinical management of transplanted patients, specially predicting relapse in those patients who do not have a molecular marker available for disease follow up.

P708

A NEW APPROACH OF DUAL-SCT WITH UNMANIPULATED HAPLO-IDENTICAL GRAFT AND UNRELATED CORD BLOOD IN PATIENTS WITH HEMATOLOGICAL DISORDERS

J Chen*, Y Xu, S Chen, X Wang, Y Wang, S Ma, A Sun, H Qiu, Y Han, X Tang, C Fu, F Chen, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Dual-SCT with T-cell depleted haplo-identical graft and cord blood (CB) has developed in recent years, which revealed a promising outcome. In China, graft manipulation is seldom performed, so we proposed an alternative dual-SCT strategy with unmanipulated haplo-identical graft co-infusing with unrelated CB unit, and published an encouraging outcome based on preliminary results.

Aims: Here we reported the recent updates of this prospective study.

Methods: This is an on-going prospective study approved by local Ethics Committee. The main inclusion and exclusion criteria are: (1) definitely diagnosed as hematological disorders; (2) with an indication of allo-SCT; (3) without an available matched related or unrelated donor. Myeloablative conditioning of either modified Bu/Cy regimen or modified TBI/Cy regimen was applied. Selection of donor, conditioning, GVHD prophylaxis and supporting care follows the principles described previously. In order to identify the superiority of dual-SCT, data of patients receiving haplo-identical donor transplantation in the same time frame were analyzed as parallel control in this report.

Results: From January 2011 through December 2014, 219 patients were recruited in this study including patients with AML (29%), ALL (38%), MDS (10%), SAA (10%) and other diseases. The median age was 26 (15-60) years old. The median counts of MNC was 10.5×10^8/Kg in haplo-identical graft and 1.83×10^7/Kg in cord blood unit, respectively. Only 4 patients achieved stable engraftment of CB unit. Univariate analysis in the study cohort suggested that lower MNC count (less than 12×10^8/Kg) in haplo-identical graft was related to a significantly lower Grade II-IV aGVHD incidence (P=0.041), lower TRM (P=0.008) and better survival (P=0.007). Comparing with 5/6 or 6/6 matched CB unit, 4/6 matched CB unit resulted in higher TRM with a statistical significance (P=0.023), and lower OS with marginal significance (P=0.071). Parallel control group contains 176 patients with roughly comparable baseline characteristics. In the comparison analysis, 2-year TRM was 14.9±3.0% *versus* 29.4±5.4% for dual-SCT and haplo-SCT (P=0.003), and 2-year relapse incidence was 14.8±3.5% *versus* 23.3%±4.4% (P=0.011), respectively. Finally, better 2-year OS (81.5±3.1% *versus* 64.4±4.2%, P<0.001) and PFS (79.1±3.0% *versus* 58.9±4.1%, P<0.001) were observed in dual-SCT group compared to haplo-SCT. No difference of GVHD incidence was identified between two groups (Figure 1).

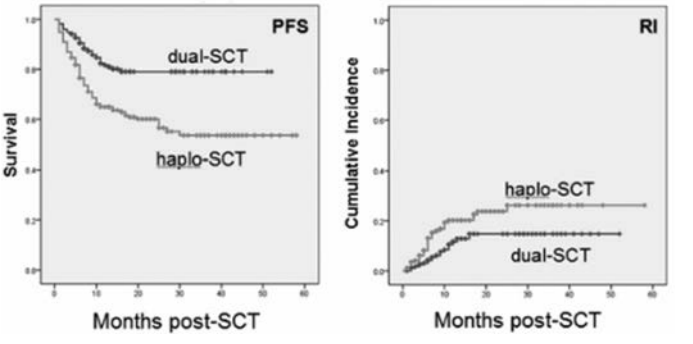


Figure 1.

Summary/Conclusions: Our report showed promising outcomes of dual-SCT with unmanipulated haplo-identical graft and unrelated CB unit. Lower MNC count in haplo-identical graft and 5-6/6 matched CB unit were related to a better prognosis after dual-SCT. Efficacy of this approach merits further confirmation by longer follow-up, and moreover, by well designed randomized clinical trials. Besides, probable mechanisms and interactions between stem cells needs to be explored.

P709

RECIPIENT CCR5 GENETIC VARIATION PREDICTS TRANSPLANT OUTCOMES AFTER HLA-MATCHED UNRELATED DONOR BONE MARROW TRANSPLANTATION

T Horio[1,*], S Mizuno[1], M Mizutani[1], K Uchino [1], I Hanamura[1], JL Espinoza[2], K Matsuo[3], M Onizuka[4], K Kashiwase[5], Y Morishima[6], T Fukuda[7], Y Kodera[8], N Doki[9], K Miyamura[10], M Takehiko[11], A Takami[1]
[1]Hematology, Aichi Medical University School of Medicine, Nagakute, [2]Hematology, Kanazawa University Graduate School of Medical Science, Kanazawa, [3]Hematology, Aichi Cancer Center Research Institute, Nagoya, [4]Hematology, Tokai University School of Medicine, Isehara, [5]Hematology, Japanese Red Cross Kanto-Koshinetsu Block Blood Center, Tokyo, [6]Hematology, Aichi Cancer Center Research Institute, Nagoya, [7]Hematology, National Cancer Center Hospital, Tokyo, [8]Hematology, Aichi Medical University, Nagoya, [9]Hematology, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, [10]Hematology, Japanese Red Cross Nagoya First Hospital, Nagoya, [11]Hematology, Keio University School of Medicine, Tokyo, Japan

Background: The chemokine receptor CCR5, mainly expressed on macrophages, dendritic cells, memory T cells, and the endothelium, plays roles in the adaptive immune response by enhancing the production of antigen-specific T cells through directing $CD8^+$ T cells to sites of $CD4^+$ T cells and dendritic interactions. Its genetic variant (rs1800023, -2086 A>G), which resides in the promoter region, has been reported to be associated with susceptibility to various infectious diseases, including HIV infection.

Aims: To investigate the impact of CCR5 genetic variation on transplant outcomes of HLA-matched unrelated donor bone marrow transplantation (BMT).

Methods: CCR5 genotyping was performed on 333 patients with hematologic malignancies who underwent BMT through the Japan Marrow Donor Program between January 2006 and December 2009 and their HLA-matched unrelated donors, and its association with the transplant outcomes was retrospectively examined.

Results: The genotype frequencies of A/A, A/G, and G/G were 34%, 49% and 17% in the recipients and 35%, 50% and 15% in the donors (*P*=0.93), respectively. The recipient A/A genotype was associated with a significantly better overall survival (OS) than the recipient A/G or G/G genotype (69% *vs* 43%, P=0.04; Figure 1A). A multivariate analysis showed that the recipient A/A genotype has a significantly advantage regarding the OS (hazard ratio [HR], 0.53; 95% confidence interval [CI], 0.30-0.93; P=0.03) and the relapse rate (HR,

0.45; 95% confidence interval [CI], 0.21-0.97; P=0.04). These effects were not seen according to the donor CCR5 genotype.
Summary/Conclusions: These results suggest an association between the recipient CCR5 genotype and the OS and relapse rate after unrelated BMT. Genotyping for the CCR5 rs1800023 polymorphism could therefore be useful in predicting the prognoses and risk-adapted management of transplanted patients and may offer novel therapeutic insights to induce the graft-*versus*-tumor effect effectively.

P710

PRESUMABLY FALSE POSITIVE MINIMAL RESIDUAL DISEASE (MRD) QPCR RESULTS AFTER ALLOGENEIC SCT UNCOVERED BY NEXT GENERATION SEQUENCING (NGS)

M Kotrova[1,*], K Muzikova[1], VHJ van der Velden[2], P Sedlacek[3], J Stary[3], JJ van Dongen[2], M Bruggemann[4], J Trka[1], E Fronkova[1]
[1]CLIP, Department of Pediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic, [2]Department of Immunology, Erasmus MC, Rotterdam, Netherlands, [3]Department of Pediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic, [4]Second Medical Department, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: MRD detection using qPCR for IG/TR rearrangements has been succesfully used in pediatric acute lymphoblastic leukemia (ALL) patients already for two decades and risk-adapted therapy based on its results has proven to be highly beneficial. Also MRD after allogeneic stem cell transplantation (SCT) in relapsed pediatric ALL has been shown to predict subsequent relapse and post-transplant MRD values have been used for guiding therapeutic interventions. We have previously shown that MRD detection by qPCR for clonal IG/TR rearrangements can yield false positive results in patients after SCT caused by massive regeneration of B-cells (Fronkova, Bone Marrow Transplantation, 2008), despite following strict EuroMRD guidelines for defining the MRD positivity (van der Velden, Leukemia, 2007). From our previous work (Kotrova, Blood, 2015), we know that NGS and qPCR have comparable sensitivity for MRD detection. We hypothesized that NGS of IG/TR rearrangements can distinguish between false and real positivities and can also identify the source of false positive results.
Aims: To detect MRD by NGS in our pediatric BCP-ALL cases after allogeneic SCT, who had at least one low-positive (not quantifiable) qPCR MRD result and remained in complete remission. No therapy intensification was implemented in these patients, except for one of them, who received DLI.
Methods: Sequencing libraries were prepared from 500ng of bone marrow DNA via a two-round PCR: in the first round rearranged IGH or TRG genes were amplified using universal primers. In the second round products from the first round were flanked by sequencing adaptors and sample-specific barcodes. Libraries were sequenced on Ion Torrent PGM sequencer using the Hi-Q chemistry. For detection of clonal leukemia-specific IG/TR rearrangements we used our in-house bioinformatic algorithm. We sequenced 30 qPCR positive (not quantifiable) post-transplant samples from 18 patients (16 patients carrying 24 IGH and 2 patients carrying 3 TRG qPCR targets) who remained in complete remission after SCT with a median follow-up of 10.4 years (range 1.8-15.5). One low-positive post-transplant sample from patient who later developed CNS relapse was added as positive control. The median coverage was 500,000 reads/sample.
Results: Besides the positive control patient, only 2 of 30 (7%) follow-up samples were found to be MRD-positive, defined as the presence of leukemia-specific sequence(s) as identified at diagnosis in the follow-up samples. One of the positive samples belonged to patient with the shortest follow-up and unclear outcome so far (1.8 years). To find the cause of false positive qPCR results we searched for matches of the clone-specific qPCR primers sequences from samples which were qPCR positive and NGS negative in all resulting fastq files. For all primers, similar sequences (with maximally 2 mismatches) were found in fastq files from different patients, thus likely explaining false positivities by qPCR analysis.
Summary/Conclusions: Our results indicate that in this specific situation of massive regeneration post-transplant qPCR can detect false positive results, despite high degree of standardization and strict rules for defining positivity.
Next generation sequencing of IG/TR rearrangements can solve this problem, because it provides the sequence of the entire CDR3 region of all rearrangements in the sample, and therefore allows specific identification of the leukemia-specific sequence.

P711

PRE-EMPTIVE THERAPY WITH IFN-A-2B FOR ACUTE LEUKEMIA PATIENTS WITH HIGH RISK OF RELAPSING TENDENCY POST ALLO-HSCT

A Wang, F Chen, X Ma, A Sun, X Zhu, H Qiu, Z Jin, S Xue, D Wu, X Tang[*]
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Relapse still remains the most frequent cause of treatment failure and mortality. According to the data of CIBMTR, relapse has become the leading cause of death following allo-HSCT. The high risk patients with more advanced disease, have a relapse rate of 40–80%.Therefore, prevention and treatment of relapse post allo-HSCT is the most likely approach to improve survival of these patients. It is well known that IFN-α had been widely used in the field of antitumor. Recently it is shown that IFN-α also play an important role in immune modulation to enhance the effect of GVL.
Aims: In order to investigate the role of IFN-α in the field of prevention and treatment of acute leukemia relapse post allo-HSCT.
Methods: We dynamically monitored the minimal residual disease of 986 AL patients who underwent allo-HSCT from January 1, 2006 to March 31, 2014 in our hospital. There were 98 patients who presented increasing tendency of MRD and were enrolled in this study and preemptive treatment were performed once a relapse tendency was detected. pre-emptive therapy was given as long as one of the following conditions were met: 1. 3–5% bone marrow blasts; 2. MRD $\geq 1\times10^{-3}$; 3. Positive specific fusion gene detection or WT-1 gene copy number >200 copies/10,000 abl copies; 4. DC ≤90% detected by short tandem repeat (STR) technology; or 5. More than two listed conditions were met.Among them, 31 patients received IFN-α-2b pre-emptive therapy, and 67 patients received non-IFN-α-2b therapy such as: withdraw immunosupressant, traditional DLI or DC-CIK immunotherapy.
Results: There were no significant differences in disease characteristics between two groups. For the 31 patients who received IFN-α-2b pre-emptive therapy (IFN group), the median time of IFN-α treatment was 60 days (range: 5–720 days), Twenty five patients had response to the treatment without progressing to hematological relapse (response rate 80.6%); 3 patients had stable disease (SD) after IFN treatment; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67 patients who received non-IFN-α-2b therapy(non IFN group), 22 patients had response to the treatment (RR 32.8%), 45 patients failed to the treatment and progressed to hematological relapse at a median time of 35 (range: 6–940) days, There was significant difference of RR between two group(P=0.000). 31 patients of IFN group tolerate well and no patient terminated therapy due to side effects. During the treatment of IFN, 18 patients(58.1%) developed GVHD: 6 patients (19.4%) with aGVHD and 14 (45.2%) with limited cGVHD. The median follow-up time was 21 (4.5-78.5) months. 22 of 31 cases of IFN group maintained disease-free survival. The 5-year overall survival rate (OS) and the leukemia-free survival rate (LFS) of IFN group were 47.0%±13.9% and 38.7%±13.1% respectively. However, the 5-yr OS and LFS of non IFN group were 14.5%±10.7% and12.5%±9.4% respectively. The difference were significantly (P=0.000,P=0.002 respectively). Patients with GVHD had significantly better response than patients without GVHD (88.9% *vs* 53.8%, P=0.043, P <0.05).
Summary/Conclusions: IFN-α-2b pre-emptive therapy can effectively prevent high-risk patients with relapsing tendencies for disease progression post allo-HSCT. Further large-scale investigation is warranted.

P712

A STUDY OF RHTPO IN COMBINATION WITH CHEMOTHERAPY AND G-CSF FOR PERIPHERAL BLOOD PROGENITOR CELL MOBILIZATION IN PATIENTS WITH RELAPSED NON-HODGKIN LYMPHOMA

H Bai[1,*], J Zhu[1], C Wang[1], S Hao[2], J Hu[3], S Zou[4]
[1]Department of haematology, Shanghai general hospital, Shanghai, China, [2]Department of haematology, Shanghai Jiaotong University Affiliated Xinhua Hospital, Shanghai, China, [3]Department of haematology, Shanghai Jiaotong University Affiliated Ruijing Hospital, Shanghai, China, [4]Department of haematology, Fudan University Affiliated Zhongshan Hospital, Shanghai, Shanghai, China

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) is the standard treatment for relapsed non–Hodgkin lymphoma patients who are still chemotherapy–sensitive. Unfortunately, collection of an adequate number of hematopoietic stem cells can be difficult in these patients, as they usually have received multiple prior cytotoxic regimens. Studys have shown recombinant human thrombopoietin(rhTPO) improved mobilization of peripheral blood progenitor cells in patients with breast cancer.Data on mobilization efficacy in patients with lymphoma are, however, still limited.
Aims: To assess the efficacy and safety of rhTPO in combination with chemotherapy and granulocyte colony–stimulating factor(G–CSF) for peripheral blood progenitor cell mobilization in patients with relapsed Non–Hodgkin lymphoma.
Methods: A total of 79 patients were included in this prospective multi–center randomized controlled clinical study. After administration of mobilizing regimens (CTX $2.5g/m^2d_{1-2}$+VP16 $200mg/m^2d_1$), patients were randomized to TPO+G–CSF (TPO group,n =40) or G–CSF (control group, n=39). Seven point five $\mu g/kg/d$ of G–CSF and 15000U/d rhTPO were subcutaneously administered from day 2 after chemotherapy and until the stem cell collection was completed. PBPCs were collected by daily leukapheresis when the white blood cell count reached $\geq 10\times10^9/L$; leukapheresis was continued until acquisition of a target dose of $\geq 5\times10^6$ $CD34^+$ cells/kg. Mobilized PBPCs were transplanted into patients after additional high–dose chemotherapy with cyclophosphamide, carmustine, and etoposide (CBV). The primary endpoint was $CD34^+$ cell yield.

Secondary endpoints included proportion of target and minimum mobilization, time of neutrophil and platelet engraftment, number of platelet transfusions,and adverse events.
Results: Addition of rhTPO significantly improved total $CD34^+$ cell yield (8.56 *vs* 4.84×10^6/kg, P<0.01). In TPO group, higher percentages of patients achieved the minimum yield of $CD34^+>2\times10^6$/kg (100% *vs* 86%; P<0.05) as well as the target yield of $CD34^+>5\times10^6$/kg (72.9% *vs* 41.3%; P<0.05).No side effects associated with TPO were observed. The median time to neutrophil engraftment was the same in both groups (12 days). No differences in platelet engraftment(12.3 *vs* 14.1 days), number of platelet transfusions (3.2 *vs* 4.4), days of fever (4.6 *vs* 3.3) were seen between TPO and control groups, respectively.
Summary/Conclusions: These results indicate that rhTPO safely and effectively enhance mobilization of PBPCs with chemotherapy and G–CSF in patients with relapsed Non–Hodgkin lymphoma.

P713

A POLYCLONAL POPULATION OF PIGA MUTANT CD52 AND GPI-ANCHOR NEGATIVE T-CELLS CAN GIVE EARLY IMMUNE PROTECTION AFTER ALEMTUZUMAB-BASED T-CELL DEPLETED ALLOGENEIC STEM CELL TRANSPLANTATION

F Loeff, JF Falkenburg, L Hageman, S Veld, M van de Meent, S Halkes, I Jedema*
Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: Alemtuzumab, a monoclonal antibody targeting the glycophosphatidylinositol (GPI)-anchored CD52 protein, is used for *in vivo* and/or *in vitro* T-cell depletion before allogeneic stem cell transplantation (alloSCT) to reduce the risk of graft rejection and graft-*versus*-host disease. Following profound lymphodepletion, we observed a rapid recovery of T-cell numbers early after transplantation, despite presence of lytic circulating levels of residual alemtuzumab. In the majority of patients, a substantial portion of these T-cells completely lacked CD52 membrane expression, explaining why these cells escaped alemtuzumab-induced cytotoxicity.
Aims: To further characterize the CD52 negative T cells arising after alemtuzumab-based T cell depleted alloSCT and to unravel the mechanism underlying the loss of CD52 membrane expression.
Methods: To study the functionality of the CD52 negative T cells, these cells were isolated by flowcytometric cell sorting from peripheral blood (PB) samples taken with informed consent from patients within 6 months after alloSCT. Presence of the GPI anchor was determined using a fluorescently labeled GPI-specific aerolysing FLAER. CD52 positive T cells were similarly isolated as control cells. For specific experiments, CD52 negative virus-specific T cells were isolated based on staining with specific peptide/HLA tetramers. Functional activity was tested in cytokine release assay and cytotoxicity assays. To investigate whether absence of CD52 expression was the result of loss of CD52 gene expression, mRNA expression analysis was performed on the CD52 negative T cells.
Results: Cytokine production and cytotoxicity assays showed that the CD52-negative T-cells which were present early after alloSCT contain functional virus-specific T-cells with lytic capacity comparable to their CD52+ counterparts. mRNA expression analysis revealed similar levels of CD52 expression in CD52-negative and CD52+ cells. Since CD52 is tethered to the membrane via the GPI-anchor, we analyzed whether loss of CD52 membrane expression resulted from loss of GPI-anchor expression by flowcytometry using counterstaining with the GPI-specific aearolysin FLAER. This analysis revealed that loss of CD52 expression on post-transplant T-cells generally resulted from loss of GPI-anchor expression. Gene expression analysis of the 26 genes that comprise the GPI-anchor biosynthesis pathway revealed no overall loss of expression for any of these genes. Since loss of GPI-anchor expression in paroxysmal nocturnal hemoglobinuria (PNH) and aplastic anemia has been described to be often the result of mutations in PIGA, we performed mutation analysis on CD52/GPI-negative (CD4+ n=53, CD8+ n=12) and CD52/GPI-positive (CD4+ n=8, CD8+ n=7) T-cell clones isolated from 3 patients after alloSCT. mRNA was isolated from each clone followed by Sanger sequencing of the PIGA coding region. We were able to detect mutations in 42/53 CD4+ and in 10/12 CD8+ CD52/GPI-negative clones. None of the individual mutations was found more than twice within clones from the same recipient, demonstrating a highly polyclonal mutational landscape. In CD52/GPI-positive clones no mutations in the PIGA coding region were found. To investigate whether these mutations in PIGA were sufficient to induce loss of GPI-anchor expression, we retrovirally transduced 35 CD52/GPI-negative CD4+ T-cell clones with constructs encoding wtPIGA. Restored GPI-anchor expression and coinciding CD52 membrane expression was observed in all 35 clones upon transduction with PIGA, but not with empty vector.
Summary/Conclusions: We conclude that loss of CD52 membrane expression in T-cells isolated early after alemtuzumab-based T-cell depleted alloSCT is the result of various mutations in the PIGA gene and consequential loss of GPI-anchor expression. We showed that these CD52-negative populations contain functional virus-specific T-cells and may therefore be essential in immune protection early after transplantation.

P714

WHICH CONDITIONING REGIMEN IS MORE EFFECTIVE FOR HIGH-RISK PATIENTS WITH AML/MDS : COMPARING LOW-DOSE DECITABINE COMBINED WITH MODIFIED BUCY WITH MODIFIED BUCY FOLLOWED BY ALLO-HSCT

J Cao, X Shi, L Ge, A Sun, X Zhu, H Qiu, Z Jin, M Miao, C Fu, X Ma, F Chen, S Xue, Y Han, M Xue, X Mao, D Wu, X Tang*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative treatment options to hematologic malignancies. However, majority of patients with refractory or resistant hematologic malignancies can not achieve remission before transplantation. It is necessary to design a safe and affective conditioning regimen to reduce the tumor burden, improve the remission rate, decrease the transplantation related mortality and improve disease-free survival in patients with advanced acute myloid leukemia(AML) and myelodysplastic syndrom(MDS). One of the promising drugs of epigenetics is decitabine (DAC), which has a significant effect on a variety of hematologic malignancies including MDS and advanced AML. Furthermore, decitabine can not only up-modulate the tumor-associated antigen express on surface of leukemia cells to increase graft-*versus*-leukemia (GVL) effect but also can reduce the incidence of graft-*versus*-host disease (GVHD) by increase the number of regulatory T Cells (Tregs).
Aims: This clinical study will investigate the security and efficacy of conditioning regimen containing low-dose decitabine combined with modified BUCY regimen for advanced AML/MDS patients, explore the role of immunomodulatory activity post transplantation and compared this regimen with conventional modified BUCY regimen.
Methods: Between January 2012 and March 2015, a total of 156 patients were enrolled in this study. In which, there were 46 patients who received a conditioning regimen of low-dose DAC (DAC group) and a modified BUCY regimen(Con group) followed by allo-HSCT, and the second cohort consisted of 110 who only received a modified BUCY regimen.Comparing the baseline of two groups, there were no significant difference except there were more advanced stage patients in DAC group(63% *vs* 32.7%,p=0.007) A modified BUCY conditioning regimen include semustine (250 mg/m^2/d) for 1 d(-10d), cytarabine (2 g/m^2 q12 h) for 2 d (-9 d to -8 d), busulfan (0.8 mg/kg/6 h) for 3 d (-7 d to -5 d), and cyclophosphamide (1.8 g/m^2/d) for 2 d (-4 d to -3 d). Meanwhile, patients in the DAC group received the DAC treatment for 3 to 4 d with a total of 100 mg/m^2before modified BUCY regimen.
Results: In the DAC group, all patients engrafted successfully, including 29/46 (63%) non-remission (NR) patients. However, there were seven patients presented graft failure in Con group.The median time of neutrophil and platelet recovery in two groups were 12 (10-21) *vs* 12 d (range: 10-23 d)(p and 13 (10-35) days *vs* 14 d (range: 9-40 d) respectively.There were no significant differences between two groups. The transplantation-related mortality (TRM) rate was 0% *vs* 16.4%(p=0.004) for DAC group and Con group. The median follow-up were 200(20-985)d and 177.5(3-1093)d. The cumulative rate of aGVHD and cGVHD were 26.7% *vs* 46.8%(p=0.034) and 68.4% *vs* 70.7% (p=0.598) respectively. The cumulative relapse rate was 26.5% and 37.8%(p=0.706)respectively. The estimated 2-year overall survival (2yr-OS) and 2 year disease-free survival (2yr-DFS) rate were 76.6% *vs* 51.2%(p=0.01) and 63.3% *vs* 41.4%(p=0.046) respectively. Furtheremore, for the patients who were in advanced stage before transplant, the The estimated 2yr-OS and 2yr-DFS rate were 77.3% *vs* 44.8%(p=0.009) and 66.5% *vs* 46.7%(p=0.031) respectively.
Summary/Conclusions: 1. Low-dose decitabine combined with modified BUCY is a safe and effective conditioning regimen for high-risk patients with AML/MDS with low toxicity and well tolerance.All patients of DAC group engrafted and transplantation-related mortality (TRM) rate was 0.
2. 100% NR patients of DAC group achieved complete remission with full donor chimerism at d30. 3.Comparing with Con group, DAC group patients had ralative lower incidence of aGVHD and TRM but relative higher estimated 2-yr OS and DFS, especially for advanced stage patients.

Stem cell transplantation - Clinical 4

ELEVATED EXPRESSION OF TIM-3 ON CD8 T CELLS CORRELATES WITH CYTOMEGALOVIRUS REACTIVATION AFTER ALLOGENIC STEM CELL TRANSPLANTATION

X Li, B Yang, L Xu, L Bin, X Wu*, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: T-cell immunoglobulin and mucin domain-containing molecule 3 (Tim-3) represents a novel mechanism of T-cell dysfunction and exhaustion in virus infections. However, the role of Tim-3 in the pathogenesis of early cytomegalovirus (CMV) reactivation after allogeneic stem cell transplantation (allo-HSCT) is not well understood.
Aims: In this study, we aimed to investigate the role of Tim-3 during CMV infection after allo-HSCT.
Methods: We detected 33 patients and 10 healthy controls in this study. Collected peripheral blood (PB) of patients 30 days, 60 days, 90 days after allo-HSCT who were neither aGVHD nor suffered from other virus infection, such as HBV, HIV, EBV, *et al.* Plasma samples were assessed for CMV-DNA by PCR, (Peripheral blood mononuclear cells) PBMCs were isolated for flow cytometry to detect Tim-3 expression on CD8+ T cells, apoptosis of Tim-3- and Tim-3+ T cells (Annexin V, AV) and IFN-γ secreted by Tim-3- and Tim-3+ T cells.
Results: The rate of CMV reactivation was 51.5% (17/33) of all the patients. Hence we divided them into three groups: CMV positive group, CMV negative group, healthy control group. An elevated frequency of Tim-3+CD8+ cells was observed in transplanted patients compared to healthy controls, and in transplanted patients, the Tim-3 expression on CD8+ T cells was significantly higher in CMV positive patients than CMV negative cases (7.048±3.060% for healthy controls, 15.55±6.314% for CMV negative patients, and 38.98±17.50% for CMV positive patients, P<0.05). The frequency of Tim-3-expression T cells correlates with viral load in CMV reactivation**.** After effective antivirus treatment and CMV became negative, the frequency of Tim-3+CD8+ T cells was decreased. IFN-γ secreted by Tim-3-CD8+ T cell was significantly higher than that produced by Tim-3+CD8+ T cells in each group (P<0.05). In healthy controls, the apoptosis of Tim-3+CD8+ T lymphocytes were significantly increased than that of Tim-3-CD8+ counterparts (2.926±0.654% *vs* 1.546±0.411%, P=0.001), while in allo-HSCT patients, there were no differences in apoptosis between Tim-3+CD8+ and Tim-3-CD8+ T lymphocyte (2.069±1.720% *vs* 1.632±0.789% in CMV negative group, 2.274±1.185% *vs* 1.871±0.265% in CMV positive group, P>0.05).
Summary/Conclusions: Tim-3 expression on T cells results in the changes of T cell function and level of apoptosis, and closely correlated with CMV infection after allo-HSCT.

INTERFERON-GAMMA GENE POLYMORPHISM ASSOCIATE WITH MORTALITY AND GRAFT-*VERSUS*-HOST DISEASE SEVERITY IN HLA-MATCHED SIBLING BONE MARROW TRANSPLANTATION

MV Palau Nagore[1,*], M Berro[2], J Bestach[1], C Foncuberta[3], A Vitriu[3], G Remaggi[4], J Martinez Rolon[4], G Jaimovich[5], A Requejo[5], K Padros[6], MB Rodriguez[6], G Kusminsky[2], I Larripa[1], C Belli[1]
[1]Departamento de Genética Hematologica, Instituto de Investigaciones Medicas (IMEX/CONICET) - Academia Nacional de Medicina, Buenos Aires, [2]Unidad de Trasplante Hematopoyetico, Hospital Universitario Austral, Pilar, [3]Unidad de Trasplante Hematopoyetico, Instituto Alexander Fleming, [4]Unidad de Trasplante Hematopoyetico, FUNDALEU, [5]Unidad de Trasplante Hematopoyetico, [6]PRICAI, Fundacion Favaloro, Buenos Aires, Argentina

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) with sibling donors is a life-saving intervention for patients with hematological malignancies. It is recognized that numerous genetic factors in patient and donor, including polymorphic variants of cytokine encoding genes, have been reported that contribute to the outcome of the procedure. Interferon gamma (IFNy) plays a central role in innate and adaptive immunity. *IFNG* gene has a regulatory element in its first intron that includes a microsatellite CA repeat which CA12 variant is associated with an increased production. Up to date there are few published data on the association between this polymorphism and allo-HSCT related complications performed in small series.
Aims: To evaluate the presence of the microsatellite polymorphism +875 (CA)n *IFNG* and its relationship with response and/or complications related to allo-HSCT.
Methods: Two hundred and twenty two (222) patient/donor pairs who underwent a sibling donor HSCT in our centers were genotyped for the presence of +875 (CA)n *IFNG* (rs3138557) variants. Transplants took place between 01/2000 and 03/2015 with a median follow up of 4.4 years.
Results: Median age of recipients was 33 years, being 90% ≥16 years old and 58% male. Prevalent diagnoses were acute myeloid leukemia 29%, acute lymphoid leukemia 23%, lymphoproliferative disorders 13%, and myelodysplastic syndrome 12%; 45% were in early stage of the disease. Myeloablative conditioning regimens were used in 59% and the prevalent source for stem cells was peripheral blood in 90% of patients. Genotypes distribution was 22% CA12/CA12, 41% CA12/CAno12 and 37% CAno12/CAno12 for recipients, and 17%, 54% and 29% for donors, respectively (Chi2 test *p=0.011*). When patients with genotype CAno12/CAno12, associated with low expression, were compared against the rest of genotypes, we observed that these patients developed less acute graft *versus* host disease (aGVHD) grades II-IV (21% *vs* 37%, Fischer exact test *p=0.053),* grades III-IV (6% *vs* 15%, *p=0.071*), chronic GVHD (26% *vs* 41%, *p=0.029*), and a later myeloid engraftment (≥15 days: 54% *vs* 26%, *p <0.001*). Moreover, this group had a significant reduction in overall survival (OS) (1-5 years, 69-40% *vs* 71-56%, Kaplan-Meier, log-rank, *p=0.03*), disease free survival (DFS 1-5 years, 54-40% *vs* 65-49%, log-rank, *p=0.07*) due to a higher relapse rate (1-5 years, 37-45% *vs* 22-32%, Gray's Test, cumulative incidence *p=0.02*), The predictive value was sustained (OS 59-31% *vs* 69-54%, *p=0.05*) and Relapse rate (38-45% *vs* 22-32%, *p=0.01*) when the cohort of patients that receive a non-myeloablative conditioning was analyzed separately.
Summary/Conclusions: The study of the polymorphism +875 (CA)n *IFNG* would be useful to identify patients with differential behavior towards allo-HSCT with sibling donors. While it is necessary to confirm our results in a larger series, genotype associated with a lower expression of IFNγ would be associated with less GVHD, later engraftment and shorter overall survival that could be related to a higher relapse rate, especially in those patients who received reduced-intensity conditioning regimens.

P717

CLINICAL OUTCOME AND IMMUNE RECONSTITUTION IN α/β T-CELL DEPLETED ALLOGENEIC STEM CELL TRANSPLANTATION FROM MATCHED RELATED AND UNRELATED DONORS

M De Witte[1,*], A Janssen[2], G Fleurke[1], L Timmerman[2], E Spierings[2], I Slaper[3], J Kuball[1,2]
[1]Hematology, [2]Laboratorium of Translational Immunology, [3]Cell Therapy Facility, University Medical Center Utrecht, Utrecht, Netherlands

Background: The outcome of allo-SCT in patients with hematological malignancies is still hampered by GVHD and relapse. Specific depletion of αβ T-cells is proposed to result in a decreased incidence of aGVHD, whereas the remaining innate cells such as NK cells and γδT cells may provide control of infected and transformed cells the first months post SCT. This strategy has been pioneered in haploindentical transplantation with encouraging results. Within this study, we extend αβT- cell depleted allo-SCT to patients with a matched related and unrelated donor.
Aims: The primary aim is to develop an allogeneic SCT protocol with a low incidence of aGVHD without an increased incidence of infections or relapse to serve as a platform for post-allo interventions such as a pre-emptive DLI or transfer of genetically modified T cells.
Methods: 55 Patients with hematological malignancies (including AML, ALL, MM, NHL, MPN) who received an αβT-cell depleted allo-SCT of a HLA matched sibling (MRD) or HLA matched (9 or 10/10) unrelated donor (MUD) were analysed. αβT-cell reduction was performed by negative selection with anti-αβTCR antibodies in combination with magnetic microbeads, using the automated CliniMACS device (Miltenyi Biotec, Bergisch Gladbach, Germany). The maximal contamination with αβT-cells was $5x10^5$/kg. The conditioning regimen consisted of: ATG (Genzyme®) 6 mg/m^2+fludarabine 120 mg/m^2+busilvex AUC=90. Part of the patients received mycophenolic acid as GVHD prophylaxis for 28 days. Patients were retrospectively analyzed for clinical parameters including immune reconstitution, engraftment, infections, GVHD, relapse, NRM and OS and compared to an historical control cohort of recipients of T cell replete allo-SCT. A retrospective cohort of recipients of T cell replete allografts was used for comparison. In addition in a subset of patients NGS of the TCRβ chain was performed using the Illumina/MiSeq sequencing platform after isolation of diverse immune subsets within the αβT-cell repertoire.
Results: αβT-cell depletion with anti-αβTCR antibodies resulted in a 4.1 (1.7-5.2) log depletion of αβT cells and a recovery of 77% (43-98%) of the CD34$^+$ cells. The median contamination with αβT-cells was $16x10^3$/kg ($0.8x10^3$/kg - $200x10^3$/kg) and infused number of CD34$^+$ cells were $6.8x10^6$/kg ($1.2 x10^6$/kg – $10.4x10^6$/kg). The combination of ATG/fludarabine/busilvex was well tolerated with hematological recovery within 3 weeks. Primary engraftment (chimerism >95%) was observed in all patients (n=55). Immune reconstitution primarily consisted of NK cells. In addition, γδT cells were detectable at normal numbers the first half year post SCT, whereas the adaptive immune repertoire showed a delayed reconstitution. The incidence of CMV infections was 54% in patients after αβT cell depleted allo-SCT without MMF, 23% in patients after αβT cell depleted allo-SCT with MMF and 38% in T cell replete allo-SCT control cohort. The incidence of EBV infections was 30,8%; 9,5% and 8,7% respectively. The incidence of aGVHD >grade II within 100 days in patients of a αβT-cell depleted allo-SCT was 0%. During this short time of follow-up (1-20 months) we observed no significant differences in EFS, NRM and OS as compared to historical control cohorts. With NGS of the TCRβ repertoire, a surprising diversity was observed in defined immune subsets ranging from clonal expansion of regulatory T cells to broad repertoires in effector memory cells.

Summary/Conclusions: Here we present the clinical outcome of a large cohort (n=55) of patients having received an αβT-cell depleted allograft of MRD/MUD. We observe a swift reconstitution of innate cells (NK cells and γδT-cells) the first 6 months post transplantation, followed by a subsequent reconstitution of the adaptive immune repertoire. The incidence of severe aGVHD was 0%, without a significant increase in infections or relapse shortly post allo-SCT. These results will be confirmed during extended follow-up and in a planned prospective multicenter study.

P718

BASELINE LABORATORY VARIABLES SERVE AS POTENT PREDICTORS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION RELATED MORTALITY

R Shouval[1,*], J Fein[2], N Shem-Tov[1], I Danylesko[1], R Yerushalmi[1], R Mehr[3], G Shafaf Lavy[3], S Hassid[3], A Shouval[4], R Unger[3], A Shimoni[1], A Nagler[1]
[1]Hematology and Bone Marrow Transplantation, Sheba Medical Center, Tel-HaShomer, Ramat- Gan, [2]Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, [3]The Mina and Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat- Gan, [4]Internal Medicine "F", Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Prognostic models for allogeneic hematopoietic stem cell transplantation (HSCT) outcomes have traditionally relied on physician-evaluated parameters, subject to interpretation. Furthermore, despite availability of comprehensive electronic medical data, their use has been limited by standard statistical techniques, requiring subjective pre-selection of variables prior to construction of prediction models.
Aims: Using Random Survival Forests (RSF), a machine learning (ML) algorithm, we sought to estimate predictive importance of a wide array of clinical and laboratory variables, including many not often assessed, in predicting HSCT related mortality (TRM). ML is a subfield of artificial intelligence, commonly applied in complex data scenarios.
Methods: We retrospectively analyzed a cohort of patients undergoing allogeneic HSCT in a single center. Patients' clinical data were crossed with laboratory data from institutional electronic medical records at baseline admission for transplantation. A total of 33 variables, mostly laboratory based (v=23), were included. An RSF model for TRM, with relapse as a competing event, was constructed and variable importance was extracted. Partial dependence plots were used to graphically explore the risk-adjusted relationship between predictors and TRM. Top RSF predictors were introduced into a Cox regression model, and cumulative incidence (CIn) was compared across individual variables.
Results: A cohort of 965 patients with a median age of 53 (16 -76) were analyzed. Indications for transplant were mostly hematologic malignancies mainly AML and MDS. The majority of patients received myeloablative conditioning (58%) and graft-*versus*-host-disease (GvHD) prophylaxis with cyclosporine and methotrexate (76%). Median follow-up time was 6.4 years. The top 15 predictors selected by RSF are presented in Figure 1a. TRM is strongly predicted by pre HSCT albumin, GvHD prophylaxis and estimated creatinine clearance, whereas these factors are less predictive of relapse. Partial dependence plotting uncovered non-linear relationships between TRM CIn and creatinine clearance (Figure 1b) and serum albumin. Seven of the top 10 RSF predictors were confirmed by a Cox regression model (Table 1) and TRM CIn plots (Figure 1c).

Table 1.

Variable		Hazard ratio	p-value
GvHD Prophylaxis	MTX *vs* MMF	1.32	0.0180
	- *vs* Other	0.734	
HLA mis-match	0 *vs* 1	2.356	0.0001
Diagnosis	AML *vs* ALL	0.934	0.0085
	- *vs* MDS/MPD	1.404	
	- *vs* Lymphoma	2.157	
	- *vs* Other	1.676	
Albumin (g/dl)	>3.7 *vs* <3.7	1.708	0.0002
Creatinine clearance (mL/min)	>60 *vs* <60	1.694	0.0007
Age	<20 *vs* 20-40	1.442	0.0085
	- *vs* >40	2.225	
Alk Phos (IU/l)	<120 *vs* >120	1.461	0.0073

Summary/Conclusions: Using a novel methodology across a comprehensive landscape of HSCT patient characteristics, we identified key predictors of TRM. Variables such as creatinine clearance and albumin display a strong non-linear relationship with the primary outcome-TRM, while TRM is linearly dependent on alkaline phosphatase. Some elements considered in existing prognostic scoring systems, such as hepatocellular transaminases, were not predictive. Taken together, these findings provide a new framework for evaluating transplantation risk in a data-rich environment, and reveal simple and objective determinants of transplant-related mortality.

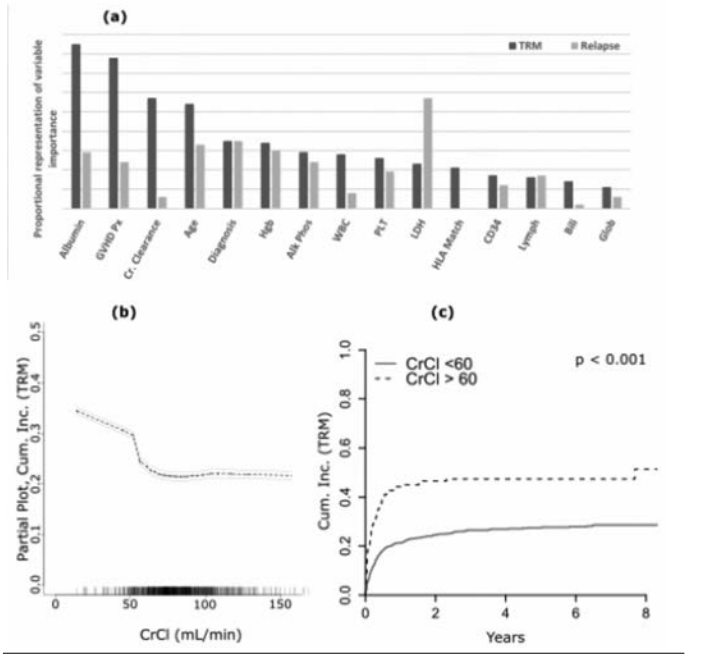

Figure 1.

P719

CYTOMEGALOVIRUS INDUCES STRONG ANTILEUKEMIC EFFECT IN ACUTE MYELOID LEUKEMIA PATIENTS FOLLOWING SIBLING HSCT WITHOUT ATG-CONTAINING REGIMEN

H Qiu*, X Bao, S Xue, X Hu, X Ma, F Chen, X Wu, S Chen, A Sun, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: A considerable number of studies have demonstrated that cytomegalovirus (CMV) reactivation after allogeneic hematopoietic stem cell transplantation (Allo-HSCT) could enforce graft-*versus* leukemia (GVL) effect in acute myeloid leukemia (AML) patients. However, the use of antithymocyte globulin (ATG) as part of graft-*versus*-host disease (GVHD) prophylaxis may dampen this beneficial effect of CMV replication.
Aims: The purpose of this study is to investigate whether the ATG or non-ATG containing regimens can all benefit from this GVL effect.
Methods: In this context, we retrospectively analyzed the effect of CMV reactivation on relapse, survival and prognosis in a total of 227 AML patients who received a myeloablative (MA) conditioning regimen at a single research center between January 2010 and April 2013.
Results: Of these 227 patients, 110 cases received non-ATG-containing regimens and 117 cases received ATG-containing regimens. CMV reactivation occurred in 45 patients (41%) among non-ATG regimen -months, a lower risk of cumulative relapse incidence associated with CMV reactivation was observed in non-ATG group in multivariate analyses (OR 0.28, 95% CI 0.10-0.79; *P*=0.016). However, CMV reactivation after transplantation did not significantly decrease the cumulative incidence of relapse in our ATG group (OR 0.28, 95% CI 0.10-0.79; *P*=0.016).
Summary/Conclusions: Collectively, our results demonstrate that in AML patients following sibling HSCT, the CMV-induced beneficial effect on relapse occurs only in the MA regimens containing no ATG, although ATG promotes CMV reactivation. the cumulative incidence of relapse in our ATG group (OR 0.28, 95% CI 0.10-0.79; *P*=0.016).

P720

COMPARING TIME-DEPENDENT PREDICTIVE PERFORMANCE OF ALLOGENEIC HSCT RISK SCORING SYSTEMS

J Fein[1,*], R Shouval[2], N Shem-Tov[2], I Danylesko[2], R Yerushalmi[2], A Shouval[3], A Shimoni[2], A Nagler[2]
[1]Sackler School of Medicine, Tel Aviv University, Tel Aviv, [2]Hematology and Bone Marrow Transplantation, Sheba Medical Center, Tel Ha-Shomer, Ramat-Gan, [3]Internal Medicine "F", Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: The European Bone Marrow Transplant (EBMT) score and Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI) predominate in the assessment of risk of allogeneic hematopoietic stem cell transplantation (HSCT)-related mortality. Though validated, both scores have been shown to fluctuate in predictive capacity between different patient populations.

Aims: To evaluate and compare the long-term performance of the EBMT and HCT-CI scores across typical transplant indications.
Methods: This is a retrospective analysis of a cohort of patients from a single center. EBMT and HCT-CI scores were calculated for the entire cohort. Cox regression modeling, with scores as covariates, was used to assess the probability of overall survival (OS) as well as treatment-related mortality (TRM) with relapse as a competing risk. Score performance in predicting each outcome at multiple time-points was compared, using receiver operating characteristics to determine time-dependent areas under the curve (AUC). AUC measures the ability of a model to differentiate between those who do and do not experience the outcome event on a scale of 0.5 (no better than random chance) to 1 (perfect discrimination). Performance was further compared within specific subgroups.
Results: A cohort of 845 patients, with a median age of 52 (16 - 76), was assessed. Indications for transplant were primarily acute leukemia and myelodysplastic syndrome. EBMT scores reflected a normal distribution; 50%, 25%, 12% and 14% of patients had HCT-CI scores of 0, 1, 2 and 3 or greater, respectively. The majority of patients had advanced disease (45.0%) and received myeloablative conditioning (67.7%). Median follow-up was 6.2 years. Patients with early or intermediate disease had a median survival >4 years; those with advanced disease had only 0.5 year. Increasing scores corresponded to distinct and increasing risk of TRM (Figure 1a, b), Table 1). Neither score predicted relapse. Predictive performance, measured by AUC, was time-dependent. While in the first 2 years post-HSCT the EBMT score showed significantly greater discrimination, the scores subsequently converged. This was seen both in the entire population and within subgroups such as disease status and conditioning regimen.

Table 1.

	Risk score	% patients	TRM HR (95% CI)	p	OS HR (95% CI)	p
EBMT	0-2	19.4%	1			
	1					
	3	22.2%	1.59 (0.96-2.63)	0.071	1.29 (0.82-2.02)	0.270
	4	23.9%	1.86 (1.15-3.00)	0.010	1.76	0.011
	5	24.1%	2.55 (1.61-4.05)	<0.001	2.25 (1.46-3.47)	<0.001
	6-7	13.0%	3.87 (2.40-6.26)	<0.001	2.62 (1.66-4.14)	<0.001
HCT-CI	0	49.9%	1		1	
	1	24.7%	1.36 (0.97-1.89)	0.072	1.28 (1.03-1.59)	0.025
	2	12.4%	1.54 (1.05-2.27)	0.028	1.39 (1.07-1.80)	0.014
	≥3	14.4%	2.09 (1.48-2.96)	<0.001	1.72 (1.36-2.17)	<0.001

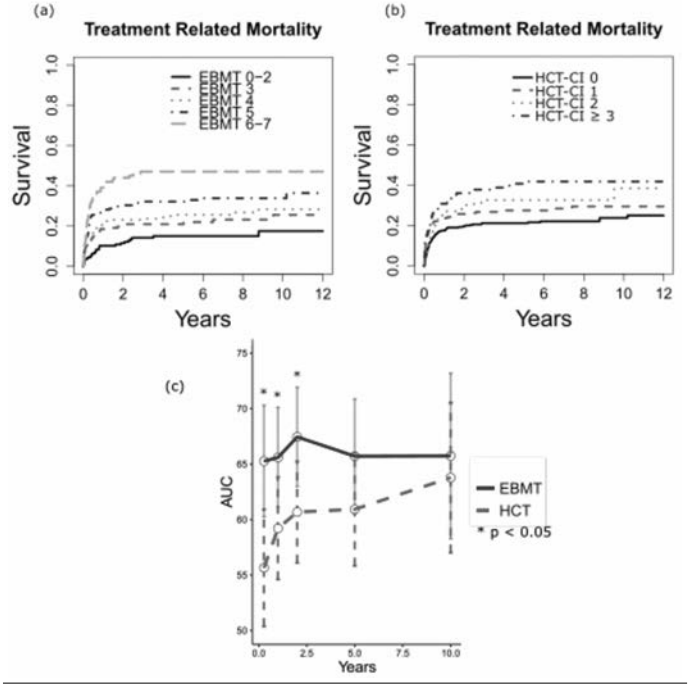

Figure 1.

Summary/Conclusions: In an allogeneic HSCT cohort with median follow-up time >6 years, predictive performance of the EBMT score is greater than that of HCT-CI in the first two years after transplantation. The HCT-CI score steadily improves until performances converge. The different components of the two prognostic models may account for the HCT-CI score's improving effectiveness over time: the EBMT score reflects primarily static features of the patient and procedure at time of transplantation; the HCT-CI score includes factors subject to subsequent improvement or deterioration. Altogether, both models provide stepwise risk estimation, however individual clinical prediction remains elusive due to limited discrimination (*i.e.* AUC).

P721

PROPHYLACTIC DLI *VS* NO DLI FOR REFRACTORY ACUTE LEUKEMIA UNDERGOING ALLO-HSCT WITH SEQUENTIAL INTENSIFIED CONDITIONING

Q Liu[1,*], L Xuan[1], Z Fan[1], Y Zhang[1], H Zhou[1], F Huang[1], D Nie[2], D Lin[3], J Sun[1], Y Xiao[4]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Department of Hematology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, [3]Department of Hematology, the Third Affiliated Hospital, Sun Yat-Sen University, [4]Department of Hematology, Guangzhou General Hospital of Guangzhou Military Command, Guangzhou, China

Background: The major obstacle is leukemia relapse for refractory leukemia undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT). We previously introduced a strategy of sequential intensified conditioning and early rapid immunosupressant withdrawal for refractory leukemia undergoing allo-HSCT, with 5-year overall survival (OS) and 3-year relapse rate of 44.6% and 33.3%.
Aims: To reduce leukemia relapse, prophylactic donor lymphocyte infusion (DLI) was administered based on our historical strategy.
Methods: We conducted a prospective multi-center study to assess the efficacy of the new strategy for refractory advanced acute leukemia. Sequential intensified conditioning regimen was: fludarabine (30 mg/m^2/day, -10 to -6 days)+cytarabine (2.0 g/m^2/day, -10 to -6 days) plus total body irradiation (4.5 Gy/day, -5, -4 days)+cyclophosphamide (60 mg/kg/ day, -3, -2 days)+etoposide (15 mg/kg/day, -3, -2 days). Immunosupressant was withdrawn by 10%/week in patients without acute graft-*versus*-host disease (aGVHD) by day +30 post-transplantation. For patients without grade II/>II aGVHD by day +60 post-transplantation, DLI was administered at a median dose of 1.0×10^{8}mononuclear cells/kg if donor lymphocytes were available. DLI was given once to all patients regardless of minimal residual disease (MRD), and was then administered based on GVHD and MRD status. If patients were MRD negative, DLI was not given again; if patients were MRD positive and without GVHD, DLI was given monthly until GVHD occurred or MRD became negative or for a total of four times.
Results: A total of 153 patients with refractory advanced acute leukemia undergoing allo-HSCT from January 2009 to June 2014 were enrolled. All patients achieved hematopoietic reconstitution except for two who died of infection and two who died of RRT within 2 weeks post-transplantation. At the time of neutrophil reconstitution, all 149 evaluable patients achieved complete remission. The incidence and mortality of regimen-related toxicities were 100.0% and 1.3%. The 5-year overall and disease-free survival post-transplantation were 51.1%±5.7% and 49.2%±5.3%. The 5-year relapse rate and non-relapse mortality (NRM) were 27.3%±4.4% and 29.7%±5.3%. According to the availability of donor lymphocytes and the criteria for DLI, 144 patients surviving day +60 were divided into two groups (80 DLI *versus* 64 non-DLI). The relapse rate was less and OS was better in patients receiving DLI than in those not receiving DLI (22.7% *vs* 33.9%, P=0.048; 58.1% *vs* 54.9%, P=0.043). NRM was similar between DLI and non-DLI groups (P=0.104). Multivariate analysis revealed that lower bone marrow blasts on day 0, DLI and chronic GVHD were associated with less relapse and better OS.
Summary/Conclusions: The strategy of sequential intensified conditioning followed by early immunosupressant withdrawal and DLI could reduce relapse of refractory acute leukemia after allo-HSCT and improve survival.

P722

THE PRE-TRANSPLANT BIOMARKER RISK INDEX BASED ON SERUM FERRITIN, ALBUMIN AND CRP CAN PREDICT OUTCOMES INDEPENDENTLY OF THE HCT-CI AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

T Suwabe[1,*], Y Shibasaki[2], T Katagiri[1], S Miyakoshi[1], H Kobayashi[1], K Fuse[1], T Ushiki[1], N Sato[3], T Yano[3], T Kuroha[3], S Hashimoto[3], M Narita[1], H Sone[1], T Furukawa[3], M Masuko[2]
[1]Department of Hematology, Endocrinology and Metabolism, Niigata University Faculty of Medicine, [2]Division of Stem Cell Transplantation, Niigata University Hospital, Niigata, [3]Department of Hematology, Nagaoka Red Cross Hospital, Nagaoka, Japan

Background: Although the Hematopoietic Cell Transplantation-specific Comorbidity Index (HCT-CI) and Comorbidity-age index are useful tools for pre-transplant risk assessments in allogenic hematopoietic stem cell transplantation (allo HSCT), c-statistic estimates for non-relapse mortality (NRM) and overall survival (OS) of them are reported to be about 0.65. Therefore, a new index rather than the HCT-CI which can predict more reliably outcomes is required to aid bedside decision making.
Aims: The purpose of this study was to create a new risk index based on three biomarkers, which are pre-transplant serum ferritin (SF), albumin (Alb), and C-reactive protein (CRP), to predict NRM and OS after allo HSCT.
Methods: We analyzed 198 adult patients who underwent allo HSCT between

2005 and 2014 at our facilities in this study, including 96 with acute myelogenous leukemia, 47 with acute lymphoblastic leukemia, 26 with myelodysplastic syndrome, 4 with myeloproliferative neoplasms, 3 with chronic myeloid leukemia, 5 with adult T-cell leukemia/lymphoma, 1 with mixed lineage leukemia, 4 with aplastic anemia, 2 with chronic active Epstein-Barr virus infection and 10 with malignant lymphoma. Median age of patients was 52.5 years (range: 16-67). A total of 57 patients received related stem cell transplantations, 82 received unrelated stem cell transplantations, and 59 received cord blood transplantations. In addition, myeloablative and non-myeloablative conditioning regimens were administered to 114 and 84 patients, respectively. The 70 patients with non-remission acute leukemia/lymphoma or refractory anemia with excess blasts were categorized as having a high disease status, and the others were categorized as having a standard disease status. We scored the pre-transplant risk index using biomarkers (Biomarker index: Bio-I) which was calculated to be assigned a 1 point for >2000ng/ml of SF, <3.4mg/dl of Alb and >1.5mg/dl of CRP respectively. We divided patients into three risk groups using Bio-I, low (score 0, N=138), intermediate (score 1-2, N=49) and high (score 3, N=11). We evaluated the utility of the Bio-I as an index for predicting post-transplant outcomes.
Results: Median pre-transplant SF was 4894ng/ml (range: 8-35185 ng/ml), Alb was 3.65g/dl (range: 2.1-5.2g/dl) and CRP was 0.16mg/dl (range: 0.01-17.9mg/dl). The Bio-I exhibited sufficient c-statistic estimates for NRM (0.613) and OS (0.662) at 1 year. These values were similar to those reported for the HCT-CI. In univariate analysis, the Bio-I was successfully used to stratify the patients into three risk groups in NRM (p=0.001) and OS (p<0.001). In multivariate analysis adjusted for the HCT-CI and disease status, the high-risk Bio-I group was found to be an independent poor prognostic factor for NRM (hazard ratio (HR): 5.16, p<0.001). Furthermore, intermediate- and high-risk groups were shown to be independent poor prognostic factors for OS (intermediate: HR 1.67, p=0.034, high: HR 4.39, p<0.001). In addition, we created a comprehensive scoring system for OS which was calculated to be assigned each point (Bio-I low: 0, intermediate: 1, high: 2, HCT-CI 0-2: 0, ≥3: 1 and disease status standard: 0, high: 1). This comprehensive scoring system displayed a higher c-statistic estimate for OS than the HCT-CI at 1 year (0.754).
Summary/Conclusions: The Bio-I, which is based on SF, Alb, and CRP levels, is a useful tool for risk assessment before allo-HSCT because it is easy to calculate, exhibits sufficient sensitivity, can be used to stratify patients into three clear risk groups, and acts as an independent (including from the HCT-CI) risk factor for predicting post-transplant outcomes.

P723

HAPLOIDENTICAL TRANSPLANTATION FOR PEDIATRIC PATIENTS WITH ACQUIRED SEVERE APLASTIC ANEMIA

L Xu*, S Zuo, X Zhang, F Wang, X Mo, T Han, W Han, Y Chen, Y Zhang, J Wang, Y Wang, C Yan, Y Sun, X Huang
Peking University Institute of Hematology, Peking University People's Hospital, Xicheng district,Beijing, China

Background: Matched sibling donor hematopoietic stem cell transplantation (MSD HSCT) is the upfront therapy for children with acquired severe aplastic anemia (SAA), but MSD is not available for most patients. The technique of haploidentical HSCT (haplo-HSCT) for SAA has been improved according to exciting results reported recently, although it is recommended to pediatric SAA patients after failure to at least 2 courses of IST based on ATG in current guidelines.
Aims: To study that who will benefit from haplo-HSCT most.
Methods: 52 SAA patients younger than 18 years received haplo-HSCT consecutively between February 2007 and November 2015 in our center. All the patients received haplo-HSCT with the protocol of using G-CSF primed bone marrow plus G-CSF-mobilized peripheral blood stem cells without *in vitro* T cell depletion. The conditioning regimen included BU(08.mg/kg q6hrsx2d), CY(50mg/kgx4d) and rATG(2.5mg/kg/dx4d). CsA, MMF and short-time MTX were used for GVHD prophylaxis.In 23 newly diagnosed patients, haplo-HSCT was administered as the upfront therapy and in the other 29 refractory patients, it was administered as non-upfront therapy.
Results: 51 patients achieved primary engraftment except one child died of regimen related toxicity on the day +1. Graft failure occurred on 3 patients (two was rejection and the other one was secondary poor graft function). The cumulative incidence (CI) of aGVHD grade II-IV and grade III-IV was 39.2±0.5% and 13.7±0.2%, respectively. The CI of cGVHD was 34.2±0.5%. The 3-year OS and FFS was 84.5±5.0% and 82.7±5.2% with a median follow-up time of 744.5d (100-3294) for surviving patients. ECOG was the only predictor of OS and failure free survival (FFS).The OS, FFS, aGVHD, cGVHD have no significant difference between the upfront therapy group and the non-upfront therapy group.
Summary/Conclusions: Both newly diagnosed and refractory pediatric SAA patients could benefit from haplo-HSCT, especially for the children with good general condition. Considering the excellent outcome, haplo-HSCT might be considered to be alternative therapy for pediatric SAA patients without MSD in selected centers. Further studies are needed to confirm this result in prospective trials.

COMPARISON BETWEEN FLUDARABINE PLUS BUSULFAN AND FLUDARABINE PLUS MELPHALAN CONDITIONING REGIMENS BEFORE SINGLE-UNIT CORD BLOOD TRANSPLANTATION FOR ADULT ACUTE MYELOID LEUKEMIA PATIENTS

J Aoki[1,*], M Tanaka[1], H Kanamori[1], N Uchida[2], K Nishiwaki[3], A Yonezawa[4], B Saito[5], H Kobayashi[6], T Eto[7], M Takanashi[8], T Ichinohe[9], Y Atsuta[10,11], A Takami[12], S Yano[13]
[1]Kanagawa Cancer Center, Yokohama, [2]Toranomon Hospital, Tokyo, [3]Department of Internal Medicine, Jikei University School of Medicine, Kashiwa Hospital, Kashiwa, [4]Kokura Memorial Hospital, Kitakyushu, [5]Showa University School of Medicine, Tokyo, [6]Nagano Red Cross Hospital, Nagano, [7]Hamanomachi Hospital, Fukuoka, [8]Japanese Red Cross Society, Tokyo, [9]Hiroshima University Hospital, Hiroshima, [10]Japanese Data Center for Hematopoietic Cell Transplantation, [11]Nagoya University Graduate School of Medicine, Nagoya, [12]Aichi Medical University, Aichi, [13]Jikei University School of Medicine, Tokyo, Japan

Background: In recent year, reduced intensity conditioning (RIC) is developed and increasingly used in allogeneic hematopoietic stem cell transplantation (allo-HSCT) for acute myeloid leukemia (AML) patients. Fludarabine plus busulfan (FB) and fludarabine plus melphalan (FM) are widely used RIC regimens. A previous study reported FB and FM provide comparable survival after allo-HSCT from HLA matched siblings for AML patients. However, outcomes of cord blood transplantation (CBT) following FB or FM are unknown in AML patients.
Aims: We conducted a nationwide retrospective study to compare FM and FB in AML patients who underwent CBT.
Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. The selection criteria included AML (excluding acute promyelocytic leukemia), aged 16 years or older, first transplantation, single-unit CBT (HLA 4-6/6 match) between January 2003 and December 2013, FB (fludarabine 120-180 mg/m^2, busulfan 8mg/kg (or intravenous injection in equivalent doses) and TBI 2-4Gy) or FM (fludarabine 120-180 mg/m^2, melphalan 80 mg/m^2 and TBI 2-4Gy). We compared outcomes (overall survival (OS), relapse, non-relapse mortality (NRM) and hematopoietic recovery) after CBT following FB or FM.
OS was estimated by the Kaplan-Meier method and was compared using a log-rank test. Relapse and NRM were considered competing risk events for each other and were compared using Gray's test. The cumulative neutrophil and platelet recoveries were also estimated and compared by Gray's test considering death without these events as a competing risk. In a multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse, NRM and hematopoietic recovery respectively, using the following variables: age, gender, disease status, cytogenetic risk category, HLA disparity, nucleated cell dose, donor-recipient gender mismatch, ABO mismatch, and transplantation year.
Results: Of the 412 patients, 122 patients (29.6%) received FB and 290 patients (70.4%) received FM. Median age were 61 (20-78) and 60.5 (17-82) years old, respectively (P=0.66). Higher proportion of FM patients received HLA 6/6 matched CBT (P=0.03) and 4Gy TBI (P=0.002). There was no difference in other factors. Three-years OS (34.0% and 33.7%, P=0.81) relapse (34.9% and 36.3%, P=0.93), NRM (33.4% and 33.4%, P=0.89), 30-days neutrophil engraftment (63.1% and 67.2%, P=0.39) and 60-days platelet engraftment (45.1% and 50.0%, P=0.33) were not significantly different between FB and FM. In multivariate analysis, FB and FM showed similar OS (HR, 0.96; P=0.78), relapse (HR, 0.98; P=0.91), NRM (HR, 1.03; P=0.88), neutrophil engraftment (HR, 1.09; P=0.51) and platelet engraftment (HR, 1.18; P=0.31).
Summary/Conclusions: The current study showed FB and FM provide similar outcomes of CBT for AML patients.

P725

MINIMAL RESIDUAL DISEASE AND GRAFT-*VERSUS*-HOST DISEASE GUIDED SEQUENTIAL CHEMOTHERAPY PLUS DONOR LYMPHOCYTE INFUSION COULD IMPROVE SURVIVAL OF PATIENTS WITH ACUTE LEUKEMIA WHO RELAPSED AFTER ALLO-HSCT

CH Yan[1,*], Y Wang[2], XD Mo[3], XH Zhang[4], LP Xu [4], KY Liu[4], XJ Huang[4]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2] Peking University Institute of Hematology, Peking University People's Hospital, Bejing, [3]Peking University People's Hospital, Peking University Institute of Hematology, [4]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Allogeneic hematopoietic cell transplantation (allo-HSCT) is an effective therapy for acute leukemia, but relapse remains a major problem. Our recently article confirmed that chemotherapy plus DLI was superior to chemotherapy alone in patients with acute leukemia who relapsed after allo-HSCT, but the disease-free-survival (DFS) was only 20% at 2 years post-DLI and the cumulative risk of re-relapse was nearly 60% at 2 years post-DLI. Some articles have confirmed that chronic graft-*versus*-host disease (GVHD) post-DLI was a favorable prognostic factor for DFS. Besides, minimal residual

disease (MRD) identified by multi-parameter flow cytometry (FCM) and real-time quantitative polymerase chain reaction (RQ-PCR) could represent leukemic load and predict relapse.
Aims: To perform a prospective study and investigate the impact of MRD and GVHD guided sequential chemotherapy plus DLI on re-relapse and DFS in patients with acute leukemia who relapsed after HSCT.
Methods: From January 1, 2013 to February 28, 2015, consecutive 70 patients with acute leukemia who relapsed after allo-HSCT and received chemotherapy plus DLI to treat relapse were enrolled in this study and were defined as study group. When patients relapsed after allo-HSCT, induction chemotherapy plus DLI would be given firstly, and then, if patients achieved complete remission (CR), sequential chemotherapy plus DLI would be given based on the state of MRD and GVHD post-DLI. Besides, from January 1, 2000 to December 31, 2008, 54 patients with acute leukemia who relapsed after allo-HSCT only received induction chemotherapy plus DLI to control relapse and were defined as historical group.
Results: In study group, cumulative risk of re-relapse, overall survival (OS) and disease-free survival (DFS) at 1-year post-DLI was 45.7%, 56.9% and 50.0%, respectively. As well, multivariate analysis suggested that no chronic GVHD post-DLI (P=0.019, HR=5.093) and persistent MRD-positive state post-DLI (P<0.0001, HR=14.178) were unfavorable factors for re-relapse. Furthermore, based on the risk factors, 70 patients were further stratified into low-risk group, intermediate-risk group and high-risk group. Cumulative risk of re-relapse was significantly lower, DFS and OS were significantly better in low-risk group than that in other two groups (re-relapse: 22.3% *vs* 80.0% *vs* 92.5%, P<0.0001; DFS: 75.1% *vs* 0.0% *vs* 0.0%, P<0.0001 and OS: 94.7% *vs* 60.0% *vs* 0.0%, P<0.0001). Besides, compared with historical group, cumulative risk of re-relapse was significantly lower, DFS and OS were significantly better in study group (re-relapse: 45.7% *vs* 70.4%, P<0.0001; DFS: 50.0% *vs* 24.1%, P<0.0001 and OS: 56.9% *vs* 29.6%, P<0.0001).
Summary/Conclusions: These data suggest that based on the state of MRD and GVHD post-DLI, sequential chemotherapy plus DLI could improve outcomes of patients with acute leukemia who relapsed after allo-HSCT.

TERMINAL NK CELL MATURATION IS CONTROLLED BY CONCERTED ACTIONS OF T-BET AND ZEB2

S Goossens[1,*], M van Helden[1], C Daussy[2], B Lambrecht[1], T Walzer[2], G Berx[1]
[1]Inflammation Research Center, VIB, Ghent University, Ghent, Belgium, [2]CIRI, Université de Lyon, Lyon, France

Background: ZEB2 is a Zinc finger E-box binding transcription factor known to control epithelial-to-mesenchymal transition during development and disease. We recently have demonstrated that it is as well essential in multiple hematopoietic lineage differentiation decisions and for hematopoietic stem/progenitor migration.
Aims: We found that the Zeb2 is the most highly induced transcription factor during NK cell maturation. The aim of this project was to elucidate the role of Zeb2 in NK cells.
Methods: Using conditional loss and gain-of function mouse models we generated a cohort of mouse models with graded expression levels of Zeb2 specifically in the NK cell lineage.
Results: Targeted deletion of Zeb2 resulted in impaired NK cell maturation, survival and exit from the bone marrow. NK cell function was preserved but mice lacking Zeb2 in NK cells were more susceptible to B16 melanoma lung metastases. Reciprocally, ectopic expression of Zeb2 resulted in a higher frequency of mature NK cells in all organs. Moreover, the immature phenotype of Zeb2 null NK cells closely resembled that of Tbx2 null NK cells. This was due both to a dependence of Zeb2 expression on T-bet and to a probable cooperation of these factors in gene regulation. Transgenic expression of Zeb2 in Tbx21 null NK cells partially restored a normal maturation, establishing that timely induction of Zeb2 by T-bet is an essential event during NK cell differentiation. Finally, this novel transcriptional cascade could also operate in human as T-bet and Zeb2 are similarly regulated in mouse and human NK cells.
Summary/Conclusions: Here, we demonstrate that Zeb2 is essential to promote terminal NK cell maturation and that it functions downstream of T-bet.

BIFURCATION INTO HEMATOPOIETIC STEM CELL TYPES IS DEPENDENT UPON THE DEVELOPMENTAL SIGNALING MOLECULES

M Crisan[1,2,*], P Solaimani Kartalaei[2], CS Vink[3], T Yamada-Inagawa[2], A Neagu[2], S Karkanpouna[2], K Bollerot[2], C Purini[2], W van Ijcken[4], R van der Linden[2], SMC de Sousa Lopes[5], R Monteiro[5], C Mummery[5], E Dzierzak[2,3]
[1]BHF Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, United Kingdom, [2]Cell Biology, Erasmus MC Stem Cell Institute, Rotterdam, Netherlands, [3]Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom, [4]Centre for Biomics, Erasmus MC, Rotterdam, [5]Department of Anatomy and Embryology, Leiden University Medical Centre, Leiden, Netherlands

Background: All hematopoietic stem cells (HSC) are not alike. Clonal HSC transplantations and refined cell sorting based on HSC surface markers or reporters or responsiveness to signalling pathways have identified HSC subtypes with different functional properties. HSC subtype behaviours include preferred/biased lineage output following transplantation. The source of this HSC heterogeneity has yet to be identified. Since bone morphogenetic protein (BMP) affects the development of HSCs while they are generated, HSC subtypes may be differentially controlled by the BMP signaling pathway. However, the canonical BMP pathway is dispensable in the fetal liver and adult bone marrow, tissues where HSCs migrate during development.
Aims: Investigate whether HSC subtypes are programmed intrinsically during the developmental emergence of HSCs and/or whether their heterogeneity is determined by extrinsic factors encountered in different developmental hematopoietic tissues.
Methods: We examined whether HSCs in the embryo, fetus and adult are directly responsive to BMP signaling and the relationship of BMP signaling to HSC heterogeneity. To this objective, we used the *BRE GFP* transgenic reporter mouse model. GFP is expressed in *BRE–GFP* mice when BMP and the BMP receptor signal through Smad1/5 to activate transcription from the *BRE* sequence. GFP expression denotes BMP activation at the moment of cell observation/isolation and does not represent previous BMP activation history. Prospectively isolated cell types based on GFP expression and/or specific marker combinations were further transplanted into irradiated recipients or analyzed by RNA sequencing.
Results: We show that BMP signalling directly regulates HSCs as they are first generated in the aorta-gonad-mesonephros (AGM) region. However, in expansion conditions upon explant culture, we find that the AGM harbors two types of adult-repopulating HSCs: One type is BMP-activated and the other is a non-BMP-activated HSC type that is indirectly controlled by Hedgehog signalling through the VEGF pathway. Importantly, the two types of HSCs are

also found in the murine fetal liver and adult bone marrow *in vivo*. Clonal transplantation demonstrates that they have distinct haematopoietic lineage outputs. Transcriptomic analyses show that the two HSC types differ in intrinsic genetic programs, thus supporting a role for the developmental signalling pathways in the regulation of HSC heterogeneity and lineage output.
Summary/Conclusions: Our results reveal that the bifurcation in HSC types take place from early embryonic stages and suggest that their development is dependent upon the signalling molecules in the microenvironment they reside. Our findings provide insight into the molecular control mechanisms that define HSC types and have important implications for reprogramming cells to HSC fate and treatments targeting distinct HSC types.

LACK OF MIR-127 DOWN-REGULATION IN THE TRANSITION FROM HEMATOPOIETIC STEM CELLS TO MULTI-POTENT PROGENITORS LEADS TO PANCYTOPENIA AND DEFECTIVE SELF-RENEWAL

L Crisafulli[1,2], S Muggeo[1,2], P Uva[3], L Susani[1,2], M Cleary[4], P Vezzoni[1,2], B Gentner[5,6,7], F Ficara[1,8,*]
[1]Milan Unit, Istituto di Ricerca Genetica e Biomedica, CNR, Milan, [2]Humanitas Clinical and Research Center, Rozzano (MI), [3]CRS4, Science and Technology Park Polaris, Piscina Manna, Pula, Italy, [4]Department of Pathology, Stanford University School of Medicine, Stanford (CA), United States, [5]Vita Salute San Raffaele University, San Raffaele Scientific Institute, San Raffaele Hospital, [6]Hematology and Bone Marrow Transplantation Unit, [7]San Raffaele Telethon Institute for Gene Therapy, San Raffaele Hospital, Milan, [8]Fondazione Humanitas per la Ricerca, Rozzano (MI), Italy

Background: The ability of balancing self-renewal and differentiation is a key hallmark of somatic stem cells; however, the molecular pathways underlying this regulation are not completely understood, including any role for microRNAs (miRNAs). To identify miRNAs involved in the maintenance of hematopoietic stem cells (HSCs) identity we employed Pbx1-conditional knockout (KO) mice. Pbx1 is a homeobox transcription factor that positively regulates HSC quiescence. Its absence in post-natal HSCs causes a premature myeloid differentiation and an excessive proliferation that ultimately leads to their exhaustion, indicating a profound self-renewal defect [1]. Moreover, Pbx1maintains proto-oncogenic transcriptional pathways involved in myeloproliferative disorders [2].
Aims: Our aim was to assess if miRNAs contribute to regulate the balance between self-renewal and differentiation in HSCs, which is malfunctioning in myeloproliferative disorders and/or leukemia.
Methods: To achieve our aim we employed Pbx1-conditional KO mice, whose stem cells display a profound self-renewal defect. We reasoned that miRNA profiling of Pbx1-null HSCs, which are defective in their main functions, would lead to uncover miRNAs playing a role in HSC biology. Therefore, TaqMan-based miRNA profiling of HSCs and of their immediate downstream progeny of multi-potent progenitors (MPPs) from wt and Pbx1-conditional KO mice was performed. The expression of the most differentially expressed (DE) miRNAs was validated through independent real time PCR analysis, and was assessed in additional BM cell populations. Finally, we performed *in vivo* functional studies through lentiviral-mediated over-expression in primary murine bone marrow (BM) cells followed by transplantation in irradiated recipient mice.
Results: Unsupervised hierarchical clustering indicates a clear distinction between HSCs and MPPs at the level of miRNA expression, in accordance with the hypothesis that miRNAs contribute to regulate the first transition step in the adult hematopoietic development. Within each group, Pbx1-null and wt cells cluster separately, suggesting that Pbx1 directly or indirectly might regulate the expression of miRNAs involved in HSC self-renewal. Importantly, we found a group of miRNAs that are concordantly DE both in the physiological HSC-to-MPP transition and in Pbx1-null HSCs compared to wt HSCs. Among this list, miR-127 is the most DE. Its level of expression is comparable to that of other miRNAs previously associated to HSCs. However, it is the only one whose down-regulation occurs at the first transition from HSCs to MPPs, and that is strongly HSC-specific, since it is not re-expressed further down in the hematopoietic hierarchy within the BM. Interestingly, it is up-regulated in $CD34^+$ cells from chronic myeloid leukemia patients. Lack of miR-127 down-regulation in $Lineage^-$ (Lin^-) cells, achieved through lentiviral-mediated constitutive expression, led to their *in vivo* competitive disadvantage over untransduced Lin^- cells in long-term transplantation assays, and to a self-renewal defect as assessed in secondary recipients. In addition, transduced Lin^- cells transplanted in the absence of competition gave rise to pancytopenia.
Summary/Conclusions: A tight regulation of miR-127 is crucial to maintain HSC functions.
Funding: AIRC-Fondazione Cariplo (TRIDEO#15822); MIUR (FIRB#RBAP 11H2R9).

NAMPT-NAD+-SIRT2 PATHWAY-TRIGGERED DEACETYLATION OF LMO2 PROTEIN IS INDISPENSABLE IN THE EARLY HEMATOPOIESIS THROUGH COMPLETE TAL1 COMPLEX FORMATION

T Morishima[1,*], C Lindner[1], R Bernhard[1], A Zahabi[1], B Dannenmann[1], M Nasri[1], B Samareh[1], L Kanz[1], K Welte[2], J Skokowa[1]
[1]Department of Oncology, Hematology, Immunology, Rheumatology and Pulmonology, University Hospital Tuebingen, [2]University Children's Hospital Tuebingen, Tuebingen, Germany

Background: Nicotinamide phosphoribosyltransferase (NAMPT) is known as a rate-limiting enzyme in the biosynthesis of nicotinamide adenine dinucleotide (NAD^+) and supplies NAD^+ to sirtuins (SIRTs) that require NAD^+ to activate their protein deacetylase functions. We already reported that NAMPT-NAD^+-SIRT1 pathway is essential for granulopoiesis (Skokowa J, *et al.* Nat Med. 2009).
Aims: To analyze the roles of NAMPT-NAD^+-SIRT pathway in early hematopoiesis and elucidate new molecular mechanisms.
Methods: We used human induced pluripotent stem (iPS) cells model and a serum- and feeder-free monolayer hematopoietic differentiation system. We added NAMPT- or SIRT-inhibitors to the cells and analyzed hematopoietic differentiation.
Results: First of all, we cultured iPS cells in the presence or absence of the specific inhibitor of NAMPT, FK866. Interestingly, we found marked reduction of $VEGFR2^+CD34^+$ early hematopoietic progenitor cells at day 6 of differentiation by inhibition of NAMPT. As a results of qRT-PCR results which shows *SIRT2* mRNA expression is increasing in this differentiation stage, we tested SIRT2 specific inhibitor AC93253 and found that inhibition of SIRT2 also significantly suppressed differentiation into $VEGFR2^+CD34^+$ early hematopoietic progenitor fraction. Furthermore, the emergence of $CD43^+$ hematopoietic progenitor cells and colony forming ability at day 13 was completely suppressed by inhibition of SIRT2. These results indicate that NAMPT-NAD^+-SIRT2 signaling is needed for early hematopoiesis. To evaluate downstream targets of NAMPT-NAD^+-SIRT2, we analyzed mRNA and protein expressions of well-known early hematopoietic genes (*GATA2, RUNX1, LMO2, and TAL1*) in differentiated iPS cells on day 6 and found that both of them in these factors were not down-regulated by NAMPT or SIRT2 inhibition. With the idea of post-transcriptional modifications, we tested protein-protein interaction between SIRT2 and these candidate proteins in these cells using Duolink technique. We found that RUNX1, LMO2 and TAL1 proteins interact with SIRT2 protein. To identify the target of SIRT2-triggered deacetylation, we quantified and compared the Duolink signals from total- and acetylated- candidate proteins in the cells treated or not with SIRT2 inhibitor using flow cytometry. This analysis revealed that only LMO2 is deacetylated by SIRT2. LMO2 is known as a component of TAL1 complex, which consist of LMO2, TAL1, LDB1, E47 and GATA1/2 proteins and has transcriptional activity as a complex on hematopoiesis-specific target genes. Interestingly, mRNA expression levels of all these target genes were markedly downregulated by inhibition of NAMPT or SIRT2. Next, we predicted possible acetylated lysine residue in LMO2 protein and found K74 and K78 as strong candidates. We made LMO2 protein expression constructs containing acetylation- (KQ) and deacetylation- (KR) mimic mutants at these lysine residues and compared LMO2-LDB1 interaction between WT and mutant LMO2 constructs by co-immunoprecipitation. This experiment revealed that KQ-mutant had impaired interaction with LDB1 protein in comparison to WT and KR-mutant LMO2. These results indicate that deacetylation of LMO2 protein by SIRT2 is required for the interaction between LMO2 and LDB1 proteins.
Summary/Conclusions: NAMPT-NAD^+-SIRT2 pathway plays an indispensable role in the early hematopoiesis by deacetylation of LMO2 protein which enables the interaction between LMO2 and LDB1 proteins and complete TAL1 complex formation.

Background: B lymphopoiesis is a process that has been extensively studied for decades, which has led to the discovery of several transcription factors that are indispensible for the formation of B-cells.
The transcription factor ERG has previously been shown to influence hematopoietic stem cells and various cancers. However, its role in B-cell development is, thus far, largely uncharacterized.
Aims: To characterize the role of the transcription factor ERG in the development of B lymphocytes with particular emphasis on elucidating underlying transcriptional mechanisms.
Methods: We have created an *Erg*$^{fl/fl}$*:CD2iCre* mouse model, in which the

DNA-binding domain of *Erg* is deleted exclusively in the lymphoid cells rendering the transcription factor non-functional in this cell compartment.
Phenotypic characterization of the knock-out mouse was done using a combination of flow cytometry and *in vitro* differentiation assays.
To elucidate the mechanisms behind the influence of ERG on B lymphopoiesis, we have examined gene expression changes in B cell progenitors following its deletion using a microarray-based approach. For examination of changes at the chromosomal level, we are using ATAC-sequencing, which assesses chromatin accessibility.
Results: The lymphoid-specific knock-out of *Erg* leads to a dramatic loss of B-cells, which can be detected as a decline in the number of mature B-cells in the peripheral lymphoid organs. In the bone marrow, a substantial reduction in B-cell progenitors is seen already at an early progenitor stage with the cell loss becoming gradually worse throughout differentiation. These findings are recapitulated in *ex vivo* experiments.
The loss of B-cells can partly be ascribed to changes in the propensity of B cell progenitors to undergo apoptosis and proliferation.
Accordingly, gene expression analyses show a reduced expression of cell cycle-related genes in the B-cell progenitors. Furthermore, we see a deregulation of genes associated with B-cell differentiation.
On the chromosomal level, the deficiency of ERG leads to marked changes in genome-wide DNA accessibility in the B-cell progenitors.
Summary/Conclusions: We have identified ERG to be of central importance for the development of B-cells. Loss of ERG in the lymphoid cell compartment leads to a severe reduction in B-cells, which can be detected already at an early progenitor stage. The deficiency of ERG leads to changes in key cell properties, gene expression and genome-wide chromosomal accessibility.

P731

EXPRESSION OF BCL2, BUT NOT STAT5 SIGNALING, RESCUES LYMPHOPOIESIS IN THE ABSENCE OF HHEX

JT Jackson[1,*], ND Huntington[2], DM Tarlinton[3], W Goh[2], A Light[3], K O'Donnell[3], MP McCormack[1]
[1]Cancer & Haematology Division, [2]Molecular Immunology Division, [3]Immunology Division, The Walter & Eliza Hall Institute of Medical Research, Parkville, Australia

Background: The transcription factor Hhex (Hematopoietically-expressed homeobox gene) is important for the development of definitive hematopoietic progenitors and B-lymphocytes during embryogenesis. We have previously shown that Hhex is essential for adult lymphoid development, with its absence resulting in a severe defect stemming from a block in Common Lymphoid Progenitor (CLP) differentiation. This block was characterised by cell cycle arrest of B cell progenitors, as well as apoptosis and defective Stat5 phosphorylation in response to IL-7.
Aims: The aim of this study is to determine the roles of apoptosis and defective Stat5 signaling in the lymphoid developmental failure caused by loss of Hhex.
Methods: To investigate the pathways mediating this developmental block we have crossed Mx-Cre inducible conditional Hhex knock-out mice with transgenic mice expressing Bcl2 or constitutively active Stat5. We employed steady-state flow cytometric cell phenotyping, competitive bone marrow transplantation and *in vitro* differentiation experiments to assess lymphoid development. In addition, B-cell function was assessed by *in vitro* proliferation assays of splenic B-cells.
Results: We found that overexpression of Bcl2 rescued B-cell development in the absence of Hhex, as well as restoring the development of T, B and natural killer (NK) lineages during *in vitro* differentiation and *in vivo* transplantation experiments. In contrast, constitutively active Stat5 failed to rescue lymphoid development *in vitro* or *in vivo* in the absence of Hhex. Further analysis of Hhex-null, Bcl2-transgenic B-cells *in vitro* demonstrated that they were capable of proliferation, indicating that these rescued B-cells were functional.
Summary/Conclusions: These results indicate that Bcl2 expression can overcome the lymphoid deficiencies observed in the absence of Hhex, suggesting that the primary role of this transcription factor is to promote survival of lymphoid progenitors during early lymphoid development.

P732

ANAMORSIN IS ESSENTIAL FOR B-CELL TERMINAL DIFFERENTIATION

Y Hamanaka[*], H Shibayama, A Tanimura, T Yokota, S Ezoe, M Ichii, T Ishibashi, Y Doi, Y Nagate, K Oritani, Y Kanakura
Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan

Background: Anamorsin (AM, also called CIAPIN1) is a cell death-defying factor, which we have cloned as a molecule that conferred resistance to apoptosis induced by growth factor deprivation. AM-deficient mice die during late gestation, and AM KO embryos are anemic and very small compared to wild-type embryos (J Exp Med 2004; 199: 581–592), suggesting that AM is essential for embryo growth and hematopoiesis. The embryonic lethality of AM KO mice impedes detailed analysis of the roles of AM. AM is important in Fe-S cluster protein biogenesis (BBRC 2011; 408: 329–333), which is indispensable in many biological processes, suggesting that AM may be required for critical biological pathways.
Aims: To overcome the embryonic lethality of AM KO, here we generated AM conditional KO ($AM^{flox/flox}$) mice. The Cre-loxP system enabled cell type-specific genetic modification. Since we previously reported AM overexpression in ~30% of B-cell-type malignant lymphoma, here we focused on the role of AM in B-cell development.
Methods: We generated and analyzed CD19-Cre/$AM^{flox/flox}$ mice, with AM deleted specifically in $CD19^+$B cells (from Pro-B cells to mature peripheral B cells in B-cell development). B-cell development progresses through the pro-B-cell, pre-B-cell and immature-B-cell stages in BM and then exit from BM to spleen, where they pass through transitional stages; transitional type 1 (T1) and transitional type 2 (T2), and mature to either follicular B cells or marginal zone B cells.
Results: Compared with control CD19-Cre mice, CD19-Cre/$AM^{flox/flox}$ mice exhibited fewer $B220^+$B cells in the spleen (40.8±2.6% *vs* 56.8±3.8%, $P<0.001$), peripheral blood (23.2±2.5% *vs* 51.0±4.4%, $P<0.001$), and LN (8±2.3% *vs* 31.7±1.0%, $P<0.001$). To further examine how AM deficiency impacted B-cell differentiation, BM and spleen cells were categorized into B-cell subsets—from hematopoietic stem cells to mature follicular and marginal zone B cells—based on marker expression patterns using flow cytometry. Compared to control mice, CD19-Cre/$AM^{flox/flox}$ mice showed significantly fewer follicular type I (FO-I) cells ($B220^+$, $AA4.1^-$, $sIgM^{low}$, $CD23^+$, $sIgD^+$), which are the most matured follicular B cells in the spleen (7.9±0.1% *vs* 15.1±1.0%, $P<0.01$). Immunohistochemistry using monoclonal anti-B220 antibody in formalin-fixed paraffin-embedded spleen sections showed smaller B-cell follicles in CD19-Cre/$AM^{flox/flox}$ mice. Since AM was originally isolated as an anti-apoptotic molecule, spleen cells were treated with FITC-conjugated annexin V to determine the percentage of apoptotic cells, revealing greater apoptotic cell accumulation in CD19-Cre/$AM^{flox/flox}$ mice compared to controls (30.0±4.4% *vs* 19.8±1.3%, $P<0.05$). This suggested that follicular B cell development was blocked by increased apoptosis in the CD19-Cre/$AM^{flox/flox}$ mice. Furthermore, CD19-Cre/$AM^{flox/flox}$ mice lacked splenic $CD19^+B220^{-/low}$ cells, which display a plasmablast phenotype.
Summary/Conclusions: Although AM expression was consistent throughout the differentiation stages of $CD19^+$ B cells, AM deficiency predominantly affected terminal differentiation of B cells, especially from T2 to FO-I. Immature B cells mature through transient T2 B cells into follicular or marginal zone B cells, and their follicular *versus* marginal zone fate partly depends on the strength of BCR signaling. Reduced numbers of FO-I B cells and $CD19^+B220^{-/low}$ cells in the spleen are also reported in mice with defects in Bruton's tyrosine kinase (BTK), which is activated in downstream of BCR signaling. The phenotypic similarity between Btk-deficient mice and our CD19-Cre/$AM^{flox/flox}$ mice suggests that AM may affect B-cell development through the BCR-BTK pathway. Overall, our present results show that AM plays essential roles in B-cell terminal differentiation, suggesting the potential involvement of some Fe-S cluster proteins in B-cell terminal differentiation. Moreover, our novel $AM^{flox/flox}$ mice will enable further investigation of the functions of AM and the related Fe-S cluster proteins in various organs.

DOWNREGULATION OF CD44 FUNCTIONALLY DEFINES HUMAN T-CELL COMMITMENT

K Canté-Barrett[1,*], R Mendes[1], Y Li[1], E Vroegindeweij[1], K Pike-Overzet[2], T Wabeke[3], A Langerak[3], R Pieters[4], F Staal[2], J Meijerink[1]
[1]Pediatric Oncology/Hematology, Erasmus MC, Rotterdam, [2]Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, [3]Immunology, Erasmus MC, Rotterdam, [4]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: T-cell development in the thymus is a complex process that depends on sequential transcriptional and epigenetic events that induce T-cell lineage commitment and simultaneously suppress alternative cell fates. Human T-cell development is less well studied than its murine counterpart due to the lack of genetic tools and the difficulty of obtaining cells and tissues. However, recent technological advances have enabled the identification of the transcriptional landscape of differentiating human thymocytes. Research has focused on mimicking the thymus environment in *in vitro* T-cell differentiation cultures starting from hematopoietic stem/progenitor cells (HSCs) derived from human cord blood or bone marrow.
Aims: We aimed to compare *in vitro* T-cell differentiation at the level of gene expression with gene expression of *in vivo* murine and human early T-cell development. Recapitulation of gene expression at the correct stage of differentiation would validate this model beyond the level of surface markers that are commonly used to identify sequential differentiation stages *in vitro* and *in vivo*, and helps identify novel markers that delineate specific stages and commitment points.
Methods: We have utilized the OP9-DL1 *in vitro* co-culture system to gradually differentiate $CD34^+$ HSCs from umbilical cord blood into the T-cell lineage. HSCs in this co-culture will recapitulate *in vivo* T-cell development as measured by incremental acquisition of surface markers CD7, CD5, CD1a, CD4, and CD8. We investigated and compared gene expression profiles of 11 human T-cell differentiation subsets collected by FACS sorting at 5 different time-points.

We determined the TCRβ rearrangement status and functionally defined T-cell commitment of several human early thymocyte subsets.
Results: The changes in gene expression of subsequent early T-cell developmental stages closely resemble those of human and murine *in vivo* thymocyte subsets, validating the OP9-DL1 co-culture as a true representative of *in vivo* human T-cell development. These analyses let us to define a gene signature that distinguishes pre- and post- αβ T-cell commitment. We searched for various candidate surface markers that could pinpoint the exact transition from pre- to post-T-cell committed human thymocytes; both in human thymocytes *in vivo* as well as in differentiating cells *in vitro*, loss of CD44 marks T-cell commitment in early CD7+CD5+ cells, before the acquisition of CD1a surface expression. The CD44-CD1a- post-committed thymocytes have initiated in frame TCR rearrangements and have completely lost the capacity to develop into myeloid, B- and NK-cells, unlike uncommitted CD44+CD1a- thymocytes.
Summary/Conclusions: The gene expression profiles of 11 human *in vitro* T-cell differentiation subsets closely resemble those of early T-cell development of murine and human thymocytes. Therefore, the OP9-DL1 co-culture closely mimics *in vivo* T-cell development. Moreover, this model has enabled us to pinpoint human αβ T-cell commitment using CD44. In conclusion, loss of CD44 represents a previously unrecognized stage that defines the earliest committed T-cell population in the human thymus.

KNOCKDOWN OF THE ADHESION G-PROTEIN COUPLED RECEPTOR 56 IMPAIRS HUMAN CORD BLOOD STEM AND PROGENITOR CELL FUNCTION

L He[1,*], S Garg[1], T MacRae[2], F Barabé[3], G Sauvageau[2], C Müller-Tidow[1], C Pabst[1]
[1]Department of Internal Medicine IV, Hematology and Oncology, University Hospital Halle, Halle(Saale), Germany, [2]Laboratory of molecular genetics of stem cells, Institute for Research in Immunology and Cancer, University of Montreal, Montreal, [3]Centre de recherche du CHU de Québec, Centre de recherche en infectiologie du CHUL, Quebec, Canada

Background: Knowledge about the differences and similarities between normal hematopoietic stem and progenitor cells (HSPCs) and their malignant counterparts is an essential prerequisite for the development of novel therapeutic approaches for the treatment of hematologic diseases such as acute myeloid leukemia (AML). We recently identified the adhesion G-protein coupled receptor 56 (GPR56) as novel leukemia stem cell marker in AML. While GPR56 has been attributed a role in homing and endothelial to hematopoietic stem cell transition in mice and zebrafish its functional role in human primary HSPCs has not been fully characterized yet.
Aims: Here we set out to determine the functional role of GPR56 expression for normal HSPC function in the human hematopoietic system.
Methods: We knocked down GPR56 via lentiviral shRNA vectors in cord blood (CB) CD34+ cells. Gene knockdown was confirmed by FACS analysis upon lentiviral transduction prior to subjecting the cells to *in vitro* and *in vivo* assays. GFP+ cells were sorted into methylcellulose and colony formation potential was determined after 12 days. Furthermore, cells were injected in NSG mice and bone marrow was analyzed for total and lineage specific human engraftment at 4, 8, and 20 weeks post transplantation. RNA-Sequencing (RNA-Seq) was performed in CB CD34+ cells 3 days post infection to determine differences in gene expression.
Results: We observed a rapid decrease in the fraction of GFP+ cells infected with two different shRNA vectors against GPR56, but not when infected with shLuciferase control vector. Furthermore, colony formation capacity of CD34+ cord blood cells was severely impaired upon knockdown (KD) of GPR56 with greater reduction in the more immature GEMM and BFU-E colonies compared to G- and M-colonies. Moreover, we found that the repopulating potential of CB CD34+ cells was significantly impaired in cells with near complete KD of GPR56. Accordingly, we observed an inverse correlation between the level of GPR56 KD and contribution of GFP+ cells to engraftment. In addition, we observed significant differences in the lympho-myeloid-lineage-ratio to the disadvantage of the lymphoid lineage when harvesting human cells from mouse bone marrow 20 weeks post transplantation of GPR56 KD HSCs compared to controls. RNA-Seq of CB CD34+ cells upon GPR56 KD *vs* controls revealed enrichment for several GO terms connected to the regulation of hematopoiesis, apoptosis, and survival.
Summary/Conclusions: Together, our findings indicate that GPR56 is not only involved in survival and proliferation, but also in the maintenance of the multipotent undifferentiated state of human HSPCs.

P735

DISSECTING THE ROLE OF THE MICROENVIRONMENT IN APLASTIC ANEMIA USING AN *IN VIVO* HAEMATOPOIETIC STEM CELL NICHE MODEL

IM Michelozzi[1,*], AS Pievani[1], F Pagni[2], L Antolini[3], M Verna[4], P Corti[4], A Rovelli[4], M Riminucci[5], F Dazzi[6], A Biondi[4], M Serafini[1]
[1]Dulbecco Telethon Institute at Centro Ricerca Tettamanti, Department of Pediatrics, University of Milano-Bicocca, [2]Department of Pathology, [3]Centro di Biostatistica per l'epidemiologia clinica, School of medicine, University of Milano-Bicocca, [4]Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital/Fondazione MBBM, Monza, [5]Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy, [6]Department of Haemato-Oncology, Rayne Institute, King's College London, London, United Kingdom

Background: Aplastic anemia (AA) is a bone marrow failure disorder in which the microenvironment seems to play a role.
Mesenchymal stromal cells (MSC) have been investigated in AA for their essential function in bone marrow microenvironment. However, there are limited and controversial *in vitro* studies characterizing patient-derived MSC. Therefore, *in vivo* models would be tremendously useful to better understand the effective role of the stromal compartment in AA niche. Indeed, the establishment of simplified haematopoietic stem cell niche models potentially allows to recapitulate haematopoietic and stromal defects and to dissect the functional role of different cell populations involved in the development of specific diseases.
Aims: Using our recently described *in vivo* model which accurately mimics the miniature of a bone/bone marrow organ, we aim to investigate the role of MSC in AA reproducing pathological microenvironment and testing their ability to support haematopoiesis (Serafini *et al.*, 2014).
Methods: We isolated MSC from 7 newly diagnosed AA pediatric patients (AA-MSC) and 7 age-matched healthy donors (HD-MSC), after informed consent according to institutionally approved protocols. MSC cultures were characterized by evaluating clonogenicity, cell growth, immunophenotype, and differentiation potential *in vitro*. Additionally, we analyzed immunohistologically and functionally the haematopoietic and stromal compartment of the ossicles obtained after the *in vivo* implant of chondrogenic pellets derived from MSC of both groups.
Results: AA-MSC displayed morphology, phenotypic profile, proliferation and *in vitro* differentiation capacities similar to their normal counterparts, albeit exhibited a lower colony forming efficiency. Moreover, we showed that AA-MSC maintain the capacity to establish *in vivo* an ossicle constituted by cortical bone filled with normal host-derived haematopoiesis. Immunohistochemistry analysis of the haematopoietic tissue in the intertrabecular space within the ossicles revealed the presence of murine macrophages, myeloid cells, megakaryocytes, red blood cells and osteoclasts in similar proportion in normal and patient-derived sections. Moreover, within the AA ossicle-derived marrows, it was possible to determine the presence of haematopoietic clonogenic progenitors and quantify the same number of cells belonging to the erythroid, myeloid and megakaryocytic lineages as their normal counterparts. Also the human stromal compartment of the ossicles originated from AA-MSC and HD-MSC resulted similar. A comparable amount and disposition of adipose marrow was observed in AA ossicles and in controls. Ossicles derived from both sources of MSC preparations similarly presented osteoblasts lining the osseous trabeculae, bone marrow interstitial fibrosis, reticulin deposition and iron storages.
Summary/Conclusions: This is the first study which addresses the *in vivo* ability of AA-MSC to support haematopoiesis. Using our *in vivo* model, we have been able to demonstrate that AA-MSC generate normal ossicles characterised by cortical bone, marrow cavity, donor-derived marrow stroma, and host-derived haematopoietic tissue. Further studies are needed to expand this investigation to a larger cohort of patients, in order to understand if these observations could be confirmed in MSC preparations derived from AA patients of different age and/or disease classification. Moreover, this work demonstrates that our experimental system could be suitable to model *in vivo* haemopoietic diseases and paves the way for studies on AA and other disorders.

P736

A HIGH RESOLUTION GENETIC ATLAS OF BLOOD CELL VARIATION AND FUNCTION IN HUMANS

W Astle[1,2,*], H Elding[3], T Jiang[4], D Allen[5], D Roberts[6], W Ouwehand[1], A Butterworth[4], N Soranzo[3]
[1]Department of Haematology, University of Cambridge, [2]MRC Biostatistics Unit, Cambridge, [3]Department of Human Genetics, Wellcome Trust Sanger Institute, Hinxton, [4]Institute of Public Health, University of Cambridge, Cambridge, [5]Blood Research Group, NHS Blood and Transplant, [6]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom

Background: Human blood production releases around 10^{11} cells per day into circulation. These originate from a minute population of haematopoietic stem cells, which differentiate towards mature cells by the clonal expansion of progenitor cells, following lineages of increasingly restricted fate. The molecules and pathways involved in lineage choice have been studied in great detail, but our understanding of the networks of proteins controlling cell fating is partial.
Aims: We sought to identify genetic variants controlling iron metabolism, haemotopoeisis, blood cell differentiation and blood cell clearance by a hypothesis free genomewide study; the largest population association analysis of blood cell traits to date.
Methods: We studied 36 haematological traits (measuring the properties of reticulocytes, red cells, platelets and the white cell subtypes) derived from the full blood counts of 173,480 individuals of European ancestry, selected from the

UK Biobank and INTERVAL cohorts. We analysed 29.5 million genetic variants (many of which were rare, with minor allele frequencies as low as 0.01%), imputed from genotypes measured using the UK Biobank Affymetrix Axiom array.
Results: We identified 182,105 variants significantly associated with at least one trait and could explain these associations using 1,652 distinct sentinel variants, 148 of which corresponded to previously reported GWAS hits, validating almost all the blood trait associations known for European populations. The associations of the remaining 1,504 sentinel variants were novel, augmenting the number of known associations by over 10-fold. Remarkably, we identified 270 rare and 258 low-frequency variants (allele frequency <1% and 1-5% respectively), and 44 "high impact" variants with additive allelic effects of more than 0.5 phenotypic standard deviations.
Summary/Conclusions: Almost three quarters of the associated variants are in the non-coding part of the genome with a striking enrichment in DNAse-I hypersensitivity sites with an enhancer signature. Gene sets containing associations were enriched in haematological pathways, genes implicated in rare blood and immune disorders, and genes predisposing to human complex disease, confirming the importance of our results for the understanding of haematopoietic processes and pathogenesis.

P737

EFFICIENT GENOME EDITING OF MOUSE HEMATOPOIETIC CELLS USING CRISPR/CAS9 TECHNOLOGY
E Sarrou[1,*], B Gibson[2], K Keeshan[1]
[1]Institute of Cancer Sciences, University of Glasgow, [2]Department of Haematology, Royal Hospital for Sick Children, Glasgow, United Kingdom

Background: A number of techniques have been used to study hematopoietic malignancies including viral overexpression of human oncogenes, RNA interference (RNAi) and transgenic animals. Each of these have their caveats for cell specific targeting, particularly RNAi approaches that are characterised by incomplete genetic inactivation without changing the genetic code. Genome editing technologies, including clustered regularly-interspaced short palindromic repeats (CRISPR), have been used to stably modulate the genome of several model organisms. The genome engineering of hematopoietic cells is complicated mainly due to the low efficiency of the non-viral delivery methods.
Aims: To generate efficient and stable genome edited murine hematopoietic models using CRISPR/Cas9 technology.
Methods: Two different guideRNAs (gRNAs) targeting either Mcm6 (gRNA5 and 8) or Sirt1 (gRNA3 and 9) were designed and cloned into the pLCRISPR.EFS.GFP lentiviral vector. These genes were chosen as they are involved in hematopoietic progenitor and stem cell (HSPC) properties. GFP$^+$ 32D Cl3 mouse hematopoietic cells were FACS sorted at day 5 post-transduction. Knockout efficiency was confirmed by both western blotting and qRT-PCR. Functional analysis was performed by the SURVEYOR assay and Sanger sequencing. Murine HSPCs were isolated from 5FU treated C57BL/6 mice (CD45.2+), transduced with the most efficient gRNA for either Sirt1 or Mcm6 and injected into B6.SJL mice. Engraftment was measured by FACS analysis of blood sampling at 4 weeks post-transplant.
Results: CRISPR/Cas9 efficiency was first tested on the mouse 32D cell line *in vitro*. Decreased protein and mRNA levels of Sirt1 were detected in 32D GFP$^+$ bulk population transduced with gRNA9 (32D+gRNA9) at day 5 which was not evident with gRNA3. SURVEYOR assay revealed that Cas9-mediated cleavage efficiency was higher in 32D+gRNA9 cells (16.3% indels) compared to 32D+gRNA3 cells (12.5% indels). 32D+gRNA9 cells were further expanded and FACS sorted for single clones. 5/20 clones showed complete absence of Sirt1 at the protein level (25% of Cas9 efficiency). Efficient clones were further used for genotype analysis by Sanger sequencing to confirm the type of indels. On the other hand, we saw complete absence of Mcm6 protein expression in 32D GFP$^+$ bulk cells transduced with gRNA5 or gRNA8, and >2-4-fold mRNA reduction was observed when transduced with gRNA5 and 8, respectively. Our CRISPR/Cas9 system was further tested *in vivo* using primary cells. Murine CD45.2$^+$ HSPCs were isolated, transduced with equal viral titre of empty vector, Mcm6-gRNA8 or Sirt1-gRNA9 and transplanted into CD45.1$^+$ mice. Blood sampling revealed high levels of engraftment as determined by CD45.2% and CRISPR transduction efficiency determined by the GFP levels at 4 weeks post-transplant. Our results show that CD45.2$^+$GFP$^+$ cells engrafted at 4 weeks showing effective CRISPR/Cas9 mediated transduction and transplantation of Mcm6 and Sirt1 knockout primary HSPCs.
Summary/Conclusions: In this study we successfully generated *in vitro* and *in vivo* CRISPR/Cas9 models for efficient genome editing on hematopoietic cells. Our findings demonstrate a complete gene knockout *in vitro* but with variable Cas9-mediated cleavage which was further confirmed by our clonal analysis. This suggests that Cas9 function might depend on both the targeted gene and/or the gRNA. Also, transduction of HSPCs was sufficient to ensure engraftment of GFP$^+$ cells. Long-term serial analysis will be further conducted to ensure stable expression and test Cas9-mediated cleavage *in vivo*.

COMPREHENSIVE PROTEOMIC ANALYSIS OF HUMAN ERYTHROPOIESIS
EF Gautier[1,2,*], S Ducamp[1,2], M Leduc[3], V Salnot[3], F Guillonneau[3], M Dussiot[4], J Hale[5], MC Giarratana[6], A Raimbault[2], L Douay[7], C Lacombe[2], N Mohandas[5], F Verdier[2,8], Y Zermati[2,8], P Mayeux[2,8]
[1]co-first, authors, [2]Institut Cochin/Université Paris Descartes/INSERM U1016/CNRS UMR8104/Laboratory of Excellence GReX/Ligue Nationale Contre le Cancer, [3]Plateforme de protéomique de l'Université Paris-Descartes (3P5), [4]Laboratory of Excellence GReX, PARIS, France, [5]New York Blood Center, New York, United States, [6]UPMC Univ Paris 06, UMR_S938 CDR Saint-Antoine, INSERM, Prolifération et Différentiation des Cellules Souches, F-75012/Laboratory of Excellence GReX, [7]UPMC Univ Paris 06, UMR_S938 CDR Saint-Antoine, INSERM, Prolifération et Différentiation des Cellules Souches, F-75012/Laboratory of Excellence GReX, PARIS, [8]co-senior, authors, France

Background: Erythropoiesis is a complex process starting from pluripotent medullary progenitors and leading to the production of enucleated erythrocytes. Several transcriptomic analyses of erythroid differentiation have been published to better understand the molecular mechanisms of erythropoiesis. However, it is now clearly established that the proteome cannot simply be deduced from the transcriptome and that post transcriptomic modifications are responsible for a large part of the proteome variations. Consequently, a direct proteomic analysis of the erythroid differentiation is required to accurately assess the modifications that occur during this process.
Aims: Our goal was to provide a deep analysis of the proteome evolution of human erythroid cells during their differentiation, from the BFU-E up to the orthochromatic erythroblast, and a quantitative analysis of the repartition of the proteins between the pyrenocyte and the reticulocyte after enucleation. The absolute quantification of proteins will be determined rather than their relative evolution all along the differentiation process.
Methods: We used CD34$^+$ cord blood progenitors and an optimized cell culture method allowing the production of highly synchronized cell populations of erythroid cells at various differentiation stages. Cellular populations from erythroid progenitors up to reticulocytes were submitted to mass spectrometry label-free analysis. To analyze the repartition of proteins after enucleation, pyrenocytes and reticulocytes were sorted by FACS. Equal numbers of reticulocytes and pyrenocytes were analyzed by mass spectrometry after iTRAQ labelling.
Results: Our analysis led to the absolute quantification, as protein copy number per cell, of more than 6100 proteins involved in many various biological process throughout the erythroid differentiation, with a false discovery rate of less than 1%. The range of quantified protein expression extended to around 7 logs. Absolute quantification was validated by several ways including the comparison of calculated values with those already published for several proteins and the classical differentiation markers expression pattern. All erythroid transcription factors were quantified. A comparison between mRNA and protein expression showed only a modest correlation as usual. Interestingly, this analysis revealed proteins with unexpected expression in erythroid differentiation such as optineurin, an autophagy inducer, or phospho1, a phosphatase involved in bone mineralization, which increased along differentiation, or leptin receptor, known to activate JAK2 and STAT5, which peaked at the proE/BasoI stage. Furthermore, the absolute quantification allows the calculation of protein ratio of different complexes. Regarding to segregation of proteins between reticulocytes and pyrenocytes, our study allowed the quantitative repartition of 1300 proteins. Flow cytometry imaging was used to calculate the cell surface area and the cytoplasmic volumes of pyrenocytes and reticulocytes allowing to determine whether a protein segregates passively or whether it is actively sorted. This method revealed proteins with unexpected localization and the active segregation of several proteins including most erythrocyte-specific membrane proteins which actively segregate with reticulocytes.
Summary/Conclusions: All these results significantly increase our knowledge of the protein expression pattern during erythropoiesis and should constitute a valuable data base for subsequent studies regarding both physiological and disordered erythropoiesis. A similar analysis is currently ongoing on murine erythroid differentiation to compare human and murine erythroid proteomes.

P739

AN IMBALANCE BETWEEN PLASMA ANNEXIN-A5 AND PHOSPHATIDYLSERINE EXPRESSION IN ERYTHROCYTES PROMOTES VASCULAR INJURY DURING SICKLE CELL DISEASE
S Sadoudi[1,*], S Le Jeune[2], P Bonnin[3], D Charue[1], C Boulanger[1], O Blanc-Brude[1]
[1]'ParCC' Paris Cardiovascular Center - UMRs970, INSERM, Université Paris-Descartes, AP-HP, Paris, [2]Arterial Hypertension, Avicenne hospital, AP-HP, Bobigny, [3]Vascular explorations, Lariboisière hospital, AP-HP, INSERM, Université Paris-Descartes, Paris, France

Background: Chronic hemolytic anemia, including Sickle Cell Disease (SCD) is characterized by painful vaso-occlusive crises (VOC), vascular injury, red blood

cell (RBC) aggregation and vesiculation, and intravascular hemolysis. At steady state, RBC release hemoglobin, heme and microparticles (MP) in plasma. This increases again during VOC. Stressed RBC and the MP they release express phosphatidylserine (PS) at their surface and contain cytotoxic heme, with deleterious impact on endothelial cells and vascular function. On the other hand, annexin-A5 is an intracellular protein that associates with membranes during cell stress and can be found in plasma. Annexin-A5 acts as a PS inhibitor, neutralizing PS-mediated effects of stressed cells and MP, and is generally thought to be an anti-inflammatory and anti-thrombotic protective agent.

Aims: We aimed to determine whether PS expression in red blood cells and MP in SCD is counterbalanced by annexin binding, and whether annexin-A5 in particular is modulated during vaso-occlusions. More specifically, we wanted to assess whether the plasma levels of annexin-A5 were all consumed during vaso-occlusions, or whether some annexin-A5 remained bioavailable for new interactions.

Methods: 1) We collected plasma and erythrocytes from a cohort of SCD patients during steady state or VOC, and matched controls. We studied plasma MP, plasma annexin-A5 levels and erythrocyte and MP expression of PS. 2) We designed a novel ELISA-based assay to capture PS+ MP with an anti-annexin-A5 antibody. It quantified annexin-A5-covered MP in plasma, but also estimated ligand-free functional annexin-A5. We characterized plasma MP by FACS with labeling of ligand-free PS with annexin-A5 and anti-CD235a, and size by NTA (50-1500 nm). 3) We tested recombinant annexin-A5 to block ROS production induced by SCD MP in cultured endothelial cells. 4) We used a model of hypoxia-induced vaso-occlusion in transgenic mice with SCD and tested PS neutralization *in vivo* with recombinant annexin-A5.

Results: In controls, RBC displayed little labeling with exogenous annexin-A5 by FACS. ELISA revealed that MP were few and covered with endogenous annexin-A5. Moreover, some annexin-A5 remained bioavailable in plasma. In SCD, plasma levels of annexin-A5 were increased, and MP levels were increased significantly, materializing hemolysis as expected. Surprisingly, SCD RBC and plasma MP all showed increased PS expression, as mean fluorescence intensities (MFI) by FACS. Hence, SCD RBC and MP bore more 'free' PS at their surface, available to exogenous annexin-A5 binding. In acute stage VOC, MP levels were increased even further and bore cytotoxic heme. RBC PS externalization increased even further in intensity, and we still found virtually no ligand-free annexin-A5 in plasma. *In vitro*, recombinant annexin-A5 inhibited the pro-oxidant effects of SCD MP on cultured endothelial cells. *In vivo*, recombinant annexin-A5 released vaso-occlusions triggered by hypoxia in transgenic mice with SCD, characterized by echo-Doppler measurements of renal perfusion.

Summary/Conclusions: We concluded that the equilibrium between PS expression and annexin-A5 is compromised in SCD. Endogenous plasma anenxin-A5 appears to be entirely consumed by excess PS externalization, unable to quench new bouts of PS expression during hemolysis, and insufficient to neutralize the high levels of PS+ MP produced by stressed RBC. In SCD, the therapeutic use of recombinant annexin-A5 may thus help compensate the imbalance between PS+ MP and annexin-A5.

P740

STAPHYLOCOCCUS AUREUS PROTEIN ISDH INHIBITS THE CD163 PATHWAY FOR HAPTOGLOBIN-FACILITATED HEMOGLOBIN SCAVENGING

KL Madsen[1,*], K Stødkilde[2], C Dickson[3], A Etzerodt[2], JH Graversen[1], D Gell[3], CBF Andersen[2], SK Moestrup[1]

[1]Department of Cancer and Inflammation Research, University of Southern Denmark, Odense C, [2]Department of Biomedicine, Aarhus University, Aarhus, Denmark, [3]School of Medicine, University of Tasmania, Hobart, Australia

Background: Hemolysis induced by bacterial α-toxin is a common complication in septic infections with *Staphylococcus aureus* and other bacteria, which utilize heme as a source for exogenous iron. The *S. aureus* uptake of heme occurs by a sophisticated heme-extraction mechanism that involves proteins from the iron-regulated surface determinant (Isd) system. Sequestration of heme from the hemoglobin-haptoglobin (Hb-Hp) complex is initiated by binding of Hb-Hp to the Isd protein H (IsdH). IsdH contains three the near-iron transporter (NEAT) domains; N1 and N2 anchors to hemoglobin, while the third NEAT domain N3 extracts heme. Normally, Hb-Hp is rapidly scavenged by the macrophage receptor CD163. However, since IsdH bind Hb-Hp close to the binding site of CD163, IsdH can potentially interfere with the uptake.

Aims: The objective of this study was to test the effects of recombinant IsdH on Hb-Hp binding to CD163 and cellular uptake.

Methods: To study effects of IsdH, recombinantly expressed full-length $IsdH^{N1N2N3}$ and two truncated variants of $IsdH^{N1}$ and $IsdH^{N2N3}$ were used. Endocytotic uptake of fluorescently labelled Hb-Hp by CD163-expressing Chinese hamster ovary (CHO) cells in presence of IsdH was evaluated by confocal microscopy and image-cytometry. Binding kinetics of IsdH was further characterized by SPR analysis.

Results: Our present data show that the high-affinity binding of IsdH to Hb-Hp strongly inhibits concomitant binding to and uptake by the human macrophage receptor CD163. Full-length $IsdH^{N1N2N3}$ showed the strongest inhibition of Hb-Hp uptake in CD163 expressing CHO cells and displayed the highest overall affinity for binding to Hb-Hp compared to the truncated versions. The single domain, $IsdH^{N1}$, which is not directly involved in the heme extraction, was also a potent inhibitor of both CD163 binding and endocytosis of Hb-Hp (Figure 1).

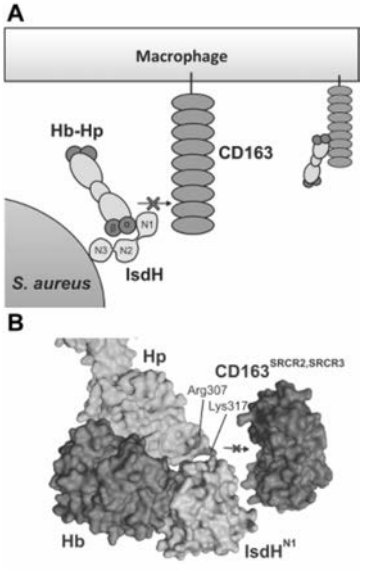

Figure 1.

Summary/Conclusions: Inhibition of the CD163 uptake of Hb-Hp could benefit the bacterium by keeping hemoglobin accessible a source of iron. Furthermore, dampening of the CD163-mediated hemoglobin degradation pathway, which converts the pro-inflammatory hemoglobin to anti-inflammatory metabolites, may further spark a septic inflammation supporting bacterial growth. Finally, it may skew the diagnostic negative correlation between hemolytic activity and the plasma concentration of haptoglobin. We suggest that inhibition of CD163-mediated Hb-Hp uptake is an additional function of IsdH.

P741

BODY IRON STATUS HAS A LARGER IMPACT ON UTILIZATION EFFICIENCY OF DIETARY IRON FOR ERYTHROPOIESIS THAN ERYTHROPOIETIC STIMULATION

Y Matsuo-Tezuka*, Y Shimonaka

Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: In a previous study, we demonstrated that dietary iron uptake and mobilization of stored iron are both up-regulated through suppression of serum hepcidin levels during erythropoietic stimulation by administration of Epoetin beta pegol (C.E.R.A.), a long-acting erythropoiesis-stimulating agent. It was also demonstrated that up-regulation of ferroportin (FPN) in reticuloendothelial macrophages and up-regulation of divalent metal transporter 1 (DMT1) and FPN in enterocytes are followed by hepcidin suppression. To determine the contribution of dietary iron for erythropoiesis under iron intervening conditions and erythropoietic stimulation, we labeled dietary iron with stable iron isotope ^{57}Fe and assessed it by inductively coupled plasma mass spectrometry (ICP-MS). By using them, we demonstrated that the utilization of dietary iron for erythropoiesis was increased under erythropoietic stimulation and decreased under iron loading. However, it is not elucidated which intervention has stronger impact on the utilization efficiency of dietary iron for erythropoiesis.

Aims: In this study, we compared the impact of body iron status and erythropoietic stimulation on the utilization efficiency of dietary iron for erythropoiesis.

Methods: To assess dietary iron-derived hemoglobin synthesis, a diet containing 200 ppm of ^{57}Fe instead of natural iron (^{57}Fe-diet) was used. A diet containing 200 ppm of natural iron (native Fe diet) was used as a control. C57BL/6NCrl mice were fed the native Fe diet and were intravenously administered 0.2 or 0.4 mg/mouse of iron-dextran (iron-loading condition) or dextran (control). Five days after iron loading, the diet was switched to the ^{57}Fe-diet immediately after intravenous injection of 2 or 10 μg/kg of C.E.R.A. or vehicle. On 10 days after C.E.R.A. treatment, mice were euthanized by exsanguination under anesthesia with isoflurane, and hemoglobin levels were measured. To quantify dietary iron-derived hemoglobin synthesis, the content of hemoglobin containing ^{57}Fe (^{57}Fe-hemoglobin) was measured by ICP-MS. The utilization efficiency of dietary iron for erythropoiesis was assessed as a ratio of ^{57}Fe-hemoglobin to hemoglobin levels.

Results: On 10 days after C.E.R.A. administration, hemoglobin levels were increased in C.E.R.A. 10 μg/kg-treated groups compared with vehicle-treated groups, as well as ^{57}Fe-hemoglobin levels. On the other hand, iron-loading did not affect hemoglobin levels. However, ^{57}Fe-hemoglobin levels were decreased in the iron-dextran 0.4 mg/mouse-treated groups as well as in the

iron-dextran 0.2 mg/mouse-treated groups under steady-state erythropoiesis. The utilization efficiency of dietary iron for erythropoiesis was significantly lowered in iron-dextran 0.4 mg/mouse-treated groups compared with dextran-treated group, whereas the utilization efficiency of dietary iron for erythropoiesis was not significantly different between vehicle- and C.E.R.A.-treated groups.
Summary/Conclusions: In the previous study, we demonstrated that both erythropoietic stimulation and iron intervention influenced the dietary iron utilization for erythropoiesis. Furthermore, in the present study, we demonstrated that iron intervention, in spite of mild iron loading conditions which did not affect the hemoglobin levels, reduced the utilization efficiency of dietary iron for erythropoiesis and it had larger effect than erythropoietic stimulation. It suggested that iron loading could potentially drop the utilization efficiency of dietary iron for erythropoiesis and therefore it is important to optimize the iron replacement therapy for renal anemia patients.

P742

AG-519 IS A POTENT ACTIVATOR OF MUTANT PYRUVATE KINASE ASSOCIATED WITH HEMOLYTIC ANEMIA

J Hixon[1,*], PA Kosinski[1], M Clasquin[1], K Johnson[1], J Popovici-Muller[1], B Zahler[2], G Cianchetta[1], L Silverman[1], L Dang[1], C Kung[1]
[1]Agios Pharmaceuticals, Inc., Cambridge, [2]PharmD Consulting, LLC, Pennington, United States

Background: Pyruvate kinase (PK) deficiency is an autosomal recessive enzymopathy that is the most common cause of hereditary nonspherocytic hemolytic anemia. PK deficiency is a rare disease characterized by a life-long chronic hemolysis with severe co-morbidities. It is hypothesized that mutations in PK result in insufficient energy production, in the form of adenosine triphosphate (ATP), to maintain red cell membrane homeostasis, leading to chronic hemolysis. Treatment is generally palliative, focusing on the resultant anemia, and there are no approved drugs that directly target mutated PK. AG-519 is an orally available, allosteric activator of the red cell isoform of PK (PK-R). AG-519 is currently in a randomized, double-blind, phase 1 study in healthy volunteers (NCT02630927), with the objective of identifying a safe and pharmacodynamically active dose and schedule to be used in subsequent clinical studies in subjects with PK deficiency.
Aims: We describe the mechanism of action and cellular effects of AG-519 in *in vitro* and *ex vivo* settings on mutant PK-R proteins associated with PK deficiency.
Methods: Mutant PK-R enzymes were expressed in E. coli and the kinetic parameters of the purified enzymes were evaluated in the presence or absence of AG-519. For thermostability studies, mutant enzymes were pre-incubated with control or AG-519 and then subjected to elevated temperature (53°C) followed by assessment of residual activity over time. Peripheral blood was obtained from patients with PK deficiency and the red cells were incubated with AG-519 for up to 24 h, followed by assessment of PK-R activity and ATP levels.
Results: We demonstrate that AG-519 can potently activate a spectrum of recombinantly-expressed PK-R mutant proteins associated with PK deficiency. All tested mutant enzymes exhibited at least 2-fold activation compared to baseline. The binding of AG-519 attenuated the thermostability defect of several mutant alleles of PK-R, including the commonly observed R510Q mutant, which had a half-life of ~2% of that of wild-type PK-R when incubated at 53°C. Pre-incubation of the R510Q protein with AG-519 restored the half-life to that of the wild-type enzyme. PK-deficient red cells are characterized by changes in metabolism associated with defective glycolysis, including a deficiency in ATP. PK-deficient red cells from several patients with distinct compound heterozygous PK-R mutations exposed to AG-519 *ex vivo* had increased PK-R enzyme activity (up to 4-fold over control) and increased ATP levels (up to 100% over control). These experiments demonstrate that AG-519 can effectively activate mutant PK-R within patient red cells. In these *ex vivo* settings, ATP levels in AG-519-treated cells can reach levels that are typical of normal, non-PK-deficient red cells (Figure 1).

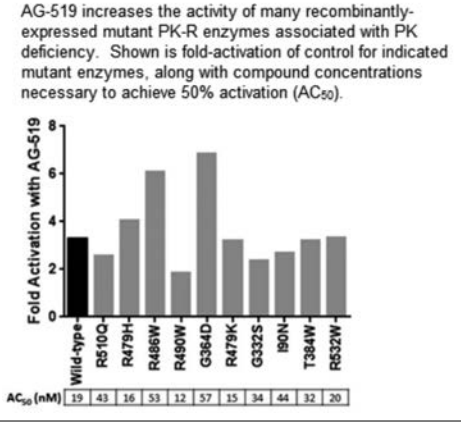

Figure 1.

Summary/Conclusions: These data support the hypothesis that drug intervention with AG-519 may restore glycolytic pathway activity and normalize red cell metabolism *in vivo*. This therapeutic approach may be an effective way to correct the underlying pathology of PK deficiency and, importantly, provide clinical benefit to patients.

P743

REDPLEX: A TARGETED NEXT GENERATION SEQUENCING-BASED DIAGNOSIS FOR PATIENTS WITH HEREDITARY HEMOLYTIC ANEMIAS

R Russo[*], I Andolfo, F Manna, A Gambale, P Pignataro, G De Rosa, A Iolascon
Molecular Medicine and Medical Biotechnologies, University "Federico II", CEINGE - Biotecnologie Avanzate, Naples, Italy

Background: Mutations in more than 30 genes cause hereditary hemolytic anemias (HHA), a highly heterogeneous group of rare anemias characterized by complex and often unexplained genotype-phenotype correlations. In the group of HHA are included: (1) hyporegenerative anemias (HA), as congenital dyserythropoietic anemias (CDA); (2) hemolytic anemias due to red cell membrane defects (HAMD), as hereditary spherocytosis (HS) and hereditary stomatocytosis (HST). Although the workflow to diagnose these conditions is a normal clinical practice, differential diagnosis, classification, and patient stratification among HHA are often very difficult. Indeed, the variety of unspecific and overlapping phenotypes often hampers a correct clinical management of the patients. Beyond achieving a definitive diagnosis, knowing the genetic basis of these patients can be valuable also for guiding treatment.
Next generation sequencing (NGS) refers to non-Sanger-based high-throughput DNA sequencing technologies. This technology plays a major role either in disease gene discovery or in clinical use for establishing a genetic diagnosis. Particularly, the major current application of NGS in diagnostics is through targeted (t)-NGS, in which a selected fraction of genes is sequenced.
Aims: The main aim of our study is the development of a fast, accurate, reliable and cost effective diagnostic tool for HHA based on t-NGS.
Methods: In order to assess the reliability of this diagnostic method we created a t-NGS gene panel, named RedPlex, composed by 34 *loci* causative or candidates of HHA. *In silico* design of RedPlex was performed by Agilent Sure Design web tool. For each *locus*, all predicted exons and 100 flanking nucleotides were always included in the electronic design. Sequence length was set at 150×2 nucleotides, and the predicted target size amounted to 538 regions (239.764 kb). Targeted enrichment was performed on 44 patients by HaloPlex Target Enrichment System (Agilent Technologies). High-throughput sequencing was performed by Illumina NextSeq 500. SureCall software (Agilent Technologies) was used for bioinformatic and computational analyses. All focused variants were confirmed by Sanger sequencing and by the analysis of inheritance pattern.
Results: RedPlex panel showed high sensitivity and specificity. It was able to capture at least 99.4% of 538 exons with high and uniform coverage. Indeed, approximately 97.0% and 90.0% of regions were covered by at least 100 and 200 reads, respectively.
Several non-synonymous variants of unknown significance were identified in the largest genes. However, we were able to obtain a conclusive diagnosis in 32 out 44 patients with ambiguous phenotypes; instead, 12 patients remained undiagnosed. We also identified some patients showing multiple disease-associated variants suggesting complex inheritance.
Summary/Conclusions: NGS studies have identified a greater-than-expected number of genetic variations in the human genome. This suggested that existing clinical monogenic testing systematically can miss very relevant information. Our analyses demonstrated that RedPlex represents a reliable diagnostic tool for HHA patients. Indeed, it resulted to be a robust platform that overcomes for power, costs, speed, sensitivity and specificity the gene-by-gene strategy. Moreover, this approach also allowed the identification of "polygenic" conditions, *i.e.* patients in which the phenotypic variability could be explained by the presence of modifier variants associated to causative mutations.

P744

SOLUBLE FAS AND FAS LEGEND LEVELS IN YOUNG PATIENTS WITH SICKLE CELL DISEASE: ROLE IN NEPHROPATHY AND CARDIOPULMONARY COMPLICATIONS

A Adly[1,*], E ismail[2], N Gamal[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Sickle cell disease (SCD) is characterized by chronic inflammation due to ischemic tissue damage, accentuated during acute complications. Fas and its ligand (FasL) are members of tumor necrosis factor receptor superfamily and a major pathway for induction of apoptosis. Fas/FasL interactions may be related to augmentation of inflammatory response.
Aims: We assessed the levels of sFas and sFasL in 35 children and adolescents with SCD compared with 35 healthy controls in relation to hemolysis, iron overload, sickle vasculopathy including kidney disease.
Methods: SCD patients, in steady state, asymptomatic for heart disease and pulmonary hypertension were studied. All patients were subjected to detailed

medical history and thorough clinical examination with special emphasis on disease duration, history of sickling crisis, acute chest syndrome, stroke, evidence of pulmonary or cardiac disease, spleen status, transfusion hsitory and hydroxyurea/chelation therapy. Serum ferritin, urinary albumin creatinine ratio (UACR), high-sensitivity C-reactive protein (hs-CRP) and soluble Fas/FasL (sFas/FasL) levels were assessed. Screening for pulmonary hypertension and cardiovascular abnormalities was performed by the noninvasive echocardiograpghy to evaluate left ventricular function, pulmonary artery pressure, tricuspid regurgitant jet velocity (TRV). A TRV ≥2.5 m/s was used as a proxy for patients at risk for pulmonary hypertension.
Results: A total of 20% of patients were splenectomized, 31.4% had pulmonary hypertension and 14.3% had heart disease. Nephropathy was found in 54.3% of patients sFas and sFas/sFasL ratio were significantly higher in SCD patients compared with the control group (p<0.001) while sFasL was significantly lower in patients (p=0.022). sFas/sFasL ratio was significantly higher in patients compared with controls and in patients with pulmonary hypertension, nephropathy and those who had history of frequent sickling crisis or serum ferritin ≥2500 (p<0.001). SCD patients treated with hydroxyurea had lower sFas/sFasL ratio than untreated patients. sFas/sFasL ratio was positively correlated to transfusion index, white blood cells, hs-CRP, serum ferritin and UACR. Multiple linear regression analysis showed that WBCs and serum ferritin (p<0.001) were independently related to sFas/sFasL ratio in patients with SCD. The cutoff value of sFas/sFasL at 8.75pg/mL could differentiate SCD patients with and without nephropathy while the cutoff value at 22pg/mL could differentiate SCD patients with and without pulmonary hypertension risk with high sensitivity and specificity.
Summary/Conclusions: sFas/sFasL ratio may be considered as a marker for vascular dysfunction in SCD patients and is related to inflammation, iron overload and albuminuria level. Thus, it may be a reliable method to assess renal impairment in SCD. Our findings could be of pathophysiological importance, because they provide evidence that diminishing inflammation in general, and perhaps the levels of sFas in particular, may have a role to play in altering SCD related-vasculopathy.

P745

ELEVATED PLASMA ASYMMETRIC DIMETHYLARGININE LEVELS IN CHILDREN WITH BETA-THALASSEMIA MAJOR MAY BE AN EARLY MARKER FOR ENDOTHELIAL DYSFUNCTION

O Gursel[1,*], S Tapan[2], E Sertoglu[2], E Taşcılar[3], I Eker[1], T İleri[4], Z Uysal[4], E Kurekci[1]
[1]Department of Pediatric Hematology, [2]Department of Biochemisty, [3]Department of Pediatric Endocrinology, GULHANE MILITARY MEDICAL ACADEMY AND MEDICAL FACULTY, [4]Department of Pediatric Hematology, Ankara University Medical Faculty, Ankara, Turkey

Background: Thalassemia, resulting from defects in the production of alpha- and beta-globin chains of hemoglobin, is the most common form of inherited anemia all over the world, *as well as in Turkey*. Beta-thalassemia major requires regular blood transfusions to maintain an adequate supply of hemoglobin and sustain life, and patients suffer from the long-term consequences of iron overload which may lead to various complications, including damage of parenchymal organs and cardiovascular system. *In vitro* studies have revealed that iron-loading has been linked with endothelial dysfunction due to peroxidative tissue injury resulting from blood transfusions, circulating cholesterol oxidation products, and possibly coronary artery disease. Asymmetric dimethylarginine (ADMA) is an early marker for endothelial dysfunction and also regarded as an independent predictor of future cardiovascular events. In addition, endothelial adhesion molecules [soluble intercellular adhesion molecule-1 (sICAM-1), soluble vascular cell adhesion molecule-1 (sVCAM-1) and P-selectin] are also considered as early endothelial dysfunction markers, and there is scarce data that highlights the significance and role of these molecules in endothelial dysfunction development in pediatric beta-thalassemia major patients.
Aims: Based on all these informations, in the present study we aimed to assess circulating levels of ADMA between patients with beta-thalassemia major and control group and determine its correlation with markers of endothelial adhesion molecules (sICAM-1, sVCAM-1 and P-selectin), and Pentraxin-3 as prognostic factors for vascular risk stratification and subclinical atherosclerosis.
Methods: A total of 31 children with beta-thalassemia major aged between 4-16 year old (study group) and 36 age and gender matched healthy controls were enrolled in the study. Fasting blood samples were obtained from the antecubital vein. The samples for the measurement of sICAM-1, s-VCAM-1, P-selectin, Pentraxin-3 and ADMA were centrifuged for 15 min at 2000 g, aliquoted, and immediately frozen at -80 ºC until analysis. Plasma ADMA was measured along with soluble vascular cell adhesion molecule-1 (sVCAM-1), soluble intercellular adhesion molecule-1 (sICAM-1), P-selectin, and Pentraxin-3. Circulating levels of sICAM-1, s-VCAM-1, P-selectin, Pentraxin-3 and ADMA were determined with commercially available ELISA kits (ADMA were by Immunodiagnostic Systems, Boldon, UK; Pentraxin-3 was by R&D Systems, USA; sICAM-1, s-VCAM-1 and P-selectin were by eBioscience, San Diego, CA, USA).
Results: Age, gender and body mass index were similar in two groups. The beta-thalassemia major patients had significantly higher serum ferritin, sICAM-1, s-VCAM-1 and ADMA levels than controls (p <0.001 for ferritin, s-VCAM-1, ADMA; and p =0.003 for sICAM-1, respectively). There was a significant positive correlation between ADMA and ferritin, VCAM-1 and ICAM-1 levels while a negative correlation was noted between ADMA and BMI, and Hb concentrations (p <0.001 for Hb, ferritin, VCAM-1; p =0.031 for BMI; and p =0.001 for ICAM-1). On the other hand, there was no significant correlation between ADMA and age, WBC count, platelet count, serum P-selectin and Pentraxin-3 measurements (p >0.05).
Summary/Conclusions: In conclusion, as far as we know, this is the first study evaluating ADMA and endothelial adhesion molecules together in children with beta-thalassemia major and this makes the *results of our study more meaningful compared to previous studies.* These findings support the hypothesis that a serious degree of endothelial activation and damage underlie the pathophysiology of beta-thalassemia major and endothelial dysfunction may participate in the progression of common complications encountered in these subjects.

Red blood cells and iron - Clinical 2

P746

A NATION-WIDE POPULATION STUDY OF REFERENCE INTERVAL FOR HEMOGLOBIN LEVEL

J Yang[1], YJ Kim[2,*], TS Park[3], JM Byun[4], J Yoo[5], T Youk[6]
[1]Ongjin Public Health Center, Incheon, [2]School of Medicine, [3]Kyung Hee University, [4]Internal Medicine, Seoul National University Hospital, Seoul, [5]National Health Insurance Service Ilsan Hospital, Goyang, [6]Department of Statistics, Korea University, Seoul, Korea, Republic Of

Background: Attempts to define the 'norm' for hemoglobin level have proposed different reference intervals depending on influential factors such as age, sex, pregnancy, altitude and ethnicity. Changes in life style and public health affect those factors and reference intervals require an update accordingly.
Aims: Reference interval for hemoglobin can be variable and an obstacle for this problem is the absence of large database that enables exclusion of individuals that are not 'normal'. Here we attempt to provide an update of reference interval regarding age and sex groups based on large national database, which so far is the largest used for establishing a reference interval of hemoglobin level.
Methods: The National Health Insurance (NHI) program is a government-operated mandatory health insurance program of Republic of Korea, providing general health screening once every two years. Participation rate of general health screening of NHI is steadily increasing, reaching 74.8% of registered individuals in 2014. Between the period of January 2009 and December 2013, total of 6,759,566 individuals and their hemoglobin value were analyzed after applying the exclusion criteria. The exclusion criteria were in brief, a) diagnosed diseases; respiratory diseases including tuberculosis, hypertension, obesity, anemia, diabetes mellitus, dyslipidemia, hepatitis, nephrotic diseases, b) life style; smoking, alcohol consumption and c) physiologic conditions; pregnancy. Questionnaire used for general health screening is available online (http://minwon.nhis.or.kr/exam/i/file/english_n.pdf). Reference intervals were based on median value and 2.5~97.5 percentile. Data were categorized by sex and age group by 10 years. All statistical analyses in this study were done using SAS v9.4 (SAS Institute Inc., Cary, NC, USA).
Results: Reference intervals for each respective groups are shown in Figure 1. The data included threefold more women than men, as men were much more excluded by smoking and alcohol consumption criteria. The reference interval for whole population using median (2.5~97.5 percentile) was 14.8(12.5~16.8) g/dL in men and 12.8(10.6~14.7) g/dL in women. Men had higher median hemoglobin level of 2g/dL than women at the age group of 40s, which the difference has decreased thereafter. Hemoglobin level decreased along with increasing age, as expected.

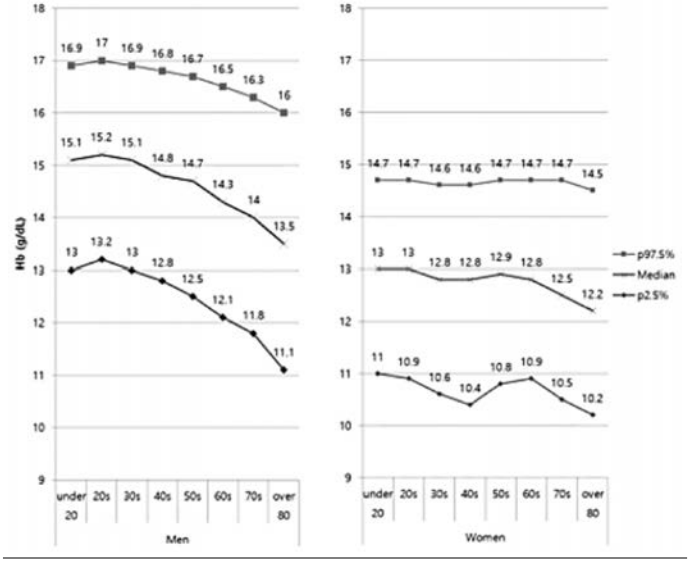

Figure 1.

Summary/Conclusions: Establishing a reference interval requires consideration of many variables other than age, sex, geographic location and ethnicity such as standardization of methods. Laboratory standardization is well established in Republic of Korea and this reference interval of hemoglobin level using large national database is capable of accurately representing this specific population. An updated reference interval will improve diagnostic orientation and decisions for therapy.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA SCREENING PRACTICE FROM UK CENTRES: A REPORT FROM THE UK PNH NETWORK

M Griffin[1,*], C Couzens[2], W Ingram[2], R Karim[2], M Koh[3], M Layton[4], K Lowndes[5], M McMullin[6], P Medd[7], L Mitchell[8], L Morgan[2], S Narayanan[9], I Neilly[10], M Nikolousis[11], J Ros[12], N Sharma[6], A Hill[1]
[1]Hematology, Leeds teaching hospitals, Leeds, [2]Hematology, University Hospital of Wales, Cardiff, [3]Hematology, St Georges Hosptial and Medical School, [4]Hematology, Hammersmith hospitals, London, [5]Hematology, Hampshire Hospitals NHS foundation trust, Winchester, [6]Hematology, Centre for cancer research and cell biology, Belfast, [7]Hematology, Plymouth Hospitals NHS trust, Plymouth, [8]Hematology, NHS Lanarkshire, Lanarkshire, [9]Hematology, University hospital Southampton, Southampton, [10]Hematology, Northumbria healthcare trust, Northumbria, [11]Hematology, Heart of England NSH trust, Birmingham, [12]Hematology, St Georges Hospital and Medical School, London, United Kingdom

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is an acquired clonal stem cell disorder with an associated complement mediated morbidity and mortality. International flow cytometry guidelines recommend PNH screening in 'at risk' patients. These include patients with bone marrow failure syndromes; Intravascular hemolysis; unexplained hemolysis with iron deficiency, oesophageal spasm, thrombocytopenia or granulocytopenia; unusual thrombosis with unexplained cytopenia or hemolysis; or other acquired direct coomb's test negative hemolytic anaemias.
Aims: The aim of this retrospective audit is to determine application of the International flow cytometry guidelines in UK practice.
Methods: The UK PNH network members (hematologists with an interest in PNH) provided anonymised data for analysis. PNH screens analysed from January 2014 to December 2014 were included.
Results: 1579 PNH screens were assessed (53% male; mean age 53 yrs), of which 9.4% were positive. Screening indications included aplastic anaemia (AA) (5.3%) of which 40% were positive, cytopenias (36.7%) of which 11% were positive, thrombosis (28%) of which 2% were positive, haemolysis (5.7%) of which 12% were positive, MDS (0.4%) of which 6% were positive, and other reasons (6.9%) with 6% positive. 257 (16%) screens had no clinical details provided. PNH clone size varied with the majority less than 1% (53%). 22% had a clone size of 1-10%, and 12% had a clone of 10-50%. 18 (12%) had a clone of more than 50%, of these 5 were screened for haemolysis, 7 cytopenias, 4 no clinical details, 1 thrombosis and 1 AA. 377 patients with repeat testing were assessed, 91% of whom had a known PNH clone. The majority had clinical PNH (218), of whom 25% had evolved from preceding AA and 3% from MDS.
Summary/Conclusions: This is the largest audit of PNH screening requests from UK centres. It's reassuring that recommendations are adhered to with very few patients screened inappropriately. 40% of AA patients had a PNH clone in keeping with current evidence. The subgroup analysis highlights the importance of PNH clone monitoring in patients with underlying bone marrow disorders, as they may subsequently develop clinical PNH and require treatment. Ongoing education is essential for the screening and monitoring for this rare but potentially fatal disease.
Disclosure: Alexion UK provided funding to support the UK PNH network meetings.

P748

DIAGNOSTIC VALUES FOR IRON DEFICIENCY ANEMIA IN CHILDREN AND WOMEN USING SERUM HEPCIDIN AND ZINC PROTOPORPHYRIN (ZPP)

G Kanuri*, D Chichula, S Majumdar, J P Rao, A Shet
Hematology Research Unit, St. Johns Research Institute, Bangalore, India

Background: Iron deficiency with or without anemia is a major health problem, affecting more than 2 billion people worldwide. Widely used tests *e.g.* serum ferritin and sTfR are confounded by inflammation and erythropoietic activity respectively. Serum hepcidin and ZPP are potentially useful biomarkers in the diagnosis of iron deficiency (ID) and iron deficiency anemia (IDA). However, diagnostic values for iron deficiency anemia from participants in resource limited settings are not available.
Aims: We determined the optimal cutoff values, sensitivity and specificity of these two biomarkers in children and their mothers in a low middle income setting where both conditions are highly prevalent.
Methods: Healthy rural community dwelling children aged 12-59 months and their mothers from randomly selected villages in a province of South India were prospectively enrolled after obtaining informed consent. Participants were categorized biochemically into healthy, ID and IDA groups based on previously published criteria. Serum hepcidin concentration was quantified by enzyme immunoassay kit (PenninsulaLabs) according to the manufacturer's protocol. Washed red cells were used to measure ZPP in triplicate using a hematofluorometer (AvivBiomedical). Receiver operator characteristics were performed using the sTfR/log Ferritin index as a gold standard and optimized using the Youden index.
Results: The demographic characteristics, hematological and biochemical parameters of the different study groups are shown in Table 1. Mean hemoglo-

bin was significantly lower in IDA compared to healthy or ID subjects (p<0.001). In children, a serum hepcidin cut off value ≤13ng/mL diagnosed IDA with 92% sensitivity and 87% specificity (area under ROC curve (AUC^{ROC}): 0.972 (95%CI,0.939-0.990)) and a cutoff value ≤23ng/mL detected ID with 71% sensitivity and 80% specificity (AUC^{ROC}:0.768 (95% CI,0.703-0.824)). In women, serum hepcidin cutoff value ≤4.5ng/mL diagnosed IDA with 97% sensitivity and 92% specificity (AUC^{ROC}:0.975 (95% CI, 0.956-0.994)) and cutoff value of ≤7.4ng/mL had 90% sensitivity and 69% specificity (AUC^{ROC}: 0.792(95% CI,0.694-0.890)) to diagnose ID. Similarly, ZPP in children at a cutoff value of ≥83 µmole/mole heme diagnosed IDA with 94% sensitivity and 84% specificity (AUC^{ROC}: 0.941 (95%CI,0.90-0.97)). In women, ZPP at a cutoff value ≥123 µmole/mole heme diagnosed IDA with 98% sensitivity and 69% specificity (AUC^{ROC}: 0.894 (95% CI,0.848-0.939)). In both women and children, the AUC^{ROC} for ZPP to diagnose ID was less than 0.5.

Table1. Hematological and biochemical parameters.*Median (Interquartile range); [a]p<0.05 compared with respective healthy subjects, [b]p<0.05 compared with respective ID subjects.

	Healthy		Iron deficiency (ID)		Iron deficiency anemia (IDA)	
	Women(n=90)	Children(n=101)	Women(n=100)	Children(n=109)	Women(n=100)	Children(n=104)
Age±SD	26±3.7	3.7±0.9	26±3.9	3.4±0.9	25±3.8	2.4±0.8[a,b]
Gender M:F	na	49:52	na	40:69	na	56:48

Ferritin*(ng/mL)	39(33,48)	35(32,45)	13*(7,18)	13*(10,18)	3.7*[a] (2.9,5.3)	3.7*[a](2.6,5.1)
Biomarkers						
Hepcidin*(ng/mL)	17.7(9,38)	42.6(25, 62)	4.9*(1.5,11)	13.4*[a](6.2,28)	0.6*[a,b] (0.2,1.3)	1.2*[a,b](0.5,3.6)
ZPP*(µmol/molheme)	66(53,83)	49(39,60)	65(50,85)	48*[a](40,59)	155*[a,b](101,243)	151*[a,b](104,263)

Summary/Conclusions: Cutoff values for diagnostic markers hepcdin and ZPP to diagnose IDA in two high risk groups provide guidance for practitioners in limited resource settings. Serum hepcidin has higher sensitivity and specificity to diagnose IDA than ID. ZPP may diagnose IDA with higher sensitivity and specificity, it is a technically simple, rapid, and cheap point of care test to detect IDA in both practice and community settings.

P749

UTILITY OF RED CELL INDICES TO DIAGNOSE IRON DEFICIENCY IN RURAL INDIAN CHILDREN

S Majumdar*, G Kanuri, A Shet
Hematology Research Unit, St Johns Research Institute, Bangalore, India

Background: The prevalence of anemia in Indian children aged 6-59 months is high (56%) with 62% cases attributable to iron deficiency. However, this condition is underdiagnosed in India, in part due to unavailability of diagnostic tests for iron deficiency anemia (IDA) in rural settings. Red cell distribution width (RDW) appears to be sensitive in the diagnosis of iron deficiency and values >14.3% was found to predict iron deficiency in anemic toddlers. RDW measurements are provided routinely while measuring complete blood counts and are operator independent. Thus, we investigated the potential of RDW as a point of care test to diagnose iron deficiency anemia.
Aims: To determine utility and establish cutoff values for RDW to diagnose IDA in rural Indian children
Methods: Healthy community dwelling children aged 1-5 years living in randomly selected villages in a South Indian province provided a venous blood sample. A complete blood count inclusive of RDW was performed using a field based automated cell counter. Serum ferritin (SF) and Ferritin Index (FI) were measured at the central laboratory. Subjects were classified into healthy (HL); iron deficient (ID) and iron deficiency anemia (IDA) as shown in Table 1.The coefficient of variation in red cell size (RDW-CV) was expressed as a percentage. Receiver's operator characteristics (ROC) were performed to examine the sensitivity and specificity of RDW CV when compared with a gold standard SF to diagnose ID or IDA and optimized using Youden index.
Results: Majority of the children in this study had ID (66%) or IDA (27%) with only a small portion of the population that demonstrating normal ferritin values. Baseline demographic, hematological and biochemical parameters of children enrolled in the study are tabulated (Table 1).

Table 1: Demographic, hematological and biochemical characteristics in HL,ID and IDA

Baseline characteristicsMarker	Age*(y)	Hb* (g/dl)	MCV*(fl)	SF ** (ng/ml)	RDW*
HL (n=44) (Hb >11g/dl andSF >30ng/ml)	3.4±0.85	11.8±0.58	76.9±3.2	35.2 (32-41)	13.4%±1.1
ID (n=466) (Hb >11g/dl and SF <30ng/ml)	3.1±0.90	11.9±0.69	75.3±4.3	11.8 (7.8-16.6)	13.9%±1.4
IDA (n=192) (Hb <11g/dl and SF <12ng/ml or FI >1.03)	2.4±0.90	9.8±0.82	66.6±6.0	4.3 (3.1-6.9)	16.7%±2.1

**Mean±SD; **Median+IQR.*

Mean RDW CV was found to be significantly higher in IDA (16.7%) compared to HL (13.4%) and ID (13.9%) (p <0.001). IDA was diagnosed at cutoff of RDW >14.6% with 90% sensitivity and 84.9% specificity (AUC^{ROC}: 0.94, 95%CI 0.89-0.97) (Figure 1). However, RDW >13.5% detected iron deficiency with only low sensitivity (65.9%) and specificity (55.9%) (AUC^{ROC} :0.63, 95%CI 0.52-0.71). Those subjects with an RDW >14.6% were more likely to have iron deficiency (OR 6.9, 95%CI 2.4-19.6, p value 0.003).

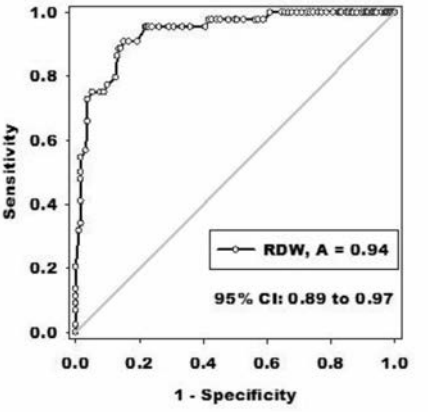

Figure 1. Receiver operator characteristic curve to predict ID anaemic children.

Summary/Conclusions: In a rural population of children, with a very high prevalence of ID and IDA, we found that an RDW CV value >14.6% diagnosed IDA with 90% sensitivity and 85% specificity. Use of this RDW cut off value could guide primary health care decisions regarding iron supplementation in rural children with ID/IDA.

P750

GROWTH AND DEVELOPMENT DURING A 5-YEAR OBSERVATIONAL STUDY OF IRON CHELATION THERAPY WITH DEFERASIROX IN PEDIATRIC PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS (ENTRUST)

E Vichinsky[1,*], A El Beshlawy[2], A Alzoebie[3], A Kamdem[4], S Koussa[5], T Chotsampancharoen[6], A Bruederle[7], G Gilotti[8], J Han[8], M Elalfy[9]
[1]Children's Hospital & Research Center, Oakland, United States, [2]Cairo University, Cairo, Egypt, [3]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, [4]Centre Hospitalier Intercommunal, Créteil, France, [5]Chronic Care Center, Hazmieh, Lebanon, [6]Songklanagarind Hospital, Songkhla, Thailand, [7]Novartis Pharma AG, Basel, Switzerland, [8]Novartis Pharmaceuticals, East Hanover, United States, [9]Ain Shams University, Cairo, Egypt

Background: Regular transfusion and iron chelation therapy (ICT) are often indicated for pediatric patients (pts) with chronic anemias such as β thalassemia major (βTM), sickle cell disease (SCD) and Diamond–Blackfan anemia (DBA). Delayed growth and development can occur as a result of iron overload, indicating optimal management of iron loading is required. Growth retardation has also been reported in young patients (<3 yrs) receiving intensive ICT with DFO (de Virgillis S *et al. J Pediatr* 1998) and thus regular monitoring of growth is essential. In a 5 yr clinical trial of deferasirox in βTM pediatric patients (2–<16 yrs), growth and development progressed normally (Cappellini MD *et al. Blood* 2011). Here we report growth and development during deferasirox treatment in real-life clinical practice in young pts with transfusional hemosiderosis from the 5-yr multinational, observational ENTRUST study.
Aims: To assess growth and development during long-term deferasirox treatment in an unselected population of transfusion-dependent children with chronic iron overload.
Methods: Over 5 yrs, pts with transfusional iron overload aged 2-<6 yrs at enrollment received deferasirox in accordance with local (country-specific) prescribing information. An initial deferasirox dose of 10-30 mg/kg body weight was recommended and adjusted based on serum ferritin (SF), therapeutic goals, tolerability and changes in pt weight. Parents/guardians provided written, informed consent. Pt height and weight were recorded at baseline and end of each year and mean annual growth velocity was calculated for pts on treatment; data were analyzed by geographical region (Europe, Americas, Middle East/Africa, Asia).
Results: In total, 267 pts (mean age at study entry 3.2 yrs; 52.1% male) with βTM (n=176, 65.9%), SCD (n=52, 19.5%), DBA (n=12, 4.5%) and other anemias (n=27, 10.1%) were enrolled and received ≥1 deferasirox dose. Most pts (n=172; 64.4%) received an average blood intake >7 mL/kg/month. Median SF level decreased from 1702 ng/mL at baseline to 1127 ng/mL after 5 yrs. Overall, mean deferasirox dose increased from a planned starting dose of 26.2±5.9 mg/kg/day to a final actual dose of 28.6±7.7 mg/kg/day. Actual average dose was generally aligned with weight; however, initially deferasirox doses received were suboptimal to manage iron intake and dose adjustments based on weight gain were delayed. Mean growth velocity was 4.86–5.95 cm/yr in male and 5.44–6.08 cm/yr in female pts (Table 1), which is in line with public growth curves for children aged 2-≤11 yrs; as observed across all geographical

regions. Mean weight increased steadily over time (Table 1) in line with mean growth velocity. Median serum creatinine increased steadily over time (28.0 µmol/L at baseline to 39.4 µmol/L) in line with median height, and by association with increasing muscle mass. One patient with βTM experienced an adverse event of below normal height that was not suspected to be drug-related.

Table 1. Growth velocity, height, and weight during treatment with deferasirox in male and female patients aged 2-<6 years at baseline.

	Mean (SD) Weight (kg)	Mean (SD) Height (cm)*	Mean (SD) growth velocity (cm/year)
Male patients (n=137)			
Baseline	15.82 (2.94)	98.76 (9.53)	n/a
Year 1	17.39 (3.07)	104.35 (9.23)	5.95 (3.70)
Year 2	19.20 (3.36)	109.44 (8.83)	5.37 (2.36)
Year 3	20.93 (3.72)	114.58 (8.50)	5.27 (2.28)
Year 4	23.02 (4.47)	119.37 (8.29)	4.88 (3.95)
Year 5	25.22 (4.71)	124.43 (7.76)	4.86 (2.47)
Female patients (n=124)			
Baseline	14.87 (2.98)	97.38 (9.04)	n/a
Year 1	16.53 (3.16)	101.85 (8.85)	6.08 (3.74)
Year 2	17.90 (3.25)	107.22 (8.20)	5.91 (6.77)
Year 3	20.10 (3.91)	112.62 (8.37)	5.67 (3.19)
Year 4	21.92 (4.93)	117.74 (9.20)	5.57 (3.16)
Year 5	24.07 (5.32)	122.63 (9.57)	5.44 (4.80)

*Negative height increments were considered 'no growth' by assigning a nominal value of 0.01. Negative height increments were attributed to different measurement methods as standard guidance was not given. n/a, not available; SD, standard deviation

Summary/Conclusions: In accordance with previous deferasirox trials, this long-term, 'real-life' safety study in young pediatric pts with transfusional iron overload showed expected growth velocities and weight gain for a prepubertal population across all geographical regions. Careful monitoring of pts and appropriate weight-based adjustment of deferasirox dose ensures effective management of long-term ICT and control of transfusional iron loading.

SEARCH AND YOU SHALL FIND – VARIANT HEMOCHROMATOSIS GENE MUTATIONS AS A CAUSE OF HYPERFERRITINEMIA IN BLOOD DONORS

AH Laursen[1,*], K Magnussen[2], L Friis-Hansen[3], JL Marott[4], T van Overeem Hansen[3], OW Bjerrum[1]
[1]Department of Haematology, [2]Centre for Donor Hemoglobin and Iron, [3]Department of Genomic Medicine, Rigshospitalet, [4]The Copenhagen City Heart Study, Frederiksberg Hospital, Copenhagen, Denmark

Background: Blood donors in the capital region of Denmark undergo frequent ferritin measurements to prevent blood donation-related depletion of iron storages. Somewhat surprisingly, some patients actually demonstrate hyperferritinemia, despite regular blood donations. Hyperferritinemia is often the result of inflammatory conditions or liver diseases, but hereditary hemochromatosis (HH) is also a frequent cause of elevated serum ferritin concentrations. HH is in most cases an autosomal recessive genetic disorder characterized by mutations in different genes related to iron metabolism. HH is associated with an increase in intestinal iron absorption and excessive iron deposition in variant tissues (*e.g.* liver, heart and endocrine glands) with risk of concomitant organ dysfunction. The primary HH gene defect is a missense mutation (C282Y) in the HFE gene and C282Y homozygosity is by far the most frequent genotype in HH. However, several different HFE genotypes can also lead to HH. Furthermore, non-HFE phenotypic HH with iron overload can result from other genetic defects in proteins related to iron metabolism, including mutations affecting hepcidin (HAMP), ferroportin 1 (SLC40A1), hemojuvelin (HFE2) and transferrin receptor 2 (TFR2) gene expression.
Aims: The purpose of our study was to explore the relevance of extensive HH mutational analyses in a selected population of healthy Danish blood donors with hyperferritinemia.
Methods: 49 consecutive donors (f=6, m=43) were included prospectively from the Capital Regional Blood Center. Inclusion criteria were either a single ferritin value above 1000µg/L or repeated hyperferritinemia with at least one value above 500µg/L. Included donors were evaluated with a full physical examination, a medical history and extensive biochemical investigations, including a complete blood count, parameters of iron metabolism and relevant organ function tests. Genetic testing was carried out by next generation sequencing using a hemochromatosis gene panel including mutational status of the HFE gene, the HFE2 gene, the HAMP gene, the SLC40A1 gene and the TFR2 gene.
Results: 40 of 49 donors were mutation positive, combining for a total of 67 mutations. 18 patients had 1 mutation, 18 patients had 2 mutations, 3 patients had 3 mutations and 1 patient had 4 mutations. Interestingly, there were only 11 patients with C282Y homozygosity. Thus, of the 40 mutation positive donors, 29 had phenotypic evidence of HH, albeit with a more atypical HH genotype. An overview of the mutational frequencies is shown in Figure 1.
Summary/Conclusions: Our view on the genetic background of HH is constantly expanding due to the documentation of several different genotypes resulting in phenotypic HH. Screening of blood donors with hyperferritinemia could be a straightforward way of identifying individuals with a high probability of HH since iron overload in healthy blood donors adherent to the blood donor program could be suggestive of significant malfunction of iron metabolism. Although standard genetic testing for C282Y mutational status is available at a relatively low-cost, it obvioulsy does not account for the genotypic variations in HH pathogenesis. Thus, a more complete genetic workup should be considered in order to improve HH diagnostic testing in individuals with unexplained hyperferritinemia.

A PHASE 1, SINGLE AND MULTIPLE ASCENDING DOSE STUDY OF SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF AG-519, AN ALLOSTERIC ACTIVATOR OF PYRUVATE KINASE-R IN HEALTHY SUBJECTS

A Barbier[1,*], J Cutie[2], G Connor[1], E Merica[1], C Kung[1], K Le[1], H Yang[1], PA Kosinski[1], L Silverman[1], ZJ Yuan[1], S Agresta[1], M Cohen[3]
[1]Agios Pharmaceuticals Inc., Cambridge, [2]Viola Medica, Lexington, [3]MBC Pharma Solutions, Newtown, United States

Background: Pyruvate kinase (PK) deficiency is an inborn error of metabolism affecting children and adults that results in lifelong hemolytic anemia, and is associated with serious long-term comorbidities such as poor growth and development in children and chronic iron overload in adults. PK deficiency is caused by a functional deficiency of the red blood cell isoform of PK (PK-R). As a result of this defect in glycolysis, levels of 2,3-diphosphoglycerate (2,3-DPG) in the blood are elevated and adenosine triphosphate (ATP) levels are low. AG-348, an orally available allosteric activator of PK-R currently being tested in a phase 2 clinical trial in adult patients with PK deficiency (NCT02476916), has been shown to increase ATP and decrease the levels of 2,3-DPG in healthy volunteers. A drug discovery effort aimed at eliminating the aromatase inhibitory activity observed with AG-348 resulted in the identification of AG-519.
Aims: AG-519 is currently in a randomized, double-blind, phase 1 study in healthy volunteers (NCT02630927), with the objective of identifying a safe and pharmacodynamically active dose and schedule to be used in subsequent clinical studies in subjects with PK deficiency. Here we report the single ascending dose phase of this study.
Methods: Healthy men and women (non-childbearing potential) aged 18–60 years and providing informed consent are eligible. Four dose levels (from 50 mg to up to 1250 mg) will be explored sequentially, starting with the lowest dose. At each dose level, 8 subjects will be enrolled and randomized to receive a single oral dose of AG-519 (n=6) or placebo (n=2), with an option to enroll 2 additional dose cohorts (n=8 each) to assess alternative single dose levels. Safety assessments include adverse events (AEs), vital signs, electrocardiogram and clinical laboratory parameters. Serial blood samples will be drawn to measure plasma AG-519 concentrations and whole blood 2,3-DPG and ATP concentrations for pharmacokinetic and pharmacodynamic assessments.
Results: Eight subjects have been enrolled at 50 mg and a further 8 subjects enrolled at 250 mg to date. Blinded safety reviews indicated no safety concerns in healthy volunteers receiving a single dose of AG-519 given as 50 mg or 250 mg, or placebo. Plasma AG-519 exposure was dose-dependent, with low to moderate variability in the pharmacokinetic parameters of AG-519. Investigation of the pharmacodynamic effects of AG-519 after a single dose indicated that there was a substantial dose-dependent decrease in blood 2,3-DPG concentration (Figure 1). There was no effect on blood ATP concentration, indicating that ATP change requires more than one dose, as observed in the single ascending dose study for AG-348. Based on these encouraging results, single dose escalation is ongoing, and the multiple ascending dose component has been initiated, with dose escalation proceeding in order to determine maximal tolerated dose and/or optimally effective dose and effects on sex hormones. Further data from the single ascending dose and multiple ascending dose cohorts will be presented.

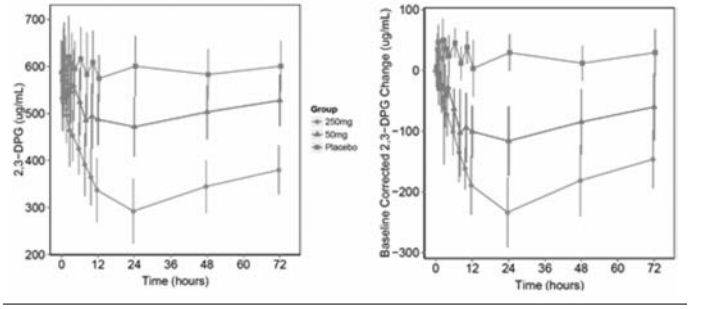

Figure 1. Actual and change from baseline concentration-time profiles of 2,3-DPG in blood following a single dose of AG-519 (n=6 for 50 mg and 250 mg, n=4 for placebo.

Summary/Conclusions: AG-519 is well tolerated, with exposure-dependent decreases in 2,3-DPG concentrations when given as a single daily dose in healthy subjects. Fourteen day dosing results from this trial will further inform the potential for AG-519 as a second potential molecule for the treatment of PK deficiency.

Non-malignant hematopoietic disorders

ANALYSIS OF MOLECULAR MECHANISMS OF DOMINANT-INTERFERING FAS MUTATIONS

D Schäfer[1,*], S Nabhani[1], C Schipp[1], L Loizou[2], PT Oommen[1], HJ Laws[1], B Fleckenstein[3], A Borkhardt[1], P Stepensky[4], U Fischer[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, University Clinic of the Heinrich Heine University, Düsseldorf, Germany, [2]Archbishop Makarios III Hospital, Nicosia, Cyprus, [3]Department of Clinical and Molecular Virology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, [4]Department of Pediatric Hematology-Oncology, Hadassah Hebrew University Medical Center, Jerusalem, Israel

Background: The autoimmune lymphoproliferative syndrome (ALPS) is clinically characterized by lymphadenopathy, hepatosplenomegaly, autoimmunity, hypergammaglobulinemia, and an increased number of $CD3^+TCR\alpha\beta^+CD4^-CD8^-$ double-negative T (DNT) cells. Defects in the FAS signaling pathway lead to impairment of lymphocyte apoptosis and hence to accumulation of activated and autoreactive lymphocytes. In approximately 70% of ALPS cases, mutations in the trimeric FAS receptor have been identified (classified as ALPS-FAS). Most ALPS patients harbor heterozygous dominant interfering mutations with in part unclear mechanisms.
Aims: To better understand the pathogenesis of ALPS-FAS and the molecular mechanisms of dominant-interfering FAS mutations we tried to identify and to functionally analyze novel FAS mutations in a cohort of 35 patients with an ALPS-like clinical phenotype.
Methods: DNA was isolated from blood of 35 patients with an ALPS-like clinical phenotype using standard methods and *FAS* was subjected to Sanger sequencing and compared to the annotated wildtype sequence. Activated and expanded T cells were stimulated with recombinant FAS ligand, staurosporine or were left untreated and apoptosis was measured by Annexin V-FITC/PI staining via flow cytometry. Immunophenotyping was carried out by flow cytometry. Immortalized T cell lines were generated using *Herpes virus saimirii*.
Results: We identified six patients with heterozygous *FAS* mutations. Five mutations were novel (p.R102C, p.R250G, p.NVQ266-268KQT, p.W281L, p.Q283K), one was a known splice site mutation frequently found in ALPS patients (p.E218MfsX*4). One mutation affected the extracellular domain of the receptor (p.R102C), the others occurred in the death domain. All patients with *FAS* mutations fulfilled the two required ALPS diagnostic criteria: 1) chronic (>6 months), nonmalignant, noninfectious lymphadenopathy or splenomegaly or both and 2) elevated DNT cells (≥1.5% of total lymphocytes). Secondary diagnostic criteria were also fulfilled: all patients had a typical ALPS immunophenotype and impaired FAS signaling led to resistance of primary patient T cells to FAS ligand-mediated apoptosis. All six patients can be classified as ALPS-FAS cases.
Summary/Conclusions: With heterozygous *FAS* mutations, statistically one in eight FAS trimers is made of wildtype proteins only. This is a mechanism by which the FAS signaling in ALPS patients is impaired. Among the identified *FAS* mutations was a known splice site mutation leading to skipping of exon 8, frameshift and premature termination in exon 9. This mutation abrogates recruitment of the adapter molecule FADD to the receptor. The R250G mutation is novel, but other amino acid exchanges (Q,P,L or termination) have been described at this site. By analogy, p.R250G should reduce binding of FADD. Reported structural analyses indicate that p.Q283K also dominantly interferes with FADD recruitment. Two further mutations affected the death domain and may interfere with binding of proteins via death domain interaction (p.W281L and p.NVQ266-268KQT). The latter mutation resulted from six consecutive missense mutations leading to the exchange of three amino acids. To our knowledge, six consecutive missense mutations have not been described for ALPS patients or in general. One patient harbored a mutation in the extracellular domain of the receptor (p.R102C). This may lead to a wrong formation of a cystin-bridge. Further analysis of *FAS* mutations regarding their structure and functional impact are performed and will be reported.

Background: Evans syndrome (ES) is a rare autoimmune disorder in children with generally unknown aetiology at onset. In France, a collaborative immunopediatric network recently presented comprehensive data on a large series of 156 non selected childhood ES (OBS'CEREVANCE cohort): 70% of the cases were suspected to be secondary to potential immune defects.
Aims: This prospective study reports the genetically identified primitive immune deficiencies (PID) in those 156 non selected children with ES.
Methods: Complete data from birth to last follow-upare registered in real-time. Relevant immune events are defined, leading to the subgroup of suspected secondary ES: lymphoproliferation, systemic or organ-specific auto-immunity, hypogammaglobulinemia, non microbial pulmonary, digestive or neurological diseases. Etiological investigations at the initial diagnosis were consistent with national guidelines and repeated during the follow-up. Complete immunophenotyping was performed in laboratories of the national CEREDIH network. All the children underwent screening for autoimmune lymphoproliferative syndrome (ALPS). Functional and genetic studies (Sanger sequencing or NGS) were mainly addressed to the French CEDI reference laboratory, Necker, Paris and to the INSERM unit 1163, Institut IMAGINE, Paris.
Results: In January 2016, 156 children from 26 centres diagnosed between 1981 and 2014 with ES were analysed. The median age at initial cytopenia was 5.4 (0.2-17.2) years old. The median follow-up from ES diagnosis was 6.5 years (0.1-28.8). 14 children had aetiologies that might explain the autoimmune cytopenia (13 pediatric systemic lupus erythematosus (pSLE), and one 22q11.4 deletion). Lymphoproliferation at presentation led to the exploration of apoptosis pathways in 55 patients and to ALPS biomarkers in most patients. Six patients (11% of the tested patients) had an apoptosis defect, related to a germ line FAS mutation (ALPS-FAS) in 5 cases (9%) and to a somatic KRAS mutation in 1 case. A genetic search (Sanger sequencing or NGS) has been performed on 43 patients with clinical relevant criteria. A monogenic defect was found after the ES diagnosis in 8 patients: 2 STAT3 gain of function mutations, 4 CTLA4 deficiencies, 2 LRBA deficiencies. In the 35 other patients, genetics studies are ongoing. ES was thus secondary to pSLE in 13 patients (8.3%) or to an identified PID in 15 patients (9.6%). In 52% of the patients in the present cohort, and even in apparently primary cases (chronic isolated bi-cytopenia), ES could be related to an as yet unidentified genetic defect.
Summary/Conclusions: At the present time, in this cohort, a PID could be identified in 10% of ES patients. This proportion will certainly grow up in a near future following this genetic strategy based on well characterized clinical and immunological features. More specific therapies (mTOR inhibitors in ALPS patients, or CTLA4-targeted therapies in CTLA4 and LRBA deficient patients) can already be proposed. The current challenges are therefore to rapidly complete this genetic approach and to further define new candidate genes, to identify additional targeted therapies.

P755

MRI SKELETAL MANIFESTATIONS IN GAUCHER DISEASE: UTILITY OF SPANISH-MRI (S-MRI) SCORE AT DIAGNOSIS AND FOLLOW-UP

M Andrade-Campos[1,*], E Valero-Tena[2], P Irun[1], P Alfonso[1], P Giraldo[3], M Roca-Espiau [4]
[1]Translational Research Unit, IIS-Aragon. CIBERER., [2]Rheumatology, HCU-LB., Translational Research Unit, IIS-Aragon, [3]Translational Research Unit, IIS-Aragon. CIBERER. FEETEG., [4]Dra. Roca Image Diagnostic Center, International Skeletal Society, Zaragoza, Spain

Background: Gaucher disease (GD), the most prevalent lysosomal storage disorder is characterized by multisystem involvement, secondary to the accumulation of glucosyil-ceramide in the reticule-endothelial system. Bone disease, is on of the most frequent manifestations, it's caused by several factors: derived cell accumulation, vascular events and cytokine release – chronic inflammatory state. MRI has demonstrated to be the gold standard for assesses bone involvement, including bone infiltration, bone crisis, infarcts and avascular necrosis; others like vertebral collapses secondary to infiltration-osteopenia and osteoporosis are also common. The Spanish-MRI score (S-MRI), described by Roca *et al.* in 2006 is a semi quantitative tool combining the assessment of the bone marrow burden (infiltration), (BMB) in vertebra, pelvis and femurs (0-12 points), with the presence of bone vascular events (4 points for every lesion). Despite the value of S-MRI to assess the initial involvement of GD patients,

their value during follow up is also remarkable. The MRI was incorporated in our unit since 1993 for routinely evaluation.
Aims: To analyses our experience with MRI bone-assessment in our unit, especially focus on the role of S-MRI at diagnosis, follow-up and identification of bone lesions.
Methods: All patients included in the Spanish Registry of Gaucher disease had signed an inform consent for the management of the information relative to the disease. A total of 131 patients have been evaluated by MRI in the radiodiagnostic center of the unit, following the same protocol and by the same radiologist specialized in muscle-skeletal MRI, summarizing ~340 MRI studies.
Results: From 131 patients, in 64 (49.6%) was part of the initial assessment previous to start any therapy, 63(48.1%) were under enzymatic replacement therapy (ERT) and 4 under substrate reduction therapy (SRT). Mean age: 37.5 y (13-74), M/F: 70/61, type 1 GD: 124, type 3 GD: 7. The genotype N370S/L444P was the most frequent (37.1%). At first MRI 104 (79.4%) present at least one lesion related with GD, mean S-MRI: 11.6 (2-28) points, mean BMB 7.1 (0-12) points, vascular complications was presents in 67 (64.4%) patients and 44 (33.8%) presents lesions not related with GD. During follow-up 62 (47.3%) patients were evaluated sequentially. A reduction in the BMB scored by S-MRI was observed after 5 years of therapy (Figure 1). 14 patients on therapy (12 ERT and 2 SRT) and one without therapy present a vascular event, mean time on therapy (8.4 y; 1.5-16). Of them, three cases registered a bone crisis in small feet bones (two in calcaneus, scaphoids); two cases developed multiple foci lesions in lower limbs, mainly in tibia after severe infections. Into the not previously GD-related lesions we want to highlight the presence of hemangiomas in vertebra in 11 (8.4%), discopathies in 27 (20.6%) patients, two cases with neuronopathic-like arthropathy without manifestations of peripheral neuropathy but with severe bone involvement and 3 patients with bone alterations that lead a neoplasm diagnosis.

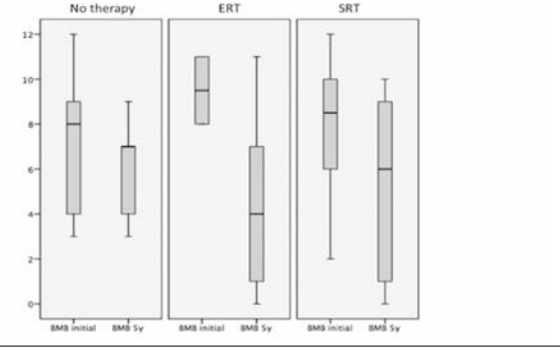

Figure 1. Evolution of BMB after 5 years on MRI follow-up (62 patients).

Summary/Conclusions: The bone disease is the most important issue in type 1 Gaucher disease patients, the most debilitating alterations have been identified since the description of the disease, despite the bone related MRI lesions, there were many findings registered. It's difficult to say if GD predispose to others manifestations like here described. In our experience, MRI assessment permits to optimize the follow-up of the patients on therapy and identified early complications.

P756

SEVUPARIN DEMONSTRATES BINDING TO KEY ADHESION RECEPTORS INVOLVED IN PATHOGENESIS OF SICKLE CELL DISEASE

M Lindgren[1,*], R Brock[2]
[1]SCD, Dilaforette AB, Stockholm, Sweden, [2]Dept. of Biochemistry, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Sevuparin is a novel drug candidate with potential as therapeutic agent for patients with sickle cell disease (SCD). Sevuparin has an anti-adhesive mechanism of action and is currently studied in a clinical phase II study in SCD patients hospitalized for acute painful vaso-occlusive crisis (VOC). Sevuparin's anti-adhesive effects have previously been demonstrated in both *in vitro* and *in vivo* models. SCD is the most common haemoglobinopathy, affecting millions of people worldwide. A single point mutation in the β-globin gene results in synthesis of abnormal sickle haemoglobin (HbS), which polymerizes and causes sickling of red blood cell (RBC) under hypoxic conditions. RBCs containing predominantly HbS (SS-RBCs) also demonstrate an adhesive phenotype, where degree of adhesiveness correlates with frequency of vaso-occlusive events in SCD patients. The pathogenesis of VOC involves decreased blood flow caused by microvascular obstructions from the adhesion between the different blood cells and the vessel endothelium as well as endothelial cell activation. The abnormal adhesion has been studied and several key adhesion proteins identified; Selectins are involved in the initial attachment of cells to the vessel wall. More firm binding is exerted via the integrins, such as thrombospondin (TSP), von Willebrand Factor (vWf) and fibronectin (FN). Among the selectins, P-selectin is the most extensively studied adhesion receptor in SCD, contributing to SS-RBC adhesion and vaso-occlusion both *in vitro* and *in vivo*. Blocking P-selectin has demonstrated improvement in blood flow. However, both E-selectin and L-selectin have been indicated to be involved as well. E-selectin is upregulated during inflammatory processes and participates in adhesion between white blood cells. L-selectin contributes to lymphocyte and neutrophil trafficking and is cleaved from leukocytes during cell activation. Several other, non-membrane bound proteins, such as FN, vWF and TSP, have been shown in pre-clinical model systems to contribute by serving as anchoring or bridging proteins between the blood cells and the activated endothelium in SCD.
Aims: To determine the binding characteristics of sevuparin with key adhesion proteins known to be involved in SCD vaso-occlusion and thereby provide evidence of the multiple anti-adhesive properties at a molecular level for this new investigational treatment.
Methods: The binding characteristics were determined by Fluorescence Correlation Spectroscopy (FCS). Pharmacokinetic studies were performed in mice.
Results: Dissociation constants were determined by FCS, using a competitive titration approach. Kd for the key adhesion proteins was determined to 0.49±0.38μM for P-selectin, 4.48 μM for E-selectin, 0.45±0.43μM for L-selectin, 2.25±0.34μM for Fibronectin, 0.48±0.34μM for von Willebrand Factor and 0.42±0.18μM for Thrombospondin. To understand which of the interactions would be relevant in the clinical setting, a pharmacokinetic study was performed in mice. From this, the target plasma concentration of 2.5 μM was calculated. Applying the target plasma concentration to the Kd values reported above, sevuparin would bind to the adhesion proteins P-selectin, L-selectin, vWF and TSP while the interaction with FN and E-selectin would be limited. Figure 1. Illustration of possible multimodal mechanism of sevuparin action. The Figure 1 demonstrates the potential interactions between sickle blood cells and the blood vessel wall endothelium.

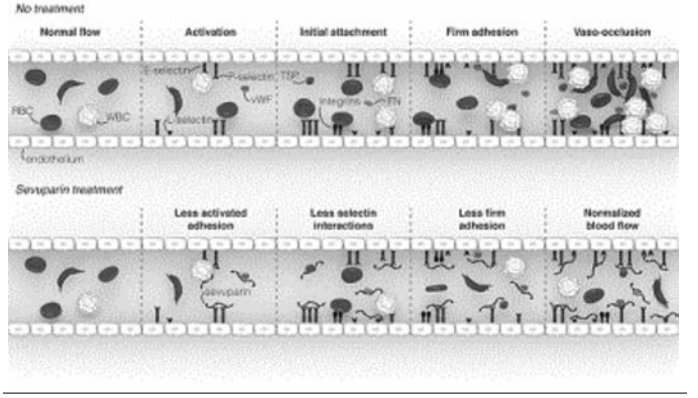

Figure 1.

Summary/Conclusions: Binding experiments with isolated adhesion receptors suggest that multiple interactions contribute to the anti-adhesive effect demonstrated *in vitro* and *in vivo* with sevuparin. Sevuparin shows significant binding to P-selectin, L-selectin, vWF and TSP, but a weaker binding to FN and E-selectin. An illustration of the potential multimodal mechanism of sevuparin action can be found in Figure 1.

P757

GLUTATHIONE S TRANSFERASE GENE POLYMORPHISMS AND THE RISK OF CNS COMPLICATIONS OF SICKLE CELL DISEASE IN EGYPTIAN PATIENTS

H Ellithy[1,*], S Yousry[2], G Shaheen[2]
[1]Internal Medicine- Hematology Unit, [2]Clinical Pathology Departement, Kasr Al-Ainy School of Medicine- Cairo University, Cairo, Egypt

Background: Sickle cell disease (SCD) is characterized by multisystem complications with marked variability in disease severity between individuals. Clinical manifestations of SCD are mainly resulted from sickling of Hb S, which is augmented by oxidative stress. The glutathione system plays an important role in scavenging the products of intracellular oxidation, so protects Hb S from oxidation, minimizing manifestations of SCD. SCD patients with genetically defective glutathione system due to glutathione S transferases (GSTs) gene polymorphisms, are expected to develop sever forms of SCD.
Aims: Exploring the possible association of the GST gene polymorphisms (*GSTM1*, *GSTT1* and *GSTP1)* and the severity of manifestations of SCD in Egyptian patients, as the GST gene polymorphisms may be considered as a critical genetic modifier in SCD patients.
Methods: We studied the frequency of the GSTs (GSTM1, GSTT1 and GSTP1) genes polymorphisms in 100 Egyptian adult SCD patients and 80 age-and sex-matched controls, GSTM1 and GSTT1 gene polymorphisms were examined by multiplex polymerase chain reaction (PCR) with using a housekeeping B globin gene as internal control. A polymerase chain reaction-restriction fragment length polymorphism assay [PCR-RFLP] was used to detect GSTP1 polymorphism. We studied the association between the GSTs gene polymorphisms in

the SCD patients, and the risk of developing severe clinical manifestations, including CNS complications in the form of transient ischemic attacks (TIAs) and strokes, avascular necrosis (AVN) of the head of femur (diagnosed by MRI of the hip), and renal injury by estimation of Albumin /creatinine ratio (A/C ratio).
Results: Among our study population, GSTM1, GSTT1 and GSTP1 genotypes distribution was similar between SCD patients and controls. CNS complications were observed in 66.7% of the SCD patients, 33.3% of the patients had no history of CNS complication. AVN of the head of femur was observed in 61.5% of the patients, while 38.5% of the patients had no previous AVN of the head of femur. The A/C ratio was ranging from 0.01 to 4, mean=0.5±0.6 and median =0.3. The *GSTM1 null genotype was significantly associated with CNS complications* (P value=0.03), *it was also associated with AVN of the head of the femur (Odd ratio=7) and raised A/C ratio* (mean=0.6±0.82 *vs* 0.49±0.42 for null genotype and non-null genotype respectively), however it was not of statistical significance (P-Value=0.2 and 0.8 respectively). *GSTT1 null genotype was also associated with CNS complication* (Odd ratio=5.1)*, AVN of the head of femur* (Odd ratio=4.2), *and raised A/C ratio* (mean=0.55±0.65 *vs* 0.49±0.44 for null genotype and non-null genotype respectively), however it was not statistically significant (P-Value=0.4, 0.5 and 0.9 respectively). Non wild GSTP1 polymorphisms (Homozygous and heterozygous) were not associated with sever clinical manifestations of SCD in the form of CNS complications, AVN of the head of the femur and A/C ratio (P value=0.5, 0.6 and 0.8 respectively).
Summary/Conclusions: As GSTM1 and GSTP1 null genotypes were associated with unfavorable clinical outcomes, GST gene polymorphisms may be used as a genetic marker, of a predictive value for defining patients at risk of developing sever SCD complications, due to impaired anti-oxidative defense mechanism. Patients with GSTM1 and GSTP1 null genotypes may get benefits of using prophylactic treatments aimed at reduction of oxidative stress to protect them against severe complications. However, further studies on a large scale including different ethnicities are required to prove our observation.

P758

LUSPATERCEPT INCREASES HEMOGLOBIN, REDUCES LIVER IRON CONCENTRATION, AND IMPROVES QUALITY OF LIFE IN NON-TRANSFUSION DEPENDENT ADULTS WITH BETA-THALASSEMIA

A Piga[1,*], S Perrotta[2], A Melpignano[3], C Borgna-Pignatti[4], MR Gamberini[4], E Voskaridou[5], V Caruso[6], P Ricchi[7], A Pietrangelo[8], X Zhang[9], D Wilson[9], A Bellevue[9], A Laadem[10], M Sherman[9], K Attie[9]
[1]Turin University, Turin, [2]Second University of Naples, Naples, [3]Ospedale "A Perrino", Brindisi, [4]University of Ferrara, Ferrara, Italy, [5]Laiko General Hospital, Athens, Greece, [6]Garibaldi Hospital, Catania, [7]AORN "A. Cardarelli", Naples, [8]CEMEF, Medicina 2, Modena, Italy, [9]Acceleron Pharma, Cambridge, MA, [10]Celgene Corporation, Summit, NJ, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIB, is being developed for the treatment of β-thalassemia. Luspatercept binds to GDF11 and other ligands in the TGF-β superfamily to promote late-stage erythroid differentiation. Luspatercept corrected the effects of ineffective erythropoiesis in a thalassemia mouse model (Suragani R, Blood 2014) and was well tolerated and increased hemoglobin (Hgb) in a phase 1 clinical study (Attie K, Am J Hematol 2014).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study followed by a long-term extension study to evaluate the effects of luspatercept in adults with β-thalassemia, including a subgroup that was non-transfusion dependent (NTD, <4 Units RBC/8 wk). Endpoints included Hgb, liver iron concentration (LIC) by MRI, safety, and patient-reported quality of life questionnaires (FACT-An, SF-36).
Methods: Inclusion criteria included age ≥18 yr and Hgb <10 g/dL (NTD pts). Luspatercept was administered SC every 3 wks for up to 5 doses in the dose-ranging study (completed) with a 2-month follow-up unless enrolled directly into a 2-year extension study (ongoing). Six sequential cohorts (n=35 total) were treated at escalating doses from 0.2 to 1.25 mg/kg. An additional expansion cohort (n=29) was treated with a starting dose of 0.8 mg/kg with escalation up to 1.25 mg/kg. Of the 64 patients treated in the dose-ranging study (including 34 NTD), 51 were enrolled in the extension study.
Results: Data (as of 25 Sept 2015) were evaluable for 31 of 34 patients who were NTD. Median age was 37 yr, ranging from 20 to 61 yr, and 68% had prior splenectomy. Median Hgb was 8.4 g/dL (range 6.5-9.6 g/dL) and mean (±SD) LIC was 5.6±3.8 mg/g dw. 12 patients were receiving iron chelation therapy (ICT) at baseline. Mean increase in Hgb was greater in patients treated with 0.8-1.25 mg/kg than in patients treated with 0.2-0.6 mg/kg. Of the patients treated in the longer-term extension study, 11/17 (65%) achieved a ≥1.0 g/dL increase in mean Hgb over any 12-week period, and 8/17 (47%) increased by ≥1.5 g/dL. 5/14 (36%) patients with baseline LIC ≥5 mg/g dw had a mean decrease in LIC ≥2 mg/g dw (mean decrease 3.2 mg/g dw, 32.1%) over the 16-week base study period. 14/14 (100%) patients with baseline LIC <5 mg/g dw maintained LIC <5 mg/g dw. Four NTD patients with long-term, persistent leg ulcers experienced complete or partial healing with luspatercept treatment. Increases in the FACT-An anemia subscale and the SF-36 physical component summary (PCS) at Week 24 (n=15, last observation carried forward) correlated with Hgb increases ($p<0.05$). Luspatercept was generally well tolerated, with no related serious adverse events reported to date. Adverse events in the NTD subgroup were mostly mild-moderate and the most frequent related adverse events (≥3 patients) were bone pain, headache, musculoskeletal pain, myalgia, and arthralgia.
Summary/Conclusions: Luspatercept treatment was well-tolerated and led to increased hemoglobin levels, decreased LIC, and improved quality of life in NTD adults with β-thalassemia. The increase in hemoglobin correlated with improvement in QOL anemia symptom score. These changes represent a significant reduction in disease burden reflected in improved patient quality of life for patients with NTD β-thalassemia; further studies in this population are planned.

P759

AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS) AND ALPS-RELATED SYNDROME (ARS). DIFFERENCES ON CLINICAL AND BIOLOGICAL FEATURES AND TREATMENT RESPONSE: A SINGLE CENTER EXPERIENCE.

F Fioredda[1,*], E Palmisani[1], C Micalizzi[1], M Calvillo[1], F Pierri[1], F Tucci[1], I Olivieri[1], M Mazzoni[1], P Terranova[1], I Caviglia[2], C Dufour[1], M Miano[1]
[1]Haematology Unit, [2]Infectious Diseases Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: ALPS is a rare, inherited disorder of the immune system due to defective Fas mediated-apoptosis, characterized by lymphoproliferation, autoimmunity and frequently cytopenias. Immunological/autoimmune disorders with an ALPS phenotype but not completely fitting ALPS full diagnostic criteria, are frequently seen by heamatologists and often represent a therapeutic challenge.
Aims: is to describe clinical and biological features and treatment response of a cohort of ALPS and ARS patients seen at our Centre.
Methods: patients with ALPS and ARS treated at the our Centre from January 2001 to December 2015, were considered eligible to the study. ALPS was defined according to the revised diagnostic criteria established by a work shop in 2009. ARS has been arbitrarily defined by the presence of i) cytopenia+at least one "Required Criteria" or one "Primary Additional Criteria" or b) two "Required criteria"+one Secondary Additional Criteria. Anagraphical, clinical, biochemical data were collected for each patient. Response to immunosuppression was defined partial or complete according to a melioration/resolution of cytopenia or other symptoms.
Results: 90patients (49 males, 41 females) whose median age at diagnosis was 10 yrs (0-39.8) with ALPS (37) or ARS (53) were evaluated. Lymphoproliferation was present in 71% (64/90)patients and consisted of isolated lymphoadenopathy (31%>28/90-), isolated splenomegaly (54%>49/90), or both (19%>17/90). Lymphoadenopathy was more frequent (49%)in ALPS than in ARS (19%; $p<0.01$) and so was splenomegaly (84% in ALPS *vs* 34% in ARS patients, ($p<0.01$). The median percentage of Double Negative T-cells/total lymphocytes was and again was higher in ALPS 2.6% (0.6-14.8) over ARS (2.2% 0.6-19.5) ($p<0.01$). Cytopenia was present in 80% subjects; of these 32% (26) were ALPS and 64% (46) ARS ($p=0.05$) and involved one (62%) or more cell lineages (38%). Isolated thrombocytopenia was significantly more frequent in ARS (79%) *vs* ALPS (21%)($p=0.01$), while neutropenia (52%) and hemolytic anemia (44%) were more represented in ALPS *vs* ARS ($p=0.03$ and $=0.01$ respectively). Trilinear cytopenia was present almost exclusively in ALPS (86%) *vs* ARS (14%) ($p<0.01$). Vitamin B12 values above1500 ng/l and autoimmune symptoms were more frequent in ALPS than in ARS ($p=0.02$ and $p<0.01$). Fourteen out of 89 patients (16%)did not need any treatment. Of the remaining 75, 14 (19%) responded to steroids and/or immunoglobulin, while 61(81%)required a second/third line therapy. Of these 61, 41 (67%) received MycophenolateMofetil (MMF) which resulted in a partial/complete response in 70%. Response rate was 78% in ALPS and 61% in ARS (p=ns). Twenty eight of 61 (46%) received Sirolimus, including 15 patients who had previously failed MMF treatment. Partial/complete response was seen 92% of ALPS and in 77% of ARS patients (p=ns).
Summary/Conclusions: Lymphoprolipheration and autoimmune symptoms characterizes mainly ALPS, while cytopenia is a peculiarity of ARS. Isolated thrombocytopenia is more frequent in ARS patients, while neutropenia/haemolytic anemia or trilinear cytopenia is more typical of ALPS. MMF and Sirolimus represent a valid option for the treatment of ALPS and ARS being effective in more than ¾ of the cohort thus sparing steroids. The definition of the genetic profiles of these patients might enable treatments tailored on the different pathogenic mechanisms.

P760

INCREASED LEVELS OF CIRCULATING IMMATURE GRANULOCYTES IN SEPSIS HAVE A SIGNIFICANT IMPACT ON SURVIVAL: RESULTS OF THE FRENCH MULTICENTRIC SEPTIFLUX 2 STUDY

E Guerin[1,*], T Daix[2], R Jeannet[1], E Tavernier[3], O Herault[4], E Legac[5], N Chapuis[6], O Wagner-Ballon[7], J Guy[8], K Allou[9], M Roussel[10], A Roggy[11], S Bouyer[12], MC Béné[13], J Feuillard[1], B Francois[2]
[1]Hematology Laboratory, CHU/UMR CNRS 7276, [2]Intensive Care Unit,

CHU/INSERM CIC 1435, Limoges, [3]CIC INSERM 1415, [4]hematology laboratory, CHU, Tours, [5]hematology laboratory, Nouvel Hôpital d'Orléans, Orléans, [6]hématologie laboratory, INSERM U1016, Cochin, Paris, [7]hematology laboratory, hopital Henri Mondor, Créteil, [8]hematology laboratory, CHU, Dijon, [9]hematology laboratory, CHU, Bordeaux, [10]hematology Laboratory, CHU, Rennes, [11]EFS, Besancon, [12]hematology laboratory, CHU, poitiers, [13]Hematology Laboratory, CHU, Nantes, France

Background: In industrialized countries, overall survival of sepsis is 27%, and each year, as many patients die of sepsis as of heart attack. In the first hours of sepsis, increased percentage of band cells and late immature granulocytes (Imm Gran), the cytologic equivalent of CD10dim and CD16dim immature granulocytes, has long been described. Recently, we suggested in a proof-of-concept monocentric study that Imm Gran CD10dim and CD16dim quantification by flow cytometry may have a prognostic interest in septic patients. We also showed that this cell compartment contains myeloid derived suppressor cells (MDSCs).
Aims: Here we demonstrate prospectively that the prognostic value of this the CD10dim and/or CD16dim granulocyte counts in a multicentric study including 12 centers and 781 patients.
Methods: Prospectively, between November 2013 and June 2015, all patients admitted for less than 24 hours in 12 french hospitals for Sepsis, severe Sepsis or septic shock were eligible. A blood count and a eight colors cytometry staining (CD64/CD10/CD14/CD16/CD24/CD11b/CD3/CD45) were performed to quantify CD3 cells, CD64+ granulocytes, CD10dim and CD16dim immature granulocytes, monocytes and although the inflammatory monocytes (CD16+). The intensity of CD10 and CD16 was also compared (mean, mode, CV).
Results: 1062 patients were screened and 281 excluded mainly due to unconfirmed infection. 781 were analyzed. Patients were segregated in 3 groups regarding the severity of sepsis: 343 Sepsis (67+/-75 years), 192 severe sepsis (67+/-67 years) and 246 with septic shock (65+/-15 years). In each group we have followed the clinical deterioration (8%, 12% and 9%) at 48 hours and the mortality rate (0%, 1% and 9%) respectively. Corresponding to the emergence of CD16dim Imm Gran, an increased CV of CD16 expression (CV=52, p<0.01) was found in deteriorating patients compared to patients with a stable or improved condition at 48 hours (CV=44.2, p<0.01). At day 0, the absolute count of Imm Gran was 2 G/L *vs* 4.7 G/L (p<0.01) in patients who survived or not at day 7, and 1.9 G/L *vs* 4.6 G/L at day 30 (p<0.01). The proportion of Imm Gran was 19.8% *vs* 66.4% (p<0.01) in patients who survived or not at day 7, and 19.1% *vs* 55.2% at day 30 (p<0.01). Thus, both absolute count and proportion of Imm Gran had a negative prognostic value on mortality at day 7 and 30. A CD3 lymphopenia had also a significant impact on survival, 0.5 G/L *vs* 0.3 G/L (p<0.01) at day 7 and 0.6 G/L *vs* 0.4 G/L (p<0.01) at day 30.
Summary/Conclusions: These results demonstrate in a multicentric manner on a very large prospective cohort of patients that increased levels of CD10dim and CD16dim Imm Gran, as quantified by daily routine flow cytometry in hospital laboratories, have a strong pejorative prognosis value on survival at day 7 and 30 in Sepsis. Early Sepsis management being known to prevent deterioration of patients, we strongly suggest that setting up the precise quantification of immature granulocytes by flow cytometry could benefit to septic patients with a tailored specific management.

USEFULNESS OF A THIRTY ONE-GENE PANEL BY NEXT-GENERATION SEQUENCING FOR THE MOLECULAR DIAGNOSTIC OF INHERITED BLEEDING COAGULATION DISORDERS

JM Bastida Bermejo[1,*], M Del Rey[2], R Benito[2], K Jasnuz[2], A Hortal[2], ME Sarasquete[2], ML Lozano[3], LJ García-Farde[4], R Fisa[5], ME Fontecha[4], C Aguilar[6], MP Martinez-Badas[7], C Aguilera[8], MJ Cebeiro[9], JM Martín-Antoran[10], N Bermejo[11], M Lopez-Parra[12], R Ramos[13], B Perez[14], R Garcia-Sanz[12], M Gonzalez[12], JM Hernández-Rivas[12], JR González-Porras[12]
[1]Hematologia, Hospital Clinico Salamanca, [2]Hospital Clinico Salamanca, Salamanca, [3]Hematologia, Hospital Universitario Morales Meseguer, Murcia, [4]Hospital Universitario Rio Hortega, Valladolid, [5]Hospital General, Segovia, [6]Complejo Asistencial de Soria, Soria, [7]Complejo Asistencial Avila, Avila, [8]Hospital General El Bierzo, Ponferrada, [9]Hospital Clinico Universitario Valladolid, Valladolid, [10]Hospital Rio Carrion, Palencia, [11]Hematologia, Hospital San Pedro Alcantara, Caceres, [12]Hematologia, Hospital Clinico Salamanca, Salamanca, [13]Hematologia, Hospital Merida, Badajoz, [14]Hematologia, Complejo Asistencial Leon, Leon, Spain

Background: Molecular testing of Inherited bleeding coagulation disorders (IBCDs) not only offers confirmation of diagnosis, but also aids in genetic counseling, prenatal diagnosis and in certain cases genotype–phenotype correlations are important for predicting the clinical course of the disease and to allow tailor-made follow up of individuals. Until recently, genotyping has been mainly performed by Sanger sequencing, a technique known to be time consuming and expensive. Currently, Next-Generation Sequencing (NGS) offers a new potential approach that enables the simultaneous investigation of multiple genes at manageable cost.
Aims: To analyze the applicability of a 31-gene NGS panel in the molecular diagnosis of patients with IBCDs.
Methods: We enrolled a total of 30 patients (19 males and 11 females; median age, 20 years, ranging from 1 to 61 years old), with previously confirmed coagulation factor deficiencies. IBCDs genotype was studied using NGS technology. A custom target enrichment library was designed to capture thirty-one genes known to be associated with IBCDs. Probes were generated for 343 targets to cover 103.3 kb regions (all exons and flanking regions) of these genes. Sanger sequencing was performed to validate all causative variants identified by NGS.
Results: The use of this 31-gene panel approach allowed us to identify the causative variants of the IBCDs in all patients. Overall, thirty pathogenic variants were found (five hypodysfibrinogenemias, five von Willebrand disease, three FVII deficiencies, one FV, FX, FXII, FXIII, Prekallykrein deificiency, each other, two FXI deficiencies, eight Hemophliia A and 2 Hemophilia B), including eight novel mutations affecting F8, FGA, FGG, F11, F10, F5 and VWF genes and twenty-two previously reported variants were detected. Most of them, 27 were missense/nonsense and 3 were frameshift changes due to microdeletions. NGS and Sanger sequencing were 100% concordant (Table 1).

Table 1.

Hemostasis function	Genes
Intrinsic pathway	*KLKB1, HRG, KNG1, F12, F13A1, F13B, F11, F8, F9, VWF*
Extrinsic pathway	*F2, F3, F5, F7*
Vitamin-K dependent-carboxylation	*GGCX, VKORC1, F10*
Combined factor synthesis	*MCFD2, LMAN1*
Fibrinolysis	*PLAT, PLAUR, PLG, PLGRKT, TFPI*
Fibrinogen synthesis	*FGA, FGB, FGG, FIBCD1*
Complement system	*C1QBP, CLEC3B, CPB2*

Summary/Conclusions: Inherited coagulation disorders could be successfully molecularly characterized by using our 31-gene Next Generation DNA Sequencing panel. This approach allowed the diagnosis of the disease at a molecular level in all patients, and the identification of novel genetic variants in 26% of the cases included. Our results demonstrate that this approach could be an accurate, reproducible, and reliable tool in the rapid genetic diagnosis of IBCDs.

Background: Molecular diagnosis should be performed for all patients with hemophilia A (HA) and/or B (HB), highlighting any excess risk of inhibitor development associated with specific mutations, and enabling carrier testing for female relatives and prenatal or possible pre-implantation genetic diagnosis or to distinguish von Willebrand disease (VWD). Currently, Next-Generation Sequencing (NGS) offers a powerful approach that enables the simultaneous exploration of exons, introns and regulatory regions of various genes.
Aims: To evaluate the usefulness of a molecular diagnostic algorithm for hemophilia A and B based on NGS to analyze full-length *F8*, *F9* and *VWF* genes.
Methods: Overall of 100 DNA samples were analyzed. Ninety-five unrelated hemophilic patients (HA=78 and HB=17) and 5 females for her hemophilia carriers' status in whom the index case were unknown. Our molecular algorithm first step catalogues severe HA patients carrying intron 22 or intron 1 inversions detected by long range PCR. In a second step, severe HA patients without previous alterations as well as rest of different types of FVIII or FIX deficiency and female carriers were considered for NGS studies. (Figure 1). Whole regions (exonic, flanking, regulatory and intronic) were sequenced by the NGS enrichment target. In those patients without pathogenic variants, multiplex ligation-dependent probe amplification (MLPA) was performed.
Results: In the global analyses, genotyped were identified in 94 out of 100 samples (94%). Fourteen novel variants were detected. Only in 6 mild HA patients, pathogenic variants were not found. All severe HA patients (n=20) were genotyped. In 11 of them, IVS22 were confirmed (55%). None IVS1 was found. In the remaining 7 out of 8 patients (IVS22 and IVS1 negative), genetic variants were found by NGS analyses and it allowed us to detect 3 nonsense, 2 microdeletion, 1 duplication and 1 missense pathogenic variant. MLPA approach reached a complex mutation (gross deletion and duplication) in the last severe HA patient. Most of HA patients included were mild/moderate phenotype (n=54 and n=4; 75%). In 52 out of 58 patients (90%), missense pathogenic variants were found. In 5 of them, a new accurate diagnose was established due to detection of pathogenic *VWF* variants: one case with a VWD type 2N, one carrier of VWD type 2N and 3 cases of VWD type 1. In the remaining 6 cases, intronic variants are being analyzed. About HB patients, genotype was confirmed in all patients (n=17). All variants were missense except one nonsense variant. Most of them (n=10; 63%) affected to the catalytic domain. About hemophilia carrier status, 5 females were included because their index cases were not known. Three pathogenic variants were confirmed in *F8* gene (IVS-22, p.Arg427* and c.5374-19delT; IVS-16), in three of them. In the remaining two symptomatic females (mild FVIII deficiency), a pathogenic variant (c.2561G>A; p.Arg854Gln) in exon 20 of *VWF* gene was found. Accordingly, a new type 2N-VWD diagnose was established.

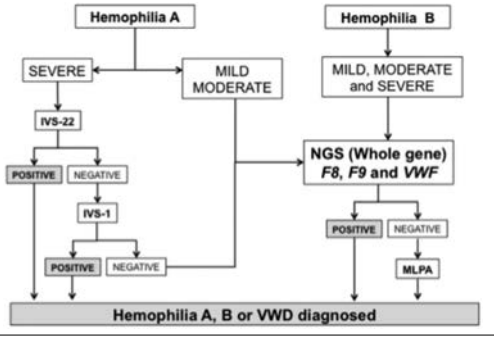

Figure 1.

Summary/Conclusions: The use of this molecular-algorithm approach allowed us to identify the causative variants of the HA and HB patients, correctly redefine VWD and to establish the status of female carriers.

ASSAY DISCREPANCY IN MILD HAEMOPHILIA A PATIENTS WITH MUTATIONS IN FVIII A DOMAIN

A Trampuš Bakija[1,*], M Debeljak[1], J Kovač[1], I Preložnik Zupan[2], J Jazbec[1]
[1]Childrens' hospital, [2]Division of Internal Medicine, University Medical Centre, Ljubljana, Slovenia

Background: Significant discrepancy between one-stage clotting assay (FVIII:C1) and chromogenic method (FVIII:CR) for FVIII activity measurement is common in mild haemophilia A (HA) patients. Different missense mutations are identified in families with discrepant HA. Such mutations are located mainly within exons encoding C2 and A2 domains of FVIII. Missense mutations in A2 domain can cause instability of molecule leading to reduced FVIII:CR. The differences in FVIII levels may lead to an incorrect biochemical phenotype and diagnosis of haemophilia. The global haemostasis tests may represent an option for better prediction of the mild HA clinical phenotype.
Aims: Genetic background was determined in patients with discrepant FVIII activity in Slovenian patients with mild haemophilia A. The structural elements in FVIII molecule were characterised. Further specific and global coagulant assays were investigated to determine their usefulness.
Methods: *F8* gene mutations were determined with Sanger sequencing and analyzed with *in silico* methods. FVIII activity tests were performed with one stage clotting assay (APTT-SP reagent and FVIII deficient plasma, both Instrumentation laboratory-IL, USA) on ACL TOP 500 instrument (IL, USA) and chromogenic assay (Electachrome Factor VIII, IL, USA) using spectrofotometric manual method (Multiskan EX, Thermolabsystem, Finland). FVIII antigen (FVIII:Ag) was determined with Asseracgrom FVIII:Ag kit (Stago, France). APTT wave clot analysis was performed on ACL TOP 500 instrument and thromboelastometry on ROTEM®delta instrument (Pentapharm GmbH, Germany).
Results: Twelve patients from 7 families presented with FVIII:C1 measurement significantly higher than those obtained with FVIII:CR method. FVIII activity ratio range was from 2.6-4.2. The p.Ser308Leu variant in A1 domain (previously described) was identified in seven patients. All of them had reduced FVIII:C1 ranged from 21 to 48% and normal FVIII:Ag ranged from 52 to 112%. Three novel missense variants clustered in A2 domain (p.Val670Phe, p.Tyr683His, p.Asp685Gly) were associated with fourfold discrepancy. Four patients with those variants had FVIII:Ag from 26 to 62% however, they would be classified as having moderate form of HA using FVIII:CR method. All three genetic variants are located at the interface between A2 and A3 domain (Figure 1). APTT was normal in 5 patients carrying the p.Ser308Leu variant. The wave clot analysis shows that 92% of our patients demonstrated normal acceleration of APTT reaction (max2 parameter) in the contrast with nondiscrepant HA, where max2 is normal in only 17% (data not shown). For INTEM test of ROTEM analysis, clotting time has sensitivity of 42%. Clinical data classified all our patients as mild haemophiliacs with bleeding episodes provoked only by surgical interventions or trauma.

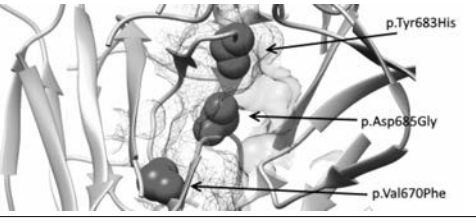

Figure 1. Close-up view of the FVIII A2 (orange) – A3 (magenta) domain interface. Amino acids at position 670, 683 and 685 contribute to FVIII interdomain.

Summary/Conclusions: Three novel genetic variants were described causing a discrepant biochemical phenotype of HA. The nature and position of variants are strongly associated with phenotype and contribute to the FVIII molecule instability. High results of FVIII:Ag showed that the endogenous synthesis and secretion of FVIII is less affected. The APTT test could be in normal range in discrepant patients, however, wave clot analysis shows good differentiation between discrepant and nondiscrepant patients and could provide additional information in managing HA. ROTEM poorly discriminates between normal individuals and mild HA patients and the method is unlikely to be helpful in discrepant HA identification. One-stage and chromogenic method should be used in diagnostics of non-severe HA to avoid the misdiagnosis and to complement the genetic findings.

ARTHROPATHY IN PATIENTS WITH MODERATE AND SEVERE VON WILLEBRAND DISEASE

K Van Galen[1,*], P de Kleijn[1], W Foppen[2], J Eikenboom[3], K Meijer[4], R Schutgens[1], M Cnossen[5], K Fijnvandraat[6], A van der Bom[7], J de Meris[8], B Laros-van Gorkom[9], F Leebeek[10], E Mauser-Bunschoten[1]
[1]Van Creveldkliniek, [2]Radiology, University Medical Center Utrecht, Utrecht, [3]Vascular medicine, Leiden University Medical Center, Leiden, [4]Hematology, University Medical Center Groningen, Groningen, [5]Pediatrics, Erasmus Medical Center Rotterdam, Rotterdam, [6]Pediatrics, Emma childrens hospital Academic Medical Center Amsterdam, Amsterdam, [7]Epidemiology, Leiden University Medical Center, Leiden, [8]Dutch patient society on haemophilia and allied disorders, Nijkerk, [9]Hematology, radboud university medical center, Nijmegen, [10]Hematology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands

Background: The 'Willebrand in the Netherlands' study group has previously

published that almost a quarter of patients with moderate and severe Von Willebrand disease (VWD) reported joint bleeds. Those bleeds had a negative impact on health related quality of life and joint integrity, according to patient-reported and retrospective medical file data. However, besides that, little information is available for VWD patients on the prevalence and severity of arthropathy and its influence on joint function and daily life activities.
Aims: To assess the prevalence and severity of arthropathy and its impact on joint function and daily life in moderate and severe VWD patients (trial number NTR 4548).
Methods: Dutch patients with moderate and severe VWD (VWF activity<30 IU/dL and <10 IU/dL, respectively) and documented treatment for at least one joint bleed were invited to participate. The same number of controls (moderate and severe VWD patients without joint bleed treatment) were selected and matched for age (±2 years), gender and FVIII level (±10%). A single experienced physiotherapist conducted the Haemophilia Joint Health Score (HJHS, 0-124). X-rays were made from all joints with prior bleeds, contralateral joints and one control joint. One radiologist scored the X-rays according to Pettersson (PS, 0-13 per joint). Arthropathy was defined as a clinical HJHS score ≥3 or PS>0. All participants completed the Haemophilia Activity List (HAL, 0-100) questionnaire. The Visual Analogue Score (VAS, 0-10 cm) was used to assess joint pain.
Results: 48 patients and 48 controls were included, 60% males, mean age 46 years (range 18-80). Mean FVIII levels were 26 IU/dL in the patients and 31 IU/dL in the controls (p=0.19). More patients had type 3 VWD (19/48 *vs* 3/48 controls). In the control group of patients without documentation on joint bleed treatment, 14/48 patients did report one or more joint bleeds but none of them more than five. In contrast, 56% of the 48 patients had more than five joint bleeds. Arthropathy occurred in 37/48 (77%) patients and 35/48 (73%) controls (p=0.51). Overall, arthropathy occurred in both severe (47/64) and moderate VWD (25/32) and in all three VWD types (22/28 type 1; 30/46 type 2; 20/22 type 3). The median HJHS was significantly higher in the patients compared to the controls (5 *vs* 1.5, p<0.01, maximum score 47 *vs* 29). PS>3 occurred in 2 controls compared to 12 patients (p<0.01) and overall most in type 3 VWD patients (9/22 type 3 *vs* 3/46 type 2 *vs* 2/28 type 1). The total HAL score as well as the scores on the three separate HAL components were significantly lower for the 48 patients compared to the controls (median scores HAL Sum: 88 *vs* 100, p<0.01; Upper Extremity Activities: 93 *vs* 100, p=0.01, Basic Lower Extremity Activities: 87 *vs* 100, p<0.01; Complex Lower Extremity Activities: 80 *vs* 100, p<0.01). Clinically relevant joint pain (mean VAS score >3) was reported by 17 patients and 9 controls (p=0.07).
Summary/Conclusions: Arthropathy, according to our stringent definition, was seen in 77% of patients with moderate and severe VWD treated for joint bleeds. Notably, arthropathy was also found in 73% of matched control VWD patients without joint bleed treatment. Joint function and –integrity in the VWD patients treated for joint bleeds was affected, consistent with higher HJHS and joint X-rays scores. These patients experienced a significant impact on daily life activities (HAL, both upper and lower extremities) and 35% also reported clinically relevant joint pain (VAS).

A COMPREHENSIVE NEXT GENERATION SEQUENCING TEST FOR THE DIAGNOSIS OF INHERITED BLEEDING, THROMBOTIC AND PLATELET DISORDERS

I Simoni[1], S Sivapalaratnam[1,2,*], D Greene[1,2,3], M Laffan[4], A Mumford[5], K Megy[1,2], K Freson[6], K Gomez[7], W Ouwehand[1,2,8], E Turro[1,3]
[1]Haematology, University of Cambridge, [2]NHS Blood and Transfusion, [3]MRC Biostatistics Unit, Cambridge Institute of Public Health, Cambridge, [4]Haematology, Imperial College, London, [5]Haematology, Bristol University, Bristol, United Kingdom, [6]Haematology, University of Leuven, Leuven, Belgium, [7]Haematology, Royal Free, London, [8]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: Inherited bleeding, thrombotic and platelet disorders (BPDs) are rare diseases affecting approximately 300 individuals per million births. With the exception of haemophilia and von Willebrand disease patients, a molecular analysis for BPD patients is often unavailable. Many specialised tests are usually required to reach a putative diagnosis and they are typically performed in a slow, step-wise manner to control costs. The results of these tests may be used to prioritise genes for Sanger sequencing if a genetic diagnosis is required. This approach causes significant delays and a conclusive molecular diagnosis is often never reached, which can compromise treatment and impede rapid identification of affected relatives.
Aims: Our aim was to design a platform through which accurate and rapid testing of inherited BPDs would be possible.
Methods: We designed a high-throughput sequencing (HTS) platform targeting all 87 known BPD disease genes. The platform can call single nucleotide variants, short insertions/deletions and large copy number variants (though not inversions), which are subjected to automated filtering for diagnostic prioritisation.
Results: We sequenced 159 and 141 samples respectively from individuals with and without previously known causal variants. Among the latter group, 61 cases had phenotypes strongly indicative of a particular molecular aetiology while the remainder had an aetiology that was *a priori* highly uncertain. All the previously detected variants were recapitulated and, when the aetiology was suspected but unknown, a molecular diagnosis was reached in 56 of 61 cases.
Summary/Conclusions: The ThromboGenomics platform provides a comprehensive and affordable DNA-based test to diagnose patients suspected of having a known inherited BPD thereby significantly reducing the current diagnostic delay.

P766

THE ROLE OF CD72 IN THE REGULATION OF B CELL ACTIVATION THROUGH CD40 IN PRIMARY IMMUNE THROMBOCYTOPENIA

M Lyu[1,*], Y Hao[2], Y Li[2], W Liu[2], C Lyu[2], S Wang[2], Y Guan[2], H Li[2], R Yang[2]
[1]State Key Laboratory of Experimental Hematology, [2]Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, tianjin, China

Background: CD72 is considered to be an important B cell co-receptor for its prominent role in immune regulation. Previous studies show that CD40 signals play a more important role in mechanism of primary immune thrombocytopenia (ITP) by activating B cell and inducing B-cell growth with Ig secretion. NF-κB activation is a pivotal pathway in CD40 signaling. However, the effect of CD72 on B cells activated by CD40 in ITP remains unknown.
Aims: This study aimed to explore the effect of CD72 on B cell activation through CD40 in ITP.
Methods: Activation-associated surface markers (CD80, CD86 and CD40), the proliferation, apoptosis, plasmablasts and platelet-associated IgG were analyzed by flow cytometry in patients with active ITP and health controls. In cultures vitro, peripheral blood mononuclear cells (PBMCs) were stimulated by anti-CD40 in the presence or absence of CD40L, IL-4 and IL-21, autologous platelets. Production of IgG and IgM in the culture supernatants was determined by enzyme-linked immunosorbent assay. The levels of NF-κB P65 and IκBα mRNA were assessed by real-time quantitative polymerase chain reaction.
Results: Our data showed that CD40 expression was significantly decreased on CD19+ B cells after CD72 ligation in ITP patients compared to controls. The higher levels of activation markers CD80, CD86 on CD19+ B cell stimulated by anti-CD40 was reduced by anti-CD72 in ITP patients and controls. CD40 stimulation significantly promoted the survival of CD19+ B cells, and reduced the apoptosis of CD19+ B cells in ITP patients compared to that observed in controls. CD72 ligation corrected the effect of CD40 stimulation on apoptosis and proliferation of B cells. The CD40-mediated the differentiation of B cells into plasmablasts was blocked by CD72 ligation in ITP patients and controls. However, the role of CD72 on B cell differentiation was stronger in ITP patients than in controls. CD72 ligation had only a minor effect on reducing platelet-associated IgG in ITP patients. Following stimulation with anti-CD40 and IL-21, synthesis of IgM by B cell was diminished in the presence of anti-CD72, whereas the IgG levels were barely reduced. The reduced ratio had no difference in ITP patients and controls.CD72 signaling significantly reduces NF-κB P65 and IκBα expression at the mRNA levels in PBMCs activated by anti-CD40 in ITP patients compared to controls.
Summary/Conclusions: These findings indicate that CD72 is a key molecule in regulating B cell activation, proliferation, apoptosis and antibody secretion mediated by CD40 signaling in ITP patients.Thus, CD72 may be involved in the pathogenesis of ITP and antagonizing CD72 could be a novel strategy for the therapy of ITP.

P767

IMPACT OF BRUTON'S TYROSINE KINASE INHIBITORS ON COLLAGEN-INDUCED PLATELET AGGREGATION: A PHARMACOKINETIC/PHARMACODYNAMIC PERSPECTIVE

J Chen[1], T Kinoshita[1], T Gururaja[1], J Sukbuntherng[1], D James[1], M Versele[2], BY Chang[1,*]
[1]Pharmacyclics LLC, an AbbVie Company, Sunnyvale, United States, [2]Janssen Pharmaceuticals, Beerse, Belgium

Background: Bruton's tyrosine kinase (BTK) is expressed in platelets (PLTs) and mediates collagen-induced aggregation of PLTs. TEC, a member of the TEC family kinases, is also expressed in human and mouse PLTs. Studies in PLTs from BTK-deficient X-linked agammaglobulinemia patients (Quek 1998; Lipsky 2015), and BTK and/or TEC KO mice suggest that the 2 kinases likely possess redundant functions in collagen-induced aggregation; however, BTK is thought to play a more dominant role than TEC, as BTK deficiency alone reduces robust aggregation at lower collagen concentrations (Atkinson 2003). Ibrutinib (ibr) is a once-daily, first-in-class, covalent inhibitor of BTK approved for various B-cell malignancies. Additional BTK inhibitors (BTKis) have been evaluated in clinical trials, with bleeding as a common adverse event (AE) observed not only for ibr but also for ONO-4059 (Walter 2016), ACP-196 (Byrd 2016), and BGB-3111 (Tam, ASH 2015). Early-phase clinical data reported to date for these follow-on molecules have been limited due to small patient numbers and minimal follow-up, where ACP-196 and ONO-4059 had bleeding events of petechiae and contusion among the most common AEs (hematoma was also frequently reported with ONO), and BGB similarly had a 33% bleeding rate. These compounds are potent BTKis with additional activity against TEC;

therefore, inhibition of BTK or both BTK and TEC may contribute to bleeding.
Aims: This study investigated how ibr and other clinical-stage BTKis, with a focus on selectivity over TEC, impact PLT function and their potential implication in bleeding events in patients on BTKi therapy.
Methods: On-target potency and selectivity of BTKis over TEC were investigated with recombinant enzymes using 3 different assays: LabChip® MSA, TR-FRET, and ^{33}P HotSpot activity. Cell activity was tested in human whole blood for BCR activation and in PLTs by light transmission aggregometry (LTA). The activity of BTKis was also evaluated by measuring cellular TEC phosphorylation levels in the presence of BTKis.
Results: Ibr had potency of approximately 1 nM or below with 0.7- to 11-fold selectivity for BTK over TEC in all 3 biochemical assays. ACP-196 had variable potency (3-135 nM) towards BTK; however, the selectivity profiles against TEC were similar to ibr, with <3-fold differences in the ratios (Table 1). Ibr, ACP-196, and ONO-4059 had IC_{50}s 20-40 nM in BCR assays, but in LTA with PLTs from healthy human donors, a 3-fold difference was observed compared with ibr (Figure 1). However, this difference in patients with CLL, in whom ACP-196 is administered twice daily, plasma C_{max} levels were approximately 1-2 µM, 3- to 5-fold higher than those after ibr (0.2-0.4 µM) in CLL patients (Table 2). Moreover, inhibition of TEC phosphorylation in PLTs was similar between ibr and ACP-196.

Table 1. Recombinant kinase assays.

	Ibrutinib (nM)			ACP-196 (nM)		
	BTK	TEC	*Ratio*	BTK	TEC	*Ratio*
Kinase Activity IC_{50} (LabChip MSA/TR-FRET/ ^{33}P Hotspot)	0.3/1.1/0.1	0.5/0.8/1.1	*1.7/0.7/11*	3.0/135/33	8.0/10/130	*2.7/<0.1/3.9*
Binding affinity	0.8	0.9	*1.1*	10	8	*0.8*

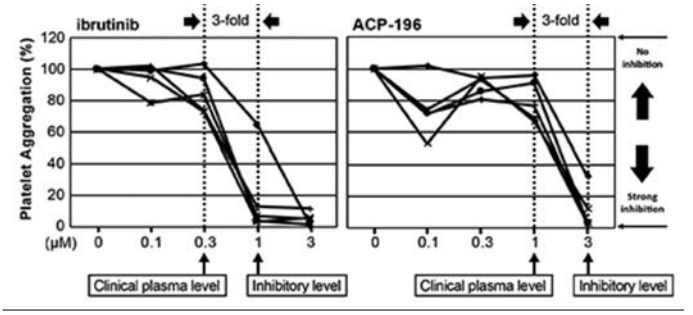

Figure 1. Platelet aggregation after ibrutinib or ACP-196 treatment.

Table 2. Pharmacokinetic parameters.

	Dose	$C_{max,ss}$ (µM)	AUC_{ss} (µM•hr)	LTA-induced inhibition (µM)
Ibrutinib	420 mg QD: CLL	0.3	1.7	0.3-1
ACP-196*	100 mg BID: CLL	1.8	2.0	1-3

*Byrd et al. *N Engl J Med.* 2016.

Summary/Conclusions: BTKis tested did not show a definitive selectivity advantage against TEC in enzymatic or cellular phosphorylation assays. When compared at the clinically and pharmacologically relevant plasma concentrations, both ACP-196 and ibr had similar effects on PLT aggregation. These results appear consistent with clinical data on bleeding events for both ACP-196 (Byrd 2016) and ibr (Byrd 2014). Only double-blinded placebo-controlled studies can address the potential risks and benefits of these subtle differences.

P768

QUALITATIVE AND QUANTITATIVE ANALYSIS OF INTRAHEPATIC BLOOD FLOW CHANGES IN PATIENTS WITH HEREDITARY HEMORRHAGIC TELANGIECTASIA (HHT)

R Schelker[1,*], AP Barreiros[2], W Herr[1], EM Jung[2]
[1]Department of Internal Medicine III, Hematology & Oncology, [2]Department of Radiology, University Hospital of Regensburg, Regensburg, Germany

Background: Hereditary hemorrhagic telangiectasia (HHT) is a rare inherited abnormality characterized by systemic vascular dilatation resulting in arteriovenous fusion including hepatic vascular malformations (HVaMs) with the risk of bleeding events. Due to current efforts to sub-classify a high risk group of asymptomatic patients with HVaMs on the one side and the experienced benefits of bevacizumab on the other side, cost-effective screening of HHT patients for hepatic involvement become more and more attractive.
Aims: To analyze HVaMs in a group of patients (n=18) applying CEUS and adding quantitative time intensity curve analysis (TIC analysis).
Methods: US/CEUS imaging data of 18 patients (2 men/16 women; mean age 59.4±12.1y; range, 21-83y) diagnosed with HHT in the Ear-Nose-Throat (ENT) department of the University Hospital of Regensburg between Jan 2015 and Jan 2016 were retrospectively analyzed with a high-end US scanner. SonoVue 1.0-2.4 ml was applied i.v. as contrast agent. Findings on B-Mode, color coded Doppler sonography (CCDS) and Power Doppler (PD) were analyzed in respect of suggested sonographic grading and staging criteria and by considering the "color spots". In order to perform TIC analysis eight regions of interest (ROIs) with a diameter of 5 mm were placed in the perfused hepatic artery, portal vein, shunt region and hepatic parenchyma, two ROIs per region. For quantitative investigation, the area under the curve (AUC) and time to peak (TTP) was considered.
Results: HVaMs could be identified in all patients, being localized particularly in the central area, segment 8 and the left lobe of the liver. All patients showed dilated hepatic artery (mean diameter 11,5 mm). Another major Caselitz criteria "intrahepatic arterial hypervascularization" was found in only 61,1% of the cases, while minor criteria "tortuous course of the extrahepatic artery" was described in 83,3%. The other 3 minor criteria (Vmax and RI hepatic artery; Vmax portal vein) were on average somewhat above the norm. Altogether, in only 55,6% of our patients the two major criteria were positive, while 16,7% did not reach diagnostic criteria for HVaMs. Buonamico reported higher sensitivity for "color spots" compared to Caselitz criteria, but 27,8% of our patients showed no spots at all. With regard to sonographic staging by Buscarini L. and grading criteria by Buscarini E., stage III and grade 3 could be demonstrated most frequent (~ 40%). We found arterioportal HVaMs in more than half of the patients (61,1%), however always in combination with arteriovenous malformations. In 16,7% even portovenous malformations were associated. HVaMs with early hyperenhancement during the arterial phase could be demonstrated by CEUS in all patients. Significant lowest TTP and highest AUC were detected in the hepatic artery and highest TTP and lowest AUC in the hepatic parenchyma and the portal vein. TTP and AUC values of the shunt region were between those of hepatic artery and portal vein. US/CEUS covered all subtle patterns and proved more accurate in diagnosis of challenging lesions like high-flow angiomas when compared to MRI, CT or angiography (Figure 1).

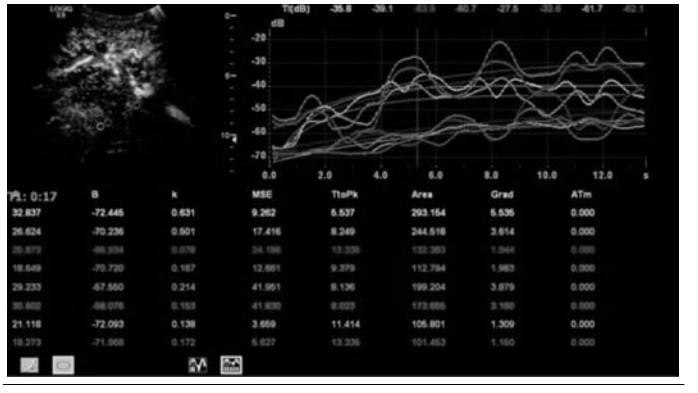

Figure 1.

Summary/Conclusions: For the first time we analyzed CEUS findings of a group of 18 HHT patients regarding macro- and microcirculation. Our data demonstrate significant differences in TTP and AUC values in the four selected regions: hepatic artery, shunt region, portal vein and hepatic parenchyma.

P769

C-EDGE IBLD: EFFICACY AND SAFETY OF ELBASVIR/GRAZOPREVIR (EBR/GZR) IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS (HCV) INFECTION AND INHERITED BLOOD DISORDERS (IBLD)

C Hezode[1,*], M Colombo[2], U Spengler[3], Z Ben-Ari[4], S Strasser[5], W Lee[6], L Morgan[7], J Qiu[7], P Hwang[7], M Robertson[7], BY Nguyen[7], E Barr[7], J Wahl[7], B Haber[7], R Talwani[7], V Di Marco[8]
[1]Henri Mondor Hospital, Creteil, France, [2]Università degli Studi di Milano, Milan, Italy, [3]University of Bonn, Bonn, Germany, [4]Sheba Medical Center, Ramat Gan, Israel, [5]A W Morrow Gastroenterology and Liver Centre, Sydney, Australia, [6]The University of Texas Southwestern Medical Center, Dallas, [7]Merck & Co., Inc., Kenilworth, United States, [8]University of Palermo, Palermo, Italy

Background: Complications from chronic HCV infection remain a major cause of morbidity and mortality among individuals with IBLD, including those with hemophilia (HEM), beta thalassemia (BTHAL), von Willebrand disease (VWD), and sickle cell anemia (SCA). Inability to tolerate ribavirin and frequent comorbidities have limited HCV treatment options in these patients. The efficacy and safety of a once-daily, fixed-dose combination of EBR 50 mg (NS5A inhibitor) and GZR 100 mg (NS3/4A protease inhibitor) has been demonstrated in a broad population of HCV-infected patients and supported evaluation in the IBLD population.

Aims: To assess the safety and efficacy of EBR/GZR in patients with HCV infection and SCA, BTHAL, or HEM/VWD.
Methods: C-EDGE-IBLD is a double-blind, placebo-controlled study that randomized treatment-naïve and peg-interferon/ribavirin treatment-experienced (TE) HCV genotype (GT)1, 4, or 6-infected patients in a 2:1 ratio to either an immediate-treatment group (ITG; 12 weeks of EBR/GZR) or deferred-treatment group (DTG; 12 weeks of placebo followed by EBR/GZR). Randomization was stratified according to cirrhosis status and IBLD group, defined as 1) HEM (A or B) or VWD, 2) BTHAL, or 3) SCA. The primary endpoints for this study were proportion of patients in the ITG who achieved an SVR12 (HCV RNA <15 IU/mL 12 weeks after study treatment completion) and a comparison of the safety and tolerability of EBR/GZR in the ITG relative to placebo treatment in the DTG. All patients provided written informed consent.
Results: Mean age was 44 years; 75% male; 18% black; 40% GT1a; 44% GT1b; 11% GT4; 26% cirrhotic; 50% TE; 6% HIV/HCV co-infected; 43% HEM/VWD; 38% BTHAL; 18% SCA. SVR12 was achieved by 93.5% (100/107) patients receiving EBR/GZR in the ITG. Of the 7 patients who failed to attain SVR12, 6 patients relapsed and 1 patient discontinued treatment early with noncompliance and did not participate further in the study. SVR12 was high in all blood disorder groups (Table 1). There were 3 (2.9%) patients with serious adverse events (SAEs) (1 drug-related, 2 related to IBLD) in the ITG with no discontinuations due to safety events. In the DTG, 1 patient discontinued due to AEs and 1 withdrew consent; 6/52 (11.5%) had SAEs (1 drug-related, 3 related to IBLD). No patient in either arm prematurely discontinued from the trial due to worsening of underlying IBLD. There was 1 hepatic event of clinical interest (alanine aminotransferase >3× baseline and >100 U/L) in each arm.

Table 1. SVR12 in the ITG (full analysis set population).

Description	SVR12† [n/N (%)]
Overall ITG	100/107 (93.5)
HEM/VWD	42/47 (89.4)
BTHAL	40/41 (97.6)
SCA	18/19 (94.7)
Cirrhosis	26/26 (100)

†Hepatitis C virus RNA IU/mL 12 weeks after completion of treatment.

Summary/Conclusions: EBR/GZR is well tolerated and effective in patients with HCV GT1, 4, or 6 with or without cirrhosis with IBLD.

P770

DOES HIGH HISTONE LEVEL LEAD US TO DETERMINE COAGULOPATHY EARLY AFTER TRAUMA IN PEDIATRIC PATIENTS?
E Ulusoy[1], M Duman[1], A Çağlar[1], T Küme[2], A Er[1], F Akgül[1], H Çitlenbik[1], D Yılmaz[1], H Oren[3,*]
[1]Pediatric Emergency Care, [2]Biochemistry, [3]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, Izmir, Turkey

Background: Acute traumatic coagulopathy occurs after trauma with impairment of hemostasis and activation of fibrinolysis. Some endogenous materials may take role on this failure of coagulation system. Extracellular histone is one of the molecules taking attention recently.
Aims: This study investigated the association between plasma histone complexed DNA fragments (hcDNA) and coagulation abnormalities in pediatric trauma patients.
Methods: This case control study conducted in pediatric patients with multipl trauma or isolated brain injury. Fifty trauma patients and 30 healthy controls were enrolled. Demographic data, anatomic injury characteristics, coagulation parameters, computerized tomography findings, trauma and thrombosis scores were recorded. Venous blood samples for hcDNA were collected into two hours after injury and assessed by enzyme linked immunosorbent assay.
Results: Eighteen patients had isolated brain injury, 32 patients had multiple trauma. Twenty seven patients had mild, 11 patients had moderate and 12 patients had severe trauma according to Glasgow Coma Scale. Although no patient had overt disseminated intravascular coagulation, 13 patients had acute coagulopathy of trauma shock (ACoTS). Plasma hcDNA levels were significantly higher in trauma patients than healthy controls (0.474 AU and 0.145 AU, respectively). There was an association between plasma hcDNA levels and trauma severity according to Glasgow Coma Scale, Pediatric Trauma Score, Injury Severity Score. AcoTS patients had higher plasma histone levels than without AcoTS (0.703 AU and 0.398 AU; respectively). Plasma hcDNA levels were significantly correlated with the International Society of Thrombosis and Hemostasis score, length of intensive care unit stay, prothrombin time, D- dimer levels, and also there were negative correlations with fibrinogene levels and pediatric trauma scores.
Summary/Conclusions: This study indicated for the first time that hcDNA levels increase in pediatric trauma patients associated with coagulopathy. Further studies are needed to clarify the role of high hcDNA levels in determining the functional significance of these changes in disseminated intravascular coagulation and predicting mortality.

AAV-MEDIATED GENE THERAPY FOR HEMOPHILIA B-EXPRESSION AT THERAPEUTIC LEVELS WITH LOW VECTOR DOSES
KA High[1], L George[2], S Sullivan[3,*], A Luk[1], T Urich[1], J Teitel[4], A Cuker[5], F Wright[1], Y Chen[1], D Hui[1], K Wachtel[1], A Galvao[6], LE McMillan[7], D Takefman[1], ME Carr[8], L Couto[1], X Anguela[1]
[1]Spark Therapeutics, [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, [3]University of Mississippi Medical Center, Jackson, [4]St. Michael's Hospital, Toronto, [5]Perelman School of Medicine of the University of Pennsylvania, [6]The Children's Hospital of Philadelphia, Philadelphia, [7]The University of Mississippi Medical Center, Jackson, [8]Pfizer, Philadelphia, United States

Background: Published data from Nathwani *et al.* (NEJM 2014) demonstrated long-term expression of Factor IX in men with hemophilia B infused with an AAV8 vector expressing wild-type Factor IX. However, levels of expression ranged from 1.4%>2.2% normal at the lowest dose (2 x 10^{11} vector genomes [vg]/kg body weight) to 2.9-7.2% normal at the highest dose (2 x 10^{12}vg/kg). Moreover, 4/6 subjects infused at the highest dose required a course of prednisolone to reduce rising transaminases associated with the highest dose (but not observed at the lower doses of 2 x 10^{11} or 6 x 10^{11} vg/kg). Data from a natural history study of patients with hemophilia by den Uijl *et al.* suggest that circulating levels of ~12% are required to eliminate spontaneous joint bleeds (Haemophilia 2011).
Aims: We sought to develop a high specific activity vector that would drive therapeutic levels of FIX activity at doses low enough to avoid the need for immunomodulation with steroids.
Methods: We developed a vector containing: 1) a novel bioengineered AAV capsid with tropism for liver; and 2) a Factor IX expression cassette that carries a strong liver-specific promoter driving the expression of FIX Padua (R338L). The Padua variant shows an ~8-fold increase in specific activity compared to wild-type FIX (Simioni *et al.*, NEJM 2009). Based on studies in non-human primates, we predicted that therapeutic FIX activity levels, >10%, would be attained at doses as low as 5 x 10^{11} vg/kg. We further predicted that the ability to observe therapeutic levels of FIX activity at lower doses of vector would limit potential need for a course of immunomodulation with steroids.
Results: Here we report data on the first three subjects with severe hemophilia B infused with this novel vector. The first two subjects, ages 23 and 18 respectively, had no prior history of liver disease, while the third, age 47, had a history of HCV infection but had cleared spontaneously. These subjects had been screened for neutralizing antibodies to the novel AAV capsid and found to be negative. Subjects were infused intravenously with *SPK-FIX* at a dose of 5 x 10^{11} vg/kg over a period of ~1 hour. FIX activity levels (shown in Figure 1) in the first two subjects have plateaued at 28% and 30% respectively at 18 and 7 weeks post infusion, while subject #3 is currently at 16% 3 weeks after infusion. Subject #3 treated himself with an extended half-life product for a suspected ankle bleed 2 days after vector infusion; other than this there have been no other factor infusions and no bleeds in the 28 cumulative weeks of observation. There have been no transaminase elevations higher than 1.5 times upper limit of normal, and steroids have not been administered to any subjects thus far. ELISPOTs were used to monitor T cell responses to AAV and to FIX in all subjects and have shown no or very low responses. Of note, the time course of rise in Factor IX levels to a plateau level has been remarkably consistent among the three subjects to date.

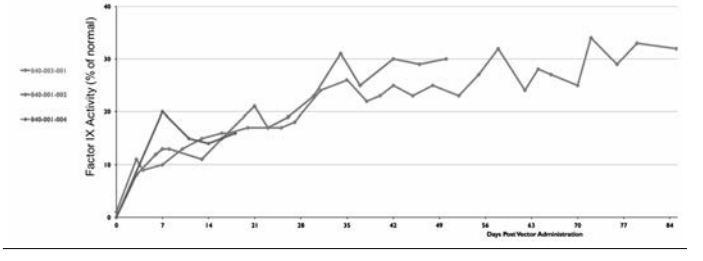

Figure 1.

Summary/Conclusions: Conclusion/Summary: We report the first clinical results using a novel bioengineered AAV capsid expressing a high specific activity FIX transgene. This has led to plateau FIX activity levels of 28% and 30% in the first two subjects infused, with no factor use since vector infusion. The development of a vector that can direct high level clotting factor expression at low doses, so that immunosuppression is not required, represents an important goal for liver-directed gene therapy.

Coagulation - Basic Research

RECOMBINANT THROMBOMODULIN AMELIORATES HEMATOLOGICAL MALIGNANCY-INDUCED DISSEMINATED INTRAVASCULAR COAGULATION MORE PROMPTLY THAN CONVENTIONAL THERAPY WITHOUT CAUSING SEVERE HEMORRHAGIC EVENTS

N Kurita*, Y Yokoyama, H Muto, T Kato, M Sakata-Yanagimoto, N Obara, Y Hasegawa, S Chiba
Department of Hematology, University of Tsukuba, Tsukuba, Japan

Background: Disseminated intravascular coagulation (DIC) is a lethal complication in patients with hematological malignancies. Although standard therapy against DIC remains to be established, soluble recombinant thrombomodulin (rTM), which serves as a receptor for thrombin, has been developed as a promising anti-DIC agent. However, the position of rTM needs to be determined in the treatment of DIC associated with hematological malignancy.
Aims: We retrospectively compared outcome of hematological malignancy-related DIC treated with rTM or other conventional anticoagulant therapies in order to clarify the effectiveness of rTM.
Methods: Consecutive DIC episodes of 217 in 195 patients with hematological malignancies (AML except for APL, 69; APL, 26; ALL, 27; NHL, 44; myeloma, 12; CML, 7; other; 10) hospitalized between January 2004 and Dec 2015 in University of Tsukuba Hospital were analyzed using medical records. Diagnosis of DIC was based on the DIC scoring system proposed in the Japanese Ministry of Health and Labor Welfare criteria (Kobayashi *et al.,* Bibl Haematol 1983). DIC was induced by hematological malignancy itself (h-DIC) or severe infection secondary to hematological malignancy (i-DIC) in 140 and 77 episodes, respectively. In 125 episodes, 380 units/kg/day of rTM was administered intravenously from the onset of DIC for median of 6 (range, 1-41) days. Other DIC episodes were treated with conventional anticoagulant therapies (low molecular weight heparin, 65; gabexate mesilate, 16; other anticoagulants, 11) for median of 11 (range, 1-30) days. Every anticoagulant therapy was accompanied by treatment for DIC-causing disease. We compared recovery time from DIC (the day when the DIC score was decreased to 5 or less), overall survival, and severe hemorrhagic events related to the treatment, between rTM- and conventional anticoagulant-treated groups.
Results: Bleeding tendency was documented in 63 DIC episodes at the onset. In h-DIC, recovery from DIC was significantly more prompt in rTM-treated group than conventional therapy group with the recovery rates of 55% (95% CI: 43-65) and 32% (95% CI: 21-44), respectively at day 7 after the therapy initiation (P=0.03, Figure 1). By contrast, recovery from i-DIC was significantly worse than that from h-DIC, and was not influenced by anticoagulant therapies; recovery rates from i-DIC at day 7 were 23% (95% CI: 13-36) in the rTM-treated group and 33% (95% CI: 17-50) in the conventional therapy group (P=0.6). Day 60 overall survival rates in h-DIC were 81% (95% CI: 69- 88) and 79% (95% CI: 65 - 88) in the rTM-treated and conventional therapy groups. In i-DIC, on the other hand, 35% (95% CI: 21-49) and 38% (95% CI: 32 - 55) survived with the rTM and conventional therapies, respectively. Severe hemorrhagic events that led to discontinuation of anticoagulant therapy was significantly less in the rTM-treated group (3%; 95% CI, 0-7) compared with that in the conventional therapy group (15%; 95% CI: 5-23; P=0.02).

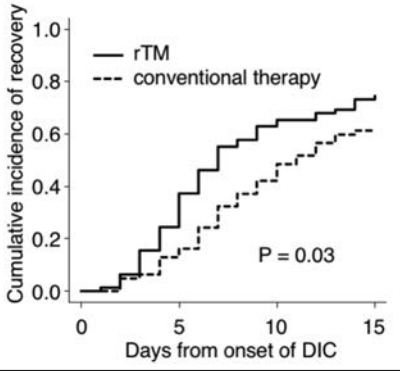

Figure 1. Recovery from h-DIC.

Summary/Conclusions: The recovery from h-DIC treated with rTM was more prompt compared to that with conventional anticoagulant therapy, although survival was not influenced by the therapy. We emphasize that rTM can be an effective anti-DIC agent without causing adverse hemorrhagic events even in DIC cases with preexisting bleeding tendency. However, the outcome was still significantly worse in i-DIC secondary to hematological malignancies even after introduction of rTM. Further development of anticoagulant therapy is required particularly for the control of i-DIC.

P772

EXTRACELLULAR HISTONES ENHANCE FACTOR XA MEDIATED PROTHROMBIN ACTIVATION WITHOUT PHOSPHOLIPID REQUIREMENT

Y Sahraoui[1,*], S Abrams[1], D Su[1], Y Alhamdi[1], J Foley[2], G Wang[1], CH Toh[1,3]
[1]Institute of Infection and Global Health, University of Liverpool, Liverpool, [2]Katharine Dormandy Haemophilia and Thrombosis Centre, Royal Free Hospital, London, [3]Roald Dahl Haemostasis & Thrombosis Centre, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Thrombin generation *in vivo* is central to coagulation activation and its dysregulation is pivotal to the development of disseminated intravascular coagulation (DIC) and multiple organ failure (MOF). Typically, thrombin is generated when the prothrombinase complex, composed of activated factor X (FXa), activated co-factor V (FVa) and phospholipids, cleaves prothrombin in the presence of calcium. Whilst histones form the basis of chromatin within cells, circulating histones released after extensive cellular injury are significantly elevated in critically ill patients with associations to enhanced thrombin generation. However, the underlying pathophysiological mechanism remains to be fully elucidated.
Aims: To characterise the mechanistic role of elevated extracellular histones in enhancing thrombin generation in critical illness.
Methods: Histone-prothrombin interactions were determined by binding assays. Thrombin generation was evaluated by *in vitro* prothrombin cleavage and thrombin generation assays.
Results: Here, we demonstrate that extracellular histones promote thrombin generation by acting as a co-factor to FXa. Unlike FVa which requires a phospholipid surface to form functional prothrombinase complexes, histones can substitute for FVa in the absence of phospholipids. The addition of histones to $FV^{-/-}$ deficient plasma restored thrombin generation, suggesting that histones can bypass FVa to induce thrombin generation. Mechanistically, histones directly bind to prothrombin (H3 [$Kd=6.8x10^{-7}$ M] and H4 [$Kd=7.0x10^{-7}$ M]), to facilitate FXa-induced prothrombin cleavage and thrombin generation (H4 [12.25±1.25 fold] and H3 [8.82±0.67 fold]). FXa levels are the limiting factor of histone-enhanced thrombin generation since this process was inhibited in $FX^{-/-}$ plasma unless exogenous FXa was added. Specifically, using either heparin or specific anti-histone antibodies to block histones, histone-prothrombin interactions, prothrombin cleavage and subsequent thrombin generation were significantly reduced.
Summary/Conclusions: This novel role for extracellular histones in increasing thrombin generation, independent of FVa, may offer insight into the underlying pathological mechanism for systemic dissemination of thrombin generation in critical illness. Importantly, it identifies circulating histones as a potential target for therapeutic intervention in reducing the development of DIC and subsequent MOF in critical illness.

PHORBOL 12-MYRISTATE-13-ACETATE INDUCES VON WILLEBRAND FACTOR PROPEPTIDE RELEASE FROM ENDOTHELIAL CELLS FROM 2 DISTINCT COMPARTMENTS

R Bierings[1,2,*], L Knipe[1], N Hellen[1,3], I Conte[1,4], T Carter[1,4]
[1]The Francis Crick Institute, London, United Kingdom, [2]Plasma Proteins, Sanquin Research, Amsterdam, Netherlands, [3]National Heart and Lung Institute, Imperial College, [4]Cardiovascular and Cell Science Research Institute, St. George's University, London, United Kingdom

Background: Von Willebrand factor (VWF) and its propeptide (VWFpp) are stored for secretion within specialized endothelial secretory organelles called Weibel-Palade bodies (WPBs). Release of their content into the vascular lumen through a process called exocytosis enables the endothelium to actively participate in the arrest of bleeding and to slow down and direct leukocytes to areas of inflammation. WPBs undergo exocytosis upon stimulation with agonists that elevate intracellular free Ca^{2+} ($[Ca^{2+}]_i$) or cAMP concentrations.
Aims: Phorbol 12-myristate-13-acetate (PMA) is also a potent VWF secretagogue, and it is generally assumed that PMA-evoked VWF secretion arises solely from WPB exocytosis (the VWF storage compartment). Here we present evidence that PMA activated VWF release comprises an early (0-15 minutes) and a late (>15 minutes) component that originate from distinct intracellular compartments.
Methods: Using live cell imaging of WPB exocytosis in endothelial cells expressing fluorescently tagged WPB probes we have characterized PMA-evoked VWF secretion.
Results: A significant fraction of the early phase of PMA-evoked VWF secretion from human endothelial cells arises from a cycloheximide (CHX)-sensitive (*i.e.*, nascent or non-storage) compartment: stimulation for 15 minutes with either PMA (100 ng/ml) or histamine (100 µM) caused similar amounts of VWF secretion. However, prior inhibition of protein synthesis (10 µM CHX for 24 hours) reduced PMA-evoked secretion by ~70% while histamine-evoked secretion was unaffected. Optical analysis of live cells expressing VWFpp-EGFP targeted to WPBs showed that the first 15 minutes of histamine stimulation was associated with exocytosis of 41.4±4.0% (mean±sem, n=12) of fluorescent WPBs, compared to 8.4±2.1% (n=11) for PMA. The latter was independent of WPB matu-

ration state and for both stimuli, the percentage of fluorescent WPB exocytotic events was unaffected by CHX treatment. This suggests that the early phase of PMA-evoked VWF release originates from a compartment other than WPBs. Since VWFpp is proteolytically cleaved from proVWF in the *trans*-Golgi network (TGN), we focused on this compartment as the potential source of early PMA-evoked secretion. Phospholipase D (PLD) is a key enzyme regulating trafficking from the TGN. Inhibition of PLD with the pan-PLD inhibitor FIPI resulted in a reduction in the early phase of PMA-evoked VWFpp secretion, similar to that seen with CHX, although at later times VWFpp secretion was unaffected. Pre-incubation (10 minutes) with PMA (100 ng/ml) produced a profound shift in the Ca^{2+}-sensitivity of VWF secretion, to close to resting levels.
Summary/Conclusions: Together the data suggest that at early times PMA causes VWF release predominantly from a non-WPB compartment, most likely the TGN, while at later times WPB exocytosis accounts for the majority of secreted VWF. The slow onset in PMA-evoked WPB exocytosis could reflect a time-dependent shift in the Ca^{2+}-sensitivity of exocytosis. Our data help clarify the mechanisms by which PMA induces VWF secretion in endothelial cells, and highlight the need for care when interpreting PMA-evoked secretion data in terms of the underlying mechanisms regulating WPB exocytosis.

NEWLY DIAGNOSED PLASMA CELL DYSCRASIAS ARE ASSOCIATED WITH ENHANCED TF PATHWAY ACTIVATION, THROMBIN GENERATION AND INCREASED CONCENTRATION OF PROCOAGULANT MICROPARTICLES
D Fotiou[1], F Zagouri[1], TN Sergentanis[1], K Stametelopoulos[1], T Psaltopoulou[1], E Kastritis[1], E Terpos[1], I Efmorfiadis[2,3], A Rousseau[3], P Van Dreden[4], I Elalamy[2,3], AK Larsen[3], MA Dimopoulos[1,5], G Gerotziafas[2,3,*]
[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, Athens, Greece, [2]Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, [3]Cancer Biology and Therapeutics, INSERM U938, Institut Universitaire de Cancérologie (IUC), Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Paris, France. Faculté de Médecine Pierre et Marie Curie, Paris, [4]Clinical Research Department, Diagnostica Stago, Gennevilliers, France, [5]School of Medicine, Kapodistrian University of Athens, Athens, Greece

Background: Multiple myeloma (MM) and other plasma cell dyscrasias (PCD) as well as the associated immunomodulatory treatments are linked to increased risk of venous thromboembolism (VTE). The identification of patients at VTE risk and the optimization of VTE prevention is an unmet medical need. Elaboration of a risk assessment model (RAM) specific for patients with PCD, which includes biomarkers of hypercoagulability, could improve the management of VTE risk.
Aims: We conducted a longitudinal observational study, to explore the relationship of MM with cellular and plasma hypercoagulability aiming to identify the most relevant biomarkers for use in a RAM for VTE in combination with clinical risk factors.
Methods: Newly diagnosed patients with PCD (n=186) were recruited from July 2014 to Dec 2015; including 27 with monoclonal gammopathy of undetermined significance (MGUS), 40 with asymptomatic multiple myeloma (AMM), 79 with multiple myeloma (MM), 30 with AL-amyloidosis, 8 with Waldenstrom's Macroglobulinemia (WM) and 2 with solitary plasmacytoma. They were compared against 30 healthy age and sex-matched individuals (CG). A systematic compression ultrasound was performed at baseline and at 6-12 months. Blood samples were obtained at diagnosis and at 6-12 months (n=89). Samples of platelet-poor plasma were assessed for thrombin generation (TG) with PPP-Reagent® (TF 5pM and 4 μM phospholipids), P-selectin, D-dimers (D-Di), activated FVII (FVIIa), Tissue Factor (TFa), fibrin monomers (FM), and procoagulant phospholipid-dependent clotting time (Procag-PPL). The upper and lower normal limits (UNL and LNL) were calculated by the mean±2SD.
Results: Median age was 67 years (37-89) and 49% of the population was male. Median time to follow up was 7 months (1-12 months). Among MM cases (n=79) symptomatic VTE rate was 10% (n=8) and mortality rate 7.5%. The events included 2 central venous catheter thromboses, 1 Pulmonary Embolism, 2 Deep vein thromboses, 2 superficial vein thromboses and 1 mesenteric vein thrombosis. Cases had significantly shorter PPL-ct, higher FTa and DDi, TG (increased Peak), heparanase and P-selectin compared to controls (p<0.001). Along the MGUS- AMM- MM continuum, D-Di concentration (p<0.0001), FM concentration (p<0.05), lag time (p<0.027) and MRI were highest in MM patients. Sixty percent of MM patients had Procoag-PPL: below the LNL, in 63% TFa levels were above the UNL, and 31% had MRI lower than LNL. After 6 months of treatment, FTa, DDi, MRI, peak thrombin and P-selectin levels decreased (p<0.05) and TM and ATIII levels increased (p<0.05).
Summary/Conclusions: In patients with PCD, increased procoagulant microparticles of cellular origin is a generalized phenomenon. In addition, patients with MM, are at high risk of VTE and present with significant TF pathway activation and increased TG. A significant fraction, but not all, of the patients present strong signs of plasma hypercoagulability. The finding of high inter-individual variability of TG underlines the heterogeneity of blood coagulation alterations in PCD patients. The data of the prospective part of this study will allow validation of the clinical significance of this finding.

P775

ROLE OF ROTATIONAL THROMBELASTOMETRY (ROTEM®) IN RAPID ESTIMATION OF RIVAROXABAN DRUG LEVEL
H Chuah[1,2,*], D Pepperell[2], M Leahy[1], T Dixon[3], A Mukhtar[4,5], M Kesavan[2,6], J Ling[7], D Sankhesara[7], P Brownell[7], S P'ng[2]
[1]Haematology Department, Royal Perth Hospital, Perth, [2]Haemophilia and Haemostasis Centre, Fiona Stanley Hospital, [3]PathWest Laboratory Medicine, Fiona Stanley Hospital Network, Murdoch, [4]Centre for Population Health Research, Curtin University, Bentley, [5]Western Australia Country Health Service, Department of Health, Perth, [6]University of Western Australia, Crawley, [7]Fiona Stanley Hospital, Murdoch, Australia

Background: Rivaroxaban, a direct factor Xa inhibitor, allows the use of fixed dosing schemes and eliminates the need for routine coagulation monitoring. However, rapid assessment of the degree of rivaroxaban anticoagulation is required in certain scenarios, *e.g.* major haemorrhage, before thrombolysis or urgent surgery. Clinically significant Rivaroxaban drug levels have been proposed between 30-50ng/mL using a calibrated anti-Xa assay, but the turnaround time for the test is slow. Therefore, rapidly available results using a point-of-care haemostasis test like ROTEM® might be beneficial in these scenarios.
Aims: The aim of this study was to evaluate the role of conventional rotational thrombelastometry (ROTEM®) and modified low tissue factor activated ROTEM® (LowTF-ROTEM®) in estimating rivaroxaban drug level in in-vivo setting.
Methods: In this multicenter study, we analysed 77 patients receiving Rivaroxaban for therapeutic indications including treatment of venous thromboembolism, long-term prevention of recurrent venous thromboembolism and stroke prevention in non-valvular atrial fibrillation. Patients' citrated whole blood samples were tested on the ROTEM® delta analyser using commercially prepared EXTEM reagent according to manufacturer's instructions. Modified low tissue factor ROTEM® test was also performed, using a recombinant tissue factor reagent (Siemen's INNOVIN), used at a dilution of 1:1000 of the normal working concentration used for INR testing. Patients' Rivaroxaban levels (ng/mL) were determined in citrated platelet poor plasma by analysis on the Stago STA-R Evolution analyser, using a chromogenic anti-Xa method (Diagnostica Stago Liquid anti-Xa), paired with specific Rivaroxaban calibrators and controls (Diagnostica Stago).
Results: The relationship between ROTEM® clotting time (CT) and Rivaroxaban level is of moderate strength (R^2=0.461). Based on this relationship, we are 95% confident that for ROTEM® CT of 61 seconds or less, Rivaroxaban level will be less than 50 ng/ml. For prediction of clinically significant Rivaroxaban levels of >50ng/mL, ROTEM® CT has a positive predictive value of 81% and negative predictive value of 100%. The relationship between LowTF -ROTEM® clotting time (CT) and Rivaroxaban level is of a low strength (R^2=0.142) (Figure 1).

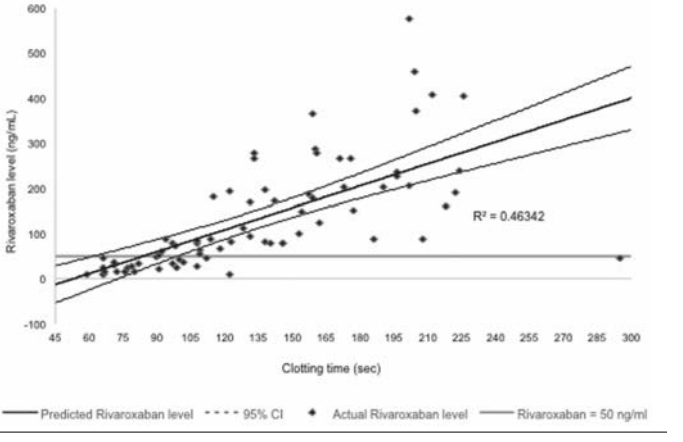

Figure 1.

Summary/Conclusions: ROTEM®, a point-of-care test, has utility in excluding clinically significant Rivaroxaban level, which may be critical for patients requiring urgent surgery or thrombolysis.

P776

PLATELET DERIVED MICROPARTICLES, AGGREGATES AND MARKERS OF IMMUNE ACTIVATION AND DISEASE PROGRESSION IN HIV INFECTED TREATMENT NAIVE ASYMPTOMATIC INDIVIDUALS
B Nkambule[1,*], G Davison[2], H Ipp[3]
[1]Laboratory Medicine and Medical Science, University of Kwazulu-Natal, Durban, [2]Biomedical Science, Cape Peninsula University of Technology, Bellville, [3]Pathology, Stellenbosch University, Cape Town, South Africa

Background: Chronic immune activation in human immunodeficiency virus (HIV) infection induces activation of leucocytes and platelets, resulting in the

formation of microparticles (MPs). Platelet microparticles (PMPs) are prothrombotic and have been described in inflammatory disease. Increased levels of platelet aggregation have been reported in HIV. PMP levels may be a more sensitive marker of platelet activation, compared to surface CD62P expression on activated platelets.
Aims: We aimed at measuring MPs, PMPs and platelet aggregates in HIV infected individuals, using flow cytometry based whole blood assay. Optimised to ensure artefactual platelet activation is kept minimal by omitting any centrifugation and platelet isolation steps. Moreover, we aimed at evaluating associations between MPs, PMPs, platelet aggregates and markers of immune activation and disease progression in asymptomatic treatment naïve HIV infected individuals.
Methods: Forty-Eight (48) antiretroviral therapy (ART) naïve HIV infected and 40 uninfected individuals were recruited in a clinic in Cape Town. Microparticles (MPs), Platelet microparticles (PMPs), platelet aggregates and platelet P-selectin CD62P were measured using flow cytometry. These were then correlated with CD4 count, viral load and %CD38 on CD4+ T cells.
Results: HIV infected individuals showed increased levels of median platelet %CD62P 2.93[1.23-12.88] *vs* control 1.15[0.19-3.59]; circulating MPs HIV group median 1.7[0.95-2.83] *vs* 1.12[0.63-1.57] Control group, p=0.0160; levels PMPs median %PMPs 26.64[11.33-36.62] *vs* control 20.02[18.08-26.08], p=0.0133. In the HIV group, levels of activated platelets correlated with; platelet aggregates (r=0.5530, p=0.011); activated PMPs (r=0.594, p=0.007). Baseline %platelet aggregates were similar between the groups. However the platelet aggregates in the HIV group showed increased levels of activation, platelet aggregates median %CD62P 14.10[5.49-39.94] *vs* 0.17[0-10.99] control group, p=0.0097. The HIV group showed increased levels of immune activation, median %CD38 on CD8+ cells 24.03[15.76-43.92] *vs* control 9.23[6.8-12.96], p<0.0001. In the HIV group levels of %CD38+ CD8+ T cells correlated with; %PMPs (r=0.4730, p=0.0196), %MPs (r=0.4386, p=0.025) and %PLT aggregates (r=0.321, p=0.135). In the HIV group %MP showed no correlation with; CD4+T cell count (r=-0.026, p=0.894); Viral load (r=0.207, p=0.355). %PMPs also showed no correlation with Viral load (r=0.152, p=0.511), CD4+ T cell count (r=0.-0.361, p=0.07).
Summary/Conclusions: We describe an optimized whole blood flow cytometry based assay for the evaluation of circulating MPs, PMPs and levels of activated platelets and aggregates. That mimics the *In vivo* physiological environment of MPs. Furthermore we report on increased levels of circulating MPs and PMPs in HIV infected asymptomatic individuals. We also describe increased levels of activated PMPs and platelet aggregates in HIV.

Background: Paroxysmal nocturnal hemoglobinuria (PNH) clones have been rarely observed in association with atypical site venous thrombosis, mainly of the splanchnic veins, in absence of a known PNH diagnosis.
Aims: Primary aim of the current study was to evaluate the incidence of PNH clones in patients with a first episode of thrombosis localized at the cerebral sinus veins (CVT). Patients without known PNH were tested for PNH clone by high-sensitivity flow cytometric analysis on peripheral blood at CVT diagnosis.
Methods: All the enrolled patients had an objectively confirmed first episode of CVT. At enrollment, an accurate personal and familial clinical history was taken and a complete determination of known inherited and acquired risk factors for venous thromboembolism was performed. At CVT diagnosis, patients were assayed for PNH clone on peripheral blood at their enrolling institutions. In case of a positive PNH clone determination, a second sample was centrally assayed at the laboratory of the Study Coordinating Center at " Ospedale Ferrarotto", Catania. All PNH clone assays were performed using a high-sensitivity multiparameter flow cytometric analysis able to identify an abnormal population of >0.01% PNH cells. Enrolled patients underwent standard anticoagulant treatment for CVT and a two years clinical follow-up after diagnosis. If any sign or symptom of venous thrombosis recurrences occurred, a PNH clone was tested again. Descriptive statistic was adopted for the purpose of this study. The study was conducted in accordance with the Declaration of Helsinki and Ethics Committee approval was obtained at each enrolling center. Data were collected in a dedicate database
Results: Seventy seven subjects were enrolled (40 Females, 37 males; mean age: 41 years, range 19-87). Anticoagulant treatment was administered for a mean of six months (range:4-13 months); warfarin was administered in 64.9% of patients, Low Molecular Weight Heparin in 35.2% of patients. Adverse events related to anticoagulant therapy were not reported. CVT was associated with factor V Leiden gene mutation at heterozygous state in 5 patients (6.5%), FII (G20210A) gene mutation at heterozygous state in 6 patients (7.8%), JAK2 V6167F in 2 (2.5%) patients, Protein S deficiency in one case (1.2%), Lupus Anticoagulant and anti-phospholipid antibodies in five cases (6.5%), combined inherited and acquired risk factors in 3 cases (3.8%), recent surgery in 10.2%, oral contraceptives in 6.4% and pregnancy in 3.8% cases. Among screened patients, 38 (49.3%) did not have any of the known risk factor for venous thromboembolism. The incidence of PNH clones observed in our cohort was of 2.5%. PNH clones were detected in 2 cases: in one patient a small one (size 0.08%) was not further confirmed at the centralized determination, while in another case a clear demonstrable clone (size 1.5%) was confirmed on two consecutive independent determinations. The patient (a 27 years old Caucasian female) had a positive familial history of venous thromboembolism and an otherwise unremarkable personal thrombophilia screening, in absence of any symptom or other laboratory sign of PNH. Two venous thrombosis recurrences occurred at two years follow-up, both cases without any evidence of PNH clones.
Summary/Conclusions: Testing for PNH can be taken into account as part of the standard etiology-screening in atypical site venous thrombosis.However, at the present it is not clear whether detection of relatively small PNH clone, in absence of other signs and symptoms suggestive for PNH, may suggest specific therapy beyond anticoagulation.

P779

REGULATION OF WEIBEL-PALADE BODY EXOCYTOSIS FROM ENDOTHELIAL CELLS BY SYNTAXIN-3 AND STXBP5 CONTAINING SNARE COMPLEXES

M Schillemans[1], D van Breevoort[1], M Hofman[1], M Wahedi[1], A Gangaev[1], H Meems[1], M van den Biggelaar[1], R Adam[2], H Janssen[3], S Meijer[1], J Voorberg[1], R Bierings[1,*]
[1]Plasma Proteins, Sanquin Research, Amsterdam, Netherlands, [2]Pediatric Gastroenterology, University Medical Centre, Mannheim, Germany, [3]Cell Biology, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Immediate release of a pre-stored cocktail of hemostatic, inflammatory and angiogenic mediators from endothelial secretory organelles, Weibel-Palade bodies (WPBs), forms the first line of defense of the vessel wall in response to vascular trauma. By releasing Von Willebrand factor (VWF), the main component of WPBs, the endothelium actively participates in the arrest of bleeding. This process also directs leukocytes to sites of inflammation. Dysregulation of VWF levels is associated with cardiovascular disease or can result in a bleeding tendency, such as Von Willebrand disease. Several components that are critical for regulated WPB exocytosis have been identified, including the small GTPase Rab27A and its effector Slp4-a, but the mechanism remains unclear. We have previously identified syntaxin binding protein 1 (STXBP1) as an endogenous Slp4-a binding partner involved in WPB release, along with the SNARE protein syntaxin-3.
Aims: In this study we investigated the possible role of syntaxin-3 in WPB trafficking and exocytosis.
Methods: The subcellular location of syntaxin-3 in endothelial cells was characterized using immunocytochemistry and density gradient ultracentrifugation. Iterative interactomics was performed to map the interacting proteome of syntaxin-3 and STXBP5.
Results: Interestingly, we found that the t-SNARE syntaxin-3 was primarily associated with WPBs. To further explore its role in WPB biology we mapped the endothelial interactome of syntaxin-3 through an unbiased label-free mass spectrometry approach. Among its interaction partners are various SNAREs and associated proteins such as syntaxin binding proteins 2 and 5 (STXBP2/5), N-ethylmaleimide-sensitive factor (NSF), SNAP23 and α-SNAP, suggesting we successfully pulled down a SNARE complex and its regulatory machinery that are involved in exocytosis. Taking forward one of the candidate, STXBP5, we found that silencing of STXBP5 expression using siRNA potentiated agonist-induced VWF release from endothelial cells, which suggests it acts as a negative regulator of WPB exocytosis. We narrowed down the inhibitory role of STXBP5 to the C-terminal Vamp-like domain (VLD), which interacts with syntaxins and attenuates histamine-induced VWF secretion upon lentiviral expression in endothelial cells. To further investigate the role of syntaxin-3 in endothelial cells we isolated blood outgrowth endothelial cells (BOECs) of a patient suffering from variant microvillous inclusion disease (MVID), a severe gastrointestinal disorder, caused by a homozygous mutation in *STX3* that leads to complete syntaxin-3 deficiency. WPBs of MVID BOECs are entirely devoid of syntaxin-3, display immature WPB morphology and have a reduced secretory potential when challenged with histamine.

Summary/Conclusions: Our data show that WPB exocytosis is regulated by a complex interplay between the WPB-associated SNARE syntaxin-3 and STXBP5.

COMPARISON OF QUALITY OF LIFE BETWEEN LONG-TERM SURVIVORS OF INDOLENT AND AGGRESSIVE LYMPHOMA: RESULTS OF A SINGLE CENTER PROSPECTIVE COHORT STUDY

SJ Kim[1,*], WS Kim[1], J Cho[2], D Kang[2]
[1]Medicine, [2]Health Sciences and Technology, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Lymphoma is a basically curable disorder by chemotherapy and or radiotherapy. As clinical features and treatment outcomes are different according to subtypes of lymphoma, the various treatment strategies have been applied from intensified treatment such as high-dose chemotherapy followed by autologous stem cell transplantation to observation without any treatment. Thus, patients experience different treatments based on the nature of their diseases so-called indolent and aggressive lymphomas. However, there is limited ata about the health-related quality of life of long-term survivors of indolent and aggressive lymphoma.
Aims: The primary objective is to evaluate the health-related quality of life at diagnosis and after treatment in long-term survivors of indolent and aggressive lymphomas. The secondary objective is to evaluate psychosocial wellbeing in long-term survivors such as fear of recurrence, social support and spiritual well-being.
Methods: Patients were diagnosed with Hodgkin and non-Hodgkin lymphoma according to the diagnostic criteria of the World Health Organization between 2008 and 2011. Patients were enrolled into the Samsung Medical Center Prospective Cohort Study (NCT#01877109) and their health-related quality of life was assessed by the EORTC QLQ-C30. The follow-up evaluation of the health-related quality of life was done with long-term survivors in 2014. The quality of life at the time of diagnosis was compared with that of patients at the time of long-term follow-up, and they were compared according to indolent and aggressive lymphomas.
Results: Among 953 patients registered in the cohort study, 642 alive patients were requested to conduct the follow-up survey about their health-related quality of life. As we failed to get response from 242 patients due to refusal to respond, follow-up loss, and incomplete survey, we analyzed 400 patients' health-related quality of life and psychosocial wellbeing. 305 patients were diagnosed with aggressive lymphoma such as diffuse large B-cell and peripheral T-cell lymphoma whereas 95 patients were diagnosed with indolent lymphoma such as follicular and marginal zone lymphoma. The socioeconomic characteristics such as age, marital status, monthly family income, education and working status were not significantly different between indolent and aggressive lymphomas. Although the baseline health-related quality of life was significantly better in patients with indolent lymphoma that aggressive lymphoma, the follow-up survey showed the improvement of quality of life in patients with aggressive lymphoma. However, several aspects of psychosocial wellbeing such as fear of recurrence, social support, happiness, satisfaction and life purpose were impaired in patients with indolent and aggressive lymphoma (Figure 1).

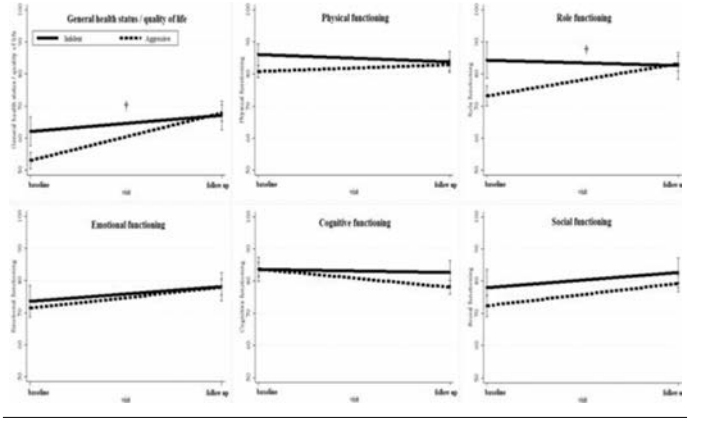

Figure 1.

Summary/Conclusions: The health-related quality of life could be recovered in long-term survivors with indolent and aggressive lymphoma after treatment. However, a majority of long-term survivors still suffer from impaired psychosocial wellbeing, especially fear of recurrence. Thus, more education about disease course and support for psychosocial wellbeing could be helpful for long-term survivors with lymphoma.

P781

IMPACT OF IRON DEFICIENCY ON QUALITY OF LIFE AND WORK CAPACITY OF WOMEN

L Caramelo[1,*], A Mezzacasa[2], D Mansour[3]
[1]Global Communications and Public Affairs, [2]Global Medical Affairs, Vifor Pharma, Glattbrugg, Switzerland, [3] Sexual Health, Newcastle upon Tyne Hospitals NHS Foundation Trust, New Croft Centre, Newcastle upon Tyne, United Kingdom

Background: The most severe stage of iron deficiency (ID), iron deficiency anemia (IDA)is a global problem, with the greatest prevalence among women and children.[1] IDA has been shown to negatively impact on cognitive performance and ability to concentrate and can result in fatigue.[1]
Aims: This survey aimed to gain an understanding of the awareness, prevalence and perceptions of ID/IDA within a European population.
Methods: An online, quantitative survey was carried out across Europe between in July and August 2015. The survey included respondents from the UK, France, Germany, Spain, Italy, Portugal and Sweden. In general the questionnaire was designed to take only 5 minutes. Respondents who reported a confirmed diagnosis of ID/IDA at some point in their lives completed a more in-depth questionnaire taking approximately 20 minutes.
Results: A total of 10,272 people completed the survey, with 7,025 aware of ID or IDA, and 934 of those having had a confirmed diagnosis of ID or IDA at some point in their lives.The awareness and prevalence of iron deficiency are higher amongst women than men (14% women *vs* 4% men). In general practice, heavy menstrual bleeding (HMB) is recognized as the primary cause of ID/IDA in women.[2] This was reflected in public perception, with 59% associating heavy periods or menstruation as the main cause of ID/IDA in women, and 50% of women ranking it among the top 5 causes. Results from the survey show that 28% of patients suffer from HMB in addition to their ID/IDA. The first symptom experienced most frequently was tiredness/fatigue, which was also the main driver for patients to seek medical help (54% reported it as their reason for visiting an HCP). On average, people experienced symptoms for 2.5 years before visiting a doctor. 63% of all patients felt that their ID/IDA had a negative impact on their ability to concentrate, affecting a greater proportion of women than men (64% of female *vs* 55% of male patients). Concern over skin pallor was also greater for women (49% of female patients *vs* 36% of male felt their ID/IDA made them look ill). Patients reported that their ID/IDA had the greatest impact on their personal well-being (79% citing a slight or severe negative impact). The second most significant impact was on working life, affecting 49% of patients.
Summary/Conclusions: This survey highlights the greater impact of ID/IDA among women than men, reflected in awareness, prevalence and effect on concentration and working life. Recent epidemiological studies suggest that the gender gap for anemia (primarily caused by ID) is widening further.[1]

IRON DEFICIENCY: UNDERSTANDING PERCEPTIONS OF SUFFERERS AND THE GENERAL PUBLIC

L Caramelo[1,*], A Mezzacasa[2], NJ Kassebaum[3]
[1]Global Communications and Public Affairs, [2]Global Medical Affairs, Vifor Pharma, Glattbrugg, Switzerland, [3]Institute for Health Metrics and Evaluation, Department of Anesthesiology and Pain Medicine, Seattle Children's Hospital and University of Washington, Seattle, United States

Background: Iron deficiency anaemia (IDA) is the third-leading specific cause of global years lived with disability, impacting large portions of the global and European populations,[1] despite the availability of simple, effective treatment.
Aims: This survey aimed to gain an understanding of the level of awareness of iron deficiency (ID) and/or IDA amongst the general population, as well as perceptions of the disease and its symptoms.
Methods: A quantitative, online survey across Europe, UK, France, Germany, Spain, Italy, Portugal and Sweden was conducted in the period July 21st- August 21st, 2015. Approximately 1,000 participants from each nation, and representative of the population aged 18 years or over, were surveyed.
Results: A total of 10,272 people completed the survey, with 7,025 aware of ID or IDA and 934 of those reported having had a confirmed diagnosis of ID or IDA at some point in their lives. Tiredness/fatigue was the symptom most strongly associated with iron deficiency and IDA, followed by paleness. However, 36% of respondents who were aware of ID/IDA only knew the name and could not identify causes or symptoms. The main symptom leading patients to present to their General Practitioner (GP) was fatigue/tiredness (54%). 21% of patients did not experience symptoms before their diagnosis. In patients who experienced symptoms, these appeared an average of 9 months before they visited their GP, with a further 6 months required to receive a confirmed diagnosis. Despite having been diagnosed with ID/IDA, 11% of patients have never received a prescription for their ID/IDA. Patients felt that the most significant impact of their ID/IDA was on their personal well-being (79%), with 49% reporting a negative impact on their working life.
Summary/Conclusions: This survey revealed only low-level awareness of ID/IDA within the general European population. There is also a long delay between the appearance of symptoms and an appropriate diagnosis, despite the significant impact ID/IDA has on a patient's work and quality of life.

CIRS COMORBIDITY SCORE IS USEFUL FOR TREATMENT CHOICE AND PREDICT TREATMENT OUTCOME IN ELDERLY PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

J Poisson[1], N Carnel[1], T Guerekobaya[1], F Plassart[2], B Poujol[3], P Genet[1], A Andreoli[1], A Al Jijakli[1], Ta Botin Lopez[1], L Mesbah[1], L Sutton[1], D Chaoui[1,*]
[1]Hematology, [2]Pharmacy, [3]Geriatric, Centre Hospitalier Victor Dupouy, Argenteuil, France

Background: The Cumulative Illness Rating Scale (CIRS) seems to be a reliable tool for the evaluation of the burden of comorbidity in elderly cancer patients (Extermann M, J Clin Oncol 1998). CIRS score is widely used in chronic lymphocytic leukemia clinical trials to identify fit and unfit patients and influence therapeutic decision-making.
Aims: The aim of our study was to evaluate CIRS impact in elderly patients with other hematological diseases treated in real life.
Methods: This was a longitudinal, prospective, monocentric study. We focused on patients aged 70 or older who received their first cycle of chemotherapy between September 1st 2014 and August 31th 2015. We recorded the multidisciplinary treatment decision taken: curative, symptomatic and palliative treatment. Geriatric tools recorded (G8 score, CIRS score, sheet A SEGA (Short Emergency Geriatric Assessment) frailty score, ADL, IADL) were not used during treatment decision. The first course of chemotherapy was considered as the standard dose. We analyzed during the following chemotherapy courses: dose reduction, chemotherapy delaying, early discontinuation. Impact of geriatric tools especially CIRS comorbidity score, SEGA frailty score on treatment choice (palliative *versus* curative treatment) was performed in all patients included in our study (n=141). Analysis of CIRS and other geriatric tools impact on treatment chemotherapy adaptation was performed in 118 patients (exclusion of palliative and symptomatic treatments).
Results: during the one year period analysis, 141 patients >70 years old (70-95) were discussed during our weekly multidisciplinary meeting. Average age was 80. The most frequent hematological diseases were distributed as follow: NHL (32%), multiple myeloma (29%), CLL (13%) and MDS (8%). Twenty one percent of patients and 18% were assigned to Bendamustine and Bortezomib based chemotherapy. Other chemotherapy regimens included (CHOP and CHOP like treatment +/- rituximab (10%), 5-azacytidine (8%), IMID (8%). Palliative and symptomatic treatments decisions were taken in 11 and 12 patients respectively. At diagnosis, the median scheet A SEGA score was 6 (0-18) indicating that the subjects included were mostly not frail. Median CIRS total rate excluding hematological malignancy was 6 (0-18). High CIRS score (median 10) and SEGA score (median 12) were significantly associated with palliative treatment, p=0,001 and p=0,01 respectively. Regarding patients assigned to curative approach, treatment was prematurely stopped in 32% of patients, dose reduction in 30% and chemotherapy was delayed in 18%. Only 33% did not experienced one of these events. CIRS grade 3 or 4 and CIRS score >6 were strongly associated with early chemotherapy discontinuation (p=0,0014 and 0,0008), respectively. In contrast no impact was observed regarding chemotherapy delaying or dose reduction. SEGA score was not associated with early discontinuation, nor dose reduction and chemotherapy delaying.
Summary/Conclusions: CIRS score and SEGA score could be helpful in treatment choice. Palliative treatment could be the best approach in patients with CIRS score >10 and or SEGA score >12. Patients CIRS score more than 6 are at higher risk of early chemotherapy discontinuation. A special attention is required for these patients to avoid such events. Reason of early discontinuation and impact on response will be presented at the EHA meeting.

P784

THE RELATIVE BURDEN OF AL AMYLOIDOSIS ON HEALTH-RELATED QUALITY OF LIFE

M Bayliss[1], MK White[1], KL McCausland[1], S Guthrie[2,*]
[1]Optum, Lincoln, RI, [2]Prothena Biosciences Inc, South San Francisco, CA, United States

Background: The SF-36v2® Health Survey (SF-36v2) is a widely used general patient-reported outcome survey that can describe and quantify the impact of disease and its treatment on health-related quality of life (HRQoL). Light chain (AL) amyloidosis is a rare disease characterized by misfolded amyloid protein deposits in tissues and vital organs, and little is known about the burden of AL amyloidosis on HRQoL.
Aims: To compare the HRQoL profile of patients with AL amyloidosis and key patient subgroups to a general US population (USP) sample.
Methods: The SF-36v2 was administered in an online, cross-sectional study of adults (≥18 years of age) with self-reported AL amyloidosis (n=341). The SF-36v2 measures eight domain scales (physical functioning (PF), role limitations due to physical health problems (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role limitations due to emotional health problems (RE), and mental health (MH)) and two component summary measures: physical (PCS) and mental (MCS). Analysis of variance was used to compare the norm-based SF-36v2 scores from patients with AL amyloidosis to samples representing the USP. The USP sample size ranged from 4,024 – 4,036 for specific SF-36v2 scores. The USP data were adjusted to the age and gender distribution of the patient sample using separate ordinary least-squares regression models, with each SF-36v2 scale or summary score as a dependent variable. Using the same method, we evaluated the burden of two key subgroups: 1) patients with recent diagnosis (within the past year) (n=52); and 2) patients with cardiac involvement (n=178).
Results: Relative to USP norms, HRQoL of patients with AL amyloidosis is significantly worse on scores from all eight SF-36v2 domain scales and both summary measures (p <0.05 for all). The largest decrement was in GH, where the AL amyloidosis patient mean was a full standard deviation worse than the USP (39.3 *vs* 49.0, respectively, Cohen's d -0.654; p <0.001). Large decrements (more than a half standard deviation) also were seen in PF (24.5 *vs* 36.9), RP (40.5 *vs* 47.6), VT (44.5 *vs* 50.2), SF (43.6 *vs* 49.6), and PCS (40.7 *vs* 46.7). Subgroup analysis showed that, relative to the USP, patients (1) recently diagnosed with AL amyloidosis and (2) with cardiac involvement had large decrements in each of the SF-36v2 domain scales and both summary measures (p <0.05 for all). The largest decrements for each subgroup, relative to USP, were:
• Recently diagnosed: All scores except BP were at least a half standard deviation lower than USP, with three domain scores at least one standard deviation lower (RP, GH, SF).• Cardiac involvement: Four domain scores and one summary measure score were at least a half standard deviation lower than USP (PF, RP, GH, VT, and PCS).
Summary/Conclusions: Results indicate that AL amyloidosis patients have broad HRQoL deficits across all areas of physical and mental functioning compared to the general USP, with greater impact evident among key AL amyloidosis subgroups – in particular, patients diagnosed within the past 12 months. Understanding the burden of AL amyloidosis can help physicians identify ancillary treatments and services that may ease their burden and ultimately improve patients' HRQoL.
Study supported by: Prothena Biosciences Inc.

P785

OUTCOME OF PATIENTS WITH RELAPSED/REFRACTORY LYMPHOMA IN A LARGE COHORT INSIDE A PHASE 1 CLINIC DEPARTMENT

JM Michot[1,*], L Benajiba[1], C Baldini[1], L Faivre[2], A Danu[3], C Bigenwald[3], L Haddag-Miliani[4], J Arfi-Rouche[4], J Lazarovici[3], D Ghez[3], W Rahali[3], C Falet[3], V Vergé[5], C Bonnet[1], F Bigot[1], JC Soria[1], V Clayette[6], V Ribrag[3], J Bosq[5]
[1]DITEP, [2]Biostatistic Departement, [3]Hematology, [4]Radiology, [5]Hematology and biopathology departement, [6]Research and Translationnal Laboratory, Gustave Roussy Cancer Campus, Villejuif, France

Background: Treating relapsed/refractory lymphoma remains a challenge. While phase 1 trials classically aim to determine the recommended phase 2 dose (RP2D), the search of anti-tumor activity is increasingly evaluated.
Aims: We aimed to assess the tolerance and efficacy of phase 1 trial and to determine a simple scoring system to identify patients who will prematurely discontinue phase 1 studies (before six weeks), in a large cohort of patients with relapsed/refractory (r/r) lymphoma.
Methods: Data from 137 consecutive patients with refractory/r lymphoma treated within a panel of 22 phase 1 trials were collected, between 2008 and 2016. At inclusion, median age was 66 years [range: 23-86]. Lymphoma histological patient's types were: 79 (55%) aggressive non-Hodgkin lymphoma (59 diffuse large B-cell lymphoma, 6 T-cell lymphoma and 14 Mantle cell lymphoma), 40 (29%) indolent non-Hodgkin lymphoma and 18 (13%) Hodgkin lymphoma. The predefined Gustave Roussy (GR) score combined two simple variables, PS and baseline serum albumin (+1 if PS=0, +1 if albumin≤35g/l).
Results: Grade 3 or 4 adverse events related to study drug were experienced by 39/137 (28%) patients, in 27/39 (69%) during first cycle and in 12/39 (31%) after first cycle. Dose-limiting toxicity was seen in 12/137 (9%) of patients. Any toxic death was recorded. With a median follow-up of 13 [0.3-85] months, median OS and progression free survival (PFS) were respectively 22 ($CI_{95\%}$: 17-38) and 4 ($CI_{95\%}$: 2-5) months. Best overall response rate Cheson 2007 analysis shown overall response rate and disease control rate at 30% and 63%, respectively. Median overall survival was better in responder (undefined) compare to disease controllers (31 months) and non-responder patients (12 months) (p=0.0003). At inclusion WHO performance status (PS) >0, baseline albumin ≤35 g/l and baseline LDH ≥250 UI/L were significantly associated with poorer OS. Patients with a GR score=0 experienced significantly better OS compared to patients with a score=1 and a score=2 (37 months *vs* 17 months *vs* 9 months; p=0.007). A premature study discontinuation was recorded in 46/137 patients (34%). The GR score distinguishes patients most likely to remain on study for more than 6 weeks. A molecular portrait was performing in 40 patients to improve the patient orientation in the trials.

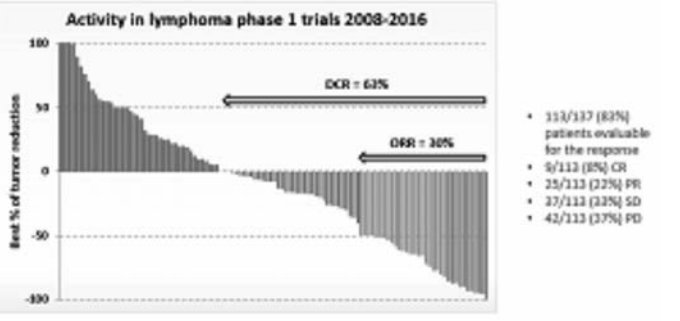

Figure 1.

Summary/Conclusions: The three parameters WHO performance status (PS) >0, baseline albumin ≤35 g/l and baseline LDH ≥250 UI/L are associated with OS and premature withdrew of study and could serve as a basis to better select patient in hematological phase 1 trials. Survival was dramatically better in responder's patients, pledging to accelerate the search for efficacy signals from phase 1.

P786

QUALITY OF LIFE IN SURVIVORS OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: CHILDREN'S AND PARENTS' PERCEPTION

S Sarı[1], D Kızmazoğlu[1], M Evim Sezgin[2], A Kantarcıoğlu[2], Ö Tüfekçi[1], B Baytan[2], S Yılmaz Bengoa[1], A Meral Güneş[2], H Oren[1,*]
[1]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, Izmir, [2]Pediatric Hematology, Uludağ University Faculty of Medicine, Bursa, Turkey

Background: Improved outcome and predicted long survival for children with acute lymphoblastic leukemia (ALL) make the early and efficient therapy, quality of life, and psychosocial intervention more important. It is well known that quality of life is negatively affected in ALL survivors who are cured.
Aims: The aim of this study is to investigate the social, physical, emotional, family, and functional factors that may affect the quality of life in children with ALL to find out how we can support their lives after treatment to provide better quality of life in our country.
Methods: The study population consisted of 46 children who were diagnosed with ALL and had been treated at both centers with ALL-BFM 95 chemotherapy protocol. We included children who had been completed therapy at least two years ago and were 7-17 years-old. The control group consisted their siblings at closest age and gender. The sociodemographic data of patients were recorded from hospital files. Patients and their siblings were evaluated with KINDL questionnaire for measuring health-related quality of life in children and adolescents. The perception of child about quality of life also evaluated by the parents.
Results: No significant differences could be found among life quality scores with respect to variables as gender, therapy type, risk group, time after the end of therapy, income status, and having chronic illness. Mean quality of life scores of patients were as follows: Physical well-being 75.27±19.9, emotional well-being 76.77±16, social functioning 79.21±18, family 82.74±19.7, self-esteem 60.73±24.4, and school 63.99±19.3. Mean quality of life scores of siblings (between 7-17 years) were as follows: Physical well-being 61.36±20.12, emotional well-being 85.22±11.27, social functioning 86.36±15, family 79.54±27.96, self-esteem 69.88±24.97, and school 64.20±14.54. Total mean quality of life score of patients and siblings were 73.12±13.4 and 74.43±11.28, respectively. Mean quality of life scores of parents questionnaires were as follows: Physical well-being 78.06±20.80, emotional well-being 77.13±15.76, social functioning 81.38±14.64, family 82.74±15.74, self-esteem 71.28±19.44, and school

63.70±14.60; total mean quality of life score was 75.51±11.60. When we investigated the questionnaires of patients and parents, we found that the self-esteem scores of the patients were significantly lower than the parents evaluation (p=0.037); we found no correlation in school subscales between patients' and parents' evaluation. There was good positive correlation between physical well-being, emotional well-being, and social functioning. When the results of patients and their siblings were compared, mean physical well-being scores of siblings were lower than the patients (p=0.049).
Summary/Conclusions: The quality of life scores of 7-17 years-old ALL survivors were not affected by gender, therapy type, risk group, time after the end of therapy, income status, and having chronic illness. Physical well-being scores were higher in patients than their siblings. Our findings demonstrated that the parent evaluated self-esteem and school scores differed from their child; we think that the parents should follow-up their children more closely for their self-esteem development and school performances.

P787

HEALTH-RELATED QUALITY OF LIFE ASSESSMENT IN LONGITUDINAL STUDIES INCLUDING MULTIPLE MYELOMA PATIENTS: A CRITICAL REVIEW OF INTERPRETING CHANGES OF SCORES OBTAINED BY EORTC QLQ-C30

L Kongsgaard Nielsen[1,*], M Jarden[2], CL Andersen[3], H Frederiksen[4], N Abildgaard[1]
[1]Odense University Hospital, Department of Haematology, HFE-X, Odense, [2]University Hospitals Center for Health Research (UCSF) and Center for Integrated Rehabilitation of Cancer Patients (CIRE), Rigshospitalet, Copenhagen, [3]Roskilde University Hospital, Department of Haematology, Roskilde, [4]Odense University Hospital, Department of Haematology, Odense, Denmark

Background: Multiple myeloma (MM) patients report more symptoms and more severe symptoms than patients with other hematological malignancies, resulting in reduced health-related quality of life (HRQoL). The goal of MM treatment and care is to prolong progression free survival and overall survival, and to reduce symptoms with least possible side effects to therapy. Because survival is improving in MM patients there is increasing focus on HRQoL.
Aims: The aim of the review is to evaluate longitudinal studies including MM patients according to minimal important difference (MID) for physical function, global QoL, fatigue and/or pain, according to the two available guidelines by Cocks (Eur J Cancer 2012, 48:1713-21) and Kvam (Eur J Haematol 2010, 84:345-53).
Methods: A literature search was performed 14 December 2015 in PubMed and Embase and 29 December 2015 in PsycINFO and CINAHL. Publications with longitudinal follow-up using EORTC QLQ-C30 for HRQoL measurement of physical function, global QoL, fatigue or pain were included, if the mean score at baseline and minimum one follow-up time point were presented in the text, a table or a figure, or the change in mean score from baseline over a given time point was specified. Publications concerning patients with mixed hematological diagnoses were excluded, if the results were not presented for MM patients separately. Articles in other languages than English were excluded.
Results: A total of 25 publications were identified, which relates to 15 primary and 5 relapse studies, one population-based and one mixed population study. Evaluation of change in score concluded by guidelines of Cocks compared to Kvam, showed diversity in the interpretation of changes of HRQoL scores over time. Large improvement (only possible for pain) and medium improvement in one or more of the evaluated HRQoL parameters were only achieved in studies including newly diagnosed MM patients. During primary treatment with autologous hematopoietic stem cell transplantation (ASCT), temporary large deteriorations are seen, but three months after ASCT equalization occurs with even large improvements in physical function, global QoL, fatigue and pain. In the studies of MM patients undergoing relapsed treatment regimes, no MID or variable degrees of deteriorations are generally documented. Only two relapse studies documented improvement during relapse treatment, which both were for pain, one with small and one with medium improvement. The population-based study demonstrated deterioration in global QoL, fatigue and pain at one year follow-up.
Summary/Conclusions: Several longitudinal studies of changes in HRQoL scores during MM treatments have been published over the last two decades, and guidelines for interpreting HRQoL changes with thresholds of MID have been developed. In return, these methods are not definite, and further research is required. It is still unresolved, which is the optimal duration between the two measuring points for interpretation of MID and possible different thresholds for MID in younger *vs* frail patients, and in newly *vs* relapsed MM patients, respectively. Based on our review, it is clear that improvements in HRQoL are far more likely during treatment of newly diagnosed patients compared to relapsed patients. Whether this is due to the trajectory of the MM disease, differences in the type and/or efficacy of anti-myeloma regimens used in the primary or relapsed settings, or individual factors such as comorbidity or response shift/calibration, should be in focus in future studies.

Aggressive lymphoma with emphasis on novel agents

S788

CLINICAL CHARACTERISTICS AND PROGNOSTIC FACTORS OF IMMUNOCOMPROMISED AND NON IMMUNOCOMPROMISED PLASMABLASTIC LYMPHOMA PATIENTS: ANALYSIS OF 135 PATIENTS TREATED IN THE LYSA GROUP

E Tchernonog[1,*], P Faurie[2], P Coppo[3], H Monjanel[4], A Bonnet[5], C Besson[6], M Mercier[7], J Dupuis[8], F Bijou[9], C Herbaux[10], A Delmer[10], C Laurent[11], B Fabiani[12], S Le Gouill[5], E Gyan[4], H Ghesquières[13], G Cartron[1]

[1]Hematology, CHRU Montpellier, Montpellier, [2]Hematology, Centre Léon Bérard, Lyon, [3]Hematology, Assistance Publique des Hopitaux de Paris, Saint Antoine hospital, Paris, [4]Hematology, CHRU Tours, Tours, [5]Hematology, CHRU Nantes, Nantes, [6]Inserm U1186, Kremlin-Bicêtre Hospital, Paris, [7]Hematology, CHRU Angers, Angers, [8]Lymphoid malignancies unit, Henri Mondor hospital, Créteil, [9]Hematology, Institut Bergonié, Bordeaux, [10]Hematology, CHRU Lille, Lille, [11]Department of biopathology, CHRU Toulouse, Toulouse, [12]Department of biopathology, Assistance Publique des Hopitaux de Paris, Saint Antoine hospital, Paris, [13]Hematology, CHRU Lyon Sud, Lyon, France

Background: Plasmablastic lymphoma (PBL), initially described in 1997 in the oral cavity of HIV positive patients, is now recognized as a distinct aggressive and rare entity of diffuse large B-cells lymphoma by the World Health Organization classification. Others cases have been reported since the original description, both in immunocompromised and immunocompetent patients. However, these latter are largely derived from case reports or small series, and PBL remains a diagnostic and therapeutic challenge with an aggressive clinical course.
Aims: The aim of this study was to specify the clinical, biological, pathological features and outcome of patients with PBL.
Methods: The clinical, biological, pathological features and outcome of a cohort including 135 patients with PBL diagnosed after 2000 in the LYSA centers were reported and analyzed.
Results: The median age was 58 years, with a male predominance. The cohort was divided into 56 HIV-positive patients, 17 post-transplant patients, and 62 non immunocompromised patients including 11 patients with local or systemic inflammatory disease, 13 patients with history of cancer and 31 elderly patients. Despite PBL in immunocompetent patients has already been described in the literature, this study highlights that this subtype of patients finally presents some degree of immunodepression, confirming a strong relationship between immunodeficiency and PBL. The most frequent primary involved site was the oral cavity in 19% of cases. Immunophenotype showed CD138 positivity in 88% of cases and CD20 negativity in 90% of cases. EBER expression was observed in 62% of cases. Chemotherapy was administered to 108 of 135 patients, with a complete response rate of 55%. The use of rituximab, combined with chemotherapy, seems to be interesting with a trend towards improved complete response rate and event free survival. The median overall survival was 32 months. In the multivariate prognostic analysis, International Prognostic Index score, chemotherapy and complete response rate were associated with survival benefit. HIV positive status showed better overall survival when compared with HIV negative status, but only in univariate analysis.
Summary/Conclusions: This cohort, the largest reported to date, lead to a better understanding and increase the spectrum of knowledge on PBL. However specific guidelines to clarify all the treatment options are lacking, and may improve the poor prognosis of this rare disease.

S789

SUBGROUP ANALYSES OF DIFFUSE LARGE B-CELL LYMPHOMA AND INDOLENT LYMPHOMA COHORTS FROM A PHASE IIA STUDY OF SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED OR REFRACTORY NON-HODGKIN'S LYMPHOMA

W Jurczak[1,*], PL Zinzani[2], G Gaidano[3], A Goy[4], M Provencio[5], Z Nagy[6], T Robak[7], K Maddocks[8], C Buske[9], S Ambarkhane[10], M Winderlich[10], J Endell[10], K Blum[8]

[1]Department of Hematology, Jagiellonian University, Kraków, Poland, [2]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, [3]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, [4]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, [5]Department of Medical Oncology, University Hospital Puerta De Hierro, Madrid, Spain, [6]First Department of Internal Medicine, Semmelweis University, Budapest, Hungary, [7]Department of Hematology, Medical University of Lodz, Lodz, Poland, [8]Department of Internal Medicine, Division of Hematology, The Ohio State University Comprehensive Cancer Center, Columbus, United States, [9]Comprehensive Cancer Center Ulm, Institute of Experimental Cancer Research, University Hospital of Ulm, Ulm, [10]MorphoSys AG, Martinsried, Germany

Background: There is a high unmet medical need for new efficacious and tolerable regimens for patients with relapsed or refractory (R-R) non-Hodgkin's lymphoma (NHL). CD19 is expressed by most B-cell NHLs; in contrast to other targets, CD19 expression is maintained at a stable level during the course of the disease. MOR208, an Fc-engineered, humanized monoclonal CD19 antibody demonstrates activity in certain leukemia and lymphoma model systems through enhanced antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis. A phase I study showed MOR208 to be safe and well-tolerated with encouraging single-agent activity in patients with chronic lymphocytic leukemia. Therefore MOR208 may have clinical use as a new therapeutic agent in this setting.
Aims: This analysis focused on the preliminary efficacy and safety of MOR208 in diffuse large B-cell lymphoma (DLBCL) and indolent (i) NHL cohorts. The primary endpoint was investigator assessed overall response rate (ORR).
Methods: This is an open-label, multicenter, phase IIa study of MOR208 in R-R NHL patients progressing after at least one prior rituximab-containing therapy. Patients were enrolled into 4 cohorts of aggressive (DLBCL and mantle cell lymphoma) and iNHLs (follicular lymphoma and other iNHLs). Patients received single-agent MOR208, 12 mg/kg IV, weekly, for 8 weeks (2 cycles); treatment could continue for 4 additional weeks in patients with at least stable disease after 2 cycles. MOR208 maintenance could be given (every 2 or 4 weeks) until progression in patients with complete (CR) or partial response (PR) at 12 weeks.
Results: In total, 92 patients were enrolled including 35 (38%) with DLBCL and 45 (49%) with iNHL. ORR was 26% in DLBCL (9/35 patients; 2 CRs and 7 PRs), and 27% in iNHL (12/45 patients; 5 CRs and 7 PRs). In evaluable patients (those who completed at least 2 cycles and had a response assessment) the ORR was 36% in DLBCL (25 evaluable patients), and 30% in iNHL (40 evaluable patients), respectively. Median duration of response was 13.7 months for DLBCL patients (1.2-26, 3 ongoing and >20 months in remission) and 8.4 months for iNHL patients (2.5-20.3, 6 ongoing, including 1 patient >20.3 months in remission). In DLBCL responders, 5/9 were rituximab-refractory (either no response or response lasting<6 months to a previous rituximab-containing therapy), of which 2 patients had a response duration of >19.8 months and 1 patient of >1 year under MOR208 treatment. The incidence of grade ≥3 hematologic treatment emergent adverse events was low (DLBCL: 9/35, 26%; iNHL: 4/45, 9%), including neutropenia, anemia and thrombocytopenia in 14%, 9% and 6% of DLBCL patients and 4%, 0% and 0% of iNHL patients. Infusion-related reactions were seen in 3/35 (9%) and 4/45 (9%) patients in the DLBCL and iNHL cohorts, all of grade 1-2 except for one grade 4 dyspnea. There were no treatment-related deaths and no trend towards late toxicity.
Summary/Conclusions: Single-agent MOR208 was associated with a promising ORR including CRs and long-lasting responses in both DLBCL and iNHL, including in patients with rituximab-refractory disease. These efficacy data, and the excellent safety and tolerability profile of MOR208 further justify the development of MOR208 as part of a combination therapy in B-cell malignancies.

S790

HAPLOTRANSPLANTS *VERSUS* HLA-IDENTICAL DONOR (HID) FOR ALLOGENEIC STEM-CELL TRANSPLANTATION (ALLOSCT) IN REFRACTORY NON-HODGKIN LYMPHOMA (NHL)

H Huang[*], D Wu
Soochow University, Suzhou, China

Background: AlloSCT is an effective therapeutic option for patients with refractory lymphoma. However, the donor source is the biggest problem for alloSCT. The feasibility of haploSCT has dramatically expanded the donor pool, making allogeneic transplantation available for the vast majority of patients, especially for patients with rapidly progressing disease in whom unrelated donor search cannot be awaited.
Aims: In this study, we aim to compare outcome of haplotransplants with conventional related and matched unrelated donor transplants for refractory relapsed or high risk NHL.
Methods: Seventy-eight patients who had undergone alloSCT between January 2006 and October 2015 in our center were analyzed retrospectively. The median age was 30 years (range, 12 to 58 years). The histological subtypes included diffuse large B cell lymphoma (13), mantle cell lymphoma (3), Burkett's lymphoma (1), B-cell lymphoblastic lymphoma (8), other type mature B cell lymphoma (10), T-cell lymphoblastic lymphoma (18), peripheral T cell lymphoma (18) and NK/T cell lymphoma (7). Bone marrow was involved in 65 patients, 9 patients had experienced treatment failure with prior autologous SCT. All of the patients received a myeloablative conditioning regimen which is TBI/Cy or Bu/Cy. 33 patients received Haplo Donors, 45 patients received HID, including sibling and matched unrelated donors. Before alloSCT, 49 patients were in CR, 12 patients were in PR, 18 patients were in NR. Primary refractory or progression was more common in the HAPLO group (p=0.001), other variables were balanced.
Results: Seventy-eight patients were engrafted successfully and all patients achieved full donor chimerism. There is no difference for hematopoietic recovery between two groups. In HAPLO group, the median time of neutrophils and platelets recovery were 12 days (range, 9d to 15d) and 17 days (range, 11d to 60d). In HID group, the median time of neutrophils and platelets recovery were 11 days (range, 9d to 16d) and 17days (range, 12d to 45d), respectively. After transplantation, 75 patients acquired complete response, another 3 patients

acquired partial response. In HAPLO group, 6 patients had recurrent disease, and 5 patients died from transplantation-related (TRM) including infection and other organ failure at 1-year. In HID group, 6 patients had recurrent disease and 8 patients died of TRM. The median follow-up duration was 23 months (range, 2-139) in HAPLO group, 29 months (range, 2-139) in HID group. Among HAPLO and HID recipients, the 3-year progress free survival rate was 56.8% and 60.0% (P =0.45), respectively; overall survival rate was 58.9% and 62.1% (P=0.48), respectively; the 3-year cumulative incidences of relapse were 48.4% and 47.7% (P =0.36), and those of the 2-year-non-relapse-mortality were 25.2% and 27.8% (P =0.86), respectively. The cumulative incidences of grade 3–4 acute GVHD were 28.4% (95% CI =7.2-28.1%) and 20.5% (95% CI =5.7–22.2%)(P =0.43), respectively. Univariate analysis showed that disease status before alloSCT may be a factor affecting OS and PFS (p=0.001).

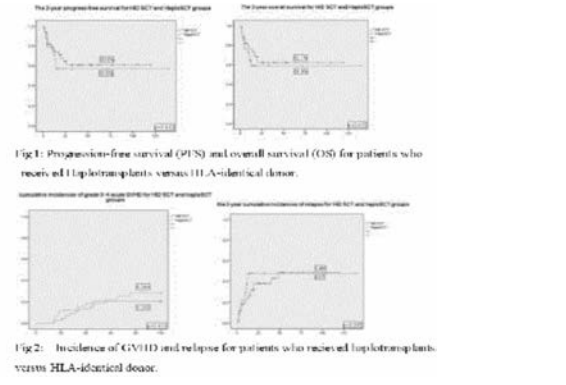

Fig 1: Progression-free survival (PFS) and overall survival (OS) for patients who receive d Haploiransplants versus HLA-identical donor.

Fig 2: Incidence of GVHD and relapse for patients who received haploiransplants versus HLA-identical donor.

Figure 1.

Summary/Conclusions: This retrospective study showed haploSCT resulted in similar clinical efficacy compared to HID in patients with refractory/relapsed or high risk lymphoma. Importantly, TRM and acute GVHD were acceptable without obvious difference between two groups. HaploSCT provides a chance of long-term disease control even for patients without HID.

S791

UPDATED RESULTS FROM ZUMA-1: A PHASE 1-2 MULTICENTER STUDY EVALUATING THE SAFETY AND EFFICACY OF KTE-C19 (ANTI-CD19 CAR T CELLS) IN REFRACTORY AGGRESSIVE B-CELL NON-HODGKIN LYMPHOMA (NHL)

T Siddiqi[1,*], SS Neelapu[2], FL Locke[3], NL Bartlett[4], JC Chavez[3], C Hosing[2], AF Cashen[4], LE Budde[1], J Rossi[5], M Sherman[5], L Navale[5], Y Jiang[5], J Aycock[5], M Elias[5], JS Wiezorek[5], WY Go[5]

[1]City of Hope National Medical Center, Duarte, [2]The University of Texas MD Anderson Cancer Center, Houston, [3]Lee Moffitt Cancer Center, Tampa, [4]Washington University School of Medicine in St. Louis, St. Louis, [5]Kite Pharma, Inc., Santa Monica, United States

Background: Non-Hodgkin lymphoma (NHL) is the most prevalent hematologic malignancy in the US and the 5th most deadly cancer with nearly 19,790 deaths/year. Diffuse large B-cell lymphoma (DLBCL) is the most common NHL subtype, representing 25-35% of new cases annually. Approximately 1 in 3 patients treated in the first line will be refractory to treatment or relapse post-treatment and represent a significant unmet medical need. Patients with relapsed/refractory B-cell malignancies demonstrated durable remissions when treated with CD28/CD3zeta anti-CD19 CAR T cells at the National Cancer Institute (NCI) (Kochenderfer, JCO 2015; NCT00924326). KTE-C19 includes the same CAR construct as that used in the NCI trial, but is centrally manufactured in a streamlined 6- to 8-day process. Updated data from the phase 1 portion of the ZUMA-1 clinical trial are reported.
Aims: The primary goal was to determine the safety of KTE-C19. Secondary aims included evaluation of overall response rate, duration of response, blood concentrations of CAR T cells, and serum cytokine levels.
Methods: Patients with relapsed/refractory aggressive B-cell NHL were treated with a single target dose of 2×10^6 anti-CD19 CAR T cells (KTE-C19)/kg following a fixed dose of cyclophosphamide/fludarabine conditioning chemotherapy. Key inclusion criteria were ECOG 0-1 and chemo-refractory disease, which was defined as progressive or stable disease as best response to last line of therapy or disease progression ≤12 months after autologous stem cell transplantation. All patients provided informed consent.
Results: Seven patients received KTE-C19 as of January 15, 2016. A previously reported dose-limiting toxicity of grade 4 cytokine release syndrome and neurotoxicity occurred in one patient. All other grade ≥2 cytokine release syndrome and neurotoxicity adverse events resolved within one month. There were no other adverse events due to KTE-C19 after one month post-dosing. The overall response rate was 71%, with a complete response rate of 57%. Ongoing complete responses of 3 to 6+ months were present in 3 patients who previously demonstrated disease progression within 6 months of autologous stem cell transplantation. Levels of CAR T cells peaked within 2 weeks and remained detectable 1 to 6+ months after infusion. Updated results will be presented.
Summary/Conclusions: Additional follow up of patients enrolled in the ZUMA-1 trial demonstrated durable complete remissions after a single dose of KTE-C19, with no new KTE-C19-related adverse events. The KTE-C19 regimen and central, streamlined manufacturing process were safe and feasible for future studies. The phase 2 portion of the ZUMA-1 clinical trial (NCT02348216) is ongoing.

S792

LOW-DOSE CHEMOTHERAPY FOLLOWED BY ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELLS INDUCES REMISSIONS IN PATIENTS WITH ADVANCED LYMPHOMA

JN Kochenderfer[1,*], RP Somerville[2], T Lu[2], V Shi[1], JC Yang[2], RM Sherry[2], CA Klebanoff[2], US Kamula[2], SL Goff[2], A Bot[3], J Rossi[3], M Sherman[3], A Perez[3], A Xue[3], T Feldman[4], JW Friedberg[5], MJ Roschewski[6], S Feldman[2], L McIntyre[2], MA Toomey[2], SA Rosenberg[2]

[1]Experimental Transplantation and Immunology Branch, National Cancer Institute (NCI), National Institutes of Health (NIH), [2]Surgery Branch, NCI, NIH, Bethesda, [3]Kite Pharma, Inc., Santa Monica, [4]Lyphoma Division, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [5]University of Rochester School of Medicine, Rochester, [6]Lymphoid Malignancy Branch, NCI, NIH, Bethesda, United States

Background: Non-Hodgkin lymphoma (NHL) is the most common hematologic malignancy in the US and the 5th deadliest cancer with almost 20,000 deaths per year. Anti-CD19 CAR T cells achieve durable remissions in patients with relapsed/refractory B-cell malignancies. Pre-treatment with chemotherapy allows depletion of recipient leukocytes, which improves the anti-cancer effects of adoptively transferred T cells. Increased serum concentrations of interleukin (IL)-15 is believed to contribute to this beneficial effect of chemotherapy. We (Kochenderfer et al. *Journal of Clinical Oncology*, 2015) and others previously reported effects of high-dose chemotherapy administered before anti-CD19 CAR T-cell therapy. We now report the effects of low-dose conditioning chemotherapy followed by anti-CD19 CAR T-cell infusion.
Aims: The main goals of the study were to evaluate efficacy and safety of low-dose conditioning chemotherapy followed by anti-CD19 CAR T cell therapy in patients with advanced lymphomas.
Methods: Twenty-two patients with advanced lymphoma were included in the study. Eighteen patients were treated with cyclophosphamide 300 mg/m^2 daily for 3 days; the remaining 4 patients received cyclophosphamide 500 mg/m^2 on this same schedule. Fludarabine 30 mg/m^2 was provided to all patients on the same schedule and days as cyclophosphamide. A single dose of CAR T cells was administered 2 days after chemotherapy was completed. CAR T cell concentrations and cytokine levels were examined in blood samples collected from patients. Informed consent was received from all patients.
Results: Among 19 patients with diffuse large B-cell lymphoma of various subtypes, 8 demonstrated complete response, 5 partial response, 2 stable disease, and 4 progressive disease. A complete response was also noted in one patient with mantle cell lymphoma. Two patients with follicular lymphoma both obtained complete response. Duration of response ranged from 1 to 20 months, with 10 remissions that remain ongoing. All but 4 patients had either chemo-refractory lymphoma or relapsed lymphoma following autologous stem cell transplantation. Neurological toxicities were the most commonly observed adverse events. Fever and hypotension were also observed. The median peak blood CAR+ cell concentration was 47/μL (range 4-1217/μL), with higher levels found in patients who demonstrated complete or partial response than in those with stable or progressive disease. The mean serum IL-15 level was 4 pg/mL prior to administration of conditioning chemotherapy and 32 pg/mL after chemotherapy (P<0.0001).
Summary/Conclusions: Low-dose conditioning chemotherapy followed by anti-CD19 CAR T cells induced remissions in patients with advanced B-cell lymphomas.

Relapsed Hodgkin Lymphoma & Primary Mediastinal Large B-Cell Lymphoma (PM-DLBCL)

CHECKMATE 205: A PHASE 2 STUDY OF NIVOLUMAB IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION AND BRENTUXIMAB VEDOTIN

A Engert[1], A Santoro[2], M Shipp[3], PL Zinzani[4], J Timmerman[5], S Ansell[6], P Armand[3], M Fanale[7], V Ratanatharathorn[8], J Kuruvilla[9], J Cohen[10], G Collins[11], K Savage[12], M Trneny[13], K Kato[14], B Farsaci[14], S Parker[14], S Rodig[15,16], A Younes[17,*]

[1]University Hospital of Cologne, Cologne, Germany, [2]Humanitas Cancer Center, Humanitas University, Rozzano (Milan), Italy, [3]Dana-Farber Cancer Institute, Boston, United States, [4]Institute of Hematology, University of Bologna, Bologna, Italy, [5]University of California, Los Angeles, [6]Mayo Clinic, Rochester, [7]University of Texas MD Anderson Cancer Center, Houston, [8]Barbara Ann Karmanos Cancer Institute, Detroit, United States, [9]Princess Margaret Cancer Centre and University of Toronto, Toronto, Canada, [10]Winship Cancer Institute - Emory University, Atlanta, [11]Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United States, [12]British Columbia Cancer Agency Center for Lymphoid Cancer, Vancouver, Canada, [13]Charles University in Prague and General University in Prague, Prague, Czech Republic, [14]Bristol-Myers Squibb, Princeton, [15]Brigham and Women's Hospital, [16]Center for Immuno-Oncology, Dana-Farber Cancer Institute, Boston, [17]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Classical Hodgkin lymphoma (cHL) is characterized by Hodgkin Reed–Sternberg cells, which contain genetic aberrations at 9p24.1 leading to overexpression of the programmed death receptor-1 (PD-1) ligands PD-L1 and PD-L2. Thus, cHL may be uniquely sensitive to PD-1 blockade. Nivolumab (Nivo) is a fully human IgG4 immune checkpoint inhibitor antibody targeting PD-1 that showed promising results in a phase 1b study (NCT01592370) in patients (pts) with relapsed/refractory cHL (Ansell SM et al. NEJM 2015;372:311-9) who currently have limited treatment options.
Aims: This study, Cohort B of the phase 2 Checkmate 205 study (NCT02181738), evaluated the efficacy and safety of nivo in pts with cHL who had received brentuximab vedotin (BV) after failed autologous stem cell transplantation (ASCT).
Methods: Nivo was given at 3 mg/kg IV every 2 weeks (wk). Response was assessed using 2007 IWG criteria, by both an independent radiologic review committee (IRRC) and investigators (Inv). The primary endpoint was IRRC-assessed objective response rate (ORR). Quality of life was assessed by EQ-5D VAS (0–100 scale) and EORTC QLQ-C30. Written informed consent was obtained for all pts. Results of the primary ORR analysis after approximately 6 months (mo) minimum follow-up are reported.

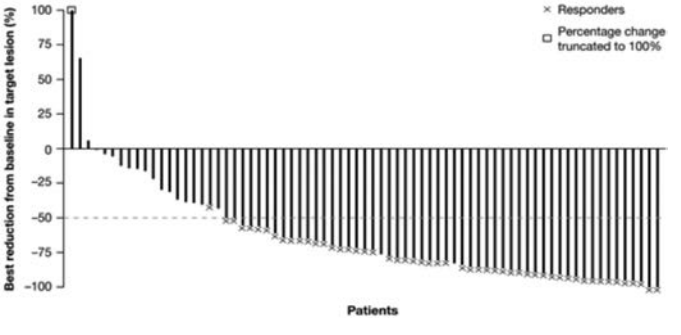

Figure 1. Best change from baseline in target lesions for all response-evaluable patients (IRRC assessment).

Results: Among 80 pts enrolled and treated, the main characteristics included median (range) age, 37 years (18–72) and median (range), 4 prior regimens (3–15). 33 pts enrolled from Europe; 47 were from the US or Canada. At data cut-off (October 2015), 51 pts (64%) remained on therapy. Of 29 pts (36%) who discontinued, the most common reason was disease progression (n=13). Only 4 pts discontinued due to an AE. 90% of pts had drug-related AEs, including 25% Grade 3–4 AEs and 1% Grade 5 (multi-organ failure). The most common drug-related AEs were fatigue (25%), infusion reaction (20%), and rash (16%). The most common serious AEs were pyrexia, tumor progression, arrhythmia, infusion reaction, septic meningitis, and pneumonia (≤4% each). Most common immune-mediated AEs were hypothyroidism/thyroiditis (14%), rash (10%), and hypersensitivity (6%). All 6 pts who stopped nivo and received subsequent stem cell transplant were alive at data cut-off. After median (range) follow-up of 8.9 mo (1.9–11.7), IRRC ORR (95% CI) was 66% (54.8%, 76.4%); CR and PR rates were 8.8% (3.6%, 17.2%) and 57.5% (45.9%, 68.5%), respectively. Almost all pts had some degree of tumor regression (Figure). All but one responder had tumor reduction of ≥50% from baseline; the other had response determined by negative FDG-PET scan. In 43 pts who had no response (SD or PD) to BV, nivo treatment resulted in IRRC ORR of 72% (31/43). Median (range) time to response was 2.1 mo (1.6–5.7). Inv ORR (95% CI) was 73% (61.4%, 81.9%); CR and PR rates were 27.5% (18.1%, 38.6%) and 45.0% (33.8%, 56.5%), respectively. At data cut-off, 62% (33/53) of IRRC responders remained in response. IRRC 6-mo PFS was 77%; OS was 99%. Mean EQ-5D VAS score increased over time, from 62 at baseline to 80 at Wk 33, with a clinically meaningful improvement in health state by Wk 9 (>7-point change). EORTC QLQ-C30 findings suggested a trend towards improvement in functional, symptom, and global health scores.
Summary/Conclusions: In pts with cHL who progressed following ASCT and BV, nivo is associated with a high response rate, long-lasting responses, and an acceptable safety profile. PFS and OS are encouraging in this heavily pretreated population. Patient reported outcomes suggest improvement in quality of life while on nivo treatment.

MULTICOHORT PHASE 2 STUDY OF PEMBROLIZUMAB FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA (R/R CHL): KEYNOTE-087

C Moskowitz[1], PL Zinzani[2], MA Fanale[3], P Armand[4], N Johnson[5], V Ribrag[6], J Radford[7], B von Tresckow[8], A Tomita[9], MA Shipp[4], Y Wang[10], AD Ricart[10], A Balakumaran[10], R Chen[11,*]

[1]Memorial Sloan Kettering Cancer Center, New York, United States, [2]University of Bologna, Bologna, Italy, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Dana-Farber Cancer Institute, Boston, United States, [5]Jewish General Hospital, Montreal, Canada, [6]Institut Gustave Roussy, Villejuif, France, [7]Christie Hospital NHS Foundation Trust, Manchester, United Kingdom, [8]Uniklinik Koln, Cologne, Germany, [9]Fujita Health University School of Medicine, and Nagoya University, Toyoake, Japan, [10]Merck & Co., Inc., Kenilworth, [11]City of Hope National Medical Center, Duarte, United States

Background: Patients with cHL who relapse after autologous stem cell transplantation (ASCT) or progress after brentuximab vedotin (BV) have a poor prognosis. In cHL, nearly universal 9p24.1 amplification, as well as less likely mechanisms such as Epstein-Barr virus infection and chromosomal rearrangements, induce PD-L1 and PD-L2 expression on the tumor cell surface, suggesting that cHL may have a genetically determined dependence on the PD-1 pathway. Pembrolizumab is a humanized monoclonal antibody against PD-1 that blocks interaction with PD-L1 and PD-L2. In the phase 1b KEYNOTE-013 study, pembrolizumab demonstrated high antitumor activity (objective response rate [ORR] of 65%) in heavily pretreated patients with cHL. KEYNOTE-087 is a phase 2 study designed to further evaluate the clinical activity of pembrolizumab in this patient population.
Aims: To determine the ORR, safety, and tolerability of pembrolizumab in patients with R/R cHL.
Methods: KEYNOTE-087 (NCT02453594) is a multicenter, single-arm, multicohort phase 2 study designed to evaluate the clinical activity of pembrolizumab in 3 cohorts: R/R cHL after ASCT and subsequent BV therapy (cohort 1); ineligible for ASCT due to chemo-resistance (no response to salvage chemotherapy) and BV therapy failure (cohort 2); and R/R cHL after ASCT but not treated with BV after ASCT (cohort 3). Patients received pembrolizumab at a fixed dose of 200 mg intravenously every 3 weeks. Primary end point was ORR, with response assessed every 12 weeks according to Revised Response Criteria for Malignant Lymphomas. A prespecified interim analysis, based on investigator-assessed response, was performed after 30 patients in cohorts 1 and 2 reached the first response assessment. Informed consent was obtained for all patients.
Results: At the time of data cutoff (Feb 1, 2016), 60 patients were evaluable for cohorts 1 and 2. Median (range) age was 36 (19 - 64) years in cohort 1 and 33 (20 - 71) in cohort 2. 35% had primary refractory disease (no response to frontline therapy), 67% received ≥4 prior lines of therapy, and by design 100% failed prior BV. ORR among 30 patients in cohort 1 was 70% (95% CI, 51% - 85%). 6 patients (20%) achieved complete response (CR; residual mass permitted if PET negative), 15 (50%) partial response (PR), and 6 (20%) stable disease as best response. ORR among 30 patients in cohort 2 was 80% (95% CI, 61% - 92%). 8 patients (27%) achieved CR, 16 (53%) PR, and 4 (13%) stable disease as best response. With a median of 6 treatment cycles, the most common treatment-related AEs (TRAEs) were pyrexia (13%), diarrhea (8%), and fatigue, platelet count decrease, dry skin, and cough (7% each). There were 7 grade 3 TRAEs in 3 patients: neutropenia, colitis, diarrhea, cytokine release syndrome, herpes zoster infection, increased amylase, and lichen planus; and only 1 grade 4 TRAE, increased lipase. There were no treatment-related deaths.
Summary/Conclusions: PD-1 blockade with pembrolizumab shows frequent responses in heavily pretreated patients with cHL. Of note, pembrolizumab provided a high ORR (80%) in patients who were not candidates for ASCT and failed previous BV therapy. Cohort 3 continues accrual and interim analysis results will be presented.

S795

VERY LATE RELAPSE >5 YEARS AFTER FIRST DIAGNOSIS OF HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP HD7-HD12 TRIALS

PJ Bröckelmann*, H Görgen, C Kohnhorst, M Fuchs, P Borchmann, A Engert
Department I of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

Background: Patients who are free of Hodgkin lymphoma (HL) for >5 years after first diagnosis are usually considered cured. Nevertheless, late relapses occur and biology, clinical characteristics, therapeutic approaches and prognosis are currently poorly understood.
Aims: Our study hence aimed at a comprehensive analysis of very late relapse (VLR) of HL.
Methods: We retrospectively analyzed 5149 patients of the GHSG HD7-HD12 trials, who were observed and relapse-free for >5 years after first diagnosis to estimate the incidence of VLR of HL. Cumulative incidence of VLR was calculated with death without preceding relapse considered as competing risk and compared between groups using Gray's test. To investigate, whether VLR can be considered as new cases of HL, standardized incidence ratio (SIR) was estimated using age- and sex-specific reference values for the German population. Overall survival (OS) was estimated according to Kaplan-Meier from first diagnosis to death from any cause. Additionally, OS from date of relapse was estimated for patients with VLR and compared with a group of 487 patients from the respective trials having early relapse (≤5 years from first diagnosis). Patient characteristics and therapy at relapse were analyzed descriptively.
Results: With a median observation time of 10.3 years, a total of 169 relapses >5 years after first diagnosis were observed. In patients relapse-free for >5 years, cumulative incidences at 10, 15 and 20 years rose in a linear fashion and were 2.8%, 5.1% and 8.6%, respectively, with an SIR of 97.1 (95% CI: 83.0-112.9). VLR were more frequently observed in patients with early-stage favorable than early-stage unfavorable or advanced-stage disease at first diagnosis (15-year cumulative incidence 8.0% *vs* 4.4% and 4.2%, respectively, p<0.001). OS was significantly worse in patients with VLR when compared to non-relapse survivors (10-year OS: 95.9% *vs* 88.5%, HR: 2.4, 95% CI: 1.7-3.4, log-rank p<0.001). Compared to patients with early relapse, fewer patients with VLR were treated with autologous stem-cell transplantation (ASCT, 35% *vs* 49%). Instead, they often received polychemotherapies such as BEACOPP (18% *vs* 13%) or ABVD (15% *vs* 11%). Compared to early relapse, we observed superior OS after VLR (HR: 0.5, 95% CI: 0.3-0.8, p<0.01) after adjustment for type of therapy and risk group at first diagnosis. In addition, relapse characteristics, changes in histologic subtype and risk factors for VLR will be presented.
Summary/Conclusions: Besides therapy-associated side effects, survivors after initially successful HL-therapy are at a 100-fold increased risk of re-occurrence of disease compared to German reference values. After modern risk-adapted treatment strategies especially in early-stage favorable HL, thorough regular follow-up is hence needed for timely detection. With adequate treatment, prognosis of VLR seems favorable when compared to early relapses.

ALLOGENEIC STEM CELL TRANSPLANTATION AND BRENTUXIMAB VEDOTIN IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA: A MULTICENTER EXPERIENCE

M Festuccia[1,*], A Busca[1], F Zallio[2], R Sorasio[3], L Brunello[1], E Maffini[1], C Dellacasa[1], R Passera[4], G Iovino[1], S Aydin[1], N Mordini[3], M Pini[2], M Boccadoro[5], B Bruno[1], L Giaccone[1]
[1]SSCVD Trapianto di Cellule Staminali, AOU Città della Salute e della Scienza di Torino, Torino, [2]Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Arrigo, Alessandria, [3]Division of Hematology, Azienda Sanitaria Ospedaliera S.Croce e Carle, Cuneo, [4]Statistical Consultant, [5]Division of Hematology, AOU Città della Salute e della Scienza di Torino, Torino, Italy

Background: Patients with relapsed/refractory (RR) Hodgkin lymphoma (HL) have a very poor prognosis. Allogeneic stem cell transplantation (allo-HCT) has been used in this setting with controversial results.
Aims: Aim of our study is to investigate the role of allo-HCT in RR HL.
Methods: This study reported on 69 patients with RR HL, median age 34 (range, 18 - 64), consecutively transplanted between 2000 and 2015 in 3 transplant center in Northwest Italy. Coordinator of the project was the Division of Hematology of the University of Torino. Patients were heavily pre-treated with a median of 4 therapy lines (range, 2 - 6). Sixty-four patients (93%) received previous high-dose chemotherapy and autologous transplantation. At the time of allo-HCT, 52 patients (75%) were at least in partial remission (PR) and were defined responsive. The remaining 16 patients (23%) had progressive disease (non-responsive). The disease status of 1 patient was not available. Brentuximab Vedotin (BV) was given as bridge to transplant in 11 patients. Moreover, 7 patients received BV after allo-HCT as salvage. The majority of patients underwent reduced intensity allo-HCT, 64 patients (93%). Donors were HLA-matched unrelated in 39 cases (57%), HLA-matched siblings in 28 cases (41%), HLA-haploidentical in 2 cases (3%). The stem cells source was peripheral blood in 61 patients (88%), bone marrow in 7 patients (10%) and cord blood in 1 patient (1%).
Results: Overall, 32 patients (46%) have died at the time of last contact, including 20 patients who had relapsed. This resulted in a median overall survival (OS) [Figure 1], and relapse-free survival (RFS) of 5.1 years (range, 0 - 13.8), and 1.3 years (range, 0-12.6), respectively. Median follow-up among the 37 survivors was 7.2 years (range, 0.1-13.8). The 5-year cumulative incidence of treatment related mortality (TRM) and relapse were 17.7% and 43.4%, respectively. As expected, patients younger than 35 had a lower 5-year TRM compared to older patients (8.7% *versus* 27.1%). The day-100 cumulative incidence of grades II-IV acute graft-*versus*-host disease (GvHD) was 36.7% (60 evaluable patients). Only 8 patients had grade III disease. No grade IV acute GvHD was reported. The cumulative incidence of limited or extensive chronic GvHD was 45.6% (57 evaluable patients). The 5-year estimated of RFS was significantly higher in responsive compared to non-responsive patients, 46.9% *versus* 12.5%, respectively, p= 0.009. There was a trend to improved 5-year OS in responsive patients, 54.6% *versus* 37.5%, respectively, p= 0.19. The RFS advantage of responsive patients was confirmed by multivariable Cox regression (HR= 3, 95% CI 1.4 - 6.4, p= 0.005). The 5-year relapse incidence was 35.3% and 68.8% in responsive and non-responsive patients, respectively. Eleven patients received BV as bridge to allo-HCT for a median of 6 cycles. Only 3 patients failed to achieved at least PR. Then, BV was used as salvage for post-alloHCT relapse in 7 patients. All patients achieved at least PR. None of patients treated with BV had unexpected toxicity or GVHD worsening.

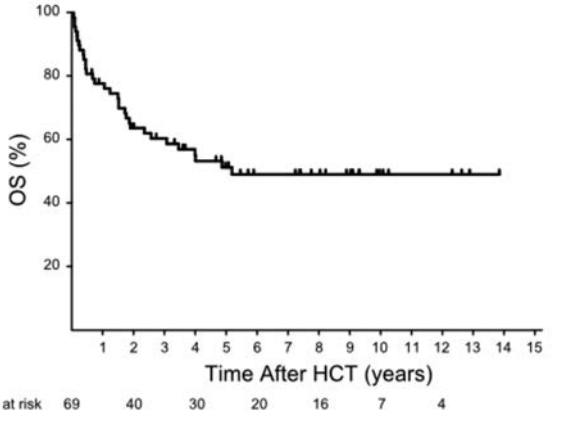

Figure 1.

Summary/Conclusions: Allo-HCT is a feasible and effective option for RR HL. In our series, the disease status at HCT was the main predictor of outcomes, primarily relapse. Furthermore, BV showed efficacy as a bridge to allo-HCT as well as post allo-HCT rescue.

PHASE 1B STUDY OF PEMBROLIZUMAB IN PATIENTS WITH RELAPSED/REFRACTORY PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: KEYNOTE-013

PL Zinzani[1,*], V Ribrag[2], CH Moskowitz[3], JM Michot[2], J Kuruvilla[4], A Balakumaran[5], S Thompson[5], P Marinello[5], S Chlosta[5], MA Shipp[6], P Armand[6]
[1]University of Bologna, Bologna, Italy, [2]Institut Gustave Roussy, Villejuif, France, [3]Memorial Sloan Kettering Cancer Center, New York, United States, [4]Princess Margaret Cancer Centre and University of Toronto, Toronto, Canada, [5]Merck & Co., Inc., Kenilworth, [6]Dana-Farber Cancer Institute, Boston, United States

Background: Primary mediastinal large B-cell lymphoma (PMBCL) frequently exhibits 9p24.1 alterations, leading to overexpression of the PD-1 ligands, PD-L1 and PD-L2. This provides a possible mechanism of immune evasion and suggests that PMBCL could have a genetically determined vulnerability to PD-1 blockade. Pembrolizumab is a humanized monoclonal antibody that blocks the interaction between PD-1 and its ligands. Pembrolizumab has already demonstrated robust antitumor activity in advanced solid tumors and in classical Hodgkin lymphoma. KEYNOTE-013 (NCT01953692) is a multicenter, multicohort phase 1b study designed to evaluate the safety and preliminary efficacy of pembrolizumab in patients with hematologic malignancies. Preliminary results of the PMBCL cohort of KEYNOTE-013 are reported.
Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab in patients with relapsed/refractory (R/R) PMBCL.
Methods: Patients with R/R disease who have relapsed after or are ineligible for autologous stem cell transplantation (ASCT) received pembrolizumab IV 10 mg/kg Q2W or 200 mg Q3W for up to 2 years or until confirmed disease progression or unacceptable toxicity. Primary end points were safety and ORR.

Response was evaluated using computed tomography (CT) and positron emission tomography (PET) at weeks 6 and 12, and every 8 weeks thereafter, using IHP 2007 criteria. Other end points included complete remission rate and duration of response (DOR). Informed consent was obtained for all patients.
Results: As of February 1, 2016, 16 patients were enrolled and treated in this cohort. The first 11 patients received pembrolizumab 10 mg/kg every 2 weeks; the next 5 patients received a fixed dose of 200 mg every 3 weeks, which has demonstrated equivalence based on PK/PD studies. Median age was 30 years (range, 22-62), 44% had ≥4 prior lines of therapy, 31% had prior ASCT, and 75% had prior radiation. 10 patients (62%) experienced treatment-related AEs, most commonly grade 1-2 decreased appetite, diarrhea, fatigue, hypothyroidism, nausea, and pyrexia (2 patients each). Only 1 patient experienced a grade 3 treatment-related AE (neutropenia), and there were no grade 4 treatment-related AEs or treatment-related deaths. 4 patients experienced serious AEs, including grade 3 pneumonia in 3 patients and grade 3 cough in 1 patient; all were unrelated to study drug. No patients discontinued for toxicity. Among the 16 treated patients, the median follow-up was 5.0 months (range, 0.8-22 months) and the objective response rate (ORR) was 37.5% (6/16), with 1 patient (6.25%) achieving a complete remission and 5 patients (31.25%) achieving a partial response. One subject discontinued treatment based on clinical progression before the first assessment and was considered a non-responder. The median DOR has not been reached (range, 0.03+-17+ months), with 5 responses ongoing at the time of data cutoff. 9 have discontinued treatment: 5 because of progressive disease based on imaging, 3 because of clinical progressive disease, and 1 because of physician decision.
Summary/Conclusions: The preliminary results of KEYNOTE-013 indicate that PD-1 blockade with pembrolizumab is associated with a tolerable safety profile and a promising response rate in heavily pretreated patients with R/R PMBCL. These patients often have a very poor outcome with conventional therapy, justifying further studies of pembrolizumab in this population.

TRANSCRIPTION-COUPLED GENETIC INSTABILITY MARKS ACUTE LYMPHOBLASTIC LEUKEMIA STRUCTURAL VARIATION HOTSPOTS

M Heinäniemi[1,*], T Vuorenmaa[1], S Teppo[2], M Kaikkonen[3], V Zachariadis[4], J Mehtonen[1], H Niskanen[3], M Bouvy-Liivrand[1], S Laukkanen[2], T Liuksiala[2], K Teittinen[2], O Lohi[2]
[1]School of Medicine, University of Eastern Finland, Kuopio, [2]Tampere Center for Child Health Research, University of Tampere, Tampere, [3]A. I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, Finland, [4]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Next generation sequencing technologies have drawn attention to the analysis of genetic alterations across different cancer genomes. Precursor leukemias are unique in that they often harbor structural variations (SV) and have relatively few mutations. Instead, the maturing lymphoid cells are vulnerable to off-target effects downstream of the recombination activating genes (RAG) and activation-induced deaminase (AID, encoded by the *AICDA* gene) activity that is required for immune gene rearrangement.
Aims: Earlier *in vitro* studies on DNA binding and genome-wide binding profiles of RAGs have shed light on the mechanisms how this complex is recruited to DNA; however these studies have been carried out using normal cells or mouse models that limit their integration with patient WGS data. More recently, a functional role of transcription in genomic instability has begun to emerge: AID can generate off-target DNA breaks at loci that harbor highly active enhancers and display convergent transcription (transcription from both strands) in lymphomas. The present study represents a systematic investigation of SVs detected in acute pre-B-cell leukemia (pre-B-ALL) in the context of global transcriptional activity in leukemic cells.
Methods: RNA polymerases engaged into primary transcription across the genome can be measured using Global-Run-On sequencing (GRO-seq). Therefore, this method is ideally suited to distinguish features of transcription at SV sites. Transcriptional activity was assayed using GRO-seq from ALL cells representing seven different pre-B-ALL cytogenetic subtypes, and jointly analyzed with public WGS data from the ETV6-RUNX1 (51 cases), high hyperdiploid (16 cases), hypodiploid (20 cases) and MLL-rearranged (22 cases at diagnosis and 2 relapses) subtypes of precursor B-ALL. Pre-B-ALL patient expression profiles (N=1,382), B-lymphoid cell chromatin conformation capture (HiC), RNA polymerase ChIP-seq and DNAse hypersensitivity (DNAse-seq) data were used as additional data.
Results: The active transcriptional profiles from ALL patients revealed striking similarity at SV sites to AID off-target lesions reported in lymphomas. Based on pre-B-ALL transcriptomes, high *AICDA* levels were particularly prevalent in sample clusters that corresponded to high-risk ALL cases and 62% were cytogenetically classified to the subtype "other". The highest level of *AICDA* expression was presented by a relapsed ALL case with high expression already at diagnosis. SV with RAG recognition motifs (RSS motif) also associated strongly with features of transcriptional activity. We could show that elevated levels of convergent transcription that typically occurs at intragenic enhancers positively correlated with detected R-loop levels (needed for AID recruitment) and number of RNA polymerase stalling events at breakpoints. The wide stalling regions identified correlated with highly accessible DNA regions. Accordingly, RNA polymerase stalling sites detected at TSS regions with breakpoints harboring the RAG recognition motif were significantly wider than stalling sites found at TSS regions with no breakpoints, indicating that RNA polymerase stalling could mediate RAG access to its cleavage sites.
Summary/Conclusions: The results support a model in which transcriptional features (convergence of transcription and Pol2 stalling), through altering access to DNA, could act to guide secondary DNA lesions and therefore leukemia progression. Our results position RAG among complexes involved in transcription-coupled genomic instability. Moreover, we present evidence of expression of *AICDA* in high-risk / cytogenetic class "other" pre-B-ALL cases.

TRIGGERING THE TCR DEVELOPMENTAL CHECKPOINT ACTIVATES A THERAPEUTICALLY TARGETABLE TUMOR SUPPRESSIVE PATHWAY IN T-CELL LEUKEMIA

A Trinquand[1,*], NR dos Santos[2], C Tran Quang[3], M Belhocine[4], C Da Costa de Jesus[3], L Lhermitte[1], M Tesio[1], M Dussiot[5], FL Cosset[6], E Verhoeyen[6], F Pflumio[7], N Ifrah[8], H Dombret[9], S Spicuglia[4], L Chatenoud[10], DA Gross[10], O Hermine[11], E Macintyre[1], J Ghysdael[3], V Asnafi[1]
[1]Laboratoire d'hématologie, Hopital Necker, Paris, France, [2]Centre for Biomedical Research, University of Algarve, Faro, Portugal, [3]INSERM U1005, CNRS UMR3306, Institut Curie, Orsay, [4]Université de la Méditerranée, Marseille, [5]INSERM UMR 1163, Paris, [6]ENS de Lyon, Lyon, [7]Commissariat à l'Energie Atomique, Fontenay-aux-Roses, [8]CHU Angers, Angers, [9]Hopital Saint-Louis, [10]Institut Necker Enfants Malades, [11]Hopital Necker, Paris, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) results from the leukemic transformation of thymic cell precursors caused by a multistep pathogenesis involving numerous genetic and epigenetic abnormalities. They are characterized by high relapse rates and poor prognosis, calling for the search of novel therapeutic options. T lymphocytes differentiate in the thymus according to a highly orchestrated process involving developmental checkpoints. Among these, negative selection is a major process by which thymocytes recognizing self-Major Histocompatibility complex with high affinity are eliminated by TCR-mediated apoptosis.
Aims: In this study, we hypothesized that tissue homeostatic regulators may be amenable to reactivation in tumor cells. We inferred that experimentally chronic/persistent induced TCR signaling in T-ALL could initiate a molecular program similar to negative selection of thymic T-cell progenitors and induce cell death.
Methods: We used the transgenic Marilyn TCR-HY in a human T-ALL cell line (ALL-SIL) and in a mouse model of TEL-JAK2-induced T-ALL, to test TCR activation by its cognate peptide/MHC. We evaluated chronic/persistent TCR activation by anti-CD3ε monoclonal antibody *in vitro* (in TCR-HY ALL-SIL and in a panel of 36 primary T-ALL patients cases) and *in vivo* (in TJK2/CD3ε+ and TJK2/CD3ε- mouse T-ALL model and in xenotransplanted mice with 7 human T-ALL).
Results: Using the Marilyn TCR-HY transgene, we showed that TCR activation by its cognate peptide/MHC induced apoptosis *in vitro* (ALL-SIL TLX+ cell line) and dramatically impaired development/maintenance of leukemias *in vivo* (murine TEL-JAK2-induced T-ALL) exclusively in DBY-expressing male mice. Anti-CD3ε monoclonal antibody stimulation mimicked high affinity self-peptide/MHC-induced TCR signaling (human OKT3; murine, 145-2C11): this led to massive leukemic cell death and remarkably induced a gene expression program similar to thymic negative selection. In addition, *in vitro* stimulation of CD3/TCR complex with an anti-CD3ε antibody resulted in cell death of primary CD3/TCR-expressing T-ALL (n=36) regardless their underlying oncogenetic characteristics. Keeping with this, *in vivo* treatment by anti-CD3ε monoclonal antibody prevented from the emergence of the leukemic process in several TCR+ T-ALL murine models, whereas it had virtually no impact on the survival of mice engrafted with murine CD3ε$^{-/-}$ T-ALL cells. Importantly, anti-CD3ε treatment hampered leukemogenesis in xenotransplanted mice with human TCR/CD3+ T-ALL (n=7) in both preventative and curative settings.
Summary/Conclusions: In our study, we found that reactivation in T-ALL blasts of the lineage-specific checkpoint control normally set by TCR signaling during T-cell development, displays anti-tumoral functions. Importantly, despite the multiple and complex oncogenic mechanisms driving T-ALL, this TCR-dependent checkpoint remains switchable to induce massive tumor cell apoptosis. These data provide a strong rationale for targeted therapy based on anti-CD3 treatment of TCR-expressing T-ALL patients and demonstrate that endogenous developmental checkpoint pathways are amenable to therapeutic intervention in cancer cells.

S800

FAST GENERATION OF CONDITIONAL ROSA26-BASED MOUSE MODELS THAT RECAPITULATE GENOMIC EVENTS IN HUMAN T-ALL

T Pieters[1,2,3,*], S Goossens[1,3], S T'Sas[1,3], L Haenebalcke[1,3], T Hochepied[1,3], B Lintermans[2], S Peirs[2], F Matthijssens[2], J Haigh[4], G Berx[1,3], P Van Vlierberghe[2]
[1]Inflammation Research Centre, VIB, Zwijnaarde, [2]Center for Medical Genetics Ghent, [3]Department for Biomedical Molecular Biology, Ghent University, Ghent, Belgium, [4]Mammalian Functional Genetics Laboratory, Division of Blood Cancers, Australian Centre for Blood Diseases, Department of Clinical Haematology, Monash University and Alfred Health Alfred Centre, Melbourne, Australia

Background: T-cell acute lymphoblastic leukemias (T-ALLs) are aggressive hematologic tumors that result from the malignant transformation of T-cell progenitors. Due to intensified chemotherapy, the prognosis of T-ALL has gradually improved. Nevertheless, this clinical improvement is most pronounced in pediatric treatment protocols, whereas adult patients more often present with primary resistant or relapsed disease.
Aims: Our Aim is to develop new mouse models that mimic oncogenic lesions identified in human disease. These mouse models are critically required to further enhance our knowledge on the molecular mechanisms that drive T-cell leukemogenesis. Moreover, they serve as important pre-clinical models to evaluate new therapeutic strategies for the treatment of human T-ALL.
Methods: Here, we generated a fast method for embryonic stem cell (ESC) targeting and mouse chimera production. We constructed gateway-compatible vectors that allow tailor-made targeting vector design, including conditional expression of a transgene combined with an eGFP/luciferase reporter from the ROSA26(R26)-promoter or from (inducible) exogenous promoters. The final targeting vector is recombination-mediated cassette exchange (RMCE)-compatible and can be inserted in a genetically engineered R26-locus via RMCE. Correct integration of the incoming construct reactivates the NeoR gene and results in up to 100% ESC targeting efficiencies.
Results: Using our technology, we generated R26-based conditional knock-in mouse models for putative oncogenes that have previously been implicated in T-ALL disease biology. More specifically, the MYB leucine zipper transcription factor is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations (t(6;7)(q23;q34)) or genomic duplications of the MYB locus itself. Moreover, Myb was found to be crucial for the initiation of oncogenic superenhancers in T-ALL. In addition, another subset of T-ALLs show specific TCR-mediated translocations that drive aberrant expression of the cell cycle regulator Cyclin D2 (CCND2). To study the *in vivo* roles of cMyb and Ccnd2 in the pathogenesis of T-ALL, we used the above-mentioned genomic engineering technology to generate cMyb and Ccnd2 conditional knockin mouse models. These animals were crossed with Lck-Cre mice to obtain T-cell specific expression of the oncogenes of interest at moderate pathophysiological relevant levels. Currently, we are monitoring tumor development in T-cell specific homozygous knockin mice. In addition, Myb and Ccnd2 transgenic animals are crossed into a Pten null background to accelerate disease onset. Preliminary data shows that T-cell specific Ccnd2 overexpression cooperates with Pten loss to decrease T-ALL latency.

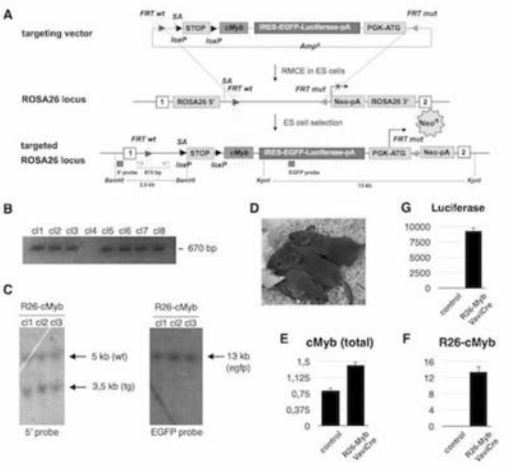

Figure 1.

Summary/Conclusions: All together, we have used a fast genomic engineering pipeline to develop new and pathophysiological relevant conditional overexpression mouse models for human T-ALL.

S801

ACTIVATED JAK-STAT SIGNALING COOPERATES WITH HOXA9 AND DRIVES LEUKEMIA DEVELOPMENT

C De Bock[*], S Demeyer, S Degryse, C Vicente, B Sweron, O Gielen, R Vandepoel, E Geerdens, E Radaelli, J Cools
VIB Center for the Biology of Disease / KU Leuven, Leuven, Belgium

Background: The JAK-STAT signaling pathway is critical for the normal development and proliferation of hematopoietic cells. Mutations in JAK1 or JAK3 occur within ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases and have also been described in other malignancies. We have previously shown that JAK3 mutations are able to transform hematopoietic cells *in vitro* and cause long latency T-ALL in a mouse model.
Aims: To determine mutations which are significantly associated with ectopic activation of the JAK-STAT signaling pathway and determine whether they cooperate in leukemia development *in vivo*.
Methods: Targeted-resequencing of 115 genes across 155 diagnostic T-ALL samples and qPCR on patient derived xenograft (PDX) samples was used to evaluate candidate genes significantly associated with mutations within the JAK-STAT5 pathway. Oncogenic cooperation and transformation to cytokine independent growth was evaluated using primary hematopoietic progenitor cells *ex vivo*. *In vivo* leukemia cooperation was assayed using a modified bone marrow transplant assay using either wild type or CD4-Cre donor mice in conjunction with either a retroviral vector for constitutive expression in all hematopoietic lineages or a novel antiparallel lox66/71 retroviral vector for restricted expression within developing T-cells.
Results: Mutations in JAK3 were found to frequently co-occur with HOXA cluster rearrangement and our qPCR analysis of PDX samples identified HOXA9 as the most upregulated HOXA gene in cases with mutant JAK3. Constitutive expression of the JAK3(M511I) mutant together with HOXA9 transformed murine hematopoietic progenitors to cytokine independent growth *ex vivo*, while JAK3 mutant or HOXA9 alone did not transform cells *ex vivo*. To model the possible cooperation of JAK3(M511I) and HOXA9 in vivo we initially used the bone marrow transplant model with constitutive expression of JAK3(M511I) and HOXA9. This led to the rapid development of a mixed myeloid-lymphoid leukemia in vivo (median survival=82 days) compared to JAK3(M511I) alone (median survival=164 days) or HOXA9 alone (no disease). To study the cooperation during T-ALL development specifically, we modified the bone marrow

transplant model by using a novel inducible retroviral vector in combination with CD2-Cre or CD4-Cre donor bone marrow cells so that JAK3(M511I) and HOXA9 expression is delayed to lymphoid progenitors or T-cells. All models confirmed a clear cooperation between JAK3(M511I) and HOXA9, and ChIP-seq, ATAC-seq, and RNA-seq on the leukemic cells confirmed cooperation at the transcriptional level between STAT5 (downstream of JAK3) and HOXA9
Summary/Conclusions: JAK3 mutations and ectopic expression of HOXA9 cooperate to transform hematopoietic cells and cause rapid leukemia development *in vivo.*

S802

BET INHIBITOR AS A NOVEL THERAPEUTIC APPROACH FOR THE TREATMENT OF MLL-REARRANGED INFANT ACUTE LEUKEMIA
M Bardini[1,*], L Trentin[2], F Rizzo[1], M Vieri[1], AM Savino[1], P Garrido Castro[3], G Fazio[1], E Van Roon[3], N Smithers[4], R Prinjha[4], R Stam[3], R Pieters[3], G te Kronnie[2], G Basso[2], A Biondi[1], G Cazzaniga[1]

Background: Despite the improvements in the field of pediatric leukemia achieved in the last decades, some groups of patients still suffer from a low cure rate. Acute lymphoblastic leukemia occurring in infants carrying the *MLL* gene translocation (MLL+ infant ALL) has an overall poor outcome due to drug resistance and high relapse rate. Numerous studies have shown that the perturbation of the chromatin structure and the transcriptional deregulation induced by the MLL translocation represent the main mechanism of leukemogenesis. Therefore, new therapeutic strategies targeting the chromatin structure and/or the recruitment of the transcriptional complex represent nowadays the most promising approaches.
Aims: In this study we aimed to investigate the effect of Bromodomain and Extra Terminal (BET) inhibition by using the inhibitor I-BET151. BET is a family of adaptor proteins, including BRD2, BRD3 and BRD4, which bind to the acetylated residues of the histone core, and function as epigenetic readers.
Methods: The anti-leukemic effects of I-BET151 administration was tested *in vivo* in a mouse model of human MLL+ infant ALL. A human MLL+ cell line or primary samples derived from infant patients were transplanted into immunedeficient mice, in order to recapitulate the disease in vivo. Subsequently, the animals were treated with I-BET151 or with the vehicle only, via intraperitoneal injection. Additionally, the biological mechanism of the compound was further elucidated at the molecular lever, both *in vitro* using several human MLL+ ALL cell lines, as well as *ex vivo* in patients-derived xenograft (PDX) samples from mice.
Results: Herein we observed that I-BET151 administration reduces the engraftment and the disease burden of MLL+ infant ALL *in vivo* and prolongs the survival in mice. Importantly, the anti-leukemic effect of I-BET151 was also confirmed in a "curative setting" experiment, where the treatment was started when the leukemia was already consolidated in mice. Furthermore we elucidated the biological mechanism of the compound and demonstrated that I-BET151 is able to block cell proliferation (G0/G1-phase arrest) and induce apoptosis through the downregulation of known BRD4 target genes (i.e. *c-MYC*, *BCL2* and *CDK6*) and the impairment of the IL7Ra/STAT5 signaling pathway. Moreover, the analysis of transcriptional profile changes of PDX samples exposed to I-BET151 *ex vivo* allowed us to identify a specific "I-BET core signature" of genes deregulated upon treatment and belonging to the BRD4 and HOXA gene network. The function of these newly identified genes and their potential role in MLL leukemogenesis is currently under investigation. Finally, we have observed that I-BET151 in combination with HDAC inhibitors is even more efficient compared to the single therapy, as these two compounds have a synergic activity.
Summary/Conclusions: Taken together our data show that I-BET151, alone or in combination with HDAC inhibitors, exerts a potent anti-leukemic effect on MLL+ infant ALL. Notably, our study demonstrated for the first time the efficacy of I-BET151 in primary patients' samples. In conclusion, given the aggressiveness of the disease and the lack of a cure for infant patients with MLL leukemia, this study is extremely novel and particularly relevant in the field of hematology, as I-BET151 may represent in the future a promising novel approach for the treatment of this high-risk leukemia.

AML Biology - Novel targeted therapies

Background: Homeobox (HOX) proteins and the receptor tyrosine kinase FLT3 are frequently highly expressed and mutated in acute myeloid leukemia (AML). Aberrant *HOX* expression is found in nearly all AMLs that harbor a mutation in the *NPM1* gene (*NPM1^{mut}*), and *FLT3* is concomitantly mutated in ~50% of these cases. Little is known how these cells maintain aberrant gene expression. Since specific chromatin regulatory complexes control *HOX* expression in normal hematopoiesis and in leukemias expressing an oncogenic MLL-fusion protein, we hypothesized that they might also regulate *HOX* expression in other settings, and that inhibition of *HOX* and *FLT3* expression would produce an antiproliferative effect in *NPM1^{mut}* AML.
Aims: To investigate dependencies of *NPM1^{mut}* AML on MLL and DOT1L complexes and to delineate their potential role in control of leukemogenic gene expression.
Methods: CRISPR-Cas9 genome editing across exons encoding specific protein domains was used in a negative selection screen to assess potential dependencies of *NPM1*^{mut} AML on specific MLL protein domains, and this concept was extended with inhibitors of the menin-MLL interaction (MI2-2 and MI503). Dependencies on DOT1L were explored using the inhibitor EPZ4777. *In vitro* and *in vivo* target validation was performed in two conditional murine knock-in models (*Npm1*$^{CA/+}$*Flt3*$^{ITD/+}$; *Npm1*$^{CA/+}$*Rosa*$^{SB/+}$) and in a disseminated human xenograft model of *Npm1^{mut}* AML.
Results: Using a CRISPR-Cas9 negative selection screen, we discovered the menin binding site of MLL as a dependency in *NPM1^{mut}* OCI-AML3 cells, a region critically involved in chromatin binding of the MLL complex. We next sought to assess treatment effects of MI2-2 and MI503 and observed dramatic suppression of *HOX* and *MEIS1* expression, differentiation induction, and profound growth inhibition in human OCI-AML3 cells and murine *Npm1^{mut}* AMLs. Of interest, ectopic expression of *Meis1, Hoxb4,* or *Hoxa9-Meis1* rescued the antiproliferative effects of menin-MLL inhibition. *In vivo* MI503 treatment of leukemic OCI-AML3 xenografts resulted in profound *HOX* and *MEIS1* suppression, significant reduction of leukemia burden, and in a significant survival advantage of both, human xenografts and secondarily transplanted *Npm1*$^{CA/+}$*Rosa*$^{SB/+}$ mice compared to vehicle controls. As *MEIS1* was most dramatically suppressed across all three models, we determined drug effects on *FLT3* expression, a reported target gene of *MEIS1* and found consistent suppression of *FLT3* to almost undetectable levels. MI503 treatment depleted menin and H3K4me3 on *HOX* and *MEIS1* loci. We also observed a significant decrease of H3K79me2 at those loci, pointing to a potential role for DOT1L, the sole H3K79 methyltransferase. Treatment with EPZ4777 resulted in *HOX, MEIS1,* and *FLT3* down regulation, cell growth inhibition, and profound differentiation of *NPM1^{mut}* AML blasts just as we found with inhibition of the menin-MLL interaction. Next, we investigated effects of combinatorial menin-MLL and DOT1L inhibition and found superior suppression of *HOX* and *FLT3* expression, dramatically more pronounced differentiation, and synergistic growth inhibition. Combinatorial drug treatment further reduced leukemia initiating potential of *NPM1^{mut}* AML cells dramatically compared to single drug treatment *in vivo.*
Summary/Conclusions: MLL and DOT1L are chromatin regulators that control *HOX*, *MEIS1* and *FLT3* expression in *NPM1^{mut}* AML. Combinatorial small-molecule inhibition has synergistic on target activity and represents a potential therapeutic opportunity that should soon be ready for clinical assessment.

CHEMO-GENOMIC INTERROGATION OF PRIMARY ACUTE MYELOID LEUKEMIA WITH BIALLELIC CEBPA MUTATIONS REVEALS RECURRENT CSF3R MUTATIONS AND SUBGROUP SENSITIVITY TO JAK INHIBITORS
VP Lavallée[1,2,*], J Krosl[2], S Lemieux[2], G Boucher[2], P Gendron[2], C Pabst[2], I Boivin[2], A Marinier[2], S Meloche[2], CJ Guidos[3,4], J Hébert[1,2,5], G Sauvageau[1,2,5]
[1]Division of Hematology, Maisonneuve-Rosemont Hospital, [2]Institute for Research in Immunology and Cancer, Université de Montréal, Montréal, [3]Program in Developmental and Stem Cell Biology, Hospital for Sick Children Research Institute, [4]Department of Immunology, University of Toronto, Toronto, [5]Quebec Leukemia Cell Bank, Maisonneuve-Rosemont Hospital, Montréal, Canada

Background: Acute myeloid leukemias (AML) with *CEBPA* mutations define a provisional entity in the WHO 2008 classification. Patients with biallelic *CEBPA* (*CEBPA*^{bi}) mutations comprising N-terminal frameshift and C-terminal in frame mutations (hereafter termed typical *CEBPA*^{bi} AML) characteristically present a normal karyotype and have a favorable clinical outcome. In contrast, characteristics of samples with other combinations of mutations (atypical *CEBPA*^{bi} AML) are less well established.
Aims: Using the RNA-sequencing data from 415 primary AMLs in Leucegene cohort, we aimed to refine the transcriptomic and mutational landscape of 14 *CEBPA*^{bi} AML samples (7 typical and 7 atypical) present in this collection, and to interrogate the novel mutations identified in this subgroup in a targeted chemical inhibitor screen.
Methods: We performed RNA-sequencing, comparative transcriptomic analysis, mutation detection, cell culture and chemical screening using the methods previously reported (Lavallée *et al*, Nature Genetics, 2015).
Results: The 7 typical *CEBPA*^{bi} specimens are best characterized by 95 differentially expressed genes. Using this gene expression profile (GEP), we next performed a principal component analysis and determined that 4/7 atypical *CEBPA*^{bi} samples clustered with typical *CEBPA*^{bi} (hereafter termed GEP+), while 3/7 atypical *CEBPA*^{bi} samples did not (GEP-). Identification of low *HOXA9* expression alone was sufficient to discriminate between GEP+ and GEP- atypical *CEBPA* AML (>300 fold median *HOXA9* expression ratios). In our cohort of *CEBPA*^{bi} AML we identified 23 mutated genes, including the previously reported mutations in *WT1* and *GATA2* in 3/14 (21% each). The most frequent mutations in *CEBPA*^{bi} AML was the activating *CSF3R* T618I mutation present in 29% (4/14) of this subgroup compared to only 3/401 *CSF3R* mutated samples in other AML subtypes (p<0.0001). *CSF3R* encodes the granulocyte colony stimulating factor receptor (G-CSFR) and is a direct target of CEBPA, suggesting a selective pressure for acquisition of these mutations in *CEBPA*^{bi} AML cells. Interestingly, an additional mutation in G-CSFR pathway (STAT5B N642H) was present in a fifth *CEBPA*^{bi} AML sample. Considering the high frequency of *CSF3R* mutations in *CEBPA*^{bi} AML we conducted a targeted chemical screen employing a collection of compounds (n=11) enriched for JAK inhibitors. Inhibitors were tested in a dose response assays using *CEBPA*^{bi} (n=14) and control normal karyotype *CEBPA* wild-type (NK *CEBPA*^{wt}, n=14) primary AML cells. Results showed that all *CSF3R* T618I mutated samples were sensitive to JAK inhibitors (*e.g.* median ruxolitinib IC_{50}=66nM (range: 48 - 94)). Most interestingly, *CEBPA*^{bi} GEP+ samples (n=11), irrespective of their *CSF3R* mutation status, were uniformly and significantly more sensitive than NK *CEBPA*^{wt} specimens to JAK inhibitors (*e.g.* ruxolitinib median IC_{50}: 62 *vs* 181 nM, p=0.01), but not to other inhibitors such as dasatinib or sorafenib, or to cytotoxic agents daunorubicin and cytarabine. This may suggest that networks upstream of JAK-STAT are aberrantly activated in a majority of these specimens. In contrast, *CEBPA*^{bi} GEP- were less sensitive to JAK inhibitors (*e.g.* ruxolitinib median IC_{50}: 285, range: 48 to >10,000 nM), with the exception of a single sample carrying *CSF3R* T618I mutation. These results indicate that the transcriptionally distinct *CEBPA*^{bi} GEP- AML are also distinguishable from *CEBPA*^{bi} GEP+ AML in their responses to various chemical compounds.
Summary/Conclusions: Our study reports a novel co-occurrence of mutations within the *CEBPA*/*CSF3R* pathway in *CEBPA*^{bi} AML and reveals a uniform sensitivity to JAK inhibitors in the transcriptionally uniform *CEBPA*^{bi} GEP+ AML cells. Altogether, it paves the way to personalized clinical trials repositioning JAK inhibitors for *CEBPA*^{bi} AML.

AGONISTIC TARGETING OF TLR1/TLR2 FORCES ACUTE MYELOID LEUKEMIA CELLS INTO DIFFERENTIATION

M Eriksson[1,*], P Peña-Martínez[1], R Ramakrishnan[1], M Chapellier[1], C Högberg[1], G Glowacki[1], JC Mulloy[2], VL Lazarević[3], G Juliusson[3], J Richter[3], T Fioretos[1], BL Ebert[4], M Järås[1]
[1]Department of Clinical Genetics, Lund University, Lund, Sweden, [2]Cincinnati Children's Hospital Medical Center, University of Cincinnati, Cincinnati, United States, [3]Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden, [4]Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Background: Acute myeloid leukemia (AML) is a fatal disease that is characterized by a rapid expansion of myeloid leukemic blasts with impaired differentiation that accumulate in the bone marrow. Because the prognosis for AML is poor and the treatment for most AML subgroups has remained similar for almost four decades, demand is strong for new types of therapies in this disorder. It is thought that one of the major obstacles in successfully treating AML is to efficiently target the AML cells with leukemia-initiating capacity, which often evade standard chemotherapy treatments, leading to disease relapse.
Aims: The aim of this project has been to characterize Toll-like receptor 1 (TLR1) as a therapeutic target on primitive AML cells.
Methods: A murine AML model driven by retroviral *MLL-AF9* fusion expression was used for the mouse studies. Flow cytometry was used to measure Tlr1 expression, for cell cycle analysis, and to measure activated AKT and NFκB. For studies of human AML, *MLL-AF9* transformed cord blood cells were used, and also AML patient samples. Global gene expression profiling was performed using RNA-sequencing.
Results: In search for candidate therapeutic cell surface targets in AML, we here identified TLR1 as upregulated in primitive AML cells relative to corresponding normal bone marrow cells. Stimulating primitive leukemic cells with Pam3CSK4, a Tlr1/Tlr2 agonist, resulted in an increase in actively cycling cells and cell expansion. Morphologic analysis and enhanced CD11b expression indicated rapid myeloid differentiation of the cells. Moreover, Pam3CSK4 strongly suppressed their leukemia-initiating capacity as assessed in *ex vivo* treatment experiments followed by transplantations into sublethally irradiated recipient mice. In contrast, *ex vivo* Pam3CSK4-stimulation of normal hematopoietic stem and progenitor cells only mildly suppressed their long-term repopulating ability in competitive transplants. In human leukemia, Pam3CSK4-stimulation of *MLL-AF9*-transformed cord blood cells pushed them into differentiation and eradicated their colony-forming capacity accompanied by AKT and NFκB activation. In AML patient samples, Pam3CSK4 caused cell differentiation, evidenced by morphological changes consistent with macrophage outgrowth and an increase in CD15-expressing cells, whereas minor effects were observed in normal bone marrow cells. The Pam3CSK4-induced differentiation showed strong correlated (r=0.98) with the level of TLR1 expression in AML $CD34^+CD38^-$ cells. Hence, our data suggest that AML patients with high TLR1 expression would be more susceptible to treatments targeting TLR1.
Summary/Conclusions: In summary, these findings demonstrate that TLR1 is upregulated in primitive AML cells and that agonistic targeting of the TLR1/TLR2 complex forces AML cells into differentiation, revealing a new putative strategy for therapeutically differentiating AML cells.

S806

GPR56 CONTRIBUTES TO THE DEVELOPMENT OF ACUTE MYELOID LEUKEMIA IN MICE

D Daria[1], N Kirsten[1,*], A Muranyi[1], M Mulaw[1], S Ihme[1], A Kechter[1], L Bullinger[2], K Döhner[2], H Döhner[2], M Feuring-Buske[2], C Buske[1]
[1]Institute of Experimental Cancer Research, Comprehensive Cancer Center, University Hospital, [2]Department of Internal Medicine III, University Hospital, Ulm, Germany

Background: One of the major goals in AML research is to identify key characteristics of leukemic stem cells (LSCs) in patients with AML. Gene expression profiling in functionally validated primary AML LSCs has established a gene signature, which consists of 42 genes associated with LSC properties and inferior treatment outcome in patients with AML (Eppert et al., Nature Medicine 2011). Among these 42 genes the G-protein coupled receptor 56 (GPR56) was highly expressed in the LSC enriched fraction compared to the CD34-negative leukemic bulk.
Aims: The aim of this study was to determine the functional role of Gpr56 in AML and to test its accessibility for antibody-mediated targeting of human AML LSCs.
Methods: For this retrovirally engineered overexpression of Gpr56 and the murine bone marrow transplantation model was used. For analyses in the human system NSG xenografting was employed.
Results: 43 clinically and molecularly annotated AML samples of different genotypes were analysed by RQ-PCR, confirming high expression in NPM1c mutated AML and lower expression in the CBF INV16 AML subtype with a 4.7fold difference between the two genotypes. Of note, expression of GPR56 was highest in normal $CD34^+$ hematopoietic stem and progenitor cells, indicating that there is substantial, but not aberrantly high GPR56 expression in human AML cells. To test whether expression levels of GPR56 correlated with treatment outcome, microarray based GPR56 expression of 423 clinically and molecularly annotated newly diagnosed patients treated in two independent prospective clinical trials was correlated with event free and overall survival: when the median expression level of GPR56 was taken as cut-off, high GPR56 expression was associated with inferior event free and overall survival in the total cohort of patients (n=423) as well as in the patients with normal karyotype (n=184) Functional relevance of GPR56 expression was validated in mice, in which co-expression of Gpr56 and Hoxa9 induced leukemia in transplanted mice after a median time of 148 days post transplantation (range 93-264) in contrast to the Hoxa9 and Gpr56 controls, which did not develop any signs of disease in the observation period of up to 380 days post transplant. Vice versa, the onset of leukemia was significantly delayed by shRNA-mediated knockdown of GPR56 in Hoxa9/Meis1 transduced cells when transplanted into mice. Overexpression of Gpr56 grossly changed the molecular phenotype of Hoxa9 transduced cells affecting pathways involved in G-coupled protein receptors and associated intracellular signaling. As GPR56 is part of the LSC signature in human AML, associated with inferior prognosis and as we had shown that GPR56 in collaboration with the oncogene Hoxa9 contributes to myeloid leukemogenesis, it was tested whether antibody-mediated blockage of the surface receptor GPR56 impairs leukemic engraftment in the NSG mouse model. Blockage of GPR56 with a monoclonal naked antibody significantly impaired engraftment into NSG mice. Importantly, also $FLT3\text{-}ITD3^+$ $NPM1c^-$ primary patient samples showed an up to 68% decrease in BM engraftment at 12 weeks (p<0.04).

Summary/Conclusions: Taken together, these data demonstrate that high expression of GPR56 is able to contribute to AML development and characterize the GPR56 as a potential novel target for antibody-mediated anti-leukemic strategies.

S807

SUPER-ENHANCER ANALYSIS DEFINES NOVEL AML AND MDS SUB-TYPES SENSITIVE TO SY-1425, A POTENT AND SELECTIVE RARA AGONIST

M Mckeown[1,*], E Lee[1], C Fiore[2], M Eaton[2], J Lopez[1], R Corces-Zimmerman[3], R Majeti[3], K Stephens[1], C Fritz[1], E Olson[1]
[1]Biology, [2]Computational Biology, Syros Pharmaceuticals, Cambridge, [3]Cancer Biology, Stem Cell Biology and Regenerative Medecine, Stanford University School of Medicine, Palo Alto, United States

Background: Super-enhancers (SEs) are exceptionally large, highly active chromatin regions that are densely occupied by transcription factors. They have been implicated in directing gene expression programs that define cell identity and also regulate oncogenes critical to the pathogenesis of cancer. One such target, the retinoic acid receptor alpha (RARα) was identified by the asymmetric distribution of its enhancer in a cohort of 60 non-APL AML patient samples profiled by our gene control platform.
Aims: This study sought to characterize the relationship between a *RARA* super-enhancer and response to SY-1425, a potent and selective RARα agonist, in AML patient samples, cell lines, and mouse models. MDS patient samples were also tested for comparable *RARA* enhancer levels and elevated biomarker.
Methods: ChIP-seq and RNA-seq were used to study the presence of SEs and correlated mRNA in patient samples. ChIP-seq, RNA-seq, and expression arrays were used in AML cell lines for the same profiling in addition to characterization of the transcriptional and chromatin level response to SY-1425. The effect of SY-1425 was studied in proliferation assays for AML cell lines and in patient-derived murine xenograft models of AML.
Results: The presence of a SE at the *RARA* gene locus was found to predict anti-proliferative sensitivity to the potent, selective RARα agonist, SY-1425, both *in vitro* and *in vivo.* SY-1425 is a clinical stage RARα agonist with greater potency, selectivity, and improved PK over the pan-RAR agonist, ATRA. SY-1425 is not susceptible to auto-induced metabolism and markedly inhibited growth of *RARA* SE-selected patient-derived murine xenograft models in which ATRA had no significant benefit. Normal bone marrow blast cells have low levels of *RARA* enhancer activity. However, the formation of the SE at the *RARA* gene locus drives RARα transcription in excess of endogenous ligand level, favoring the unliganded, repressive state of the transcription factor that leads to myeloid differentiation block. SY-1425 treatment of SE-containing AML cells strongly induces activation of these formerly repressed genes, halting proliferation and promoting differentiation. To examine transcriptional response to SY-1425, ChIP-seq for enhancer (H3K27ac) and RARα binding was paired with mRNA profiling before and after treatment. Following treatment, loci with strong RARα peaks showed increased acetylation and there was formation of new enhancers where little acetylation was previously observed, consistent with RARα serving as a repressor when unliganded and as a transcriptional activator with SY-1425 bound. Moreover, the genes near the SY-1425-induced enhancers are found to be strongly upregulated. This effect is exemplified by enhancer and mRNA upregulation of *TGM2*, a canonical ATRA differentiation response gene in APL. This mechanism is similar to PML-RARα differentiation blockade and SY-1425-induced gene expression changes are very similar to those observed with retinoid treatment of APL cells. In addition to AML, a sub-population of MDS patient samples also contain elevated levels of RARA SE and associated biomarker, suggesting the potential utility of SY-1425 in this closely related disease. Furthermore, ChIP-seq analysis has established that SEs exist in MDS which are comparable to those in *RARA* SE-driven AML.
Summary/Conclusions: In summary, our gene control platform has identified novel subsets of non-APL AML and MDS patients who may respond to the selective RARa agonist, SY-1425. Based on these findings, a phase 2 clinical investigation of SY-1425 in AML and MDS patients, using an SE-derived biomarker to enrich for patients likely to respond, is planned for later this year.

Treatment in specific AML subgroups

S808

HIGHER DOSE DAUNORUBICIN APPEARS BENEFICIAL IN PATIENTS HARBOURING A FLT3-ITD MUTATION: UPDATED RESULTS OF THE UK NCRI AML17 TRIAL

N Russell[1,*], R Hills[2], J Kell[3], J Cavenagh[4], L Kjeldsen[5], MF McMullin[6], P Cahalin[7], M Dennis[8], L Friis[5], A Grech[2], D Milligan[9], R Clark[10], A Burnett[11]
[1]Department of Haematology, Nottingham University Hospitals NHS Trust, Nottingham, [2]HCTU, Department of Haematology, Cardiff University School of Medicine, [3]Department of Haematology, University Hospital of Wales, Cardiff, [4]Department of Haematology, St Bartholomew's Hospital, London, United Kingdom, [5]Department of Haematology, Rigshospitalet, Copenhagen, Denmark, [6]Department of Haematology, Queen's University, Belfast, [7]Department of Haematology, Blackpool Victoria Hospital, Blackpool, [8]Department of Haematology, Christie Hospital, Manchester, [9]Department of Haematology, Birmingham Heartlands Hospital, Birmingham, [10]Department of Haematology, Royal Liverpool University Hospital, Liverpool, [11]Department of Haematology, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: The use of anthracycline and ara-C has been standard induction therapy for Acute Myeloid Leukaemia for at least 30 years. Several trials have compared 90mg/m^2 of daunorubicin with 45mg/m^2 and found benefit either overall or in subgroups. In the NCRI AML17 trial we compared 90mg/m^2 with the more commonly used control arm of 60mg/m^2 in the first course of chemotherapy. Our preliminary findings showed no benefit for increasing the dose of daunorubicin, with increased early mortality (Burnett et al, Blood 2015,125, 3878).However, follow-up was short at only 14.8 months, and there was a suggestion of heterogeneity, with FLT3-ITD mutant patients potentially benefitting. We present here an updated analysis with a median follow up of 28 months.
Aims: To establish whether high dose daunorubicin in induction therapy for AML patients predominantly aged 18-60 years improved survival overall or in any cytogenetic or genetic subgroup.
Methods: Between 09/2011 and 10/2013, 1206 patients were randomised in 1:1 to daunorubicin 90mg/m^2 or 60mg/m^2 (d1,3,5) in course 1, then 50mg/ m^2 (d1,3,5) in course 2, with Ara-C 100mg/m^2 12-hourly d1-10 (course 1) and d1-8 (course 2). The median age was 53yrs (16-72); 54% were male; 84% had de novo AML, 10% secondary, and 6% high risk MDS; median presenting WBC was 8.5 (0.3-430); 10% had favourable cytogenetics; 72% intermediate and 18% adverse.
Results: Overall, 60-day mortality remained higher with DA90 (10% *vs* 5%, p=0.002), and 3-year overall survival did not differ (50% *vs* 47%, p=0.7) suggesting that no overall survival benefit has emerged for DA90. However, analysis stratified by FLT3-ITD showed significant heterogeneity (p=0.02). In ITD WT patients, DA90 did not improve outcome (51% *vs* 49%, p=0.3), but in ITD mutant patients a survival significant benefit (54% *vs* 34%, p=0.03) has emerged with longer follow up. 60-day mortality was not different (7% *vs* 6%, p=0.8). Although numbers were small the benefit appeared greater with higher allelic ratio (p=0.01 for trend). We did not observe a benefit related to age, cytogenetic group, NPM1 mutation status, nor in patients with a FLT3 TKD mutation.

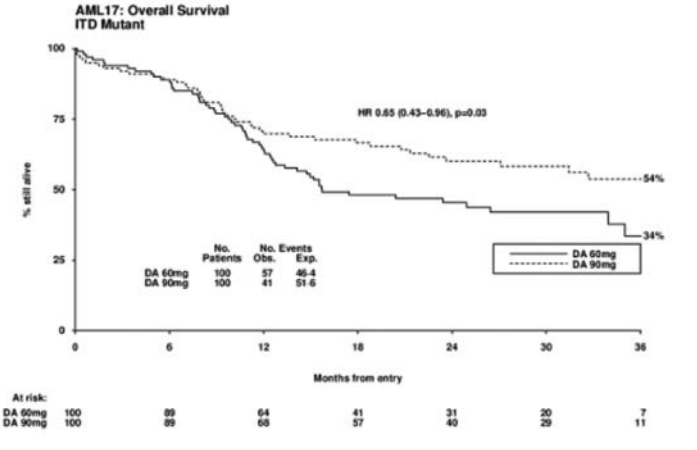

Figure 1.

Summary/Conclusions: These results indicate a potential role for higher doses of daunorubicin in patients with FLT3-ITD mutations. Such therapy could complement the use of FLT3-inhibitors, but its delivery is dependent on early knowledge of mutation status or possibly delivery of the escalated dose in the second course of induction therapy.

Background: Somatic mutations affecting isocitrate dehydrogenase 1 (*IDH1*) or 2 (*IDH2*) genes are found in 15% to 20% of patients (pts) with acute myeloid leukemia (AML). The incidence of these mutations increases with age, which is mainly attributed to *IDH2* mutations. The mutated enzymes emerge as promising therapeutic targets given their abnormal function to produce the oncometabolite 2-hydroxyglutarate. First selective inhibitors of mutant IDH1 and IDH2 proteins are in early clinical development, however, it is currently unknown how results from single-agent inhibitor therapy compare to those of conventional salvage therapy.
Aims: The primary objective of this study was to assess the outcome of patients with refractory or relapsed AML with *IDH1/2* mutations.
Methods: A total of 2825 adults with AML [median age: 55 years (yrs), range 18-84 yrs] who entered eight prospective first-line AMLSG trials of intensive conventional induction and consolidation therapy were included in the study. Refractory disease (RD) was defined as failure to achieve complete remission (CR) after two cycles of induction. Mutational status of *IDH1* and *IDH2* was assessed at the time of initial diagnosis using a combination of denaturing-high-performance liquid chromatography followed by direct DNA-sequencing.
Results: Overall, *IDH1/2* mutations were identified in 530 (18.8%) of 2825 pts; *IDH1* mutations in 7.5% (212/2822) and *IDH2* mutations in 11.5% (326/2825) of pts; 8 pts had a mutation in both *IDH1* and *IDH2*. All but one *IDH1* mutation involved codon R132. Among the *IDH2* mutated cases, *IDH2*^{R140} and *IDH2*^{R172} mutations were detected in 246 (75%) and 75 (23%) pts, respectively; there were 5 cases with *IDH2* mutations involving other codons. In *IDH1/2* mutated AML the CR rate after induction therapy was 62% (327/530) (*IDH1*: 64%; *IDH2*: 61%). A total of 138 pts, including those who only received one induction cycle, were refractory to the primary induction; among the pts receiving two induction cycles 82 had RD (*IDH1*, n=31; *IDH2*, n=50; *IDH1+IDH2*, n=1). Two hundred and eight *IDH1/2* mutated pts relapsed (*IDH1*, n=112; *IDH2*, n=92; *IDH1+IDH2*, n=4). Median overall survival (OS) in pts with RD (measured from the date of RD) and relapse (RE; measured from the time of RE) was 1.03 yrs and 0.79 yr, respectively; in *IDH1* mutated AML 0.53 yr and 0.63 yr, respectively, and in *IDH2* mutated AML 1.22 yrs and 1.09 yrs, respectively. The median OS in all *IDH1/2* mutated pts with RD/RE was 0.81 yr; pts with *IDH2* mutations had a longer (P=.003) survival, which was mainly attributed to the cases carrying *IDH2*^{R172} mutations. Of the 82 pts with RD, 39 (48%) received allogeneic hematopoietic-cell transplantation (alloHCT); the median survival time with alloHCT was 1.80 yrs compared to 0.53 yr in those who did not undergo alloHCT. Of the 208 relapsed patients, 153 received intensive chemotherapy or alloHCT, and 89 (58%) of the 153 pts subsequently achieved a CR/CRi. Seventy-four relapsed pts received alloHCT. Median survival after relapse of pts receiving alloHCT was 1.50 yrs compared to 0.63 yr in those not receiving an alloHCT.
Summary/Conclusions: *IDH1/2* mutations represent a frequent (in this study ~19%) molecular alteration in AML. A substantial proportion of AML pts with *IDH1/2* mutations have RD or relapse. Median survival with conventional salvage treatment in these pts was 0.81 yr, with *IDH2* mutated pts and those receiving alloHCT having significantly longer survival. Our results represent a benchmark for clinical trials evaluating IDH inhibitors in this clinical setting.

Background: Aberrant expression levels of mRNA and microRNA (miR) transcripts have been shown to associate with clinical outcome of cytogenetically normal acute myeloid leukemia (CN-AML) patients (pts). Recently, long non-coding RNA (lncRNA) expression was found to be an independent prognostic marker in older CN-AML pts (Garzon et al. PNAS 2014;111:18679-84). However, the prognostic value and biological implications of lncRNA expression in younger CN-AML patients are unknown.
Aims: The aims were to determine whether lncRNA expression is associated with clinical features, recurrent mutations and prognosis of younger CN-AML patients, and to obtain biological insights into the function of lncRNAs in this disease setting.
Methods: We performed whole transcriptome profiling (RNA-seq) in 377 younger (<60 years) *de novo* CN-AML adult pts and investigated the associations of lncRNA expression with recurrent, prognostically-relevant gene mutations and clinical features. All patients were treated on frontline Alliance/Cancer and Leukemia Group B (CALGB) protocols. Analysis of gene mutations was performed using targeted amplicon sequencing (*NPM1*, *DNMT3A*, *TET2*, *WT1*, *FLT3*-TKD, *IDH2*, *IDH1*, *RUNX1* and *ASXL1*) and Sanger sequencing (*FLT3*-ITD, double *CEBPA*). Small RNA sequencing was performed for miR profiling. The 377 patients were randomly divided into a training set for exploratory analyses (n=263) and a validation set (n=114).
Results: We derived gene mutation-related lncRNA signatures in the training set and tested their accuracy in detecting the pts' mutational status in the validation set. Of the mutations tested, only double *CEBPA* mutations, *NPM1* mutations and *FLT3*-ITD associated with distinct lncRNA signatures. These signatures were able to predict mutated or wild-type gene status in the validation set with high accuracy (sensitivity and specificity >72% in all cases). Using the training set, we identified 24 lncRNAs associated with event-free survival ($P<10^{-6}$). A small number of these lncRNAs associated with prognostic gene mutations (1 with *FLT3*-ITD, 4 with double *CEBPA* mutations). Linear combination of the weighted expression values of the 24 lncRNAs yielded a prognostic lncRNA score. Using the median value as a cut-off, the lncRNA score divided the training set into two groups with very different prognoses; pts with high lncRNA scores had shorter disease-free (DFS, *P*<.001) and overall survival (OS, *P*<.001) than pts with low lncRNA scores. In the validation set, pts with high lncRNA scores were more likely to have higher white blood cell counts (*P*=.009), *FLT3*-ITD (*P*=.007) and high miR-155 expression (*P*<.001) at diagnosis. There was no significant difference in complete remission rates between pts with high and low lncRNA scores (84% v 89%). After a median follow-up of 6.2 years, pts with high lncRNA scores had shorter DFS (*P*<.001; 5-year DFS, 17% v 51%) and OS (*P*=.002; 5-year OS, 26% v 52%) than those with low lncRNA scores. In multivariable analyses, the association of high lncRNA score with shorter DFS (HR: 2.16, *P*=.01) and OS (HR: 1.75, *P*=.04) remained significant after adjusting for other covariates. We also correlated the lncRNA score with mRNA and miR expression and identified several oncogenes (*FOSB*, *JUN*, *ETS2*, *SRC*, *RET*) and cell-cycle regulators (*PLK2*, *PLK3*), which were highly expressed in pts with high lncRNA scores. Gene Ontology analysis revealed enrichment for genes implicated in apoptosis, programmed cell death and inflammation in the high lncRNA score pts. Similarly, miRs that associate with aggressive malignant phenotype (e.g., miR-155, miR-500, miR-362) were overexpressed in pts with high lncRNA scores.
Summary/Conclusions: We conclude that lncRNA profiling provides meaningful prognostic information and identifies potentially targetable oncogenic pathways in younger CN-AML adult pts.

S811

RESPONSE-ADAPTED SEQUENTIAL AZACITIDINE AND INDUCTION CHEMOTHERAPY IN PATIENTS >60 YEARS OLD WITH NEWLY DIAGNOSED AML ELIGIBLE FOR CHEMOTHERAPY (RAS-AZIC): INTERIM ANALYSIS OF THE DRKS00004519 STUDY

N Jaekel[1,*], K Hubert[2], R Krahl[1], M Haenel[3], G Maschmeyer[4], R Herbst[3], C Jakob[4], S Schulze[1], SY Wang[1], M Cross[5], O Brosteanu[6], D Niederwieser[1], HK Al-Ali[1]

[1]Department of Hematology/Oncology, University Hospital of Leipzig, [2]Department of Hematology/Oncology, University of Leipzig, Leipzig, [3]Department of Hematology/Oncology, Klinikum Chemnitz, Chemnitz, [4]Department of Hematology/Oncology, Klinikum Ernst von Bergmann, Potsdam, [5]University Hospital of Leipzig, [6]Clinical Trial Centre Leipzig, University of Leipzig, Leipzig, Germany

Background: Treatment options for AML in patients (pts) >60 years (y) include intensive chemotherapy (IC) and/or azacitidine (AZA). Yet, AZA and IC need not automatically be mutually exclusive.
Aims: In the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO), first-line treatment with AZA followed by AZA or IC in pts >60 y with AML was evaluated. Data of a planned interim analysis per protocol of the first 40 consecutive pts are presented.
Methods: Patients >60 y with newly diagnosed AML and eligible for IC were included irrespective of white blood count (WBC). In the phase I part of the trial, safety of upfront AZA (75 mg/m2/day s.c.) for 7 days followed by IC (mitoxantrone 10 mg/ m²/day on day (d) 1-3 and cytarabine 1g/ m²/BID on d 1, 3, 5, 7) on d 17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d 15 bone marrow (BM) blast count (<45 *versus* ≥45%) and CR, CRi on d 56 previously identified as early predictors for long-term response to AZA in AML (Al-Ali et al., *Leuk Lymph* 2012). The primary endpoint was response (OR) [CR, CRi, and PR] at d 90 according to the International Working Group criteria. Safety, OS, and TRM were main secondary end points. On the basis of an optimal two-stage design (Simon, *Control Clin Trials* 1989), an expected OR of 61% at the end of the trial was estimated. Thus, in an intention-to-treat analysis, if ≤19 of the first 40 pts did not achieve the primary endpoint, protocol treatment would be considered inferior to standard IC. The trial is supervised by an independent Data Monitoring Committee. Adverse events (AEs) are reported according to the NCI CTCAE 4.03. All pts gave written informed consent.
Results: The median age of the 40 pts was 70y (55% males). *de novo* AML was present in 63% of pts. Median BM blasts and WBC were 39% and 6.7x10^9/L respectively. Cytogenetics was high- in 29% and intermediate-risk in 71% (normal cytogenetics 50%) of 38 pts. *FLT3* and *NPM1* were mutated in 11% and 17% of 36 pts respectively. All pts received the upfront AZA. 37 (92.5%) pts received protocol assigned treatment based on BM blasts on d 15 (54% continued with AZA; 46% received IC). Overall, in the 33 (82.5%) pts who continued therapy per protocol until d90, an OR was achieved in 27 (82%) pts [CR/CRi (n=17/7); PR (n=3)]. In the intention-to-treat cohort (n=40), this represents an OR of 67.5% [CR/CRi (60%); PR (7.5%)] with AZA+one IC cycle (n=28) or two IC cycles (n=3). TRM on d 30 and d 90 was 0% and 5% respectively. After a median follow-up of 202 days, OS for the entire cohort was 84.5%. OS for responding pts was 95.5%. Except for one patient, upfront AZA was not complicated by leukocytosis even in pts with WBC >15x10^9/L and was generally well tolerated. Constipation grade 1+2 was the most frequently reported AE under AZA (45%). Overall, the most frequent grade 3+4 non-hematologic AE was infection [11 times in 31 IC-cycles (35%); 7 times in 60 AZA-cycles (12%)].

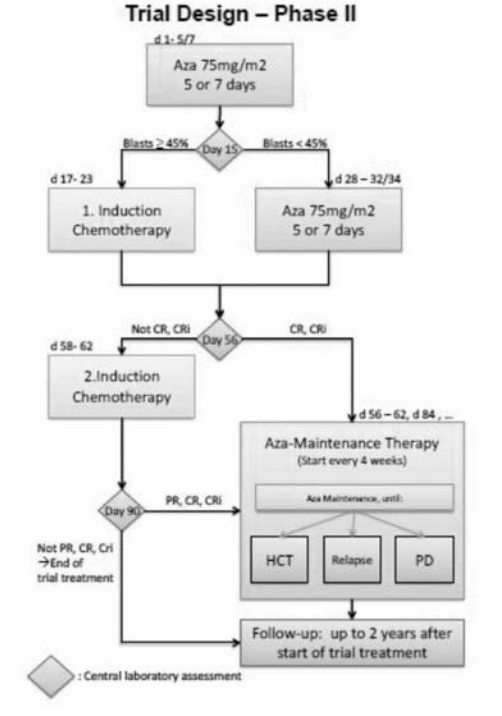

Figure 1.

Summary/Conclusions: These data imply that sequential epigenetic therapy and intensive chemotherapy in elderly pts with AML in an individualized response-based approach is feasible with a very low treatment-related mortality and yields responses that are at least comparable to those achieved after repeated cycles of standard chemotherapy. The final results of this trial will substantiate these data and scrutinize the impact of this approach on long-term survival.

S812

RESULTS FROM ONGOING PHASE 2 REGISTRATION STUDY OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM (BPDCN)

N Pemmaraju[1,*], A Lane[2], K Sweet[3], A Stein[4], S Vasu[5], W Blum[5], D Rizzieri[6], E Wang[7], M Duvic[1], J Chen[8], S Shemesh[8], P McDonald[8], C Brooks[8], H Kantarjian[1], M Konopleva[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Dana-Farber Cancer Institute, Boston, MA, [3]H. Lee Moffitt Cancer Center, Tampa, FL, [4]City of Hope National Medical Center, Duarte, CA, [5]The Ohio State University, Columbus, OH, [6]Duke University Medical Center, Durham, NC, [7]Roswell Park Cancer Institute, Buffalo, NY, [8]Stemline Therapeutics, Inc., New York, NY, United States

Background: SL-401 is a novel targeted therapy directed to the interleukin-3 receptor (IL-3R; CD123). IL-3R is overexpressed by many hematologic cancers, including blastic plasmacytoid dendritic cell neoplasm (BPDCN), acute myeloid leukemia (AML), myeloproliferative neoplasms (MPN) and multiple myeloma. In a prior Phase 1/2 trial, SL-401 demonstrated clinical activity, including multiple complete responses (CRs), in patients with BPDCN, a highly aggressive malignancy of unmet medical need and poor prognosis. Building on this prior experience, we report herein updated efficacy and safety data from our ongoing SL-401 registration trial in BPDCN.
Aims: This Phase 2 trial is a single-arm, open-label, two-stage study consisting of a lead-in dose escalation (stage 1) and subsequent expansion stage (stage 2) designed to generate safety and efficacy data to support potential registration in BPDCN.
Methods: In stage 1, pts with BPDCN or relapsed/refractory (r/r) AML received SL-401 as a daily IV infusion for up to 5 days (7, 9, 12 or 16 µg/kg/day) every 21 days. In stage 2, pts with BPDCN receive SL-401 at the optimal stage 1 dose and schedule. Response criteria include assessment of skin by modified severity weighted assessment tool (mSWAT), and bone marrow, lymph node and viscera by standard measures. Clinical CR (CRc) is defined as no detectable disease in bone marrow, lymph nodes or viscera with microscopic-only skin disease.
Results: At data cut-off (1/20/16), 48 pts (18 BPDCN; 30 r/r AML) were treated with SL-401. 18 BPDCN pts (9+9 in stages 1&2) received SL-401 (7 µg/kg, n=3 [stage 1]; 12 µg/kg, n=15 [6+9 in stages 1&2]); median age 70 yrs (range 45-82 and 1 compassionate use pt age 15); data on 30 r/r AML pts (14+16 in stages 1&2) to be reported separately. Most common treatment-related AEs (all grades) are transient transaminase elevation (57%) and hypoalbuminemia (40%). Transient thrombocytopenia was also noted (15%). Two stage 1 pts had capillary leak syndrome (CLS): gr 5 (7 µg/kg) and gr 4 (12 µg/kg). Safety precautions were developed and successfully implemented to minimize risk of severe CLS. Since adoption, severe CLS has not been observed at doses up to 12 µg/kg. No cumulative side effects were observed over multiple cycles. In stage 1, 12 µg/kg was the maximum tested and recommended stage 2 dose for BPDCN and MTD in r/r AML; MTD was not reached in BPDCN. An 87% (13/15) overall response rate (ORR) was observed in 15 evaluable BPDCN pts, with marked disease reductions in skin, bone marrow, lymph node and viscera. A 100% (10/10) ORR was observed in evaluable first-line BPDCN pts, with 90% (9/10) of pts achieving CR (n=7) or CRc (n=2). A 100% (8/8) ORR was observed in evaluable first-line BPDCN pts treated at the optimal dose (12 µg/kg), and all 8 pts achieved either CR (n=6) or CRc (n=2). 6 of the 8 pts either remain on SL-401 in CR (n=4; duration ongoing at 3+ to 8+ cycles) or were bridged to stem cell transplant (n=2; 1 CR, 1 CRc after 7, 4 cycles).
Summary/Conclusions: SL-401 demonstrated robust single-agent activity in BPDCN, including 100% ORR in first-line, and 87% in all-lines, with multiple CRs; response duration data are maturing and encouraging. This trial (NCT02113982) is designed to support registration in BPDCN and updated data will be presented. SL-401 is also being developed in additional IL-3R/CD123+ hematologic malignancies, including AML in CR with minimal residual disease and high-risk MPN.

RICOLINOSTAT (ACY-1215), THE FIRST SELECTIVE HDAC6 INHIBITOR, COMBINED WITH POMALIDOMIDE AND DEXAMETHASONE SHOWS PROMISING EARLY PHASE 2 RESULTS IN RELAPSED-AND-REFRACTORY MULTIPLE MYELOMA: ACE-MM-102

N Raje[1,*], E Terpos[2], C Cole[3], N Bahlis[4], W Bensinger[5], E Libby[5], A Palumbo[6], S Lonial[7], I Sandhu[8], C Arce-Lara[9], S Jagannath[10], J Valent[11], A Rosko[12], D Reece[13], J Supko[1], D Tamang[14], S Jones[14], C Wheeler[14], R Markelewicz[14], P Richardson[1]
[1]Massachusetts General Hospital, Boston, United States, [2]University of Athens, Athens, Greece, [3]University of Michigan, Ann Arbor, United States, [4]University of Calgary, Calgary, Canada, [5]University of Washington, Seattle, United States, [6]University of Torino, Torino, Italy, [7]Emory University, Atlanta, United States, [8]University of Alberta, Alberta, Canada, [9]Medical College of Wisconsin, Milwaukee, [10]Mount Sinai Hospital, New York City, [11]Cleveland Clinic, Cleveland, [12]Ohio State University, Columbus, United States, [13]University of Toronto, Ontario, Canada, [14]Acetylon Pharmaceuticals Inc., Boston, United States

Background: Ricolinostat (Rico, ACY-1215), an oral selective HDAC6 inhibitor, is well tolerated as monotherapy (Raje *Blood* 2012) and demonstrates potent synergistic activity with lenalidomide (Len) and pomalidomide (Pom) in preclinical models (Quayle *Blood* 2013). Pan-HDAC inhibitors vorinostat and panobinostat are active in MM in combo with bortezomib (Btz) and Len, but toxicities limit dosing and treatment exposure, with resulting diminished efficacy. Rico selectively targets HDAC6 while retaining reduced and tolerable levels of HDAC1, 2, 3 inhibition that down-regulates expression of critical transcription factors regulating cancer cell proliferation, such as c-Myc and IRF4.
Aims: This trial explored activity of Rico in combo with Pom and dexamethasone (Dex) in a population comparable to both the MM-002 and MM-003 trials for Pom/Dex (Richardson *Blood* 2015; San Miguel *Lancet Oncol* 2013). At the primary endpoint of PFS in MM-003, the ORR was 16.6% at 18.1 wks med follow-up, and was 31% at 10 mos. In our trial, 7 pts were treated and no DLTs were observed in Phase 1b (Raje *Blood* 2015), and Phase 2 results are now presented.
Methods: Pts had measurable paraprotein, adequate BM reserve and hepatic function with CrCl ≥45 mL/min. Refractory disease was defined as progression on or within 60 days of last therapy (RRMM). Pts with non-secretory MM, prior Pom or HDAC inhibitor therapy were excluded. Blood samples were obtained for PK/PD assessment of acetylated tubulin and histones. A sample size of 66 was determined to be adequate to detect an ORR of 44% against a historical rate of 29%.
Results: Phase 2 opened at a dose of 160 mg BID, with a predetermined SRC review to occur after 6 pts had completed 1 cycle of therapy. No DLTs were observed with 160 mg BID dosing; however, diarrhea or fatigue leading to dose reductions prompted SRC recommendation for QD dosing in ongoing Phase 2 to maintain maximum therapeutic exposure. Enrollment was closed in Nov 2015 after 96 pts were enrolled in Phase 2. Med age was 67 (39-87) yrs and med number of prior regimens was 2 (2-7). 93% were refractory to Len, 64% were refractory to Btz, and 49% were refractory to both Len and Btz as defined in the entry criteria. Treatment was very well tolerated and common toxicities were predominantly low grade and included neutropenia (44%), fatigue (39%), anemia (30%), diarrhea (28%), thrombocytopenia (19%) and upper respiratory tract infection (16%). Important related grade 3/4 toxicities included neutropenia (22%), thrombocytopenia (7%), anemia (5%), diarrhea (4%), and fatigue (3%). Serious related adverse events reported included bradycardia (n=1), bronchitis (n=1), chronic cardiac failure (n=1), dehydration (n=1), dyspnea (n=1), febrile neutropenia (n=1), general physical health deterioration (n=1), hypoxia (n=1), pneumonia (n=2), renal failure (n=1), and thrombocytopenia (n=1). PK/PD relationship demonstrates selective inhibition of HDAC6 (increasing acetylated tubulin) *vs* nonselective HDAC inhibition (increasing acetylated histones) at therapeutic doses. There was no evidence of Rico accumulation or drug-drug interaction with Pom. 84 efficacy evaluable pts at 4 mos med follow-up demonstrated: PR or better (ORR) of 36%, MR or better (clinical benefit rate, CBR) of 52%, SD or better (disease control rate, DCR) of 89%, med PFS of 5.5 mos, and med DOR of 9 mos. Of these pts, 51 were enrolled at least 6 mos prior to the data cut, with a 5 mos med follow-up and demonstrated an ORR of 47%, CBR of 63%, DCR of 90%, med PFS of 7 mos, and med DOR of 13 mos. This compares favorably to the MM-003 trial of 16.6% ORR at time of primary PFS analysis (med follow-up of 18.1 wks) and ORR of 31% (10 mos med follow-up), as well as similar data from MM -002, with efficacy data continuing to mature.
Summary/Conclusions: These results establish proof of concept and demonstrate that the addition of ricolinostat (a potent oral selective HDAC6 inhibitor) to Pom/Dex is an active regimen in RRMM, leading to superior and durable responses compared to the historical experience with Pom/Dex alone in RRMM.

S814

PHASE 1 STUDY OF VENETOCLAX MONOTHERAPY FOR RELAPSED/ REFRACTORY MULTIPLE MYELOMA

S Kumar[1,*], R Vij[2], JL Kaufman[3], J Mikhael[4], T Facon[5], B Pegourie[6], L Benboubker[7], C Gasparetto[8], M Amiot[9], P Moreau[9], S Diehl[10], S Alzate[10], J Ross[10], M Dunbar[10], M Zhu[10], S Agarwal[10], J Leverson[10], P Maciag[10], M Verdugo[10], C Touzeau[9]
[1]Mayo Clinic, Rochester, [2]Washington University School of Medicine, St. Louis, [3]Winship Cancer institute of Emory University, Atlanta, [4]Mayo Clinic Arizona, Phoenix, United States, [5]CHRU Lille, Hopital Huriez, Lille, [6]CHU Grenoble, La Tronche, [7]CHRU Tours, Saint-Avertin, France, [8]Duke University, Hematologic Malignancies & Cellular Therapy, Durham, United States, [9]CHU de Nantes, Hotel Dieu-HME, Nantes, France, [10]AbbVie, Inc., North Chicago, United States

Background: The anti-apoptotic protein BCL-2 has been implicated in the survival of multiple myeloma (MM) cells. Venetoclax (VEN) is an oral, highly selective BCL-2 inhibitor, which induces cell death in MM cell lines and primary samples, particularly those with t(11;14), and a high BCL-2 and low BCL-$_{XL}$ profile.
Aims: The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.
Methods: After 2-week dose-ramp-up, VEN was given daily at 300, 600, 900, or 1200 mg in dose escalation cohorts and 1200 mg in the safety expansion cohort.
Results: As of 9/17/15, 48 patients were enrolled: 30 in the dose escalation and 18 in the safety expansion. Median age was 65 and 28 patients had ISS stage II/III. Median (range) number of prior therapies was 5 (1–15), and 45 patients had prior bortezomib (32 refractory), 46 lenalidomide (37 refractory), and 40 had SCT. 18 patients had t(11;14)-positive MM. Adverse events (AEs) in ≥30% of patients were diarrhea (40%), nausea (40%), and thrombocytopenia (31%). Grade 3/4 AEs in ≥10% were thrombocytopenia (29%), anemia and neutropenia (17% each). SAEs in ≥2 patients were sepsis (n=3), cough, malignant neoplasm progression, and pyrexia (2 each). Median (range) time on VEN was 1.9 (0.2–13.8) months. 33 (69%) patients discontinued (DC): 26 related to disease progression, 4 due to AEs (worsening shortness of breath, hypokalemia, nausea, lung disorder), 2 withdrew consent, 1 due to death (brain hemorrhage following injury). 5 deaths occurred (3 disease progression, 1 brain hemorrhage, 1 lung disorder). 2 DLTs were seen at 600 mg (cohort was expanded): epigastric pain,and nausea with abdominal pain. Steady state mean C_{max} and AUC_{24} were ~dose proportional at all doses except 900 mg (n=21). 43 of 48 patients were evaluable for efficacy (Table). In the patients with complete responses, these were maintained for 9.7 (600 mg) and 9.0 months (900 mg, ongoing). Very good partial responses were reported for 3 patients, all in the 1200 mg dose cohort.

Table 1.

Best response, n (%)	With t(11;14) (n=17)	Without t(11;14) (n= 26)	All (n= 43)
ORR	4 (24)	1 (4)	5 (12)
CR	2 (12)	0	2 (5)
VGPR	2 (12)	1 (4)*	3 (7)
MR	1 (6)	0	1 (2)
SD	5 (29)	12 (46)	17 (40)
PD	6 (35)	12 (46)	18 (42)
DC before assessment	1 (6)	1 (4)	2 (5)

**Patient has translocation of chromosome 14 with unknown partner*

Summary/Conclusions: Venetoclax monotherapy has a tolerable safety profile in R/R MM. Preliminary efficacy, including complete responses, and very good partial responses, support venetoclax single agent activity in this population, primarily in patients with MM harboring the t(11;14) chromosomal translocation.

S815

A PHASE 2, OPEN-LABEL, MULTICENTER STUDY OF ELOTUZUMAB MONOTHERAPY IN PATIENTS WITH HIGH-RISK SMOLDERING MULTIPLE MYELOMA

P Richardson[1], E Wong[2], K Stockerl-Goldstein[3], C Rosenbaum[4], M Dhodapkar[5], YM Jou[6], M Lynch[6], M Robbins[6], E Bleickardt[6], S Jagannath[7,*]
[1]Dana-Farber Cancer Institute, Boston, [2]VA Connecticut Healthcare System, West Haven, [3]Washington University, St. Louis, [4]University of Chicago Medicine, Chicago, [5]Yale University, New Haven, [6]Bristol-Myers Squibb, Princeton, [7]Mount Sinai Medical Center, New York, United States

Background: Smoldering multiple myeloma (SMM) is an asymptomatic precursor of active multiple myeloma (MM), with no approved therapies. Patients (pts) with MM have compromised natural killer (NK) cell function; during early disease, pts may have better immune activity. Elotuzumab is an IgG1 immunostimulatory antibody targeted against SLAMF7, a glycoprotein expressed by myeloma and NK cells.[1] Progression from SMM to MM, and association between NK cell status and tumor burden, is incompletely understood. SMM provides a disease setting to assess elotuzumab monotherapy in less immune compromised pts.

Aims: To explore the association between baseline (BL) CD56^{dim} NK cells in bone marrow and maximal change in serum M protein (measure of tumor burden) in pts with high-risk SMM treated with elotuzumab. Efficacy and safety of elotuzumab monotherapy were also assessed.
Methods: Pts with high-risk SMM participated in this Ph 2, open-label study (NCT01441973). High risk was defined as serum M protein ≥3 g/dL and bone marrow plasma cells (BMPCs) ≥10% (criteria 1); serum M protein 1–3 g/dL, BMPCs ≥10%, and an abnormal free light chain (FLC) ratio (<0.125 or >8.0) (criteria 2); or urine M protein >200 mg/24 h, BMPC ≥10%, and an abnormal FLC (≤0.125 or ≥8.0; criteria 3).[2] Two high-risk cohorts, enrolled serially, were examined to explore different dosing schedules: pts in cohort 1 (C1) received elotuzumab 20 mg/kg IV in 28-day cycles (cycle 1: Days 1 and 8; cycle 2+: once monthly); in cohort 2 (C2), pts received elotuzumab 10 mg/kg IV in 28-day cycles (cycles 1 and 2: wkly; cycle 3+: twice monthly). Tumor response was assessed every 4 wks. Pts received elotuzumab until disease progression per modified International Myeloma Working Group (IMWG) criteria (including progressive disease or progression to symptomatic active myeloma). Primary endpoint was association between BL percent of bone marrow CD56^{dim} NK cells (CD45^{+}/CD3^{-}/CD56^{dim}/CD16^{+}) and maximal change in serum M protein. Secondary endpoints were progression-free survival (PFS) and overall response rate (ORR). Safety was an exploratory endpoint. Informed written consent was obtained for all pts.
Results: 31 pts were treated (C1, n=15; C2, n=16). Across both cohorts, 32% of pts met criteria 1 for high-risk SMM, 61% met criteria 2, 13% met criteria 3. At data cut-off (January 26, 2016), 27% and 38% of pts from C1 and C2, respectively, were still on treatment. Main reason for discontinuation was disease progression (C1, 47%; C2, 31%). A clear association between BL percent CD56^{dim} cells and maximal change in serum M protein (p=0.779) and between BL CD56^{dim} cells and response (≥minimal response; p=0.988) was not established. PFS and ORR are reported (Table). AEs were reported in all pts in both cohorts. No grade 5 AEs were reported. Most common AEs of any grade were upper respiratory tract infection (C1, 53%; C2, 63%) and fatigue (C1, 47%; C2, 38%). Infusion reactions were reported in 13% of pts; all grade 1–2. SAEs were reported in 53% of pts in C1 and 44% in C2.

Table 1. Progression-free survival and overall response rate.

	Cohort 1 (n=15) Elotuzumab 20 mg/kg	Cohort 2 (n=16) Elotuzumab 10 mg/kg	Total (N=31)
IMWG progression-free survival (PFS)*			
Number of events, n (%)	7 (47)	7 (44)	14 (45)
1-year PFS rate, % (90% CI)	79 (54, 91)	81 (58, 92)	80 (65, 89)
2-year PFS rate, % (90% CI)	71 (45, 86)	54 (31, 72)	62 (45, 75)
Median PFS, months (95% CI)	38 (12, NE)	NE (12, NE)	38 (15, NE)
Best overall response (BOR), n (%)			
Partial response (PR)	2 (13)	1 (6)	3 (10)
Minimal response (MR)	1 (7)	5 (31)	6 (19)
Stable disease (SD)	12 (80)	10 (63)	22 (71)
Progressive disease (PD)	0	0	0

*Progression based on modified IMWG criteria. NE, not estimable.

Summary/Conclusions: An association between BL percent CD56^{dim} NK cells in bone marrow and changes in serum M protein with elotuzumab treatment was not established. Elotuzumab monotherapy may delay SMM progression to MM, as most pts achieved a best overall response of SD or MR, with ≥MR in 29% of pts, including PR in 10%, and favorable PFS. Treatment was generally well tolerated; the AE profile was consistent with prior elotuzumab experience.

DELETION OF CDKN2C DRIVES THE PROGNOSTIC IMPACT OF DELETION 1P IN MULTIPLE MYELOMA
D Begum[1], S Ellis[1], A Price[1], C Smith[1], A Sherborne[1], P Proszek[1], D Johnson[1], B Walker[2], J Jones[1], C Pawlyn[1], M Jenner[3], M Drayson[4], R Owen[5], R Houlston[1], D Cairns[6], W Gregory[7], G Cook[8], F Davies[2], G Morgan[2], G Jackson[9], M Kaiser[1,*]

Background: Survival in multiple myeloma is highly variable and predicting high risk behaviour is key for implementation of risk-adapted therapies. Ultimately, drivers of high risk myeloma need to be identified and directly targeted to turn risk markers into predictive markers for precision medicine.
Aims: To identify the prognostic impact of different genetic lesions affecting chromosome 1p.
Methods: CD138 immunomagnetically selected bone marrow tumour material of 1,036 newly diagnosed myeloma patients enrolled in the NCRI Myeloma XI trial were studied. The trial investigated CTD *vs* CRD induction therapy as well as lenalidomide maintenance *vs* no maintenance and enrolled both young and fit patients who received intensive chemotherapy (n=598 in this analysis), as well as elderly and less fit patients (n=438) who were treated on the non-intensive arm. Cases were molecularly profiled using a combination of MLPA and qRT-PCR (Boyle EM, et al. Gen Chrom Canc 2015; Kaiser MF, et al. Leukemia 2014). These high-throughput methods run on standard molecular biology equipment and allow for robust parallel assessment of multiple genetic lesions in one molecular reaction, including different lesions at chromosome 1p.
Results: Of the 1,036 patients, 10% carried deletion of CDKN2C at 1p32, 18% deletion DPYP (1p21.3), 15% deletion COL11A1 (1p21.1) and 25% deletion FAM46C (1p12), consistent with previous reports. In 7% CDKN2C and COL11A1 co-occurred and also in 7% CDKN2C and FAM46C co-segregated. In 8% of COL11A1 and 18% of FAM46C deleted cases CDKN2C copy number was normal. Only CDKN2C was affected by recurrent homozygous deletions, which was seen in 2% of cases. Deletion of CDKN2C (1p32) was associated with inferior outcome in the 598 intensively treated, younger patients with median progression free survival (PFS) of 21.8 *vs* 33.8 months (P=0.028) and 24-months median overall survival (OS) of 80% *vs* 88% (P=0.003). Deletion of CDKN2C was not associated with shorter survival in the elderly group of patients. Deletions of DPYP, COL11A1 and FAM46C were not associated with shorter PFS in the intensively treated group. Deletion of COL11A1 was associated with inferior OS (P=0.02). However, this was dependent on co-occurrence of deletion CDKN2C and was not significant when looking at cases with isolated COL11A1 deletion (P=0.6). No significant impact of deletion FAM46C on outcome was observed.
Summary/Conclusions: Deletion of chromosome 1p is an established risk factor in intensively treated patients. Our analysis suggests that CDKN2C at 1p32, rather than DPYP (1p21.3), COL11A1 (1p21.1) or FAM46C (1q12) is the relevant gene conferring poor prognosis. This has important implications for the potential development of therapeutic strategies for del(1p) myeloma.

S817

CARDIAC UPTAKE IN AL AMYLOIDOSIS OF 99MTC-DPD AS A NOVEL MARKER OF POOR PROGNOSIS IN SYSTEMIC AL AMYLOIDOSIS
J Zheng[1,*], D Hutt[2], J Gillmore[2], C Whelan[2], C Quarta[2], M Fontana[2], P Hawkins[2], A Wechalekar[2]
[1]Haematology, Royal Free Hospital, London, [2]National Amyloidosis Centre, University College London, London, United Kingdom

Background: The prognosis and outcomes in systemic AL amyloidosis are determined by cardiac involvement. The standard method for assessing degree of cardiac impairment in AL amyloidosis has relied on cardiac biomarkers like NT-proBNP and cardiac troponin-T. However, these markers are not specific for cardiac amyloidosis and other factors like renal failure or fluid overload may affect the levels and limit their utility in determining the prognosis. Thus far, no imaging modality has accurately predicted outcomes in AL amyloidosis. In recent years, the role of bone scintigraphy tracers like technetium-99m-labelled 3,3-diphosphono-1,2-propanodicarboxylic acid (^{99m}Tc-DPD) has been evaluated. They are very sensitive in non-AL amyloidosis. The utility of ^{99m}Tc-DPD scintigraphy in AL amyloidosis has not been studied.
Aims: We report here in a series of 189 patients in which cardiac uptake using ^{99m}Tc-DPD scintigraphy is a marker of very poor outcome in AL amyloidosis.
Methods: All patients who underwent ^{99m}Tc-DPD scintigraphy with a confirmed diagnosis of AL amyloidosis were identified from the database of the UK National Amyloidosis Centre. 189 patients with systemic AL cardiac amyloidosis had ^{99m}Tc-DPD scans at diagnosis from June 2010-November 2015. All patients also had a full protocolized amyloid assessment including cardiac biomarkers, haematology, biochemistry, echocardiography and SAP scintigraphy. All patients are followed up every 3-6 months for prospective protocolized follow up. The characteristics of patients with a positive scan were compared with those patients in whom the scan did not show cardiac uptake. The survival outcomes were assessed by the method of Kaplan and Meier. Cox regression was used to determine univariate and multivariate variables impacting survival.
Results: A total of 189 patients were identified. 114 (60%) had no cardiac uptake on ^{99m}Tc-DPD scans (DPD-negative) and 75 (40%) had cardiac uptake on ^{99m}Tc-DPD scans (DPD-positive); 57 (76%) had grade 1 cardiac uptake, 13 (17%) had grade 2 and 5 (7%) grade 3. There was no significant difference between the DPD-positives and DPD-negatives in terms of NYHA class I/II *versus* III/IV (64% and 36% in the DPD-positives *vs* 67% and 33% in the DPD-negatives, p=0.75); Mayo staging 1/2 *vs* 3 (17% and 83% *vs* 25% and 75%, p=0.20); supine systolic blood pressure (112 *vs* 116, p=0.26). The echocardiographic parameters were also similar in the positive and negative groups: LVEF (50% *vs* 55%, p=0.1); mean LV wall (15mm *vs* 15mm, p=0.39); e/e' (18 *vs* 17, p=0.58). Organ involvement did not show a significant difference between the DPD-positives and DPD-negatives (renal: 52% *vs* 48%, p=0.66; autonomic nervous system: 20% *vs* 14%, p=0.32). The serum free light chains showed no

significant difference (median dFLC 343mg/L *vs* 316mg/L, p=0.40). However, the cardiac biomarkers were significantly greater in the DPD-positives compared to the DPD-negatives: N-terminal fragment of brain natriuretic peptide (NT-proBNP) (8296 ng/L *vs* 4411 ng/L, p=0.005) and high sensitivity troponin (hsTNT) (113 ug/L *vs* 83 ug/L, p=0.001). The overall median survival of the whole cohort was 7 months (95% CI 3 to 11 months). In the DPD-positive group the median survival was 4.3 months compared to 11.8 months in those with cardiac involvement by conventional criteria but DPD-negative (p=0.045). On univariate analysis factors impacting survival were: cardiac involvement, Mayo disease stage, presenting dFLC levels, NT-proBNP, hsTNT and cardiac uptake on ^{99m}Tc-DPD scintigraphy. Multivariate models will be presented.
Summary/Conclusions: ^{99m}Tc-DPD scintigraphy is a useful imaging modality in cardiac AL amyloidosis showing cardiac uptake in 40% of patients with cardiac involvement by conventional criteria. Patients with positive scans for cardiac uptake have significantly higher NT-proBNP and hsTNT compared to those with negative scans. Cardiac uptake on ^{99m}Tc-DPD scan is associated with very poor outcomes. We believe that uptake on a ^{99m}Tc-DPD scan shows advanced cardiac disease independent of all other markers of cardiac involvement in AL amyloidosis. These findings suggest that ^{99m}Tc-DPD scintigraphy should be considered as a simple baseline prognostic investigation in all patients with cardiac AL amyloidosis.

Stem cell transplantation - Clinical 2

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is one important treatment option for patients with aggressive adult T cell leukemia/lymphoma (ATLL). Mogamulizumab (anti-CCR4 monoclonal antibody; Mog) was recently approved as a treatment for ATLL. There are major concerns regarding the possible adverse effects of pretransplant Mog, as Mog depletes regulatory T cells (Tregs) for several months.
Aims: Here, we aimed to assess the impact of pretransplant Mog on the clinical outcomes after allo-HSCT.
Methods: We included 996 allo-HSCT recipients aged 70 years old or younger with aggressive ATLL who were diagnosed between 2000 to 2013, and received intensive chemotherapy using multiple chemotherapeutic drugs as first-line therapy. Before allo-HSCT, 82 patients received Mog with a median interval 45 days from the last Mog to allo-HSCT.
Results: Pretransplant Mog was associated with an increased risk of grade III-IV acute GVHD (30.9% *vs* 17.2%, P<0.01) and refractoriness to systemic steroid for acute GVHD (48.9% *vs* 23.5%, P<0.01). The cumulative incidence of 1-year non-relapse mortality was significantly higher in patients with pretransplant Mog compared to those without Mog (43.7% *vs* 25.1%, P<0.01). The probability of 1-year overall survival was also significantly inferior in patients with pretransplant Mog compared to those without Mog (49.4% *vs* 32.3%, P<0.01). In particular, use of Mog with intervals<50 days to allo-HSCT was associated with a dismal clinical outcome.
Summary/Conclusions: Our study clearly showed that pretransplant Mog significantly worsened the clinical outcome, which strongly supports the important relevance of Tregs in allo-HSCT in humans as in animal models. In clinical practice, Mog should be cautiously used for patients with ATLL who are eligible for allo-HSCT.

REDUCED INTENSITY CONDITIONING (RIC) ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADULT DE NOVO ACUTE LYMPHOBLASTIC LEUKEMIA: A PROSPECTIVE STUDY FROM THE UKALL14 TRIAL (ISRCTN 66541317)

D Okasha[1,2,*], A Kirkwood[3], M Copland[4], E Lawrie[5], A McMillan[6], T Menne[7], N Morley[8], C Rowntree[9], DS Richardson[10], P Smith[5], A Fielding[11], D Marks[12]
[1]Cancer Institute, UCL, London, United Kingdom, [2]Alexandria Faculty of Medicine, Alexandria, Egypt, [3]CRUK and UCL Cancer Trials Centre, UCL, London, [4]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, [5]UCL Cancer Trials Centre, UCL, London, [6]Centre for Clinical Haematology, Nottingham City Hospitals NHS Trust, Nottingham, [7]Freeman Hospital, Newcastle Upon Tyne, [8]Royal Hallamshire Hospital, Sheffield, [9]Heath Hospital, Cardiff, [10]University Hospitals Southampton, Southampton, [11]Department of Hematology, UCL Cancer Institute, London, [12]University Hospitals Bristol NHS Trust, Bristol, United Kingdom

Background: Allogeneic hematopoietic stem cell transplantation (alloHSCT) is a potentially curable treatment modality for adults with acute lymphoblastic leukaemia (ALL) with significant improvement in overall survival (OS) and reduction in relapse incidence. However, in the donor *versus* no donor analysis of the UKALL12/E2993 trial in adult ALL, the OS benefit did not extend to older patients in whom myeloablative allogeneic hematopoietic cell transplant related mortality (TRM) was 35% at 2 years and outweighed the reduction in relapse risk. To address this elevated TRM, reduced intensity conditioning (RIC) has been introduced. In our current UK National Cancer Research Institute

UKALL14 study all patients ≥41 years in CR, regardless of Philadelphia (Ph+) status and other high risk factors, are considered "high risk" and recommended a RIC alloHSCT with a matched sibling (sib) or matched unrelated donor (MUD) after a 2 course induction and high dose methotrexate.

Aims: The primary endpoint is event free survival (EFS). We report here the early outcome of 120 patients with at least day 100 follow up (FU) who received RIC alloHSCT on UKALL14 trial.

Methods: Standard reduced intensity conditioning was with fludarabine 30mg/m^2 d -6 to -2, melphalan 140 mg/m2 d -2 and alemtuzumab 30mg d -2 to-1 (MUD) or d-1 (sib). Graft *versus* host disease (GVHD) prophylaxis was ciclosporin A only. A small group of patients did not receive the standard conditioning protocol. Multilineage chimerism (MC) and minimal residual disease (MRD) were assessed 3 monthly post alloHSCT. Escalating doses of donor lymphocyte infusions (DLI) were given for T-cell mixed chimerism or MRD, starting dose 1 x 10^6 CD3 cells/kg, escalating by half log increments every 3 months.

Results: Five hundred and ninety seven patients were registered on the trial to date, 173 were registered for a RIC alloHSCT, 122 have completed the transplant, 120 of whom have sufficient follow up to report. Median age was 51 years (range 29 to 64). Donor was sib in 39 and MUD in 81 patients, respectively. Median WBC at diagnosis was 8.7 x 10^9/L (0.6-557.23). 57 of 106 (54%) evaluable patients had high-risk cytogenetics, 31 (26%) were Ph+. 18 of 74 (24%) with MRD data were MRD +ve pre-alloHSCT. Post-alloHSCT, myeloid engraftment occurred in 111 patients at a median of 14 days, 9 had missing data. No graft failures were reported. Acute graft *versus* host disease (GVHD) occurred at grade 1 in 34 patients (28%) and grade 2-3 in 12 patients (10%). 47 patients developed chronic GVHD (40% of 117 patients surviving beyond D100), 20 limited and 27 extensive. Of 15 patients who suffered transplant-related mortality (TRM), 8 died of infection (one post-transplant lymphoproliferative disease). Other causes of TRM included organ toxicity (2) and GVHD (2). TRM was not associated with age or donor type. 27 patients relapsed at a median time of 230 days (range 97-1034) with a relapse risk of 27.5% (18.9-38.1) at 22 months post alloHSCT. Of those, 16 (of 25 with data) had high-risk cytogenetics (EFS, p=0.11) and 10 (of 19 with data) were MRD +ve pre-alloHSCT (EFS, HR 2.41, p=0.025). 37 patients in total received 84 DLI (median maximum dose 1 x 10^6 CD3 cells/kg) including 20 for mixed chimerism, 6 for rising MRD and 9 for both. 5 patients (14%) developed post-DLI GVHD at grade 1 (n=4) and grade 2 (n=1). Serial MC data is available for 43 patients. By 6 months post transplant, 34 out of 43 patients (79%) achieved full donor total peripheral blood chimerism whereas only 15 (35%) achieved full donor chimerism in the T-cell compartment. With longer follow up, 26 patients (60%) achieved full donor T-Cell chimerism (median 9 months), 10 after receiving DLI (38%). Figure 1 shows Kaplan Meier curves of OS 66.3% (55.0-75.5, 95% CI) and EFS 59.4% (48.6-68.7) at 22 months (median follow-up).

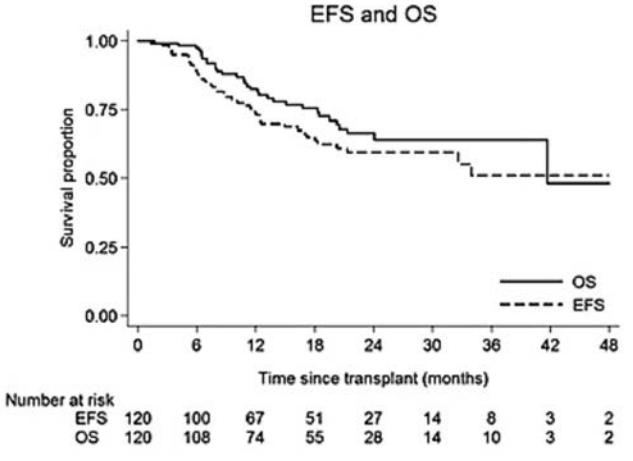

Figure 1.

Summary/Conclusions: This is early follow up from the first prospective data of RIC alloHSCT in older adults with ALL from a large, multicenter trial and the early results are promising. Severe GVHD and TRM were relatively low leading to a higher EFS than expected for this age group, however, longer follow up is needed. T-cell mixed chimerism was common at first MC assessment but early data indicate that conversion to full donor chimerism is achievable and safe with DLI. The impact of mixed chimerism and pre-emptive DLI on relapse remain to be evaluated.

S820

HIGH EXPRESSION OF THE STEM CELL MARKER GPR56 IS ASSOCIATED WITH AN INCREASED RELAPSE INCIDENCE IN AML AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

M Jentzsch[1,*], M Bill[1], L Schumann[1], J Grimm[1], J Schulz[1], M Knyrim[1], GN Franke[1], G Behre[1], W Pönisch[1], V Vucinic[1], C Müller-Tidow[2], C Pabst[2], D Niederwieser[1], S Schwind[1]

[1]Hematology and Oncology, University Hospital Leipzig, Leipzig, [2]Hematology and Oncology, University Hospital Halle, Halle, Germany

Background: In acute myeloid leukemia (AML) leukemia initiating cells (LICs) are believed to exist within the CD34+/CD38- cell compartment. Recently, the G protein-coupled receptor 56 (GPR56) was shown to define a novel LIC compartment independent of the CD34+/CD38- phenotype. LICs are assumed to be responsible for AML maintenance & relapse & may be less immunogenic than AML bulk cells. Hematopoietic stem cell transplantation (HSCT) is a consolidating approach mainly based on immunological graft-*versus*-leukemia (GvL) effects & its therapeutic success is associated with the elimination of AML LICs by GvL effects.

Aims: To evaluate the clinical relevance of aberrant *GPR56* expression in the context of the CD34+/CD38- burden at diagnosis in AML patients (pts) receiving HSCT.

Methods: We analyzed 148 AML pts (median age 61, range 14-75 years [y]) for whom diagnostic bone marrow aspirate material was available & who received a non-myeloablative (3x30mg Fludarabine+2Gy total body irradiation [TBI]) or myeloablative (2x60mg Cyclophosphamide+12Gy TBI) HSCT in 1st (69%) or 2nd (19%) complete remission (CR) or in CR with incomplete peripheral recovery (12%). At diagnosis, the mutation (mut) status of *CEBPA*, *NPM1*, presence of *FLT3*-ITD & expression levels of *BAALC* & *EVI1* were evaluated. For 68 pts *RUNX1*mut status was available. The CD34+/CD38- burden & common surface markers expressions were determined by flow cytometry. A 5% cut-off defined pts with a high & low CD34+/CD38- burden. *GPR56* was measured by qRT-PCR, normalized to *ABL1* & the median normalized gene expression was used to define high & low expressers. Median follow up was 4.9y.

Results: European LeukemiaNet (ELN) classification was 24% favorable, 24% intermediate-I, 17% intermediate-II, 28% adverse & 7% unknown. At diagnosis high *GPR56* expressers had lower white blood cell counts (*P*=.04), were less likely to have *de novo* AML (*P*=.02), core-binding factor AML (*P*=.01), to be *NPM1*mut (*P*=.02) & were more likely to have a del7 (*P*=.004), to be *RUNX1*mut (*P*=.09) by trend, to be *EVI1* positive (*P*=.04) & to have higher *BAALC* (*P*<.001) expression. BM blasts in the high *GPR56* group were less likely to be positive for myeloid markers (CD33, *P*=.009; CD38, *P*=.04; CD64, *P*=.04; CD15, *P*=.002; CD65, *P*=.001) & the pan-leukocyte marker CD45 (*P*=.03) & more likely to be positive for T-cell (CD7, *P*=.03; by trend CD2, *P*=.1), thrombocytic & erythroid (CD61, *P*=.005; Glykophorin A, *P*=.003) & immature (by trend CD34, *P*=.07) markers. High *GPR56* expression was associated with high CD34+/CD38- cell burden at diagnosis (*P*=.002) & with a higher cumulative incidence of relapse (CIR, *P*=.04, Figure 1A) in AML pts receiving HSCT. Since *GPR56* defined a novel LIC compartment independent of the CD34+/CD38- phenotype, we analyzed the impact of aberrant *GPR56* expression in the low CD34+/CD38- burden pts. Similar clinical, cytogenetic & molecular associations were observed as in the entire set of pts. In the low CD34+/CD38- burden group, high *GPR56* expression identified a group of AML pts with a higher CIR as compared to pts with low *GPR56* expression (*P*=.05, Figure 1B).

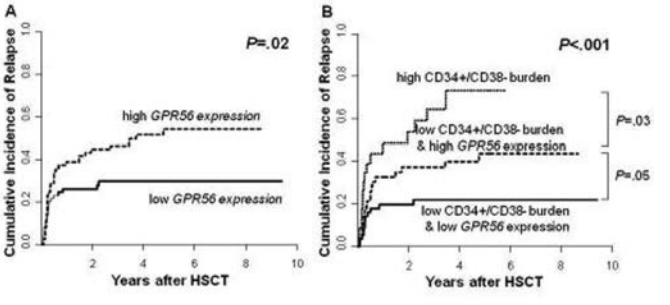

Figure 1.

Summary/Conclusions: High *GPR56* expression was associated with a higher relapse rate & worse outcome predictors. Among pts with low CD34+/CD38- burden high *GPR56* expression defined a subgroup with higher CIR after HSCT possibly due to an independent *GPR56*-defined LIC population. HSCT-associated therapeutic GvL effects might be insufficient to control the disease in pts with high LIC burden defined by the CD34+/CD38-phenotype & *GPR56* expression status at diagnosis.

Background: The feasibility of cord blood transplantation (CBT) in adults is limited by the relatively low number of hematopoietic stem/progenitor cells contained in one single CB unit. The infusion of two CB units from different partially HLA-matched donors (double CBT) is frequently performed in patients who lack a sufficiently rich single CB unit. In patients given CBT following myeloablative conditioning, previous studies have demonstrated that, although double CBT extended the use of CBT for patients lacking a single unit with adequate cells (>2.5 x 10^7 total nucleated cells (TNC)/kg), it failed to improve engraftment and outcomes.
Aims: Here we investigated whether these observations remained true in the setting of reduced-intensity conditioning (RIC) CBT.
Methods: Inclusion criteria included adult (>18 yrs) patients, acute myeloid leukemia (AML) or acute lymphoblastic leukemia (ALL), complete remission (CR) at the time of transplantation, first single (with a cryopreserved TNC ≥2.5 x 10E7/kg) or double CBT between 2004 and 2014, and RIC conditioning.
Results: Data from 534 patients with AML (n=408) or ALL (n=126) receiving a first single (n=172) or double (n=362) CBT were included in the analyses. In comparison to patients transplanted with a single CB, double CB recipients had a shorter follow-up (34 *vs* 54 months, P=0.0005), were more frequently male (56 *vs* 41%, P=0.002), received more frequently a conditioning combining TBI, cyclophosphamide and Flu (TCF regimen, 83 *vs* 66%, P<0.001), and received less frequently ATG (16% *vs* 37%, P<0.001). In univariate analysis, in comparison to patients transplanted with a single CB, double CB recipients had a suggestion for a higher incidence of grade II-IV acute GVHD (36 *vs* 28%, P=0.08) but a similar incidence of neutrophil engraftment (83 *vs* 77%, P=0.3). Further, at 3-year, in comparison to single CB recipients, double CB recipients had a similar incidence of chronic GVHD (36 *vs* 28%, P= 0.17), a similar incidence of relapse (32 *vs* 35%, P=0.4), a similar incidence of nonrelapse mortality (22 *vs* 29%, P=0.17) but a better OS (51 *vs* 41%, P=0.03) and LFS (46 *vs* 36%, P=0.06) (Figure 1). In multivariate analyses OS (HR=0.8, 95% CI 0.7-1.1, P=0.20) and LFS (HR=0.8, 95% CI 0.6-1.1, P=0.17) were no longer significantly better in double CB than in single CB recipients, although there remained a trend in that direction.

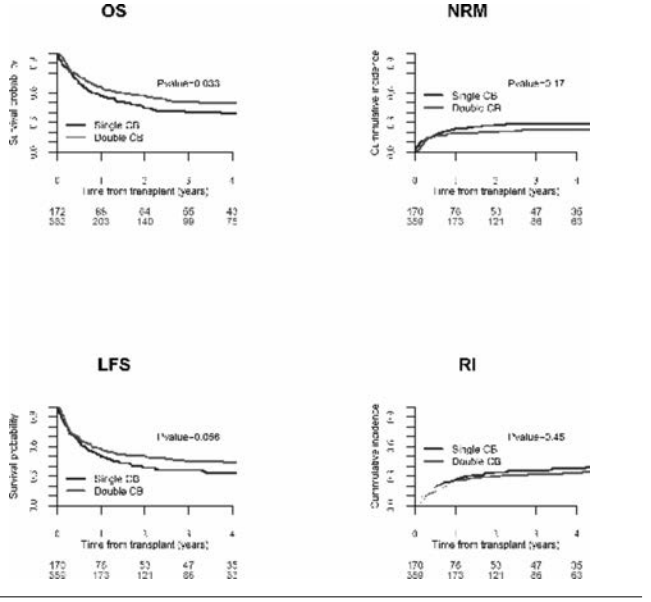

Figure 1. Unadjusted CBT outcomes in patients transplanted following RIC with a single or a double CB.

Summary/Conclusions: These data suggest that LFS and OS are not different for double than single UCB with an adequate TNC dose in the RIC setting. These observations should serve as basis for future prospective randomized studies.

S822

DONOR AND RECIPIENT TOLL-LIKE RECEPTOR 1 VARIATIONS COMPARABLY PREDICT TRANSPLANT-RELATED MORTALITY AFTER UNRELATED BONE MARROW TRANSPLANTATION

K Uchino[1,*], S Mizuno[1], M Mizutani[1], T Horio[1], I Hanamura[1], JL Espinoza[2], K Matsuo[3], M Onizuka[4], K Kashiwase[5], Y Morishima[6], T Fukuda[7], Y Kodera[8], N Doki[9], N Doki[9], K Miyamura[10], T Mori[11], A Takami[1]
[1]Division of Hematology, Department of Internal Medicine, Aichi Medical University School of Medicine, Nagakute, [2]Cellular Transplantation Biology, Kanazawa University Graduate School of Medical Science, Kanazawa, [3]Division of Molecular Medicine, Aichi Cancer Center Research Institute, Nagoya, [4]Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, [5]Japanese Red Cross Kanto-Koshinetsu Block Blood Cente, Tokyo, [6]Division of Epidemiology and Prevention, Aichi Cancer Center Research Institute, Aichi, [7]Hematopoietic Stem Cell Transplantation Unit, National Cancer Center Hospital, Tokyo, [8]epartment of Promotion for Blood and Marrow Transplantation, Aichi Medical University, Nagakute, [9]Hematology Division, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, [10]Department of Hematology, Japanese Red Cross Nagoya First Hospital, Nagoya, [11]Division of Hematology, Department of Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Toll-like receptor 1 (TLR1), the most ubiquitous among the TLR family, plays an essential role in the innate immunity system through initiating the production of inflammatory cytokines. Its genetic variant (rs5743551, -7202 A>G), which resides in the promoter region, has been reported to be associated with susceptibility to various infectious diseases and the mortality and morbidity.
Aims: To investigate the impact of *TLR1* variation on transplant outcomes of bone marrow transplantation (BMT).
Methods: *TLR1* genotyping was performed on 333 patients who underwent unrelated HLA-matched BMT for hematologic malignancies through the Japan Marrow Donor Program between May 2006 and April 2009 and their donors, and its association with the transplant outcomes was retrospectively examined.
Results: The genotype frequencies of A/A, A/G, and G/G were 10%, 39% and 50% in the recipients and 11%, 36% and 51% in the donors (*P*=0.82), respectively. The A/A genotype *vs* A/G or G/G genotype both in the donors (37% *vs*. 18%, respectively; *P*=0.0042) and the recipients (39% *vs* 17%, respectively; *P*=0.021) was associated with a significantly higher 3-year transplant-related mortality (TRM). The A/A genotype in the donors (hazard ratio [HR], 3.4; 95% confidence interval [CI], 1.6-7.2; *P*=0.0017) and the recipients (HR, 2.6; 95% CI, 1.3-5.4; *P*=0.0093) remained statistically significant in the multivariate analysis for 3-year TRM.

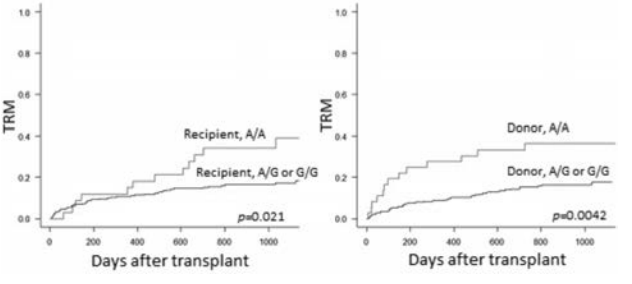

Figure 1.

Summary/Conclusions: These results suggest an association of the donor and recipient *TLR1* A/A genotype with increased TRM after unrelated BMT. An analysis of the *TLR1* genotype could therefore be useful for selecting the donor, managing patients in a risk-adapted manner, and creating therapeutic strategies to prevent TRM after hematopoietic stem cell transplantation.

PLATELET PROPERTIES IN A PATIENT WITH STORMORKEN SYNDROME (STIM1 MUTATION) - ADHESION RECEPTOR LEVELS, CALCIUM HOMEOSTASIS AND PHOSPHATIDYLSERINE EXPOSURE

KD Cummins[1,*], EE Gardiner[2], J McFadyen[1,2], RK Andrews[2], J Jing[2], P McCarthy[3], MM Ryan[4], CA McLean[5], SM Jane[1,2]
[1]Department of Haematology, The Alfred Hospital, [2]The Australian Centre for Blood Diseases, Monash University, [3]The Ronald Sawyers Haemophilia Centre, The Alfred Hospital, [4]Department of Neurology and Murdoch Children's Research Institute, Royal Children's Hospital, [5]Anatomical Pathology, The Alfred Hospital, Melbourne, Australia

Background: Stormorken syndrome is a rare monogenic disorder, recently attributed to a gain-of-function mutation of the stromal interaction molecule 1 (STIM1) gene, which is involved in calcium homeostasis. While this syndrome is associated with macrothrombocytopenia and a bleeding phenotype of variable severity, the pathophysiology underlying the platelet abnormalities is not fully described.
Aims: Evaluate parameters in platelets from a patient with Stormorken syndrome and assess the value of platelet flow cytometry in aiding differential diagnosis of Stormorken syndrome in patients with bleeding not fully explained by macrothrombocytopenia.
Methods: The presence of a p.R304W mutation in STIM1 exon 7 was confirmed after a Stormorken syndrome-like phenotype was recognised in a 21-year old male with long-standing thrombocytopenia, hyposplenism, pupillary miosis and tubular aggregate myopathy. Citrated blood was analysed by flow cytometry for platelet adhesion receptor levels, intracellular calcium levels (both at rest and flux in response to agonists, using Fluo-3-AM), microparticles and platelet phosphatidylserine (PS) exposure (annexin-V binding). Testing on two occasions compared samples from the patient, his unaffected mother, and healthy donors.
Results: Flow cytometry of platelet-rich plasma from the patient confirmed the morphological finding of macrothrombocytopenia, with altered forward and side scatter properties, and also increased numbers of CD41-positive microparticles. In comparison with the control samples, levels of metalloproteinase-sensitive adhesion receptors GPVI and GPIbα were present at the lowest end of normal ranges. The ratio of GPIbα:CD41 was significantly reduced, indicating that GPIbα receptor density was independent of mean platelet volume. Levels of sGPVI were within the normal range suggesting that aberrant metalloproteinase-mediated shedding was not responsible for reduction in GPVI levels. Resting intracellular calcium levels were elevated ~5-fold, and calcium flux in response to ionophore was significantly enhanced. Resting platelet PS exposure was at the upper end of the normal range.

Table 1.

	Microparticles		Calcium ratio		PS exposure	
	Total (%)	CD41+ (%)	Resting	Activated	Resting (%)	Activated (%)
Healthy donor	0.08	6.22	1.94	29	0.69	97.9
Patient	30.6	20.35	8.91	45.8	2.9	94.3

Summary/Conclusions: Using flow cytometry, platelets from a patient with a confirmed gain-of-function mutation of STIM1 demonstrated altered physical properties, reduced adhesion receptor levels, enhanced PS exposure, significantly increased intracellular calcium at rest and an exaggerated calcium flux response to platelet agonists. Blood samples contained elevated levels of platelet-derived microparticles. Flow cytometric analyses of Stormorken syndrome platelets demonstrate reproducible abnormalities, which begin to inform the structural and functional differences in platelets that may contribute to the bleeding phenotype of this rare monogenic disorder, in particular with regards to surface receptor expression and calcium homeostasis.

S824

IMPAIRED FUNCTION OF MESENCHYMAL STEM CELLS FROM IMMUNE THROMBOCYTOPENIA PATIENTS IN INDUCING REGULATORY DENDRITIC CELL DIFFERENTIATION VIA NOTCH2/JAGGED-1 SIGNALLING PATHWAY

LL Xu, JM Zhang, QM Wang, Y Kong, YJ Chang, XS Zhao, XY Zhao, M Lv, LP Xu, KY Liu, XJ Huang, XH Zhang[*]
Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Immune thrombocytopenia(ITP) is characterized by platelet destruction and megakaryocyte dysfunction due to the breakdown of self-tolerance. Mesenchymal stem cells(MSCs) play a pivotal role in immune tolerance. Bone marrow MSCs(BMMSCs) residing in bone marrow stroma (BMS)have been shown to induce regulatory dendritic cell(regDC) differentiation from CD34+ haematopoietic progenitor cells (HPCs). MSCs from ITP patients (ITP-MSCs) exhibit increased senescence and apoptosis, but whether ITP-MSCs have an impaired ability to instruct regDCs remains unknown. Notch is a major factor mediating the interaction between HPCs and BMS.BMS has been reported to prevent the terminal differentiation of DCs through the Notch ligand Jagged-1. Moreover, Jagged-1 has been shown to be involved in the immunosuppressive effects of MSCs on T cells and DCs. It has shown that Notch signalling is important for the modulation of MSCs.
Aims: To investigate whether ITP-MSCs displayed impaired function in inducing regulatory dendritic cell differentiation via notch2/jagged-1 signalling pathway.
Methods: CD34+HPCs were differentiated in the absence or presence of ITP-MSCs or control-MSCs, and then immature DCs were harvested and induced to mature with LPS in the absence of MSCs. MGG staining, flow cytometry and ELISA were performed to characterize the DCs. Mature DCs were then cocultured with CD4+T cells, and proliferation, differentiation, and the anergic and regulatory features of T cells were assessed by flow cytometry. The differential expression of notch receptors, notch intracellular domain(NICD),hes-1, and Jagged-1, was assessed by RT-PCR, flow cytometry and western blot analysis.NICD2-expressing lentivirus,Notch2-targeting shRNA lentivirus, exogenous Jagged-1, and anti-Jagged-1 Ab were used to analyse the underlying mechanism(s).
Results: ITP-MSCs showed impaired function in inhibiting morphological and phenotypic development, proliferation, interleukin-12(IL-12) secretion, and in enhancing endocytosis and interleukin-10(IL-10) production of DCs. DCs that were differentiated in the presence of ITP-MSCs(ITP-MSC-DCs) exhibited a dramatically impaired ability to inhibit allogeneic CD4+ T cell proliferation and to change Th2 polarization. The ITP-MSC-DCs had a deficient capacity to induce anergic and regulatory T cells. Jagged-1 expression and Notch2 signalling pathway activation were down-regulated in ITP-MSCs. The application of exogenous Jagged-1 and anti-Jagged-1 Ab revealed an involvement of Jagged-1 in the development of regDCs. And NICD2 overexpression of ITP-MSCs displayed elevated Jagged-1 expression and an enhanced ability to induce regDCs, which was suppressed after treatment with anti-Jagged-1 Ab. The attenuated function of control-MSCs following Notch2 knockdown was reversed by exogenous Jagged-1. Thus, the Notch2 signalling pathway may modulate regDC differentiation in a Jagged-1-dependent manner. Following pre-treatment with aspirin, both ITP-MSCs and control-MSCs exhibited an up-regulation of the Notch2/Jagged-1 signalling pathway and an enhanced ability to induce regDCs.
Summary/Conclusions: ITP-MSCs show defects in the induction of regDC development, which may play a role in the pathogenesis of ITP. The Notch2/Jagged-1 signalling pathway is involved in the impaired function of ITP-MSCs, and agents targeting this pathway may have great potential for the treatment of ITP.

S825

NOVEL RARE VARIANTS IN EXON 4 OF GP6 HAVE LARGE EFFECTS ON GPVI EXPRESSION AND PLATELET FUNCTION

S Jansen[1,2], W Ouwehand[1,2,3], S Sivapalaratnam[1,2,*]
[1]Haematology, University of Cambridge, [2]NHS Blood and Transplant, Cambridge, [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: One of the initial steps in primary haemostasis is the binding of collagen by the GPVI signalling receptor on platelets. We have an interest in genetic variation in GP6 with an effect on expression and function. Platelets from GPVI-deficient patients are not activated by collagen, but do not show any severe bleeding phenotype. Therefore the GPVI receptor is a promising target for chronic anti-thrombotic treatment. Common variants in the *GP6* gene are known to influence GPVI expression, but they only account for 16% of the observed variation seen in large cohort studies.
Aims: We hypothesized that a large proportion of the variation would be explained by rare variants in GP6 with a greater effect on expression and function.
Methods: The study was performed in the Cambridge Platelet Function cohort of 1500 health consented volunteers. GPVI function and expression was determined by flow cytometry and levels confirmed by Western blotting and ELISA. We planned on Sanger sequencing *GP6* and *FCER1G* in the extreme cases with combined function and expression defects of GPVI. Where possible pedigrees of index cases with rare and functionally relevant GP6 variants, were recruited. Site-directed mutagenesis was performed to introduce individual identified variants and final plasmids verified by Sanger sequencing to test the functionality of the variants. The effect of the variants on thrombus formation was determined by the van Kruchten methodology.
Results: We identified two outlier individuals with approximately 50% reduction in GPVI expression levels and reduced functional responses. Sequencing in one of the individuals, identified a rare G/A variant at position 584 in the *GP6* coding sequence, causing a serine to asparagine substitution at residue 195 (S195N). This variant had a frequency of 0.011% in 72.590 Caucasian individuals of the ExAC database. Sequencing of the second individual and their 4 pedigree members revealed a pattern consistent with the inheritance of a novel rare C/A variant at position 580 in the *GP6* coding sequence, encoding a proline to threonine substitution at residue 194 (P194T). This variant was unobserved in the ExAC database. Both the S195N and P194T variants occur in a key

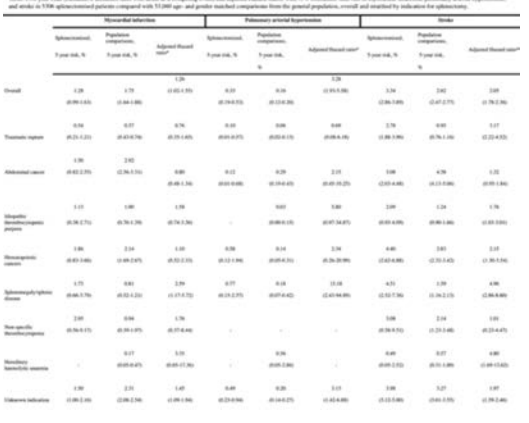
structural motif of the second immunoglobulin-like domain of the receptor. In cell lines the S195N variant resulted in no expression of GPVI, whereas P194T did have expression. Both variants did effect thrombus formation in flowing whole blood over collagen-coated surfaces.
Summary/Conclusions: We have used a combination of platelet GPVI expression and function phenotypes, combined with sequencing of outliers, to identify rare variants with large effect on the native configuration of the cellular receptor and thereby its function and expression.

S826

LONG-TERM RISK OF CARDIOVASCULAR EVENTS FOLLOWING SPLENECTOMY-A DANISH POPULATION-BASED COHORT STUDY
M Rørholt[1,*], W Ghanima[2], D Farkas[3], H Toft Sørensen[3], M Nørgaard[3]
[1]Pediatrics, [2]Haematology & Research, Østfold Hospital trust, Sarpsborg, Norway, [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: The most frequent medical indications for splenectomy are hematological disorders and although, splenectomy has been used for decades to treat various medical and surgical conditions, it is known to be associated with various short and long term complications. An increased risk of venous thromboembolism following splenectomy is well documented while data on long-term risk of cardiovascular events following splenectomy are scarce.
Aims: This study aimed to assess risk of acute myocardial infarction (MI), pulmonary arterial hypertension (PAH), and stroke following splenectomy among patients splenectomised for a variety of indications compared with the risks in the general population and to determine whether these events were related to the procedure or to the underlying pathology by comparing the risk among patients who underwent splenectomy with that among non-splenectomised patients with similar medical conditions.
Methods: We used population-based medical databases to identify patients splenectomised in Denmark during 1996-2012, and constructed an age- and sex-matched general population comparison cohort and a disease-matched comparison cohort. We classified splenectomised patients into 8 subgroups based on the underlying indication for splenectomy: (1) traumatic rupture of the spleen; (2) idiopathic thrombocytopenic purpura (ITP); (3) unspecified thrombocytopenia; (4) hematopoietic cancer; (5) hereditary haemolytic anaemia; (6) abdominal cancer; (7) splenomegaly/other splenic diseases; (8) no indication recorded. We computed 5-year cumulative incidence rates (treating death as a competing event) and adjusted hazard ratios (aHRs) with corresponding 95% confidence intervals (CIs) of MI, PAH, and stroke for the 3 cohorts. We controlled for age, sex, and pre-existing chronic obstructive pulmonary disease, obesity, pulmonary embolism and heart failure.
Results: We identified 5,306 splenectomised, 53,060 population comparisons and 11,651 disease-matched comparisons. The most frequent indications for splenectomy were traumatic rupture (19.5%), abdominal cancers (16.6%), hematopoietic cancers (7.9%), and ITP (7.1%). Within 5 years of follow-up (table), 1.28% of splenectomised patients had MI compared with 1.75% in the general population, yet corresponding aHR was 1.26 (95%CI 1.02-1.55). The 5-year cumulative incidence of PAH was 0.33% among splenectomised and 0.16% [aHR 3.28(95%CI 1.93-5.58)] in the general population, and for stroke 3.34% *versus* 2.62% [aHR 2.05(95%CI 1.78-2.36)]. When comparing the splenectomised cohort with the disease-matched cohort, only stroke-risk was elevated, occurring in 2.99% of the splenectomised *versus* 2.32% in disease-matched [aHR 1.49(95% CI 1.23-1.81)].

Table 1.



Summary/Conclusions: The higher risk of stroke in splenectomised compared with the disease-matched and the general population indicates that splenectomy increases the risk of stroke. Risk of MI and PAH was not higher in splenectomised patients than in disease-matched comparisons, indicating that the higher risk in splenectomised patients compared with the general population can largely be explained by the underlying indication.

S827

QUANTIFICATION OF IGG ANTI-ADAMTS13 ANTIBODY LEVEL CAN PREDICT THE LIKELIHOOD OF MORTALITY IN ACUTE THROMBOTIC THROMBOCYTOPENIC PURPURA
F Alwan[1,2,*], K Langley[2], S McGuckin[1], M Thomas[1,2], JP Westwood[1,2], M Scully[1,2]
[1]Department of Haematology, University College London Hospital, [2]Haemostasis Research Unit, University College London, London, United Kingdom

Background: Acute Idiopathic Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening disorder caused by inhibition of the Von Willebrand factor cleaving protein ADAMTS13 by acquired antibodies, usually of the IgG subclass. Its prevalence has been estimated at four to six cases per million per year and is characterized by hemolytic anemia, thrombocytopenia, fever, neurological symptoms and renal dysfunction. Untreated, mortality has been documented at 90% but even with treatment, it remains around 15-20%. Plasma Exchange (PEX) is the mainstay of treatment but immunosuppressive/immunomodulatory therapy is often also required. Since January 2009, the United Kingdom TTP registry has been collecting information on all acute presentations of TTP across the country. In addition to testing for ADAMTS13 activity, confirmation of the presence of Anti-ADAMTS 13 IgG antibodies forms part of the initial work up.
Aims: A retrospective review to evaluate whether the presenting IgG ADAMTS13 antibody level can predict the likelihood of mortality in acute presentations of TTP.
Methods: 360 acute events were identified from the registry involving 314 patients treated in 63 hospitals. Only acquired TTP was considered with all cases of congenital TTP excluded. Acute TTP was defined as ADAMTS13 protease activity below 10% (FRETS vWF-73 assay, NR: 60-120%) or between 10-20% with a detectable IgG ADAMTS13 antibody present. Acute events were then stratified into groups depending on the presenting IgG ADAMTS13 antibody level (0-29%, 30-59%, 60-89%, >90%).
Results: Of the events identified, 68% of those involved were female with a median age of 46 (range 5-90 years) and a median ADAMTS13 at diagnosis of<5% (range<5%-57%). There was no statistically significant difference when considering these factors between the subgroups. 40 deaths were noted in total, accounting for 11.1% of all events. There was a statistically significant increase in mortality in patients with a presenting IgG ADAMTS13 antibody level above 30% compared to those with a level below 30% (p=0.0023). Subgroup analysis of those presenting with an IgG ADAMTS13 antibody level above 30% found no significant difference in mortality if the level was 30-59%, 60-89% or above 90% (p=0.83).
Summary/Conclusions: There is an increased risk of mortality seen in patients with acute TTP and a presenting IgG ADAMTS13 antibody level above 30%. Such patients should be considered for more aggressive treatment from initial diagnosis. Mortality does not appear to increase with further increases in the antibody level.

Non-malignant hematopoietic disorders

S828

MASITINIB FOR THE TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT AND SMOLDERING SYSTEMIC MASTOCYTOSIS: A RANDOMIZED, PLACEBO-CONTROLLED, INTERNATIONAL, PHASE 3 STUDY

Background: Indolent systemic mastocytosis (ISM) and smoldering systemic mastocytosis (SSM) are life-long conditions associated with a significant reduction in quality-of-life. Masitinib (AB1010) is a selective oral tyrosine kinase inhibitor targeting wild-type KIT (WT-KIT), LYN and FYN. Masitinib does not inhibit KIT-D816V mutated mast cells (MC) but does target normal MCs. This is in part via dual inhibition of LYN and FYN modulating MC degranulation in a KIT-independent manner, and secondly by greatly reducing the normal MC burden through inhibition of WT-KIT.
Aims: To assess the efficacy and safety of masitinib (6 mg/kg/day over 24-weeks with a possible extension period) against placebo in severely symptomatic ISM/ISM patients (pt) who were unresponsive to optimized symptomatic treatments.
Methods: Severely symptomatic ISM/SSM pts were defined as having at least one baseline symptom among: pruritus score ≥9, number of flushes/week ≥8, Hamilton rating scale for depression score ≥19, or Fatigue Impact Scale (FIS) total score ≥75. Treatment-effect was tested using repeated measures methodology for rare diseases via the generalized estimating equation (GEE) model in a modified intention-to-treat (mITT) population. Response was defined as a ≥75% improvement from baseline for any one of the aforementioned severe symptoms. Primary endpoint (4R75%) was cumulative response (timeframe W8-W24) in at least one severe baseline symptom. Long-term analysis was performed over the timeframe of W8-W96. Secondary endpoints included outcomes related to safety, patient-reported symptomatic endpoints and objective endpoints representative of MC activity or burden.
Results: A total of 135 pts were enrolled. Masitinib showed a significant improvement over placebo in its primary endpoint, 18.7% *vs* 7.4%, respectively, odds ratio of 3.6 (95%CI 1.2-10.8, P=0.008). Masitinib sustained a significant 4R75% response over the long-term with odds ratio of 3.5 (95%CI 1.3-9.7, P=0.016). This result was corroborated by statistically significant outcomes in various sensitivity and secondary analyses. For example, at W24 the mean change of tryptase level relative to baseline in pts with baseline tryptase level >20µg/L was a decrease of 18.0% in the masitinib arm *vs* an increase of 2.2% in the placebo arm, *i.e.* an absolute difference of 20.2% (P<0.001). The response of urticaria pigmentosa to masitinib was also statistically significant when compared with placebo (P=0.02), an observation supported by abolition of Darier's sign (P=0.02). Toxicities were predominantly gastrointestinal or skin events, consistent with masitinib's known safety adverse events (AE) profile and typically manageable via dose reduction. Severe AE reported with a >4% difference between treatment-arms were diarrhea (9.8%), rash (5.7%), and asthenia (4.1%). The most frequent serious AEs in the masitinib arm were diarrhea (4.3%) and urticaria (2.9%). There were no deaths or life-threatening AEs in the masitinib arm. Long-term safety assessment revealed comparable incidence of AEs between treatment-arms.
Summary/Conclusions: Masitinib generated a significant therapeutic benefit across a diverse range of symptoms in pts with severely symptomatic ISM/SSM who were unresponsive to optimized symptomatic treatments. Moreover, the response criterion of ≥75% improvement in at least one severe baseline symptom constitutes a clinically meaningful effect. Data from the study's extension period showed that masitinib was capable of maintaining remission of symptoms for over 2 years. This is an important observation given that ISM and SSM are a life-long conditions requiring chronic management. Masitinib was associated with increased frequency of AEs during the first 6 months of treatment, although no toxicities were life-threatening, and over the long-term the incidence of AEs was similar between masitinib and placebo. In summary, masitinib has shown a positive benefit/risk ratio and may be an important future treatment option for severely symptomatic ISM/SSM pts.

S829

STAT3 GAIN-OF-FUNCTION MUTATIONS CAUSE AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME LIKE DISEASE BY DYSREGULATING EXPRESSION OF FAS AND BCL2 PROTEINS AND CAN BE THERAPEUTICALLY TARGETED BY BH3 MIMETICS

S Nabhani[1], H Miskin[2], C Schipp[1], C Levin[3], T Dujovny[3], A Koren[3], D Harlev[2], S Revel-Vilk[4], M Gombert[1], S Ginzel[1,5], A Borkhardt[1], P Stepensky[4], U Fischer[1,*]
[1]Pediatric Oncology, Hematology and Clinical Immunology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [2]Pediatric Hematology Unit, Shaare Zedek Medical Center, Jerusalem, [3]Pediatric Hematology Unit, Emek Medical Center, Afula, [4]Department of Pediatric Hematology-Oncology, Hadassah Hebrew University Medical Center, Jerusalem, Israel, [5]Department of Computer Science, Bonn-Rhein-Sieg University of Applied Sciences, Sankt Augustin, Germany

Background: Autoimmune Lymphoproliferative Syndrome (ALPS) like disease is typically characterized by lymphadenopathy, hepatosplenomegaly, autoimmune cytopenias and an elevated number of double negative T cells (DNT cells, $CD3^+$, $TCR\alpha/\beta^+$, $CD4^-$, $CD8^-$). 70% of patients suffering from classical ALPS harbor germline or somatic mutations in genes involved in the apoptotic FAS death receptor signaling pathway (*FAS*, *FASLG* or *CASP10*). For about 30% of ALPS or ALPS-like patients the genetic cause is unknown.
Aims: The objective of this study was to identify novel gene candidates underlying ALPS like disease of unknown genetic cause and to test potential targeted therapeutic approaches.
Methods: 30 patients with clinical ALPS like symptoms, but without classical mutations were analyzed by whole-exome sequencing. Candidate genes were identified using an in-house developed bioinformatic analysis pipeline for gene prioritization. Candidate mutations were validated by Sanger sequencing. Their impact on Fas signaling and apoptosis was studied and potential therapeutic approaches tested.
Results: We identified two patients with *de novo* germline mutations (p.R278H, p.M394T) of the *Signal Transducer And Activator Of Transcription 3 (STAT3).* Elevated levels of phosphorylated STAT3 (pSTAT3-Tyr705) indicated constitutive activation of STAT3. Patient 1 presented with Coombs positive hemolytic anemia, thrombocytopenia, generalized progressive, non-infectious, non-malignant lymphadenopathy and splenomegaly at the age of nine. Immunophenotyping revealed increased numbers of DNT cells (20% in peripheral blood) and over time the patient developed panhypogammaglobulinemia. Patient 2 presented with early-onset insulin dependent diabetes mellitus and non-infectious, non-malignant lymphadenopathy, splenomegaly, thrombocytopenia, neutropenia and mild anemia. DNT cells and immunoglobulin levels were normal. We could demonstrate that constitutive activation of STAT3 led to decreased *FAS* expression on primary patient T cells and to reduced FAS ligand induced apoptosis similar to the effect of *FAS* mutations in classical ALPS. Therapeutic targeting of STAT3 is challenging and so far none of the developed STAT3 inhibitors has been approved for clinical use. To determine alternative targets we analyzed STAT3 signaling in primary and transformed lymphocytes of the patients. *STAT3* gain-of-function mutations led to increased expression of STAT3 target genes, including *SOCS3* and key anti-apoptotic factors of the BCL2 family of proteins (*BCL-2, BCL-XL*), whereas expression of pro-apoptotic factors (*BAX, BAK*) was decreased. Consistently, patient cells were resistant to cell death induced by stimuli (*e.g.* IL-21, staurosporine) mediating cell death via the BCL2 protein family. Treatment with a STAT3-specific inhibitor (S3I-201) normalized the expression of these factors and rescued the apoptotic response. Cells harboring *STAT3* mutations were significantly more sensitive than normal cells to death induced by the BH3 mimetic inhibitor ABT-737 that targets BCL2,

BCL-XL and BCL-W providing proof-of-concept evidence and indicating a novel therapeutic option.
Summary/Conclusions: We report here on dominant *STAT3* gain-of-function mutations that caused clinical phenotypes similar to ALPS like disease. We demonstrated that constitutive active STAT3 caused decreased *FAS* expression and a skewed balance of pro- and antiapoptotic BCL-2 factors resulting in apoptosis evasion that may be therapeutically targeted by BH3 mimetics.

PRECLINICAL PHARMACOKINETICS AND PHARMACODYNAMICS OF AG-519, AN ALLOSTERIC PYRUVATE KINASE-R ACTIVATOR
Y Chen, R Nagaraja, K Le, PA Kosinski, G Histen, C Kung, H Kim, C Prakash, L Dang, J Popovici-Muller, J Hixon, L Silverman, S Biller, H Yang*
[1]Agios Pharmaceuticals Inc., Cambridge, United States

Background: Pyruvate kinase (PK) deficiency is a rare genetic disease causing chronic hemolytic anemia. Symptoms vary in severity and include splenomegaly, iron overload and jaundice, and current treatments are supportive only. PK deficiency is caused by mutations in the red blood cell (RBC) isoform of PK (PK-R), a key enzyme in RBC glycolysis. Functional PK-R deficiency leads to increases in the upstream metabolite 2,3-diphosphoglycerate (2,3-DPG) and decreases in the product adenosine triphosphate (ATP) in blood. Small molecule activation of mutant PK-R could restore the glycolytic pathway, and decrease hemolysis, leading to patient benefit. AG-519 is an orally available allosteric activator of both mutant and wild type PK-R currently in clinical development.
Aims: To explore the pharmacokinetic/pharmacodynamic (PK/PD) relationships of AG-519 with PK-R activity, ATP and 2,3-DPG in wild type PK-R mice, and to use data from animal studies to project the pharmacokinetic profile and efficacious dose of AG-519 in humans.
Methods: *In vitro* intrinsic clearance (CL_{int}) was calculated in microsomes and hepatocytes from all species tested. *In vivo* PK/PD was analyzed in PK-R wild type C57/BL6 female mice. AG-519 or vehicle was given orally as a single dose, or for 5 and 13 twice-daily (BID) doses, at 1, 10, 50 and 150mg/kg. Blood or plasma concentrations of AG-519, ATP and 2,3-DPG were measured at 0, 3, 6, 12, 24, 36, 48 and 72 h following the last dose by liquid chromatography with tandem mass spectrometry, with PK-R activity measured by colorimetric assessment of the reaction rate in blood cell lysates. For *in vivo* pharmacokinetic profiling of AG-519 in Sprague Dawley rats, Beagle dogs and cynomolgus monkeys, clearance (CL), volume of distribution at a steady state (Vss), terminal half-life (t½), and oral bioavailability (F) were calculated. The human profile was predicted by allometric scaling with correction factors.
Results: AG-519 showed moderate CL (1.13-2.51L/h/kg), moderate Vss (2.08-6.44L/kg), moderate to long t½ (6.3-9.8h), rapid absorption (T_{max} ≤1.2h) and moderate oral bioavailability (6.9-19.5% with suspension formulation) in mouse, rat, dog and monkey. There was good *in vitro* to *in vivo* correlation in the CL estimates across species. In mouse PK/PD studies, dose-dependent increases in blood ATP levels were observed after 5 and 13 BID doses, but not after a single dose. In addition, dose-dependent decreases in 2,3-DPG were observed following both single and multiple doses of AG-519. There were dose-dependent increases in blood PK-R activity after single and multiple AG-519 doses. The AG-519 exposure to biomarker response (2,3-DPG, ATP and PK-R activity) relationship was described by an E_{max} model. With the projections of an effective t½ (4.1-7.1h), CL (0.414L/h/kg), Vss (2.95L/kg), and F (22.5%) in humans, twice-daily dosing of 111mg (range 62-134mg) of AG-519 in humans is anticipated to achieve the $EAUC90_{(0\text{-}12h)}$ (the exposure required to achieve 90% of maximal effect on all three biomarkers) of 421 h•ng/mL.
Summary/Conclusions: AG-519 showed a favorable pharmacokinetic profile in several animal species, allowing prediction of its profile in humans. This, along with the clear PK/PD relationship established in the mouse model demonstrating activation of PK-R, allowed prediction of the AG-519 efficacious dose in humans. These data supported the decision to bring AG-519 into a phase 1 healthy volunteer study (NCT02630927).

S831

HAPLO-IDENTICAL TRANSPLANTATION FOR ACQUIRED SEVERE APLASTIC ANEMIA IN A MULTI-CENTER PROSPECTIVE STUDY
LP Xu[1,*], SQ Wang[2], DP Wu[3], JM Wang[4], SJ Gao[5], M Jiang[6], CB Wang[7], X Zhang[8], QF Liu[9], LH Xia[10], X Wang[11], XJ Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China, Beijing, [2]Guangzhou First People's Hospital, Guangzhou, [3]The First affiliated Hospital of Soochow University, Soochow, [4]Changhai Hospital affiliated to Second Military Medical University, Shanghai, [5]The First Hospital of Jilin University, Changchun, [6]The First affiliated Hospital of Xinjiang Medical University, Urumchi, [7]Lanzhou Military Area General Hospital, Lanzhou, [8]Xinqiao Hospital affiliated to Third Military Medical University, Chongqing, [9]Nanfang Hospital affiliated to Southern Medical University, Guangzhou, [10]Xiehe Hospital affiliated to Huazhong University of Science and Technology, Wuhan, [11]Shandong Provincial Hospital, Jinan, China

Background: Severe aplastic anemia (SAA) is a life-threatening disorder for which allogeneic hematopoietic stem cell transplantation (HSCT) is the available curative approach. Haplo-identical donor (HID) as an alternative source, should be considered in the absence of matched related or unrelated donor after failing to respond to immunosuppressive therapy (IST). Obvious superiority arises from the immediate availability of a suitable haplo-identical donor for most patients within appropriate time-frame. However, initial outcomes of HID for SAA were far from satisfactory owing to poor engraftment, refractory graft-*versus*-host disease (GVHD) and delayed immune reconstitution.
Several small-sample studies using various approaches of haplo-identical transplantation revealed the mixed success, with short-term survival rates reaching 67%>100% and graft failure rates ranging from 0% to 25%. However, the recent reports of haplo-identical transplantation for SAA are rather heterogeneous and almost all series are limited by small numbers of patients.
Aims: To further prove the therapeutic effect of haplo-identical SCT in the treatment of SAA, we conducted a prospective multi-center study using uniform protocol, and compared outcomes of haploidentical SCT with those of all contemporaneous transplantation from MRD.
Methods: This was a disease-specific, multicenter, prospective study. All eligible patients treated at 11 participating institutions were included. Patients were administered with BU/CY+ATG conditioning regimen, G-BM combined with peripheral blood stem cells without in vitro T-cell depletion and a combination of CsA, MTX and MMF as graft-*versus*-host disease (GVHD) prophylaxis. The primary endpoint was engraftment. Various outcomes of HID were compared with those of contemporaneous transplantation from matched related donors (MRD).
Results: For patients receiving HID-SCT, all cases surviving for more than 28 days achieved donor myeloid engraftment. The median time for myeloid engraftment was 12 (range, 9-25) and for platelet was 15 (range, 7-101) days with a cumulative platelet engraftment incidence of 94.1±0.1%. With a median follow up of 18.3 (3.0-43.6) months and when compared with MRD, HID recipients had more cumulative incidence of grade II-IV acute GVHD (aGVHD; 33.7% *vs* 4.2%, *P*<0.001), more chronic GVHD (cGVHD; 22.4% *vs* 6.6%, *P*=0.014) at 1 year, but similar grade III-IV aGVHD (7.9% *vs* 2.1%, *P*=0.157), 3-year estimated overall survival (OS, 89.0% *vs* 91.0%, *P*=0.555) and 3-year estimated failure free survival (FFS, 86.8% *vs* 80.3%, *P*=0.659). Multivariate analysis showed no significant difference in primary engraftment and survival outcomes between two cohorts.
Summary/Conclusions: Haplo-identical transplantation using our protocol was proved to be an effective and safe choice in SAA patients who failed previous IST. It could be recommended for those who lack a MRD as higher priority.

S832

SUCCESSFUL HEMATOPOIETIC STEM CELL TRANSPLANTATION IN TEN PATIENTS WITH SEVERE CONGENITAL NEUTROPENIA USING AN INTENSIVE IMMUNOMYELOSUPPRESSIVE CONDITIONING REGIMEN: THE RESULTS OF A SINGLE INSTITUTE
Y Mizoguchi*, S Karakawa, T Doi, M Shimomura, K Tomioka, S Sakata, A Furue, I Chijimatsu, S Okada, M Miki, H Kawaguchi, M Kobayashi
Pediatrics, Hiroshima University Graduate School of Biomedical & Health Sciences, Hiroshima, Japan

Background: Severe congenital neutropenia (SCN) is a rare heterogeneous genetic disorder categorized as a bone marrow failure syndrome. The main clinical feature of patients with SCN is recurrent bacterial infections from early infancy due to severe chronic neutropenia. Majority of SCN patients have benefitted by the treatment with granulocyte colony-stimulating factor (G-CSF). However, patients on long-term G-CSF therapy have a relative risk of developing myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML). The only curable treatment for SCN patients is hematopoietic stem cell transplantation (HSCT). Recently, HSCT with reduced intensity conditioning (RIC) regimens have been applied to the treatment for SCN patients prior to malignant transformation. However, the optimal conditions of HSCT for SCN patients have not been established.
Aims: In this study, we conducted bone marrow cell transplantations (BMT) in ten patients with SCN using an immunomyelosuppressive conditioning regimen to minimize early and late transplant-related morbidity in Hiroshima University Hospital.
Methods: A total of eleven HSCT procedures were performed in ten patients with SCN from 2009 to 2015. Four of ten patients had experienced the engraftment failure of initial HSCT and three of them were referred to our hospital for re-transplantation. Nine of ten patients (90%) had a heterozygous mutation in the *ELANE* gene. Bone marrow cells (BM) were obtained from five HLA-matched related (MRD), three HLA-matched unrelated (MUD), and three HLA-mismatched unrelated (7/8) donors (MMUD), respectively. Conditioning regimen consisted of fludarabine (125 mg/m^2), cyclophosphamide (140 mg/m^2), melpharan (90 mg/m^2), and total body irradiation (3.6 Gy). Antithymocyte globulin (ATG, 10–12 mg/kg) was also administered, but two patients from MRD did not receive ATG, and one patient from MUD received low-dose ATG (i.e., 2.5 mg/kg instead of 10–12 mg/kg). Short-term methotrexate and tacrolimus were administered for the prophylaxis of graft-*versus*-host disease (GVHD).

Results: Engraftment of neutrophils was observed within post-transplant 24 days in all but 1 case who developed graft failure. This case, who had undergone initial HSCT with MUD-derived bone marrow using our conditioning regimen with low-dose ATG (2.5mg/kg), was rescued by second HSCT with BM from another MUD receiving the same conditioning regimen with a 12mg/kg of ATG. Two patients received HSCT from HLA-matched related donor developed stable mixed chimerism without neutropenia in peripheral blood. Although one patient who received donor lymphocyte infusion due to mixed chimerism developed acute GVHD grade II and limited chronic GVHD, the others did not develop severe GVHD (acute GVHD gradeII-III 9%, chronic GVHD 9% respectively). All patients are alive for 6 months to 8 years after HSCT with no signs of severe infections or transplantation-related morbidity.
Summary/Conclusions: Our results demonstrate that BMT together with a sufficient immunosuppressive conditioning regimen may be a feasible and effective treatment for SCN patients, irrespective of initial engraftment failure. The excellent results in our cohort suggest that indications for proceeding to HSCT could be extended to patients without malignant transformation. The further analyses of accumulated cases are necessary to assess the efficacy, safety, and less late adverse effects related to HSCT including fertility.

Transfusion medicine

RED CELL ALLOIMMUNISATION RISK IN PATIENTS WITH DIFFERENT TYPES OF INFECTIONS

D Evers[1,*], J van der Bom[2], J Tijmensen[1], R Middelburg[2], M de Haas[3], S Zalpuri[1], K de Voogt[4], D van de Kerkhof[5], O Visser[6], N Péquériaux[7], F Hudig[8], JJ Zwaginga[9]
[1]Center for Clinical Transfusion Research, Sanquin, [2]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, [3]Department of Immunohaematology Diagnostics, Sanquin, Amsterdam, [4]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, [5]Department of Clinical Chemistry and Haematology, Catharina Hospital, Eindhoven, [6]Department of Haematology, VU Medical Center, Amsterdam, [7]Department of Clinical Chemistry and Haematology, Jeroen Bosch Hospital, 's Hertogenbosch, [8]LabWest, Haga Teaching Hospital, The Hague, [9]Department of Immunohaematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands

Background: Red cell alloantigen exposure can lead to antibody associated morbidity. A valid alloimmunisation prediction score will support identification of high-risk patients, consequently followed by offering them extended matched red cell products. Murine models have suggested inflammation as an important modulator of the humoral response towards red cell antigens.
Aims: We set out to quantify the alloimmunisation risk of various types of infections in humans.
Methods: We performed a multicenter case-control study in a source population of patients who received their first and subsequent red cell transfusions during an eight year follow-up period. Cases, defined as patients developing a first transfusion-induced red cell alloantibody, were each compared with two randomly sampled controls, defined as non-alloimmunised patients receiving at least the same number of red cell units. Logistic regression analysis, stratifying for potential confounders, was used to evaluate the association between red cell alloimmunisation and the presence of various types of infections during a 5-week 'alloimmunisation risk period'. Tissue-invasive bacterial infections were defined as 'severe' or 'mild' according to the expected induced systemic inflammatory response accompanying the type of infection. Bacteremiae were subclassified into Gram-positive or Gram-negative bacteremiae according to the causative microorganism. Viraemia and disseminated viral zoster infections were defined as 'disseminated viral infections', hereby contrasting local viral infections.
Results: Within a cohort of 24,063 newly transfused patients, 505 cases and 1,010 matched controls received a median of eight (interquartile range 4-16) red cell transfusions. During the risk period, 159 cases (31.5%) and 314 controls (31.1%) were diagnosed with at least one infectious episode. Alloimmunisation incidences increased upon red cell antigen exposure during severe, but not mild, bacterial infections (adjusted relative risk (RR) 1.34 with 95% confidence interval (CI) 0.97-1.85; figure). RRs were further pronounced when these bacterial infections were accompanied with long-lasting fever (RR 3.06, CI 1.57-5.96). Disseminated viral disorders demonstrated a RR of 2.41 (CI 0.89-6.53, figure). Surprisingly, bacteraemia with Gram-negative, but not with Gram-positive, microorganisms, coincided with a 2-fold reduction in alloimmunisation incidences (RR 0.58, CI 0.13-1.14, figure 1). Fungal infections, as well as elevated CRP values, and (level of) leucocytosis were not associated with red cell alloimmunisation.

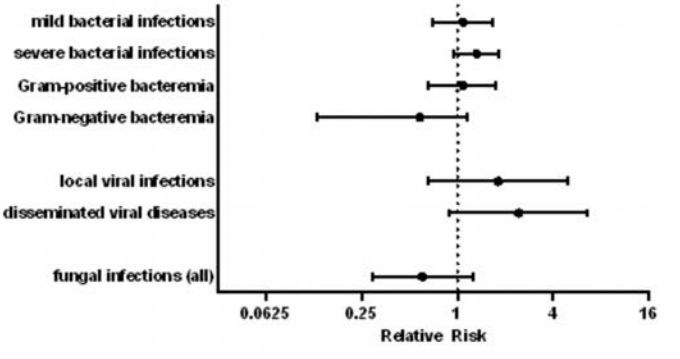

Figure 1.

Summary/Conclusions: Our findings corroborate animal studies suggesting that red cell transfusions in a setting of severe bacterial or viral infections increase the risk of alloimmunisation, contrasting Gram-negative bacteraemia which substantially reduce alloantibody formation. Data on recent or existing infections should thus be incorporated into an alloimmunisation prediction score, enabling selecting high-risk patients who will benefit most from extended matched red cell transfusions.

S834

THE USE OF PEGYLATED CARBOXYHEMOGLOBIN BOVINE IN PATIENTS FOR WHOM BLOOD IS NOT AN OPTION

A Abuchowski, R Jubin*, J Berryman, R Prince
Prolong Pharmaceuticals, South Plainfield, United States

Background: Severe hypoxia due to low hemoglobin (Hb) levels causes significant morbidity and mortality. This is of great concern for patients who cannot receive blood transfusions due to personal (i.e., Jehovah's Witness) or medical (i.e., hyperhemolysis) reasons, or simply due to the lack of availability. PEGylated-carboxyhemoglobin (PEG-HbCO; SANGUINATE™) is a novel therapeutic agent designed to release carbon monoxide to reduce vascular inflammation and then transfer oxygen to hypoxic tissue and cells. PEG-HbCO has been used in 24 patients under the USA emergency Investigational New Drug (eIND) program. A retrospective analysis of these patients was performed.
Aims: Perform post-hoc analysis of clinical findings; their relationship to individual patient diagnosis/associated comorbidities and PEG-HbCO intervention.
Methods: 23 patients with hemoglobin levels under 5 g/dL and 1 sickle cell disease patient with Hb of 8.7 were determined to be near death or at serious risk of severe morbidity and were treated with PEG-HbCO. Applications included AML, sickle cell disease (SCD) comorbidities, trauma and hemorrhagic shock. Patients ranged in age from 19 to 61. A unit of PEG-HbCO consists of 500 mL (40 mg/mL). Total doses ranged from 1 unit up to 8 units given over 9 days.
Results: No serious adverse events associated with PEG-HbCO were reported. All patients provided with timely emergency treatment with PEG-HbCO were reported by the investigator to show clear signs of improved mental function that was temporally associated with infusion of PEG-HbCO despite continuing low Hb levels. Improvements in cerebrovascular oximetry, cerebral blood flow, pulmonary infiltrates, renal function and serum biochemistry (bilirubin, liver function, LDH) were reported in various patients. A SCD patient with acute chest syndrome showed clearing of pulmonary infiltrate within 24 hours of PEG-HbCO infusion. Nine of eleven (81%) severely anemic patients showed improvement upon administration of PEG-HbCO, defined by an initial improvement in mental alertness and culminating in hospital discharge (excluding trauma patients with ISS score ≥25).
Summary/Conclusions: The varied results seen in these critical care patients represent preliminary evidence of substantial improvement in clinically significant endpoints used by the clinicians to assess response to treatment in the urgent care setting. Most important is the evidence of response despite no immediate improvement in the hemoglobin level which, if left untreated, may have lead many of these patients to significant morbidity and potential mortality. While severe anemia persisted for most of these patients, it appears that the life-threatening hypoxia did not. There is a significant unmet medical need to treat hypoxia in patients for whom blood is not an option. PEG-HbCO is under development for the treatment of the life-threatening effects of acute severe anemia (Hb ≤5 g/dL) in patients who cannot receive red blood cell transfusions. PEG-HbCO is also in clinical development for the treatment of SCD comorbidities, delayed graft function following renal transplantation and reduction of delayed cerebral ischemia following subarachnoid hemorrhage.

S835

INTRODUCTION OF A PREOPERATIVE ANAEMIA CLINIC IMPROVES PERI-OPERATIVE TRANSFUSION USE

R Cader[1,*], M Lewin[1], N Jones[2], A Klein[2], M Besser[1]
[1]Haematology, Addenbrookes hospital, Cambridge University Hospitals NHS trust, [2]Anaesthetics, Papworth Hospital, Cambridge, United Kingdom

Background: Preoperative anaemia is a potentially modifiable risk factor for perioperative morbidity and mortality. Strategies for anaemia correction have been outlined by the UK Joint Blood and Transplant Professional Advisory Committee, the 2015 NICE (National Institute of Clinical Excellence) guidelines for blood transfusion and a guideline by the British Committee for Standards in Haematology. Here we present the results of a pilot study, where we introduced a preoperative clinic aimed at correcting treatable anaemia without delaying cardiac surgery at Papworth hospital, UK.
Aims: The aims of this study were to evaluate whether introduction of a preoperative anaemic clinic improves patient blood management or clinical outcome following major cardiac surgery.
Methods: All patients listed for major cardiac surgery between May to December 2015, Papworth Hospital, UK were screened for anaemia at surgical pre assessment clinic. 107 patients with a haemoglobin <130g/l (males) and <120g/l (females) were recruited and underwent further testing for ferritin, vitamin B12, plasma folate, creatinine and TSH. Patients were then reviewed at clinic by a consultant haematologist, who decided upon appropriate anaemia management. 25 patients with a ferritin level<100g/L received 1g of Ferinject® (Fe-Carboximaltose) as a single dose infusion up to 6 weeks preoperatively. For another 23 patients the above ferritin criterion was met, but for a variety of reasons preoperative iron could not be administered. 4 patients received oral iron. The remaining patients were advised to commence B12, folate or combinations thereof or proceeded to surgery in the absence of a treatable cause of anaemia. We collected information on blood products administered, total hospital stay, intensive care stay and mortality. Data were compared to a previously published historic control group of anaemia patients undergoing cardiac surgery (n=165;Pap60) and compared by t-test.
Results: Patients assessed in the preoperative anaemia clinic received significantly less red cell transfusion than patients proceeding directly to surgery in the Pap60 study (2.2±3.2 units *vs* 3.9±4.0 units; mean±S.D., p=0.027) and had significantly shorter hospital stay (12.9±10.6 days *vs* 16.0±9.9 days; mean±S.D., p<0.01). However there was no difference in transfusion use or hospital stay between iron treated and non-iron treated, low ferritin patient subgroups, nor were these significantly different in comparison to the whole anaemia clinic cohort.

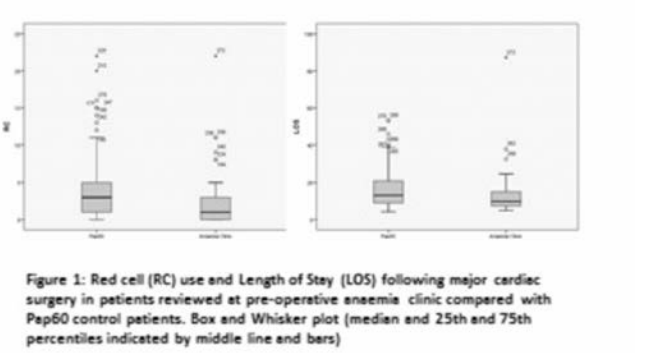

Figure 1: Red cell (RC) use and Length of Stay (LOS) following major cardiac surgery in patients reviewed at pre-operative anaemia clinic compared with Pap60 control patients. Box and Whisker plot (median and 25th and 75th percentiles indicated by middle line and bars)

Figure 1.

Summary/Conclusions: In conclusion, we have found that our preoperative anaemia clinic improves overall patient blood management in the peri-operative period with a reduction in blood transfusion usage. However intravenous iron when given in the context of major cardiac surgery seems to have no additional benefit in this pilot study.

S836

LUSPATERCEPT DECREASES TRANSFUSION BURDEN AND LIVER IRON CONCENTRATION IN REGULARLY TRANSFUSED ADULTS WITH BETA-THALASSEMIA

A Piga[1,*], S Perrotta[2], A Melpignano[3], C Borgna-Pignatti[4], MR Gamberini[4], E Voskaridou[5], V Caruso[6], P Ricchi[7], A Pietrangelo[8], X Zhang[9], D Wilson[9], A Bellevue[9], A Laadem[10], M Sherman[9], K Attie[9]
[1]Turin University, Turin, [2]Second University of Naples, Naples, [3]Ospedale "A Perrino", Brindisi, [4]University of Ferrara, Ferrara, Italy, [5]Laiko General Hospital, Athens, Greece, [6]Garibaldi Hospital, Catania, [7]AORN "A. Cardarelli", Naples, [8]CEMEF, Medicina 2, Modena, Italy, [9]Acceleron Pharma, Cambridge, MA, [10]Celgene Corporation, Summit, NJ, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIB, is being developed for the treatment of β-thalassemia. Luspatercept binds to GDF11 and other ligands in the TGF-β superfamily to promote late-stage erythroid differentiation. Luspatercept corrected the effects of ineffective erythropoiesis in a thalassemia mouse model (Suragani R, Blood 2014) and was well tolerated and increased hemoglobin in a phase 1 clinical study (Attie K, Am J Hematol 2014).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study followed by a long-term extension study to evaluate the effects of luspatercept in adults with β-thalassemia, including a subgroup on regular transfusions (≥4 units RBC/8 weeks). Endpoints included RBC transfusion burden (units/12 weeks), liver iron concentration (LIC) by MRI, safety, and quality of life questionnaires.
Methods: Inclusion criteria included age ≥18 yr and genetic confirmation of β-thalassemia. Luspatercept was administered SC every 3 wks for up to 5 doses in the dose-ranging study (completed) with a 2-month follow-up unless enrolled directly into a 2-year extension study (ongoing). Six sequential cohorts (n=35 total) were treated at escalating doses from 0.2 to 1.25 mg/kg. An additional expansion cohort (n=29) was treated with a starting dose of 0.8 mg/kg with escalation up to 1.25 mg/kg. Of the 64 patients (pts) treated in the dose-ranging study (including 30 pts regularly transfused), 51 enrolled in the extension study. RBC transfusions during the study were administered based on each patient's usual pre-transfusion hemoglobin threshold.
Results: Data (as of 25 Sept 2015) were evaluable for 28 of 30 pts on regular RBC transfusions. Median age was 37.5 yr, ranging from 21 to 54 yr, and 57.1% had prior splenectomy. At baseline, median transfusion burden was 8 units/12 weeks (range 4-18 units). Mean (±SD) LIC was 4.5±4.6 mg/g dw. 27 pts were on iron chelation therapy (ICT) at baseline. 21/28 (75%) pts achieved ≥33% decrease and 16/28 (57%) achieved ≥50% decrease in transfusion burden over any 12-week period compared with the 12 weeks prior to treatment (mean decrease was 56% in 23 pts with at least 12 weeks on study). 4/8 (50%) pts with baseline LIC ≥5 mg/g dw had a decrease in LIC ≥2 mg/g dw (mean decrease 3.1 mg/g dw, 35.1%) during the 16-week base study; 14/14 (100%)

pts with baseline LIC<5 mg/g dw maintained LIC<5 mg/g dw. Luspatercept was generally well tolerated, with no related serious adverse events reported to date. Adverse events in this regularly transfused subgroup were mostly mild-moderate and the most frequent related adverse events (≥4 pts) were bone pain, myalgia, arthralgia, headache, asthenia, and musculoskeletal pain.
Summary/Conclusions: Luspatercept treatment was well-tolerated and led to decreased RBC transfusion requirements in regularly transfused patients with β-thalassemia. The decrease in RBC transfusions correlated with decreases in liver iron concentration. These changes represent a significant reduction in disease burden for regularly transfused patients with β-thalassemia. A Phase 3 study of luspatercept in adults who require regular RBC transfusions due to β-thalassemia is ongoing (BELIEVE study; clinicaltrials.gov NCT02604433).

BENEFIT OF RITUXIMAB AS SECOND LINE TREATMENT CHOICE FOR AUTOIMMUNE HEMOLYTIC ANEMIA IN CHILDREN: A PROSPECTIVE FRENCH COHORT

S Ducassou[1,*], N Aladjidi[1], H Fernandes[1], G Leverger[2], H Chambost[3], Y Bertrand[4], C Armari-Alla[5], B Nelken[6], F Monpoux[7], C Guitton[8], T Leblanc[9], A Fisher[10], O Lejars[11], Y Perel[1]
[1]Pediatric Oncology Hematology Unit / CEREVANCE / CIC 1401, Inserm CICP, University Hospital of Bordeaux, Pediatric Hospital, Bordeaux, [2]Pediatric Onco-Hematology Unit, Hopital Trousseau, APHP, Paris, [3]Pediatric Hematology Unit, Hospital La Timone Enfants - APHM, Marseille, [4]Pediatric Immuno-Hematology Unit, Institut d'Hematologie et d'Oncologie Pédiatrique (IHOP), Lyon, [5]Pediatrics Unit, University Hospital of Grenoble, Grenoble, [6]Pediatrics Unit, University Hospital of Lille, Lille, [7]Pediatric Onco-Hematology Unit, University Hospital of Nice, Nice, [8]Pediatrics Unit, University Hospital Bicêtre - APHP, Le Kremlin-Bicêtre, [9]Hematology Unit, Hopital Robert Debré - APHP, [10]Immuno-Hematology Unit, Hopital Necker - APHP, Paris, [11]Pediatric Onco-Hematology Unit, University Hospital of Tours, Tours, France

Background: Childhood autoimmune hemolytic anemia (AIHA) requires in 30-50% of cases immunosuppressive therapy for steroid resistance or prolonged dependence. Although there are no pediatric guidelines for the second line strategy, in small retrospective studies or rare controlled studies, rituximab appears to be indicated.
Aims: This prospective observational national study reports the practice, efficiency and tolerance of rituximab in non-selected children with isolated AIHA or AIHA in context of Evans syndrome (AIHA/ES).
Methods: For this study, all children under 18 years old, living in France, who had been treated, by rituximab for an AIHA, whatever the context was, between January 1, 2000 and December 31, 2012, registered in the OBS'CEREVANCE cohort, were included. The end point for analysis was December 31, 2013, ensuring more than 1 year's follow-up for each patient. Response criteria were defined, relapse free survival (RFS) curves were provided, and tolerance was assessed from patient's medical records.
Results: Sixty one children with AIHA were given rituximab, 375 mg/m²/dose for a median of 4 weekly doses. All patients had previously received steroids, 26 had received one to four supplementary line of treatment. The median age at rituximab initiation was 8.5 [0.3; 17.6] years. The median delay from diagnosis to rituximab was 9.9 [0.2; 153.1] months. With a median follow-up of 4 years (0.3 - 11) from rituximab initiation, 46 patients responded (75%), 40 complete response (CR) and 6 partial response (PR). 20 patients (43%) relapsed in a median delay of 10.8 (1.7-57.6) months after treatment by rituximab The proportion of relapses among responder patients was significantly lower in patient who were treated early after diagnosis (p=0.03). In all children rituximab allowed decrease of steroid therapy. Compared to AIHA/ES, in isolated AIHA, the proportion of CR was significantly higher (74% *vs* 54%, p=0.02), and RFS was significantly higher (p=0.04). Ten patients were aged less than one year at rituximab initiation. In this subgroup, the median time between diagnosis and rituximab initiation was 1.6 months, shorter than 12 months in the rest of the cohort (p=0.006). Seven patients responded (70%), 6 CR and RFS was 71%. Two children presented allergic reactions. No case of progressive multifocal leuco-encephalopathy was observed. A total of 40 children received IVIg replacement, whose duration was temporary in 31 and prolonged in 9. Five patients died and among them one severe sepsis associated with agranulocytosis could be reliable to rituximab therapy.
Summary/Conclusions: In our hands, in this large series of childhood AIHA, rituximab was a valuable second line treatment, allowing steroid withdrawal in 60-70% of cases, with 30% long term responders, even in infants, mainly in isolated AIHA and when it was precociously used. Two serious concerns on safety are abrupt severe neutropenia, and prolonged hypogammaglobulinemia: adequate screening of underlying primitive immune deficiency before treatment is mandatory.

OOVERALL SURVIVAL IN RELAPSED/REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS RECEIVING INOTUZUMAB OZOGAMICIN *VS* STANDARD CARE IN THE PHASE 3 INO-VATE STUDY

HM Kantarjian[1,*], DJ DeAngelo[2], A S Advani[3], M Liedtke[4], W Stock[5], N Goekbuget[6], S O'Brien[7], G Martinelli[8], K Wang[9], T Wang[10], ML Pacagnella[10], B Sleight[10], E Vandendries[11], M Stelljes[12]
[1]MD Anderson Cancer Center, Houston, TX, [2]Dana Farber Cancer Institute, Boston, MA, [3]Cleveland Clinic, Cleveland, OH, [4]Stanford Comprehensive Cancer Center, Stanford, CA, [5]University of Chicago, Chicaago, IL, United States, [6]Goethe University, Frankfurt, Germany, [7]University of California–Irvine, Orange, CA, United States, [8]Institute Seragnoli, University of Bologna, Bologna, Italy, [9]Pfizer Inc, Pearl River, NY, [10]Pfizer Inc, Groton, CT, [11]Pfizer Inc, Cambridge, MA, United States, [12]Universitätsklinikum Münster, Münster, Germany

Background: CD22 is expressed in most (>90%) cases of B-cell acute lymphoblastic leukemia (ALL) and is an attractive target for the treatment of B-cell malignancies. Inotuzumab ozogamicin (InO), a humanized anti-CD22 antibody conjugated to calicheamicin, has demonstrated significantly superior response *vs* standard care (SC) in the first 218 randomized patients with relapsed/refractory (R/R) ALL in the phase 3 INO-VATE trial (data presented previously, DeAngelo, European Hematology Association [EHA] 2015 meeting [LB2073]).
Aims: To assess overall survival (OS) and progression free survival (PFS) of adults with R/R ALL receiving InO *vs* SC
Methods: In this ongoing global, 2-arm, randomized phase 3 trial (NCT01564784), patients with R/R ALL (including ~15% of patients in each arm with Philadelphia-positive ALL) due to receive salvage (S) 1 or 2 therapy were randomized to InO (starting dose 1.8 mg/m^2/cycle [0.8 mg/m^2 on day 1; 0.5 mg/m^2 on days 8 and 15 of a 21-28 day cycle (≤6 cycles)]) or SC (either fludarabine/cytarabine [ara-C]/granulocyte colony-stimulating factor [FLAG], ara-C plus mitoxantrone, or high-dose ara-C). Study was designed with two primary endpoints: 1) OS and 2) complete remission (CR)/CR with incomplete hematologic recovery (CRi) assessed in first 218 patients randomized (results previously presented). Overall study-wise type-I error was controlled by splitting 1-sided α to 0.0125 for each endpoint. Safety was assessed in all patients who received ≥1 dose of study drug. Per protocol, the final OS analysis was to occur upon observing ~248 events; 252 events (122 with InO and 130 with SC) were observed on March 8, 2016; data as of this date are presented.
Results: The ITT analysis population included 326 patients with both arms being well balanced for baseline stratification factors. The OS hazard ratio (HR) between InO and SC was 0.77 (97.5% CI, 0.58-1.03) with 1-sided P=0.0203 and median OS 7.7 [95% CI, 6.0-9.2] *vs* 6.7 [95% CI, 4.9-8.3] months. The second primary objective of demonstrating a statistically significant improvement in final OS with InO *vs* SC was not met at prespecified significance level of 0.0104. The 2-year OS rate for InO *vs* SC was 23% (95% CI, 16-30%) *vs* 10% (95% CI, 5-16%). It was noted, however, that the OS departed from the proportional hazards assumption. Given this, a restricted mean survival time (RMST) analysis was applied and showed: mean OS was 13.9 months for InO *vs* 9.9 months for SC, a difference that met statistical significance. PFS was significantly longer with InO *vs* SC (HR, 0.45 [97.5% CI, 0.34-0.61]; 1-sided P
Summary/Conclusions: Compared with SC, InO provided evidence of longer OS and significantly prolonged PFS in adult patients with R/R ALL.

LB2234

PLATELET TRANSFUSION IN CEREBRAL HAEMORRHAGE (PATCH): A RANDOMISED CONTROLLED TRIAL

M Koopman[1,*], I Baharoglu[2], C Cordonnier[3], R Al-Shahi Salman[4], K de Gans[5], A Brand[1], C Majoie[6], L Beenen[7], H Marquering[8], M Vermeulen[2], P Nederkoorn[2], R de Haan[9], Y Roos[2]
[1]Transfusion Medicine, Sanquin Bloodbank, [2]Neurology, Academic Medical Center , Amsterdam, Netherlands, [3]Degenerative & vascular cognitive disorders, CHU, Univ. Lille, Inserm U1171, Lille, France, [4]Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, United Kingdom, [5]Neurology, Groene Hart Ziekenhuis, Gouda, [6]Radiology, Acedemic Medical Center, [7]Radiology, Academic Medical Center, [8]Biomedical Engineering and Physics, University of Amsterdam, [9]Research Unit, Academic Medical Center, Amsterdam, Netherlands

Background: Antiplatelet therapy use at time of intracerebral haemorrhage (ICH) is associated with higher mortality. Reduction of haematoma growth using platelet transfusion might improve outcome.
Aims: To investigate whether platelet transfusion improves outcome compared to standard care at three months in people with spontaneous ICH taking antiplatelet therapy.
Methods: This was a multicentre prospective, randomised, open, blinded-endpoint (PROBE) parallel group trial, conducted at 60 hospitals in The Netherlands, Scotland and France. We enrolled patients with spontaneous supraten-

torial ICH aged ≥18 years using antiplatelet therapy for ≥7 days preceding ICH, if Glasgow Coma Scale was ≥8. Participants were randomised (1:1, with a secure web-based system using permuted blocks, stratified by study centre and type of antiplatelet therapy) to receive either platelet transfusion (intervention) within six hours of start of symptoms and 90 minutes of diagnostic brain imaging, or standard care without platelet transfusion (comparator). The primary outcome was modified Rankin Scale (mRS) score assessed blinded to treatment allocation at three months after ICH. PATCH was registered with the Netherlands trial register (NTR1303).
Results: Between February 2009 and October 2015, 97 participants were randomised to platelet transfusion and 93 to standard care. Mean age with standard deviation was 74.0, 10.2 years in the interventional and 73.5, 11.2 years in the comparator group. The odds of death or dependence at three months were higher after platelet transfusion compared to standard care (adjusted common OR 2·05, 95% CI 1·18 to 3·56), with no evidence of treatment effect modification in sub-groups of interest. Platelet transfusion did not reduce ICH growth at 24 hours.
Summary/Conclusions: Platelet transfusion seems inferior to standard care for people using antiplatelet therapy before ICH.

LB2235

HIV-1-CONTAINING PLATELETS ARE PRESENT IN HIV-1 INFECTED PATIENTS *IN VIVO* AND ARE INTERNALIZED BY MACROPHAGES *IN VITRO*

F Real[1,2,3,*], C Capron[4], E Cramer-Bordé[4], M Bomsel[1,2,3]
[1]Mucosal Entry of HIV and Mucosal Immunity, Institut Cochin, Paris-Descartes University, [2]INSERM U1016, [3]CNRS UMR8104, Paris, [4]Hematology and Immunology Service, Hôpital Ambroise Paré, Boulogne, France

Background: Mainly regarded as actors of primary hemostasis, human platelets are also capable of directly interact and internalize, by endocytosis, the human immunodeficiency virus (HIV)-1 *in vitro*. Although patients with acquired immunodeficiency syndrome can present thrombocytopenia and, as we showed earlier, when highly viremic, present HIV-containing platelets, the *in vivo* relevance of virus endocytosis by platelets and its role in HIV pathogenesis remain to be elucidated. We speculate that HIV enclosed within platelets can be sheltered from host immune system response and transported, by circulating platelets, to macrophages from different tissues, where the virus can establish viral reservoirs.
Aims: We therefore investigated whether HIV-1-containing platelets could be internalized by macrophages, triggering productive infection and possibly establishing a viral reservoir vectored by platelets.
Methods: To approach the question, we obtained platelet-enriched plasma (PRP) from seropositive patients (n=40) treated or not with highly active antiretroviral therapy (HAART) and established a flow cytometry/confocal microscopy method to: i) quantify the amount of HIV-1-containing platelets present in HIV-1 seropositive patient PRP ; and ii) observe the interaction of HIV-1-containing platelets from patient PRP with human peripheral blood monocyte-derived macrophages (M0) *in vitro*, and determine qualitatively and quantitatively the distribution of the virus.

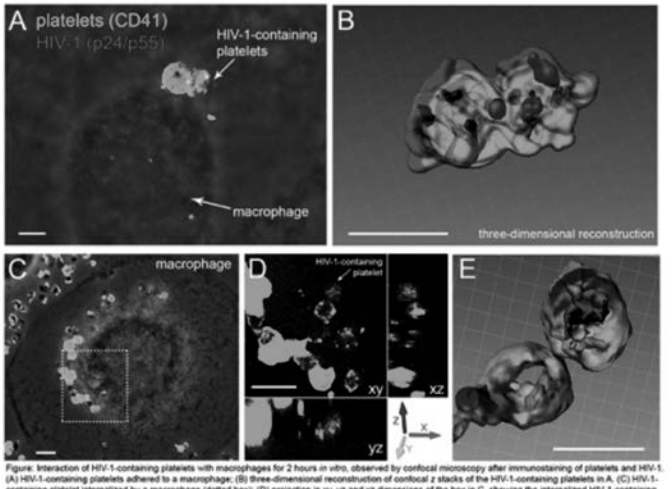

Figure: Interaction of HIV-1-containing platelets with macrophages for 2 hours *in vitro*, observed by confocal microscopy after immunostaining of platelets and HIV-1. (A) HIV-1-containing platelets adhered to a macrophage; (B) three-dimensional reconstruction of confocal *z* stacks of the HIV-1-containing platelets in A. (C) HIV-1-containing platelet internalized by a macrophage (dotted box); (D) projection in xy, yz and xz dimensions of the box in C, showing the internalized HIV-1-containing platelets in detail; (E) three-dimensional reconstruction of confocal *z* stacks of the HIV-1-containing platelets indicated in D.

Figure 1.

Results: Here, we show that HIV is consistently retrieved within platelets of HIV-infected patients. These patients with detectable HIV-1-containing platelets had lower numbers of $CD4^+$ (< 300/ul) and total T lymphocytes in the blood when compared with patients lacking detectable HIV-1 in platelets. In contrast, detection of HIV-1-containing platelets was not correlated to patient viral load, treatment or thrombocytopenia. This suggests that HIV-1 can also circulate, sheltered within platelets, in the blood of patients with undetected cell-free virus and unaltered platelet count. When incubated for 2 hours with M0 *in vitro*, platelets derived from patient PRP interacted rapidly with M0, either being internalized by M0 or remaining attached to M0 surface (figure). Viral p24/p55 capsid antigens were detected within M0 after the interaction period. The higher the number of HIV-1-containing platelets detected in PRP (detected by flow cytometry), the higher the number of HIV-1-containing platelets interacting with M0 (detected morphologically). The amount of HIV-1-containing platelets associated to macrophages correlated negatively with patients $CD4^+$ and total T lymphocytes numbers, highlighting that association of HIV-1-containing platelets with M0 could occur *in vivo* in patients with bad prognosis.
Summary/Conclusions: Although the outcome of HIV-1 retention by platelets and a platelet mediated-immunity during viral infection are still under investigation, this study demonstrates that HIV-1 can circulate in the bloodstream of seropositive, HAART-treated patients with undetected blood viral load using platelets as carriers, and that macrophages internalize HIV-1-containing platelets derived from these patients. The results highlight an alternative pathway, via platelets, for viral dissemination to tissue macrophages. Considering that inhibitors of platelet function have been employed for the treatment of different diseases, the study contributes to reveal a novel and promising therapeutical target for blocking HIV-1 spread and establishment of viral reservoirs.

Interni Klinika, Klinika Hematologie, Praha 2, Czech Republic, [8]Irmandade Da Santa Casa De Misericordia De São Paulo, São Paulo, Brazil, [9]University Medical Center of the Johannes Gutenberg-University, Third Department of Medicine, Mainz, Germany, [10]University Hospital of Salamanca/IBSAL, Salamanca, Spain, [11]Weill Cornell Medical College, New York, NY, [12]Janssen Research & Development, Spring House, PA, [13]Janssen Research & Development, Raritan, NJ, [14]Janssen Research & Development, Horsham, PA, United States, [15]Janssen Research & Development, Beerse, Belgium, [16]Malignant Haematology and Stem Cell Transplantation Service, Alfred Health-Monash University, Melbourne, Australia, [17]Department of Hematology, Erasmus MC, Rotterdam, Netherlands

Background: Daratumumab (D), a human anti-CD38 IgGκ monoclonal antibody, induces deep and durable responses with a favorable safety profile in patients with relapsed or refractory multiple myeloma (RRMM). We report a pre-specified interim analysis of the first randomised controlled study of daratumumab (CASTOR; NCT02136134).
Aims: To compare the efficacy and safety of daratumumab plus bortezomib (V) and dexamethasone (d) *versus* Vd alone in patients with RRMM in a phase 3 study.
Methods: Patients who received ≥1 prior line of therapy were randomised (1:1) to 8 cycles (q3w) of Vd (bortezomib: 1.3 mg/m^2 subcutaneously on Days 1, 4, 8, 11; dexamethasone: 20 mg orally on Days 1, 2, 4, 5, 8, 9, 11, 12) with or without daratumumab (16 mg/kg intravenously qw in Cycles 1-3, Day 1 of Cycles 4-8, then q4w until progression). The primary endpoint was progression-free survival (PFS).
Results: 498 patients (DVd, 251; Vd, 247) were randomised. Baseline demographics and disease characteristics were well balanced. Patients received a median of 2 prior lines of therapy (range 1-10). 66% received prior bortezomib; 76% received prior immunomodulatory drug (IMiD); 48% received prior proteasome inhibitor (PI) and IMiD; 33% were IMiD-refractory; and 32% were refractory to last line of prior therapy. With a median follow-up of 7.4 months, daratumumab significantly improved median PFS (61% reduction in the risk of progression/death) for DVd *versus* Vd (Figure 1). Addition of daratumumab to Vd also significantly delayed median time to disease progression (TTP) *versus* Vd (not reached [NR] *vs* 7.3 mo; hazard ratio, 0.30; 95% confidence interval, 0.21-0.43; P <0.0001). Daratumumab significantly increased overall response rate (ORR; 83% *vs* 63%, P <0.0001), in addition to doubling the rates of very good partial responses (VGPR) or better (59% *vs* 29%, P <0.0001) and complete responses (CR) or better (19% *vs* 9%, P = 0.0012) for DVd *versus* Vd, respectively. The median duration of response was NR for DVd *versus* 7.9 months for Vd. All planned sensitivity analyses demonstrated that DVd was better than Vd, which was consistent with the results from the primary analysis. In addition, pre-specified subgroup analyses on PFS demonstrated that the

treatment effect of DVd over Vd was consistent across all selected subgroups. Most common (>25%) treatment-emergent adverse events (TEAEs; DVd/Vd) were thrombocytopenia (59%/44%), peripheral sensory neuropathy (47%/38%), diarrhoea (32%/22%) and anaemia (26%/31%). Most common grade 3/4 TEAEs (>10%) were thrombocytopenia (45%/33%), anaemia (14%/16%), neutropenia (13%/4%). 7%/9% (DVd/Vd) of patients discontinued due to a TEAE. Daratumumab-associated infusion-related reactions (IRR; 45% of patients) mostly occurred during the first infusion (98% of patients with IRR); most were grade 1/2 (grade 3/4, 9%/0%).

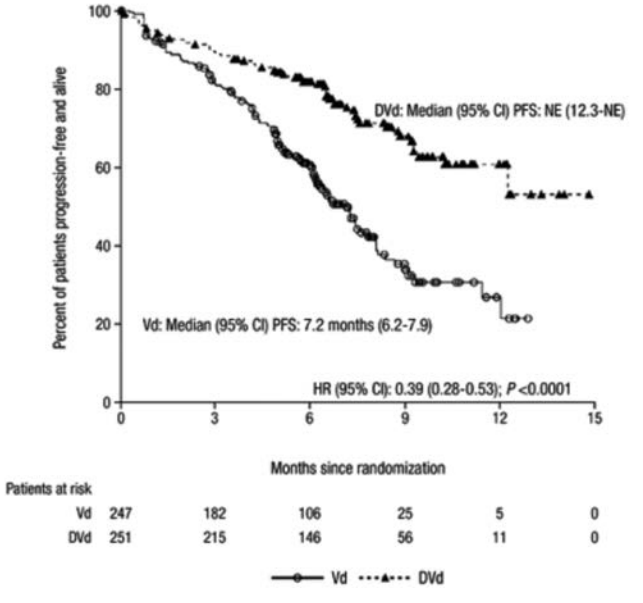

Figure 1.

Summary/Conclusions: Daratumumab significantly improved PFS, TTP, and ORR in combination with Vd *versus* Vd alone. DVd doubled rates of both VGPR or better and stringent CR/CR *versus* Vd alone. Safety of DVd is consistent with the known safety profile of daratumumab and Vd. The addition of daratumumab to Vd should be considered a new standard of care for patients with RRMM currently receiving Vd alone.

LB2237

THE ANTI C1S COMPLEMENT ANTIBODY TNT009 INDUCES RAPID COMPLETE REMISSIONS OF ANAEMIA IN PATIENTS WITH PRIMARY COLD AGGLUTININ DISEASE

U Jäger[1,*], J C Gilbert[2], S Panicker[3], G C Parry[3], M Fillitz[4], T Schenk[5], C Sillaber[1], J Bartko[6], B Jilma[6]
[1]Internal Medicine, Division of Haematology, Medical University Of Vienna, Wien, [2]True North Therapeutics, South San Francisco, Austria, [3]True North Therapeutics, South San Francisco, United States, [4]Internal Medicine, Hanusch Krankenhaus, Wien, [5]Internal Medicine, Universitätsklinikum St. Pölten, St Pölten, [6]Clinical Pharmacology, Medical University Of Vienna, Wien, Austria

Background: Cold agglutinin disease (CAD) is a difficult to treat autoimmune haemolytic anemia in which IgM antibodies bind to erythrocytes at low temperature and fix complement. This complement deposition opsonizes erythrocytes which undergo extravascular haemolysis in the liver.
Aims: Based on preclinical studies (Shi *et al.*, 2014 Blood), we hypothesized that TNT009, an antibody directed against complement component C1s, could stop haemolysis in CAD patients.
Methods: This represents an interim analysis of a first-in-human trial, where we have included four female CAD patients. Patients received a test dose of 10 mg/kg TNT009, followed by a full dose of 60mg/kg 1-4 days later, and three additional weekly doses of 60 mg/kg.
Results: All infusions were well tolerated without premedication and without relevant adverse effects. Out of four patients, three had been transfusion-dependent either previously (one patient within the last year) or recently (2 patients within 14 days of their enrolment into the trial). These three patients unequivocally responded immediately to TNT009 infusion, and are described below. TNT009 blocked the classical pathway of complement as demonstrated by an immediate drop in CH50 and rise in C4. TNT009 rapidly abrogated extravascular haemolysis, normalizing bilirubin levels in all three patients from a median of 1.7mg/dL (range: 1.6-2.6) to 0.7mg/dL (0.6-0.7) within 24 hours. Infusion of TNT009 immediately decreased the destruction of reticulocytes which rose from 131 (103-140) to 185 (175-286) x10E9/L within 24h. Haptoglobin levels normalized within one week and confirmed the complete halt of haemolysis. Haemoglobin levels rose from a median haemoglobin of 7.5g/dL (range: 6.8-8.3) before the test dose by 1.6 g/dL (1.1-1.6) within the first week, and completely normalised (>12 g/dL Hb by end of study in two patients; one patient still under observation) within 5-6 weeks. Normalisation of these parameters corresponded to complete remission of CAD-induced haemolysis. The time course of all these changes was highly significant (Friedman ANOVA $p<0.001$). Haemolysis recurred when effective drug levels were completely cleared from the circulation about 4 weeks after the last dose of TNT009. Re-exposure to TNT009 in a named patient programme recapitulated the immediate onset of effect, and the rapid and complete stop of haemolysis in these patients. The only patient who did not respond to TNT009 was suffering from secondary CAD and had a 70% bone marrow infiltration with chronic lymphocytic leukaemia accompanied by CLL-driven severe hypocomplementaemia.
Figure 1: Early changes within one week after TNT009 infusion (60mg/kg) in the three responders. Individual patients are depicted by the same symbols throughout. Haptoglobin is slightly offset for better visibility of similar values.

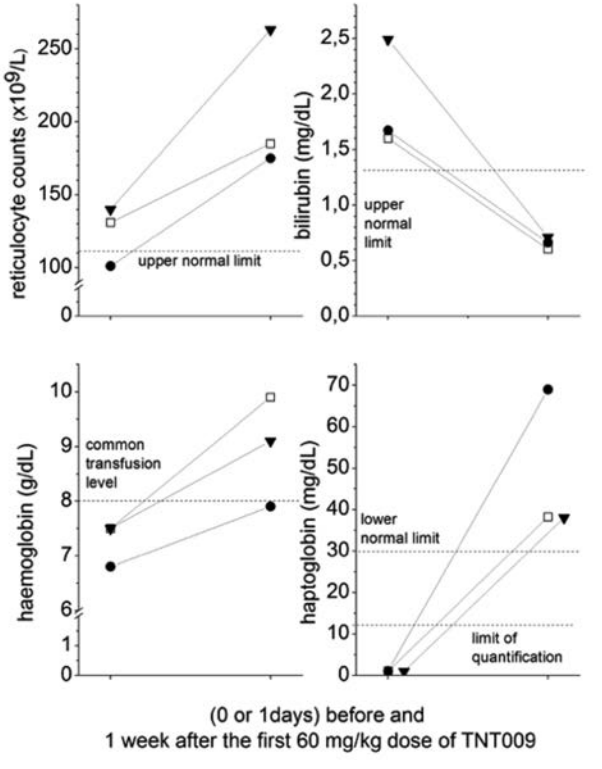

Figure 1.

Summary/Conclusions: TNT009 has an immediate onset of action, and showed remarkable and unprecedented efficacy in CAD patients in need of treatment. The three responding patients became transfusion independent while on TNT009. The results are encouraging and instrumental in planning for upcoming pivotal studies.

Background: Daratumumab (D), a human anti-CD38 IgGκ monoclonal antibody, was associated with rapid, deep, and durable responses and a favorable safety profile when combined with lenalidomide and dexamethasone (Rd) in a phase 1/2 study of relapsed or relapsed and refractory multiple myeloma pts (Plesner T, *et al.* ASH 2015, Abs. 507).
Aims: To compare the efficacy and safety of D in combination with Rd *vs* Rd alone in pts with RRMM in a randomised, open-label, multicenter, phase 3 study (POLLUX; NCT02076009).
Methods: Pts who received at least 1 prior line of therapy for myeloma were randomised (1:1) to R 25 mg orally on Days 1-21 of each 28-day cycle and d 40mg weekly, with or without D (16mg/kg qw for 8 weeks, q2w for 16 weeks, then q4w until progression). The primary endpoint is progression-free survival (PFS). Secondary endpoints are time to progression (TTP), overall response rate (ORR), rate of very good partial response (VGPR) or better, minimal residual disease-negative rate, overall survival (OS), duration of response, time to response, and safety.

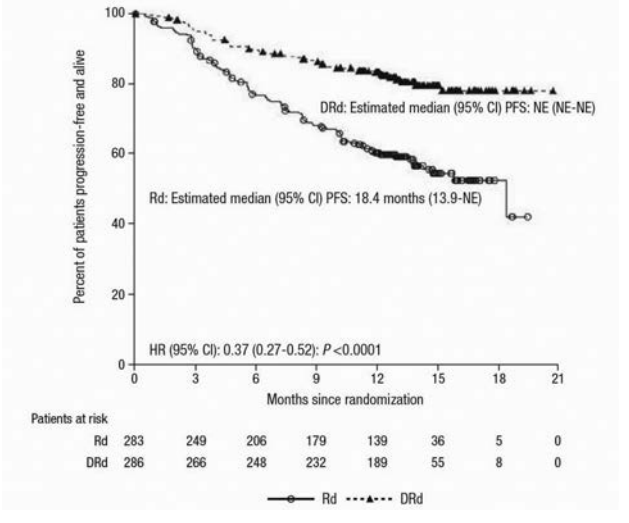

Figure 1.

Results: 569 pts were randomised. Median age of pts was 65 years old. Pts received a median of 1 prior line of therapy (range 1-11), with 19% of pts with ≥3 prior lines of therapy. Eighty-six percent received a prior PI, and 55% received prior IMiD, including 18% prior R, with 44% having received both a PI and an IMiD; 27% were refractory to the last line of prior therapy, 18% were PI refractory, and none were R refractory. After a median follow-up of 13.5 months, D significantly improved median PFS (63% reduction in the risk of progression/death) for DRd *vs* Rd (Figure 1). Addition of D to Rd significantly delayed TTP *vs* Rd (not reached [NR] vs estimated median of 18.4 mo; hazard ratio, 0.34; 95% CI, 0.23-0.48; P<0.0001). D significantly increased ORR (93% *vs* 76%, P<0.0001) and rates of VGPR or better (76% vs 44%, P<0.0001) and complete response (CR) or better (43% *vs* 19%, P<0.0001) for DRd *vs* Rd, respectively. The median duration of response was NR for DRd *vs* 17.4 months for Rd. All preplanned sensitivity analyses were consistent with results from the primary analysis. Pre-specified subgroup analyses of PFS demonstrated that the treatment effect of DRd over Rd was consistent across all pre-specified subgroups. The most common (<25%) TEAEs (DRd/Rd) were neutropenia (59%/43%), diarrhea (43%/25%), fatigue (35%28%), upper respiratory tract infection (32%/21%), anemia (31%/35%), constipation (29%/25%), cough (29%/13%), thrombocytopenia (27%/27%), and muscle spasms (26%/19%). Most common grade 3/4 TEAEs (>10%) were neutropenia (52%/37%), thrombocytopenia (13%/14%), and anemia (12%/20%). The rate of Grade 3/4 infections/infestations was 28% in the DRd group and 23% in the Rd group and the most common Grade 3/4 infections/infestations TEAE (≥5%) was pneumonia (8%/8%). Similar rates of treatment discontinuation due to TEAEs were observed (7%/8%). D-associated infusion-related reactions (IRR; 48% of pts) mostly were grade 1/2 (grade 3/4, 5%/0%); most (92% of IRRs) occurred during the first infusion.
Summary/Conclusion: DRd was superior to Rd alone. A significant reduction in the risk of disease progression/death was demonstrated with DRd *vs* Rd. DRd induced deep and durable responses, including doubling stringent CR/CR rates and significantly increasing the rate of VGPR or better *vs* Rd alone. DRd was associated with a manageable safety profile consistent with the known safety profile of D and Rd. The combination of D and Rd potentially represents a new standard of care for pts with >1 prior treatment.

Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy

Background: The introduction of novel chemotherapy protocols has improved the outcome of T-cell acute lymphoblastic leukemia (T-ALL) patients, but refractory and/or relapsing disease remains a major concern. In this context, a major contribution was provided by the introduction of the nucleoside analogs and in particular nelarabine, approved for salvage treatment of refractory/relapsed T-ALL patients.
Aims: A serious nelarabine drawback is that it induces a dose-dependent neurotoxicity. To improve nelarabine efficacy, it is essential to study its molecular targets, testing selective inhibitors of such targets, to be administered in combination with nelarabine, allowing for a lower dosage of the chemotherapeutic.
Methods: Human T-ALL cell lines (HBP-ALL, DND41, Jurkat, MOLT-4, MOLT16, CEM, CEM-R drug-resistant, ALL-SIL, Loucy, HSB2, Peer, PF382, P12-ICHIKAWA) and primary T-ALL refractory/relapsed lymphoblasts from patients were incubated with increasing concentrations of nelarabine alone or combinated with PI3K/mTOR inhibitors for cell viability assays and absolute cell counting by flow cytometry. Flow cytometry was also performed to analyze apoptosis and for phenotyping analyses. Protein expression was evaluated by Western Blot. ENT1/ENT2 gene expression was measured by quantitative real time PCR in T-ALL settings.
Results: We examined cell viability of cell lines and primary T-ALL refractory/relapsed cells. Cell viability assays indicated the presence of T-ALL cell lines sensitive to nelarabine (IC_{50}<5μM) and others which displayed higher IC_{50} (>15μM). The most resistant cell line (IC_{50}>300μM) was Loucy, which is representative of ETP-ALL, a T-ALL subtype with a very poor prognosis. Nelarabine sensitive cells showed a significant increase of apoptotic cells after 48h treatment with 2-5 μM nelarabine, as demonstrated by flow cytometric analyses of stained with AnnexinV FITC/PI cells and western blot analyses of caspases 8, 9, 3, and PARP. In contrast, resistant T-ALL cells were not perturbated. It has been reported that the levels of expression of ENT 1/2 nucleoside transporters were related to in vitro nelarabine sensitivity of T-ALL cell lines and primary samples. The expression of ENT1/2 transporters could be also dependent on interactions between leukemic cells and tumor microenvironment. No significant differences in ENT1/2 mRNA levels between samples sensitive or resistant to nelarabine were seen. Modulation of ENT1/2 gene expression was not related to nelarabine treatment, even if in some cases the co-culture with human stromal cells HS-5, which mimic the bone marrow microenvironment, partially supported cell survival. Upregulated phosphoinositide 3-kinase (PI3K)/mammalian target of rapamycin (mTOR) signaling is a common feature of T-ALL, where it portends a poorer prognosis by influencing leukemic cell proliferation, survival, and drug-resistance. We analyzed the effects of nelarabine on the phosphorylation status of key components of the PI3K/mTOR pathway in T-ALL settings. Sensitive T-ALL cells showed a strong decrease in the phosphorylation of Ser473 p-Akt and Ser235/236 p-S6 ribosomal protein (S6RP). In contrast, resistant cells treated with nelarabine alone, showed a hyperactivation of PI3K/mTOR and MEK/ERK signaling pathways. The combination of nelarabine with the pan PI3K inhibitors ZSTK474 or BKM120 was synergistic in reducing cell viability and in inducing strong apoptosis in all the resistant cell lines and in relapsed T-ALL patient samples with upregulated PI3K/mTOR signaling.
Summary/Conclusions: Nelarabine combined with PI3K inhibitors efficiently reduced cell viability and induced apoptosis in T-ALL settings, allowing for a lower dosage of nelarabine and therefore, synergizing with conventional therapies in relapsed/refractory T-ALL patients with upregulation of PI3K signaling.

ROLE OF G9A AND EPIGENETIC CHANGES IN LEUKEMIA CELL MIGRATION AND THEIR REGULATION BY VLA4 INTEGRIN

J Redondo-Muñoz[1,*], X Zhang[2], P Whang[3], P Cook[4], E Zindy[1], CJ Williams[5], TA Jowitt[6], AS MacDonald[4]

[1]Wellcome Trust Centre for Cell-Matrix Research, [2]University of Manchester, [3]CRUK Manchester Institute, [4]Manchester Collaborative Centre for Inflammation Research, [5]Materials Science Centre, [6]Wellcome Trust Centre for Cell Matrix Research, University of Manchester, Manchester, United Kingdom

Background: T-Acute Lymphoblastic Leukemia (T-ALL) originates from neoplastic T cell precursors in the thymus. Usually, T-ALL cells have to migrate from the thymus into other tissues, where residual cells might persist after treatments. The nuclear deformability of these tumor cells, and the signals from the cell receptors called integrins are critical to allow cancer cells to squeeze and cross physical barriers. Epigenetics, a novel cancer hallmark that comprises histone modification, histone variants and DNA modifications, leads a new drug generation to prime cancer cells to death. But some epigenetic changes, such as H3K9me3, have been linked with cancer invasion, and might have additional functions leading cancer progression.
Aims: The objective of this study was to explore how epigenetic changes induced by the integrin VLA4/α4β1 control, in a transcriptional independent manner, the nuclear deformability and infiltration of ALL cells.
Methods: Human T (Jurkat) leukemia cell lines, and normal primary T cells were cultured in suspension or on integrin ligands for different times and the levels of H3K9me3 were determined. Nuclear deformability was evaluated using several biophysical techniques, such as Atomic Force Microscopy. To identify the molecular mechanism induced by α4β1 integrin, and how this would be relevant for T-ALL cell migration, different biochemical and cell biology methods were performed.
Results: We showed that acute lymphoblastic leukemia (ALL) cells cultured on VCAM1 or Fibronectin (ligands of α4β1 integrin) presented higher levels of H3K9me3 than cells in suspension. We confirmed that ALL cells were more sensitive to this effect than normal T-cells. We determined that G9a, a histone methyltransferase, localized at the nuclear envelope and was responsible for H3K9 methylation when T-ALL cells were cultured on VCAM1. We used stable Jurkat cells depleted for G9a to demonstrate that H3K9 methylation contributed to the nuclear stiffness and the ability of ALL cells to migrate in response to chemotaxis and in 2D and 3D environments.
Summary/Conclusions: Our results reveal novel functions for G9a in modulating ALL migration, which might contribute to tumor cell dissemination and leukaemia progression.

DYNAMICS OF EARLY RESPONSE TO TREATMENT OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IS ASSOCIATED WITH GENE DEFECTS

A Pastorczak[1,*], L Sedek[2], M Braun[1], J Taha[1], E Polakowska[1], M Bartlomiejczyk[1], A Sonsala[2], J Madzio[1], W Fendler[1], E Ulinska[3], M Matysiak[3], K Derwich[4], M Lejman[5], J Kowalczyk[5], A Koltan[6], B Kazanowska[7], T Szczepanski[2], W Mlynarski[1]

[1]Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, [2]Department of Pediatric Haematology and Oncology, Medical University of Silesia, Zabrze, [3]Department of Paediatric Haematology and Oncology, Medical University of Warsaw, Warsaw, [4]Department of Pediatric Haematology, Oncology and Transplantology, University of Medical Sciences, Poznan, [5]Department of Paediatric Haematology and Oncology, Medical University of Lublin, Lublin, [6]Department of Pediatric Haematology and Oncology, Collegium Medicum, Bydgoszcz, [7]Department of Pediatric Haematology, Oncology and Transplantology, Medical University of Wroclaw, Wroclaw, Poland

Background: Genetic abnormalities such as *BCR-ABL1* translocations, *MLL* and *CRLF2* rearrangements and *IKZF1* deletions influence blast clearance during induction phase of childhood B-cell precursor ALL (BCP-ALL). Minimal residual disease (MRD) at different time-points of the induction protocol reflects chemosensitivity and may provide information about resistance of leukemic cells to cytotoxic drugs.
Aims: We investigated early response to treatment at three time-points of induction protocol (days 8, day 15 and 33) in patients with childhood ALL with respect to genetic abnormalities.
Methods: 481 children (median age 4.33 yrs), with newly diagnosed BCP-ALL treated between 02-2009 and 08-2015 with the ALL-IC BFM09 protocol in centers of the Polish Pediatric Leukemia/Lymphoma Study Group were enrolled into analysis. Targeted copy number screening was performed on available DNA samples (n=457) using the P335-B2 SALSA MLPA kit (MRC-Holland, Netherlands). *IKZF1* deletions were confirmed with breakpoint-specific multiplex-PCR. CRLF2 protein expression on leukemic cells was determined by flow cytometry (FCM). Steroid resistance was defined as the presence of ≥1000 leukemic cells/μl of peripheral blood after 7 days of steroid therapy. MRD was measured at day 15 (MRD15) and day 33 (MRD33) of induction therapy using 8-color flow cytometry. Chemosensitivity of leukemic cells to L-asparaginase, antracyclines and steroids was tested *in vitro* using an MTT assay (n=27).
Results: The frequency of cytogenetic abnormalities and microdeletions in selected genes were as follow: *BCR-ABL1* fusion n=11 (2.4%), *MLL* rearrangements n=24 (5.2%), *IKZF1*del n=96 (20%), *PAX5* del n=100 (22%), *PAR1* del n= 42 (10%), *CDKN2A* del n=128 (28%), *CDKN2B* del (26%), *BTG1* del n=39 (8.5%), *ETV6* del n=101 (22%), *EBF1* del n=21 (4.5%), *RB1* del n=30 (6.5%). TLSPR expression was observed in 6% of patients (22/358). Poor steroid

response was present in 42 cases (42/452=9.3%) and was not associated (all p>0.15) with any of the analyzed genetic factors. Median MRD15 and MRD33 were 5.67% and 0.01% respectively. In univariate analysis median MRD level at day 15 was significantly higher among patients with *BCR-ABL1* fusion [12.69(2.5-37.78)% *vs* 0.31(0.03–3.28)% p=6x10^{-4}], *IKZF1*del [1.005(0.072-12.54)% *vs* 0.3(0.03-2.7)%, p=4x10^{-4}] and *ETV6*del [0.6(0.075-6.615)% *vs* 0.32(0.029-3.94)%, p=0.02]. Also median MRD level at day 33 was elevated in patients with *BCR-ABL1* fusion [0.03(0.0001-0.08)% *vs* 1x10^{-4}(0.0001-0.005)%, p=0.02] and in patients with *IKZF1* deletion [1x10^{-4}(0.0001-0.05)% *vs* 1x10^{-4}(0.0001-0.003)%, p=0.02]. Multivariate analysis of MRD15, MRD33 and ΔMRD was done for variables with univariate significance of p<0.15 (log_{10}WBC, age at diagnosis, sex, poor steroid response, hypodiploidy, *MLL* rearrangements, *BCR-ABL1* fusion, *IKZF1* del, *ETV6* del, *EBF1* del, *PAR1* del). A mixed effects model was used to evaluate intraindividual changes of MRD15 and MRD33 and factored in genetic covariates. The following variables were significant for MRD15 and MRD33 timepoints: log_{10}WBC (β=0.28, p=1x10^{-7}) and (β=0.09, p=0.05), age at diagnosis (β=0.22, p=1x10^{-7}) and (β=0.23, p=1x10^{-6}), *IKZF1* del (β=0.14, p=1x10^{-3}) and (β=0.08, p=0.08), respectively. Additionally the following variables were significantly associated with the absolute difference of MRD between MRD33 and MRD15: logWBC (β=-0.15, p=4x10^{-4}), steroid resistance (β=-0.38, p=1x10^{-6}), IKZF1 del (β=-0.19, p=2x10^{-2}), and PAR1 del (β=-0.13, p=3x10^{-3}). MTT confirmed increased resistance to asparaginase of IKZF1 del positive blasts (p=0.01).
Summary/Conclusions: Poorer blast clearance during induction protocol in ALL patients harboring *IKZF1* deletions may result partly from chemoresistance to L-ASP, which was noted for the first time in both clinical and in vitro settings.

E841

THE WEE1 INHIBITION DEEPLY SENSITIZES ACUTE LYMPHOBLASTIC LEUKEMIA CELL LINES AND PRIMARY CELLS TO THE CYTOTOXIC EFFECT OF DIFFERENT ANTINEOPLASTIC COMPOUNDS
A Ghelli Luserna Di Rorà[1,*], I Iacobucci[1], N Beeharry[2], C Papayannidis[1], E Imbrogno[1], V Robustelli[1], A Ferrari[1], V Guadagnuolo[1], M Cavo[1], G Martinelli[1], TJ Yen[2]
[1]Department of Hematology and Medical Sciences "L. and A. Seràgnoli, Bologna, Italy, [2]Cancer Biology Program, Fox Chase Cancer Center, Philadelphia, United States

Background: Although the efficacy of Checkpoint kinase inhibitors have been established in different kind of tumors, only few studies have been performed in order to evaluate their effectiveness on hematological disorders. The Wee1, ATR/Chk1 and ATM/Chk2 pathways are involved in cell cycle regulation, DNA damages response and DNA repair. Wee1 is a checkpoint kinase, involved mainly in the regulation of G2/M transition through the phosphorylation of both Cyclin-dependent kinase 1 (CDK1) and 2 (CDK2).
Aims: In this study we evaluated the in vitro/ex vivo efficacy of a Wee1 inhibitor, MK-1775, in single agent and in combination on Acute Lymphoblastic Leukemia (ALL) cell lines and primary samples.
Methods: A panel B-/T-ALL cell lines and different primary cells isolated from adult ALL patients were treated in single agent or in combination with different compound (nucleoside analogue, Clofarabine; tyrosine kinase inhibitor, Bosutinib; Chk1/Chk2 inhibitor, PF-00477736) and then was evaluated the reduction of the cell viability (MTS reagent), the reduction of the proliferation(Trypan blue exclusion dye assay), cell cycle modification (Propidium iodide staining), induction of apoptosis (Annexin V/Pi staining), protein modification (Western blot) and protein expression modification (Prime PCR plate).
Results: MK-1775 deeply reduced the cell viability in a dose and time-dependent manner in all the treated cell lines. The reduction of both cell viability and proliferation were associated with the increment of apoptosis and the activation of different DNA damage markers (gH2AX and Parp-1), confirming the cytotoxicity of MK-1775 in single agent. We hypothesized that targeting Chk1, a kinase upstream, of Wee1, would be more effective in reducing cell proliferation. Indeed, the concomitant inhibition of Chk1 and Wee1 kinases, using the PF-0477736 in combination with MK-1775, synergized in the reduction of the cell viability, inhibition of the proliferation index and induction of apoptosis. We undertook further studies to understand the chemo-sensitizer activity of the compound, thus MK-1775 was combined with different drugs (Clofarabine, Bosutinib Authentic, Bos, and a particular isomer of Bosutinib, Bos-I).The combination between MK-1775 and clofarabine showed an additive effect in terms of reduction of the cell viability and induction of apoptosis. Finally the Wee1 inhibitor was combined with the tyrosine kinase inhibitors Bos and Bos-I. Both isomers in combination with MK-1775 showed an additive effect in term of reduction of the cell viability and induction of apoptosis. The cytotoxic effect of Bos-I was stronger on the Philadelphia-negative cell lines in comparison to the positive counterpart. Western blot analysis highlighted that this compound, but not the Bos, interfered with the Chk1/Chk2 and Wee1 pathway. The results found on the different cell lines were confirmed also on primary leukemic cells.
Summary/Conclusions: In our opinion the results of this study identify the Wee1 kinase as a promising target for the treatment of ALL. As monotherapy the inhibition of Wee1 increases the genetic instability of leukemic cells, promoting cell death caused by progressive addition of DNA damages. As chemosensitazer agent, the MK-1775 inhibits the DNA damage response pathway, increasing the cytotoxicity of different compounds. CHARACTERISATION OF JAK3 KINASE DOMAIN MUTANTS
S Degryse[1,2,*], M Vanden Bempt[1,2], S Demeyer[1,2], K Jacobs[1,2], E Geerdens[1,2], J Cools[1,2], CE de Bock[1,2]
[1]Center for the Biology of Disease, VIB, [2]Center for Human Genetics, KU Leuven, Leuven, Belgium

Background: Janus kinase 1 (JAK1) and JAK3 are cytosolic tyrosine kinases that are required for cytokine receptor signaling. Recent studies have identified both JAK1 and JAK3 mutations in ALL, AML and lymphoma. JAK3 is mutated in 16% of T-ALL cases. The maojority of these mutations are found within the pseudokinase and kinase domains of JAK3.
Aims: To determine the transforming mechanism of newly identified JAK3 kinase domain mutants L875H, P906S and E958K and to characterize their sensitivity to various JAK inhibitors.
Methods: We studied six JAK3 mutations, two pseudokinase (M511I and R657Q) and four kinase domain (L857Q, L875H, P906S and E958K) mutants. We expressed these proteins in Ba/F3 (proB-cell) and ex vivo cultured primary mouse T-cells. CRISPR/Cas9 genome editing was used to generate common gamma chain (Il2rg) and Jak1 knock out cells.
Results: All six JAK3 mutants were able to transform Ba/F3 cells to growth factor independent growth. The JAK3 L857Q and L875H mutants were able to transform the Ba/F3 cells in the absence of Jak1 or Il2rg, indicating that these two kinase domain mutants do not require binding to a cytokine receptor and do not require Jak1 as a signaling partner. In contrast, the JAK3 M511I, R657Q, P906S and E958K mutants required the presence of Jak1 and Il2rg. Moreover, the growth of these four JAK3 mutants was decreased by overexpression of wild type JAK3 showing that the JAK3 mutants compete with wild type Jak3 for binding to the receptor. Using a proT-cell model, the two JAK3 kinase domain mutants L857Q and L875H showed increased transformation to cytokine independent growth compared to the remaining JAK3 mutants. We next determined the sensitivity of the cells transformed by the JAK3 mutants to either JAK3 selective inhibitors (tofacitinib and decernotinib) or JAK1 selective inhibitors (ruxolitinib and baricitinib). Decernotinib was able to inhibit all JAK3 mutants. While tofacitinib was able to inhibit most JAK3 mutants, the L875H mutant was resistant to this compound. Whilst the JAK1 selective inhibitors were able to inhibit the JAK3 M511I, R657Q, P906S and E958K, they were not able to inhibit the JAK3 L857Q and L875H mutants that were shown to transform cells independently of JAK1.
Summary/Conclusions: The majority of JAK3 mutant proteins require binding to a cytokine receptor complex for full activation and transformation of cells to cytokine independent growth and are sensitive to JAK1 selective inhibition. All data indicated that the transforming mechanism of the two kinase domain mutants L857Q and L875H differ from the other JAK3 mutants. They can activate downstream signaling independent of the receptor complex and are not sensitive to JAK1 selective inhibition. In addition, the L857H mutants show a high tolerance for the JAK inhibitor tofacitinib.

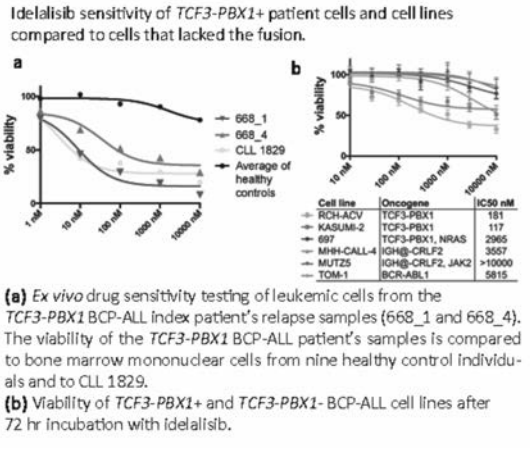
IDELALISIB SENSITIVITY AND MECHANISMS OF DISEASE PROGRESSION IN RELAPSED TCF3-PBX1 ACUTE LYMPHOBLASTIC LEUKEMIA
S Eldfors[1,*], H Kuusanmäki[1], M Kontro[2], MM Majumder[1], A Parsons[1], H Edgren[3], T Pemovska[1], O Kallioniemi[1], K Wennerberg[1], N Gökbuget[4], T Burmeister[5], K Porkka[2], C Heckman[1]
[1]Institute for Molecular Medicine Finland, University of Helsinki, [2]Hematology Research Unit Helsinki, University of Helsinki and Helsinki University Central Hospital Cancer Center, [3]Medisapiens Ltd., Helsinki, Finland, [4]Department of Medicine II, Goethe University, Frankfurt, [5]Department of Hematology, Oncology and Tumorimmunology, Charité Universtätsmedizin Berlin, Berlin, Germany

Background: *TCF3-PBX1* (*E2A-PBX1*) is a recurrent gene fusion in B cell precursor lymphoblastic leukemia (BCP-ALL) resulting from translocation t(1;19)(q23;p13). The majority of human *TCF3-PBX1* BCP-ALLs are pre-B-cell receptor positive. *TCF3-PBX1* BCP-ALL patients typically respond to chemotherapy; however, many relapse and subsequently develop resistant disease with few effective treatment options. Mechanisms driving disease progression and therapy resistance have not been studied previously in *TCF3-PBX1* BCP-ALL.
Aims: Here, we aimed to identify novel options for treating *TCF3-PBX1* BCP-ALL by profiling leukemic cells from a 25-year-old male who relapsed after chemotherapy and allogeneic bone marrow transplant. In addition, we sought to identify molecular mechanisms underlying disease pathogenesis and progression.

Methods: Bone marrow (BM) aspirates and a skin biopsy were collected from the index patient at diagnosis and relapse. The sensitivity of BM mononuclear cells was assessed against a library of 302 investigational and approved anti-neoplastic drugs. To understand molecular mechanisms underlying the pathogenesis and progression of the disease, we performed in-depth molecular profiling of the patient samples. Exome sequencing was used to identify somatic mutations and copy number aberrations at diagnosis and relapse, while RNA sequencing was performed to identify aberrant gene expression. Drug classes effective at inhibiting the viability of the patient cells were further investigated using *TCF3-PBX1*+ BCP-ALL and control cell lines that lacked the fusion.
Results: Drug sensitivity testing showed that leukemic blasts from relapse samples of the index patient were sensitive to several classes of targeted drugs. Among the most effective was idelalisib, inhibitor of phosphatidylinositide 3-kinase delta (p110δ) and approved as a second line treatment for CLL and follicular lymphoma. Testing of two relapse samples from the index patient (668_1 and 668_4), positive control CLL and healthy controls showed that the index BCP-ALL and CLL cells were similarly sensitive to idelalisib (Figure 1a). To determine whether idelalisib sensitivity is common to all BCP-ALLs, we tested the sensitivity of *TCF3-PBX1* positive (n=3) and negative (n=3) BCP-ALL cell lines. Two *TCF3-PBX1*+ cells lines were sensitive while all negative cell lines were resistant (Figure 1b). The *TCF3-PBX1*+ 697 cell line had a mutation to *NRAS*, likely resulting in RAS pathway activation and altering sensitivity to idelalisib. Idelalisib sensitivity of *TCF3-PBX1*+ BCP-ALL cells was further supported by evidence showing TCF3-PBX1 directly regulates expression of *PIK3CD*, the gene encoding p110δ. RNA sequencing of the relapse samples showed high *CXCR4* expression, which was not observed in a cohort of diagnostic phase *TCF3-PBX1* BCP-ALLs (N=15). CXCR4 mediates interactions with CXL12 expressing BM stromal cells and has been implicated in contact mediated drug resistance. Idelalisib inhibits CXCR4 signaling providing a rationale for using this drug to counter drug resistance. The index patient's leukemia acquired mutations to both *TP53* alleles at relapse. In addition, the patient's leukemic cells had an *MTOR* mutation, which was associated with high sensitivity to mTOR inhibitors, which has not been observed before in *TCF3-PBX1* BCP-ALL.



(a) *Ex vivo* drug sensitivity testing of leukemic cells from the *TCF3-PBX1* BCP-ALL index patient's relapse samples (668_1 and 668_4). The viability of the *TCF3-PBX1* BCP-ALL patient's samples is compared to bone marrow mononuclear cells from nine healthy control individuals and to CLL 1829.
(b) Viability of *TCF3-PBX1*+ and *TCF3-PBX1*- BCP-ALL cell lines after 72 hr incubation with idelalisib.

Figure 1.

Summary/Conclusions: Our results suggest idelalisib is a promising treatment option for patients with *TCF3-PBX1* BCP-ALL, while other drugs could be useful depending on the genetic context of individual patients.

E844

INFANT T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA SHOWS CHARACTERISTIC GENETIC FEATURES COMPARED TO CHILDHOOD CASES

J Hoell[1,*], M Dörrenberg[1], A Klötgen[1], M Gerzmehle[2], W Wössmann[3], M Stanulla[4], A Borkhardt[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University Duesseldorf, Duesseldorf, [2]ALL BFM Trial center, University Hospital Schleswig-Holstein, Kiel, [3]Department of Pediatric Hematology and Oncology, University Hospital Gießen and Marburg, Gießen, [4]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: Survival rates of infants (<1 year of age) diagnosed with acute lymphoblastic leukemia (ALL) remain poor with a 4-year event free survival of 47% (Interfant-99). Beside their often highly aggressive initial clinical presentation, these patients usually do not respond well to current therapies. For reasons not yet understood, nearly all of those patients present with B cell-ALL with T cell-ALL remaining an absolute rarity in infants.
Aims: Given its rarity, the biology of infant T-ALL is not understood. Also, it is not clear whether it presents a distinct disease compared to T-ALL diagnosed in later childhood. The aim of our present study therefore was to identify the landscape of genetic alterations of infant T-ALL by whole-exome sequencing (WES), transcriptome and microRNA sequencing.
Methods: We analyzed a total of three infant T-ALL patients and six childhood T-ALL patients as comparison. All sequencing was performed on a HiSeq 2500 (Illumina). Obtained sequence reads were aligned to the human reference genome. Resulting variation calls were annotated by Variant Effect Predictor. MuTect and VarScan2 were employed for identification of somatic nucleotide variations (SNVs). Correlation analyses based on public databases for miRNA-mRNA targeting were performed to reveal miRNA-mRNA pairs expressed in a negative correlation fashion.
Results: In total, 4504 genes had SNVs in any of the three infant patients, 1305 were recurrent in at least two and 557 in all three infant patients. We did not detect any SNVs in Notch1, however, we found SNVs in Notch2 and Notch3. On transcriptome level, 676 genes were differentially expressed ($|\log FC| \geq 1$, FDR<0.05) between the patient groups. Out of these genes, 194 were downregulated in infants and 482 were upregulated when compared to childhood cases. The hierarchical clustering of these significantly differentially expressed genes clearly separated the two patient groups. To analyze the differences between infant and childhood T-ALL samples on an epigenetic level, we performed miRNA sequencing and found 55 miRNAs which were differentially expressed between infant and childhood cases. Correlation analysis for differentially expressed miRNA-mRNA target pairs revealed 34 miRNA-mRNA pairs (Spearman's Rho ≤ -0.6, FDR ≤0.05). Pathway analyses (Ingenuity Pathway Analysis/IPA, Qiagen) showed 51 pathways which were differentially regulated between infant and childhood patients (p-value<0.05). Most perturbed pathways fell into categories with functions in the immune system or were cancer-related, including differentiation, proliferation, apoptosis or cell survival signaling. Examples include ERK5 and TLR signaling. Both toll-like-receptors 2 (TLR2) and 4 (TLR4) were predicted to be inhibited by IPA leading to an aberrant expression of their downstream targets. TLR2 was not significantly downregulated in T-ALL infant samples with a logFC of -1.21 (FDR=0.5), because of variant expressions within the groups. However, one infant case showing a slightly higher expression of TLR2 was carrying an SNV in its coding sequence leading to a missense variant. Several TLR2 targets including SELP, ITGA2B, IL1B, CXCL8 and CD86 were significantly downregulated in infant compared to childhood T-ALL samples.
Summary/Conclusions: Our analyses on exome, transcriptome and miRnome level suggests that infant T-ALL has distinct disease features compared to childhood T-ALL. Differences were observed on both transcriptomic and epigenetic level. Moreover, we describe several differentially expressed pathways including ERK5 and TLR signaling pathways.

E845

IDENTIFICATION OF THE GENOMIC AND TRANSCRIPTOMIC CHANGES CORRELATED WITH THE EX VIVO RESISTANCE TO DAUNORUBICIN AND DOXORUBICIN IN PEDIATRIC ACUTE LEUKEMIAS

J Laskowska[1,2,*], J Szczepanek[1,2], A Tretyn[1,2], J Styczyński[3]
[1]Centre for Modern Interdisciplinary Technologies, [2]Department of Plant Physiology and Biotechnology, Nicolaus Copernicus University, [3]Department of Pediatric Hematology and Oncology, Collegium Medicum, Nicolaus Copernicus University, Torun, Poland

Background: Drug resistances in leukemias correlates with numerous genomic and transcriptomic changes, but the significant majority is still unidentified. Daunorubicin (DNR) and doxorubicin (DOX) are chemotherapeutics of the anthracycline family frequently used in acute leukemias (AL) treatment.
Aims: The objective of the experiment was to identify changes on the genome and transcriptome level and compare them with *ex vivo* resistance to DNR and DOX in pediatric patients with acute lymphoblastic (ALL) or myeloblastic (AML) leukemia.
Methods: In order to determine the *ex vivo* drug resistance profiles to DOX and DNR, MTT cytotoxicity assay was performed on mononuclear cells from 155 patients with ALL or AML. Gene expression profiles (51 patients with ALL, 16 with AML) were prepared on the basis of cRNA hybridization to oligonucleotide arrays of the human genome (Affymetrix). CGH array profiles, (34 patients with ALL, 12 with AML) were prepared on the basis of gDNA hybridization to oligonucleotide arrays of the human genome (Agilent). Data were analyzed using bioinformatics tools (Partek GS, GeneSpring, Feature Extraction, CytoGenomics) and data bases (UCSC Genome Browser, GeneCards, PantherDB). Validation of array results was performed by RT-qPCR with the use of UPL probes for 20 genes comparing to 4 reference genes. The relative expression was calculated by Pfaffl method of quantification in REST-2009 (Qiagen).
Results: Ontological analysis of selected genes in transcriptomic profiles revealed, that hydrolases were mostly overexpressed in lymphoblasts resistant to DNR and DOX, but contrarily hydrolases showed differential expression level in AML cells resistant to DNR. Moreover, in both leukemic blasts resistant to DNR, chemokines were overexpressed. Additionally, in myeloblasts resistant to DNR, genes involved in transcription from RNA polymerase II promoter were downregulated, in ALL cells resistant to DOX-overexpressed, and in ALL blasts resistant to DNR genes showed differential expression. On the basis of achieved aCGH results, we singled out a couple of recurrent genomic changes identified among children with AL. Amp8p12-p11.21 is statistically significant

rearrangement in resistant DNR profile, additionally del9p21.3 and amp22q11.22 are in resistant DOX profile. In blasts sensitive to DNR, we also identified del5q32-35.3, amp14q32.33, del15q11.1-11.2 and del21.11.2-p11.1. What is more, the results of relative expression analysis of candidate and reference genes are presented in Table 1.

Table 1. Microarray and qPCR expression level analysis for all valifated genes.

Summary/Conclusions: The multidimensional analyses revealed, that resistance to DNR and DOX are the result of recurrent genomic and transcriptomic changes in leukemic blasts. We presume, that chromosome aberrations del9p21.3 and amp22q11.22 may associate with resistance to DOX, and amp8p12-p11.21 with lack of sensitivity to DNR and DOX. Additionally, basing on the Real-Time PCR results, we selected presumable target genes, such as *ANXA1, ARAP1, FGR, HK3, SERP1, ITGAM, DUSP2, RETN, ITGB2* in DOX and IDA profiles. All of them were overexpressed. Interestingly, *CASP1* was unique target gene in DOX resistant profile and *PCDH9* in DNR resistant profile. Overexpression of *CASP1* may influence on immune response in leukemia. Furthermore, the decreased expression level of cadherins (such as *PCDH9*) may have impact on the interactions of hematopoietic progenitors and bone marrow stromal cells, resulting breakdown of adhesive mechanisms and enhancement of cell proliferation. This study was supported by Grant from the National Science Centre No. DEC-2011/03/D/NZ5/05749.

SLOWER EARLY RESPONSE TO TREATMENT AND DISTINCT EXPRESSION PROFILE OF CHILDHOOD HIGH HYPERDIPLOID ACUTE LYMPHOBLASTIC LEUKAEMIA WITH DNA INDEX<1.16

M Zaliova[1], L Hovorkova[1], M Vaskova[1], O Hrusak[1], J Stary[2], J Zuna[1,*]
[1]CLIP, Dept. of Paediatric Haematology and Oncology, [2]Dept. of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic

Background: Acute lymphoblastic leukaemias (ALL) with 51-67 chromosomes in leukaemic cells are defined as high-hyperdiploid (HHD). Besides the number of chromosomes, the hyperdiploid ALL can be determined also by DNA index (DNAi; established by flow cytometry), representing ratio of DNA content in leukaemic *vs* normal diploid cells. In childhood, HHD leukaemias comprise 25-30% of all cases, typically arise from B lymphocyte precursors and are generally associated with good prognosis. However, several studies show heterogeneity in HHD-ALL and suggest that the favourable prognosis is associated rather with cases presenting with higher ploidy defined by DNAi >=1.16 or with a presence of specific single or combined trisomies. Thus, cases with DNA index >=1.16 and<1.6 are often considered as "typical" high hyperdiploid ALLs while leukemias with >50 chromosomes and DNA index<1.16 are only rarely studied separately.
Aims: In this study we analysed childhood HHD-ALL patients divided into groups with lower (<1.16) and higher (>=1.16) DNAi to reveal biological and clinical differences between the two subgroups.
Methods: Eighty-nine childhood HHD-ALL patients were analysed by single nucleotide polymorphism array to determine extra chromosomes and to correlate the data with DNA content established by flow cytometry. Moreover, we analysed treatment response, presence of secondary aberrations, mutations in Ras pathway genes (NRAS, KRAS, FLT3, PTPN11) and also gene expression profile (GEP) to reveal possible differences between the two subgroups.
Results: Our results show that vast majority of cases with 51 to 54 chromosomes have DNAi between 1.1 and 1.16 and cases with 55 and more chromosomes have usually DNAi >=1.16. The groups with lower and higher DNAi have distinct response to early treatment - the better response of the group with higher DNAi is probably associated with specific chromosomal gains (trisomy of chromosome 10 or combined with trisomies 4 and/or 17) highly enriched in the group with higher DNAi. Moreover, patients with lower and higher DNAi show distinct GEP in unsupervised clustering analysis; importantly, analysis of the differentially expressed genes and number of its genomic copies suggests, that gene dosage effect probably does not play a driving role in the different behaviour of the two HHD-ALL subgroups.
Summary/Conclusions: The distinct GEP suggests that cytogenetically defined HHD-ALL is in fact composed of two biologically distinguishable subgroups. These differences should be taken into account when defining ALL with excellent prognosis; if treatment deintensification is considered for childhood HHD ALL, only cases with DNAi >=1.16 and gain of chromosome 10 plus chromosomes 4 and/or 17 should be taken into account. Support: The study was supported by grants from Ministry of Health, Czech Republic: IGA NT/14350-3 and project 00064203 (UH Motol).

DIFFERENT PROGNOSTIC ROLE OF RECURRENT COPY NUMBER ABERRATIONS IN B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA WITHOUT RECURRENT FUSION GENES IN 3 CONSECUTIVE AGE COHORTS

M Messina[1,*], S Chiaretti[1], AL Fedullo[1], A Piciocchi[2], MC Puzzolo[1], S Grammatico[1], V Apicella[1], G Te Kronnie[3], M Vignetti[2], AM Testi[1], A Vitale[1], A Guarini[1], R Foà[1]
[1]Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, [2]GIMEMA Data Center, Rome, [3]Department of Women and Child Health, University of Padova, Padua, Italy

Background: In B-lineage acute lymphoblastic leukemia negative (B-NEG ALL) for recurrent fusion genes (*BCR-ABL1*, *MLL*-rearrangements, *TCF3-PBX1, ETV6-RUNX1*), the most common copy number aberrations (CNAs) - *i.e. IKZF1*, *PAX5*, *EBF1*, *BTG1*, *CDKN2A*, *RB1*, *CRLF2* deletions - increase with age progression (Messina et al, 2016). While the prognostic role of *IKZF1* deletion (Δ*IKZF1*) has been extensively studied, novel data on the potential role of other CNAs are currently emerging. With the number of novel prognostic markers increasing exponentially, ALL risk assessment is becoming complex; thus, it is crucial to provide a simplified, integrated predictor, possibly adjusted for age-cohort.
Aims: 1) To correlate the most common CNAs with the clinico-biological features of B-NEG ALL patients; 2) to assess their prognostic role; 3) to evaluate whether their impact on outcome varies across age-cohorts.
Methods: CNAs of the above mentioned genes were studied by Multiplex Ligation-dependent Probe Amplification (Salsa MLPA P335 ALL-IKZF1 kit, MRC-Holland) in 157 B-NEG ALL, including 56 adults, 56 adolescents/young adults (AYA) and 45 children. CNAs were correlated with age, gender, Hb levels, white blood cell (WBC) and platelets counts, and with RAS and JAK/STAT pathway mutations. The impact of CNAs on disease free survival (DFS) was analyzed.
Results: Overall, 46.6% of children, 82.4% of AYA and 87.5% of adults, carried at least 1 CNA. In particular, deletions of *IKZF1* were detected in 41.4%, of *CDKN2A* in 36.9%, of *PAX5* in 25.5%, of *ETV6* in 17.8%, of *EBF1* in 12.1% and of *BTG1* in 10.2% of patients, with *IKZF1*, *CDKN2A*, *PAX5* and *BTG1* deletions being significantly more frequent in adults and AYA than in children, as already mentioned. *EBF1* and *CDKN2A*-deleted patients had a significantly higher WBC count. *BTG1* deletions occurred exclusively in males (p=0.002). Furthermore, JAK/STAT mutations were significantly associated with *EBF1* (p=0.033) and *CDKN2A* deletions (p=0.026). Survival analyses on the whole cohort with clinical data available (N=133) showed that *CDKN2A*-deleted patients had a significantly worse DFS than *CDKN2A*-WT cases at 5 years (39.7% *vs* 64.1%, p=0.005); *EBF1*-deleted patients also had a significantly poorer DFS than *EBF1*-WT cases (33.3% *vs* 60.1%, p=0.003). A trend towards a worse DFS was observed for *BTG1*-deleted cases, with its negative impact being more evident when considering only AYA (30% *vs* 61.4%, p=0.095). *CDKN2A* and *EBF1* deletions retained their negative impact on DFS also when considering the adult cohort only. Indeed, *CDKN2A*-deleted had a shorter DFS than *CDKN2A*-WT cases (12.8% *vs* 54%, p=0.03); similarly, DFS of *EBF1*-deleted was inferior than *EBF1*-WT cases (0% *vs* 38.3, p=0.002); a trend was observed combining adults with AYA, while no impact was found in children. At variance, a trend towards a better DFS for *ETV6*-deleted *vs ETV6*-WT cases was observed (100% *vs* 65%, p=0.065) in children, recalling the favorable prognostic impact of *ETV6-RUNX1*. In the present cohort, the role of Δ*IKZF1* remains controversial: nevertheless, by combining adults and AYA, patients harboring Δ*IKZF1*-only or no CNAs had a trend towards a longer DFS than the remaining cases (62.6% *vs* 39.1%, p=0.068).
Summary/Conclusions: Besides the heterogeneous distribution, we also found a different impact on prognosis of CNAs across age cohorts, with *CDKN2A* and *EBF1* deletions influencing adult patients' outcome and *BTG1* negatively impacting on AYA survival; notably, these lesions did not impact on the outcome of childhood ALL. These findings indicate that, apart from the mutational status, risk assessment of ALL should also include the evaluation of selected CNAs.

CALCINEURIN COMPLEX ISOLATED FROM T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL) CELLS IDENTIFIES NEW SIGNALING PATHWAYS WHOSE INHIBITION SYNERGIZE WITH CALCINEURIN INHIBITION TO PROMOTE T-ALL CELL DEATH

V Tosello[1], V Saccomani[2], J Yu[3], F Bordin[2], A Amadori[2], E Piovan[2,*]

[1]Istituto Oncologico Veneto-IOV-IRCSS, [2]Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy, [3]Department of Systems Biology, Columbia University, New York, United States

Background: Calcineurin (Cn) is a calcium activated protein phosphatase, composed of a catalytic subunit (PPP3CA) and a regulatory subunit (PPP3CB). It is critically involved in calcium signaling in diverse cells and is involved in many aspects of normal T cell physiology, however the role of Cn and/or its downstream targets in leukemogenesis are still ill-defined.
Aims: Available evidence shows that Nuclear Factor of Activated T cells (NFAT) transcription factors are mediators of Cn action in different cancers. However, it is possible that NFAT factors are not the only targets of Cn in leukemogenesis, as Cn can dephosphorylate other factors possibly relevant to its oncogenic properties. Aim of this study was to identify putative downstream targets/effectors involved in the pro-oncogenic activity of Cn in T-cell acute lymphoblastic leukemia (T-ALL), evaluate if the interactors are enriched in cellular signaling pathways relevant for T-ALL pathogenesis and if novel drug combinations can be proposed to enhance the efficacy of chemotherapeutic drugs and/or reduce the side effects of clinically relevant immunosuppressive drugs targeting Cn.
Methods: In order to identify putative downstream targets/effectors involved in the pro-oncogenic activity of Cn in T-ALL we used tandem affinity chromatography, followed by mass spectrometry (MS) to purify novel Cn-interacting partners. Novel interactions were validated by immunoprecipitation following transient overexpression in 293T cells or as native interactions in T-ALL cells. Drug synergisms using relevant drug combinations were evaluated through the execution of cell viability assays (bioluminescent method and annexin V-PI staining). Effects of Cn activity modulation on cellular signaling pathways found to be enriched in our MS list were evaluated by western blotting and flow cytometry.
Results: We identified numerous PPP3CA interactors, including proteins implicated in leukemia pathobiology such as NPM1, BCL11B, GSK3b and KDM1. The identified Cn-interacting proteins were found to be part of diverse cellular signaling pathways including eIF2 signaling, cell cycle control of chromosomal replication, mammalian target of Rapamycin (mTOR) signaling and 14-3-3 mediated signaling. Interestingly, modulation of Cn activity (by inhibitors and activators) lead to alterations in the identified signaling pathways including PI3K-AKT-mTOR signaling and eIF2 signaling. In addition, jointly targeting pathways enriched in our Cn complex (such as PI3K-mTOR signaling, cell cycle control of chromosomal replication mediated by topoisomerase II) together with Cn unveiled novel synergistic pro-apoptotic drug combinations.
Summary/Conclusions: The signaling pathways reported here will contribute to identify novel drug combinations which could enhance the efficacy of chemotherapeutic drugs and/or reduce the side effects of clinically relevant immunosuppressive drugs targeting Cn.

E849

OVEREXPRESSION OF PTP4A3 IN ETV6-RUNX1 ACUTE LEUKEMIA

T Grönroos[1,*], S Teppo[1], J Mehtonen[2], S Laukkanen[1], T Liuksiala[1,3], M Nykter[3,4], M Heinäniemi[2], O Lohi[1]
[1]Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, [2]Institute of Biomedicine, School of Medicine, University of Eastern Finland, Kuopio, [3]Institute of Biosciences and Medical Technology, University of Tampere, [4]Department of Signal Processing, Tampere University of Technology, Tampere, Finland

Background: Acute leukemia is the most common cancer in childhood. The ETV6-RUNX1 (E/R) fusion gene is present in 25% of childhood precursor B cell acute lymphoblastic leukemia (pB-ALL). E/R fusion is acquired *in utero* by a translocation between chromosomes 12 and 21 (t[12,21][p13;q22]). Translocation creates an aberrant fusion transcription factor which induces genome-wide repression of regulatory sequences and gene transcripts. The family of protein tyrosine phosphatase 4A (PTP4A) proteins are phosphatases with dual specificity. The family consists of three closely related members (PTP4A1-3) and they participate in a wide range of cellular activities, including cell proliferation, migration and invasion. Kinases and phosphatases have an intricate relationship in balancing intracellular signalling activity, and this balance is often deregulated in malignancies.
Aims: There are indications that members of the PTP4A family are involved in pathogenesis of various hematological malignancies. This motivated us to investigate the role of PTP4A3 in acute lymphoblastic leukemias by using gene expression data on patient samples, bioinformatic analyses and experimental manipulation of cell lines.
Methods: We investigated expression of members of PTP4A family across acute and chronic leukemias, cell lines and healthy cells of hematopoietic origin in a large collection of patient samples assayed by Affymetrix HU2.0 microarray and retrieved from GEO database. After normalization and manual curation, a two-dimensional "leukemia-map" was generated by t-SNE to visualize the data. We used experimental manipulation of cell lines to validate our findings from the "leukemia-map".
Results: PTP4A3 showed markedly increased expression among pre-B-ALL and decreased expression in acute myeloid leukemias, chronic leukemias and healthy cells. In further scrutiny, strong expression of PTP4A3 coincided with the E/R subtype of pB-ALL, showing approximately four-fold higher expression as compared to other pB-ALL leukemias (p=5.449805e-50). To validate the finding, two more patient data sets were retrieved to confirm the higher expression of PTP4A3 in the E/R subtype. In agreement, induction of E/R fusion in Nalm-6 cells increased the level of PTP4A3 mRNA. At primary transcript level, as assayed by global nuclear run-on sequencing (GRO-seq), the decrease of PTP4A3 expression after E/R knockdown was evident. Further, we identified a number of potential E/R binding sites upstream of PTP4A3 gene. Inhibition of PTP4A3 phosphatase activity in E/R positive REH cells was better tolerated as compared to other tested ALL cells.
Summary/Conclusions: We show that expression of PTP4A3 is markedly upregulated in the E/R subtype of acute pB-ALL. Our data hint that PTP4A3 expression is regulated by the E/R fusion itself, suggesting further studies on the surrounding regulatory elements. The potential role of PTP4A3 inhibitors will be further evaluated in combination with the known anti-leukemic drugs.

DROPLET DIGITAL PCR ANALYSIS FOR DIAGNOSIS AND MINIMAL RESIDUAL DISEASE MONITORING IN ADULT PH+ ACUTE LYMPHOBLASTIC LEUKEMIA

F Albano[*], N Coccaro, A Zagaria, L Anelli, G Tota, P Orsini, C Brunetti, L Impera, A Minervini, CF Minervini, C Cumbo, P Casieri, E Parciante, D Pastore, P Carluccio, G Specchia
Hematology - University of Bari, Bari, Italy

Background: *BCR-ABL1* tyrosine kinase inhibitors (TKIs) are considered an important component of treatment for adult patients affected by Philadelphia-positive (Ph+) acute lymphoblastic leukemia (ALL). In fact, recent studies reported that treating Ph+ ALL with the combination of imatinib and multi-agent chemotherapy improved the overall outcome. Currently, no data are available on the impact of TKIs on minimal residual disease (MRD) in Ph+ ALL. In fact, although the real-time quantitative PCR (RQ-PCR) method, usually employed for monitoring the *BCR-ABL1* residual transcript, is sensitive and easy to perform, it lacks a full standardization and international quality validation.
Aims: Here, we describe a highly sensitive and reproducible droplet digital PCR (ddPCR) test to monitor *BCR-ABL1* transcript level in Ph+ ALL. The aim of the study is to demonstrate that ddPCR represents a sensitive and rapid method for both diagnosis and MRD monitoring of Ph+ ALL patients.
Methods: *BCR-ABL1* expression analysis by ddPCR was performed in twenty-two newly diagnosed adult Ph+ ALL patients. The diagnosis was confirmed by qualitative RT-PCR specific for the *BCR-ABL1* p190 fusion gene detection. ddPCR experiments were successfully performed in all twenty-two patients at the onset; several follow-up points were evaluated in thirteen patients. ddPCR experiments were performed using primers and probes specific for *BCR-ABL1* p190. *GUSB* was used as control gene. Fifty ng and 750 ng of cDNA templates were used for the onset and for the post-treatment samples, respectively. To increase the limit of detection (LOD), three replicates were run for the post-treatment samples. ddPCR experiments were performed by Bio-Rad's QX200 system and ddPCR data were analyzed with QuantaSoft analysis software (version 1.7.4). Target concentration was expressed as *BCR-ABL1* copies/mg.
Results: First, we defined the LOD of the *BCR-ABL1* p190 ddPCR system, a 10-fold dilution series (10^0, 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}, and 10^{-5}) of a pool of p190 positive patients using a diluent-pool of healthy volunteers. This analysis showed remarkable linearity, trueness, and precision down to 10^{-5}. After converting to log-log scale, linear regression showed no concentration-dependent bias, and R^2 equaled 0.996. Because the negative samples showed no background, even the detection of a single droplet per well was considered a positive result. The median concentration of the *BCR-ABL1* transcript at the onset was 233.8 (min 3.24-max 1744) x 10^3 *BCR-ABL1* copies/mg. Concerning the analysis of follow-up samples, among the thirty-four points that were negative to qualitative nested RT-PCR, twenty-three (68%) resulted to be positive by ddPCR analysis, with a median concentration of 44.95 (min 0.27-max 573.3) *BCR-ABL1* copies/mg. Follow-up points that were negative in ddPCR remained negative even when the experiments were repeated increasing the depth of the analysis, evaluating a total quantity of 4.5 micrograms of RNA.
Summary/Conclusions: This study indicates that, as compared to RQ-PCR, ddPCR increases the depth of the quantitative analysis of *BCR-ABL1* p190 fusion transcript by allowing the evaluation of larger amounts of RNA. Moreover, our preliminary data revealed that the amount of the *BCR-ABL1* fusion transcript at diagnosis is heterogeneous and that the ddPCR is much more sensitive than nested qualitative RT-PCR analysis, as the 68% of samples negative to nested PCR during the follow-up resulted to be positive by ddPCR. Therefore, we suggest that ddPCR represents a precise, sensitive and rapid method for both diagnosis and MRD monitoring of Ph+ ALL patients.

E851

ABNORMAL EXPRESSION OF THE CYSTEINE AND GLYCINE-RICH PROTEIN 2 GENE IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

SJ Wang[1,*], WM Wang[2], WY Lu[1], YH Feng[1], QM Yao[1], J Zhou[1], XJ Huang[1], KY Liu[1], GR Ruan[1]

[1]Institute of Hematology, Peking University People's Hospital, Beijing, [2]Department of Hematology, First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: Cysteine and glycine-rich protein 2(CSRP2) is a member of the CSRP family of genes, encoding a group of LIM domain proteins, which may be involved in regulatory processes important for development and cellular differentiation. It has been reported that determination of CSRP2 protein level had a significant meaning for cardiovascular and respiratory diseases. In view of the important function of CSRP2 in cell growth and differention, CSRP2 may also have a role in carcinogenesis. However, the expression of CSRP2 has not been explored in leukemia, especially in B-cell acute lymphoblastic leukemia (ALL).
Aims: The purpose of this study was to investigate the expression of human CSRP2 messenger RNA in B-cell acute lymphoblastic leukemia by real-time fluorescent quantitative reverse transcription-polymerase chain reaction assay.
Methods: A real-time quantitative RT-PCR based on TaqMan fluorescence methodology was used to quantify the CSRP2 mRNA copy number in the bone marrow cells from patients with leukemia and in 11 human leukemic cell lines. Normal marrow samples from the allogeneic stem cell transplantation donors were served as control. Informed consent was obtained for every marrow sample.
Results: Expression levels of the CSRP2 gene in leukemic cell lines, leukemia patients and normal donor marrow are shown in Figure 1. These results showed that the relative levels of CSRP2 gene expression in marrow from the 212 newly diagnosed B-cell ALL was significantly higher than those of marrow from the 43 healthy donors(p<0.01). No statistical significant difference was observed in 18 newly diagnosed T-cell ALL, 73 AML and 43 healthy donors (p's >0.05), but it was higher in SupB15, BV-173 cells from B-cell ALL cell lines than in other cells from AML or T-cell ALL cell lines. Focusing on B-cell ALL patients, the median level of CSRP2 in 212 newly diagnosed patients was 42.13%(range 0-740.55%), while the median level in 290 treated patients who achieved CR decreased to 0.55%(range 0-21.21%). However, in 17 refractory patients and 22 relapsed patients, the median level was 60.83%(range 2.89-548.47%) and 43.17%(range 0.08-346.81%), respectively. In newly diagnosed B-cell ALL, 8 patients with MLL-AF4 translocation showed higher CSRP2 expression levels compared with 124 patients without this translocation(p<0.01). Figure1.Expression levels of CSRP2 in leukemic cell lines, leukemia patients and normal donor marrow. HD denotes healthy donors; De nove denotes newly diagnosed; CR denotes complete remission; Horizontal lines represent median CSRP2 expression for each group.* indicates p<0.05 compared with HD; & indicates p<0.05 compared with De novo B-cell ALL; # indicates p<0.05 compared with CR B-cell ALL.

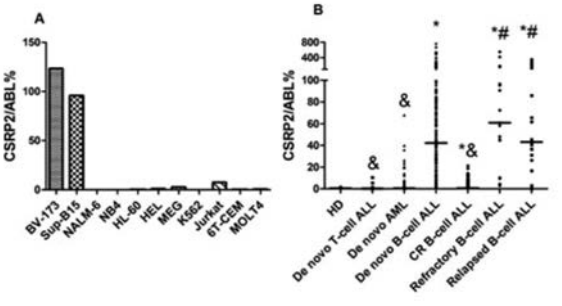

Figure 1.

Summary/Conclusions: These findings suggest that abnormal expression of CSRP2 in leukemia may be involved in the pathomechanism of B-cell ALL.

E852

IL7R OVEREXPRESSION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): PROGNOSTIC IMPLICATIONS IN B-LINEAGE ALL WITHOUT RECURRENT FUSION TRANSCRIPTS

V Gianfelici[1,*], M Messina[1], F Paoloni[2], M Vignetti[2], AL Fedullo[1], F Di Giacomo[3], A Vitale[1], A Guarini[1], S Chiaretti[1], R Foà[1]
[1]Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University, [2]GIMEMA Data Center, GIMEMA, Rome, [3]Department of Molecular Biotechnology and Health Science and Center for Experimental Research and Medical Studies, University of Torino, Torino, Italy

Background: The IL7 receptor alpha chain (IL7R) heterodimerizes either with the IL2RG to form the IL7 receptor or with CRLF2 to form the receptor for the thymic stromal lymphopoietin (TSLP) both in T and B-cells. Signaling from these receptors activates the JAK/STAT pathway that is frequently altered both in T- and B-lineage acute lymphoblastic leukemia (ALL), due to mutations of its members. Among them, *IL7R* mutations are relatively common in adult B-ALL without recurrent transcripts (B-NEG) and in T-ALL. In a cohort of adult ALL previously studied by gene expression profiling (GEP) we observed that *IL7R* expression levels were variable, with a considerable number of B-NEG and T-ALL cases overexpressing it, thus suggesting that its deregulation may rely on different mechanisms.
Aims: To evaluate the clinical relevance of *IL7R* expression levels in adult B-NEG and T-ALL, we correlated the levels of *IL7R* expression with patients' outcome and analyzed the transcription profile of *IL7R*-high cases.
Methods: *IL7R* expression levels were inferred from previously performed GEP studies (Affymetrix) of adult ALL, including 78 B-NEG and 68 T-ALL. Martingale residual analysis was used to select the optimal *IL7R* cut-off, which was computed separately for these two groups. Differences in survival curves of *IL7R*-high and *IL7R*-low were calculated by the log-rank test. GEP of *IL7R*-high was analyzed and correlated with the molecular and immunophenotypic features. Screening of the JAK/STAT genes recurrently mutated was performed by Sanger in 66/78 B-NEG (*IL7R*, *CRLF2*, *JAK2)* and 38/68 T-ALL (*IL7R, JAK1/3, STAT5B*).
Results: *IL7R* expression levels were extremely heterogeneous both in B-NEG (mean 656.9, range 43.8-3000) and in T-ALL (mean 1047 range 58.9-5874). Martingale residual analysis provided a cut-off of 500 for B-NEG and 1000 for T-ALL. By using these cut-points, 47% of B-NEG and 41% of T-ALL cases were defined as *IL7R*-high. In B-NEG, correlation between *IL7R* expression levels and outcome showed that *IL7R*-high cases had a significantly shorter OS at 4 years than *IL7R*-low (31% *vs* 62%, p=0.04). Similarly, in T-ALL a trend towards a poorer OS was observed in *IL7R*-high patients than *IL7R*-low (27% *vs* 40%, p=0.2). The comparison of *IL7R*-high and *IL7R*-low by supervised GEP analysis identified a set of differentially expressed genes both in B-NEG (157 genes) and T-ALL (208 genes); only 11 transcripts overlapped. Indeed, functional annotation analysis of upregulated genes in *IL7R*-high highlighted an enrichment of JAK/STAT, Wnt and ErbB signaling members in B-NEG cases and of JAK/STAT and Notch pathway members in T-ALL, suggesting the involvement of different downstream cascades. As per the associations with other biological features, *IL7R* levels were significantly lower in *TAL1* cluster than in other subgroups (p=0.005). Notably, we observed a significant association between *IL7R* high expression and JAK/STAT pathway mutations both in B-NEG and T-ALL (p=0.001 and 0.03, respectively), thus indicating that *IL7R*-high might be a marker of an underlying JAK/STAT mutation.
Summary/Conclusions: Overall, our findings indicate that *IL7R* altered expression may represent a novel prognostic marker in B-NEG cases and, to a lesser extent, in T-ALL. Given the different GEP observed between *IL7R*-high B-NEG and *IL7R*-high T-ALL, it is intriguing to speculate that *IL7R* deregulation may activate different pathways. Furthermore, *IL7R* overexpression should prompt the investigation of JAK/STAT mutations both in B-NEG and T-ALL. However, given the overall incidence of JAK/STAT mutations it is likely that *IL7R* overexpression might be also sustained by other mechanisms that are currently under investigation.

Acute lymphoblastic leukemia - Clinical

E853

NEGATIVE PRE TRANSPLANT MINIMAL RESIDUAL DISEASE, ASSESSED BY FLOW CYTOMETRY, IMPROVES OUTCOME IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA, ESPECIALLY IF CLEARENCE IS ACHIEVED EARLY DURING INDUCTION

M Gambella[1,*], F Guolo[1], P Minetto[1], D Guardo[1], E Coviello[1], N Bisso[1], N Di Felice[1], A Kunkl[2], F Ballerini[1], M Clavio[1], M Miglino[1], RM Lemoli[1], M Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Service of Flow Cytometry, IRCCS AOU San Martino-IST, Genoa, Italy

Background: With the introduction of pediatric-inspired induction regimen, prognosis of adult acute lymphoblastic leukemia (ALL) has substantially improved, leading to an increased assessment of minimal residual disease (MRD) during all induction course and a progressive use of MRD-driven therapeutic approach. In most modern pediatric protocols, persistence of MRD during the first courses of induction therapy is an adverse prognostic factor and constitutes a strong indication for early allogeneic bone marrow transplantation (BMT). However, it remains unclear if an effort towards MRD eradication should be attempted before BMT, as relatively few data are available on outcome of MRD positive adult ALL patients.
Aims: The aim of this study was to analyze the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk and to evaluate the impact of day 33 MRD status in pre-BMT MRD negative patients.
Methods: We retrospectively analyzed the outcome of 53 consecutive ALL patients receiving allo-BMT, with available pre-BMT multicolour flow cytometry (MFC) MRD assessment. Median age at transplant was 30 years. Disease phase was CR1 in 20 (38%), CR2 in 17 (32%), and CR3 in 14 patients (30%). Thirty-five patients (66%) had B lineage ALL, whereas 18 (34%) had T-ALL. Relapse-free survival (RFS) was calculated from the time of transplantation until last follow-up or documented leukemic relapse. Overall Survival (OS) was calculated from the time of transplantation until death by any cause or last follow-up. Median follow up was 62 months.
A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5 total events (threshold of$2.5x10^{-4}$ residual leukemic cells) at four-color flow-cytometry.
Results: Relapse occurred in 30 patients (57%). Three-year RFS was 42.2% (median 10 months). The probability of relapse was significantly affected by disease status at BMT (CR1 *vs* CR2 or p<0.001), karyotype (p<0.03) and MFC MRD (both day 33 and pre-BMT, p<0.03). Pre-BMT MFC-MRD was a strong predictor of longer relapse free survival: 5 relapses occurred in the 17 MFC-MRD negative patients and 3-years RFS was 69.4% (median not reached), compared to 25 relapses observed in 36 MFC MRD positive patients, with a 3-year RFS of 29.4% (median 5 months). Multivariate analysis revealed that MFC MRD and disease status at transplantation were significant predictors of RFS duration (p<0.001 and p<0.05, respectively). Eleven patients with pre-BMT MRD negative had available day +33 assessment. Two relapses were observed among the 3 day 33 MRD positive patients (66%), compared to three relapses among 8 day 33 MFC MRD negative patients (37%). MRD evaluation was a strong predictor of long term survival, as 3- years OS was 65% for MFC MRD negative compared to 49.8% for MFC MRD positive patients (p<0.05).
Summary/Conclusions: Pre transplant MFC MRD evaluation is a feasible and reliable predictor of relapse risk in adults ALL patients. Patients with positive MFC MRD have a very high relapse risk and a poor outcome after BMT. Although small numbers prevented us to drive conclusion, persistence of MRD at day 33 seems to confer a worse prognosis in pre-BMT MRD patients. In the era of targeted therapy, at least for B-ALL, persistence of MRD after induction could be an indication for innovative approach, such as attempts of MRD eradication using recently developed immunoconjugated monoclonal anti-CD-22 antibodies or anti-CD3/anti-CD-19 bispecific antibodies.

E854

MOLECULAR DETECTION OF ALL IN THE PERIPHERAL BLOOD IS MORE SENSITIVE THAN FLOW CYTOMETRIC ANALYSIS OF THE BONE MARROW IN PATIENTS WITH TREATMENT-RELATED HYPOCELLULARITY

I Kirsch[1,*], H Smithers[2], O Finney[2], B Crossley[1], M Jensen[2], R Gardner[2]
[1]Translational Medicine, Adaptive Biotechnologies, [2]Pediatric Oncology, Seattle Children's Hospital, Seattle, United States

Background: Minimal residual disease detection (MRD) is an important tool for early detection and monitoring relapse. Traditionally, bone marrow is collected and analyzed by flow cytometry (FC) to evaluate MRD status in acute lymphoblastic leukemia patients (ALL). More recently, highly sensitive molecular methods such as high throughput sequencing (HTS) allow for more sensitive detection of MRD below 1 in 10^{-5}. Although the bone marrow is considered to be more representative of leukemic burden than sampling the blood, bone marrow collection is more invasive, traumatic, and costly than peripheral blood draws and therefore is performed only at specified and limited intervals. Paired bone marrow and blood samples from ALL patients can be assessed and compared for MRD at different time points in therapy.
Aims: In this study, we analyzed paired blood and bone marrow samples from the Adaptive Biotechnologies assay of IgH and TCRG in order to determine whether HTS performed on a peripheral blood sample is as informative as HTS and FC on a bone marrow sample in the assessment of MRD.
Methods: ALL patients enrolled in the Seattle Children's Pediatric Leukemia Adoptive Therapy (PLAT-02) trial undergo MRD assessment pre and post CD19 CAR T cell infusion by FC of the bone marrow. We have used high throughput sequencing (HTS) in paired blood and bone marrow samples from these patients. Samples taken prior to therapy evaluate the complete B cell repertoire and detect any dominant sequences which may be used for subsequent tracking. Samples taken at intervals during therapy assess the levels of MRD up to 63 days post-infusion.
Results: We have obtained 38 paired bone marrow and peripheral blood samples to date. We have observed a significant correlation in both the frequency of total reads and the number of malignant cells per million in paired peripheral blood and bone marrow samples by HTS. Of these, 26/38 (68%) of bone marrow samples were determined either aparticulate or hypocellular. Importantly, 8/14 (57%) of patients who were MRD negative in the bone marrow by FC were MRD positive in the blood by HTS. While it may only be true of patients receiving this particular form of treatment, there were some samples assayed by immunosequencing in which peripheral blood was a more sensitive measure of tumor burden than simultaneously acquired bone marrow. These data suggest, that, in cases where the bone marrow is hypocellular or aparticulate, peripheral blood samples evaluated by HTS are more sensitive than traditional flow cytometric analysis in the bone marrow for detection of MRD.
Summary/Conclusions: The impact of B cell aplasia may be important in increasing the sensitivity of HTS in the detection of MRD. The ability to detect an ALL B cell clone in the blood through HTS has many clinical implications; blood can be sampled more often, is less of a burden to patients, and can provide earlier prediction of relapse.

E855

DE-ESCALATION OF INTENSITY DID NOT AFFECT THE LONG-TERM OUTCOME NEITHER IN T-ALL NOR IN BCP-ALL IF NON-INTERRUPTIVE TREATMENT IS APPLIED: RESULTS OF THE RUSSIAN ALL STUDY GROUP

E Parovichnikova[1,*], V Troitaskaya[1], A Sokolov[1], G Kliasova[1], L Kuzmina[1], S Kravchenko[1], E Gribanova[1], S Bondarenko[2], O Baranova[3], Z Akhmerzaeva[1], O Gavrilina[1], G Baskhaeva[1], T Obukhova[1], M Rusinov[1], S Kulikov[1], E Zinina[4], M Grishunina[5], E Zotina[6], T Kaporskaya[7], L Gavrilova[8], V Savchenko[1]
[1]National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, [2]Research institution of children oncology, hematology and transplantology, Saint Petersburg, [3]Russian Cancer Research Center, Moscow, [4]Regional clinical hospital, Surgut, [5]Regional clinical hospital, Nizhnii Novgorod, [6]Regional clinical hospital, Kirov, [7]Regional clinical hospital, Irkutsk, [8]Regional clinical hospital, Saransk, Russian Federation

Background: More aggressive pediatric-like protocols and high portion of allogeneic HSCT are now a standard approach to treatment in adult acute lymphoblastic leukemia (ALL). Here we report the results of the adult (15-55 yy) Ph-negative ALL protocol based on the different approach: de-escalated but non-interruptive treatment with low numbers of allo-HSCT. The study is registered on the ClinicalTrials.gov public site; NCT01193933.
Aims: To assess non-intensive and non-interruptive approach to ALL treatment.
Methods: The ALL-2009 is based on: (1) the replacement of prednisolone (Pdn) 60mg/m^2 with dexamethazone (Dexa) 10mg/m^2 if blast cells are ≥25% in b/m after prephase (7d); (2) de-intensified but non-interruptive 5 months induction/consolidation treatment (5 wks Pdn/Dexa with 3 instead of 4 Dauno/Vncr pulses, 4 weeks of 6MP with 5 L-asp, 2 instead of 4 ARA-C blocks, 1 instead of 2 Cph injections during induction; induction-like 3 consolidations for 3wks, 2wks, 4wks –continuously without intervals), followed by (3) 2 late (at 6 mo) intensifications– with 1 day HD MTX (1,5 g/m^2)and with 1 d HD ARA-C (2 g/m^2), both with L-asp and 3 d dexa and (4) 2-yrs continuous 6MP/MTX maintenance with doses modification according to myelosuppression with monthly 3-days dexa/vncr/L-asp pulses (∑ L-asp=590.000IU/m^2). The protocol was identical for all risk groups. For T-ALL patients auto-HSCT after non-myeloablative BEAM conditioning followed by the protocol maintenance was an option as late consolidation. Allo-HSCT was indicated only for extremely high-risk BCP-ALL (t(4;11), L>100). No central MRD monitoring was performed. Since Apr 2009 till Feb 2016, 298 Ph-negative ALL pts with a median age 28 years (15-55), f/m 137/161 were recruited. In 6 pts phenotype was unknown, B-lineage ALL was diagnosed in - 62,4% (n=182), T-lineage ALL-36,6% (n=107), biphenotypic -1% (n=3). In BCP-ALL 31 patients (n=17%) were not qualified by the risk in the data-base; 72,8% (n=110) were in the high risk (HR) group (WBC ≥30; EGIL BI, LDH >2N; late CR; t(4;11)-positive). In T-ALL 7 patients (n=8%) were not qualified by the risk in the data-base; 76% (n=76) were in the high risk (HR) group (WBC ≥100; EGIL TI/II,TIV, LDH >2N; late CR). The analysis was performed in february 2016.
Results: CR rate in 284 available for analysis pts was 86,7% (n=246), induction death occurred in 9,1% (n=26), resistance was registered in 4,2% (n=12). Late

responders constituted 13,1% (n=20) in BCP-ALL and 28,9% (n=24) in T-ALL. In 89 CR T-ALL pts 35 auto-HSCT were performed at a median of 5,8 mo of CR. Allogeneic BMT was performed only in 18 of 256 patients who survived induction (7,0%). Totally 49 pts (19,9%) had relapsed. At 60 mo OS for the whole cohort constituted-58,9% (BCP-ALL -53,3%, T-ALL-67,5%), DFS-64.9% (BCP-ALL-56,2%, T-ALL-79,5%), relapse probability (RP)-25% (BCP-ALL - 30,6%, T-ALL-15,8%). In a univariate analysis among various risk factors (age< ≥30y, initial risk group, WBC, LDH, immunophenotype, late response >35d) age (≥30 y) for BCP-ALL became statistically significant for OS and RP, WBC for DFS and RP, risk group for DFS, LDH for RP, t(4;11) for OS, DFS and RP. In T-ALL in a univariate analysis only LDH was significant for OS. In a multivariate analysis no common risk factors were significant non in T-ALL, nor in BCP-ALL.
Summary/Conclusions: Our data demonstrate that the de-escalation of intensity but constant non-interruptive treatment is rather effective in adult ALL producing more than 50% OS in BCP-ALL and 65% in T-ALL. We believe that this approach, without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT may become an alternative and reproducible approach in adult Ph-negative ALL, though we have to stress that the compliance of the pts to the protocol should be very strict.

SERIAL MONITORING OF BCR-ABL BY REAL-TIME POLYMERASE CHAIN REACTION IN NEWLY DIAGNOSED PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH IMATINIB

S Lim[1,*], YD Joo[1], BS Sohn[2]
[1]Internal Medicine, Haeundae Paik Hospital/Inje University College of Medicine, Busan, [2]Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Korea, Republic Of

Background: The positive impact of imatinib on treatment outcome in patients with Philadelphia Chromosome-Positive (Ph+) acute lymphoblastic leukemia (ALL) is well known, and the kinetics of the BCR-ABL transcript correlated with the patient's clinical course.
Aims: The aim of this study was to evaluate the relationship between imatinib dose intensity and molecular response of BCR-ABL.
Methods: Imatinib (600 mg/day orally) was administered continuously with combination chemotherapy, starting from eighth day of remission induction treatment, then through 5 courses of consolidation or until allogeneic hematopoietic cell transplantation (HCT). Patients who were not transplanted were maintained on imatinib for 2 years. Molecular response monitoring was performed at the central lab with quantitative RT-PCR assays for peripheral blood or bone marrow BCR-ABL RNA in serial; at the time of diagnosis, at hematologic complete remission (HCR), and every 3 months thereafter. The molecular response was defined as complete (MCR) if the *BCR-ABL/G6PDH* ratio was less than $1x10^{-5}$.

Table 1.

Risk Factor	Molecular relapse-free survival		
	P	HR	95% CI
Using G-CSF during induction treatment			
No	0.034	0.376	0.152-0.944
Yes		1	
Dose intensity of imatinib			
Initial dose intensity within 7 weeks			
≥90%	0.017	0.405	0.192-0.853
<90%		1	
Total dose intensity during entire study period			
≥80%	0.902	1.070	0.361-3.173
<80%		1	
Early complete molecular response within 3 months after remission induction			
Yes	0.001	0.251	0.111-0.570
No		1	
Underwent allogeneic stem cell transplantation			
Yes	0.002	0.284	0.130-0.621
No		1	

Results: Between October 2005 and February 2009, total 87 patients, aged 16-71 years, with newly diagnosed Ph+ALL were enrolled. With median follow-up of 5 years among survivors (range: 2.6-8.9 years). At the time of diagnosis, the BCR-ABL transcript amount showed no correlation with WBC count and peripheral blast percent. Eighty-two patients (94%) achieved HCR at a median 25 days (range, 14-69 days) and 45 patients (57.7%) of 78 evaluable patients achieved MCR at the same time. Within three months after induction treatment, 59 patients (67.8%) achieved molecular complete remission. Total MCR rate was 88.5% during the entire study period and the median time from treatment to MCR was 54 days (range, 13-384 days). Among these 77 MCR patients, 32 experienced molecular recurrence which was defined as BCR-ABL transcript positive conversion from $1x10^5$. On subsequent follow-up, regardless of allogeneic HCT, 24 additional patients achieved MCR at 3 to 9 months. Of 54 patients who underwent allogeneic HCT while in first CR, with quantitative PCR being performed at a median 2.1 months (range, 0.1-4.0 months) prior to allogeneic HCT, 43 (80%) showed BCR-ABL transcript amount below $1x10^5$. After allogeneic HCT, 49 of 50 evaluated patients (98%) achieved MCR. Median time of MCR duration was 13 months (range, 0.9-60.3 months) and median molecular relapse-free survival was 28 months. Patients with loss of MCR at any time had a higher cumulative incidence of leukemia relapse and a lower relapse-free survival (RFS). Thirty two patients who lost of MCR had significantly inferior RFS (P<0.0001) and OS (P=0.001) then 41 who maintained MCR. MCR achievement within 3 months after remission induction was significant predictor of RFS (P=0.004) and OS (P=0.003). In univariate analyses, the duration of MCR was affected by using G-CSF during remission induction (P=0.0046), initial dose intensity of imatinib within 7 weeks (P=0.001), ≥90% *vs*<90%, total imatinib dose intensity during whole study period, and allogeneic HCT (P=0.002). Multivariate analyses after adjusting the Cox model was described in Table 1.
Summary/Conclusions: Prospective assessment of the extent of molecular response and imatinib dose intensity during imatinib-based treatment and post-allogenic HCT is likely to be useful in identifying subgroups of Ph+ALL patients at a high risk of relapse and we will be able to apply the risk-adapted or minimal residual disease based therapeutic approaches for Ph+ALL patients.

KPT-8602 IS A SECOND-GENERATION XPO1 INHIBITOR WITH IMPROVED IN VIVO TOLERABILITY AND POTENT IN VIVO ACTIVITY AGAINST ACUTE LYMPHOBLASTIC LEUKEMIA

J De Bie[1,*], J Neggers[2], A Dagklis[1], T Vercruysse[2], O Gielen[1], E Baloglu[3], W Senapedis[3], S Shacham[3], Y Landesman[3], A Uyttebroeck[4], N Boeckx[5], J Cools[1], D Daelemans[2]
[1]Center for human genetics, KU Leuven - VIB, [2]Rega Institute for Medical Research, KU Leuven, Leuven, Belgium, [3]Karyopharm Therapeutics, Newton MA, United States, [4]Pediatric Haematology and Oncology, [5]Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium

Background: Human exportin-1 (XPO1) is a transport protein that exports a wide variety of different cargo proteins from the nucleus to the cytoplasm. Selective Inhibitor of Nuclear Export (SINE^{TM}) compounds block the formation of the XPO1-cargo complex leading to accumulation of tumor suppressors in the nucleus and show potent anti-cancer activity. Selinexor (KPT-330) is currently in Phase-II/IIb clinical trials for treatment of both hematologic and solid tumors, while KPT-8602 is in Phase 1/2 clinical trials for treatment of relapsed refractory multiple myeloma.
Aims: We investigated the *in vitro* and *in vivo* activity of KPT-8602, a second-generation clinical stage XPO1 inhibitor with improved tolerability, against acute lymphoblastic leukemia (ALL).
Methods: We performed co-localization experiments and a phenotypic reporter assay to evaluate the anti-XPO1 activity of KPT-8602. We cultured 5 T-ALL and 3 B-ALL cell lines with different concentrations of the drug and assessed cell viability after 72h exposure. CRISPR/Cas genome editing was used to mutate XPO1 in ALL cell lines. For the *in vivo* experiments, NSG mice were injected with a T-ALL patient derived xenograft (PDX) sample, and animals were treated with KPT-8602 10mg/kg or placebo once a day by oral gavage for 3 weeks. Mice were bled weekly to measure the total white blood cell count and number of human leukemic cells.
Results: KPT-8602 strongly inhibited XPO1-cargo interaction as well as XPO1-dependent nuclear export at nanomolar concentrations and induced potent cytotoxicity on T-ALL and B-ALL cell lines *in vitro* (EC_{50} values ranging from 25 to 140 nM). To determine the drug-target specificity, we used CRISPR/Cas mediated genome editing to introduce XPO1 mutations that prevented KPT-8602 binding and resulted in loss of inhibitory activity, indicating that the inhibitory effects of KPT-8602 are completely dependent on XPO1 inhibition. Daily oral treatment with KPT-8602 could block leukemic expansion in mice engrafted with a JAK3 mutant T-ALL at an early stage of disease development. Also when KPT-8602 treatment was initiated at day 28 after injection (when more than 5% of human leukemic cells were detected in the blood), we observed a significant reduction of leukemia cell numbers, without affecting normal erythropoiesis. KPT-8602 treatment during 3 weeks led to prolonged survival of the animals, compared to placebo treated animals (p=0.0041).
Summary/Conclusions: KPT-8602 is a highly specific second-generation XPO1 inhibitor with potent anti-ALL activity both *in vitro* and *in vivo*. It displays better tolerability compared to selinexor, which allows for daily dosing and warrants further evaluation of this new drug in patients.

E858

DETAILED CHARACTERIZATION OF LAIP PROFILE AND HETEROGENEITY AT TIME OF DIAGNOSIS PREDICTS MINIMAL RESIDUAL DISEASE IN B-CELL PRECURSOR ALL

S Modvig[1,*], NF Øbro[1], S Rosthøj[2], GW Jürgensen[1], K Schmiegelow[3,4], HV Marquart[1]
[1]Department of Clinical Immunology, Copenhagen University Hospital Rigshospitalet, [2]Section of Biostatistics, University of Copenhagen, [3]Department of Pediatric and Adolescent Medicine, Copenhagen University Hospital Rigshospitalet, [4]Institute of Clinical Medicine, Faculty of Health and Medical Scences, University of Copenhagen, Copenhagen, Denmark

Background: Early and accurate risk stratification in B-cell precursor acute

lymphoblastic leukemia (BCP-ALL) is essential for individualized treatment strategies in order to improve prognosis and lower treatment associated toxicity. Leukemia-associated immunophenotype (LAIP) heterogeneity is common at time of diagnosis (Øbro et al, Leukemia, 2011) yet current immunophenotyping methods do not include heterogeneity. Furthermore, studies of the LAIP prognostic value have not shown consistent results.

Aims: To characterize in detail the LAIP and the frequency of immunophenotypically distinct subpopulations by flow cytometry at time of diagnosis and to evaluate their prognostic value for end-of-induction minimal residual disease (MRD) in BCP-ALL.

Methods: Flow cytometry data from time of diagnosis was re-evaluated retrospectively in 125 patients with BCP-ALL consecutively diagnosed between October 2011 and June 2015 and treated according to the NOPHO ALL 2008 protocol. The expression of intracellular and surface B-lineage markers (CD45, CD19, CD34, CD38, CD10, CD20, CD22, nTDT, cyCD79a, and cyCD22) and cross-lineage expressed markers (CD123, CD66c, CD133, CD13, CD33, and CD15) was scored as negative, positive dim, positive (normal) or positive bright, and broad or bimodal expression was registered. Corresponding normal populations in unaffected bone marrow samples were used as reference (methodological details will be presented). Groups were compared by the Mann-Whitney U test. The prognostic potential of LAIP expression was assessed in a multiple regression model with end-of-induction flow-MRD as outcome adjusting for age, WBC at diagnosis, cytogenetic group (high risk comprised hypodiploid, MLL, and iAMP21, non-high risk comprised t(12;21), hyperdiploid, t(1;19), dic(9;20), and no cytogenetic aberration) and NOPHO diagnostic treatment regime (high/standard risk).

Results: Distinct immunophenotypic subpopulations defined by bimodal expression of one or more markers were observed in 66 patients (53%), with nine patients (7%) having three or more subpopulations. The most frequently bimodal marker was CD34, displaying bimodality in 37 patients (30%). In patients with a homogeneous expression of CD34 we found higher end-of-induction flow-MRD in patients with CD34 positive blasts compared with CD34 negative (p=0.0008, figure 1). Accordingly, in patients with bimodal expression of CD34 we assessed the expression level of the dominant blast subpopulation and found that patients with a CD34 positive dominant blast subpopulation displayed higher end-of-induction MRD (p=0.0095, figure 1). When including all patients (CD34 homogeneous negative/dim/normal/bright and heterogeneous predominantly negative/positive) in an adjusted multiple regression model, we confirmed the prognostic value of CD34 score on MRD (p=0.0003). Since risk stratification of patients without identified cytogenetic aberrations is more difficult, we analyzed this subgroup separately, and found that CD34 expression is an independent predictor of high MRD (p=0.0074, multiple regression, n=37) in this group as well.

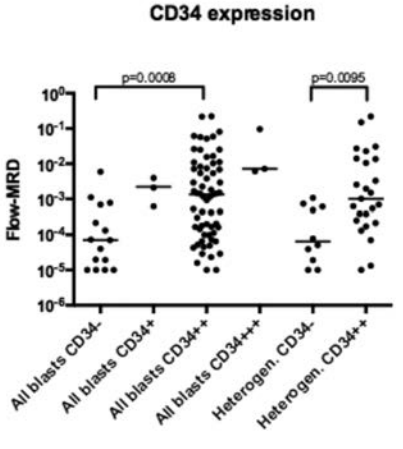

Figure 1. Flow-MRD in patients according to CD34 expression. Lines represent median values. -: negative, +: positive dim, ++: positive (normal), +++: positive bright.

Summary/Conclusions: Detailed characterization of the CD34 expression level of blasts and immunophenotypically distinct subpopulations seems to bring valuable information on BCP-ALL prognosis regardless of age, WBC and cytogenetic findings. Detailed and standardized LAIP characterization is a readily accessible prognostic tool and could potentially be taken into consideration in future risk evaluations of BCP-ALL patients.

E859

PHASE I STUDY OF MOXETUMOMAB PASUDOTOX IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

F Ravandi[1,*], J Cortes[1], D Thomas[1], M Rytting[1], N Daver[1], M Konopleva[1], P Kebriaei[1], W Wierda[1], C DiNardo[1], C Bivins[1], D McCue[2], S Pierce[1], A Richie[1], H Kantarjian[1]

[1]Leukemia, [2]Pharmacy, University of Texas - MD Anderson Cancer Center, Houston, United States

Background: Moxetumomab pasudotox (MP), previously known as HA22 or CAT-8015, is a recombinant immunotoxin composed of the Fv fragment of a humanized IgG4 anti-CD22 monoclonal antibody fused to a 38-kDa truncated fragment of Pseudomonas exotoxin A. CD22 is expressed on the surface of blasts in over 90% of patients with precursor B-acute lymphoblastic leukemia (ALL) as well as in other lymphoid neoplasms and is an attractive target for monoclonal antibody-based therapy. MP and its predecessor compound, BL22 have been investigated for the treatment of patients with relapsed hairy cell leukemia (HCL) as well pediatric patients with relapsed B-ALL and have demonstrated promising activity.

Aims: This single center, phase I study was conducted to determine the maximum tolerated dose and potential efficacy of MP in adult patients with relapsed and/or refractory B-ALL.

Methods: Patients were eligible if they were 18 years or older, with previously treated B-ALL (either relapsed after having achieved prior response or refractory to prior therapy) and had adequate performance status and organ function with bilirubin ≤1.5mg/dL, liver enzymes ≤2 x upper limit of normal (ULN) and creatinine ≤2mg/dL. Patients with cardiac ejection fraction less than 40%, active hepatitis or HIV infection, history of microangiopathic hemolysis, symptomatic CNS involvement, recent prior therapy (including systemic chemotherapy in the past 14 days, monoclonal antibodies in the past month, or allogeneic stem cell transplant in the past 100 days) were excluded. Dose escalation in the phase I portion of the study was based on a standard 3+3 design starting at a dose of MP 30μg/kg every other day (qod) for 6 doses with subsequent dose levels at 40 and 50μg/kg qod for 6 doses and 50μg/kg qod for 10 doses. All patients received appropriate premedication with hydroxyzine, ranitidine, corticosteroids and acetaminophen and were monitored for toxicity including previously identified risks of capillary leak syndrome and hemolytic uremic syndrome (HUS). All other supportive managements was based on standard institutional practice.

Results: Between December 2013 and September 2015, 16 patients with relapsed or refractory B-ALL were treated on this trial. Median age of the patients was 30 years (range, 18-67 years). Median number of prior therapies was 3 (range, 1-6). 4 patients had a prior allogeneic stem cell transplant and 3 had prior therapy with inotuzumab ozogamycin. 10 patients were refractory to their last prior therapy and 6 had relapsed from prior therapy (duration of prior CR less than 6 months in 2 and greater than 6 months in 4). Performance status was 0 in 2, 1 in 10 and 2 in 4 patients. Four patients had normal karyotype and 10 complex cytogenetic abnormalities which included t(4;11) in 1 patient. Another patient had t(1;19) and one patient had miscellaneous abnormality. CD22 expression was detected in all patients including 50-69% expression in 4, 70-89% expression in 4, and ≥90% expression in 8. The median number of courses of MP administered was 1 (range, 1-4) with 6 patients treated at 30 μg/kg, 4 patients at 40 μg/kg, and 6 patients at 50 μg/kg x 6 doses. The final dose regimen of 100 μg/kg x 10 doses was not studied due to early termination of the study. Only one DLT (grade 3 HUS) occurred at 50 μg/kg x 6 dose level; however, the study was terminated because the 10-dose schedule was not tolerated in a parallel pediatric trial. One patient with 5 prior regimens achieved a complete response (CR) which lasted 2.5 months. No other responses by standard criteria were reported. Non-hematological toxicity of grade 3/4 included reversible capillary leak syndrome (CLS) in 1 patient, weight gain in 2, ascites in 1, tumor lysis syndrome (TLS) in 1, elevation of liver enzymes in 3, and HUS in 1 patient. Grade 2 adverse events including CLS, edema and elevation of liver enzymes were noted in another 5 patients. No deaths directly attributable to therapy were reported.

Summary/Conclusions: MP at the doses studied in this trial is feasible and can produce response in patients with multiply relapsed B-ALL. The recommended dose for phase II trials is 50μg/kg qod x 6 doses.

E860

INTENSIVE VS. SEMI-INTENSIVE CHEMOTHERAPY IN OLDER ADULTS (55-65 YR) WITH PHILADELPHIA CHROMOSOME-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA

Background: Treatment of older adults (55-65 yr.) with ALL is difficult to standardize. The election between intensive *vs* semi-intensive therapy is frequently based on physician and/or patient preferences. Specific analyses of outcomes according to the intensity of the therapy in this age group are scarce.
Aims: To analyze and compare the baseline characteristics, the results of treatment and the outcomes of older adults (55-65yr.) with Ph-negative ALL included in intensive high-risk (HR) protocols (ALL03 and ALL11, J Clin Oncol 2014; 32:1595-604, Blood 2015; 126: 1333) *vs* semi-intensive protocols (ALLOLD07, Leuk Res 2016; 41: 12-20) from the Spanish PETHEMA Group.
Methods: The main clinical and hematologic data, as well as the response to therapy and outcome of older adults (55-65 yr.) with Ph-negative ALL treated intensively or semi-intensively according to the PETHEMA protocols were analyzed and compared. Intensive protocols (ALL03 and ALL11) included intensive induction and consolidation therapy followed by allogeneic HSCT according to MRD clearance. Semi-intensive protocol (ALLOLD07) includes non-intensive induction chemotherapy with non-genotoxic drugs, followed by semi-intensive consolidation and standard maintenance therapy (EWALL backbone); allogeneic HSCT with RIC regimen was allowed in fit patients in CR1 according to physician's criteria.
Results: From 2003 to 2015, 46 patients were treated intensively *vs* 32 treated semi-intensively. Except for age (intensive: 58[55-65] yr. *vs* semi-intenive: 61 [56-65], p=0.01), the main clinical and hematological characteristics at baseline were comparable in the two groups. Death in induction and relapse rate were higher in the semi-intensive group, with a trend for a lower CR duration in this group. However, the OS probability was not significantly different in the two groups (Table 1). The rate of HSCT realization in CR1 was low in both groups (8% *vs* 5%).

Table 1.

	LAL AR03/11 (n=46)	LAL OLD07 (n=32)	P value
Death in induction	0	4/31* (13%)	0.023
Failure	6/46 (13%)	7/31* (23%)	0.210
CR	40/46 (87%)	20/31* (64%)	
Treatment-related mortality in CR	9/40 (23%)	2/20 (10%)	0.307
Relapse	17/40 (43%)	15/20 (75%)	0.017
Median CR duration, (95% CI)	24.6 (19.6; 29.7)	9.6 (4.6; 14.6)	0.085
Median overall survival (months), (95% CI)	13.2 (0; 26.5)	9.3 (5.5; 13.2)	0.279

Summary/Conclusions: This study confirms the poor prognosis of older adults (55-65 yr.) with Ph-negative ALL, regardless of the intensity of the therapy. The low rate of HSCT in CR1 in this age group and a high rate of death in consolidation in patients treated intensively are of note. The trend for a significantly better CR duration in patients treated intensively did not translate into improved OS. Better therapies are needed in this age group of Ph-negative ALL patients.
Supported in part with the grants PI10/01417 from Fondo de Investigaciones Sanitarias and RD12/0036/0029 from RTICC, Instituto Carlos III and 2014SGR225(GRE), Generalitat de Catalunya, Spain, and a grant from "La Caixa" Foundation.

FLOW CYTOMETRY OF CEREBROSPINAL FLUID IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AT DIAGNOSIS AND RELAPSE

M Gabelli*, B Buldini, S Disarò, A Zangrando, S Francescato, P Scarparo, B Michielotto, E Bortoloso, MC Putti, G Basso
Clinica di Oncoematologia Pediatrica, Università degli Studi di Padova, Padova, Italy

Background: Acute lymphoblastic leukemia (ALL) may involve central nervous system (CNS) in 3-6% of pediatric patients. Cytology (CC) of cerebrospinal fluid (CSF) is currently used to define CNS infiltration, although sensitivity and specificity are low. Flow cytometry (FC) can identify blasts in CSF samples that are negative for cytology with higher sensitivity and specificity. The frequency and the significance of this occult cerebrospinal involvement in children with ALL is still not clear.
Aims: We explored the feasibility of CSF flow cytometric analysis at each lumbar puncture during therapy in primary and relapsed ALL. Moreover, we studied prospectively its clinical significance in comparison with cytology and cell count.
Methods: We included children (aged 1-18 years) with Philadelphia negative ALL and with ALL isolated marrow relapse diagnosed from 12.09.2013 to 31.01.2016 at our Institution, after informed consent acquisition. Treatment schedule and definition of CSF involvement were as per AIEOP-BFM ALL2009 Protocol. At each point of intrathecal therapy, CSF was collected and analyzed within 24 hours by an automated cell counter, by cytology and 8-color flow cytometry (B or T lineage panel). A tiny cluster of events with immunophenotype compatible with blasts at diagnosis was considered positive by FC (FC+).
Results: 784 samples from 76 patients with *de novo* ALL and 92 samples from 13 children with marrow relapse were considered. Median follow up was 14 months (1-28,5 months). At diagnosis 4 T-ALL patients (5%) presented CNS involvement (CNS3): 3 with positive cytology (CC+) and positive FC, 1 with cranial nerve palsy (CC-/FC-). Other 3 patients (pB-ALL) had positive cytology but<5 cell/µl (CNS2): 2 were FC+, 1 FC- (normal T and B cells). 25/76 children (33%) with no CNS leukemia (CNS1) resulted FC+: 3 T-ALL, 22 pB-ALL. 9/25 (36%) CNS1/FC+ patients were high risk (MRD based stratification). FC persisted positive at day 15 in 2 CNS3/FC+ patients, in 1 CNS2/FC+ and in 2 patients that were positive only by FC at diagnosis. Among patients who were FC+ at diagnosis, we found other isolated FC+ samples at subsequent time points: 2 during induction, 4 during consolidation. Moreover, during reinduction a child CNS3/FC+ at diagnosis presented other 3 samples FC+/CC-. Even children who had negative CSF by flow cytometry at diagnosis presented isolated FC+ samples at later time points: 1 during induction, 6 during consolidation. One child (CNS1/FC- at diagnosis) died for infection, one patient (CNS1/FC+ at diagnosis) presented early marrow relapse, the remaining 74 are alive in complete remission (4/74 after hematopoietic stem cell transplantation). Among 13 patients with isolated marrow ALL relapse, 7 (54%) had FC+ CSF at presentation. 4/7 had a second relapse (2 CNS relapse, 2 BM relapse), 3 died. Among 6 FC- patients, 1 had a second marrow relapse, 1 died of transplant related mortality, 1 showed disease progression and 3 are alive and in complete remission.
Summary/Conclusions: Flow Cytometry of CSF is a simple, rapid and cheap method that is able to identify blasts with high sensibility and specificity, allowing the detection of occult CNS infiltration. Our preliminary data suggest that FC CSF positivity may be a risk factor for BM and CNS relapse in children. A longer follow up and a larger group of patients are needed to confirm these findings in ALL at diagnosis and relapse.

E862

USE OF VOXEL-BASED MORPHOMETRY TO DETECT CEREBRAL VOLUMES ABNORMALITIES IN LONG TERM SURVIVORS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

G Aloj[1,*], G Pastorino[2], F Mazio[3], N Di Paolo[3], MP Riccio[4], A D'Amico[3], C Bravaccio[2], R Cuccurullo[1], R Parasole[1], V Poggi[1]
[1]Pediatric Hemato-Oncology Department, Santobono-Pausilipon Children's Hospital, [2]Child Neuropsychiatry Unit, Traslational Medical Science Department, [3]Neuroradiology Unit, Advanced Biomedical Science Department, "Federico II" University, [4]Child Neuropsychiatry Unit, Mental and Fisical Health and Preventive medicine Department, Second University of Naples, Naples, Italy

Background: Improvements in therapeutic strategies of pediatric Acute Lymphoblastic Leukemia(ALL) over the last decades have highly increased survival rates; consequently, there is a growing population of ALL Long Term Survivors(ALL-LTS). Treatment protocols include Central Nervous System directed Chemotherapy(CT) associated, in selected patients, to Cranial Irradiation(CI). These treatments appear able to determine neurocognitive late effects in ALL-LTS. The anatomical and molecular basis of these alterations are still largely unknown, and neuroimaging studies, such as automated whole brain segmentation of MRI images through Voxel-Based Morphometry(VBM), may be helpful in their understanding. Aim of this study was to better define neuroanatomic regions involved in neurocognitive impairment of a population of ALL-LTS, and to evaluate possible relationships of these abnormalities with type of therapy.
Aims: The primary objective was to detect the neuroanatomical alterations in ALL-LTS who received either CT alone or in combination with CI during childhood. Secondary objective was to assess the neurocognitive performance in the same two groups of LTS.
Methods: In this cross-sectional, controlled study, twentysix ALL-LTS were recruited from the ALL-LTS cohort of patients followed up in the Hemato-Oncology Department of Santobono-Pausilipon Children's Hospital of Naples. Thirteen subjects received CT and CI (group A) while thirteen received CT alone (group B). All signed written informed consent. The two groups were matched for age, sex, ethnicity, education, number of right-handed and left-handed sub-

jects, use of glasses, age at ALL diagnosis, years since therapy-discontinuation and type of therapeutic protocol used. People who underwent HSCT and relapsed subjects were excluded. Imaging were collected using a 3T Siemens Scanner. VBM analyses were conducted on MPRAGE T1 3D images in Statistical Parametric Mapping 8. Analyses of brain volumes were performed as global Gray Matter(GM), White Matter(WM) and Cerebro Spinal Fluid(CSF) volumes and as regional voxel-by-voxel analyses. Neurocognitive performance was assessed through the Wechsler Adult Intelligence Scale-Revised(WAIS-R) for over 16 years and through the Wechsler Intelligence Scale for Children 4th Edition(WISC-4th) for age 9-16 years. d2-R test and Wisconsin Card Sorting Test(WCST) were used to assess respectively attention and concentration abilities and executive function. A two sample t-test was employed for all the between group comparisons.

Results: Absolute volumes of GM, WM and CSF segments of group A *vs* group B did not differ significantly. Group A showed significantly smaller volumes than group B in superior frontal gyrus, posterior medial frontal gyrus, paracentral lobule, inferior parietal lobule, precuneus, temporal medial gyrus, parahippocampal gyrus, medial and posterior cingulate cortex. Significant differences between groups were found for intelligence, performance, attention and memory measures of WAIS-R. No significant differences were observed for WISC-4th, d2-R and WCST, but in both groups, working memory, processing speed, concentration and attention were worse than population norm.

Summary/Conclusions: In our study some neuroanatomic structures showed smaller volumes in ALL-LTS treated with CT in combination with CI than in those treated with CT alone. These findings could be related to specific neurocognitive alterations observed in these subjects, and represent an initial attempt in elucidating their anatomical basis. Further studies on more extensive pediatric series are needed to confirm our observations.

E863

HYPER-CVAD COMPARED TO BFM-LIKE CHEMOTHERAPY FOR THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA. A RETROSPECTIVE SINGLE CENTER ANALYSIS

I El Dika[1], R massoud[2], M charafeddine[1], R mahfouz[3], M kharfan-dabaja[4], A bazarbachi[2], J Elcheikh[2,*]
[1]AUBMC, beirut, Lebanon, [2]transplantation, [3]pathology, AUBMC, beirut, Lebanon, [4]moffitt, tampa, United States

Background: Multiple induction regimens have been developed for adult patients with acute lymphoblastic leukemia (ALL). However, there have been no prospective randomized trials that directly compare these regimens.

Aims: In this report, we retrospectively evaluated the outcome of 62 adult ALL patients treated with hyper-CVAD (n=38) and the (*i.e.* Berlin-Frankfurt-Munster, n=24) BFM-like protocols at the American university of Beirut medical center, Lebanon; between November 2000 and december 2015. Feasibility of allogeneic stem cell transplantation (allo-SCT) for those patients, in terms of efficacy and tolerability was also evaluated.

Methods: The median age was 38 years in the hyper-CVAD group and 20 years in the BFM-like group with a male/female ratio of 50/50 and 54/46, respectively. The majority of cases were B cell in origin (89% in the hyper-CVAD group and 79% in the BFM-like group). Thirteen patients (34%) *vs* only 2 patients (8%) were positive for Philadelphia chromosome (Ph+) in both groups respectively, (p= 0.0744). Eight patients received imatinib (7 *vs* 1) and five patients received dasatinib (4 vs1) in the first and second group respectively. Other 2 patients received imatinib than dasatinib in the hyper-CVAD group only.The disease risk score was high in 76% of patients in the hyper-CVAD group *vs* 33% of patients the BFM-like group (p=0.119).

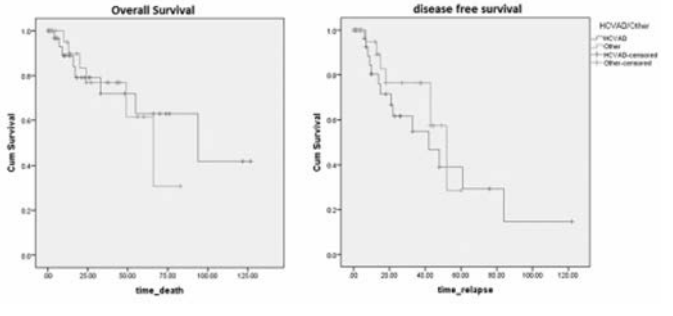

Figure 1.

Results: The median follow-up time was 29 months. Fifteen patients (39%) and ten patients (42%) underwent allo-SCT in the hyper-CVAD and BFM-like group respectively. At the last follow up 28 patients (74%) were in complete remission (CR) in the first group *vs* 18 patients (75%) in the second group. Of those, 20 patients (53%) *vs* 11 patients (46%) were MRD-negative at the last follow up respectively. The 5-year survival rate was similar in hyper-CVAD group compared to the BFM-like group (63 *vs* 62%, p= 0.808) (Figure 1). The 5 years disease free survival (DFS) rate was 29% compared to 28% in the BFM-like group, (p= 0.435) (Figure 2). Both chemotherapies were well tolerated. None of the patients died from drug related toxicity.

Summary/Conclusions: Despite the older age and more patients with high risk category and Ph+ in the hyper-CVAD group, this difference was not translated into a difference in outcome between the 2 groups. The hyper-CVAD regimen seems to be feasible for adult patients with ALL in terms of tolerability and efficacy. There is still a need for large, prospective, randomized studies in order to establish the best chemotherapy protocols for adult ALL patients.

E864

BFM REGIMEN OFFERS SIMILAR EVENT FREE SURVIVAL COMPARED TO HYPERCVAD BUT WITH LESS TOXICITY IN ADOLESCENTS AND YOUNG PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A Vega*, E Pacheco, C Fuentes, L Aguilar, C borjas, B rubio, O garces
Hematology, IMSS, Guadalajara, Mexico

Background: The experience to adapt pediatric protocols to adolescents and young adults (AYA) with acute lymphoblastic leukemia (ALL) is improving. Although there is still concern that toxicity may occur.

Aims: We present two groups of AYA treated with an adult protocol (hypercvad) and BFM developed for children. The study aimed to compare event free survival (EFS) and toxicity in both regimens.

Methods: Patients aged ≥16 and ≤40 between 2008-2015. BFM consisted of 8 blocks. Induction with vcr, pdn, asp, daunorubicine (dau) and intrathecal therapy (IT). Consolidation with ciclophosphamide (cfm), mercaptopurine (mp), cytarabine (cyt), vcr, asp and IT. CNS prophylaxis with methotrexate (mtx), followed by interim maintenance (im) combining vcr, mtx and asp. The other 4 blocks composed by delayed intensification (di) x 2 with vcr, dau, pdn, asp, cfm, mp, cyt, vcr and one im and di (as in induction). Hypercvad was prescribed with the addition of IT to each one of the 8 arms. Maintenance consisted of POMP for 2 years, and in some, combined with etoposide or anthracycline plus IT for 6 months. Rituximab (mab) was allowed at discretion if CD 20+. Ph+ cases received imatinib. Radiotherapy was permitted for mediastinal tumor. Patients changed the initial regimen if non hematological toxicity occurred during induction or by preference and registered in the regimen they continued. Variables analyzed: age (±30), WBC (≥30000 B and ≥100000 T), cytogenetic (t9;22 [ph+] and complex karyotypes), lineage, CD20, and aberrant markers. Relapse and death in CR due to toxicity were censored for the EFS analysis. Toxicity counted as one event in each block/arm (only ≥3 grade) or if admission or transfusion needed. Death during induction was excluded from the toxicity analysis.

Table 1. Toxicities. *Two similar blocks were added together.

	Hypercvad		BFM			
	Odd	Even	Intensification	Consolidation	CNS prophylaxis	Maintenance
Arms/Blocks (%)	53	67	25*	36*	22*	2*
Anemia	14 (26)	41 (61)	5 (20)	15(41)	2(9)	4(15)
Thrombocytopeni	15 (28)	55 (82)	3(12)	8(22)	2(9)	2(7)
Neutropenia	23 (43)	51 (76)	3(12)	12(33)	4(18)	4(15)
Blood support	14 (26)	52 (78)	4(16)	12(33)	3(14)	4(15)
Other toxicities	2 (4)	2 (3)	2(8)	2(6)	2(10)	3(11)
Admission	19 (36)	57 (85)	2(8)	10(28)	3(14)	3(11)
Death	2 (4)	5 (7)	0	0	1(5)	2(7)

Results: Fifty eight cases were treated. Median was 24 years (16-40). WBC was 15400 (0.6-632000). Twelve patients had karyotype and five were high risk (four ph+). Sixteen cases (33%) classified as high risk. Three cases had CNS disease. Fifty one (88%) cases were B and 48% CD 20+ (ten received mab). Seventeen had aberrant markers. Mediastinal tumor was observed in four T cell cases. The EFS of the whole group at 3 years was 30%. Forty five (78%) patients received induction with BFM with 8 deaths (17.7%), and thirteen (22%) with hypercvad with 2 deaths (15.3%). Median follow up was 12 months (1-72) with twenty one individuals in CR. Fourteen (29%) patients changed treatment, thirteen in the BFM group, 4 for pancreatitis and 9 by preference and one due to toxicity in the hypercvad group. Thirty three patients were included in BFM and twenty five in hypercvad. The EFS at three years was 32% for BFM and 28% for hypercvad p=.6. There were seventeen relapses (BFM 8 hypercvad 9) and ten deaths in CR due to toxicity (BFM 3 hypercvad 7). Toxic deaths in BFM were infectious in one and CNS toxicity in two. All toxic deaths in hypercvad were infectious Table 1. None of the variables had statistical difference. More toxic deaths occurred during the even courses and nearly 80% required admission for neutropenia and blood support (compared to a close 30% of the odd courses) in the hypercvad protocol. For the BFM, most admissions happened during consolidation (28%). The other blocks had less toxicity, although neurotoxicity occurred during maintenance. Mucositis presented barely in both groups. Coagulopathy and hepatitis rarely appeared with asp.

Summary/Conclusions: Both regimens had similar EFS but hypercvad had more deaths in CR due to myelotoxicity and more blood support and admission to the hospital. Severe non-myelotoxic events were uncommon.

E865

PATTERN OF CNS RELAPSE IN ACUTE LYMPHOBLASTIC LEUKEMIA BCR-ABL POSITIVE, THE IMPORTANCE OF CHARACTERIZATION OF ABL1 MUTATIONS IN CEREBROSPINAL FLUID

R Sanchez[1], R Ayala[2], RA Alonso[3], J Ribera[4], O García[4], S Mercadal[5], P Montesinos[6], R Martino[7], P Barba[8], J González-Campos[9], M Barrios[10], E Lavilla[11], C Gil[12], T Bernal[13], L Escoda[14], E Abella[15], ML Amigo[16], MJ Moreno[17], P Bravo[18], R Guàrdia[19], JM Hernández-Rivas[20], A García-Guiñón[21], S Piernas[22], JM Ribera[4], J Martínez-López[2,*]

Institut de Recerca contra la Leucèmia Josep Carreras, [5]ICO- Hospital Duran i Reynals (Bellvitge), Barcelona, [6]Hospital La Fe, Valencia, [7]Hospital Sant Pau, [8]Hospital Vall d'Hebron, Barcelona, [9]Hospital Virgen del Rocío, Sevilla, [10]Hospital Carlos Haya, Málaga, [11]Hospital Lucus Augusti, Lugo, [12]Hospital General Universitario de Alicante, Alicante, [13]Hospital Central de Asturias, Oviedo, [14]Hospital Joan XXIII, Tarragona, [15]Hospital del Mar, Barcelona, [16]Hospital Meseguer, Murcia, [17]Hospital Virgen de la Victoria, Málaga, [18]Hospital Fuenlabrada, Fuenlabrada (Madrid), [19]ICO-Hospital Josep Trueta, Girona, [20]Hospital Universitario de Salamanca, Salamanca, [21]Hospital Arnau de Vilanova, Lleida, [22]Hospital Parc Taulí, Sabadell (Barcelona), Spain

Background: He incidence of central nervous system (CNS) relapse among patients with BCR/ABL-positive acute lymphoblastic leukemia (ALL) is 8-17%. Although tyrosine-kinase inhibitors (TKI), especially imatinib, are included in the first-line treatment in these patients, their concentration in CNS is too low to effectively prevent CNS relapse, making CNS prophylaxis mandatory.
Aims: To study the frequency, predictors and evolution of BCR-ABL positive ALL patients with CNS relapse in two consecutive clinical trials of the PETHEMA group using imatinib and chemotherapy. As secondary objective we proposed the introduction of a new method for the study of variants of uncertain significance (VUS) in kinase domain of the BCR-ABL from cDNA of cerebrospinal fluid (CSF) blasts, in order to adapt the TKI used in relapse according to the clonal evolution from bone marrow (BM) to CSF cells.
Methods: It has been reviewed data of CNS relapse of patients included in two consecutive clinical PETHEMA trials **(**PETHEMA-LAL-PH-2008 and PETHEMA-LAL-OPH-2007), for treatment of BCR-ABL- *Ph+* ALL patients. In two patients with combined BM and CSF we analyzed the BCR-ABL mutations at diagnosis and at relapse in both sites. Kinase domain of cDNA was amplified in two steps by nested PCR in the samples of BM at diagnosis and BM or CSF at relapse, covering the whole kinase domain from residues Gly227 to Gly514. Further enzymatic fragmentation of the domain yielded ~200 bp of small fragments. Ion Torrent ultra deep-sequencing of the resulting fragments allowed us to evaluate the variants of the chimeric protein.
Results: A total of 138 ALL BCR/ABL positive patients were analyzed and 128 reached complete remission, 30 of them have relapsed (13 [43%] involving CNS [isolated or combined], 16 [53%] BM and 1 in unknown site). The overall survival probability at 2 years was 69% for the "CNS Relapse" group (IC95%: 44-94%; p=0.067) and 44% for the "Not CNS Relapse" group (IC95%: 20-68%; p=0.067, Figure 1a). In a multivariable analysis any clinical variable was associated with CNS relapse probability. In two of the CNS and BM relapsed patients we have performed massive sequencing experiments of ABL1 Kinase domain mutational status. In the first patient ultra-deep NGS of BM samples at diagnosis and at relapse did not show VUS or pathogenic variants, but the CSF study at relapse confirmed the variant c.1159 T>A, p.L387M. The same study in the second patient also found the same pathogenic variant only in CSF blast cells (Figure 1b), whereas, the VUS c.733 A>G, p.K245E was found only in the BM sample at diagnosis.

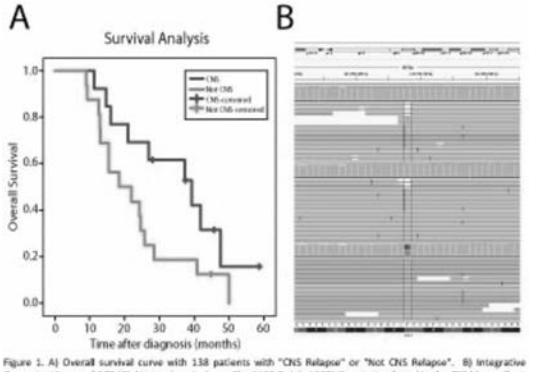

Figure 1. A) Overall survival curve with 138 patients with "CNS Relapse" or "Not CNS Relapse". B) Integrative Genomics Viewer of BCRABL kinase domain (exon 7) c.1159 T>A (p.L387M) mutation found in the CSF blast cells at relapse (bottom). Non-mutated alleles can be seen in bone marrow sample at diagnosis (top), and bone marrow at relapse (middle).

Figure 1.

Summary/Conclusions: In BCR-ABL ALL patients treated with imatinib and chemotherapy CNS relapse was a significant feature, despite CNS prophylaxis, In our series we did not find any clinical variable predicting CNS relapse. We have found the pathogenic variant p.L387M in CSF blasts of two patients with combined CNS and BM recurrence, this variant not being found in BM samples at diagnosis or at relapse. These mutations were sensitive to other TKIs with better penetration to CSF. Based on these results, a mutational study of the kinase domain of the BCR-ABL in blast cells obtained from CSF, should also be integrated in the mutation study of these patients in order to select the TKI according to the clonal evolution from BM to CSF cells.

E866

PROGNOSTIC IMPACT OF COPY NUMBER ALTERATIONS IN A SERIES OF PEDIATRIC PATIENTS WITH DE NOVO B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA IN A SINGLE CENTER

M Trabazo Del Castillo[1,*], S Rives[2,3], N Vega-Garcia[1], R Malatesta[1], C Estella[1], A Català[2,3], M Torrebadell[1,3], R Berrueco[2,3], A Ruiz-LLobet[2], L Calvente[1], A Alonso-Saladrigues[1], M Mesegué[1], M Solsona[1], M Camós[1,3]
[1]Hematology Laboratory, [2]Pediatric Hematology. Department of Hematology and Oncology, Hospital Sant Joan de Déu, University of Barcelona, Esplugues de Llobregat, [3]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Madrid, Spain

Background: Gene copy number alterations (CNAs) have been recently proposed as variables for risk stratification in acute lymphoblastic leukemia (ALL). However, their use in clinical practice is controversial, as their prognostic impact could depend on the applied therapeutical protocol and the interaction with other clinical and biological variables.
Aims: To analyze the prognostic impact of CNAs in a series of pediatric patients with B-cell precursor ALL (pre-B ALL) treated in a single center.
Methods: Pediatric patients (0-18 years) with pre-B ALL, diagnosed between 1999 and 2015 and homogeneously treated according to consecutive protocols of the Spanish Hematology and Oncology Pediatric Society (SEHOP) Cooperative Group (SHOP-99, SHOP-2005, SEHOP-PETHEMA 2013). CNAs were studied by MLPA technique with SALSA-P335 kit (MRC-Holland) and Coffalyser software.
Results: We included 55 patients with a median age of 4.7 years (range 1.1-14.9), 56% males. Only one patient had central nervous system infiltration. Median WBC count was $8.4x10^9$/L (range 1.1-296.9). All cytogenetic subtypes were represented. We observed the presence of CNAs in 29 patients (53%), including 17 (31%) cases with one CNA, 8 (15%) patients with 2 CNAs and 4 (7.5%) patients with ≥3 CNAs. The most frequent CNAs were deletions of *CDKN2A/B*, observed in 12 patients (22%), followed by *ETV6* deletions in 11 cases (20%) and *IKZF1* deletions in 9 cases (16%); also, we observed deletions of *PAX5* in 7 cases (13%), of *BTG1* in 4 patients (7%), of *RB1* in 2 cases (4%), *JAK2* deletions in one case and *CRLF2* alterations (PAR region) in one case. *IKZF1* deletions were more frequently observed in *BCR-ABL1* rearranged cases and in patients with B-other subtype (cases with absence of main cytogenetic categories), and *ETV6* deletions predominated in cases with *ETV6-RUNX1* rearrangement. Among those patients with more than one CNA, *IKZF1* was the gene most frequently involved (IKZF1*plus*, 7 cases). The presence of CNAs was significantly correlated to older age (p=0.006), hyperleukocytosis >$20x10^9$/L (p=0.018) and high levels of minimal residual disease (MRD>10%) at day 15 of induction, assessed by flow cytometry (p=0.012). A higher number of CNAs (≥2) was found in boys (p=0.026). Noticeably, the patient with CNS infiltration harbored 3 CNAs. *IKZF1* deletions were associated with high hyperleukocytosis (>$100x10^9$/L, p=0.001), older age (p=0.001), high NCI risk (p=0.008) and high MRD levels at day 15 (p<0.0001). We found the same associations for IKZF1*plus*. *CDKN2A/B* deletions showed a trend to high WBC count (>$100x10^9$/L, p=0.051) and presence of MRD at the end of induction (MRD>0.01%, p=0.082). We found no significant associations for *ETV6* or *PAX5* deletions. After a median follow up 2.6 years (0.3-11.9) all patients are alive and 3 patients relapsed, with an event free survival (EFS) at 5 years of 87±7%. The presence of ≥2 CNAs correlated to worse EFS (64±16% *vs* 100%, p=0.043).
Summary/Conclusions: in our series, the presence of CNAs, mainly *IKZF1* deletions, were associated with poor prognostic factors like older age, high WBC count and high levels of MRD at early timepoints. We are currently expanding our series to confirm our results. COMBINED BLINATUMOMAB + DASATINIB/IBRUTINIB THERAPY OF RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS-ANTILEUKEMIC EFFECT ON THE T-HELPER AND T-REGULATORY CELLS REDUCTION BACKGROUND

A Sokolov*, E Parovichnikova, V Troitskaya, I Galtseva, M Firsova, J Davidova, N Kapranov, V Savchenko
National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab, bispecific anti-CD3/CD19 monoclonal antibody,

is effective as monotherapy in the treatment of relapsed/refractory acute lymphoblastic leukemia (R/R-ALL), but long term results could be improved. T-regulatory (T-reg) and T-helper cells can inhibit effector T-cells used by blinatumomab. Tyrosine-kinase inhibitors (TKI) could be used in the treatment of both Ph-positive (Ph+) and Ph-negative (Ph-) ALL as pre-B-cell receptor signaling inhibitors.
Aims: To study T-cell subpopulations kinetics in R/R-ALL patients during combined blinatumomab+TKI treatment of relapsed ALL patients.
Methods: Two relapsed ALL patients (1 bone marrow Ph+ relapseand 1 extramedullary extraperitoneal with severe abdominal pain Ph- relapse)were treated with blinatumomab 28 mcg/day by continuous infusion 4 weeks cycles with 2 weeks intervals (3 cycles in Ph+ relapse and 2 cycles in Ph- patients). Dasatinib 140 mg/day started In Ph+ patient from the 3rd week of the first blinatumomab cycle and further continuously. Ibrutinib 560 mg/day started in Ph- patient from the 4th week of the first blinatumomab. T-cell subpopulations of the peripheral blood (T-helper, cytotoxic, T-reg, NK) were studied by flow cytometry every week during the whole treatment period. Blinatumomab was provided by Amgen sponsored Expanded Access Program.
Results: The Ph+ ALL patient treated by blinatumomab+dasatinib combination had pleural effusions and nonspecific lung infiltration fully regressed after 2 weeks dasatinib interruption. In that patient the second molecular remission was obtained after the second blinatumomab cycle+dasatinib treatment. In Ph- ALL patient the abdominal pain fully regressed and tumor size slightly decreased after the first blinatumomab cycle+ibrutinib. T-cell subpopulations study revealed only T-helper (lowered from 0,437 to 0,111x10*9/L in Ph+ ALL pt and was decreased to 0,112-0,111x10*9/L in Ph- ALL pt) and T-reg cell (was decreased to 0,006-0,002x10*9/L in Ph+ pt and lowered from 0,009 to 0,006x10*9/L in Ph- ALL pt) pools reduction. Absolute counts of cytotoxic T cells and NK cells remained within the normal reference values in both patients.
Summary/Conclusions: The correlation of the efficacy of blinatumomab treatment that uses effector cells in antileukemic effect against relapsed ALL with T-helper and T-reg pools reduction possibly indicates an overcoming the negative influence of those T-cell subpopulations. TKIs may act in synergy with blinatumomab during their concomitant use.

E868

LOW EXPRESSION OF LYMPHOID ENHANCER-BINDING FACTOR-1 (LEF1) ASSOCIATES WITH POOR PROGNOSTIC FACTORS IN PEDIATRIC ACUTE LEUKEMIA

R Malatesta[1,*], N Vega-Garcia[1], C Estella[1], S Rives[2,3], M Torrebadell[1,3], A Català[2,3], R Berrueco[2,3], A Ruiz-Llobet[2], L Calvente[1], M Trabazo[1], A Alonso-Saladrigues[1], M Mesegué[1], M Solsona[1], M Camós[1,3]
[1]Hematology Laboratory, [2]Pediatric Hematology. Department of Hematology and Oncology, Hospital Sant Joan de Déu, University of Barcelona, Esplugues de Llobregat, [3]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Madrid, Spain

Background: *LEF1* expression has been described in different types of leukemia, but its prognostic impact remains controversial. In adult patients with acute lymphoblastic leukemia (ALL), *LEF1* overexpression correlates to high-risk factors (hyperleukocytosis, *BCR-ABL1* rearrangement and complex karyotype). In contrast, overexpression of *LEF1* is a favorable prognostic factor in childhood ALL and in acute myeloblastic leukemia (AML), both in adults and children.
Aims: to analyze the prognostic impact of *LEF1* expression in a series of pediatric patients diagnosed with acute leukemia in a single center.
Methods: we included pediatric patients (0-18 years) with de novo acute leukemia, treated according to consecutive protocols of the Spanish Hematology and Oncology Pediatric Society from 2003 to 2015. mRNA expression levels of *LEF1* were assayed by quantitative PCR and analyzed with the 2^{-DDCt} method, with non-neoplastic samples used as controls for the relative quantification. Patients were grouped into quartiles (Q1-Q4) according to *LEF1* expression level: *LEF1*^{high} (Q4) and *LEF1*^{low} (Q1-Q3). Correlations with clinical and biological variables and survival analysis were performed with non-parametric, chi-square and Kaplan-Meier tests and log-rank comparison for subgroups.
Results: we analyzed 104 patients, with a median age of 4.7 years (0-17.4), including 61 boys (59%). Sixty-two patients (60%) had B-cell precursor ALL (all main cytogenetic subtypes represented), 22 patients (21%) had T-cell ALL and 20 cases AML (19%). Our AML series was enriched in infants: the median age was 2.7 (0.08-15.96), included 5 infants (25%) and 8 *MLL* rearranged cases (40%). Median expression level of *LEF1* was 6.44 (0-461), and differed significantly according to lineage (21.6 (0.1-461) in B-ALL; 4.7 (0.01-79.3) in T-ALL and 0.18 (0-13.5) in AML, p<0.0001). In the whole series of patients, *LEF1*^{low} expression was observed predominantly in infants and in patients with *MLL* rearrangement (p=0.043 and p=0.011, respectively). In addition, a trend to hyperleukocytosis was observed in patients with *LEF1*^{low} (p=0.06). After a median follow-up of 4.3 years (0.06-14.96), 14 patients died and 13 relapsed. The overall survival (OS) at 5 years was 94±3% in B-ALL patients, 80±9% in T-ALL and 63±11% in AML patients, p=0.001. In B-ALL subgroup of patients, low expression of *LEF1* was again significantly correlated to infant cases (p=0.025). Interestingly, in T-ALL patients we observed different findings: those cases with high expression of *LEF1* associated with older age (p=0.025) and worse event free survival (EFS, 61±15% *vs* 100%, p=0.02), although the number of patients is low and our results must be taken with caution. Despite the number of patients precluded the finding of statistical significance, in AML cases we observed, as in the whole series of patients, a correlation between *LEF1*^{low} and age<1 year, *MLL* rearrangement and higher WBC count (p=0.08, p=0.055 and p=0.072, respectively).
Summary/Conclusions: in our series of pediatric patients, low *LEF1* expression levels in B-ALL and AML patients correlated to adverse prognostic factors, such as age<1 year, *MLL* rearrangement and hyperleukocytosis. A larger number of patients is needed to confirm our results. GRANTS: PI12/2417, PN I+D+I, ISCIII (SGE, FIS), CIBERER, Fundación AECC, Fundación Sandra Ibarra, Fundación Cris contra el cáncer & "Força Miquel", "Candela" & "Mua" projects.

E869

CHARACTERISTICS OF PONATINIB THERAPY FOR PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH+ ALL) PATIENTS IN REAL-WORLD CLINICAL PRACTICE COMPARED TO THE PACE TRIAL

M Mauro[1,*], LJ McGarry[2], M Yang[2], S Lustgarten[2], H Huang[2]
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: The pivotal phase 2 PACE trial (NCT01207440) studied the use of ponatinib in adult patients with refractory Ph+ ALL and formed the basis of the approval of ponatinib. Prescribing data tracked by the specialty pharmacy exclusively responsible for distribution of ponatinib in the US are available from Jan 2014 onward.
Aims: To compare the PACE clinical trial data *vs* real-world pharmacy data, in order to examine similarities and differences between patient characteristics, regimens and duration of therapy evolving over time.
Methods: We compared PACE data, which enrolled patients Sep 2010 - Oct 2011 (all providing informed consent) to real-world data for Ph+ ALL patients starting ponatinib treatment Jan 2014 - Dec 2015. Real-world data source includes referring physicians, pharmacy intake forms and dispensing records. Data on co-prescribing were available for a small subset of patients. Patient characteristics and dosing were compared using non-parametric tests; average daily dose was calculated, including therapy gaps as "zero" dose. Duration of therapy was assessed using Kaplan-Meier techniques and proportional hazard regression.
Results: PACE enrolled 32 Ph+ ALL patients; 274 US real-world Ph+ ALL patients started treatment with ponatinib over a 2-year period. Demographic characteristics of PACE *vs* real-world patients, including age (median 61.5 *vs* 55.5 years; p=0.589) were similar. Most PACE patients were in their 3rd line of TKI therapy or later (19% 2nd, 44% 3rd and 38% 4th) while most real-world patients appear to be in earlier lines of TKI (29% no prior TKI reported, 32% 2nd line, 24% 3rd, and 15% 4th) (p<0.001). All PACE patients received 45 mg/day of ponatinib as their initial dose; in the real-world, 50% of patients initially received 45 mg/day of ponatinib, 41% received 30 mg/day and 9% 15 mg/day. Average dose was higher in PACE *vs* real-world (39.1 *vs* 27.3 mg/day; p<0.001). PACE only permitted monotherapy ponatinib whereas combination therapy appears to be used in a portion of real-world practice. Median time on therapy was 2.7 months in PACE *vs* 5.5 months in real-world patients (p=0.004), and nearly 50% of real-world patients remained on therapy after 6 months, *vs*<20% in PACE (Table).

Table 1.

Time on therapy in PACE vs real-world Ph+ ALL patients

Population (n)	6	12 (months)	18	24	Hazard ratio [CI] (p-value)
PACE (32)	18.8%	12.5%	3.1%	3.1%	0.573 [0.390 – 0.841]
Real-world (274)	48.2%	21.2%	9.5%	--	(0.005)

Summary/Conclusions: Real-world Ph+ ALL patients appear to be demographically similar to those enrolled in PACE, but there is evidence of ponatinib use earlier (less prior TKI treatment) in real-world patients. Starting dose in real-world reflects 50%<45 mg daily and subsequent lower dose intensity. Median duration of therapy was significantly longer for real-world patients than for PACE, with nearly one-half of real-world patients remaining on therapy at 6 months. Longer median duration of therapy may be related to lower dose intensity, use in earlier therapy lines, and use of combination therapy in real-world clinical practice. Further study of real-world use of ponatinib in Ph+ ALL is needed.

Background: Useful biomarkers for risk stratification in pediatric T-ALL are still needed. Several biological variables have been proposed as new prognostic biomarkers, including *NOTCH1, FBXW7, PTEN* & *RAS* mutations, expression of myeloid antigens and presence of copy number alterations (CNAs) of certain genes, but published results are controversial.
Aims: To analyze the prognostic impact of mutations, CNAs and myeloid antigens expression in a series of 56 pediatric T-ALL patients.
Methods: Pediatric patients (0-18 years) diagnosed with T-ALL, treated according to SEHOP (Spanish Hematology and Oncology Pediatric Society) and PETHEMA Cooperative Groups from 2001 to 2015. Mutations of *NOTCH1, FBXW7, PTEN, NRAS* & *KRAS* were screened by Sanger sequencing. CNAs were studied by MLPA technique with SALSA-P383 T-ALL kit (MRC-Holland) and Coffalyser software.
Results: Median age was 7 years (range, 0.3-15.4 years), 72% males. Central nervous system infiltration was present in 3 cases. Median WBC count was 56x10^9/L (range, 1.1-588). Twenty-four cases showed a cortical phenotype and 3 were classified as early T-cell precursor leukemia. Myeloid antigen expression (CD13 and/or CD33) was observed in 5 cases (14%). Twenty-three (41%) cases harbored *NOTCH1* mutations, including 18 single *NOTCH1* mutations (*NOTCH1*^{single}) and 5 cases with more than one mutation, located in different domains (*NOTCH1*^{double}). *FBXW7* was mutated in 9 cases (16%) and *NRAS* in 5 (9%). Overall, we observed *NOTCH1/FBXW7* mutations in 28 cases (50%). Six cases harbored *PTEN* abnormalities (mutations and/or deletions). Thirty-one of 41 analyzed cases (76%) showed ≥1 CNAs: *CDKN2A/B* deletions were the most frequent (28 cases, 60%) and were homozygous in 17 cases (*CDKN2A/B*^{homo}). We also observed *LEF1* deletions (n=4), *MYB* duplications (n=4), *CASP8AP2* deletions (n=4), and deletions (n=2) and duplications (n=1) of *EZH2* gene. *NUP214/ABL* fusion gene was detected in 2 cases. *CDKN2A/B*^{homo} was associated with higher WBC count (p=0.04). After a median follow-up of 4 years (range, 0.09-14.24), 10 patients relapsed and 12 died. The 5 years overall survival (OS) was 70±8%. All patients achieved morphological complete remission (CR) after induction. Minimal residual disease levels (≥0.01%) were detected by flow cytometry in 8 cases (28%). Five patients underwent allogeneic stem cell transplantation. The univariate analysis showed a better OS for patients with cortical phenotype (90±7% *vs* 50±20%, p=0.035) and a worse OS for *CDKN2A/B*^{homo} (44±16% *vs* 78±10%, p=0.048) and mutations in *FBXW7, NRAS* or *PTEN* abnormalities (*FBXW7*^{mut}/*NRAS*^{mut}/*PTEN*^{abn}) (50±14% *vs* 78±8%, p=0.027). In the multivariate analysis, *CDKN2A/B*^{homo} and *FBXW7*^{mut}/*NRAS*^{mut}/*PTEN*^{abn} retained their statistical significance (HR 5.5, p=0.013 and HR 6.4, p=0.006, respectively). For event free survival (EFS), hyperleukocytosis >200x10^9/L and *FBXW7*^{mut}/*NRAS*^{mut}/*PTEN*^{abn} independently predicted a worse outcome (HR 5.3, p=0.034 and HR 8.9, p=0.007, respectively).
Summary/Conclusions: In our series, the presence of *FBXW7*^{mut}/*NRAS*^{mut}/*PTEN*^{abn} predicted a worse OS and EFS, and the homozygous deletion of *CDKN2A/B* genes were independently associated with an inferior OS. Larger series of patients are needed to confirm our results. E871

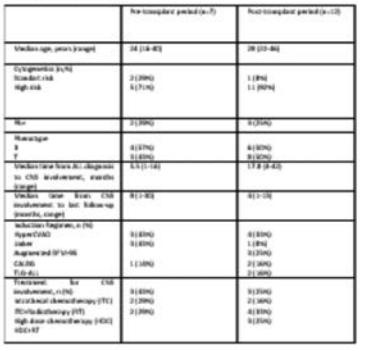
MANAGEMENT AND OUTCOME OF CENTRAL NERVOUS SYSTEM (CNS) INVOLVEMENT IN ACUTE LYMPHOBLASTIC LEUKEMİA (ALL): PRE AND POST TRANSPLANT

P Ataca Atilla*, E Atilla, S Civriz Bozdag, S Kocak Toprak, P Topcuoglu, O Arslan, H Akan, M Beksac, O Ilhan, G Gurman, M Ozcan
Ankara University School of Medicine Department of Hematology, ANKARA, Turkey

Background: The CNS is most common extramedullary site of involvement in ALL occurs in 4% to 8% of patients under chemotherapy. Allogeneic hematopoietic stem cell transplantation (Allo-HSCT) has emerged the curative treatment of ALL. The data how and which patients respond to CNS involvement treatment in pre and post transplant period remain limited.
Aims: The objectives of this study is to examine the management and outcomes of CNS involvement in pre and posttransplant period.
Methods: This single-center retrospective analysis included 137 ALL patients who underwent Allo-HSCT at Ankara University School of Medicine between 2005 and 2015. CNS involvement/relapse included 1 or more of the following criterias: evidence of leukemic blasts in the cerebrospinal fluid (CSF), cranial nerve palsy or contrast-enhancing brain or spinal mass on imaging.
Results: Pretransplant CNS involvement was diagnoesed in 7 (5%) patients whereas posttransplant CNS relapse was detected in 12 (9%) patients. The patient characteristics are shown in table. All induction regimens included prophylactic intrathecal chemotherapy (Methotrexate, ARA-C). None of the patients with pre-transplant involvement had post-transplant CNS relapse. Isolated CNS relapse was detected in 4 (33%) post-transplant patients. Median time to CNS relapse from Allo-HSCT was 8 months (range, 1-28). Twp pre-transplant (29%) and two post-transplant (16%) CNS involvement patients received reduced intensity conditioning. TBI based conditioning was prefered in 6 pre-transplant (86%) and 7 (58%) post-transplant CNS involvement patients. Peripheral blood was the stem cell source for 17 patients wheras two pre-transplant CNS involvement patients had received bone marrow from their matched relatives. None of the patients received CNS-directed prophylactic therapy after transplantation. All of the pre-transplant involvement patients were died due to disease relapse post-transplant. Two patients who received HDT and RT were alive in post-transplant CNS relapse group.

Table 1.



Summary/Conclusions: The prognosis is poor in CNS relapse detected in ALL patients posttransplant or pretransplant period. HDC and RT seems the most effective treatment strategy.

E872

NOVEL DYNAMIN2 MUTATION IN ADULT T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Z Ge[1,*], M Li[2], G Zhao[1], N Jin[1], B Chen[1], MD Yu[3], J Li[2], S Dovat[4], C Song[4]
[1]Hematology, Zhongda Hospital, Southeast University Medical School, [2]Hematology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [3]Sydney Kimmel Medical College at Thomas Jefferson University, Philadelphia, [4]Pediatrics, Pennsylvania State University Medical College, Hershey, United States

Background: Dynamin 2 (*DNM2*), a GTPase is essential for intracellular vesicle formation and trafficking, cytokinesis, and receptor endocytosis. Recently *DNM2* genetic mutations are identified in a subtype of T-cell acute lymphoblastic leukaemia (T-ALL) termed "early T-cell precursor" (ETP) ALL that comprises up to 15% of T-ALL, and is associated with treatment failure. However, study on *DNM2* genetic mutations in adult ALL is rare.
Aims: To characterize the novel *DNM2* mutations in Chinese adult T-ALL patients.
Methods: Bone marrow (BM) samples from 42 newly diagnosed T-ALL patients [31 male with median age 26 (16-62), 11 female with median age 29 (19-60)] were collected between July 2010 and December 2014 at the First Affiliated Hospital of Nanjing Medical University. The diagnosis of ALL was made according to the morphologic, immunophenotypic, cytogenetic and molecular criteria of WHO Diagnosis and Classification of ALL (2008). All the patients provided their written informed consent in accordance with the Declaration of Helsinki before enrollment in the study. The study was approved by the Institutional Review Board of the Nanjing Medical University. We performed mutational analyses of *DNM2* exons 2-22. Exons in *NOTCH1, FBXW7, PHF6, PTEN, JAK1* and *IL-7R* were also screened. Conventional cytogenetic analysis was performed at the time of diagnosis, using unstimulated short-term cultures according to the recommendations of the International System for Human Cyto-

genetic Nomenclature (ISCN). For each sample, at least 20 BM metaphase cells were analyzed. Immunophenotypic analyses were performed by flow cytometry on fresh BM samples. The cell-surface antigen was defined positive when fluorescence intensity of at least 20% of cells exceeded fluorescence of negative control.
Results: *DNM2* mutations were identified in 4 of 42 T-ALL patients (9.5%). All the four cases were point mutations (c.1081C>T, c.1453T>C, c.1609G>A and c. 1801C>T), which is located in exon 8, 13, 16 and 18. In the four identified mutations, one is nonsense mutation and three are missense mutations. All of the four mutations were lead to amino acid changes (R361X, Y485H, G537S and R601W). The R361X and Y485H are located in middle(MID) domain, while G537S and R601W in pleckstrin homology(PH) domain of *DNM2*. Interestingly, we found that the four patients with *DNM2* mutations co-existed with *NOTCH1* mutations, 3 of the 4 cases co-existed with two *NOTCH1* mutations (point mutations and / or indel mutations), which were located in *NOTCH1* exon 26, 27 and 34. Moreover, 3 of the 4 patients with *DNM2* mutations were also concomitant with *PHF6* mutations which were located in *PHF6* exon 4, 5 and 8. The clinical characteristics of the patients with *DNM2* mutations were further analyzed. It showed that one patient relapsed, one patient had initial high WBC, and two patients had complex karyotype. Importantly, the days for reaching the complete remission after induction chemotherapy were over 4 weeks for all these patients. These data indicated that the patients with *DNM2* mutations in this cohort of adult T-ALL had poor prognosis.
Summary/Conclusions: We identified 4 novel *DNM2* mutations and the co-existence of mutations in NOTCH1/PHF6 in adult T-ALL patients. We also observed the association of *DNM2* mutations with poor prognosis. Our finding suggested the *DNM2* mutations may be involved in the oncogenesis of T-ALL.

Background: Treatment outcome with conventional salvage therapy in relapsed Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) is poor and is often associated with significant morbidity. Tyrosine kinase inhibitors (TKI) have changed strategy of Ph+ ALL therapy and improved prognosis of the disease. However, despite the progress associated with TKI therapy for Ph+ ALL, the maintaining remission remains the major challenge.
Aims: We assessed the long-term outcome of relapsed adult Ph+ ALL patients treated with continuous imatinib plus combination chemotherapy.
Methods: Imatinib (600 mg/day orally) was administered continuously with combination chemotherapy, starting from eighth day of remission induction treatment, then through 5 courses of consolidation or until allogeneic hematopoietic cell transplantation (HCT). Patients who were not transplanted were maintained on imatinib for 2 years.

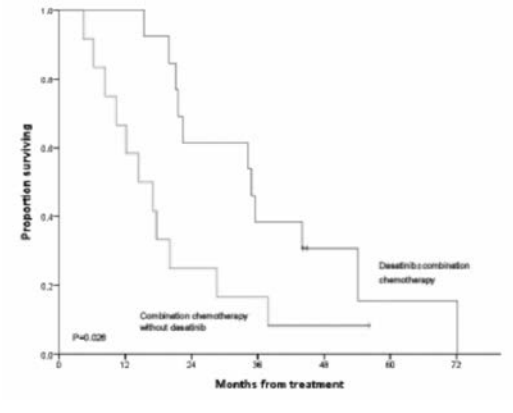

Figure 1.

Results: Between October 2005 and February 2009, total 87 patients, aged 16-71 years, with newly diagnosed Ph+ALL were enrolled. With median follow-up of 5 years among survivors (range: 2.6-8.9 years) and data was frozen up in May 2015. After remission induction, 82 patients (94%) achieved complete remission (CR). Among these patient, 44 patients (54%) experienced leukemia relapse and median time of leukemia relapse-free survival was 13.9 months (range, 0.4-89.5 months). Sites of relapse were bone marrow (79.5%), central nervous system (CNS) (9.1%), lymph nodes (6.8%), testis (2.3%) and pancreas (2.3%), respectively. Sixteen patients (36.4%) relapsed during consolidation treatment, 23 patients (52.3%) relapsed after allogeneic hematopoietic cell transplantation (HCT), and five patients (11.4%) relapsed during maintenance treatment after completion of five consolidation. The relapse rate within one year from CR was 45.5% in total patients and that within one year in patients underwent allogeneic HCT in first CR was 25.0%. Salvage treatments of relapsed Ph+ ALL were combination chemotherapy in 13 patients (29.5%), imatinib in 6 (13.6%), imatinib plus combination chemotherapy in 6 (13.6%), dasatinib in 8 (18.2%), dasatinib plus combination chemotherapy in 5 (11.4%), intrathecal methotrexate in 4 (9.1%) who relapsed in CNS, and to stop immunosuppressant therapy in one who underwent allogeneic HCT. One relapsed patient did not receive treatment due to poor performance state and died of leukemia recurrence. Patients treated with dasatinib±combination chemotherapy were demonstrated a longer survival compared with patients treated with combination chemotherapy without dasatinib (P=0.026). Dasatinib treatment had a tendency of superiority in survival but there was no statistical significance. Nineteen patients (43.2%) among evaluable 43 patients treated salvage therapy achieved a second CR. Two patients of them were received allogeneic HCT after achieving second CR. Eleven patients in twelve evaluable patients who achieved a second CR experienced a second relapse. The median time of survival was 21.3 months (range, 4.4-72.2 months). The causes of death of them were leukemia recurrence (89.2%), and infection (10.8%).
Summary/Conclusions: Inclusion of dasatinib into transplantation strategy allows obtaining sustained remission even in patients relapsed after imatinib treatment.

HEMATOPOIETIC STEM CELLS CAN BE SEPARATED FROM LEUKEMIC CELLS IN A SUBGROUP OF ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS
W Wang[1,2], E Foerner[2], L Manta[2], E Buss[2], A Jauch[3], V Eckstein[2], P Wuchter[2], AD Ho[2], C Lutz[2,*]
[1]Department of Oncology, Nanjing Medical University Affiliated Wuxi Second Hospital, Nanjing, China, [2]Departement of Medicine V, University Hospital of Heidelberg, [3]Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany

Background: Aldehyde dehydrogenase (ALDH) activity which is involved in the metabolism of intracellular aldehydes has been demonstrated to function as a marker for stem cell activity in various tissues including the hematological system. In combination with CD34-positivity and CD38-negativity high ALDH activity ($CD34^+CD38^-ALDH^+$) has been shown to be a reliable tool for the separation of hematopoietic stem cells (HSC) from leukemic cells in a subgroup of patients with acute myeloid leukemia (AML). In B-cell acute lymphoblastic leukemia (B-ALL) successful separation of normal HSC has so far been limited to a subgroup of patients. These isolations were mostly guided by CD19-negativity in combination with the $CD34^+CD38^-$ phenotype. However, in some cases leukemia initiating cells were also detectable in the pool of $CD19^-$ cells indicating that better isolation strategies are necessary.
Aims: In this study we sought to investigate the value of ALDH-activity for the isolation of HSC from leukemic cells in adult B-ALL.
Methods: Between 2011 and 2015 bone marrow (BM) aspirates of 15 ALL patients were collected after written informed consent and stratified in ALDH-numerous (≥1.9% $ALDH^+$ cells) and ALDH-rare (<1.9% $ALDH^+$ cells) cases. The cut-off value of 1,9% was determined by the amount of $ALDH^+$ cells in healthy bone marrow controls. HSC candidates ($CD34^+CD38^-ALDH^+$) and various subpopulations were analyzed for the presence of clonal marker and functionally tested in *in vitro* assays.
Results: In ALDH-rare B-ALL clonal-marker negative HSC could be reliably separated by the $CD34^+CD38^-ALDH^+$ phenotype, whereas this separation was not possible in ALDH-numerous B-ALL. Functional assays confirmed the HSC-potential of isolated cells and showed increased long- and short-term colony-initiating activity. Further analysis showed that in ALDH-rare ALL HSC-potential was uniformly restricted to $CD19^-$ cells. However, addition of ALDH-activity was necessary to further enrich for HSC-activity as $CD34^+CD38^-CD19^-ALDH^-$ cells contained no colony forming potential.
Summary/Conclusions: In summary, we provide a method to separate functionally normal HSC from leukemic cells in a subgroup of B-ALL patients that can be identified by their overall low percentage of cells with high ALDH-activity. This protocol thereby allows comparative analyses of patient matched HSC and leukemic cells in order to improve the understanding of leukemic evolution in adult B-ALL.

DOES TIMING OF CENTRAL VENOUS LINE REPLACEMENT MATTER DURING INDUCTION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA?
E Ataseven[*], D Kızmazoğlu, Ö Tüfekçi, F Demir Yenigürbüz, S Yılmaz Bengoa, H Oren
Department of Pediatric Hematology and Oncology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey

Background: The use of central venous lines (CVL) in children with acute lymphoblastic leukemia (ALL) provides comfortable administration of intensive chemotherapy and blood sampling. The optimal time for insertion of CVL in patients with ALL is controversial.
Aims: The aim of this study is to define the frequency of CVL related complications and also to analyse the frequency of cases of catheter related infection and thrombosis in relation to timing of CVL replacement.
Methods: We reviewed the records of 52 pediatric ALL patients with CVL treated during a 10-year period. Demographics, preoperative blood counts, type of central line, time of CVL replacement, CVL related complications, and blood counts during complications were all noted. All the data were collected from those with the first catheter use.
Results: Fifty two pediatric ALL patients (29 male, 23 female) with a median age of 6,1 years were included in the study. Most of the patients (92.3%) had an internal line (port). CVL was replaced before treatment day 15 (early) in twenty six patients (50%) and after 15 days (late) in 26 patients (50%). Systemic infections occurred in 24 patients (46.2%). Regarding the infection rates, no difference was found between early and late CVL replacement (p=0.09). Most of the infections (68%) were due to coagulase negative *Staphylococcus aureus*. The median absolute neutrophil count during infections was 150/mm^3 (0/mm^3 to 17,700/mm^3). There were three patients with thrombosis and no difference was found between early and late insertion of CVL replacement groups (p=0.35). Other catheter related complications was recorded in seven patients (leakage in one patient, accidental removal of line in one patient, line rupture in one patient, and line occlusion in four patients). CVLs had to be removed in seventeen patients (32.7%) before the end of chemotherapy protocol due to various reasons (catheter related infections in six patients, local skin infections in four patients, and other catheter related complications in seven patients).
Summary/Conclusions: The present study showed no relation between the timing of catheter replacement and occurrence of infection and thrombosis. Our results suggest CVLs can be replaced safely at the time of diagnosis or early period of treatment to provide a comfortable administration of chemotherapy and to decrease painful blood samplings.

TYROSINE KINASE INHIBITORS IN PHILADELPHIA-CHROMOSOME POSITIVE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA IN REAL CLINICAL PRACTICE

F Folber[1,*], J Machal[2], S Hrabovsky[1], J Mayer[1], M Doubek[1]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, [2]Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Adult patients with Philadelphia-chromosome positive acute lymphoblastic leukemia (Ph+ ALL) are at high risk of relapse. Allogeneic stem cell transplantation still remains the treatment of choice in spite of the major benefit brought by adding tyrosine kinase inhibitors (TKIs) to the standard chemotherapy. On the other side, TKIs also bear several side effects and some of them require significant dose reductions.
Aims: The aim of this analysis was to focus on treatment strategies in unselected adult Ph+ ALL patients in real clinical practice and how TKI dose reduction may influence their outcomes.
Methods: All adult patients diagnosed with Ph+ ALL and treated with TKIs at our centre between 2005 and 2015 were included into this retrospective analysis. We describe baseline features, treatment options and outcomes. The data were analysed for response and relapse rates and factors affecting survival.
Results: A total number of 41 consecutive patients aged 19 to 82 years (median 58) at the time of diagnosis of Ph+ ALL were included. Leukocyte count was 1.8 to 296 x 10^9/L (median 20) at presentation. Most commonly observed were common-B immunophenotype (73%) and p190 bcr-abl transcript (63%). Thirteen (32%) patients were treated according to pediatric-based intensive protocol, 13 (32%) using a reduced-toxicity protocol, and 15 (37%) in a palliative approach. An allogeneic transplant was performed in 17 (41%) patients. Thirty-three (85%) patients achieved a complete remission (CR) and 56% of them achieved a complete molecular response (CMR). First line TKI was imatinib in all patients, with a median daily dose of 600mg. In 18 (44%) patients the dose had to be reduced to 400, 300 or 200mg due to side effects (haematological 36%, oedemas 32%, gastrointestinal 16%, skin rash 4%). Sixteen (46%) patients in CR eventually relapsed and only 6 (38%) achieved a second CR. Second line TKI was dasatinib (12; 75%) or 800mg imatinib (3; 19%). Dasatinib was given at a median daily dose of 140mg but in a much broader range (35 to 140 mg). This dose was further decreased in 10 (83%) patients, while most common non-haematological side effects were gastrointestinal (17%), oedemas (13%) and effusion (4%). Five (83%) of these patients in CR2 experienced a second relapse. During the follow-up with a median of 12 months (range 1 to 103 months), 27 (66%) patients died; fifteen (56%) of infection, 11 (41%) of disease progression and one (4%) of a secondary malignancy. Fourteen (34%) patients are still alive in complete remission. Five-year overall survival (OS) in the whole cohort was 30%. The survival was not influenced by leukocyte count, immunophenotype nor the type of the bcr-abl transcript. The statistically significant risk factors for longer OS were: age under 55 (5-year OS 57% *vs* 8%, p<0.01), CR (37% *vs* 0%, p<0.01), CMR (54% *vs* 0%, p<0.01), allogeneic transplant (58% *vs* 8%, p<0.01) and relapse (67% *vs* 0%, p=0.01). In non-transplanted patients with imatinib dose reduction the survival was not inferior compared to patients without a reduction. Surprisingly, these patients were surviving even longer (2-year OS 38% with a reduction *vs* 8% without, p<0.01). Whether this finding represents a clinically significant phenomenon or is a mere coincidence remains a question for further investigation.
Summary/Conclusions: Adult patients with Ph+ ALL form a distinct subgroup with a very variable prognosis. The best treatment outcome can be reached in younger patients who undergo allogeneic transplant in first haematologic and molecular remission. According to our analysis, imatinib dose reduction due to side effects is not associated with inferior survival. (Supported by Czech Leukemia Study Group-for Life.).

PREDICTIVE VALUE OF IG/TR AND BCR/ABL1 PCR-BASED MINIMAL RESIDUAL DISEASE MONITORING IN PH+ PEDIATRIC ALL TREATED WITH IMATINIB IN THE ESPHALL STUDY

G Cazzaniga[1,*], P De Lorenzo[2], J Alten[3], S Roettgers[4], J Hancock[5], V Saha[6], A Castor[7], H Madsen[8], V Gandemer[9], H Cavé[10], V Leoni[1], G Ferrari[1], R Pieters[11], V van der Velden[12], J Stary[13], J Zuna[13], G Escherich[14], U zur Stadt[14], M Aricò[15], V Conter[1], M Schrappe[3], MG Valsecchi[2], A Biondi[1]
[1]AIEOP, [2]EsPhALL Trial Data Center, University of Milano-Bicocca, Monza, Italy, [3]BFM-G, Kiel, [4]BFM-G, Giessen, Germany, [5]CCLG, Bristol, [6]CCLG, Manchester, United Kingdom, [7]NOPHO, Lund, Sweden, [8]NOPHO, Copenhagen, Denmark, [9]FRALLE and EORTC, Rennes, [10]FRALLE and EORTC, Paris, France, [11]DCOG, Utrecht, [12]DCOG, Rotterdam, Netherlands, [13]CPH, Prague, Czech Republic, [14]COALL, Hamburg, Germany, [15]AIEOP, Ragusa, Italy

Background: Several studies showed that minimal residual disease (MRD) detection is a strong independent prognostic factor in childhood acute lymphoblastic leukemia (ALL) including Ph+ ALL treated with conventional chemotherapy. Very few data and of difficult interpretation are available on the predictive value of early MRD response in Ph+ ALL treated with tyrosine kinase inhibitors (TKI)s.
Aims: MRD was detected by real-time quantitative PCR of rearranged immunoglobulin/T-cell receptor (IG/TR) genes and/or BCR/ABL1 fusion transcript in the EsPhALL study to investigate its predictive value in patients treated with imatinib.
Methods: In the EsPhALL study, after induction therapy, patients received BFM high risk ALL therapy; imatinib was given intermittently during the intensive treatment phases for a total of 18 weeks or less, usually 10 weeks, if patients underwent hematopoietic stem cell transplantation (HSCT), indicated for large majority of patients. MRD on the bone marrow (BM) was monitored as an ancillary study after induction therapy (TP1), consolidation Phase IB (TP2), HR Block1 (TP3), HR Block2 (TP4), HR Block3, first and second reinduction, and at end of therapy. Quantitative PCR analysis was performed and interpreted according to Euro-MRD network guidelines for both IG/TR and BCR/ABL1.
Results: MRD negativity increases progressively, both by IG/TR (from 10% at TP1 to 57% at TP4) and by BCR/ABL1 (from 13% at TP1 to 30% at TP4). Conversely, the proportion of patients with highly positive MRD by IG/TR decreases from 78% at TP1 to 14% at TP4 and by BCR/ABL1, from 80% at TP1 to 57% only at TP4. The minority of patients IG/TR MRD negative at TP1 (N=9, 10%) had a very favorable outcome with no relapses, whereas patients with high or low MRD positivity had a similarly high 5-year cumulative incidence of relapse (CIR) (SE) of 35.2 (5.9) and 36.4 (15.4), respectively. Achieving MRD negativity at TP2 is also associated with low risk of relapse (5-year CIR (SE) 14.3 (9.8)), whereas achieving negativity only at TP3 or TP4 is associated with a CIR of 36.4 (15.5) and 42.9 (21.6), respectively, similar to that of patients with low or high positivity at any time-point. BCR/ABL1 MRD negativity (although based on small numbers) at TP1 or TP2 is reached less frequently compared with IG/TR MRD, but is associated with a similar very low risk of relapse (one relapse in 8 patients MRD negative at TP1), while patients with low or high positivity have instead a high risk of relapse, again similar to that observed for positive IG/TR MRD. The overall concordance between the two methods is 69%; for patients with positive MRD by both techniques, the estimated mean differences of BCR/ABL1 *versus* IG/TR results were significantly different from zero, and were consistent according to different TPs with significantly higher positivity by BCR/ABL1. There are also rare cases consistently negative by IG/TR and positive by BCR/ABL1 with a very favorable outcome.
Summary/Conclusions: MRD negativity by IG/TR is obtained more frequently than by BCR/ABL1 and it is highly predictive of a very favorable outcome and the earlier the negativity, the better the prognosis. Further investigations are needed to understand the biology in cases with discordant results, and in particular of those negative by IG/TR and positive by BCR/ABL1. The role of MRD in patients treated continuously with TKI inhibitors and without HSCT needs to be explored in current studies.

LB2240

OUTCOME OF PATIENTS WITH HIGH RISK ACUTE LYMPHOBLASTIC LEUKEMIA IN HAPLOID-MATCHED *VS* SIBLING-MATCHED ALLOGENEIC STEM CELL TRANSPLANTATION

H Yan, L Tan, L Gao, C Zhang, Y Liu, L Gao, P Kong, H Liu, X Zhang[*]

Department of Hematology, Xinqiao Hospital, Third Military Medical University, Chongqing, China

Background: The efficacy of allogeneic stem cell transplantation in patients with high risk acute lymphoblastic leukemia (ALL) is unclea, and the relevant prognostic factors are not well-known.
Aims: To explore the efficacy of allogeneic stem cell transplantation in patients with high risk acute lymphoblastic leukemia (ALL) and investigate its relevant prognostic factors
Methods: A total of 69 patients with ALL who were treated with allo-HSCT in our hospital from July 2007 to August 2013, all patients were followed up more than two years. They were divided into haploid-matched (haploidentical allogeneic stem cell transplantation) group (n=42) and sibling-matched(HLA sibling-matched allogeneic stem cell transplantation) *group* (n= 27). Clinical characteristics of two groups were retrospectively analyzed.Survival date were analyzed by the Kaplan-Meier method and the prognostic factors were analyzed with the COX regression model.
Results: 2 years over-all survival(OS) is 63.4% in haploid-matched group, 53.9% in sibling-matched group, difference was not statistically significant (P=0.197); and 2 year LFS(leukemia-free survival) is 59.4% and 53.7% in haploid-matched group and sibling-matched group respectively,difference was not statistically significant(P=0.17). 2 years RR(relapse rate) of sibling-matched group(39.5%) is higher than that of haploid-matched group(19.5%) (P=0.014). In hematopoietic reconstruction, Neutrophils reconstruction of the haploid-matched group later than sibling-matched group(P=0.002), and platelet reconstruction in two group is similar(P=0.072). Grade I-II aGVHD(acute graft-*versus*-host disease) in haploid-matched group is higher than sibling-matched group (P=0.008), then grade III-IV aGVHD and chronic GVHD are similar (P=0.726, P=0.81 respectively) in two group. We collected the early(six months) infection after HSCT, infection rate of haploid-matched group is higher than sibling-matched group(P=0.02). 2 year NRM(non-relapse mortality) rate of sibling-matched group is 11.1%, NRM rate of haploid-matched group is 26.2%, the difference was not statistically significant (P=0.519). The Cox regression analysis showed that disease status before transplant (not CR1) were main risk factors affecting LFS of patients(P=0.001), relative risks is 7.581. limtited GVHD (P=0.013) and shorter time from first diagnosed to transplantation (P=0.012) is protective factors,relative risks is 0.178 and 0.688 respectively.
Summary/Conclusions: In high-risk patients with ALL ,haploid-matched and sibling-matched HSCT are similar in total outcome. haploid-matched donor can be suitable source of allogeneic stem cell transplantation.

LB2241

EXPLORE THE INNER RELATION AMONG THE MORPHOLOGY, IMMUNOPHENOTYPIC, MOLECULAR GENETIC FEATURES IN MIXED PHENOTYPE ACUTE LEUKEMIA

P Wang[1], XJ Deng[1], SH Liu[1], C Zhang, X Qiang[1], HY Zhang[1], Y Gou[1], WC Yang[1], XG Peng[2,*]
[1]Department of Hematology, Xinqiao Hospital, Third Military Medical University, Chongqing, [2]Department of Hematology, Xinqiao Hospital, Third Military Medical University, Chongqing, China

Background: The mixed phenotype acute leukemia(MPAL) is rare leukemia. The biology of MPAL is unclear.
Aims: To analyze and explore the inner relation among the Morphology, immunophenotypic, cytogenetic, molecular genetic features and prognosis of MPAL.
Methods: MICM classification by morphology and cytochemistry, flow cytometric immunophenotyping,conventional cytogenetic,fluorescence in situ hybridization (FISH) and/or molecular genetic, was used to relrospectively study 2575 patients with AL from January 2008 to March 2015.
Results: The results showed that 30(1.16%) cases were diagnosed as MPAL,fulfilling WHO 2008 criteria. 13 cases of 30 MPALs'Leukemia cells presented the same kind of morphological characteristics,leukemia cells of the other 17 cases has two different morphological characteristics(The two kinds of cells were more than double in volume I. Maxicell: around 16 to 25 um, morphological characteristics similar to myeloid myeloblast and/or monoblast, POX positive II. Cellule:around 8 to 12 um,morphological characteristics similar to lymphocytes,but is not a classic myeloblast,monoblast or lymphoblast, Cytoplasm pseudopodia,burr shape change,drag the caudate,containing A particle or not, folded or irregular nuclei). Based on FAB criteria,12(40%) patients showed AML morphologies, mainly M1 and M5,the dominant subtype. 6(20%) patients were classified ALL,7(23.3%) patients were classified hybrid acute leukemia(HAL). The remaining 5(16.7%) cases resisted classification by morphology and were categorized as acute undifferentiated leukemia. Immunophenotyping data showed that 16 of 30 cases(53.3%) had combined B-lymphoid+myeloid immunophenotype(B+My),12(40%) combined T-lymphoid+myeloid immunophenotype(T+My), 1(3.33%) B+T- lymphoid immunophenotype (B+T), and in the remaining 1(3.33%) cases there was evidence of trilineage concomitant expression [myeloid, B, and T lymphoid(My+B+T)]. In addition, there are 1/16 cases of MY+B with T-lineage marker CD7+ not as trilineage. There were high expression of stem/progenitor cell markers CD123,CD34,CD38 and HLA-DR in MPAL;with the positive rate of 100%,93.3%,90% and 92.6%,respectively. A total of 11 (36.7%) had Ph chromosome and/or BCR-ABL fusion gene by FISH and/or RT-PCR. Median WBC of peripheral blood was $149x10^9$/L ranging between $1.46x10^9$/L and $797x10^9$/L.Compared with Ph-MPAL,it has statistical significance that combined B+My immunophenotype(P=0.001) and the peripheral blood was found to be immature granulocytes (promyelocytic, myelocyte and metagranulocyte) by smears for morphology (P=0.002), at the positive rate of 90.9%(10 of 11 cases) in Ph+MPALs. 7 cases of HAL by morphology associated with the BCR-ABL fusion gene(P=0.01),and these appeared as combined B+My immunophenotype. 22 of 30 patients were treated with at least 2 cycles of chemical drugs,with the complete response(CR) rate of 59.1%(13/22). This study found In these 30 cases of MPALs, according to our set of morphological classification scheme the ALL often appeared as combined B+My immunophenotype that was diagnosed by morphology;the combined T+My immunophenotype cases usually showed AML by morphological classification. While myeloid and lymphoid blast cells were simutalously seen in BM, high leukocyte and high immature granulocytes were seen in PB, and with B+My immunophenotype, it often hint MPAL with Ph chromosome or BCR-ABL fusion gene.
Summary/Conclusions: MPAL is a set of heterogeneous disease that originated in the stage of pluripotent stem cell and have directional differentiation potential,mainly presents the characteristic of myeloid differentiation.

LPS STIMULATION INDUCES ROS FORMATION, APOPTOSIS, DNA DAMAGE AND OXIDATION OF CYSTEINE RESIDUES IN FLT3-ITD POSITIVE CELL LINES RESULTING IN FLT3-TYROSINE KINASE INHIBITOR RESISTANCE

C Mueller[1,*], T Schnoeder[1], L Simeoni[2], F Heidel[1], C Thurm[2], B Schraven[2], T Fischer[1]
[1]Department of Hematology and Oncology, [2]Institute of Molecular and Clinical Immunology, University Clinic Magdeburg, Magdeburg, Germany

Background: Recurrent infections are associated with an increased incidence in the development of malignancies, including acute myeloid leukemia (AML). Inflammatory events directly induce formation of reactive oxygen species (ROS) and cause DNA damage, protein and lipid oxidation. In case of recurrent infections, bacterial peptides, like LPS, can lead to ROS induction. In particular, cysteine residues of proteins can directly be oxidized by ROS causing either loss or gain of function. However, it is still unclear how inflammatory events can induce these protein oxidation and to what extent the oxidation of cysteine residues in a subset of AML, the FLT3-ITD positive AML, causes a change of biological behavior.
Aims: The goal of our study was to characterize the role of LPS-induced oxidative stress in murine and human FLT3-ITD positive cell lines to identify responsible FLT3-ITD- and TLR related signaling pathways. To adress stress-induced cysteine oxidation of the FLT3-kinase, we generated cysteine-to-alanine mutants in murine myeloid 32D cells (FLT3-WT and FLT3-ITD) and investigated the induction of ROS formation, proliferation, cell cycle distribution and the response to TKI treatment (AC220, PKC412).
Methods: 32D cells stably transduced with either FLT3-WT or FLT3-ITD and human FLT3-ITD positive MV4,11 were stimulated with LPS (5-50 ng/ml) for 2h and with 10 ng/ml LPS for different time-points (0-90 min), respectively. ROS formation (H_2DCFDA method) and activation of FLT3-ITD and TLR-related signaling pathways were analyzed by immunoblotting. To analyze effects of chronic inflammation, FLT3-WT and FLT3-ITD positive cells were kept in culture for 12 days with repeated LPS stimulation (10 ng/ml every 48h). To address the role of cysteine oxidation within the FLT3-kinase, we mutated highly conserved cysteine residues C474 (extracellular domain) and C925 (intracellular domain) to alanine by site-directed mutagenesis and performed a retroviral transduction of 32D cells with the respective constructs. Subsequently, cysteine mutants were characterized for proliferation (MTT), ROS formation and their sensitivity to TKI treatment (AC220, PKC412; 5 to 50 nM, respectively) in comparison to standard FLT3-ITD mutant.
Results: LPS stimulation resulted in an increased time- and dose-dependent ROS induction in FLT3-ITD positive cells compared to WT cells (100ng/ml LPS for 2h: 6-fold). In addition, LPS stimulation resulted in a stronger activation of FLT3-ITD- and TLR-related signaling pathways in ITD-positive cells (Stat5, Akt, Erk, NF□B). Long-term LPS stimulation over 12 days induced an enhanced ROS formation, apoptosis and accumulation of □H2AX in both FLT3-WT, as well as in FLT3-ITD positive cells. To address the role of cysteine oxidation, we generated stable cysteine-to-alanine-mutants. However, the FLT3-ITD C925A mutation (intracelullar domain) resulted in an increase of ROS formation compared to the FLT3-ITD C474A mutation (extracellular domain; 25% increase). Furthermore, the C925A mutation resulted in a significant decrease in apoptosis after TKI treatment compared to non-mutated FLT3-ITD and the FLT3-ITD C474A mutant (AC220 50nM: 25%; PKC412 50nM: 40%). In addition, FLT3-ITD C925A mutant showed a reduced decrease in phosphorylation of Stat5 and Akt after short-term (1h) TKI treatment (AC220: 50, 100 nM; PKC412 10, 100nM) compared to non-mutated and FLT3-ITD C474A mutants.
Summary/Conclusions: Our study demonstrates that inflammatory events, like LPS stimulation, induce ROS formation, apoptosis and DNA damage in FLT3-WT and FLT3-ITD positive cells. This might lead to genetic instability and induction of critical mutations, e.g. within FLT3 kinase. Additionally, we could show that cysteine oxidation within the intracellular domain of FLT3-ITD resulted in a resistance to TKI treatment.

ANALYSIS OF SNORNA EXPRESSION AND FUNCTION IN ACUTE MYELOID LEUKEMIA

F Zhou[1], C Pauli[1], Y Liu[1], D Gerloff[1,*], C Rohde[1], M Köhn[2], D Misiak[2], S Hüttelmaier[2], C Müller-Tidow[1]
[1]Department of Internal Medicine IV, Hematology and Oncology, University Hospital Halle, [2]Section for Molecular Cell Biology, Institute of Molecular Medicine, Martin-Luther-University Halle, Halle, Germany

Background: Small nucleolar RNAs (snoRNAs) belong to the group of non-protein-coding RNAs with distinct functions in ribosomal RNA (rRNA) modification. snoRNAs are divided into the two major classes: box C/D and box H/ACA snoRNAs. SnoRNAs assembly with small nucleolar ribonucleoproteins (RNPs) and guide those snoRNPs to the rRNA, where they catalyze rRNA modifications. C/D box snoRNAs are involved in 2-O-methylation, whereas H/ACA snoRNAs guide pseudouridylation. Recent studies showed that snoRNAs play a role in cancerogenesis. Hence, we analyzed snoRNAs expression and function in leukemogenesis.
Aims: Investigation of snoRNA expression pattern and function in acute myeloid leukemia.
Methods: To understand the role of snoRNAs in leukemia, we analyzed the snoRNA expression pattern of 63 AML patients at time of diagnosis. Additionally we analyzed snoRNA expression patterns in AML1-ETO or Myc transduced lin$^-$ mouse bone marrow cells. Librarys for small RNA (40-200 nt) specific next generation sequencing (NGS) were prepared with TruSeq Small RNASample Prep Kit. NGS was performed on an Illumina HiScanSQ, using 50 cycles of single read sequencing. For functional analysis of single snoRNAs, we performed single Knockouts of 6 snoRNAs (SNORD14D, SNORD34, SNORD35A, SNORD43, SNORD53 and SNORD104) in Kasumi and MV4-11 cells using CRISPR/Cas9 technology. Mutations in the genomic sequence were confirmed by Sanger sequencing. Subsequently, expression of snoRNAs was analyzed by qRT-PCR. To analyze the effect of snoRNA knockout on colony formation ability of mutated cells, we embedded 300 cells/well in methylcellulose. Colonies were counted after 7-10 days.
Results: Next generation sequencing data revealed 229 C/D box snoRNAs and 90 H/ACA box snoRNAs were expressed in one or more patient samples. In further analyses, we compared clinical data and snoRNA expression pattern. SnoRNA expression patterns were associated with specific risk groups. High levels of snoRNA expression associated with intermediate molecular risk (269 snoRNAs, p≤0.05) and a poor response to chemotherapy (101 snoRNAs, p≤0.05). Further, we could show that snoRNAs are higher expressed in AML patient samples with NPM1 wildtype (124 snoRNAs, p≤0.05). Transduction of the oncogenes AML1-ETO9a or Myc to normal lin$^-$ mouse bone marrow cells induced an increased overall snoRNA expression. We found 93 snoRNAs downregulated and 88 upregulated during ATRA induced differentiation of HL60 cells. The functionally analyzed snoRNAs SNORD14D, SNORD34, SNORD35A, SNORD43 and SNORD53 were downregulated. CRISPR/Cas9 induced knockouts for SNORD14D, SNORD34, SNORD35A or SNORD43 significantly inhibited colony formation of Kasumi-1 cells. Also, loss of SNORD14D or SNORD35A decreased colony formation potential of MV4;11 cells. Loss of SNORD34, SNORD35A, SNORD43 and SNORD104 resulted in a significant reduction of 2´-O-methylation on the respective rRNA modification sides (28S U2824, 28S C4506, 18S C1703 and 28S C1327).
Summary/Conclusions: SnoRNA expression profiles are altered in specific AML subtypes. Further, we identified a functional relevance of snoRNAs in cell growth of leukemic cells.

E879

PERSISTENCE AND EXPANSION OF HEMATOPOIETIC CLONES IN POST CHEMOTHERAPY AML ASSESED BY TARGET SEQUENCING

D Soriano[1,*], L Rai[2], T Boneva[2], C Grace[2], S Mackinnon[3], P Kottatidis[1], E Nacheva[2,3]
[1]Haematology, Royal Free NHS Trust, [2]Haematology, Health Services Laboratories, [3]Haematology, University College London, London, United Kingdom

Background: Gene variance screening has demonstrated the persistence of pre-leukemic hematopoietic stem cells (HSC) in AML patients during complete morphological remission (CR) (*Corces-Zimmerman et al, Proc Natl Acad. 2014 and Terrence et al, Blood. 2015)* but very little is known about their gene profile, dynamics and/or clinical associations.
Aims: Assess the dynamics of the gene variance profile and its clinical correlation in 20 AML patients who achieved CR after chemotherapy treatment.
Methods: Bone marrows samples from 18 *de novo* AML and 2 secondary AML patients were analysed at diagnosis and monitored for 2 to 34 months post chemotherapy initiation. 19 patients received induction/re-induction chemotherapy including both cytarabine and an anthracycline or purine analog, 1 patient received a non intensive chemotherapy consisting of a low dose cytarabine (LDAC) composed regimen. Targeted exon sequencing of 54 genes was carried out using a commercial panel (*Illumina TruSight, myeloid panel*) with exons fully covered for 17 genes, while a set of specific exonic locations targeted in the other 37 genes. Non-synonymous gene variances with a minimum of 500 reads and ≥5% frequency were reported. Variants were identified using Illumina bio-informatics pipeline augmented by COSMIC, SNP library (dbSNP137), OMIM, 1000 genomes and published data.
Results: Of the 20 patients analysed, 15 patients showed persistence of clonal haematopoiesis with some gene variances reported as 'polymorphic' and 'tolerated', considered to represent CHIP (*Genovese et al., N Engl J Med 2014; McKerrell et al., Cell Reports 2015; Steensma et al., Blood 2015)*. None of the AML 'driver type' variances seen at diagnosis were detected in the CR samples. Certain variances (in order of frequency) in *DNMT3A, TET2, CBLB, ASXL1, ZRSR2, SRSF2, BCORL1, CEBPA, CUX1, CARL, ETV6, CBLC, ABL1* and *HRAS* genes were found to form three distinct patterns in CR: a) expansion of novel variances concurrent to the persistent diagnostic gene profile (10/20), b)

persistence of unique variances seen at diagnosis without novel additions (9/20) and c) no gene variances present after chemotherapy (1/20). Two out of 10 patients from group (a) relapsed during the follow up period with reappearance of the initial *FLT3_ITD* bearing clone or occurrence of a novel *IDH1* variance (p.R132C) respectively, while the rest remained in CR. Interestingly, a patient with a missense *TP53* variance (*Protein var: NP_000537.3: p.Cys238Tyr*) at diagnosis had a clearance of this *TP53* AML clone after being treated with LDAC composed regimen.
Summary/Conclusions: We report an expansion of hematopoietic clonal populations in 10 out of 20 patients analysed by target next generation sequencing. These results indicate that cell populations harbouring unique age related variances may have a competitive survival advantage after chemotherapy although the clinical importance this phenomenon requires further investigations. Accidentally we came across a promising treatment with LDAC and aminopeptidase inhibitor for unfit AML patients harbouring the classical TP53 mutation. Our findings are in alignment with recent studies showing persistence of clonal haemopoiesis in AML during CR, which warrants the need to monitor residual disease using appropriate gene panel.

E880

IDENTIFICATION OF NOVEL PUTATIVE SNORNAS IN AML PATIENT SAMPLES

D Gerloff[1,*], C Rohde[1], F Zhou[1], C Pauli[1], M Köhn[2], D Misiak[2], KK Knut Krohn[3], S Hüttelmaier[2], C Müller-Tidow[1]
[1]Department of Internal Medicine IV, Hematology and Oncology, University Hospital Halle, [2]Section for Molecular Cell Biology, Institute of Molecular Medicine, Martin-Luther-University Halle, Halle, [3]Interdisciplinary Centre for Clinical Research, University of Leipzig, Leipzig, Germany

Background: Small nucleolar RNAs (snoRNAs) are a large group of non-coding RNAs. Mostly snoRNAs are located in introns of host genes. They are highly abundant in eukaryotes and are divided into two major families, box C/D and box H/ACA snoRNAs, based of common sequence motifs and structural features. The box C/D snoRNAs carry the conserved boxes C (RUGAUGA, R=purine) and D (CUGA) near their 5' and 3' ends, respectively. The H/ACA box snoRNAs consist of two hairpins and two short single-stranded regions, which contain the H box (ANANNA) and the ACA box. snoRNAs guide small nucleolar ribonucleoproteins (snoRNPs) to complementary regions of ribosomal (rRNA) or small nuclear RNAs (snRNA), where the snoRNP complexes catalyze ribosomal modifications. Recent studies showed the relevance of snoRNAs for the pathogenesis of cancer.
Aims: Identification and analysis of unknown snoRNAs in AML.
Methods: To understand the role of snoRNAs in leukemogenesis, we analyzed the snoRNA expression pattern of 63 AML patients, registered in a recent clinical trial (ClinicalTrials.gov NCT00915252). RNA was isolated with Qiagen miRNeasy Kit. Librarys for small RNA specific next generation sequencing (NGS) were prepared with TruSeq Small RNASample Prep Kit and size separation of 40-200 nucleotides. NGS was performed on an Illumina HiScanSQ, using 50 cycles of single read sequencing. Sequencing data were processed with Cutadapt, mapped with Bowtie 2 to the human genome (hg19). Abundant regions were detected with Bedtools genomeCoverageBed and were annotated using snoRNABase (LBME), DASHR, UCSC snoRNA and repeatmasker track. For further analysis reads of discovered regions were calculated as reads per million (RPM). Regions without annotation were analyzed for C/D box motifs to discover putative C/D box snoRNAs.
Results: Next generation sequencing data revealed that 229 of the 269 known C/D box snoRNAs (85%) were expressed in one or more patient samples. For the H/ACA box snoRNAs we could identify 90 of 112 (80%). In addition we found 1396 mapped regions, which could not be annotated as known small noncoding RNAs. *In silico* analysis identified 90 putative C/D box snoRNAs. All of these putative snoRNAs contain the box C/D motifs and were mostly located in introns of known genes. In further analysis we compared clinical data and snoRNA expression pattern. Here we found that expression of the known snoRNAs clustered with specific risk groups. High levels of snoRNA expression are associated with intermediate molecular risk grouped patients (269 snoRNAs, $p \leq 0.05$) and a poor response to chemotherapy (101 snoRNAs, $p \leq 0.05$). Likewise, increased expression of putative snoRNAs was found in patients with an intermediate molecular risk (51 snoRNAs, $p \leq 0.05$) and in patients with a bad response to chemotherapy (20 snoRNAs, $p \leq 0.05$). To investigate putative snoRNAs during myeloid differentiation we treated HL60 cells with 1µM all-transretinoic acid (ATRA) and analyzed their expression (d0 *vs* d6). In the HL60 cells we could recover 83 putative snoRNAs out of 90 we found in the patient samples. The data show that 45 putative snoRNAs were downregulated (<0.7) while 17 putative snoRNAs were upregulated (>1.3) during myeloid differentiation. To analyze the binding of 8 putative snoRNA candidates to the snRNP complex we performed NOP58 and FBL specific RNA immunoprecipitation (RIP) in Kasumi-1 cells. Here, we could show an enriched binding of 2 putative snoRNAs to FBL and NOP58.
Summary/Conclusions: In summary, our data show that snoRNAs may contribute to neoplastic transformation. Further we identified novel unknown snoRNAs, which will be further analyzed.

E881

INHIBITION OF CXCR4 BY THE HIGH AFFINITY ANTAGONIST BL-8040 IN AML DOWNREGULATES BCL-2 THROUGH REGULATION OF MIR-15A/16-1 EXPRESSION

M Abraham[1,*], S Klein[2], B Bulvik[3], H Wald[1], O Eizenberg[1], D Holam[2], L Weiss[2], K Beider[4], O Wald[2], S Bulvik[5], A Avigdor[4], O Benjamini[4], E Galun[2], A Nagler[4], Y Pereg[6], A Peled[2]
[1]Biokine Therapeutics, Biokine Therapeutics Ltd, Rehovot, [2]Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, [3]Biokine Therapeutics, Weizman Science Park, Rehovot, [4]Hematology Division, Chaim Sheba Medical Center, Tel-Aviv, [5]Hematology Department, Laniado Hospital, Netanya, [6]BioLineRx Ltd, BioLineRx Ltd, Tel-Aviv, Israel

Background: Acute Myeloid Leukemia (AML) is a heterogeneous group of diseases characterized by uncontrolled proliferation and survival of hematopoietic stem and progenitor cells. The chemokine CXCL12 and its receptor CXCR4 are key players in the retention of AML blasts in the protective bone marrow (BM) microenvironment. The CXCL12/CXCR4 axis is also critical for the survival and maintenance of AML blasts in their stemness state. CXCR4 overexpression is associated with poor prognosis in AML patients. Signaling activated through CXCR4 was shown to be detrimental by increasing survival of tumor cells and promoting resistance to therapy.
Aims: We have studied the effect of the CXCR4-antagonist, BL-8040 on the survival of human AML blasts and investigated the molecular mechanism by which inhibition of CXCR4 signaling leads to leukemia cell death.
Methods: Human AML cell line and human primary AML samples were used for in vitro studies. The in-vivo effect of BL-8040 was tested using MV4-11, U-937, THP-1 and human primary AML cells engrafted in NOD scid gamma (NSG) mice.
Results: We found that the human AML cells MV4-11, THP-1, U-937, and human primary AML cells express high levels of CXCR4. The CXCR4 antagonist, BL-8040 was found to induce apoptosis of the tested AML cells in-vitro and in-vivo. Survival of tested AML cells was found to be dependent on BCL-2 as demonstrated by the ability of the BCL-2 inhibitor, ABT-199 to induce dose dependent apoptosis in vitro. Interestingly, treatment of AML cells with BL-8040 reduced the expression of BCL-2 together with inhibition of the ERK signaling pathway. BL-8040 dependent reduction in BCL-2 expression was associated with increased expression of miR-15a/16-1. In addition to BCL-2, increased expression of miR-15a/16-1 reduced the expression of MCL-1 and cyclin D, its other target genes. Interestingly, these effects were not observed following stimulation with the CXCR4 antagonist, AMD3100. In support of these results overexpression of miR-15a/16-1 in AML cells was shown to induce their apoptosis. In the MV4-11 in-vivo AML model, when BL-8040 was administrated for 7 constitutive days we observed decreased number of AML cells accompanied with apoptosis in BM, Spleen and blood. Following one or two injections of BL-8040 apoptosis of AML blasts was observed together with upregulation of miR-15a/16-1 and decrease of BCL-2, only in the spleen. Importantly, Human AML cells engrafted to the spleen expressed lower levels of BCL-2 as compared to AML cells in the BM suggesting that the BM required prolonged inhibition in order to overcome the high levels of BCL-2 in this microenvironment.
Summary/Conclusions: Our results demonstrate that CXCR4 signaling regulates the expression of miR-15a/16-1 and their target genes BCL-2, MCL-1 and cyclin-D1. Furthermore, these results indicate that the CXCR4 antagonist, BL-8040 may tip the balance toward cell death by down- regulating survival signals through miR-15a/16-1 pathway and inhibition of the ERK signaling cascade in AML cells.

E882

AML ORCHESTRATES MITOCHONDRIAL METABOLISM IN BONE MARROW MESENCHYMAL STROMAL CELLS THROUGH AN INCREASE OF PGC-1A

C Marlein[1,*], L Zaitseva[1], K Bowles[1,2], S Rushworth[1]
[1]Department of Molecular Haematology, University of East Anglia, [2]Department of Haematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: Acute Myeloid Leukaemia (AML) is biologically a heterogeneous disease which results from defects in haematopoiesis, characterised by the accumulation of haematopoietic myeloid cells in the bone marrow. Although there have been advances in the treatment of the disease, AML remains incurable for at least 80% of patients. It has been shown that AML cells have an increased mitochondrial mass and higher levels of oxidative phosphorylation (OXPHOS) compared to normal CD34+ cells, suggesting a dependency of OXPHOS for AML survival. Little is known about the mitochondrial activity of bone marrow mesenchymal stromal cells (BM-MSC), which provide a supportive environment for AML cells in the bone marrow.
Aims: Therefore the aim of this study is to determine if there is an increase in mitochondrial respiration in BM-MSCs from AML patients (AML BM-MSCs) compared to non-AML patients (normal BM-MSCs) and to understand how the difference is regulated.
Methods: Primary AML blasts were obtained from patient bone marrow. Primary AML and normal BM-MSCs were isolated from patients bone marrow, with informed consent and under approval from the UK National Research

Ethics Service (LRCEref07/H0310/146), using adherence. BM-MSC were characterised using flow cytometry for expression of CD90+, CD73+, CD105+ and CD45-. Mitochondrial respiration and glycolysis rates were measured using the Seahorse XF24 extracellular flux analyser. RT-qPCR and western blotting were used to determine peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α) expression and regulation. Lentiviral mediated knockdown was also used.
Results: Our results show that AML BM-MSCs have an increased ATP production after 3 days compared to normal BM-MSCs. AML BM-MSCs also show an increased oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) compared to normal BM-MSCs. This demonstrates not only an increase in mitochondrial respiration but also increased glycolysis, which correlates with the increased ATP production of the AML BM-MSCs compared to normal BM-MSCs. Mitochondrial respiration and glycolysis increase in AML BM-MSCs after co-culture with primary AML cells. This suggests that exposure to AML cells cause the increased mitochondrial respiration and glycolysis observed in the AML BM-MSCs. There is differential expression of PGC-1α mRNA and protein in AML BM-MSCs after co-culture with AML cells, suggesting regulation of mitochondrial respiration through PGC-1α.
Summary/Conclusions: These results provide evidence of an increased mitochondrial respiration and glycolysis in the AML BM-MSCs compared to the normal BM-MSCs and that the difference is orchestrated by the AML cells. In addition this difference is regulated through PGC-1α, the master regulator of mitochondrial biogenesis. We hypothesise that therapeutic intervention targeting mitochondrial activity in the AML micro-environment would make AML more susceptible to current treatment regimes.

E883

PML-RARA REGULATES AKT THROUGH HSP90 INHIBITION IN APL BLASTS

N Noguera[1,2,*], ML Piredda[1,2], G Gaur[1,2], M Divona[1], G Catalano[1], MT Voso[1], F Lo_Coco[1,2]
[1]Biomedicine and Prevention, Tor Vergata University, [2]Neuro-Oncohematology, Santa Lucia Foundation, Rome, Italy

Background: HSP90s are molecular chaperons required for conformational stabilization and trafficking of over 400 documented client proteins involved in cell growth, maturation and apoptosis. The HSP90β isoform is constant ubiquitously, whereas α/α1 isoforms are inducible, prone to increase in stress conditions. Functional Hsp90 is required for the stability of the AKT, serine - threonine kinase, which is phosphorylated in response to growth factor stimulation. Activated AKT migrates transducing the signal to over 130 substrates in the cytoplasm and nucleus playing a crucial regulatory role in cell differentiation, cell cycle, transcription, translation, metabolism and apoptosis. In acute myeloid leukemia (AML) higher levels of HSP90s have been associated with poor prognosis.
Aims: The aim of this work is to comprehensively analyze the involvement of HSP90 in pathogenesis of APL.
Methods: Seventeen APL and 22 unselected AML patients were analyzed by quantitative PCR to measure *HSP 90* mRNA expression levels. HSP90 protein levels were also analysed in 21 AML and 20 APL cases using Western Blot. In addition, HSP90 protein levels were studied in: I) PR9 cells, a Zn inducible PML/RARA cell line; II) APL patient primary blasts and PML/RARA expressing NB4 cells after treatment with ATRA. ChIP-qPCR was used to scan HSP90 regulatory sequences for the presence of PML-RARα protein. AKT mRNA and protein levels were analysed in 16 APL and 10 AML patients. *AKT* mRNA and AKT phosphorylation levels were studied in PR9 cells line plus Zn and in NB4 cells treated with 17AAG, ATRA or both. AKT half-life and ubiquitinilation levels were study using Hek293T cells transfected with PML-RARα. Localization of Hsp90 and AKT were analysed using a Confocal microscopy in PR9 cells line plus Zn.
Results: We observed a significantly lower expression of HSP90 and AKT in primary APLs, as compared to other AMLs. In vitro treatment of the NB4 cell line with ATRA upregulated HSP90s and AKT protein levels. Inhibition of HSP90 function by the 17 AAG inhibitor induced a decline of AKT and nullified the effect of ATRA indicating that HSP90 action is necessary for AKT stability. Using an inducible PML/RARα model (PR9 cell line) we observed a decline of HSP90 mRNA and protein starting at 2/4 hours, corresponding to the expression peak of the hybrid protein. AKT protein, but not mRNA, declined to 30% at 24 hours. Using confocal microscopy we observed the translocation to the cytoplasm of co-localized HSP90 and AKT proteins, 8 hours after PML/RARα induction. In Hek293T cells transfected with PML-RARα we observed ubiquitination and down-regulation of AKT. ChIP assays showed the binding of PML-RARα to the HSP90-α and β promoter regions, resulting in downregulation of expression, effect reverted by ATRA. We further detected an increase in acetylation of the DNA promoter region of the two isoforms of HSP90 after treatment of NB4 cells with ATRA, suggesting that PML-RARα inhibits HSP90s expression at the transcriptional level probably through recruitment of the HDAC-repressor complex NCOR.
Summary/Conclusions: In summary, repression of HSP90 expression by PML/RARA is associated in APL cells with loss of specific function in controlling AKT protein phosphorylation, intracellular trafficking and stability.

E884

RUNX1-MUTATED AML SHOW A HIGH FREQUENCY OF TRISOMY 8 AND TRISOMY 13 AND ARE ASSOCIATED WITH MUTATIONS IN ASXL1 AND COMPONENTS OF THE RNA-SPLICING MACHINERY

A Stengel[1,*], W Kern[1], M Meggendorfer[1], K Perglerovà[2], T Haferlach[1], C Haferlach[1]
[1]MLL, Munich Leukemia Laboratory GmbH, Munich, Germany, [2]MLL2, Praha, Czech Republic

Background: Mutations in *RUNX1* have been reported in 5 to 20% of AML. A detailed cytogenetic and molecular genetic analysis of *RUNX1*-mutated AML has not been performed yet.
Aims: 1. Comprehensive cytogenetic and molecular genetic characterization of AML with *RUNX1* mutations. 2. Analysis of potential impact of the respective markers on prognosis.
Methods: The cohort comprised 140 cases of AML with *RUNX1* mutations (95 male, 45 female). Median age was 67 years (range: 18-87 years). All patients were investigated using chromosome banding analysis (CBA). Mutation analyses by amplicon sequencing were performed for *ASXL1, BCOR, CBL, CEBPA, DNMT3A, ETV6, EZH2, FLT3*-ITD, *FLT3*-TKD, *GATA2, IDH1, IDH2, KIT, KRAS, MLL*-PTD, *NPM, NRAS, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1* and *WT1*. Variants of unknown significance were excluded from statistical analysis.
Results: CBA revealed a normal karyotype in 83/140 (59%) and an aberrant karyotype in 57/140 (41%) of patients: 37 (27%) cases harbored trisomies, 20 cases (14%) showed other aberrations. In more detail, +8 was detected in 17 cases (12%), followed by +13 (11 cases, 8%), +11 (4 cases, 3%) and +14 (4 cases, 3%). No other recurrent abnormalities were observed. A complex karyotype (>3 abnormalities) was not detected. The highest mutation frequency was observed for *ASXL1* (42%), followed by *SRSF2* (36%), *BCOR* (21%), *FLT3*-ITD (18%), *TET2* (18%), *IDH2* (17%) and *U2AF1* (16%). Mutation frequencies >5% were also detected for *DNMT3A* (14%), *MLL*-PTD (14%), *NRAS* (13%), *WT1* (12%), *IDH1* (9%), *SF3B1* (9%) and *CEBPA* (5%). Thus, mutations in genes coding for components of the RNA-splicing machinery were detected in 89 patients (64%). No *CEBPA* double mutations were identified. Totally, sequencing revealed 463 mutations in addition to *RUNX1* (mean number of additional mutations per patient: 3). In detail, 3 patients (2%) showed no, 18 (13%) one, 44 (31%) two, 43 (31%) three, 22 (16%) four, 9 (6%) five and 1 (1%) six concomitant mutations. Thus, in 98% of patients at least one molecular mutation additional to *RUNX1* was observed. Correlation analyses between cytogenetic and molecular genetic markers revealed a strong association of trisomies with mutations in splicing factor genes (spliceosome mutations in patients with *vs* without trisomies: 33/37 (89%) *vs* 55/103 (53%), p<0.001). Additionally, cases with +8 correlated with *ASXL1* mutations (*ASXL1*mut in patients with *vs* without +8: 11/17 (65%) *vs* 45/122 (37%), p=0.036). An association was revealed for a normal karyotype (NK) with mutations in *FLT3*-ITD (with NK: 20/83 (24%) with *FLT3*-ITD; without NK: 5/57 (9%) with *FLT3*-ITD, p=0.024). In the total cohort, median overall survival (OS) was 29 months. An aberrant karyotype had no influence on OS. However, mutations in *U2AF1* and *NRAS* both were associated with a significantly shorter OS (median OS, for *U2AF1* mutated *vs* unmutated, 21 *vs* 33 months; p=0.039; for *NRAS* mutated *vs* unmutated, 12 *vs* 31 months, p=0.026) and in patients with ≥3 accompanying mutations (≥3 *vs*<3 mutations, 20 *vs* 57 months, p=0.002).
Summary/Conclusions: *RUNX1*-mutated AML show a NK or specific cytogenetic abnormalities (+8 or +13) and a lack of a complex karyotype. Moreover, they depict a typical pattern of additional molecular mutations with a high frequency of *ASXL1* mutations and mutations in spliceosome genes (especially *SRSF2* and *U2AF1*), which according to Lindsley et al. (Blood 2015) is specific for secondary AML. Further, no entity-defining genetic abnormalities were observed. Thus, *RUNX1*-mutated AML might qualify for a separate entity.

E885

REACTIVE OXYGEN SPECIES (ROS) MODULATES SENSITIVITY TO FLT3-TYROSINE KINASE INHIBITORS IN MURINE AND HUMAN FLT3-ITD POSITIVE AML CELL LINES

C Mueller[1,*], L Simeoni[2], F Heidel[1], B Schraven[2], T Fischer[1]
[1]Department of Hematology and Oncology, [2]Institute for Molecular and Clinic Immunology, University Clinic Magdeburg, Magdeburg, Germany

Background: FLT3-ITD positive acute myeloid leukemia (AML) is characterized by an increased concentration of intracellular ROS and high extracellular concentrations of hydrogen peroxide (H_2O_2). Increased ROS levels regulate numerous cellular processes, such as cell cycle, apoptosis, metabolism and drug resistance. Interestingly, in leukemia driven by other oncogenes (e.g. Bcr-Abl) it has been described that modulation of ROS may improve the response to selective tyrosine kinase inhibitor (TKI) treatment. Some pathways, including STAT5/NOX4, have been reported to induce high ROS levels in FLT3-ITD-positive AML. However, it is unclear how FLT3-ITD positive AML cells modulate their cellular functions and/or drug resistance by auto-/paracrine ROS species. In addition, in leukemia driven by other oncogenes (e.g. Bcr-Abl) it has been described that modulation of ROS may improve the response to selective tyrosine kinase inhibitor (TKI) treatment.

Aims: Our goal was to identify the auto-/paracrine effects of hydrogen peroxide on proliferation and cell cycle progression in FLT3-ITD positive murine and human cell lines. In addition, we aimed to characterize the effects of H_2O_2 modulation with respect to the sensitivity to TKI treatement as a possible resistance-inducing factor.
Methods: Murine (32D, BaF3) and human (MOLM-13, MV4-11) FLT3-ITD positive cell lines were analyzed for intracellular ROS levels using H_2DCFD, extracellular H_2O_2 concentration and activities of the scavenging enzymes SOD1, SOD2, catalase, and glutathione peroxidase (GPx). For the analysis of the role of extracellular H_2O_2, cells were incubated directly with H_2O_2 (10 µM) for 2h and assayed for the activation of FLT3-ITD-dependent signaling pathways (STAT5, Akt and Erk) using immunoblotting. For the analysis of the effects of H_2O_2-generating enzyme glucose oxidase and of the H_2O_2-degrading enzyme catalase, cells were cultured for 48h and assayed for proliferation (MTT) and cell cycle progression (PI). Furthermore, the effect of extracellular H_2O_2 concentration on TKI treatment (AC220, PKC412; each 5 to 50 nM) was analyzed by FACS.
Results: Stimulation of FLT3-ITD positive cells using H_2O_2 resulted in a strongly increased time-dependent activation of FLT3-ITD-associated signaling pathways (STAT5, Akt, Erk) as compared to untreated cells. This difference was more pronounced in ITD-positive cells in comparison to WT cells particularly for AKT activation. In addition, stimulation with H_2O_2 also increased the activities of SOD1/2 and catalase. The long-term increase in extracellular H_2O_2 concentration was mimicked experimentally by addition of glucose oxidase to the culture medium (0.75 U/ml). Interestingly, this resulted in enhanced proliferation and cell cycle progression, whereas cultivation with catalase led to decreased proliferation and cell cycle arrest. Combined treatment with catalase and TKIs (AC220, PKC412; 5 and 10 nM, respectively) resulted in a significantly higher rate of apoptosis. Of note, the response to both TKIs was significantly reduced when glucose oxidase (0.75 U/ml) was added to the medium. The decrease in apoptosis was associated with stabilization of the mitochondrial potential (TMRE assay), stable expression of the anti-apoptotic proteins Mcl-1 and Bcl-XL, and a reduced cleavage of caspase 3 and caspase 8.
Summary/Conclusions: Our results strongly suggest that H_2O_2 acts as an auto-/paracrine stimulator of proliferation and cell cycle progression in FLT3-ITD positive cells. Furthermore, we could characterize H_2O_2 as a regulatory element with respect to TKI sensitivity. Our results indicate that combined inhibition of FLT3-ITD and H_2O_2 reducing agents/enzymes, like catalase, may have potential clinical application in treatment of FLT3-ITD positive AML patients.

E886

COMBINING DOT1L INHIBITOR EPZ-5676 WITH SORAFENIB TO TREAT MLL-REARRANGED (MLL-R) PEDIATRIC ACUTE MYELOID LEUKEAMIA (AML)

A Lonetti[1,*], R Masetti[2], SN Bertuccio[2], S Serravalle[2], A Astolfi[3], A Bertaina[4], F Locatelli[4], AM Martelli[1], A Pession[2]
[1]Department of Biomedical and Neuromotor Sciences, [2]Department of Pediatrics, "Lalla Seràgnoli" Hematology-Oncology Unit, [3]Giorgio Prodi Cancer Research Centre, University of Bologna, Bologna, [4]Department of Pediatric Hematology-Oncology, IRCCS, Bambino Gesù Children's Hospital, Roma, Italy

Background: About 20% of the childhood AML present MLL gene translocations, that are associated with a very poor prognosis. That is why there is a strong interest in developing novel therapeutic strategies for these patients. As DOT1L is responsible for H3K79 methylation and is associated with MLL-r leukemogenesis, DOT1L inhibitors entered in clinical trials as promising treatments. MLL-r AML also showed an overexpression of FLT3 receptor tyrosine kinase. Therefore, FLT3 inhibitors, such as the multi-tyrosine kinase inhibitor Sorafenib, demonstrated encouraging efficacy in AML.
Aims: To investigate the efficacy of a combination treatment using DOT1L inhibitor EPZ-5676 and Sorafenib to treat MLL-r AML.
Methods: MLL-r (MOLM13, NOMO1, THP1) and non MLL-r (OCI-AML3, HL60 and U937 harboring CALM-AF10 translocation) AML cell lines, and MLL-r primary samples from pediatric AML patients were used. Flow cytometry analyses were performed to assess absolute cell counting and apoptosis (AnnexinV FITC/PI staining). Protein expression and H3K79 methylation were quantified by Western blot. mRNA expression was studied by quantitative Real-Time PCR (Q-PCR).
Results: Firstly, the specific effects of DOT1L inhibition were examined in AML cell lines treated with increasing concentrations of EPZ-5676, up to 18 days. Cell growth was significantly inhibited after at least 8 days of treatment in MOLM13 and NOMO1 cells, but time-dependent apoptosis occurred only in MOLM13, thus suggesting that DOT1L inhibition alone might not be able to induce cytotoxicity. Whereas no effects were observed in HL60, U937 (non MLL-r), or THP1 (MLL-r) cells, both cell growth impairment and apoptosis were detected in non MLL-r OCI-AML3 cells, so that the impact of DOT1L inhibition could not exclusively rely on MLL rearrangements. Repression of DOT1L occurred since the 4th day of treatment, as demonstrated by the complete loss of H3K79me2. To further explore the consequence of this phenomenon, both MLL targets and key component of signaling pathways involved in AML survival (i.e. PI3K, FLT3 and MAPK) were investigated in cells treated with 1 uM EPZ-5676, up to 28 days. Gene expression of *HOXA9*, *MEIS1*, *FLT3* and CDK6 protein (MLL target) decreased in all cell lines, whereas *STAT5* and c-*Myc* mRNAs, along with STAT5 protein expression, were downregulated only in MLL-r cells. Furthermore, in MOLM13 and NOMO1 cells p-Erk was strongly reduced. Finally, p-Akt slightly decreased in nearly every case, whereas a strong induction in p-S6RP was observed only in U937 cells after prolonged treatment, suggesting the possible involvement of PI3K pathway in drug resistance mechanisms. To increase the benefit of DOT1L inhibition, both AML cell lines and MLL-r primary samples were pretreated with increasing concentration of EPZ-5676 for 4/8 days, following 24/48h treatment with Sorafenib. This combination resulted in a synergistic effect in nearly all cases. Importantly, EPZ-5676 pretreatment increased Sorafenib-induced cell growth inhibition in EPZ-5676 refractory cells HL60, U937 and THP1. Moreover, in primary AML samples both EPZ-5676 and Sorafenib showed a limited effect as single agent, whereas their combination induced a drastic increase of apoptosis.
Summary/Conclusions: These results demonstrated that the single administration of EPZ-5676 has a limited antileukemic activity, which is not restricted to MLL-r AMLs. However, the combination of EPZ-5676 with Sorafenib revealed a synergistic effect in both MLL-r and non MLL-r AMLs, paving the way to innovative and more effective treatments for pediatric AML patients.

WHOLE EXOME SEQUENCING IDENTIFIES NOVEL MUTATIONS IN RELAPSED OR REFRACTORY ACUTE PROMYELOCYTIC LEUKAEMIA (APL) UNRESPONSIVE TO ORAL ARSENIC TRIOXIDE

HS Gill[1,*], HW Ip[2], J Li[3], RLH Yim[1], G Panagiotou[3], AYH Leung[1], YL Kwong[1]
[1]Department of Medicine, [2]Department of Pathology, [3]School of Biological Sciences, The University of Hong Kong, Hong Kong, Hong Kong

Background: Arsenic trioxide (As_2O_3)-based regimens induce remissions in >90% of relapsed APL. Further relapses after As_2O_3-induced remissions portend a poor prognosis. With the use of As_2O_3 in frontline treatment of APL, relapses in patients previously treated with As_2O_3 resulting in arsenic resistance is an emerging clinical problem. There is a paucity of information on the molecular mechanisms of As_2O_3-resistance.
Aims: To determine mutations associated with As_2O_3-resistance with whole exome sequencing (WES).
Methods: Seven patients with prior As_2O_3 treatment, who had ≥2 subsequent relapses occurring during or refractory to As_2O_3 treatment, were assigned to the discovery cohort. Serial bone marrow (BM) samples that were arsenic-sensitive (taken before treatment in a relapse responding to As_2O_3) and arsenic-resistant (obtained in subsequent relapses refractory to As_2O_3) underwent WES the illumina HiSeq 1500 platform at an average depth of 100X. Exome data were analysed utilizing bioinformatic pipeline programs designed to identify single nucleotide variants (SNVs) that were present either only or at increased frequencies in the resistant samples. The functional significance of non-synonymous missense mutations was evaluated using SIFT, Polyphen2 and FATHMM programs. Putative SNVs were confirmed by Sanger sequencing. Confirmed SNVs were tested in arsenic-resistant BM samples obtained from a validation cohort of 22 relapsed patients previously salvaged with As_2O_3, who had subsequent As_2O_3-refractory relapse again. Clinicopathologic features, karyotype, *FLT3* and *PML-RARA* mutations were determined in the validation cohort.
Results: In the discovery cohort, serial WES showed following confirmed SNVs of potential functional significance showed increased allele frequency during As_2O_3-resistance: *NOTCH2, FOXD4L5, KCNJ11/18, MADCAL1, CBR3, NSD1, FLG1, CCCDC179, SIGLEC11, ROBO4, CISD2, WT1, PTCH1, KMT2D and MED17*. *PML* B2 domain mutations were not seen. The frequencies of the mutations were validated in a cohort of 22 patients with relapsed or refractory APL following oral As_2O_3-based treatment. The recruited patients comprised 14 men and 8 women with a median age of 44.5 (range:24-76) years at relapse. 1 (5%) patient had microgranular variant of APL while 2 patients (9%) had therapy-related APL. Additional karyotypic abnormalities were seen in 3 (14%) patients.14 patients (64%) had central nervous system (CNS) involvement at relapse. Internal tandem duplication of *FLT3* (*FLT3*-ITD) was detected in 7 (32%) patients. The following recurrent mutations were found in As_2O_3-refractory relapse BM samples: *NOTCH2* (n=17, 77%), *FOXD4L5* (n=22, 100%), *KCNJ11/18* (n=14, 64%), *MADCAM1* (n=15, 68%), *CBR3* (n=17, 77%), *NSD1* (n=17, 77%), *FLG1* (n=20, 91%), *CCCDC179* (n=7, 32%), *SIGLEC11* (n=5, 23%), *ROBO4* (n=3, 14%), *CISD2* (n=3, 14%), *WT1* (n=1, 5%), *PTCH1*(n=1, 5%), *KMT2D* (n=1, 5%) *and MED17* (n=6, 27%).
Summary/Conclusions: Mechanisms other than *PML* B2 domain mutations may account for As_2O_3 resistance. Novel genes regulating the cell signaling and apoptotic pathways, cellular proliferation, histone modification, DNA repair and angiogenesis were frequently mutated in As_2O_3-refractory APL. Further functional validation on the role of these mutations in conferring As_2O_3 resistance is required.

E888

MOLECULAR LANDSCAPE OF PRIMARY AND RELAPSED ACUTE PROMYELOCYTIC LEUKEMIA

A Fasan[1,*], C Haferlach[1], K Perglerová[2], W Kern[1], T Haferlach[1]

[1]MLL Munich Leukemia Laboratory, Munich, Germany, [2]MLL2 s.r.o., Praha, Czech Republic

Background: Acute promyelocytic leukemia (APL) with t(15;17)(q22;q12)/*PML-RARA* accounts for ~5% of adult AML. Two therapeutic agents, ATRA and arsenic trioxide (ATO), induce differentiation of promyelocytes in vivo resulting in complete remission. However, some patients still relapse after ATO-ATRA based treatments and the mechanisms associated with resistance to these agents are still poorly understood.
Aims: The evaluation of the mutational spectrum of APL both at initial diagnosis and relapse.
Methods: We analyzed a cohort of 124 de novo APL cases including 14 cases who showed hematologic or molecular relapse. All patients (pts) were proven to have t(15;17)(q22;q12)/*PML-RARA* by chromosome banding analysis (CBA) (n=114), fluorescence in situ hybridization (n=120) and/or RT-PCR (n=124). 69 pts were male and 55 pts were female with a median age of 47 years (range: 16-84 years). All 124 samples were analyzed by next generation sequencing (NGS) using a 24-gene panel targeting *ASXL1, CBL, CSF3R, DNMT3A, ETNK1, ETV6, EZH2, FLT3*-TKD*, GATA2, IDH1, IDH2, KIT, KRAS, NPM1, NRAS, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, WT1* and *ZRSR2*. *FLT3*-ITD was analyzed by gene scan. Relapse samples were screened for mutations within the *PML-RARA* fusion transcript by direct Sanger sequencing.
Results: Using standard CBA, additional cytogenetic aberrations were observed in 44/114 pts (27%). The most frequent secondary chromosome aberration was +8 (14/44; 32%). Using NGS 77/124 pts (62%) had at least one mutation (mut) in addition to *PML-RARA*, 17/77 (22%) had ≥2 additional mut (maximum: four). Most common were mutations in *FLT3* (*FLT3*-ITD: 47/124, 38%, *FLT3*-TKD: 15/124; 12%) and *WT1* (13/124, 10%). Mutations in other genes (*ASXL1, CBL, DNMT3A, ETV6, KRAS, NRAS, RUNX1, SF3B1* and *TET2)* were found in less than 10% of cases, respectively. Comparing the initial mutational pattern of pts who relapsed during the course of disease with those staying in molecular remission revealed no difference in concomitant molecular mutations. Solely the percentage of pts with concomitant mutations was higher in the relapse group (79% *vs* 60%; n.s.). Survival analysis revealed no influence of concomitant mutations in individual genes on prognosis. Also the amount of additional mutations had no prognostic impact. In selected cases (n=14/124), we compared changes in the patterns of genetic lesions between initial diagnosis and relapse. In 8/14 (57%) pts the initial mutation pattern changed at relapse. Mutations gained at relapse were *WT1* (2/14, 14%) followed by *DNMT3A*, *ETV6*, *FLT3*-TKD, *RUNX1* and *TP53* (each 1/14, 7%). Loss of mutations was observed in *FLT3*-TKD, *WT1* (each 2/14, 14%) as well as in *ASXL1, FLT3*-ITD and *NRAS* (each 1/14, 7%). In 4/14 relapsed pts (29%), mutations within the *PML-RARA* fusion transcript were detected. In none of the cases these mutations were detectable at initial diagnosis and thus all were acquired mutations. Missense mutations in the ligand binding domain of *RARA* were detected in 3 relapsed pts (p.Arg272Gln, p.Arg276Trp and p.Ser287Leu). In one relapsed APL pt, a mutation in the B2 domain of *PML* was observed (p.Ala216His). All mutations occurred in post-ATRA-relapse.
Summary/Conclusions: 1) 62% of APL cases carry additional molecular mutations. 2) The most frequent additional molecular mutation is *FLT3*-ITD (38%) followed by *FLT3*-TKD mutations (12%) and mutations in *WT1* (10%). 3) In 57% of relapsed APL the molecular mutation pattern changes. 4) Acquired mutations within the *PML-RARA* fusion transcript are detected in 29% of relapsed APL patients.

E889

ACTIVATION OF NRF2 IN BONE MARROW MESENCHYMAL STROMAL CELLS MEDIATES SURVIVAL AND CHEMOTHERAPY RESISTANCE IN ACUTE MYELOID LEUKAEMIA BLASTS

N Loughran*, A Abdul-Aziz, M Shafat, K Bowles, S Rushworth
Department of Molecular Haematology, University of East Anglia, Norwich, United Kingdom

Background: The bone marrow microenvironment and the cells with in it play a critical role in acute myeloid leukaemia. NRF2 regulates a range of cytoprotective transcriptional responses and acts as a master regulator of oxidative and electrophilic stress. We have previously shown that NRF2 forms part of a major cell survival pathway in protecting the AML blasts from chemotherapy induced apoptosis. Here we hypothesise that NRF2 also functions to regulate pro-survival factors in Bone Marrow - Mesenchymal Stromal Cells (BM-MSC) from patients with AML and investigate whether targeting NRF2 in the BM-MSC could enhance the efficacy of cytotoxic chemotherapy in AML.
Aims: In this study we aim to characterise the NRF2 signalling pathway in the BM-MSC and investigate how NRF2 signalling regulates oxidative stress in BM-MSC-AML niche.
Methods: Primary AML blasts and BM-MSC were isolated from AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Cytarabine, daunorubicin and hydrogen peroxide (H2O2) were used to induce NRF2 activation in AML blasts and BM-MSC. Annexin V/PI staining was used to determine apoptosis of treated cells. N-acetyl cysteine (NAC) was used to determine the role of glutathione. Cell-Titer Glo assay was performed to determine cell viability. Dichlorofluorescein-H DCFDA (DCF) dye was used to determine levels of reactive oxygen species (ROS). Western blot analysis was used to determine NRF2 expression in drug treated samples.
Results: Results show that AML blasts have increased survival in vitro when co-cultured with BM-MSC. Co-culture with BM-MSC was also shown to confer protection to AML blasts in the presence of daunorubicin, cytarabine and H_2O_2. Lower levels of ROS were observed in the AML blasts after BM-MSC co-culture, as determined by DCF fluorescence. NRF2 in BM-MSC was found to be activated by daunorubicin and cytarabine, as depicted by an increased expression of NRF2 in the nucleus after drug treatment. Moreover depletion of NRF2 in the BM-MSC reduced the protection conferred to the AML cells by the BM-MSC in response to daunorubicin, cytarabine and H_2O_2. Furthermore, the addition of NAC was shown to decrease AML blast apoptosis in culture in these assays.
Summary/Conclusions: These results demonstrate that NRF2 is induced in the non-malignant BM-MSC in response to chemotherapy with the functional consequence of promoting survival in neighbouring AML blasts. We propose targeting the actions of NRF2 in the stromal cells as a novel strategy to increase the tumour cytotoxicity of current drugs used to treat patients with AML.

MICRORNAS HSA-LET-7A AND MIR-142-3P IN T CELLS IN PATIENTS PRESENTING WITH ACUTE MYELOID LEUKAEMIA-A MEANS OF REPAIRING TUMOUR-INDUCED T CELL DEFECTS?

R Petty[1,*], X Zhang[2], C Ivan[2], G Calin[2], J Gribben[1], R Le Dieu[1]
[1]Haemato-oncology, QMUL, London, United Kingdom, [2]Experimental Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Our previous work has shown that the absolute number of T cells is increased in the peripheral blood of patients presenting with Acute Myeloid Leukaemia (AML). These T cells can form conjugates with tumour cells but subsequent immune synapse formation and recruitment of downstream signalling molecules is inhibited. We found an altered T cell gene expression profile indicative of aberrant TCR signalling and T cell activation patterns suggesting a blunted immune response. *We now hypothesize that a means by which these alterations in T cell gene expression are effected is via modulation of microRNA (miRNA) expression*.
Aims: To define miRNA deregulation in peripheral blood T cell populations in patients presenting with AML compared to healthy age-matched individuals.
Methods: In a pilot study, CD4 and CD8 T cells were isolated from stored peripheral blood samples taken from AML patients at diagnosis and pre-treatment (n=3) and age/sex matched healthy volunteers (n=3) by FACS (average purity 98%). All AML patients had intermediate cytogenetic risk. Total RNA was hybridised to custom small RNA microarrays (MD Anderson) containing probes for 18694 human miRNA and 30945 other non-coding RNA species. Duplicate normalized probe intensities were averaged and differentially expressed small RNA were determined by LIMMA (linear models for microarray data) taking a FDR p>0.05 and fold change of +/- 1.5. Unsupervised hierarchical clustering and principle component analysis (PCA) were performed in R studio V3.2.2. Supervised clustering was conducted in Cluster V3.0 and Treeview V1.1.6r4. Identification of targeted mRNA was performed using miRTarBase (www.mirtarbase.mbc.nctu.edu.tw/).

Table 1.

microRNA	T cell Fraction	miRNA fold change	Gene Target	mRNA fold change	Target gene Function
hsa-let-7a-5p	CD4	-1.6	CCND2	2.1	Regulates cell cycle progression
hsa-let-7a-5p	CD4	-1.6	CD86	3.7	Negatively regulates CD25+ (IL-2 receptor)
hsa-let-7a-5p	CD4	-1.6	CDKN1A	2.5	P21-Regulates cell cycle progression
hsa-let-7a-5p	CD4	-1.6	DICER1	2.2	miRNA processing
hsa-let-7a-5p	CD4	-1.6	EIF2C4	2.2	Levels of Ago proteins regulate differentiation and activation of T cells
hsa-let-7a-5p	CD4	-1.6	KRAS	2.4	Regulates signaling downstream TCR activation
hsa-let-7a-5p	CD4	-1.6	MAP2	2.2	Induced by KRAS
hsa-miR-19	CD4	-1.5	MDM4	3	Down-regulates PTEN impairing T cell development
hsa-miR-19	CD4	-1.5	NCOA3	2.4	Histone acetyltransferase
hsa-miR-19	CD4	-1.5	NR4A2	6.5	Induces regulatory T cell phenotype
hsa-miR-19	CD4	-1.5	RAB11	2.1	Lymphocyte trafficking and T cell activation
hsa-miR-19	CD4	-1.5	SOCS3	3	Negative regulator of cytokine signaling
hsa-miR-142-3p	CD4	-1.7	MDM2	3.6	T cell development, reduced at activation, Induces regulatory T cell phenotype
hsa-miR-142-3p	CD4	-1.7	MDM4	6.4	Normal T cell development, Induces regulatory T cell phenotype
hsa-miR-142-3p	CD4	-1.7	RORA	3	Represses IL-2 transcription
hsa-mir-147b	CD4	-1.5	KRAS	2.1	Mediates cellular responses to mitogenic signals
hsa-mir-301a	CD4	-1.6	CDKN1A	2.5	P21-Regulates cell cycle progression
hsa-miR-377-3p	CD4	-1.6	PPM1A	2.6	Represses TGF-beta signalling
hsa-let-7a-5p	CD8	-1.7	CD86	3.3	Negatively regulates CD25+ (IL-2 receptor)
hsa-let-7a-5p	CD8	-1.7	EIF2C4	2	Levels of Ago proteins regulate differentiation and activation of T cells
hsa-let-7a-5p	CD8	-1.7	MAP2	2.3	Induced by KRAS Increased in CD8+ CD1 high cells
hsa-miR-195-5p	CD8	1.6	RUNX3	-2.4	Regulates CD8 maturation
hsa-mir-214	CD8	1.5	LTF	-6.2	Granule component in Neutrophils
hsa-mir-214b	CD8	-1.5	KRAS	2	Regulates signaling downstream TCR activation
hsa-mir-337-3p	CD8	-1.6	STAT3	2.1	Inhibits IL-2 production
hsa-miR-377-3p	CD8	-2	PPM1A	3.1	Represses TGF-beta signalling
hsa-mir-429	CD8	-1.7	RORA	2.3	Represses IL-2 transcription
hsa-mir-455	CD8	-1.6	RORA	2.3	Represses IL-2 transcription
hsa-mir-1224	CD8	-1.6	STAT3	2.1	Inhibits IL-2 production

Results: Hierarchical clustering and PCA of all samples, rather than differentiating samples by T cell population, differentiated AML from healthy controls illustrating that *miRNA expression in T cells is altered by the presence of AML blasts.* Supervised clustering demonstrated 39 miRNA were differentially expressed in AML CD4 T cells - 27 down-regulated, 12 up-regulated and 71 miRNA were differentially expressed in AML CD8 T cells - 41 down-regulated, 30 up-regulated. A number of these miRNA have already been shown to have a role in T cell proliferation and cellular migration. To validate this list, this

dataset was correlated with our previously generated mRNA dataset (independent patient and control cohort) (see Figure). Crucially, *this demonstrates 2 independent datasets showing coordinated deregulation of genes critical to T cell function.* In both CD4 and CD8 cells, up-regulated genes are involved in T cell differentiation and activation (EIF2CA and KRAS) but also paradoxically in inhibition of cytokine production (STAT3 and ZEB1 in CD8 cells and SOCS3 and ZEB1 in CD4 cells) supporting our previous hypothesis of aberrant T cell activation in AML. Two candidate miRNAs whose expression may induce the observed T cell defects are hsa-let-7a-5p and miR-142-3p. *Hsa-let-7a-5p is down-regulated in both CD4 and CD8 cells and has recognised functions in the regulation of T cell proliferation via CDK6 and MYC as well as in Th2 differentiation. miR-142-3p is down-regulated in CD4 cells and its reduced expression inhibits T cell proliferation via HOX10A.*

Summary/Conclusions: These data support the hypothesis that T cell miRNA expression is altered by the presence of AML blasts. This microRNA dataset has been validated against an independent mRNA dataset. Potential miRNA of interest are hsa-let-7a-5p and miR-142-3p as they have fundamental roles in normal T cell function. These findings will now be examined in a larger cohort.

TP-1287, AN ORAL PRODRUG OF THE CYCLIN-DEPENDENT KINASE-9 INHIBITOR ALVOCIDIB

W Kim, K Soh, YS Lee, P Peterson, K Maugham, C Whatcott*, S Weitman, S Warner, D Bearss, A Siddiqui-Jain
Tolero Pharmaceuticals, Inc., Lehi, United States

Background: Alvocidib is a potent inhibitor of cyclin-dependent kinase-9 (CDK9) and induces apoptosis in cancer cells by reducing the expression of short-lived, anti-apoptotic protein such as MCL-1. Alvocidib, used in combination with cytarabine and mitoxantrone, is currently in a Phase II clinical trial in younger relapsed/refractory acute myeloid leukemia (AML) patients to evaluate the utility of a patient selection biomarker, dependent on MCL-1. Patients with AML that have a high dependence on MCL-1 are considered more likely to benefit from the alvocidib-containing regimen. Alvocidib is currently delivered by intravenous infusion which, although an effective delivery strategy, does not allow for chronic dosing and scheduling. An oral form or formulation of alvocidib could greatly expand the utility of the drug in combination with other targeted agents by allowing for more prolonged exposure. Alvocidib is highly permeable in CACO-2 monolayers and is soluble at acidic pH's but solubility is strikingly reduced at neutral or basic conditions, which might hamper the development of an oral formulation.

Aims: We hypothesized that a phosphate prodrug of alvocidib would improve solubility under neutral or basic conditions and enable the efficient systemic delivery of alvocidib via oral administration. We planned to investigate the efficacy of an orally delivered phosphate prodrug using various treatment schedules in AML mouse xenograft models.

Methods: We synthesized TP-1287, a phosphate prodrug of alvocidib, in three steps from the parent compound. The solubility of TP-1287, was determined at various pH's, in water. Pharmacokinetic studies were conducted in mice and efficacy was evaluated in AML xenograft mouse models using various dose levels and schedules. MCL-1 was evaluated as a pharmacodynamic biomarker in tumors from xenografted mice, following treatment with TP-1287.

Results: TP-1287 was found to be highly soluble under acidic, neutral, and basic conditions (1.52 mg/mL at pH 2.2; 1.81 mg/mL at pH 4.5; 9.48 mg/mL at pH 6.8 and 9.31 mg/mL at pH 8.7) compared to alvocidib (4.38 mg/mL at pH 2.2; 1.25 mg/mL at pH 4.5; 0.02 mg/mL at pH 6.8 and 0.02 mg/mL at pH 8.7). Pharmacokinetics studies in mice showed that TP-1287 was efficiently converted to the parent alvocidib (C_{max}=1922.7 ng/ml, $t_{1/2=}$4.4 hr) with high oral bioavailability (%F >100%, compared to intravenous alvocidib). TP-1287 demonstrated significant anti-tumor efficacy in an AML mouse xenograft model and produced a more than two-fold inhibition of the pharmacodynamic biomarker MCL-1 in xenografted tumors, demonstrating a wide, 75-fold therapeutic dosing window.

Summary/Conclusions: The phosphate prodrug of alvocidib, TP-1287, is highly soluble over a broader pH range than alvocidib and is efficiently metabolized to the parent compound *in vivo*. Tumor xenograft models and pharmacodynamic studies indicate that oral delivery of TP-1287 is efficacious in mice. Based on these results, we anticipate moving TP-1287, as an orally delivered CDK9 inhibitor, into a forthcoming clinical trial.

POST-INDUCTION MINIMAL RESIDUAL DISEASE ASSESSMENT BY BOTH MULTIPARAMETER FLOW CYTOMETRY AND RT-PCR PREDICTS OUTCOME IN ACUTE MYELOID LEUKEMIA

C Bories[1,*], F Dumezy[2], O Nibourel[2], G Fouquet[1], EM Boyle[1], A Willaume[1], V Deken-Delannoy[3], B Quesnel[1], C Preudhomme[2], C Berthon[1]
[1]Service des Maladies du Sang, [2]Hématologie cellulaire, CHRU Lille, [3]Unité de biostatistique, MRRC, Lille, France

Background: Minimal residual disease (MRD) assessment is essential during the follow-up of patients with acute myeloid leukemia (AML). Although it is not yet decisional, except in acute promyelocytic leukemia (APL), its evaluation by RT-PCR in AML has already shown a significant impact on survival in AML. Multiparameter Flow Cytometry (MFC) offers another option to monitor MRD, especially for acute leukemias that lack molecular markers. Furthermore, results can be obtained in a shorter timeframes, which could be of great use in the management of AML patients.

Aims: We aim to study MRD assessment by MFC and/or RT-PCR after induction therapy for AML and its impact on outcome.

Methods: Patients were retrospectively included from a database of 182 patients that had at least one MRD assessment for AML during their follow-up from 2005 to 2013. Patients that were diagnosed with AML, who received intensive chemotherapy, that obtained cytologic complete remission after one or two courses of induction-therapy, and that had their initial follow-up in our center were included. Exclusion criteria included APL patients. MRD was assessed by MFC based on leukemia-associated immunophenotype present at diagnosis, including cross-lineage markers and maturation asynchronies. RT-PCR-based MRD was evaluated by quantification of WT1 or NPM1 expression in either blood or bone marrow samples. MRD data were extracted between post-induction hematologic recovery and first consolidation for further analysis. Concordance between MFC and RT-PCR was evaluated for patients who had an MRD evaluation by both methods at the same time. Overall survival (OS) and relapse free survival (RFS) were estimated according to MRD status. OS and RFS were also evaluated after censoring data at the time of stem cell transplant.

Results: 128 patients were eligible. Median age at diagnosis was 52 (range: 16-73). 36 patients had an initial leucocytosis superior to 50G/L. ELN prognostic groups were represented as follow: 36%, 27%, 22% and 15% of patients were classified in the favourable, intermediate-1, intermediate-2 and unfavourable groups respectively. De novo AML represented 118 out of the 128 patients. 60 patients underwent an allograft, 35 at first remission. 111 patients presented at least one MRD assessment, of whom 75 (68%) by MFC and 84 (76%) by RT-PCR (84 on WT1 and 26 on NPM1 expression). Concordance between both methods was relatively good since results were consistent with both methods for 35 of 44 samples. Interestingly, discordant samples were found in both ways - negative MCF-MRD with positive RT-PCR-MRD or positive MCF-MRD with negative RT-PCR-MRD.The median follow-up was 53 months. 3 years-OS was 61%. 65 patients (51%) relapsed during their follow-up. 3-years RFS was 42%. Patients with negative MRD (either by MCF or RT-PCR) had a better 3-years OS (68% *versus* 41%, p=0.002) and RFS (51% *versus* 27%, p=0.0045) than patients with positive MRD. Censoring data at the time of stem cell transplant did not impact the significativity of the results. For patients with only RT-PCR MRD assessment, the benefit of negative MRD was also significant on OS (p=0.0027) and RFS (p=0.0005). Considering only patients with MCF MRD assessment (75 patients), MRD had no significative impact on RFS (p=0.09) and OS (p=0.52).

Summary/Conclusions: As previously reported, we found that RT-PCR assessment of MRD is associated with OS and RFS in patients with AML. However only few studies have compared monitoring of MRD by both MCF and RT-PCR at post-induction time. We found a relatively good concordance between both methods. Moreover we showed that using MCF in addition to RT PCR for MRD assessment increased the number of patient that could be monitored at post induction time and was still correlated with outcome.

E893

PHARMACOLOGICAL INHIBITION OF THE PI3K/AKT/MTOR AND NF-KB CANCER PROMOTING PATHWAYS FOR TARGETED TREATMENT OF ACUTE MYELOID LEUKEMIA PATIENTS

AG Deslauriers[1,2,*], K Reckzeh[1,2], A Mosbech[1,2], KD Rasmussen[2,3], K Helin[2,3,4], K Theilgaard-Mönch[1,2,5]
[1]Finsen Laboratory, [2]Biotech Research and Innovation Center (Bric), [3]Centre for Epigenetics, [4]The Danish Stem Cell Centre (DanStem), Copenhagen, Denmark, [5]Haematology, Lund University Hospital, Lund, Sweden

Background: Acute myeloid leukemia (AML) develops as a consequence of genetic aberrations in hematopoietic stem and progenitor cells causing a differentiation impairment and an accumulation of AML blast cells in the bone marrow. This results in bone marrow failure as well as depletion of normal blood cells. Standard treatment remains initial high-dose chemotherapy (anthracycline/cytarabine) and subsequent consolidation therapy (allogeneic transplantation), however AML patients retain a poor median 5-year survival rate, thus there is a need for more effective treatment modalities. Furthermore, due to the tremendous genetic and epigenetic heterogeneity of leukemia, it becomes important to define more personalized treatment schemes. One of the most common genetic aberration in AML is the translocation t(8;21), which forms the fusion protein and core-binding transcriptional repressor AML-ETO encoded by the fusion oncogene RUNX1-RUNX1T1. Using our bioinformatics screening of microarray gene expression datasets, aberrant signaling of the phosphatidylinositol 3-kinase (PI3K)/Akt/mammalian target of rapamycin complex 1 (mTORC1) and NF-kB pathways, involved in proliferation and survival advantages, has been identified as a causative agent of malignant transformation in t(8:21) AML patients.

Aims: The aim of this study was to use gene expression signatures associated with the t(8;21) AML subtype in order to define specific targets and evaluate the anti-leukemic activity of selected small molecule inhibitors against these targets, in a personalized treatment strategy. More specifically, the objective was to determine if a combinatorial treatment targeting the PI3K/Akt/mTOR and NF-kB pathways can block leukemic cell proliferation compared to normal cells, using a t(8;21)/TET2$^{-/-}$ AML model. AML-ETO has been shown not to be sufficient to induce leukemia and is often associated with other dominant negative mutations acquired in early progenitors, such as TET2, a methylcytosine dioxygenase, which is represented by our murine model.
Methods: The small molecule inhibitors GDC-0941, NVP-BEZ235, IKK-16, and BAY 11-7082, were used to investigate their effects on cellular proliferation in assays supporting clonogenic growth. For this, GFP^{+}-sorted murine t(8;21)/TET2$^{-/-}$ cells and normal wild type bone marrow cells were plated in semi-solid methylcellulose, in parallel. Colony formation was evaluated after treatment with the inhibitors, either individually or in combination. Furthermore, pathway blockade was evaluated using specific biomarkers, protein phosphorylation and transcription factor translocation.
Results: In our study, we demonstrate that the small molecule inhibitors inactivated their respective targeted pathways, seen through specific biomarker analysis, and inhibited cellular growth and survival of the human t(8;21) leukemic cell line Kasumi-1. Furthermore, the *in vitro* assays supporting clonogenic growth of our murine t(8;21)/TET2$^{-/-}$ AML cells showed that the small molecule inhibitors hindered colony formation in a dose dependent manner, while combinatorial inhibition of PI3K/Akt/mTOR and NF-kB showed synergistic inhibition.
Summary/Conclusions: This study demonstrates that dual targeted therapy against the PI3K/mTOR axis and NF-kB signalling, may represent a novel therapeutic modality for t(8;21) AML. It also showed that identification of specific drivers of AML subtypes can be targeted in a personalized fashion, which could potentially be used in combination with standard chemotherapeutic regimens in order to reduce patient relapse and adapt treatment depending on AML subtype.

NPM1 MUTATION AND FLT3/ITD IN A DOUBLE TRANSGENIC ZEBRAFISH RECAPITULATES FEATURES OF HUMAN ACUTE MYELOID LEUKEMIA
JW Lu[1,*], HA Hou[2], MS Hsieh[1], HF Tien[2], LI Lin[1,3]
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, National Taiwan University, [2]Department of Internal Medicine, [3]Laboratory Medicine, National Taiwan University Hospital, Taipei, Taiwan, ROC

Background: Acute myeloid leukemia (AML) is a clonal hematologic malignancy that shows great variability with regard to pathogenesis and treatment outcomes. One of the most common mutations associated with AML involves the class III receptor tyrosine kinase, FMS-like tyrosine kinase 3 (*FLT3*), which plays an important role in hematopoiesis. Constitutively activated *FLT3* occurring as internal tandem duplication (ITD) within the juxtamembrane domain is observed in 20-25% of AML patients and refers to the poorest response to current standard treatment. *FLT3*-ITD mutant was reported to be a driver mutation in myeloid leukemogenesis. Zebrafish, sharing similar leukocyte compartment with human beings, recently emerged as a promising animal model for studying diseases and for drug discovery.
Aims: To establish a transgenic *FLT3*-ITD zebrafish line, and further explore their characteristics, on which future drug screening may be developed.
Methods: We established a transgenic zebrafish that is able to express human *FLT3*-ITD or *NPM1*-Mut under the control of a myeloid-specific promoter (5.3 kb *spi-1*). Specifically, we generated two constructs, referred to as *spi1*: *FLT3*-ITD-2A-EGFP/CG2 and *spi1*:*NPM1*-Mut-PA/CG2, respectively.
Results: Cytological analysis of kidney marrow (KM) and peripheral blood (PB) smears prepared from wildtype and *FLT*3-ITD zebrafish were examined at 4, 6 and 9 months. In comparison with wild type fish, the KM from some *spi1*:*FLT3*-ITD-2A-EGFP/CG2 6- and 9-month old transgenic zebrafish had a greater number of myeloid progenitors and an excess of blast cells with focal aggregation. Hematoxylin and eosin (H&E) staining of the 6 month-old *FLT3*-ITD transgenic fish kidney showed mild effacement and distortion of kidney structure as well as increased infiltration of myeloid cells. Further morphological analysis of cytospin marrow showed that AB-wild type fish possessed the normal complement of haematological cells, whereas 2 out of 6 *spi1*:*FLT3*-ITD-2A-EGFP/CG2 zebrafish had an abnormal number of myeloid progenitors and decreased synthesis of erythroid cells at 9 month-old. Finally, leukoerythroblastosis was observed in PB. It is well recognized that the *NPM1* and *FLT3*-ITD mutations occur concurrently in AML patients, and the combined genotype that results from this (*NPM1*/*FLT3*-ITD) is the most powerful indicator of AML prognosis. To better delineate the two-hit model in zebrafish, we also generated *FLT3*-ITD/*NPM1*-Mut double transgenic mutants. In so doing, we found that *FLT3*-ITD and *NPM1*-Mut synergistically promoted myeloid blasts and the expansion of precursor cells in zebrafish as young as six months. Flow cytometric analysis and Liu's stains of the KM and PB smears from 6-month old *FLT3*-ITD/*NPM1*-Mut transgenic fish revealed myeloid hyperplasia with predominance of blast cells and depletion of erythroid series in KM, whereas immature blast cells were able to progressively infiltrate the KM and circulate into the PB. Taken above, we suggested that *FLT3*-ITD and *NPM1*-Mut synergistically promoted myeloid blasts and the expansion of precursor cells in zebrafish.
Summary/Conclusions: In conclusion, *FLT3*-ITD as a common *FLT3* mutation in AML patients could results in expanded myelopoiesis with poor differentiation in adult zebrafish. These transgenic fish could potentially provide a valuable platform to investigate leukemogenesis and screen drugs in the near future.

Background: Acute myeloid leukemia (AML) is a heterogeneous neoplastic disorder of hematopoietic progenitors. Lin28 is a conserved RNA-binding protein playing an important role in cancer stem cells. Ectopic expression of Lin28 reprograms hematopoietic progenitor cells from adult bone marrow (BM), endowing them to mediate multi-lineage reconstitution which resembles fetal hemotopoiesis. It has been reported the existence of reciprocal regulatory loops between Lin28 and *mir-128*. In particular, this miRNA is expressed in early hematopoietic progenitor cells preventing the differentiation of all hematopoietic lineages. Moreover, increased expression of *mir-128* was associated with high-risk molecular features of AML.
Aims: Since Lin28 and its *mir-128* seem to be important regulators of hematopoiesis, it could be interesting to study their involvement in the induction and maintenance of AML.
Methods: We analyzed, by qRT-PCR, *Lin28A* and *mir-128* expression levels in 37 AML patients, AML cell lines and 13 healthy donors. Lin28 protein expression was evaluated by cytofluorimetric analysis in myeloid and lymphoid precursors of 10 BM healthy subjects and in 9 AML leukemic cells (LC). Overexpression of Lin28A or silencing of *miR-128* were obtained in OCI-AML3 cell line for 24-48 h. Moreover, OCI-AML3 and ME1 cells were treated with PMA for 24, 48 and 72h. Cells were collected and used to perform cell cycle assay, apoptosis assay, caspase 3/7 assay, cytofluorimetric analysis of Lin28A, CD11b, CD45 and CD14, western blot for Lin28A and p21 and qRT-PCR for *EGR2* and *ZFP36*.
Results: Real Time PCR data indicated a down-regulation of *Lin28A* in AML patients ($p<0.001$) and cell lines ($p<0.05$) as compared with controls. To confirm this data, we also analyzed its protein expression in AML LC compared with normal myeloid precursors, showing a significant down-regulation ($p<0.01$). Furthermore, our data showed an up-regulation of Lin28A in normal myeloid precursors with respect to lymphoid ($p<0.001$) and erithroid ones ($p<0.01$). The over-expression of Lin28A in OCI-AML3 induced myeloid differentiation; in fact, we observed a significant increased of CD11b ($p<0.05$), CD14 ($p<0.05$), *EGR2* ($p<0.05$) and *ZFP36* ($p<0.01$). We also observed a significant block of cell cycle in S phase ($p<0.05$), an increased expression of p21 protein and the induction of apoptosis ($p<0.001$). To confirm the involvement of Lin28A in myeloid differentiation of LC, we treated AML cells with PMA. As expected, we observed an increase of myeloid markers (CD11b $p<0.05$, CD14 $p<0.05$, *EGR2* $p<0.01$, *ZFP36* $p<0.01$) and also a significant overexpression of Lin28A ($p<0.05$). Moreover, PMA treatment confirmed a significant block of cell cycle in G2 phase ($p<0.01$), an increased expression of p21 and the induction of caspase-dependent apoptosis ($p<0.01$). Literature data indicate that *miR-128* regulate *Lin28A*; in fact, we demonstrated by qRT-PCR its up-regulation in AML patients ($p<0.05$) and cell lines ($p<0.01$). Furthermore, its silencing in OCI-AML3 induced a significant increase of Lin28A, p21 and myeloid markers as *EGR2* and *ZFP36* ($p<0.001$), confirming their involvement in myeloid differentiation and in cell cycle arrest.
Summary/Conclusions: Our data indicate *mir-128*/*Lin28A* axis as a potential regulator of myeloid differentiation, suggesting its involvement in AML development.

DEEP SEQUENCING OF 23 GENES DESIGNATED BY TCGA STUDY IN ACUTE MYELOID LEUKEMIA PATIENTS WITH NORMAL KARYOTYPE
M Ibañez[1,*], C Alonso[2], M LLop[3], E Onecha[4], E Such[1], E Barragán[3], R Ayala[4], A Neef[1], J Martinez-López[4], I Raspado[4], B de Matteo[1], D Company[1], R Andreu[1], P Montesinos[1], MA Sanz[1], J Cervera[5]

[1]Hematology Service, Hospital Universitario y Politécnico La Fe, [2]Hematology Service, Hospital Arnau de Vilanova, Valencia, Spain, [3]Department of Medical Pathology, Hospital Universitario y Politécnico La Fe, Valencia, [4]Hematology Service, Hospital 12 de Octubre, Madird, Spain, Madrid, [5]Genetics Unit, Hospital Universitario y Politécnico La Fe, Valencia, Spain

Background: In the study carried out by The Cancer Genome Atlas Research Network (TCGA), 99% of patients with acute myeloid leukemia (AML) presented at list one mutation over 23 genes (*NPM1, FLT3, ASXL1, BCOR, CEBPA, DNMT3A*, *EZH2, IDH1, IDH2, KDM6A, KIT, KRAS, NRAS, PTPN11, RAD21, RUNX1, STAG2, SMC1A, SMC3, TET2, TP53, U2AF1* and *WT1*). However, there are not studies focused on these 23 genes to evaluate their incidence and clinical role within independent cohorts of patients lacking chromosomal aberrations, which represents nearly 50% of patients (NKAML).
Aims: To establish the frequency and prognostic influence of mutations and their interactions in the 23 genes designated by TCGA study in the context of other prognostic clinical and molecular markers in a cohort of *de novo* NKAML patients.
Methods: The study includes 112 adult patients with *de novo* AML (excluding acute promyelocytic leukemia) with normal karyotype. Available DNA sample at diagnosis was the only limiting criterion. DNA samples from Hospital Universitari i Politècnic La Fe were provided by Biobank La Fe. We carried out targeted gene sequencing (Ion Torrent Proton System–Life Technologies) using a 23 genes custom panel including all coding regions (*NPM1, FLT3, ASXL1, BCOR, CEBPA, DNMT3A*, *EZH2, IDH1, IDH2, KDM6A, KIT, KRAS, NRAS, PTPN11, RAD21, RUNX1, STAG2, SMC1A, SMC3, TET2, TP53, U2AF1* and *WT1)*. Selected variants were annotated using IonReporter® Software for clinical reporting. Non-pathogenic variants were filtered out by excluding synonymous, intronic and polymorphic variants (major allele frequency (MAF) ≥0,01 and/or included in dbSNP). *FLT3-ITD* mutations were assessed as previously reported[1].
Results: After filtering procedure we identified a total of 314 high-confidence variants, with an average of 3 mutations per sample, (range 0-7). Mutations in at least one of the genes were found in 103 out of 112 patients (95%). The most commonly mutated genes were *DNMT3A* (n= 43, 39%), *NPM1* (n= 37, 33%)*, FLT3*-ITD (n=33, 29%)*, IDH* (n=31, 28%)*, TET2* (n=30, 27%)*, RUNX1* (n=19, 17%)*, ASXL1* (n=17, 15%)*, KDM6A* (n=14, 13%), *WT1* (n=11, 15%) and *PTPN11* (n= 9, 12%). Of the 112 samples, 91% contained at least one mutation in one of eight categories defined according to biologic function with a putative role in AML pathogenesis: DNA-methylation–related (71%), encoding nucleophosmin (*NPM1*) (33%), activated signalling (37%), chromatin-modifying (27%), myeloid transcription-factor (25%), cohesin-complex (20%), tumor suppressor (16%), and spliceosome-complex (*U2AF1*)(4%). In addition, we identified a strong pattern of mutual exclusivity between *ASXL1* mutations and three other genes, in an independently manner, *U2AF1* (*P*=0.011), *TET2* (*P*=0.032) *and DNMT3A* (*P*=0.03). In addition, we found a significant co-occurrence between mutations in *DNMT3A* and *NPM1*, (*P*=0.001) and *TET2* and *IDH2* or *NRAS* (*P*=0.004; *P*=0.039, respectively). In univariate analyses, NKAML patients carrying indels in *TET2* or in *ASXL1* showed a significantly worse outcome (5-year OS, wt34% *vs*. mut 7%, *P*=0.025; 5-year OS, wt 30% *vs.* mut 12%, *P*=0.001, respectively). Further results will be presented in the meeting
Summary/Conclusions: Over 23 genes described by TCGA, 91% *de novo* NKAML patients showed at least one mutation. The most frequently mutated functional category was DNA-methylation (71%), which might trigger the process of leukemogenesis in NKAML. This work was supported by: Fundación Española de Hematología (FEHH), PI12/01047, RD12/0036/0014, PIE13/00046, PI13/01640, PI13/02387, PT13/0010/0026, PI14/01649 and PROMETEOII/2014/025.

CD97 EXPRESSION MEDIATES MIGRATION AND ADHESION OF FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA CELLS AND MODULATES THE BONE MARROW STROMAL MICROENVIRONMENT

M Wobus[1,*], M Kräter[1], A Jacobi[2], O Otto[2], U Oelschlägel[1], M Bornhäuser[1]
[1]University Hospital Dresden, [2]Biotec, TU Dresden, Dresden, Germany

Background: Bone marrow niches are specialized microenvironments that facilitate homing and survival of normal hematopoietic stem and progenitor cells (HSPCs) as well as leukemic stem cells (LCSs). Targeting the niche is a new strategy to eliminate persistent and drug-resistant LSCs. However, defined mechanisms mediating interactions of acute myeloid leukemia (AML) cells with the microenvironment remain largely unexplored. We have recently demonstrated that expression of the adhesion GPCR CD97 is elevated in blasts of FLT3-ITD positive AML patients.
Aims: Here, we investigated the underlying mechanisms in more detail and the impact on mesenchymal stromal cells (MSCs) as a main cellular component of the bone marrow niche *in vitro*.
Methods: FLT3-ITD MV4-11 and FLT3 wildtype OCI-AML3 AML cells were used for the *in vitro* experiments. CD97 knock-down was achieved by lentiviral transduction of plko1.6/shRNACD97. Primary MSCs were isolated from bone marrow aspirates of healthy donors and co-cultured with AML cell lines in direct or indirect manner. Expression analyses were carried out by flow cytometry and Western blot. Trans-well migration was analysed in a Boyden chamber assay and the deformation capacity of the AML cells was investigated by real-time deformability cytometry (RT-DC).
Results: CD97 knock-down by lentiviral transduction of plko1.6/shRNACD97 in MV4-11 leukemic cells caused inhibited trans-well migration towards FCS and LPA which is at least in part Rho-ROCK pathway dependent. Adhesion to a stromal layer was significantly decreased within two days and immunoblotting revealed inhibited Akt phosphorylation in the CD97 knock-down cells. The expression of the lysophosphatidic acid (LPA) receptor correlated with CD97 levels in FLT3-ITD MV4-11 but not in FLT3 wildtype OCI-AML3 cells indicating a physical interaction of these receptors. Changes in size as well as the deformation capacity after retroviral transduction of leukemic cells suggested effects on actin-myosin cytoskeleton dynamics. In the second part of the study, we tested the impact of leukemic cells and their CD97 expression on the MSC phenotype. FACS analysis was performed after three days of MSC incubation with leukemic cell lines or their conditioned medium, respectively. Interestingly, CD90 and CD146 expression levels were increased by about 50% after coculture with MV4-11 wildtype cells but declined to the basic level after incubation with CD97 knock-down cells. In contrast, the expression levels of CD73 were increased by MV4-11 and even further elevated by CD97 knock-down cells. Comparable results were observed after MSC culture with conditioned medium of MV4-11 cells.
Summary/Conclusions: In summary, our data suggest a modulation of the bone marrow microenvironment by FLT3-ITD positive leukemic cells expressing CD97 in association with LPA receptor rendering it a potential new theragnostic target.

E898

REPOSITIONING OF QUINACRINE FOR TREATMENT OF ACUTE MYELOID LEUKEMIA - SYNERGIES AND IN VIVO EFFECTS

A Eriksson[1,*], M Gustafsson[1], M Fryknäs[1], J Gullbo[2], P Nygren[2], M Höglund[1], R Larsson[1]
[1]Department of Medical Sciences, [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: We have previously reported that quinacrine, formerly extensively used as an antimalarial drug, may have repositioning potential for treatment of acute myeloid leukemia (AML)[1].
Aims: The aim of this study was to further evaluate the potential of quinacrine for a clinical trial in AML by investigating its possible synergistic effect with other antileukemic compounds as well as evaluating its efficacy in vivo in a mouse model.
Methods: Cytotoxic activity of quinacrine in combination with one of 9 different drugs (daunorubicin, cytarabine, azacitidine, decitabine, sorafenib, geldanamycin, All-Trans Retinoic Acid (ATRA), vorinostat, and arsenic trioxide) in AML cell lines was evaluated using the fluorometric microculture cytotoxicity assay (FMCA). Assessment of combinatorial effects and possible synergy was performed using conventional Bliss independence analysis based on results from all combinations of 4 different concentrations (including zero concentration) of each drug. Activity of quinacrine in vivo was investigated in a model with AML-PS cells injected intravenously in female SCID mice (at Accelera S.r.l). After two days, groups of ten mice were randomized to treatment with quinacrine or vehicle control. Quinacrine was administered by oral gavage at the dose of 100 mg/kg three times a week for two consecutive weeks; control animals were treated with vehicle (iv) only (twice a week for two weeks). Mice were monitored daily for mortality and clinical signs, body weights were evaluated twice a week. Blood aliquots were collected on days 30 and 31 to determine the percentage of circulating leukemic cells by FACS analysis. BD Cellquest software was used for data collection and analysis. Median survival time (MST) was calculated and the log-rank test was used to evaluate the statistical significance of differences between the control group *vs.* the quinacrine-treated group.

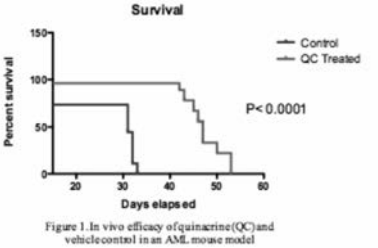

Figure 1.In vivo efficacy of quinacrine (QC) and vehicle control in an AML mouse model

Figure 1.

Results: In the in vitro drug combination analysis, several promising synergies were observed after studying duplicated experiments, for instance when combining quinacrine with geldanamycin, ATRA, cytarabine, hypomethylating agents or sorafenib. In the AML mouse model, evaluation of circulating leukemic

cells detected in blood samples (in percent of white blood cells) showed 72% human tumor cells in the control mice, whereas in mice treated with quinacrine, this was only 2.2%. In agreement with these data, the MST of control mice was 34 days whereas it was 46 days in quinacrine-treated mice ($p<0.0001$). At the tested dose, quinacrine did not decrease the body weight of treated mice.
Summary/Conclusions: These results strengthen the repositioning potential for quinacrine in AML, suggesting in vivo efficacy as well as promising synergies in combination with different agents, including geldanamycin, conventional chemotherapeutics as well as the hypomethylating agent azacitidine. These results provide further support for evaluation of the anti-leukemic effect of quinacrine in a clinical trial in AML.

PRIMARY ACUTE MYELOID LEUKEMIA CELLS WITH OVEREXPRESSION OF EVI-1 ARE SENSITIVE TO ALL TRANS RETINOIC ACID

HJ Verhagen, MA Smit, A Rutten, F Denkers, PJ Poddighe, PA Merle, M Maarse, JJ Janssen, GJ Ossenkoppele, L Smit*
Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Acute Myeloid leukemia (AML) is a heterogeneous myeloid proliferative disease that can be classified based on morphology, cytogenetics, molecular aberrations, gene expression and methylation profiles. Aberrant expression of the transcriptional regulator ecotropic viral integration site-1 (EVI-1) occurs in ~10% of adult AML patients and is associated with particularly aggressive disease and a very poor outcome. Up to 95% of EVI-1 positive patients have an overall survival of less than 1 year. Therefore, there is an urgent need for novel treatment strategies to improve the survival of EVI-1 positive AML patients. For decades, most AML patients, including the group with EVI-1 overexpression, are treated with a chemotherapy combination consisting of cytarabine-arabinoside and an anthracycline. Importantly, EVI-1-positive AML patients have an very poor initial response to this currently used combination chemotherapy; 39% of EVI-1 positive patients do not achieve a complete remission after induction therapy as compared to 18% of patients in the other AML subgroups. To date, only a few alternative treatments have shown to be slightly more effective than this combination of chemotherapeutics. The exception to this is the treatment of acute promyelocytic leukemia (APL) patients with all trans retinoic acid (ATRA). ATRA treatment has significantly increased the survival chances for APL patients and has turned APL from a poor prognostic leukemia into a curable disease.
Aims: As treatment of APL patients with ATRA is very successful, we sought to determine the response to ATRA of EVI-1 positive AML patients.
Methods: Here we investigated the response of EVI-1 positive AML to ATRA (n=14) and compared this to the response of EVI-1 negative AML cases (n=7). We studied the effect of treatment with ATRA on myeloid blast differentiation, clonogenic capacity and on the *in vitro* and *in vivo* survival of AML cells.
Results: Like induction of CD11b expression on APL cells, we observed increased CD11b expression on the cell membrane of 69% of EVI-1-positive AML cases (9/13) after 7 days of incubation with ATRA. In contrast, EVI-1 negative AML cases had no induction of differentiation after ATRA treatment. In several of the EVI-1 positive AML cases, treatment with ATRA induces apoptosis of the leukemic blasts. Moreover, pre-incubation of patient EVI-1-positive AML cells with ATRA results in enhanced sensitivity to doxorubicin. Besides low complete remission rates after initial treatment, the extreme poor prognosis of EVI-1-positive patients is because of high relapse rates. This relapse is due to chemotherapy resistant leukemic progenitors or leukemic stem cells (LSC). Eradication of these LSC is crucial to improve the outcome of EVI-1-positive patients. We observed a significant reduction in colony forming capacity of leukemic progenitors/stem cells in primary AML after treatment with ATRA but most importantly we demonstrated that *in vivo* ATRA treatment of primary EVI-1 positive AML cases leads to a significant reduction in leukemic engraftment in the bone marrow and spleen (Figure 1).

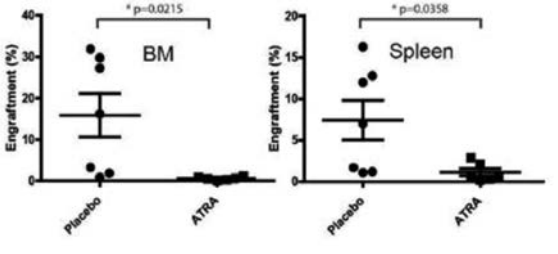

Figure 1.

Summary/Conclusions: This study is the first to show that a considerable part of the primary EVI-1 positive AML patient samples are sensitive to ATRA treatment, suggesting that combining ATRA with conventional chemotherapy might be a promising treatment strategy for this poor prognostic subgroup of AML patients.

E900

GENOME-WIDE ANALYSIS OF SINGLE NUCLEOTIDE POLYMORPHISM (SNPS) IN PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE

M Ibañez[1,*], M Martínez-Rubio[1], E Onecha[2], GS Inés[1], E Such[1], E Barragán[3], R Ayala[2], M Llop[3], M López-Pavía[1], S Jorge[4], A Neef[1], J Martinez-López[2], I Raspado[2], B de Matteo[1], D Company[1], R Andreu[1], S Leonor[1], P Montesinos[1], MA Sanz[1], J Cervera[1]
[1]Hematology Service, Hospital Universitario y Politécnico La Fe, Valencia, [2]Hematology Service, Hospital 12 de Octubre, Madrid, [3]Department of Medical Pathology, [4]Servicio de arrays, Hospital Universitario y Politécnico La Fe, Valencia, Spain

Background: Although recurrent chromosomal alterations are the main diagnostic and prognostic markers in acute myeloid leukemia (AML) at the time of diagnosis, nearly 50% of patients have an apparently normal karyotype (NKAML), displaying an intermediate risk for survival and relapse. SNP array (SNP-A) allow us to study variations in the number of copies (CNV) and regions of loss of heterozygozity (LOH) in myeloid neoplasms. Using systematically matched germline samples might ascertain the somatic nature of each lesion.
Aims: To establish the role that may play some cryptic abnormalities present in NKAML patients through the frequency, recurrence and any possible clinical association of CNVs and LOHs.
Methods: A total of 218 de novo NKAML patients were analyzed. Among them, 25 patients were enrolled in the consecutive multicenter PETHEMA trials at the Hospital Universitari i Politècnic La Fe and Hospital 12 de Octubre, with available DNA sample at diagnosis and at complete molecular remission were selected for this study. DNA from Hospital Universitari i Politècnic La Fe were provided by Biobank La Fe. We expanded the cohort with other AML series with publicly available SNP-A data to a total of 181 cases (n=49 del TCGA,[a] n=53 de Kronke J, *et al.*,[b] n=30 de Tadayuki A, *et al.*[c] y n=49 Koren-Michowitz M, *et al.*[d]). Samples were genotyped using Human CytoScan HD (n=37) and Genome-Wide Human SNP 6.0 (n=181) according to manufacturer's protocol (Affymetrix Santa Clara, C.A., U.S.A.). DNA copy number and paired LOH analyses were performed using the Genotyping Console and the Chromosome Analyses Suite (ChAS) software (Affymetrix). Filters applied for segment Copy Number Abnormalities (CNA) detection were ≥20 consecutive markers in a region of at least 100Kb, and for regions of Copy Neutral Loss of Heterozygocity (CN-LOH), ≥100 markers in at least 500Kb. All abnormalities found in the remission sample were ruled out and assume as non-somatic. Besides, every potential abnormality was checked in the Database of Genomic Variants (http://projects.tcag.ca/variation). Size, position, and location of genes were identified with UCSC Genome Browser (http://genome.ucsc.edu/). The human reference sequence used for alignment was the GRCh37/hg19assembly
Results: A total of 304 abnormalities were found as an acquired event in 143 NKAML patients (66%), resulting in 2.1 abnormalities/case. These consisted of 151 heterozygous deletions, 99duplications and 54 CN-LOH. Cryptic chromosomal aberrations were more frequents in chr 1, 2, 5, 6, 7, 11, 13, 16 and 19. The most common CN-LOH was in 13q (being *FLT3* involved in all them), 1p y 7p. In 19p (chr19:1-16300000) we detected more deletions, while in chr 1, 4, 5 and 20 more insertions. Likewise, patients harbored cryptic aberrations (mainly deletions or CN-LOH) involving *KMT2A,*(n=5), *RAD21* (n=4), *RUNX1* (n=4), *ETV6* (n=3), *EZH2* (n=3), *WT1* (n=3), *PTPN11* (n=2), *TET2* (n=2), *U2AF1* (n=2), *IDH1* (n=1) and *NPM1* (n=1). Further results will be presented.
Summary/Conclusions: This study has delineated recurrent abnormalities that may act as driver event and could explain leukemogenesis in up to 66% of NKAML cases. This work was supported by the following grants: Fundación Española de Hematología (FEHH).

A NON-FUCOSYLATED FULLY HUMAN MONOCLONAL ANTIBODY AGAINST IL-3RA, KHK2823, SHOWS PROMISING PHARMACOLOGICAL CHARACTERISTICS IN NONCLINICAL STUDIES

T Akiyama[1], Y Maekawa[1], SI Takayanagi[2], U Nishiyama[1], K Miyawaki[3], F Jinnouchi[3], T Jiromaru[3], T Sugio[3], S Daitoku[3], H Kusumoto[3], M Shimabe[2], S Nishikawa[2], K Yamawaki[2], K Iijima[1], M Hiura[1], Y Inagaki[2], T Takahashi[1], Y Kikushige[3], H Iwasaki[4], K Akashi[3], T Tawara[1,*]
[1]Research and Development Division, Kyowa Hakko Kirin Co., Ltd., Shizuoka, [2]Research and Development Division, Kyowa Hakko Kirin Co., Ltd., Tokyo, [3]Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, [4]Center of Cellular and Molecular Medicine, Kyushu University Hospital, Fukuoka, Japan

Background: Human interleukin-3 receptor alpha (IL-3Rα, CD123) is highly

expressed in myeloid malignancies, including acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS), and is considered to be an attractive target molecule for antibody targeting. We generated KHK2823, a non-fucosylated fully human IgG1 monoclonal antibody against human IL-3Rα, which is armed with ADCC-enhancing POTELLIGENT® technology.
Aims: KHK2823 is currently in Phase 1 study in the United Kingdom to investigate safety and efficacy on AML and MDS patients (NCT02181699). Here, we describe nonclinical profiles and binding characteristics of KHK2823 as a potential therapeutics against AML and other myeloid malignancies.
Methods: Binding profiles of KHK2823 were analyzed by primary cells derived from patients in AML, MDS and B-ALL, and cell lines by using flow cytometry. Epitopes were analyzed by overexpressing IL-3Rα-GM-CSF-R chimeric proteins on 293F cells. Antibody-dependent cellular cytotoxicity was measured by ^{51}Chromium release assay using AML cells as target and peripheral blood mononuclear cells as effector Effects of IL-3 signal were assessed by using IL-3-dependent TF-1 cell line. Nude rats subcutaneously transplanted with MOLM-13 cells and cynomolgus monkeys were used for evaluating pharmacological activities *in vivo*.
Results: KHK2823 bound to various hematological malignant cells and leukemic stem cells, including AML, MDS and B-ALL. ADCC assay showed high antibody-dependent cellular cytotoxic activity in patients' malignant cells. A IL-3Rα antibody 7G3 but not KHK2823 inhibited the growth of TF-1, a IL-3-dependent cell line, in the presence of human IL-3 in vitro, suggesting that KHK2823 does not interfere IL-3R to bind IL-3. For further characterization of KHK2823, we screened epitopes of IL-3Rα antibodies. Three dimensional structure of IL-3Rα protein was predicted from the homology modeling of IL-4Rα protein (PDB: 3BPNC). Three structural domains of the extracellular region of IL-3Rα, designated as A-, B- and C- domains from the N-terminal, were predicted and replaced by GM-CSFRα. For further precise epitope analyses, six regions with 7-amino acid in IL-3Rα were substituted to the equivalent regions of GM-CSFRα protein. The analyses showed that KHK2823 recognizes the epitope distant from the critical region for IL-3 signals. The data coincided with that KHK2823, in contrast to 7G3 antibody, did not interfere with the binding of IL-3 to IL-3R. The epitope analysis also unraveled that KHK2823 but not 7G3 could recognize a isoform of IL-3Rα without A-domain predicted in public database. Several in vivo studies were conducted to evaluate the nonclinical profile of KHK2823. The nude rat xenograft model showed pharmacological effects. The pharmacodynamics and the toxicology profiles of KHK2823 were assessed in cynomolgus monkeys administered by i.v. infusion, once weekly for 4 weeks. KHK2823 was found to be well tolerated in the monkey study at a maximum dose of 100 mg/kg. IL-3Rα-positive cells in the peripheral blood were depleted in all the KHK2823-administered monkeys tested.
Summary/Conclusions: The anti-IL-3Rα antibody KHK2823 possesses promising pharmacological and toxicological profiles analyzed on the animal studies and in vitro studies, and recognizes the distinctive epitope, which does not interfere with the IL-3 signals and also does not lose recognition to the isoform. These data suggest that KHK2823 might possess safer and more efficacious characteristics to show promising profiles in the future.

E902

HETEROTYPIC SIGNALLING BETWEEN BONE MARROW STROMAL CELLS AND BLASTS PROVIDES INSIGHT INTO THE CELLULAR COMMUNICATION IN ACUTE MYELOID LEUKAEMIA

A Dokal*, J Gribben, P Cutillas
Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) has a well-established role in the pathophysiology of acute myeloid leukaemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive in culture. Although it is clear that there are components of the stromal secretome that augment AML blast survival, we are currently only aware of a fraction of these factors and the precise dynamics of the stromal-blast interactions are not fully understood. In this study we were interested in dissecting the secretome and identifying novel secreted proteins that may contribute to AML cell survival outside of the current understanding (e.g. SDF-1).
Aims: The ultimate aim of this project is to determine proteins secreted by AML and bone marrow stromal cells that may mediate communication between AML blasts and the stromal environment. Further, we wanted to identify secreted proteins in AML cells harbouring different karyotypes to understand how these cells illicit heterotypic activation or inhibition of signalling pathways in cells across the different AML-subtypes.
Methods: To assess the feasibility of this approach, the secretome of 4 human AML cell lines and 1 mouse bone marrow stromal cell line were characterised by harvesting the conditioned media from each cell line individually and in co-culture (9 conditions) in triplicate (n=3). The secretomes were then purified from the conditioned media before undergoing global quantitative proteomic analysis using Liquid Chromatography Tandem Mass Spectrometry. MASCOT searches against both mouse and human proteomes allowed for discrimination between the stromal and AML proteins during bioinformatic analysis. In parallel the viability of these cell populations was recorded using a Beckman Coulter Vi-Cell cell viability analyser, functionally assessing the supportive capabilities of the BMSM after the AML cells were subjected to 24 hours of serum starvation.
Results: Secretomic analysis of the chemical crosstalk identified 520 bone marrow stromal proteins (including Osteopontin, Fibronectin, ECM proteins) and 293 AML blast proteins that satisfied identification criteria across the samples. 98 of such proteins have known functions as cytokines/growth factors. Analysis of the stromal secretome revealed a set of 20 stromal proteins whose secretion was modulated as a result of AML-stromal co-culture. These putative extracellular signalling proteins have known roles in cell adhesion, migration or microenvironment remodelling. In addition, the modulations in the composition of the AML secretome are suggestive of reactive crosstalk with the BMSM leading to stromal cell complicity. Finally, we display how serum starvation only leads to a drop in viability for AML cells cultured in isolation. It appears the BMSM is able to maintain if not increase basal AML cell viability under the same conditions. These findings are complimented by the reduction in extracellular markers of stress in the co-cultured secretomes.
Summary/Conclusions: This proteomic approach has allowed for the identification of a panel of proteins secreted by the stromal cells that can affect cell signalling and therefore behaviour of AML blast cells. Interestingly there are a number of novel signalling proteins secreted by the blasts that are indicative of orchestrating the BMSM. Analysis is now underway to fully map the progression of signalling in AML blasts that is initiated by the binding of these stromal signalling proteins. When complete this study will provide insight as to how the stromal microenvironment helps propagate leukaemic blasts across the different AML-subtypes.

E903

ONO-5390556 AS POTENTIAL TARGETED THERAPY FOR ACUTE MYELOID LEUKAEMIA WITH ETV6-NTRK3 FUSION GENE

R Kozaki*, T Yoshizawa, R Fujikawa, H Kato, N Goto
Oncology research laboratories, ONO Pharmaceuticals, Osaka, Japan

Background: Chromosomal rearrangements that target *NTRK1*, *NTRK2* and *NTRK3* are rare but recurrent abnormalities observed in some types of cancer. Fusion variants for each *NTRK* gene have been described in cancers that give rise to constitutive activation of kinase domains that are believe to drive the oncogenic process. Translocation of *NTRK3* and Ets family transcription factor 6 (*ETV6*), *ETV6-NTRK3* appears with the greatest frequency across many cancer types, including acute myeloid leukaemia (AML), radiation-associated thyroid cancer, high grade gliomas, ductal carcinoma, fibrosarcomas, congenital mesoblastic nephroma and secretory breast carcinoma. Patients bearing *ETV6-NTRK3* show resistant to chemotherapy, indicating that targeting active *NTRK* may be effective in the treatment of patients with this fusion.
Aims: ONO-5390556 is a highly potent and selective NTRK inhibitor with an IC50 in the sub-nmol/L range. We have examined the activity of ONO-5390556 against *ETV6-NTRK3* bearing cell line, IMS-M2 models both in vitro and in vivo.
Methods: Response was assessed by oral administration of ONO-5390556 once daily for 26 days in mice bearing IMS-M2 cells that were subcutaneously injected into female SCID mice. To investigate the regulation of signaling pathways by ONO-5390556 in IMS-M2 cells, western blotting was performed.
Results: IMS-M2 cell lines showed reduced proliferation (IC50: 0.8 nmol/L) compared with Ba/F3 cells (IC50 not reached at 1000 nmol/L). In the IMS-M2 xenograft model, tumour growth inhibition at the final treatment day was 62.7% in the 0.6 mg/kg treatment group and 100% both in the 2 mg/kg and 6 mg/kg treatment groups respectively (All treatment groups: $P<0.001$ v.s. Vehicle). The treatment of ONO-5390556 was well tolerated in IMS-M2 bearing SCID mice with no body weight loss. Western blotting demonstrated a dose-dependent reduction in phosphorylation of the NTRK and the downstream signaling of NTRK pathway, ERK, AKT and PLCg1.
Summary/Conclusions: The dramatic and sustained response to NTRK inhibition in IMS-M2 cells provides a rationale for the mechanisms underlying the response. Our in vivo study therefore demonstrate that ONO-5390556 has significant activity against cells containing *NTRK* rearrangement and shows promise for the treatment of patients with *ETV6-NTRK3* fusion gene positive AML.

E904

ASSESSMENT OF THE ALLELIC RATIO OF DNMT3A R882 MUTATIONS IN ACUTE MYELOID LEUKEMIA BY DIGITAL DROPLET PCR

J Grimm*, T Dick, M Bill, M Jentzsch, J Schulz, L Schmalbrock, L Bonifacio, M Knyrim, K Schubert, M Cross, W Pönisch, V Vucinic, G Behre, GN Franke, D Niederwieser, S Schwind
Hematology and Oncology, University of Leipzig, Leipzig, Germany

Background: In acute myeloid leukemia (AML) the allelic ratio (AR) of internal tandem duplication in the *FLT3* gene (*FLT3*-ITD) has been shown to impact clinical outcomes. *DNMT3A* mutations (mut) occur in approximately 20% of AML patients (pts) & the majority is found in amino acid R882. These mut arise early in leukemogenesis & their presence is associated with worse prognosis in some AML subgroups. To date the biological & clinical impact of *DNMT3A*mut AR has not been investigated. Simultaneous absolute quantification of mut & wild type

(wt) copies with the highly sensitive & specific digital droplet PCR (ddPCR) may represent an excellent tool for *DNMT3A* R882mut AR assessment.
Aims: To evaluate the feasibility of *DNMT3A* R882mut AR assessment by ddPCR at diagnosis & during disease course in AML pts.
Methods: AML pts treated at our institution between 2000 & 2015 with *DNMT3A* R882H or R882C mut & eligible diagnostic (n=33) &/or follow-up material (n=20) were analyzed by ddPCR. cDNA was applied to a duplex assay measuring *DNMT3A*mut & wt simultaneously. Absolute copy numbers of *DNMT3A*mut/ *DNMT3A*wt defined the AR. Samples with an AR<0.0001 or<3 positive droplets were rated negative according to the manufacturer's recommendations. Mut in *NPM1*, *CEPBA* & presence of *FLT3*-ITD & -TKD were assessed at diagnosis. For pts receiving hematopoietic stem cell transplantation (HSCT) data on bone marrow chimerism at day 28 & 56 after HSCT were collected.
Results: 35 pts (median age 63 years [y], range 29-87y) were identified to have a *DNMT3A* R882H (71.4%) or R882Cmut (28.6%). All mut were determined to be heterozygous by visual inspection of the Sanger sequence traces. At diagnosis 31.4% of the AML pts had a *DNMT3A* R882mut AR>1 (median AR 0.92, range 0.0002-2.3). Pts with an AR>1 had more often secondary AML by trend (36.4% *vs* 8.3%, *P*=.06), were less frequently *NPM1*mut (18.2% *vs* 65.2%, *P*=.03), had fewer platelets by trend (*P*=.08) & more blasts in peripheral blood (*P*=.04). A *DNMT3A* R882mut AR>1 at diagnosis associated with shorter overall survival (Figure 1A, *P*=.005). 27 pts received HSCT with 15 having available samples pre-HSCT. *DNMT3A* R882mut AR declined in all pts pre-HSCT (AR range 0-0.57, median 0.14; median AR reduction 67.3%, range 30.6-100%, *P*<.001). The majority of patients remained *DNMT3A* R882mut positive (86.7%) pre-HSCT. At day 28 after HSCT five pts had material available to assess *DNMT3A* R882mut AR. Four pts were positive for *DNMT3A* R882mut (AR range 0.0001-0.51) of whom three experienced relapse. One patient was negative for *DNMT3A* R882mut at day 28 & is in continuous remission. Figure 1B displays an exemplary AR course of one patient who experienced relapse after HSCT. Notably, the *DNMT3A* R882mut AR increased by two log-levels between day 28 & 56 after HSCT while the bone marrow total chimerism remained at 100%.

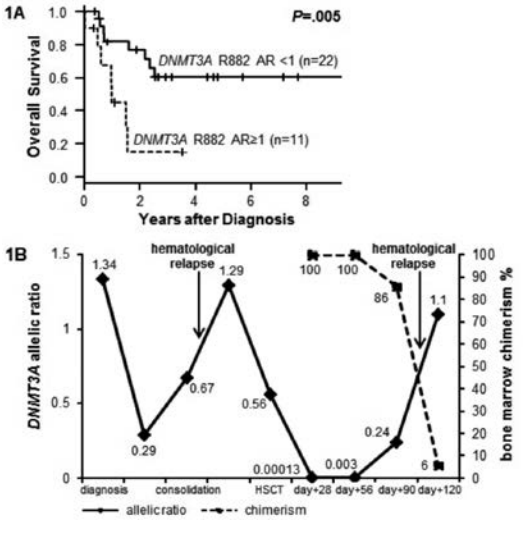

Figure 1.

Summary/Conclusions: ddPCR is a feasible method to assess *DNMT3A*mut AR during disease course. In spite of the limited number of pts, our data suggest that the *DNMT3A* R882mut AR at diagnosis may associate with biological & clinical features & outcome of AML pts. *DNMT3A* R882mut AR may be useful for monitoring minimal residual disease (MRD) after HSCT. Assessment of *DNMT3A* R882mut AR by ddPCR will be included in future clinical trials to validate its prognostic impact & its feasibility as MRD marker after HSCT in AML.

E905

USE OF NGS MULTIGENIC PANEL IN MOLECULAR DIAGNOSTIC OF MYELOID MALIGNANCIES TO STRATIFY PATIENTS FOR PERSONALIZED THERAPIES

E Franchini[1,*], E Zuffa[1], A Padella[1], G Simonetti[1], M Manfrini[1], MA Laginestra[1], G Motta[1], C Baldazzi[1], GF Prisinzano[1], C Venturi[1], MT Bochicchio[1], N Testoni[1], C Papayannidis[1], G Marconi[1], M Perricone[1], E Ottaviani[2], G Martinelli[1]
[1]Seragnoli Institute,Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, [2]S. Orsola-Malpighi Hospital, Hematology Unit, Bologna, Italy

Background: In the last years, next generation sequencing (NGS) technology resulted to be a new effective strategy in identifying genetic aberrations in myeloid neoplasms. Molecular mutation information became essential for biological subclassification, risk stratification and therapeutic decisions; the mutational status of several genes became important for understanding the complex interactions among different pathways in leukemogenesis.
Aims: Characterization of myeloid neoplasms using a multigenic panel of NGS sequencing in order to identify important alterations in a shorter time than traditional molecular methods and with a higher sensitivity. This will be helpful in a prematurely detection of small clones, important for monitoring disease progression and the inclusion in target therapy protocols.
Methods: We performed 15 runs with the TruSight Myeloid Panel of Illumina, for a total of 118 patients analyzed at diagnosis: 95 AML/sAML, 15 MPN, 3 CML, 3 MDS and 2 CMML. 25 patients (21,2%) had a normal karyotype, 25 (21,2%) presented one or two alterations, 26 (22%) had a complex karyotype, while for 42 patients (35,6%) no information about the karyotype was available. The panel is a next-generation sequencing platform to screen somatic variants in 54 genes relevant in myeloid diseases: 15 full genes (exons only) and oncogenic hotspots of 39 additional genes, for a total of 568 amplicons.
Results: The output data were then analyzed with the Illumina's software Variant Studio and the results were filtered by a coverage of minimum depth of 500 and allele frequency >3%. Variants already classified as SNP were removed. Only non-synonymous mutation were considered. The mean coverage was 3662 with a mean of 24 alterations per patient. 57,5%, 3.9% and 38.6% of the alterations had a Variant Allele frequency (VAF)<10%, between 10-30% and >30%, respectively. Three patients resulted wild-type, while 10 patients carried only one mutation. The most mutated genes were *ASXL1*, *BCOR*, *TET2*, *BCORL1*, *KDM6A*, *STAG2*, *DNMT3A*, *NOTCH1*, *ATRX*, *EZH2*, *RAD21*, *TP53*, *ETV6* (p<1e-05). We also detected 66 short deletions and 11 short insertions (max length 23 bp and 25 bp respectively). Then we proceeded with the validation of the mutations >10% of *NPM1*, *DNMT3A*, *TP53*, *FLT3*, *JAK2*, *MPL*, *SETBP1*, *IDH1* and *IDH2* with conventional molecular methods available in our laboratory (Sanger Sequencing and dPCR) and all the 145 mutations were confirmed. We also validated the alterations<10% of *CEBPa*, *TP53*, *RUNX1*, *IDH1*, *IDH2*, *CALR* and *FLT3* with the Roche GS Junior 454 and we obtained >90% of concordance. Moreover 18 AML samples were also analyzed by WES and 97,5% of the mutations were confirmed.

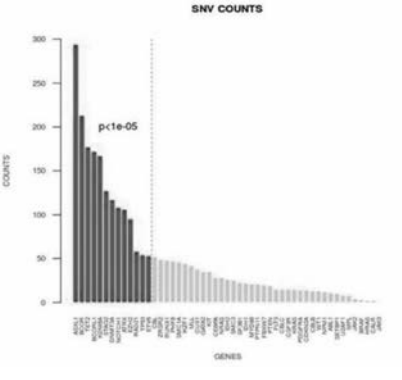

Figure 1.

Summary/Conclusions: These data suggest that a NGS multigenic panel is an effective strategy in myeloid neoplasms characterization and stratification in light of the development of novel personalized therapies (IDH-inhibitors: AG120 and AG221, MEK-inhibitors: GDC-0973, JAK-inibitors: Ruxolitinib and FLT3-inhibitors: Sorafenib, Midostaurin, AC220, ASP2215). Moreover, this approach is cheaper and time-saving and can also reveal alterations with a higher sensitivity than conventional methods. For this reason, we think that this approach could be strongly recommended for all new diagnosis/relapse myeloid neoplasm in order to obtain a more complete and premature characterization of the disease that will give advantages in term of therapeutic approach and OS of the patients. *Akcnowledgments: work supported by ELN, AIL, AIRC, Progetto Regione-Università 2010-12 (L.Bolondi), FP7 NGS-PTL project, Illumina inc.*

Universitaria di Udine, Udine, [5]Haematology Unit, Fondazione IRCCS Ca' Granda,

Ospedale Maggiore Policlinico and University of Milan, Milano, [6]Divisione Clinicizzata di Ematologia, Ospedale Ferrarotto, Catania, [7]Divisione Ematologia, Ospedale Sant'Eugenio, Roma, [8]Clinica di ematologia, Ospedlae Umberto I di Ancona, Ancona, [9]CTMO, A.O. Bianchi-Melacrino-Morelli, Reggio Calabria, Italy

Background: Acute myeloid leukemia (AML) is biologically complex due to the continuously evolving clonal architecture that marks remission and relapse. Though biological targeted therapeutics are changing clinical practice, there is still a lack of epigenetic markers of prognosis.
Aims: To identify biomarkers of relapse in elderly patients with AML in CR after conventional induction ("3+7") and consolidation chemotherapy.
Methods: In a phase III, prospective, randomized, open-label, multicenter trial, designed to assess the efficacy of post-remission treatment with 5-Azacitidine *versus* best supportive care (BSC), patients are included if: they are >60 years of age; have newly diagnosed "de novo" AML or evolving from myelodysplastic syndrome; >30% bone marrow blasts; no contraindications for intensive chemotherapy; and an ECOG performance status<3. Induction chemotherapy consists of two courses of "3+7" (Daunorubicin 40 mg/m^2 daily days 1-3 and cytarabine 100 mg/m^2 daily continuous IV infusion days 1-7). Patients in complete remission (CR) receive consolidation therapy (cytarabine 800 mg/m^2 3 hour infusion bid days 1-3) after which they are randomized 1:1 to receive BSC or 5-Azacitidine maintenance therapy up to 4 years and six months until AML relapse. Bone marrow (BM) samples were obtained from patients at diagnosis before treatment and at CR before randomization. Genomic DNA was obtained from BM mononuclear cells. Prognostic somatic mutations were evaluated by the Human Hematopoietic Neoplasm qBiomarker Somatic Mutation PCR Array (QUIAGEN) that includes DNA sequence mutation assays designed to detect the most frequent, functionally verified, and biologically significant mutations in human hematopoietic neoplasms, such as: FLT3, NPM1, IDH1, IDH2, CEBPA, KIT, KRAS, WT1, ASXL1, EZH2, DNMT3A and TP53. Various univariate logistic regression models were constructed. Each model included the treatment allocation, the dichotomous variable, "Relapse Yes/No" as the dependent variable, and each somatic mutation (mutated/wild-type) as independent variables. The median time to relapse will be estimated by the Kaplan Meier method.
Results: At interim analysis, 31 patients (14 males), mean age 69 SD±6 years achieved a CR and were randomized to receive BSC (N=13) or 5-Azacitidine (N= 18). At the time of the present report, 21 of the 31 patients have relapsed (10 in BSC arm, 11 in 5-Azacitidine arm), while the remaining 10 are alive in CR. Median time to relapse was 296 days, 95% CI 73 -519. Amongst biomarkers assessed, only TP53 (NM_000546 p179Y) at diagnosis was associated with AML relapse (p=0.007, Table 1A). Specifically, 15 out of 17 patients with mutated TP53 at diagnosis relapsed compared to 6 out of 14 patients with wild-type TP53. Of the latter 6 patients, 4 were on 5-Azacitidine. Finally, we built a logistic regression model adjusting the TP53 variable for the effect of the random allocation, which did not represent a confounder for relapse. Median time to relapse in TP53 mutant patients was 147 days, 95% CI 51-242 *versus* 389 days, 95% CI 353-425.in TP53 wild-type patients (p=0.022, Figure 1).

Table 1.

Table 1A

Variable	Unit	Odds ratio	CI (95%)	P
TP53_RP179Y (crude)	0 = Wild-type 1 = Mutated	6.177	1.627 – 62.462	0.013
TP53_RP179Y (adjusted for treatment allocation)	0 = Wild-type 1 = Mutated	9.721	1.559 – 60.622	0.015

Figure 1

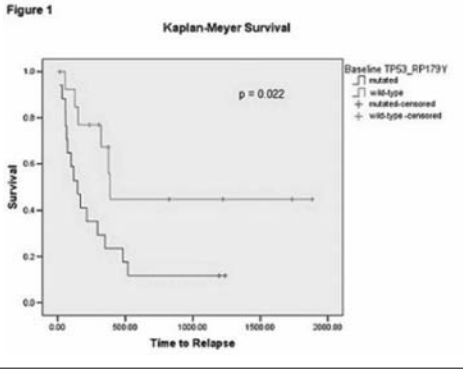

Figure 1.

Summary/Conclusions: The presence of TP53 mutation at diagnosis in elderly "fit" patients with AML undergoing induction-consolidation chemotherapy seems to confer an independent adverse clinical course which is not abrogated by post-remission treatment.

E907

PATTERNS OF INTERACTION BETWEEN MULTIPOTENT MESENCHYMAL STROMA CELLS (MSC) AND ACUTE MYELOID LEUKEMIA (AML) CELLS IN VITRO AND IN VIVO

R Schelker*, G Müller, C Hart, S Klatt, A Kratzer, W Herr, J Grassinger
Department of Internal Medicine III, Hematology & Oncology, University Hospital of Regensburg, Regensburg, Germany

Background: MSC are a key factor within the bone marrow (BM) niche by regulating hematopoietic stem cells (HSC) within the endosteal and perivascular region. Moreover, MSC are suspected to support the aberrant hematopoiesis in a similar manner.
Aims: In our study we sought to investigate the effect of MSC on AML cells *in vitro* and *in vivo*.
Methods: MSC from AML patients (LD) and donors without BM disorder (BD) were obtained from BM aspirates. Phenotypic and functional criteria of MSC were tested subsequently. Liquid culture assays were performed from LD and BD samples to compare expansion capacity. Co-cultures of AML cells (LC) on MSC were initiated and compared to those on mouse fibroblasts (MS5). Additionally, the effect of blocking CXCR4 and TGF-b_1 on proliferation of LC was tested in these co-cultures with and without cytarabine supplementation. Ultrastructural intercellular communication of MSC and LC was investigated by electron microscopy (ECM). Gene expression profiles of cultured LD-MSC *vs* BD-MSC were established by using Affimetrix gene chip. Finally, homing and engraftment of MSC, LC and combinations thereof in NSG mice were investigated.
Results: MSC were successfully harvested from BM aspirates and showed a typical differentiation pattern and surface marker profile. LD-MSC showed significant decreased expansion capacity compared to BD-MSC. Co-culture of LC on MSC resulted in a higher proliferation than on MS5. Blocking TGF-b_1 but not CXCR4 increased proliferation of LC and enhanced chemo-sensitivity towards cytarabine. ECM analysis showed no evidence for junctional bridging between LC and MSC. Gene analysis revealed a marked overexpression of stanniocalcin-1 (STC-1) in LD-MSC compared to BD-MSC. mRNA and western blot analysis as well as ELISA and immunohistological findings confirmed this observation. *In vivo* experiments emphasized that HSC and LC exhibited significant higher homing efficiency than MSC, the latter being mainly trapped within the lung. Mice treated (transplanted) with MSC showed decreased cytarabine sensibility as compared to control mice without MSC.

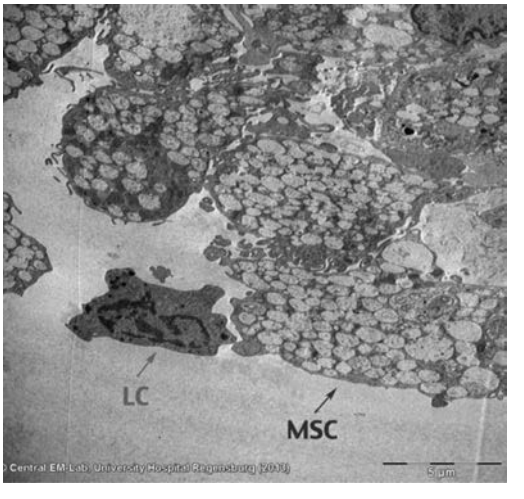

Figure 1.

Summary/Conclusions: MSC derived from patients with AML show distinct differences to MSC from BD. MSC support LC *in vitro* and *in vivo*. TGF-b_1, CXCR4 and STC-1 signaling may play an important role within the leukemic niche.

E908

THE ROLE OF THE NUCELOPHOSMIN-1 SPLICE VARIANT R2 IN ACUTE MYELOID LEUKEMIA DEVELOPMENT

M Zajac[1,*], J Zaleska[1], G Stasiak[1], O Jankowska-Lecka[2], T Gromek[2], M Soroka-Wojtaszko[2], A Szudy-Szczyrek[2], B Sokolowska[2], M Hus[2], L Bullinger[3], K Giannopoulos[1,4]
[1]Department of Experimental Hematooncology, [2]Department of Hematooncology and Bone Marrow Transplantation Unit, Medical University of Lublin, Lublin, Poland, [3]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [4]Department of Hematology, St. John's Cancer Center, Lublin, Poland

Background: A close cytogenetic and molecular analogy between *de novo* MDS and AML of elderly people indicates a common pathogenic mechanism for these conditions. The frequent mutations of the splicing machinery in MDS

suggest that alternative splicing of certain molecules of the crucial signaling pathways might drive progression to AML. Recently, we found that high expression of the *NPM1* splice variant R2 may provide prognostic value for CN-AML patients.
Aims: Assuming the common origin of MDS and AML we aimed to characterize the *NPM1* R2 splice variant expression in groups with MDS, sAML and AML patients. Moreover, NPM1 stabilizes the ARF and interacts with the tumor suppressor p53, regulates the increase in stability and transcriptional activation of p53, thus contributing to modulating growth-suppressive pathways. Therefore, we characterized expression pattern of *ARF, MDM2*, *TP53* genes with additional downstream molecules (p21, *miR-34a*) in AML, s-AML and MDS patients.
Methods: For 128 samples (58 AML, 62 MDS and 8 samples with sAML) expression levels of *NPM1* R2, *ARF, MDM2*, *TP53* and p21 were assessed by qRT-PCR. We also measured expression levels of miR-34a, miR-34b and miR-34c in CD33+ cells from 20 AML patients samples. To investigate whether R2 might disrupt localization of the NPM1 wild type protein, we used constructs with GFP-tagged NPM1-R2 and NPM1-wt under cytomegalovirus promotor to transfect WI-38 fibroblasts and performed immunohistochemistry analysis for NPM1 in 23 AML bone marrow smears.
Results: The expression of *NPM1* R2 was significantly higher in AML, s-AML and MDS groups compared to HVs (median 0.023 *vs* 0.005, p<0.001, 0.025 *vs* 0.005, p<0.001 and 0.017 *vs* 0.005, p<0.001, respectively). *NPM1* R2 positively correlated with *TP53* expression in AML (r=0.77, p<0.001) and MDS (r=0.68, p<0.001). We observed elevated expression of miR-34c in HVs group compared to AML (0.11 *vs* 0.07, p<0,001). No differences were found in miR34a, miR-34b and miR-34c expression between groups with high or low R2 expression. Transfections analyses showed that GFP-tagged NPM1-R2 was detected in nucleoplasm, whereas the GFP-NPMwt was detected in the nucleoli. However, the IHC stainings for AML samples revealed that in cases with high R2 expression we were able to determine a cytoplasmic localization of NPM1 even in the absence of its concomitant mutation. Therefore, we provide further evidence that the cytoplasmic localization of NPM1 might depend not only on its mutational status, but might be influenced by the distribution of its splice variants.
Summary/Conclusions: In our study we found that the expression levels of R2 were elevated in AML, sAML and MDS groups compared to HVs suggesting that R2 might play a role in the process of the tumorigenesis not only in AML cases but also in early stages of development of this disease. As the *NPM1* R2 splice variant represents a truncated form of *NPM1* gene, our transfections analyses confirmed that this isoform mostly localizes in the nucleoplasm, and thus might also have a biological impact in the malignant cells by interaction with other proteins. Moreover, strong positive correlation between R2 and *TP53* expression was found in AML and MDS groups suggesting biological link between these transcripts. In summary, the expression of *NPM1* R2 might be of biological importance for AML as well as for sAML and MDS patients. This work was supported by National Centre for Science Grant HARMONIA (UMO-2013/10/M/NZ5/00313).

THE ROLE OF ADENOSINE DEAMINASE AND DNA METHYLATION IN ACUTE MYELOID LEUKEMIA

N Tekin[1,2,*], K Behrens[2], M Ziegler[2], K Mills[3], H Ozdag[4], RA Padua[5], C Stocking[2]
[1]Department of Viral Transformation, [2]Retroviral Pathogenesis, Heinrich-Pette Institute Leibniz Institute for Experimental Virology, Hamburg, Germany, [3]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom, [4]Biotechnology Institute, Ankara University, Ankara, Turkey, [5]Institut Universitairé d'Hématologie, Inserm Unit 1131, Université Paris VII, Hôpital Saint-Louis, Paris, France

Background: Genes coding for epigenetic regulators are frequently mutated in acute myelogenous leukemia (AML). As epigenetic marks are reversible, drugs that target these events may have an important impact on AML survival rates. The objective of this study is to investigate the importance of a metabolic enzyme, Adenosine Deaminase(ADA), whose gene is upregulated by abnormal DNA methylation during AML induction. Analysis of the mouse microarray gene expression data showed that the *ADA* gene is highly upregulated in NRASD12/BCL2 MDS mouse models, which was validated by Q-PCR (Tekin and Padua, unpublished data). If the expression of different subtypes of AML samples is assessed, *ADA* levels are highest in the subgroup carrying inv(16) or t(8;21) chromosomal translocations. Notably, these subgroups of patients also have a conserved DNA methylation pattern (Figueroa et al. 2010).
Aims: Based on the observations, the following hypothesis has been formulated and was tested using human AML cells: *Is ADA a key enzyme regulating the hypermethylation status in AML and contributing to disease progression?*
Methods: To address the hypotheses, two approaches were taken: 1) To silence the ADA gene using shRNAs against *ADA* and to investigate its impact on DNA methylation 2) To overexpress ADA using a lentiviral vector expressing the *ADA* cDNA, and similarly investigate altered DNA methylation patterns. In initial experiments, three human cell lines were chosen: ME-1 AML cells carrying the inv(16), Kasumi-1 AML cells with t(8;21) and K562 t(9;22) cells, which was used as a control group. The cell lines were manipulated to overexpress or repress ADA by transduction with lentiviral vectors. As a control and comparison, azacitidine (AZA), a powerful demethylation agent, was also used. After transduction with lentiviral vectors and treating with AZA, RNA and DNA were extracted and proteins were purified. To investigate if inhibiting ADA mimics the effect of AZA, DNA methylation levels of Kasumi cells were measured by gene expression of the specific genes (*CDKN1A*, *ITGA2B*, *LY86)*. Bisulphite conversions of the DNA samples were carried on for the evaluation of the methylation status for the future studies.
Results: ADA protein levels were determined via western blot to ensure the success of the *ADA* gene manipulation by lentiviral transduction. Expression of *ADA* and two related genes encoding downstream enzymes from the methylation pathway DNA methyltransferase 1 (DNMT1) and S-adenosylhomocysteine hydrolase (SAHH) were investigated by Q-PCR. *ADA* gene expression levels do not impact on *SAHH* and *DNMT1* gene transcription, but we concluded that it does impact at the protein level. Interestingly, an inverse correlation between ADA and DNMT1 protein levels were determined between the cell lines. While ME-1 cell line has the highest ADA level and lowest DNMT1 level, K562 showed the highest DNMT1 levels with lowest ADA protein levels. In Kasumi cells a correlation between the expressions of methylated genes and ADA silencing was observed, which was similar to that observed upon AZA treatment. While AZA treatment resulted in >20 fold increase in the expression of methylated genes, silencing ADA increased the expression of methylated genes >2,5-10 fold.
Summary/Conclusions: The analysis of this study showed that silencing ADA can partly mimic the effect of AZA. To confirm the impact of ADA levels on DNA methylation, global gene analysis using bisulfite converted DNA samples, followed by promotor array or sequencing will be performed.

E910

NEW DELETION OF JAK2 DETECTED BY SNP ARRAY IN ACUTE MYELOID LEUKEMIA: A ROLE IN OVERALL SURVIVAL

V Guadagnuolo[1,*], MC Fontana[2], C Papayannidis[2], M Manfrini[2], G Marconi[2], G Simonetti[2], A Padella[2], E Ottaviani[2], A Ghelli Luserna di Rorà[2], A Ferrari[2], S Paolini[2], M Abbenante[2], S Parisi[2], C Sartor[2], S Lo Monaco[2], R Kralovics[3], JD Milosevic[4], N Them[4], D Chen[4], M Cavo[1], G Martinelli[1]
[1]Department of Hematology and Medical Sciences "L. and A. Seràgnoli", [2]Department of Hematology and Medical Sciences, Bologna, Italy, [3]Research Center for Molecular Medicine of the Austrian Academy of Sciences, [4]Research Center for Molecular Medicine of the Austrian Academy of Sciences, Wien, Austria

Background: In Acute Myeloid Leukemia (AML), a hematologic malignancy that originates in hematopoietic stem and myeloid progenitor cells, there is a strong need to develop new diagnostic and therapeutic options. Age and karyotype have been recognized as the most prominent prognostic factors in AML patients. Novel array-based technique-single-nucleotide polymorphism (SNP) microarray can detect cytogenetic lesions involve mostly structural alterations with losses or gains of chromosomic material. Those chromosomic abnormalities are predictive of response and are very important to define therapeutic strategies. SNP microarray can detect copy-neutral loss of heterozygosity (CN-LOH), which plays a role in oncogenesis by duplicating oncogenes, inhibiting tumor suppressors, and stimulating improper epigenetic programming.
Aims: Our objective is to evaluate the prognostic impact of these genetic alterations on clinical outcome.
Methods: We analyzed 310 AML patients (pts): 218 performed by SNP Array 6.0 (Affymetrix) and 92 performed by Cytoscan HD Array(Affymetrix) and also by Next Generation Sequencing (NGS)-WES HiSeq 2000 (Illumina). SNP Array data were analyzed by Nexus Copy Number™ v7.5 (BioDiscovery).

Table 1.

Pt	Call Start-End	Call Lenght (Bps)	Zygosity	Probe Count	From Exon	to Exon
1	5,065,391-5,084,407	19,016	Heterozygous	45	10	19
2	5,049,001-5,075,904	26,903	Heterozygous	72	9	19
3	5,074,734-5,071,809	7,075	Heterozygous	21	15	19
4	5,080,280-5,098,786	18,506	Heterozygous	28	17	22
5	5,080,280-5,098,786	18,506	Heterozygous	28	17	22
6	5,070,280-5,113,117	42,837	Heterozygous	70	17	23
7	5,070,940-5,078,433	7,493	Heterozygous	14	13	16
8	5,083,622-5,140,230	56,608	Heterozygous	65	20	24
9	5,080,280-5,083,622	3,342	Heterozygous	13	17	19
7 bis	5,083,622-5,140,230	56,608	Heterozygous	65	20	24

Results: The median age of our cohort of pts was of 52 years and they had a median age at diagnosis of 51,3 years with a female/male ratio of 51% and 49%. Copy Number Alterations (CNAs) were detected in all patients affecting all the chromosomes, in particular our cohort of pts present a percentage of CNA, divided as follow: 42% of UPD (Uniparental Disomy), 19% of Copy Number (CN) gain, 39% of CN loss. By SNP array analysis we found that several genes were preferentially deleted, for example ADAM3A (62,2% pts), TP53 (15% pts), HRAS (8,6% pts), ETV6 (7,8% pts) and JAK2 (7% pts), while genes preferentially involved in amplifications are: FLT3 (42,5% pts), KIT (36,5% pts),

KRAS (34,2% pts) and SIRPB1 (32,5% pts). We focused on a particular heterozygosis loss of JAK2, detected in 8% of pts, which goes from 5,049,001bp to 5,140,230p, involving the second tyrosine-kinase domain (figure 1). We showed that the group of patients which present this deletion had an overall survival rate better than the group with an amplification of the gene (p-value<0,01). None CN loss in this region of JAK2 had been described in hematopoietic tissue before.

Summary/Conclusions: By SNP arrays we have identified CNAs involving important cancer genes in AML and we showed that a new deletion in JAK2 may play a role in the overall survival. Future prospectives will be to confirm and correlate other cancer genes aberrations and mutations with the prognosis of AML, in order to identify new biomarkers relevant for the disease.

PROTEOMIC ANALYSIS OF RELAPSE AML IDENTIFIES OPPORTUNITIES FOR THERAPEUTIC INTERVENTION IN INDIVIDUAL PATIENTS

D Britton*, P Casado, V Rajeeve, E Wilkes, R Smith, J Fitzgibbon, J Gribben, P Cutillas

Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Background: A poor outcome in patients with acute myeloid leukaemia (AML) is usually related to chemorefractory disease or relapse after an initial response. Standard therapy generally includes days 1-3 daunorubicin (D) and days 1-7 cytarabine (A) followed by several similar courses should complete remission be achieved. Resistance of AML blasts to such treatment can be attributed to the activity of pro-survival enzymes, some of which can be inhibited by pharmacological inhibitors, therefore could potentially be repurposed for relapsed AML in a case by case basis. However, finding the right inhibitor for the right patient presents a challenge due to the plethora of possible causes of resistance in each case. Liquid chromatography – tandem mass spectrometry (LC-MS/MS) proteomics is a powerful discovery technology enabling quantification of global protein expression and enzymatic activity in samples. Hence this approach may be an effective way to identify suitable drug targets in biopsies and better understand the biochemistry of cells following chemotherapy.

Aims: Our primary aim was to identify biochemical pathways modulated in AML blasts and cell lines as a result of treatment with standard chemotherapy. We also aimed to test pharmaceutical alternatives to personalise AML treatment following thorough investigation into the expression and activity of protein drug targets in AML blasts and cell lines before and after chemotherapy.

Methods: We used LC-MS/MS proteomics and phosphoproteomics to investigate global protein expression and kinase activity in 19 matched diagnosis and relapse AML biopsies, as well as in 3 AML cell lines before and after chemotherapy. Briefly, we collected frozen biopsy specimens from Barts and the London tissue bank. After thawing the AML blasts were incubated in FBS containing media for 2 hr at 37ºC. Cell lines (HL60, MV411 and p31Fuj) were treated±D and/or A (2, 6, or 24 hr). After incubation, cells were centrifuged and washed in PBS, then proteins extracted in urea lysis buffer. For proteomics, proteins were digested with trypsin, and resulting peptides analysed directly by LC-MS/MS. For phosphoproteomics, phosphorylated peptides were first enriched using TiO_2 prior to analysis. Commercial (Mascot) and in-house (Pescal, KSEA) software were utilised to identify and quantify proteins, determine kinase activities and investigate intracellular signalling. Cell Viability of blasts±treatments were recorded using the Guava ViaCount Reagent and Cytometer.

Results: On average we identified >3000 proteins and >9,000 phosphorylation sites per sample. We observed that AML blasts showed high expression and activity of enzymes involved in DNA repair (e.g. PARP1, ATR and PRKDC) at diagnosis and several increased significantly after relapse (e.g. PLK3 and APEX1). Pro-survival signalling pathways and those regulating apoptosis and metabolism were also modulated after relapse but these were patient specific. AML cell lines were more sensitive to D than A. HL60s were most sensitive while p31Fuj cells were least sensitive. Chemotherapy induced significant increase in activity of ATM, ATR, PRKDC and CHEK2. Simultaneous inhibition of ATM and ATR significantly reduced cell viability±A.

Summary/Conclusions: We identified the most abundant and active protein drug targets in AML primary samples and cell lines. Treating AML cell lines with chemotherapy uncovered biochemical pathways involved in DNA repair and survival that determined sensitivity or resistance to these drugs. Proteins significantly modulated in expression and activity after relapse include those involved in DNA repair and pro-survival but these were patient specific, suggesting that targeted therapies will have to be personalized.

LB2243

IDENTIFICATION OF A NOVEL RNA GIANT NUCLEAR BODY IN MYELOID LEUKEMIA

H Zhou*, R Xu

Department of Hematology, Key Laboratory of Cancer Prevention and Intervention, China National Ministry of Education, Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: Constitutive synthesis of oncogenic mRNAs is essential for maintaining the uncontrolled growth of myeloid cells. However, little is known about how these mRNAs are exported from the nucleus to the cytoplasm. Cancer cells, unlike normal cells that only divide a finite number of times before they enter into a state of growth arrest or die, are able to maintain uncontrolled proliferation. The cell nucleus, which houses much of the genome and the machinery needed for its replication, maintenance, and expression, is crucial for the survival and proliferation of cells. However, no nuclear bodies have been definitively linked to the uncontrolled proliferation of cancer cells so far. EIF4E nuclear bodies were initially reported two decade ago and thought to be involved in the exporting of nuclear mRNAs associated with cell proliferation. studies have shown a positive correlation between increased eIF4E phosphorylation and cancer cell proliferation as well as tumorigenesis. Consistently, highly phosphorylated eIF4E (p-eIF4E) was frequently observed in a variety of human cancers. Therefore, we hypothesized that cancer-associated nuclear bodies as detected by p-eIF4E antibody may exist in the nuclei of cancer cells.

Aims: To identify the putative cancer-associated nuclear body, we initially stained two human leukemia cell lines KG-1 (acute myeloid leukemia, AML) by immunofluorescence staining with antibodies against phosphorylated eIF4E (p-eIF4E) or total eIF4E (t-eIF4E); To reveal the morphology and structure features of GNB; To determine whether RNA-GNB abundance was associated with the hyperproliferative phenotype in human cancer.

Methods: Cell lines and culture. Myeloid cell lines were used in this study.Hematopoietic malignant cells were cultured in RPMI-1640 supplemented with 10% fetal calf serum (FCS) at 37°C in a 95% air, 5% CO2 umidified incubator. Normal human blood samples and human leukemia cell samples. Normal blood cells and primary leukemia cell samples were isolated from healthy volunteers or leukemia patients with their informed consent in accordance with the Declaration of Helsinki. All experiments were approved by the ethics committee of Hangzhou First People's Hospital. Immunofluorescence staining. Cells were fixed with freshly prepared 3.7% paraformaldehyde in PBS (pH 7.2) for 20 min at room temperature on slides. Cells were then blocked and permeabilized with PBS containing 10% FBS and 0.1% Tween-20 for 30 min at room temperature. Staining of cells with primary antibodies was performed overnight at 4°C, and then with a FITC or rhodamine-conjugated secondary antibodies for 1 h at room temperature. After three washes with PBS, the slides were mounted in Vectashield with DAPI and sealed. Immunopurification of GNBs from leukemia cells. GNBs were purified from leukemia cells as centrifugation at 2,000 rpm for 5 minutes at 4°C. After washed three times with PBS, cells were resuspended in PBS containing protease inhibitors and transferred to a 7 mL Dounce tissue homogenizer for dounce homogenization. The homogenized suspension was collected for removing intact cells and undisrupted nuclei by centrifugation at 1,000 rpm for 5 minutes at 4°C. Separation of GNBs from nucleoli on the cell nuclei. Cells were collected by centrifugation at 2500 rpm for 5 minutes at 4°C. After removing the supernatant, the cell pellet was lysated with 0.5ml of buffer A for 5min and then centrifuged at 700 rpm, 5min at 4°C. The supernatant was carefully removed and the nuclei were washed with 1.5ml of Buffer A without NP40 by centrifugation at 700 rpm, 5min at 4°C.

Results: We report the identification of a RNA giant nuclear body (RNA-GNB) that is abundant in acute myeloid cells but rare in normal cells. The RNA-GNB contains a RNA core surrounded by a protein shell. We identify 782 proteins from acute myeloid-associated RNA-GNBs, 40% of which are involved in the nuclear mRNA trafficking. RNA-GNB is required for cell proliferation, and its abundance is positively associated with tumor burden and outcome of therapies.

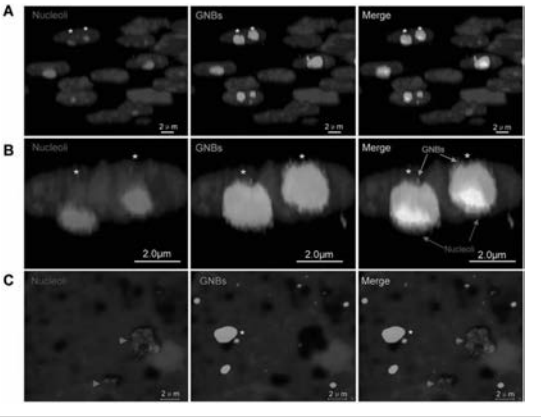

Figure 1.

Summary/Conclusions: Our studies have identified RNA-GNB as a potential nuclear mRNA trafficking organelle. Further studies will be required to characterize the components of proteins and mRNAs in RNA-GNB and reveal their functions. This will help elucidate how RNA-GNBs form and regulate the uncontrolled proliferation of cancer cells.

Acute myeloid leukemia - Clinical

PHASE 1B/2 STUDY OF VENETOCLAX WITH LOW-DOSE CYTARABINE IN TREATMENT-NAÏVE PATIENTS AGED ≥65 YEARS WITH ACUTE MYELOGENOUS LEUKEMIA

TL Lin[1], S Strickland[2], W Fiedler[3], RB Walter[4], JZ Hou[5], GJ Roboz[6], A Enjeti[7,8], KM Fakouhi[9], DE Darden[9], M Dunbar[9], M Zhu[9], J Hayslip[9], AH Wei[10,*]
[1]University of Kansas Medical Center, Kansas City, [2]Vanderbilt-Ingram Cancer Center, Nashville, United States, [3]Hubertus Wald University Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [4]University of Washington, Seattle, [5]University of Pittsburgh Medical Center (UPMC) Cancer Center, Pittsburgh, [6]Weill Cornell Medical College, New York, United States, [7]Calvary Mater Hospital Newcastle, Waratah, [8]NSW and School of Medicine and Public Health, University of Newcastle, Callaghan, Australia, [9]AbbVie, Inc., North Chicago, United States, [10]The Alfred Hospital and Monash University, Melbourne, Australia

Background: Treatment options for older patients (pts) with acute myelogenous leukemia (AML) unfit for intensive chemotherapy are limited. Expected complete remission rates for low-dose cytarabine (LDAC) are about 10% in this population. Targeting the pro-survival molecule BCL-2 has demonstrated clinical efficacy as a therapeutic strategy in various hematologic malignancies. Venetoclax (VEN), a selective BCL-2 inhibitor, shows synergy with cytarabine in several AML cell lines and primary samples.
Aims: The primary objectives of the study include evaluating the safety of VEN administered with LDAC and preliminary estimates of efficacy.
Methods: This is a non-randomized, open-label phase 1/2 dose-escalation/expansion study of VEN+LDAC, in treatment-naïve AML pts ≥65 years not eligible for intensive chemotherapy. Pts receive oral VEN once daily (QD) on days 1-28 and subcutaneous LDAC 20mg/m^2 QD on days 1–10 of each 28-day cycle. VEN dose escalation follows a 3+3 design; dose-limiting toxicities (DLTs: grade 4 toxicity, platelet count <25,000/μL, or absolute neutrophil count <500/μL within 14 days of last VEN dose) are assessed during cycle 1, up to day 42.
Results: As of Oct 1 2015, 18 pts (66.7% male; median age 74 years) have received LDAC+VEN in the phase 1 portion (VEN 600 mg target dose [n=8]; VEN 800 mg target dose [n=10]). Median time on study is 127.5 (range 30–272) days; 9 pts (50%) remain on study. DLTs of Grade 4 thrombocytopenia lasting >42 days without evidence of residual leukemia occurred in 2 pts in the VEN 800 mg dose group. The recommended phase 2 dose is 600 mg. Adverse events (AEs; ≥30% prevalence) were nausea (77.8%), anemia (55.6%), febrile neutropenia, neutropenia, fatigue (each 38.9%), vomiting, diarrhea and hypokalemia (each 33.3%). The most common serious AE was febrile neutropenia (33.3%). No clinically significant tumor lysis syndrome was observed. The overall response rate in phase 1 was 44% (complete remission, n=4; complete remission without complete marrow recovery, n=4; resistant disease, n=8; death before evaluation, n=2).
Summary/Conclusions: Initial findings suggest that VEN+LDAC has acceptable tolerability and promising clinical activity in older, treatment-naïve AML pts. Available phase 2 updates will be presented.

E912

CLINICAL OUTCOME AND EFFECT OF ALLO-SCT IN ADULT PATIENTS WITH DE NOVO OR AML-RELATED MYELOID SARCOMA. RESULTS FROM AN ITALIAN MULTICENTER SURVEY

D Lazzarotto[1,*], A Candoni[1], C Fili[1], F Forghieri[2], L Pagano[3], G Spinosa[4], A Busca[5], E Borlenghi[6], L Melillo[7], F Mosna[8], F Lessi[9], ME Zannier[1], E Simeone[1], R Fanin[1]
[1]Division of Hematology and Stem Cell Transplantation, University of Udine, Udine, [2]Division of Hematology, University of Modena, Modena, [3]Division of Hematology, Università Cattolica, Rome, [4]Division of Hematology, Hospital of Foggia, Foggia, [5]Division of Oncology, Hematology and Stem Cell Transplantation, University of Torino, Torino, [6]Division of Hematology, Spedali Civili di Brescia, Brescia, [7]Division of Hematology, IRCCS San Giovanni Rotondo, San Giovanni Rotondo, [8]Division of Hematology, Hospital of Treviso, Treviso, [9]Division of Hematology, University of Padova, Padova, Italy

Background: Myeloid Sarcoma (MS) is a rare hematologic myeloid neoplasm that can involve any site of the body. It can occur as isolated "*de novo*" extramedullary form or it can be associated with an acute myeloid leukemia (AML), a chronic myeloproliferative neoplasm (MPN) or a myelodysplastic syndrome (MDS) at onset or at relapse (secondary MS).
Aims: The rarity of MS does not enable prospective clinical trials and therefore a specific multicenter register can be very useful for the clinical and biological studies of this rare disease.
Methods: We report the clinical characteristics and outcome of 53 histologically confirmed MS, diagnosed and treated in 9 Italian Hematological Centers in the last 10 years (2005-2015).
Results: The median age of these patients (pts) was 47 years (range 15-82) and 30 (56.6%) were male. There were 9/53 *de novo* extramedullary MS, 24/53 primary AML-related MS and 20/53 were secondary MS (the median time to the onset of MS from the previous haematologic disease was 34.5 months, range 4–94). Histologic and biologic data are available in all cases. The most common extramedullary anatomic sites of disease were: skin, lymph nodes, soft tissues, bone and testis. Treatment: 46/53 pts (86.8%) underwent a program of intensive chemotherapy (combined with radiotherapy in 16/46 cases) including FLAI, HDAC-IDA, HyperCVAD and MEC schemes, with a CR Rate of 43.5% (20/46). Twenty-four (52.2%) pts underwent Allo-SCT, 9 from an HLA-identical sibling donor, 2 from an haploidentical donor and 13 from a MUD. The median OS of the whole population (53 pts) was 16.7 months with no differences between *de novo* extramedullary MS and AML-related MS (p=0.71). The OS probability at 5 yrs was 33,8%. The survival was significantly better in the pts that underwent an intensive therapeutic program (median OS: 18.3 mths *vs* 5.4 mths, P=0,006). Furthermore, among the intensively treated pts, the survival was better in those pts that underwent Allo-SCT (median OS not reached *vs* 10.6 mths, P=0,001), in pts with *de novo* or primary MS (median OS 20.4 mths *vs* 10.6 mths of the secondary MS, P=0,012) and in the pts that achieved a CR after induction chemotherapy (median OS not reached *vs* 14.6 mths, P=0,07) without differences between *de novo* extramedullary MS and AML-related MS (p=0.76). In multivariate analysis, Allo-SCT and Response to Induction therapy, were the only significant variables in predicting survival (P=0,002 and P=0,037, respectively). The median post-transplant OS of the Allo-SCT recipients was not reached after a median follow-up of 17.5 months and we observe a survival advantage in the patients who achieved a pre-transplant CR (P=0,042) and in the patients who developed a chronic GvHD after Allo-SCT (P=0,065).
Summary/Conclusions: The pts with isolated MS result to have a similar unfavourable outcome than the patients with AML-related MS. These data outline the need of underwent an intensive therapeutic program that includes Allo-SCT, whenever possible, both in isolated extramedullary MS and in AML-related MS. The outcome after Allo-SCT is positively influenced by the development of chronic GvHD suggesting a Graft *versus* MS effect.

E913

OVEREXPRESSION OF ADAM28 ENHANCES ACUTE MYELOID LEUKEMIC CELL MIGRATION AND INCREASES THE GROWTH OF XENOGRAFT TUMOURS IN MICE

XH Zhang*, CC Wang, JM Zhang, Q Jiang, H Jiang, J Lu, YJ Chang, XS Zhao, XY Zhao, LP Xu, KY Liu, XJ Huang
Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Acute myeloid leukemia(AML) is fatal as a result of primaryrefractoriness, relapse, or treatment-related mortality. Cytogenetics is the most powerful predictor of prognosis in AML, and integrating additional genetic data may further improve predictive capabilities. A disintegrin and metalloproteinases (ADAMs) are involved in various biological events, including cell adhesion, cell fusion, membrane protein shedding, and proteolysis.Our previous study has demonstrated that the expression level of ADAM28 is significantly elevated in relapsed ALL patients and is regulated via a PI3K/Akt signalling pathway.We hypothesized that overexpression of ADAM28 might contribute to invasion and metastasis in adult AML, promoting thetumourigenicity potential andproliferation of AML cells.
Aims: To investigate whether overexpression of ADAM28 was associated with relapse in de novo AML patients, we performed this prospective clinical study and explored the functions and regulation of ADAM28 overexpression in vitro.
Methods: The mRNA expression of ADAMs in the bone marrow of de novo AMLpatients was measured by qPCR. ADAM28 expression levels in BM, serum and cerebrospinal fluid were also measured. Twenty-three healthy donors as controls and 200 AML patientswere included in our group. The cumulative incidence of relapse (CIR),overall survival (OS) and event-free survival (EFS) after a 3-year follow-up were used to evaluate prognosis.Primary AML cells and different AML cell lines were cultured to examine the expression of ADAM28 in vitro. ADAM28-specific cDNA and siRNA were designed and established. Leukemic cell migration was measured using modified Boydenchambers.A nude mouse model was established to measure the effect of ADAM28 on thetumourigenicity of leukemic cells *in vivo*. The expression of Ki-67 and PCNA was detected to measure proliferation.
Results: In general, mRNA expression of ADAM28 displayed the most significant differences between patients and healthy donors among the ADAMs detected.The expression of ADAM28 was significantly increased in AML patients compared with healthy donors. Patients suffering relapse exhibited significantly higher expression levels of ADAM28 compared with those who remained in complete remission. Patients with CNSL also demonstrated significantly increased ADAM28 expression in the CSF and serum compared with non-CNSL patients. The Kaplan-Meier survival curve showed that EFS was shorter andCIR was higher in patients with high expression levels of ADAM28.The results showed that age, karyotype and ADAM28 level are inde-

pendent risk factors for OS and EFS.In vitro, the expression of ADAM28 was relatively higher in primary blast cells and SHI-1 cells, which were selected forsubsequentprocedures. Overexpression of ADAM28 promoted the proliferation and invasiveness of SHI-1 cells and primary blast cells transfected with ADAM28 cDNA; in contrast, knockdown of ADAM28 expression inhibitedproliferation and invasiveness.Following subcutaneous injection into nude mice,ADAM28 knock-down cells displayed an inhibited tumourigenicity potential, whereas ADAM28-overexpressingcells presented largerxenograft tumours.
Summary/Conclusions: Our findingsdemonstrate that overexpression of ADAM28 in AML patients is correlated to relapse; patients with higher levels of ADAM28 have a higher CIR. Overexpression of ADAM28 can enhance cell proliferation and migration, as well as tumourigenicity. These data suggest that ADAM28 may be a novel biomarker for predicting the prognosis of AML, potentially providing a new therapeutic target.

E914

PROLONGED SURVIVAL IS ACHIEVABLE FOR A QUARTER OF PATIENTS IN PRIMARY INDUCTION FAILURE FOR ACUTE MYELOID LEUKEMIA, BUT DOES NOT RELY ON REPEATED SALVAGE THERAPY-A MONOCENTRIC RETROSPECTIVE STUDY

MP Ledoux*, C Fohrer-Sonntag, C Simand, B Merle, S Natarajan-Amé, LM Fornecker, B Lioure
Hematology, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Response to first induction chemotherapy is a strong prognostic factor in patients with newly diagnosed acute myeloid leukemia (AML) eligible for intensive treatment. Primary induction failure (PIF) leads to an escalation of therapeutic means, the benefit of which remains controversial.
Aims: Allogeneic hematopoietic stem cell transplantation (HSCT) appears to be the most appropriate consolidation treatment to lower relapse risk but determining its best timing is still a challenge: disease-free (DFS) and overall survivals (OS) are known to be better if allogeneic HSCT is done in complete remission (CR), but earlier transplant is usually associated with a better outcome. These two conditions seem to pull in opposite directions in PIF AML.
Methods: We therefore conducted a retrospective monocentric study analyzing the outcome of all adult patients with newly diagnosed AML in Strasbourg University Hospital between 2002 and 2014 and failing to achieve remission after first induction.
Results: Of 704 AML patients, 394 (56.0%) received intensive chemotherapy, and 90 (22.8%) were considered PIF. Sixty-three of these patients (70.0%) received further intensive treatment, enabling a median OS of 418 days, compared to 65 days for patients on palliative care and 253 days for patients receiving hypomethylating agents only (p<0.001). Salvage chemotherapy led to CR in 40% of patients, and those having received an allogeneic HSCT while still on CR reached a median OS of 2068 days, with a three-year survival of 57.4%. Patients in CR after salvage therapy but who were not subsequently transplanted had a median OS of only 551 days. Patients receiving more than one salvage chemotherapy before being transplanted had a median OS of 418 days, compared with 467 days for patients who were transplanted while refractory without or after only one salvage therapy (p=0.7). Among the 23 patients still refractory at transplantation, allogeneic HSCT eventually led to remission in 20 patients (87%), but with a high subsequent relapse rate. Allogeneic HSCT in refractory patients led to a median OS of 467 days, with three-year survival reaching 25.6%. On the whole, the three-year survival rate of the 38 patients who received an allogeneic HSCT was 39.5% compared with 2% for the 52 patients who did not undergo transplantation.
Summary/Conclusions: Continuing intensive treatment of AML after primary induction failure is still the better therapeutic option in terms of survival for fit patients: we have observed that it can result in prolonged survival, and perhaps cure, for roughly a quarter of them, supporting this approach. However, considering our data, receiving more than one salvage chemotherapy doesn't appear to lead to a better outcome and may impair the rate of allogeneic HSCT. This might eventually affect the outcome of refractory patients, since allogeneic HSCT is a crucial step in their management. Although survival is consistently lower for patients lacking CR, allogeneic HSCT for refractory patients still offers prolonged survival to a significant proportion of PIF AML patients in spite of their initial dismal prognosis.

E915

IMPACT OF SINGLE NUCLEOTIDE POLYMORPHISMS OF ABCB1 GENE UPON THE EFFECTIVENESS AND TOXICITY OF INDUCTION CHEMOTHERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

JE Megías-Vericat[1,*], P Montesinos[2], MJ Herrero[1], F Moscardó[2], V Bosó[1], D Martínez-Cuadrón[2], L Rojas[1], D Hervás[3], R Rodríguez-Veiga[2], L Sendra[4], B Boluda[2], A Miguel[4], J Sanz[2], J Cervera[2], JL Poveda[1], SF Aliño[5], MÁ Sanz[2]

Background: The intake of anthracyclines in blast cells could be affected by efflux pumps of *ABC* family.
Aims: Previous studies suggested that single nucleotide polymorphisms (SNPs) of *ABCB1* may influence anthracycline effectiveness in acute myeloid leukemia (AML) induction therapy, although their impact in induction death and anthracycline-related organ toxicity.
Methods: The SNPs of *ABCB1* gene (rs1128503, rs1045642, rs2032582 and haplotype) were evaluated in 225 adult patients at initial diagnosis from AML using a Sequenom (iPLEX) mass spectrometry–based multiplex genotyping assay (Sequenom, San Diego, CA). All patients received induction chemotherapy consisting of idarubicin plus cytarabine (PETHEMA-LMA 99, 2007 and 2010 trials). Efficacy of first induction cycle was evaluated comparing complete remission (CR) *vs* partial remission (PR) or resistance, excluding these patients dying during induction. Induction death was defined as patients dying during induction against CR, excluding these patients with PR or resistance. Based on WHO grading scale, toxicities were grouped as binary variables (grade 0-1 *vs* grade 2-4). The grade of toxicity assigned to an organ group was the maximum grade of all the specific toxicities within that group. Genotypes were studied with a co-dominant model. Association between variables was assessed using linear and logistic regression adjusting for age, gender, cytogenetic risk, ECOG, leukocyte and platelet count, hemoglobin, creatinine, bilirubin, albumin and LDH level at diagnosis (R® version 3.1.2).
Results: The median age of patients was 51.1 years (16-78 years). There were no statistically significant differences in CR. Nevertheless, induction death was associated to *ABCB1* triple variant haplotype (40.0% *vs* 17.2%; OR: 0.2; 95%CI: 0.05-0.8; P=0.017). Besides, the *ABCB1* triple variant haplotype was related to more nephrotoxicity than the other genotypes (OR: 3.6; 95%CI: 1.3-10.4; p=0.016). The variant alleles of *ABCB1* rs1128503, rs2032582 and recessive haplotype were also related to hepatotoxicity (OR: 6.9; 95%CI: 2.2-21.2; p= 0.001; OR: 2.9; 95%CI: 1.01-8.1; p=0.049; OR: 6.0; 95%CI: 2.1-16.3; p<0.001; respectively). Regarding hematologic toxicity, time to neutropenia recovery was delayed with variant allele of *ABCB1* rs2032582 (OR: 3.0; 95%CI: 1.1-10.1; P=0.047).
Summary/Conclusions: The variant alleles of *ABCB1* polymorphisms have been related to lower anthraclycline clearance and higher tissue exposure. This could be the reason of the higher toxicity and induction death observed. This study shows a prognostic impact of *ABCB1* polymorphisms in adult AML patients regarding induction chemotherapy toxicity. Further studies with larger population are needed to validate these associations, which could be useful biomarkers in clinical practice. Study supported by grants from the "Instituto Carlos III" (PIE13/00046), "Instituto Investigación Sanitaria La Fe" (2013/0331) and the Cooperative Research Thematic Network (RTICC), Grant RD12/0036/014 (ISCIII & ERDF). Samples have been managed by the La Fe Biobank, licensed as required by Spanish Royal Decree 1716/2011 of 18 November (Ref.: PT13 / 0010/0026).

E916

CLEARANCE OF NPM1 MUTATION AT FIRST COMPLETE REMISSION AFTER INDUCTION THERAPY DID NOT PREDICT THE SURVIVAL IN FAVORABLE RISK GROUP WITH NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA

SS Lee[1,*], HJ Kim[1], JS Ahn[1], YK Kim[1], SH Jung[1], DH Yang[1], JJ Lee[1], H Kook[2], SH Choi[3], CW Jung[4], JH Jang[4], HJ Kim[5], JH Moon[6], SK Sohn[6], JH Won[7], SH Kim[8], T Kim[9,10], DDH Kim[11]

Background: The presence of minimal residual disease is known to be an independent prognostic factor for the duration of remission and survival in acute myeloid leukemia (AML). However, since AML has a molecular heterogeneity, the routine assessment of minimal residual disease (MRD) has not been adopted in the current practice of patients with AML.
Aims: Herein, we evaluated the *NPM1* mutation as a marker of MRD at first complete remission (CR) after induction therapy in normal karyotype AML (NK-AML) with favorable molecular risk group.
Methods: A total of 413 patients were included in the present study who met the following eligibility criteria: 1) age ≥15 years; 2) a diagnosis of NK-AML

confirmed by conventional cytogenetic analysis; 3) treatment with induction chemotherapy using a standard protocol (a 3-day course of anthracycline with a 7-day course of cytosine arabinoside). Analysis of *NPM1* mutations were performed using targeted resequencing by SureSelect capture and Illumina platform technology. The 184 patients (44.6%) showed *NPM1* mutation at diagnosis and, 99 patients were *NPM1* mutated and *FLT3*-ITD negative (favorable molecular risk by ELN). We have focused on the prognostic impact of *NPM1* MRD esp. in the group with favorable risk by ELN risk classification. The 52 out of 99 favorable risk patients were available the analysis of *NPM1* mutations at CR samples.

Results: In 52 patients, 37 patients (71.2%) were negative (*NPM1*$^{MRD-}$) and, 15 patients (28.8%) persistently observed the *NPM1* mutations (*NPM1*$^{MRD+}$) in CR samples. There was no difference in variant allele frequencies of *NPM1* mutations at diagnosis between *NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$ (32.7% [range, 6.85-43.9] *vs* 36.8% [range, 25.0-48.7], p=0.168). There was no difference in gender (p=0.754) or age (p=0.545). However, WBC count in *NPM1*$^{MRD-}$ group (median: 15.3 x 10^9/L, range: 0.9-142.0) was lower than in the *NPM1*$^{MRD+}$ group (median: 81.1 x 10^9/L, range: 1.7-224.6.0), (*p*=0.014). In 15 out of 52 patients received allogeneic stem cell transplantation (SCT), there was no difference of proportion of patients receiving allotransplant between *NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$ group (21.7% vs.20.0%, p=0.897). In the survival analysis according to the MRD of *NPM1* mutation, there was no difference between *NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$ group in terms of 5-year overall survival (OS) (*NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$, 66.1% vs.72.7%, p=0.699) and 5-year event free survival (EFS) (*NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$, 57.1% vs.61.1%, p=0.596). There was no difference in relapse risk at 5-year (*NPM1*$^{MRD-}$ *vs* *NPM1*$^{MRD+}$, 36.4% vs.32.2%, p=0.509). Regardless of clearance of *NPM1* mutations, allogeneic SCT substantially reduced the relapse risk (p=0.007). However, allogeneic SCT did not confer to overall survival benefit due to higher non-relapse mortality (p=0.046).

Summary/Conclusions: In this cohort, clearance of *NPM1* mutation at first CR in favorable risk group of NK-AML was not replicated as a prognostic marker to predict the survivals or relapse risk. Even in patients with *NPM1* positive at first CR in favorable molecular risk group, the most of patients demonstrated long term survival even with consolidation chemotherapy without allogeneic transplantation. To clarify the role of clearance of *NPM1* mutations, further analysis after consolidative therapy will be needed.

Background: Treatment of elderly patients (pts) with acute myeloid leukemia (AML), is still controversial. In 2013 an Italian panel of experts proposed a set of objective criteria to define pts fit or unfit to conventional intensive chemotherapy (iCT) or non intensive therapy (niT) (Ferrara et al, Leukemia, 2013). Since such criteria derived from experts opinion, they need to be validated in the clinical setting to become an useful tool for therapy decision making.

Aims: Fitness criteria were applied to a population-based series of pts with AML (not M3), to retrospectively evaluate their actual applicability, their concordance with the treatment actually given, and the outcome of pts according to "fitness", leukemia biology and treatment.

Methods: We evaluated 699 pts aged >65 y, diagnosed between 2008 and 2015, at 8 Centres of the Hematological Network of Lombardy (REL). AML was de novo in 419 pts and therapy-related or secondary to myeloid neoplasms (s-AML) in 280 pts; median age was 74 (range 65-96). The categorization according to "fitness" criteria was carried out retrospectively by physicians who had followed pts and through medical files. Pts were defined as fit to iCT (FIT), unfit to iCT (UNFIT), or unfit even to niT (FRAIL). ELN prognostic criteria could be applied to 117 (27.9%) de novo AML [12.2% favorable-risk (fav) (CBF 4.6%), 32.5% intermediate-1 (int1), 14.2% intermediate-2 (int2), and 36.4% adverse (adv) risk]. Karyotype (K) was adverse (ELN) in 193 (36%) of 537 evaluable AML. According to physicians decision, 274 pts (39.2%) received iCT, 134 pts (19.2%) niT, including low-dose ara-c, hypomethylating agents or experimental non-myelotoxic drugs, and 291 pts (41.6%) best supportive care (BSC).

Results: Fitness criteria were not applicable in 13 pts (1.9%), because of insufficient data. Among 686 evaluable pts, 292 (42.5%) were FIT, 289 (42.1%) UNFIT, and 105 (15.3%) FRAIL. Median age was 69, 78 and 76 y, respectively (p<0.0001). Median overall survival (OS) of FIT, UNFIT and FRAIL pts was 10.9, 4.2 and 1.8 months (m), respectively (p=0.000) (Figure 1). According to ELN risk, median OS was 17.5, 14.1, 8.0, 9.8 m, in fav, int1, int2 and adv risk de novo AML, respectively (p 0.008). Median OS was 12.6 and 5.9 m in not-adv and adv K, respectively (p 0.002).Overall concordance between "fitness criteria" and the treatment actually received by pts was 79.4% (76% in FIT, 82.7% in UNFIT and 80% in FRAIL pts). There was a significant interaction between disease biology and treatment actually given. FIT pts receiving niT had a higher proportion of adv K (66%) than pts receiving iCT (19%). In FIT pts median OS was best with iCT, being significantly longer than in pts actually "undertreated" (11.6 m with iCT *vs* 7.6 m with niT or BSC; p 0.006). In UNFIT pts median OS was 8.7, 9.2, 2.5 m with iCT, niT and BSC, respectively. It was significantly worse in patients actually "undertreated" with BSC only (p 0.0001), but "overtreating" UNFIT pts with iCT did not improve OS. Among FRAIL pts, "overtreatment" using niT didn't improve OS compared to BSC (2.9 *vs* 1.5 m, p:ns).

	FIT	UNFIT	FRAIL	TOT
	292 (42.5%)	289 (42.2%)	105 (15.3%)	686
iCT	222 (76%)	50 (17.3%)	2 (1.9%)	274 (40%)
niT	39 (13.4%)	76 (26.3%)	19 (18.1%)	134 (19.5%)
BSC	31 (10.6%)	163 (56.4%)	84 (80%)	278 (40.5%)

Figure 1.

Summary/Conclusions: The "fitness criteria" proposed were easily applicable even retrospectively and in a multicenter setting. Overall concordance between "fitness criteria" and treatment actually received by pts was high (79.4%). Fitness was significantly related to patient's survival. The "fitness criteria" could correctly identify patients most likely to benefit from different treatment intensities or BSC. Knowing biologic risk profile may further refine treatment decisions.

CLINICAL CHARACTERISTICS AND OUTCOME OF PEDIATRIC ACUTE MYELOID LEUKEMIA WITH DEL(5Q): A REPORT FROM THE JAPANESE PEDIATRIC LEUKEMIA/LYMPHOMA STUDY GROUP

A Kinoshita[1,*], T Taki[2], Y Hayashi[3], H Miyachi[4], H Matsushita[4], M Yabe[5], D Tomizawa[6], H Takahashi[7], A Tawa[8], K Horibe[9], T Taga[10], S Adachi[11]

Background: Deletion of chromosome 5q (5q-) confer a poor prognosis in adults with acute myeloid leukemia (AML) and associated with higher white blood cell count at diagnosis. However, since this chromosomal abnormality is rare in pediatric patients with AML, the clinical characteristics and prognostic significance are not clear.

Aims: To clarify AML with 5q- in terms of hematological and clinical characteristics, and prognosis.

Methods: Between November 2006 and December 2010, 485 consecutive patients aged<18 years with suspected AML excluding acute promyelocytic leukemia, Down syndrome, secondary AML, myeloid/natural killer cell leukemia, and myeloid sarcoma were registered in AML-05 conducted by the Japanese Pediatric Leukemia/Lymphoma Study Group. The diagnosis according to the 2008 WHO classification was determined centrally by integrating morphologic, cytogenetic, immunologic, molecular and clinical parameters. We stratified patients after the second induction course to either of the three risk groups according to the cytogenetics and *FLT3*-ITD status at diagnosis and the response to induction chemotherapy. Allogeneic hematopoietic transplantation (HSCT) was planned for the patients allocated for the high risk group including 5q- after the third or fourth chemotherapy course.

Results: Of the 485 patients registered, 32 patients were excluded because

of misdiagnosis or refusal by the guardians. Of the 453 eligible patients, a total of 11 patients (2.4%) were identified as AML with 5q-. The table 1 shows cytogenetic data for the 5q- patients. All patients with 5q- had unrelated chromosomal abnormalities >3 and were therefore diagnosed as AML with myelodysplasia-related changes. Median age at diagnosis was 1.9 years (range, 0.2-13.8) and median WBC count at presentation was 28.1×10^9/l(range, 2.1-50.7). Any significant differences were seen in age and WBC count compared to those without 5q-. Of the 11 patients, 7 (64%) had a complete response (CR) to induction chemotherapy. Of the 4 patients with induction failure, 2 were treated with HSCT and were alive. Of the 7 patients achieving CR, bone marrow relapse was recognized in 5, 2 of whom were alive after HSCT. Excluding patients with core binding factor leukemia, the 3-year event-free survival for patients with 5q- was significantly lower than for those without 5q- (18% *versus* 56%, P=0.02). However, the 3-year overall survival was not significantly different between patients with 5q- and those without 5q- (54% *versus* 70%, P=0.07).

Summary/Conclusions: Our study suggests that AML with 5q- has a poor prognosis, but that intensive therapy including HSCT may improve outcome in children with AML with 5q-.

E919

DOSE ESCALATION STUDY OF CRENOLANIB IN COMBINATION WITH HIGH DOSE CYTARABINE/IDARUBICIN SALVAGE CHEMOTHERAPY IN MULTIPLY RELAPSED FLT3 POSITIVE AML

J Cortes[1,*], F Ravandi[1], G Garcia-Manero[1], T Kadia[1], G Borthakur[1], M Konopleva[1], N Daver[1], N Pemmaraju[1], E Jabbour[1], Z Estrov[1], T Phung[2], V Urity[2], A Uchida[2], J Paradela[1], M Andreef[1], H Kantarjian[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Arog Pharmaceuticals Inc, Dallas, United States

Background: FLT3 inhibitors usually provide transient clinical benefit to patients with FLT3-mutated AML. FLT3 inhibitor-based combination therapy has been suggested to enhance such benefit. Crenolanib is a novel, type I, oral pan-FLT3 inhibitor with high single-agent activity against multiply relapsed FLT3-ITD and tyrosine kinase domain (TKD) mutant AML. We here report interim data from a Phase I trial to evaluate the safety and efficacy of salvage therapy with high dose cytarabine/idarubicin followed by crenolanib in multiply relapsed FLT3+ve AML.
Aims: Dose escalation study to determine the maximum tolerated dose (MTD) of crenolanib when combined with high dose cytarabine+idarubicin.
Methods: Pts >18y with refractory/relapsed FLT3 ITD and/or TKD+ve AML are eligible. Pts receive salvage therapy with high dose cytarabine (1.5 g/m^2/day over 3 hours for 4d or for 3d if >60y) along with idarubicin (12 mg/m^2 for 3d). Daily crenolanib starts from d5 and is continued until 72hrs prior to next chemotherapy regimen. The starting dose cohort of crenolanib is 60 mg TID and is then escalated in subsequent cohorts to 80 mg TID and 100 mg TID. Pts may receive consolidation with cytarabine (750mg/m^2 for 3d) and idarubicin (8 mg/m^2 for 2d) followed by daily crenolanib. Crenolanib may be administered for maintenance for up to 365 days.

Table 1.

Age	Sex	FLT3 Status	Prior chemo regimens	Prior Investigational agents	Crenolanib dose	Response
43	F	ITD	2	sorafenib	60 mg	CRi
67	M	D835	1		60 mg	CR
21	M	ITD	4+SCT	sorafenib, E6201	60 mg	No Response
31	M	ITD+ D835	1		80 mg	ETP-ALL
51	M	ITD	8	AG221, BGB324	80 mg	NE
30	M	D835	9+SCT	sorafenib, AG221, E6201	80 mg	NE
58	M	ITD+ D835	3	quizartinib	80 mg	CRi
57	M	ITD+ D835	2	sorafenib	80 mg	No Response
70	M	D835	3	AMG330	100 mg	pending
19	M	D835	3+2 SCT		100 mg	pending
24	M	ITD+ D835	3	quizartinib	100 mg	pending

Results: To date, 11 pts (10 males, 1 female) have been enrolled with a median age of 43 (range 19-70). Pts were heavily pre-treated with a median of 3 prior systemic treatments (range: 1-9). 8/11 pts had received prior investigation agents including 6 with prior FLT3 inhibitors. Three pts had undergone allogeneic SCT. Besides FLT3, multiple other leukemia associated mutations were present at baseline: NPM1 (40%), DNMT3A (40%), WT1 (30%), TET2 (30%), NRAS/KRAS (30%), IDH2 (20%), NOTCH1 (20%), MLL (20%), RUNX1 (10%), ASXL1 (10%) and EZH2 (10%). All 3 pts treated with cytarabine/idarubicin followed by crenolanib 60 mg TID tolerated the regimen well with no DLTs. Two achieved a CR (including one who became FLT3 negative after reinduction). Both these patients have undergone an allo SCT. 5 pts received cytarabine/idarubicin followed by crenolanib 80 mg TID. One of the three evaluable pts in this cohort achieved a CRi and has undergone SCT. The patient with ETP-ALL had no response. No pt required dose reduction in the 80mg TID cohort. All 3 pts in crenolanib 100mg TID cohort have now completed cytarabine/idarubicin salvage and are receiving crenolanib (but are too early for assessment of response).
Summary/Conclusions: Crenolanib can be safely administered with HiDAC/idarubicin salvage chemotherapy in multiply relapsed AML. 3 patients have achieved a CR/CRi which allowed them to be bridged to an allo SCT. Accrual to this trial will continue at the crenolanib 100 mg TID dose.

E920

QUANTIFICATION OF COMMON AND RARE NPM1 SUBTYPES USING A SINGLE MASSIVELY MULTIPLEX DIGITAL PCR ASSAY FOR MINIMAL RESIDUAL DISEASE IN AML

N Mencia Trinchant[*], Y Hu, F Ali, ML Guzman, GJ Roboz, DC Hassane
Weill Cornell Medicine, New York, United States

Background: Acute myeloid leukemia (AML) is a fatal disease with poor outcomes. Despite initial remissions, most patients relapse and ultimately succumb to their disease. The presence of minimal residual disease (MRD) in patients has been shown to be predictive of relapse and thus is likely to better inform therapeutic decision-making. Improved assessment methods are therefore urgently needed. Molecular assessment of MRD has been accomplished using a number of markers including NPM1 mutations (NPM1mut). The vast majority of NPM1 mutations are four nucleotide insertions in exon 12, the most common of which is type A (c.860_863dupTCTG), found in approximately 75% of NPM1 mutated AML patients. The remaining patients often have rarer subtypes with differing and often patient-specific insertion polymorphisms with over 50 such polymorphisms being reported. Currently, real time quantitative PCR (RQ-PCR) is used to assess mutant NPM1 percentages. However, RQ-PCR requires custom assays and development of plasmid standards tailored to each subtype. RQ-PCR assays have been adapted to digital PCR (dPCR) to eliminate the need for plasmid standards, but custom primers and/or probes are still needed. Moreover, in diagnostic cases where NPM1mut diagnosis is made by capillary electrophoresis without sequencing, subtype information is absent and MRD cannot be assessed reliably with standard approaches. To overcome these obstacles, we demonstrate a massively multiplex dPCR assay that operates on >95% of NPM1 polymorphisms without requiring prior knowledge of the specific polymorphism and is robust to NPM1 evolution and mixtures of NPM1 mutant clones.
Aims: To determine if a single assay can consistently quantify NPM1mut percentages in a manner that is robust to NPM1 subtype.
Methods: AML samples and synthetic reference standards with varying NPM1 mutations were quantified as NPM1 mutant copies per ABL1 copies (NPM1mut/ABL1). Subtype-specific assays were compared to massively multiplexed dPCR assay. Agreement between NPM1mut/ABL1 measurements was assessed in parallel using both methods.
Results: NPM1 mutant copies were quantified using massively multiplexed dPCR assay alongside subtype-specific assays. The massively parallel dPCR assay demonstrated excellent correlation with subtype-specific assays (r >0.95; Pearson's correlation), including rare subtypes such as NPM1-DD1. We additionally assessed mixtures of subtypes alongside standard assays. In such mixtures, our massively multiplexed assay correctly ascertained NPM1mut/ABL1 ratios whereas standard subtype-specific assays underestimated NPM1mut/ABL1 ratios, demonstrating the robustness and accuracy of this assay in samples with mixtures of NPM1 mutants. Sensitivity was comparable with standard subtype-specific assays without cross-reactivity to wild-type NPM1.
Summary/Conclusions: Massively multiplexed dPCR inexpensively allows a single assay to detect the vast majority of NPM1 mutations both common and rare. The quantification is largely impervious to NPM1 evolution/polyclonality and greatly diminishes the need for subtype-specific assays with custom primer sets and plasmid standards. It is therefore a useful strategy for the follow up of AML patients diagnosed with NPM1mut AML in MRD assessment.

E921

A SIMPLE 3-GENE MOLECULAR SCORE RETAINS HIGH PROGNOSTIC VALUE IN NON HIGH RISK ACUTE PROMYELOCYTIC LEUKEMIA TREATED WITH AIDA 2000 PROTOCOL: A RETROSPECTIVE STUDY FROM A REGIONAL REGISTER

D Guardo[*], F Guolo, P Minetto, E Coviello, M Gambella, G Rivoli, N Colombo, M Miglino, F Ballerini, M Clavio, RM Lemoli, M Gobbi
Chair of Hematology, Departement of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino IST, Genoa, Italy

Background: Non high risk acute promyelocytic leukemia (APL) patients, as

defined by WBC count at diagnosis, have nowadays a very good prognosis when treated with ATRA plus chemotherapy based protocols, with high rate of complete molecular remission after consolidation therapy. However, a small portion of patients (roughly 10%) will eventually relapse, despite the achievement of molecular CR. In the past years, some groups showed that relapse risk could be predicted by testing for some gene alterations, such as FLT3-ITD, or by break point cluster region (BCR) analysis. However, those results were not confirmed in prospective trials.

Aims: We recently showed that a simple gene-expression panel including WT1 and BAALC expression levels analysis has high prognostic value in MDS patients. The aim of the present study was to evaluate if the application of a similar panel to APL patients at diagnosis could be predictive of relapse risk and survival.

Methods: We retrospectively applied a simple 3 gene based molecular panel including WT1 and BAALC expression levels at diagnosis, FLT3-ITD mutational status (molecular profile), alongside with BCR analysis, to a cohort of de novo 66 non high-risk acute promyelocytic leukemia patients, treated in our institution between January 1st 2004 to June 30th 2015. All patients have been treated according to the Italian age-adapted AIDA protocol. Median age was 47 years (range 16-88), 17 patients were older than 60 years. Median follow up was 58 months. BCR analysis was available in all patients, 43 patients showed BCR1/2, whereas 23 patients had BCR3 (35%). Molecular profile was available in 44/66 patients (66%). Cut-off values for WT1 (25000/Abl x 10^{-4}) and BAALC (450/Abl x 10^{-4}) were arbitrary chosen after pre-analysis and comparison with our published data. Seven patients had FLT3-ITD mutation (17%), 18 (45%) patients had high WT1 expression levels and BAALC was overexpressed in 9 (23%) patients.

Results: Sixty-three patients survived induction, all of them achieved CR. Among patients who had completed the whole therapeutic program at the time of the analysis 2 showed molecular persistence of disease and therefore received further therapy achieving molecular CR. Ten patients experienced disease relapse (15%). Pre-analysis showed that FLT3-ITD, not over-expressed WT1 levels, high BAALC levels but not the presence of BCR3 were associated with higher relapse risk. None of the molecular alterations reached statistical significance if taken alone. Therefore a molecular score including those 3 genes was built: 18 patients had no risk factor, 20 had one risk factor and 6 had two risk factors. Relapse risk was influenced only by the presence of at least one molecular risk factor ($p<0.05$). Disease free survival (DFS) duration was significantly higher in patients who had no molecular risk factor when compared to patients with at least one (3-years DFS of 100% and 85%, respectively, $p<0.05$). Overall survival (OS) analysis led to similar results: patients with no molecular risk factors had a very good outcome when compared to patients with at least one alteration (3-years OS of 100% and 79% respectively, $p<0.03$). Furthermore, we observed that both in DFS and OS analysis, the presence of two molecular factors leads to a worse outcome compared to the presence of only one alteration ($p<0.05$).

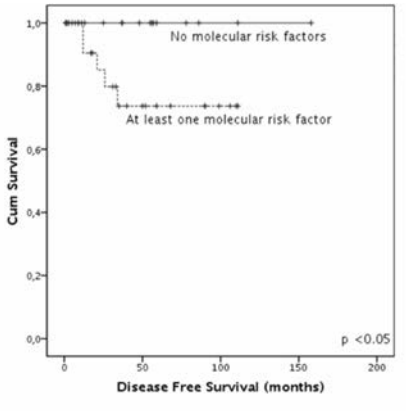

Figure 1.

Summary/Conclusions: Even in a small cohort, we demonstrate how a simple molecular profile, including FLT3-ITD and levels of expression of BAALC and WT1 could identify a subset of standard APL patients at higher risk of relapse. Sub-stratification of patients could allow us to recognize patients who may take benefit from an intensified consolidation therapy, as it is currently applied to high risk patients, in order to reduce risk of relapse.

CETLAM Group, Terrassa, [11]Hematology Department, Hospital de Mataró. CETLAM Group, Mataró, [12]Hematology Department, Hospital General de Granollers. CETLAM Group, Granollers, Spain

Background: The results of AML treatment in patients' ≥70 years are disappointing. Finding tolerable and efficacious treatments remains a major challenge. Intermediate dose cytarabine schedules in combination with other drugs allow treating patients in an outpatient basis.

Aims: The CETLAM04LAM70 semi-intensive protocol (Eur J Haematol. 2015;95:576-82) aimed to achieve a significant proportion of durable remissions in elderly (≥70 years) patients with AML based on reduction of the toxicity of full dose cytarabine. Despite this, toxicity and deaths in consolidation were of concern. In the current protocol (CETLAM11LAM70) intensive consolidations were substituted by 1 year of 5-azacitidine treatment. The aim of this study was to evaluate the tolerability and efficacy of the CETLAM11LAM70 protocol and to compare the outcomes with those from CETLAM04LAM70 protocol.

Methods: Eligible patients: 70 years of age or older with a newly diagnosed AML excluding t(15;17), biphenotypic leukemia with t(9;22) or blast crisis of chronic myeloid leukemia, ECOG 0-3 and able to attend weekly hospital visits at baseline. Treatment regimen: Induction-1 with FAG (fludarabine 25 mg/m^2 PO days 2-5, cytarabine 100 mg/m^2 SC days 2-8, filgrastim 300µg SC days 1-8), induction-2 or consolidation with IAG (idarubicin 20 mg/m^2 PO days 2-4, cytarabine 100 mg/m^2 SC days 2-8, filgrastim 300µg SC days 1-8) followed by 12 courses of AZA (5-azacitidine 75 mg/m^2 SC days 1-5 every 28 days). The main differences with the CETLAM04LAM70 protocol were the cytarabine dose (200 mg/m^2 *vs* 100 mg/m^2), the number induction/consolidation cycles and the 12 months maintenance.

Results: From January 2011 to June 2015, 44 patients were included (target 50 patients). Median age 74[70;87] years, 23 males (52%). AML characteristics: poor-risk cytogenetics 15 (34%), trilineage dysplasia 14/42 (33%), *FLT3 ITD* 6/33 (18%), mutation of *NPM1* 9/31 (29%). Outcomes: induction-related deaths 8 (18%), overall response to induction-1 26 (59%)(11/44 CR and 15/44 PR), consolidation-related deaths 3 (12%) and deaths during AZA treatment 2 (14%). Fourteen patients (32%) completed the scheduled treatment. The 1 and 2-yr (95%CI) OS, DFS and response duration are summarized in Table 1. Toxicities: Median duration of thrombocytopenia (<20x10^9/L) and neutropenia (<1x10^9/L) were 3 weeks (range 1-6) without differences between induction and consolidation. Fever in induction was observed in 30 patients (68%) and 34 (77%) were hospitalized; the median hospital stay was 15 days (1-45). Ten patients (23%) during induction and 8 (31%) during consolidation could be managed completely as outpatients. No toxicities grade >2 were observed during azacitidine treatment. No differences in OS, CR duration and DFS were observed on comparison of the two protocols (Table 1).

Table 1.

	CETLAM04LAM70 (%)	CETLAM11LAM70 (%)
1 yr OS (95%CI)	30 (14-46)	40 (25-55)
2 yr OS (95%CI)	23 (12-35)	24 (10-38)
1 yr response duration (95%CI)	50 (23-77)	67 (46-88)
2 yr response duration (95%CI)	41 (14-68)	38 (13-63)
1yr-DFS (95%CI)	35 (12-58)	43 (24-62)
2yr-DFS (95%CI)	29 (5-47)	21 (5-37)

Summary/Conclusions: The CETLAM11LAM70 protocol for elderly AML patients ≥70 years is tolerable, feasible and effective with reasonable response and induction mortality rates. Despite azaciditine was less toxic than previous consolidation strategies, the modification of the protocol did not help to improve OS. Supported: grants PI10/01417 and PI14/00450 from FIS, RD12/0036/0029 from Instituto Carlos III and 2014SGR225(GRE) from Generalitat de Catalunya, Spain.

E923

COMBINATION OF RNA- AND EXOME-SEQUENCING EFFICIENTLY ELIMINATES FALSE-POSITIVE SOMATIC POINT MUTATIONS AND INDELS-EXEMPLIFIED BY CASES OF CN-AML

L Herborg, MC Hansen*, A Roug, P Hokland
Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: Thorough annotation as a means of detecting highly relevant

mutations, and aberrated genes, is becoming more feasible as the evidence of biological pathways underlying malignant transformation compiles. However, there is a continuous risk of misinterpretating both true and false positive observations, which is closely coupled to the sheer number of observations in NGS projects. Thus, there is still a need to find ways to efficiently filter data ab initio, with little knowledge added from disease aetiology and other clinical findings in order to gain new insights.

Aims: We aimed at finding an efficient method to pinpoint true positive and known causal mutations, decreasing the need of downstream interpretation of variants to a minimum.

Methods: DNA and RNA were extracted from lysated bone marrow aspirate to a mean concentration of 35 ng/µl for both groups and 20 samples in total (Fig.). In order to streamline the alignment and variant calling workflow, we implemented CLC Biomedical Workbench (Qiagen, Aarhus, DK) to keep all dataprocessing in one simple workflow. Only regions covered by the Nextera Rapid Capture Exome kit (Illumina, CA, USA) were included and common variants excluded (dbSNP, NCBI, MD, USA). Alternative GATK and MuTect de facto standard workflow was used to survey the quality of CLC Biomedical Workbench alignment and single nucleotide variant (SNV) detection.

Results: Exome sequencing yielded an average of 9.1*10^7 sequence reads with read lengths of 100 and over 99% mapped in each sample. The combination of whole exome and RNA sequencing efficiently reduced the number of detected mutations to a median number of 6 [3, 21] somatic nucleotide variants (see figure). 6 new mutations, reported to be mutated in at least one other case of haematological neoplasms (COSMIC, Wellcome Trust, Sanger Institute, Cambridge, UK), *i.e.* not detected by routine laboratory assays at the department. Detection of NPM1 mutations confirmed results from Sanger sequencing, but were found in one additional sample. Likewise, IDH1 census mutation confirmed positive lab results, one additional mutation previously undetected and added IDH2 mutation. CLC Biomedical Workbench did not prove successful in detecting *FLT3* internal tandem repeats. The cytogenical status was confirmed by assessment of allelic frequencies from NGS (not shown).

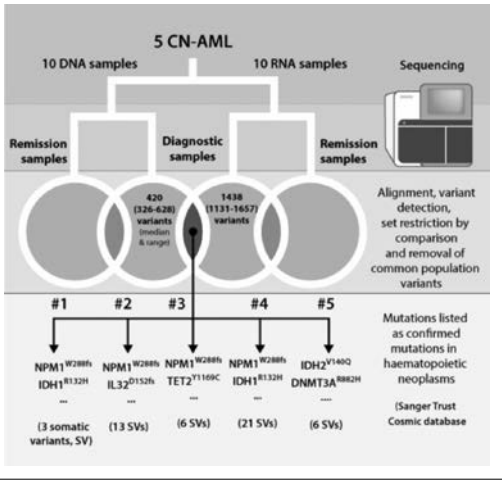

Figure 1.

Summary/Conclusions: Removal of the substantial number of false positives and irrelevant mutations are a high-priority issues when performing NGS. As CLC Biomedical Workbench, and other tools such as VarScan2, generally detects a large number of somatic variants in raw comparison of paired samples it is crucial to apply stringent and optimal filtering. We show that the inclusion of RNA sequencing in the workflow, not only provides information on malignant expression profiles excluded here, but importantly help to capture the, often very few somatic mutations of myeloid leukaemia. As signature indels, such as found in *NPM1*, *TET2* and *FLT3,* are important drivers the practicality of DNA-RNA combination is evident, as we demonstrate here-with the exception of *FLT3*-ITD aberration, which was not detected properly. This small research study not only shows how careful the large number of variants from NGS must be approached-it is also in agreement with previously reported relatively low number of somatic mutations, concluded by several studies. Although we use remission samples in both cases for added stringency, a clinical practical counterpart would be the combination of RNA and DNA malignant sample and skin biopsy or sorted control, DNA only, in whole exome or even targeted panel sequencing.

A BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM-LIKE PHENOTYPE IDENTIFIES A SUBGROUP OF NPM1-MUTATED AML PATIENTS WITH WORSE PROGNOSIS

P Minetto[1,*], F Guolo[1], A Kunkl[2], L Giannoni[1], N Bisso[1], D Guardo[1], F Ballerini[1], M Miglino[1], M Clavio[1], RM Lemoli[1], M Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Service of Flow Cytometry, IRCSS AOU San Martino-IST, Genoa, Italy

Background: NPM1-mutated acute myeloid leukemia (NPM1-mut AML) is considered by WHO classification of myeloid neoplasms a distinct entity, representing about 30% of de novo AML in adults. Isolated NPM1 mutations display a strong positive prognostic value since they are associated with high complete response rate to induction therapies, reduced relapse risk and increased overall survival. A certain degree of clinical heterogeneity is however evident among NPM1-mut patients. The prognostic relevance of NPM1-mut AML immunophenotype (IF) is unclear. NPM1-mut blasts are usually CD34 negative, CD33 and CD13 positive. "Myeloid IF" or "monocytic IF" can be distinct by the expression of monocytic antigens as HLA-DR, CD64, CD14, CD11b.

Aims: The aim of the present study was to identify leukemia-associated immunophenotypes (LAIP) in a cohort of previously untreated NPM1-mut AML patients and to possibly disclose the prognostic role of antigens-expression patterns.

Methods: We retrospectively evaluated a cohort of 38 young, de novo NPM1-mut AML patients who have been intensively treated in our institution between 2006 and 2014. All patients were treated with a fludarabine containing induction. Multi-color immunophenotypic analysis is routinely performed in our centre by analysing erythrocyte-lysed whole BM blasts collected at diagnosis to identify relevant antigen aberration patterns and the pathological leukaemia phenotype for future minimal residual disease assessment.

Results: By citofluorimetric analysis three different subgroup of patients could be identified: 16/38 patients displayed a myeloid IF [CD33/CD13/CD38/CD117/MPO (+), CD16/ CD123 (-)]; 7/38 patients displayed a moncytic IF [CD33/CD64/cyLys/CD11b/CD15 (+) with 3/7 patients CD13+]; the third group included 10 patients who displayed a "myelo-monocytic IF" [CD33/CD13/CD38/CD117/MPO/CD64/cLys/CD11b/CD15 (+)]. Differently from what reported, in our experience HLA-DR displayed a heterogeneous expression and was not associated with monocytic differentiation. No statistically significant differences in relapse free survival (RFS) and overall survival (OS) were detectable among the three groups. FLT3-ITD mutation incidence was significantly higher in the monocytic group, however this did not translate in a worse outcome; as well, the expression of CD34 did not negatively affect RFS and OS. Interestingly we found that a peculiar immunophenotype CD56/CD123/CD4 (+) was recurrent in 6 patients, it was not significantly associated with one of the previously described cytofluorimetric subgroups, and was significantly associated with worse disease free survival (p<0.01, Fig. 1). Since these markers represent part of the typical immunophenotypic pattern of blastic plasmacytoid dendritic cell-neoplasm (BPDCN) we called this phenotype "BPDCN-like". BPDCN-like phenotype was not significantly associated with the concomitant presence of FLT3-ITD mutation; moreover, median values of WT1 m-RNA expression levels were significantly lower in this subgroup of patients in comparison with the whole cohort of patients (2200 WT1/ABL copies *vs* 16090 WT1/ABL, p<0.05).

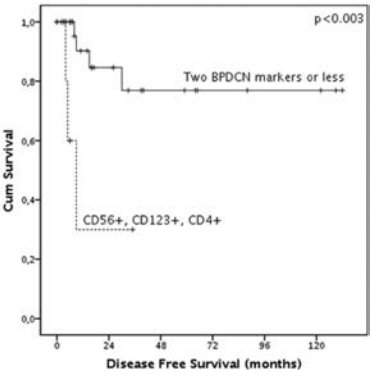

Figure 1.

Summary/Conclusions: We found a peculiar BPDCN-like immunophenotype among NPM-1 mut AML patients associated with significantly worse outcome. The biological explanation of this finding is not clear; further gene-expression profiling studies could contribute do understand our findings. We explained the lack of negative prognostic impact from FLT3-ITD mutation as consequence of the intensive fludarabine containing-induction.

E925

MFC -MRD ASSESSMENT MAY DRIVE POST INDUCTION CONSOLIDATION IN INTERMEDIATE RISK AML. IS IT TIME FOR MRD-DRIVEN DECISION MAKING?

P Minetto*, F Guolo, D Guardo, G Pastori, N Colombo, F Ballerini, M Miglino, M Clavio, RM Lemoli, M Gobbi
Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCSS AOU San Martino-IST, Genoa, Italy

Background: Since the induction therapy for acute myeloid leukemia (AML) has not changed in the last decades the optimization of post remissional therapeutic strategies is fundamental to improve patients outcome. Allogeneic

hematopoietic stem cell transplantation (BMT) offers the greatest chance of cure for most AML patients, however in the heterogeneous group of intermediate cytogenetic risk (int-risk) patients who achieve complete remission (CR) after induction courses, the role of BMT in 1st CR is not well defined.
Aims: The aim of the present study was to evaluate the prognostic role of minimal residual disease (MRD) assessment through multiparameter flow cytometry (MFC-MRD) after 1st and 2nd induction courses in int-risk patients undergoing or not BMT in 1st CR.
Methods: Fifty-five consecutive int-risk AML patients, according to MRC classification, achieving CR after induction therapy, with available post induction MFC-MRD evaluation were retrospectively included in this study. All patients were uniformly treated with a fludarabine-containing induction. Median age was 49 years. BMT in 1st CR was scheduled if an HLA identical sibling donor or, for selected patients, if an haploidentical donor was available. The remaining 34 patients proceeded to high dose cytarabine consolidation and underwent BMT in 2nd CR from any donor if available (6 patients). A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5 total events at four-color flow-cytometry. Twenty-three and 30 patients achieved MFC MRD negativity after one or two induction cycles, respectively. Median follow up was 44 months. Relapse-free survival (RFS) was calculated from the time of diagnosis until last follow-up or documented leukemic relapse.
Results: Fifty-five consecutive int-risk AML patients, according to MRC classification, achieving CR after induction therapy, with available post induction MFC-MRD evaluation were retrospectively included in this study. All patients were uniformly treated with a fludarabine-containing induction. Median age was 49 years. BMT in 1st CR was scheduled if an HLA identical sibling donor or, for selected patients, if an haploidentical donor was available. The remaining 34 patients proceeded to high dose cytarabine consolidation and underwent BMT in 2nd CR from any donor if available (6 patients). A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5 total events at four-color flow-cytometry. Twenty-three and 30 patients achieved MFC MRD negativity after one or two induction cycles, respectively. Median follow up was 44 months. Relapse-free survival (RFS) was calculated from the time of diagnosis until last follow-up or documented leukemic relapse.

Table 1.

		Num.(%)	Relapse (%)	median RFS	3-year RFS (%)	p (univ.)	p (univ.)
ALL PATIENTS		55	16 (29)	69	71.4	-	-
MFC MRD after 1st cycle negative	BMT 1st CR	9/23 (39)	1 (11)	62	100	0.748	0.003
	No BMT/2nd CR	14 /23 (61)	2 (14)	NR	83.6		
MFC MRD after 1st cycle positive	BMT 1st CR	12/32(38)	1 (8)	NR	87.5	0.048	
	No BMT/2nd CR	20/32 (62)	12 (60)	36	45.2		
MFC MRD after 2nd cycle negative	BMT 1st CR	9/30 (30)	2 (22)	62	87.5	0.790	0.098
	No BMT/2nd CR	21/30 (70)	6 (29)	NR	77.9		
MFC MRD after 2nd cycle positive	BMT 1st CR	8/19 (42)	0 (0)	NR	100	0.023	
	No BMT/2nd CR	11/19 (58)	7 (64)	15	33.3		

Summary/Conclusions: MFC-MRD assessment after induction therapy is a strong predictor of relapse risk and could improve risk stratification for intermediate patients. A deeper evaluation of MRD through MFC may overcome morphologic CR assessment becoming a powerful tool to delineate the therapeutic iter. Early BMT may improve the outcome of patients with persistence of MRD.

E927

ZYGODACTYLY IS STRONGLY ASSOCIATED WITH ACUTE MYELOID LEUKAEMIA

A Niblock[1,*], O mcconville[2], MF McMullin[1], P Morrison[3]
[1]Haematology, [2]Podiatry, [3]Genetics, Belfast city Hospital, Belfast, United Kingdom

Background: Zygodactyly is a subtype of syndactyly characteristed by bilateral partial cutaneous webbing of the second and third toes without hand involvement. It is a failure in separation of developing toes during organogenesis. The incidence of zygodactyly is approximately 4 in 10,000 men and males are affected twice as frequently as females[1]. In Northern Ireland there are 3.3 per 100,000 new cases of Acute Myeloid Leukaemia (AML) each year[2]. Podiatry assessment of two haematology ward patients with AML confirmed zygodactyly. Given its relatively low incidence in the general population we decided to inspect all our inpatients.
Aims: To assess if there is a correlation between patients with zygodactyly and the development of acute leukaemia.
Methods: On the 18th January 2016, all the inpatients with acute leukaemia were examined by a physician and a podiatrist for presence or absence of zygodactyly. There were 17 patients in total (7 male, 10 female).
Results: 14 out of 17 had partial or full zygodactyly and AML (figure 1). In the unaffected group one patient had Acute Lymphoblastic Leukaemia (ALL), two had AML (one of whom had Acute pro-myelocytic leukaemia). This ward based observational case series interestingly shows a higher frequency of Zygodactyly amongst patients with AML. It also demonstrated no particular sex predominance which one usually attributes to Zygodactyly. This raises the question of way subtle 2nd/3rd toe syndactyly is higher amongst patients with acute myeloid leukaemia?

Figure 1.

Summary/Conclusions: It is not unusual for physical abnormalities to be associated with an increased risk of developing AML. Congenital bone marrow failure syndromes demonstrate multisystemic abnormalities and a risk of AML in later life. Diamond Blackfan anaemia has physical abnormalities (~50%) including webbed neck, malformed thumbs and 5% develop AML. Over 50% of Fanconi anaemia cases have skeletal abnormalities especially the radial ray - 10-20% develop Myelodysplastic syndrome/AML over a 13 year period. Dyskeratosis Congenita is characteristed by the association of dyskeratotic nails and bone marrow failure with a signifcant increase in AML[3]. Case reports show these syndromes are occasionally diagnosed in the 3rd and 4th decades as clinical features are occasionally subtle. AML arises from genetic alterations in a stem or progenitor cell that result inuncontrolled growth. The hematopoietic microenvironment has been implicated in the pathogenesis of hematologic malignancies. Hematopoietic stem cells live in a highly specialized complex microenvironment, known as a niche[4]. The structures common to bone marrow environment and cutaneous tissues could help explain the link between physical abnormalities and the risk of AML. Zygodactyly subtype 1 (ZD1) has been linked to chromosome 3p21.31 so genes in this region may be associated with AML or may modify the niche. Further studies are needed to determine the exact causes of this interesting finding.

E928

CLINICAL DECISION SUPPORT SYSTEM (CDSS) BASED ON PATHWAYS CONSTRAINED SOMATIC MUTATIONAL DATA INTEGRATION IN ACUTE MYELOID LEUKEMIA PERSONALIZED MEDICINE

M Manfrini*, V Guadagnuolo, C Papayannidis, G Simonetti, A Padella, S Paolini, MC Abbenante, S Parisi, C Sartor, MC Fontana, E Ottaviani, G Martinelli
DIMES, Institute of Hematology, University of Bologna, Bologna, Italy

Background: Personalized medicine will strengthen the prognosis and provide better, patient-specific drug identification. This type of clinical approach is based on high throughput analysis technology available today. Cancer could benefit from targeted therapy because of high number and heterogeneity of DNA alterations. Acute Myeloid Leukemia (AML) is characterized by several type of known point mutations and chromosomal aberration. Massive parallel sequencing showed that a number of new discovered single nucleotide variants (SNV) could affect patients survival time and drug resistance. In this clinical settings next generation sequencing (NGS) is becoming a useful tool to investigate patients genome giving a detailed picture of which mutations occurred and hence an improved diagnosis.
Aims: To exploit these informations for prognosis and personalized therapies there is the need of easily available tools for clinicians. We propose a statistical model learned from data provided by NGS technology, patients cytogenetics predictive risk and clinical outcomes, which could be useful to predict drug sensitivity and prognosis for new diagnosed patients.
Methods: DNA from a cohort of 65 AML patients from S. Orsola University Hospital, Bologna, Italy, were analyzed by Whole Exome Sequencing (WES). Different computational tools were assembled in an in-house pipeline in order to achieve an optimal detection lowering false positive rate. Briefly, pre-processing was carried out following GATK guidelines and re-calibrated alignment files were analyzed by MUTECT and VARSCAN2 algorithms in order to detect single nucleotide variants (SNV) and indels. An additional AML dataset containing WES data from 200 AML patients were downloaded from TCGA database in order to collect somatic variants and clinical data. A training set (60 percent of

cases) was built stratifying patients by age and sex in order to maintain the proportion of the original entire dataset. Other 30 percent of cases were employed as testing set. SNV for each patients were mapped to Reactome and Pathways Commomns. Binary matrix factorization was applied to the patients/pathways matrix in order to find pathways signatures capable to cluster patients. To model pathways constrained mutational data toward event free survival or drug resistance we employed a generalized linear model with binary outcome, including also cytogenetics risk and presence/absence of cancer genes driver mutations from AML biomedical literature. Regression model was applied with 10-fold cross validation to find statistically significant explanatory variables.

Results: Whole exome sequencing detected 4783 somatic mutations of which 2441 labeled as non-silent. Non-silent mutations were mapped to pathways databases and binary matrix factorization. Five pathways signatures were obtained allowing clustering of patients in three groups. Recurrent driver genes involved in AML onset were found with different frequencies in patients and included in the model. Regression analysis provided a model which allow classification of patients in responder/non-responder to standard chemotherapy and toward event free survival.

Summary/Conclusions: In the complex task of interpreting NGS data collected from AML patients, this tool could be useful to guide clinician in the selection of a standard therapy *versus* experimental therapy: when poor prognosis or drug resistance is more likely associated with patients mutational data, latter could be preferable.

E929

MOLECULAR RESPONSE IN ACUTE MYELOID LEUKEMIA WITH WT1 OVEREXPRESSION HAS A STRONG PROGNOSTIC IMPACT IN PATIENS TREATED WITH CHEMOTHERAPY ONLY AND/OR UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION

C Salek*, R Petrbokova, M Kouba, J Mertova, P Soukup, V Valkova, H Hajkova, J Polak, P Cetkovsky
Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: *WT1* is a leukemia associated antigen whose expression may be used as an alternative marker for minimal residual disease (MRD) monitoring in acute myeloid leukemia (AML) mainly in patients lacking a specific molecular target.

Aims: To evaluate the prognostic impact of *WT1* expression at diagnosis and during therapy.

Methods: The cohort comprised 84 subjects (median age 52 yrs, range 21-66 yrs; median follow up 1.9 yrs, range 0.6-7.1 yrs) treated from 2008 to 2014 who had overexpressed *WT1* gene at diagnosis and attained hematological remission after up to 2 induction cycles of chemotherapy. Consolidation chemotherapy consisted of 3-4 cycles of chemotherapy or allogeneic hematopoetic stem cell transplantation (HSCT), depending on cytogenetic and molecular characteristics and response to the first induction cycle. *WT1* expression was quantified using a standardized method according to the recommendations of European LeukemiaNet. Upper normal limit of *WT1* expression was defined as ≤50 copies *WT1*/10^4 copies of reference gene *ABL* in peripheral blood. Only patients with *WT1* overexpression >500 copies/10^4 *ABL* at diagnosis were suitable for MRD monitoring. Molecular response (MR) was defined as a decrease of WT1 expression<50 copies/10^4 *ABL*.

Results: Patients with *WT1* expression at diagnosis >500 and ≤5000 copies *WT1*/10^4 *ABL* had 3yr OS 70% and EFS 40%, whereas those with >5000 copies had 3yr OS 50% and EFS 25%, respectively (p=0.036 for OS and 0.030 for EFS). Failure to reach MR was a strong prognostic factor for survival in an overal cohort (3yr OS 63% *vs* 27%, p<0.001; 3yr EFS 38% *vs* 0%, p<0.001), in patients treated with chemotherapy only (3yr OS 66% *vs* 34%, p=0.002; 3yr EFS 31% *vs* 0%, p=0.009) as well as in patients undergoing HSCT in first complete remission (3yr OS 70% *vs* 30%, p=0.009; 3yr EFS 62% *vs* 12%, p<0.001). Median time to MR was 3.0 months (95%CI 2.8-3.1) and was not dependent on the level of pre-treatment *WT1* expression. Reaching MR before start of consolidation therapy was not signicant (3yr OS 67% *vs* 51%; p=0.089). Of 43 *WT1* positive patients at that timepoint, 33 (77%) reached MR by further therapy (chemotherapy or HSCT). Of 27 patients who were *WT1* positive before consolidation I and received another consolidation cycle, 22 (81%) reached MR after consolidation II. There was no significant difference in survival between patients never reaching MR and those with molecular relapse. In a multivariate analysis, the level of *WT1* expression at diagnosis and ability to reach MR were significant prognostic factors for OS and EFS. In addition, performing HSCT as part of first line therapy was another positive prognostic factor for EFS only. *WT1* expression before HSCT was the only significant marker for OS and EFS in transplanted patients.

Summary/Conclusions: The level of *WT1* expression at diagnosis correlates with survival. Monitoring of *WT1* expression is a sensitive tool for MRD monitoring in patiens with *WT1* overexpression at diagnosis. Failure to reach MR is a potent predictor of relapse. These patients could profit from further intensification of the therapy.

E930

CHARACTERIZATION OF PATIENTS WITH RELAPSED OR REFRACTORY AML IN CONTINUED FOLLOW-UP AFTER TREATMENT WITH VOSAROXIN/CYTARABINE *VS* PLACEBO/CYTARABINE IN THE VALOR TRIAL

A Pigneux[1,*], F Ravandi[2], EK Ritchie[3], JE Lancet[4], MD Craig[5], HA Horst[6], J Maertens[7], HG Derigs[8], M Heuser[9], A Wei[10], D Hogge[11], R Clark[12], R Ward[13], JA Smith[13], AR Craig[13], RK Stuart[14]
[1]Université de Bordeaux, CHU de Bordeaux, Bordeaux, France, [2]University of Texas MD Anderson Cancer Center, Houston, TX, [3]Weill Cornell Medical Center, New York, NY, [4]Moffitt Cancer Center, Tampa, FL, [5]West Virginia University, Morgantown, WV, United States, [6]Klinik fuer Innere Medizin II, University Hospital Schleswig-Holstein, Kiel, Germany, [7]Universitair Ziekenhuis, Leuven, Belgium, [8]Klinikum Frankfurt Main, Frankfurt, [9]Hannover Medical School, Hannover, Germany, [10]The Alfred Hospital and Monash University, Medborne, VIC, Australia, [11]Vancouver General Hospital, Vancouver, BC, Canada, [12]Royal Liverpool University Hospital, Liverpool, United Kingdom, [13]Sunesis Pharmaceuticals, Inc., South San Francisco, CA, [14]Hollings Cancer Center, Medical University of South Carolina, Charleston, SC, United States

Background: Patients with relapsed/refractory (R/R) AML have a median overall survival (OS) less than 1 year. In the phase 3 VALOR trial, vosaroxin/cytarabine prolonged median OS in patients with R/R AML by 1.4 months *vs* placebo/cytarabine (7.5 *vs* 6.1 months; HR=0.87 [95% CI 0.73-1.02]; *P*=0.061). Of 711 enrolled patients, 134 (19%) were alive in follow-up at the primary analysis. After the primary analysis, ongoing patients were followed for survival.

Aims: To characterize patients who continue to be followed for survival in the VALOR trial.

Methods: In VALOR, patients with R/R AML were randomized 1:1 to receive cytarabine (1 g/m^2 IV over 2 h, d 1-5) plus either vosaroxin (90 mg/m^2 IV over 10 min d 1, 4; 70 mg/m^2 in subsequent cycles) or placebo.

Results: As of Jan 22, 2016, 83 patients (12%) were alive in follow-up: 46/356 (13%) in the vosaroxin/cytarabine arm and 37/355 (10%) in the placebo/cytarabine arm. Median follow-up in these patients was 40 months (range 28-60). Patient characteristics are presented (Table); a higher proportion of patients were ≥60 years in the vosaroxin/cytarabine arm (50% *vs* 27% with placebo/cytarabine). Most achieved complete remission (CR) on study (70% with vosaroxin/cytarabine; 51% with placebo/cytarabine); over half maintained CR at database lock (59% with vosaroxin/cytarabine; 49% with placebo/cytarabine). Nearly all received subsequent therapy (93% with vosaroxin/cytarabine; 100% with placebo/cytarabine). Most patients on vosaroxin/cytarabine (85%) and all patients on placebo/cytarabine received posttreatment stem cell transplantation (SCT). Seven patients in the vosaroxin/cytarabine arm did not undergo SCT; all were ≥60 years of age. Median follow-up in these 7 patients was 33 months (range 31-48).

Table 1. Baseline characteristics of ongoing patients.

	Vos/Cyt (n=46)	Pla/Cyt (n=37)
Median (range) age, y	59.5 (23-74)	54 (23-69)
< 60 y, n (%)	23 (50)	27 (73)
≥ 60 y, n (%)	23 (50)	10 (27)
Disease status, n (%)		
Refractory	10 (22)	11 (30)
Early relapsed	18 (39)	10 (27)
Late relapsed	18 (39)	16 (43)
Geographic location, n (%)		
US	15 (33)	16 (43)
Ex-US	31 (67)	21 (57)
ECOG performance status, n (%)		
0	32 (70)	27 (73)
1	11 (24)	9 (24)
2	3 (7)	1 (3)
Cytogenetics by NCCN Guidelines, n (%)		
Favorable	3 (10)	3 (11)
Intermediate	23 (79)	19 (68)
Unfavorable	3 (10)	6 (21)
Missing	17	9

Summary/Conclusions: A small proportion of patients with R/R AML continue to be followed for survival in VALOR. Typically, these patients achieved CR followed by SCT; however, some patients ≥60 years treated with vosaroxin/cytarabine achieved long-term survival without SCT.

E931

DETECTION OF BASOPHIL-ASSOCIATED IMMUNOPHENOTYPIC FEATURES OF ACUTE PROMYELOCYTIC LEUKEMIA BLAST CELLS AT DIAGNOSIS IS ASSOCIATED TO A HIGHER AND MORE SEVERE BLEEDING DIATHESIS

S Matarraz[1,*], V Guerri[1], E Colado[2], C Chillón[3], M Gonzalez[3], B Vidriales[3], C Salvador[4], V van der Velden[5], T Caballero[6], O Gutierrez[7], L Gutierrez[1], A Mayado[1], S Barrena[1], A López[8], A Yeguas Bermejo[9], I Martín Rubio[9], G García-Donas[10], JA García-Erce[11], J van Dongen[12], A Orfao[1]

Laboratorio de Medicina, Oviedo, [3]Hematology, Hospital Universitario de Salamanca, Salamanca, [4]Hematology, Hospital Miguel Servet, Zaragoza, Spain, Zaragoza, Spain, [5]Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Rotterdam, Netherlands, [6]Hematology, F.E.A de Hematología y Hemoterapia, Hospital Universitario Virgen del Rocio, Sevilla, [7]Hematology, Hospital Rio Hortega, Valladolid, [8]Medicine, Hospital Universitario Central de Asturias, A.G.C. Laboratorio de Medicina, Salamanca, [9]Hematology, Hospital Universitario de Getafe, Madrid, [10]Hematology, Hospital Juan Ramón Jiménez, Huelva, [11]Hematology, Hospital San Jorge, Huesca, [12]Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Rotterdam, Spain

Background: The introduction of induction therapy with *all-trans* retinoic acid and anthracycline-based chemotherapy in acute promyelocytic leukemia (APL) have translated into complete remission in most patients. However, severe hemorrhage manifestations at diagnosis and/or during induction therapy lead to early death in 10-15% of patients, which is currently a major focus of research in APL.
Aims: Here we performed an extensive immunophenotypic characterization of blast cells from APL and investigated the potential association between their differential phenotypic profiles and the bleeding diathesis depicted at baseline.
Methods: A total of 133 bone marrow samples from newly-diagnosed APL patients were immunophenotypically characterized. In all cases, 8-color flow cytometry was performed for in depth characterization of APL blast cells and residual hematopoietic cell compartments using the EuroFlow AML/MDS panel. The relatioship between the bleeding diathesis and the immunophenotypic features of blast cells at diagnosis could be studied in 86 APL cases.
Results: The multiparameter immunophenotypic characterization of marrow APL blast cells revealed that these patientes systematically depict (among 100% of their leukemic cells) CyMPO$^{+/++}$, CD33$^{+/hi}$, and CD123$^{+/hi}$ expression, together with CD15$^{-/low}$ CD117^{+}, CD71^{+} and CD9^{+}, while lacking the myelomonocytic maturing-associated markers CD16, CD10 and CD300e, as well as the expression of CD105, NG2 (7.1), CD25 and the megakaryocytic lineage-associated markers CD41, CD61, CD42a, CD42b. Other (aberrant) phenotypes were typically found in APL although at lower frequency, including CD64^{low} (55/59 cases; 93%), HLA-DR^{-} (72/78; 92%), CD13$^{+/++}$ (56/61; 92%) and CD38^{+} (47/55; 86%), followed by CD4^{low} (30/58 cases; 52%), CD203c^{+} (40/92; 44%), CD34^{+} (23/78; 30%), the cross-lineage expression of CD7 (14/47; 30%), asynchronous reactivity for CD35 (14/52; 27%) and CD22 (8/52; 15%) and ectopic CD56 (9/60 cases; 15%). The expression of several other markers was rather exceptional in APL blast cells, including, CD19 (7/58 cases; 12%), CD79a (6/57; 10%), CD14, NuTdT (3/54; 5%), CD11b (2/59; 3%) and CD36 (2/61; 1%). Of note, from all analyzed markers the expression *vs* lack of CD203c showed the strongest association with bleeding manifestations at diagnosis (90% *vs* 10% of APL cases; p<0.001), followed by CD7 (89% *vs* 11%; p=0.03), CyCD79a (0% *vs* 100%; p=0.05) and a similar trend for the expression of CD34 by blast cells (74% *vs* 26%; p=0.06). Furthermore, APL cases with severe bleeding at diagnosis depicted a significantly higher frequency of CD203 expression by blast cells, as compared to those with mild and absent bleeding symptoms at baseline (80% *vs* 46% and 10%, respectively; p<0.001). A similar association was respectively found for the expression of CD7 by blast cells (75% *vs* 31% and 7%; p=0.02) and cytoplasmic CD79a (33% *vs* 18% and 0%; p=0.05).
Summary/Conclusions: The presence of basophil differentiation features in marrow APL blast cells, as depicted by their expression of CD203c and/or CD22, and to a lower extent also of certain cross-lineage antigen expression markers (CD7 and/or CD79a) is associated to a higher frequency and severity of bleeding symptoms at diagnosis, which might point to the need of adapted therapy protocols particularly in these cases.

E932

ASSESSMENT OF BAALC AND MN1 GENE EXPRESSION LEVEL COULD CONTRIBUTE TO IMPROVED PROGNOSTIC STRATIFICATION OF THE AML-NK PATIENTS

I Marjanovic[1,*], T Karan-Djurasevic[1], J Kostic[1], T Kostic[1], M Virijevic[2], I Djunic[2], N Suvajdzic Vukovic[2,3], D Tomin[2,3], S Pavlovic[1], N Tosic[1]
[1]laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, [2]Clinic of Hematology, Clinical Center of Serbia, [3]School of Medicine University of Belgrade, Belgrade, Serbia

Background: There is a constant need for the introduction of new molecular markers in AML-NK group of patients in order to ensure more precise risk stratification. The latest attempt was the inclusion of expression level changes of some genes, like *BAALC* (brain and acute leukemia, cytoplasmic) and *MN1* (meningioma 1). MN1 is an oncoprotein found to function as transcription coactivator, while the BAALC function is not yet clearly defined. Both of the genes are highly expressed in hematopoietic progenitor cells and are down-regulated during differentiation.
Aims: Aim of this study was to evaluate the *BAALC* and *MN1* gene expression levels in *de novo* AML-NK patients, and to investigate association with other molecular and clinical data.
Methods: Fresh bone marrow (BM) samples were collected from 111 AML-NK patients at diagnosis (62 male, 49 female, median age 54 years, range 19-78). Relative quantification analysis of *BAALC* and *MN1* expression level was performed by RQ-PCR methodology, using comparative *ddCt* method with healthy controls as calibrator.
Results: The median expression level of *BAALC* and *MN1* among patients was 1.55 (0.01-4246.00) and 1.59 (0.00-67.74), while the levels detected among healthy controls was 1.00 (0.65-3.63) and 1.00 (0.40-2.53), respectively. The existence of a positive correlation between *BAALC* and *MN1* expression was detected (r=0.693). Using median value of gene expression levels among healthy individuals plus 3xSD as a cut-off value, we found that 42 patients (38%) expressed *BAALC* gene, while 43 patients (39%) expressed *MN1*. Neither *BAALC*$^{+}$ nor *MN1*$^{+}$ status, had any association with usual clinical characteristics. The *BAALC*$^{+}$/ *MN1*$^{+}$ status was not associated with the presence of *FLT3* and *IDH1*/*IDH2* mutations, but exhibited strong correlation with *NPM1*^{wt} status (p<0.001). Only 2/42 *BAALC*$^{+}$ and 2/43 *MN1*$^{+}$ patients were found to have *NPM1* mutations. When among *BAALC*$^{+}$ and *MN1*$^{+}$ patients median expression level of adequate gene was introduced as a cut-off value, patients were divided into *BAALC*^{high}/*BAALC*^{low} (21/21) and *MN1*^{high}/*MN1*^{low} (21/22) patients. *NPM1* mutations could not be found in none of the high expressing group of patients (*BAALC*^{high} or *MN1*^{high}), FLT3-ITD could be detected in only four patients, and therefore the most frequent were the patients with so called *FLT3-ITD*/*NPM1* double negative status. Compared to *MN1*^{low} group, *MN1*^{high} patients tend to have lover CR rate (41% *vs* 59%; p=0.227), and it was confirmed in the survival analyses where *MN1*^{high} patients had lower DFS (12 months *vs* 30 months; p=0.319) and also shorter OS (5 months *vs* 20 months; p=0.069). Similar findings were detected for *BAALC*^{high} patients who, in comparison with *BAALC*^{low} patients, had a tendency to lower CR (42% *vs* 58%) and resistant disease (67% *vs* 33%). In survival analyses *BAALC*^{high} patients had lower DFS (12 months *vs* 18 months; p=0.261) and OS (5 months *vs* 8 months; p=0.196).
Summary/Conclusions: In our cohort of AML-NK patients, overexpression of either *BAALC* or *MN1* is a factor of poor prognosis. This finding could especially contribute to an improved risk stratification among *FLT3-ITD*/*NPM1* double negative patients lacking a reliable prognostic marker.

E933

ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA AND NORMAL KARYOTYPE HAVE A FAVOURABLE OUTCOME AFTER INTENSIVE THERAPEUTIC PROGRAMS

M S Bernardi[1,*], M Carrabba[1], C Messina[1], L Seghezzi[2], A Forcina[1], E Sala[1], F Pavesi[1], L Vago[1], B Gentner[1], R Milani[3], C Corti[1], J Peccatori[1], F Lorentino[1], F Ciceri[1]
[1]Onco-Haematology, [2]Laboratory Medicine-Cytogenetics, [3]Laboratory Medicine-Cytomorphology, San Raffaele Scientific Institute, Milano, Italy

Background: Outcome of AML patients (pts) older than 60 years is poor because of unfavourable disease characteristics; comorbidities frequently tailor under-powered treatment. When standard induction is given to elderly pts the complete remission (CR) rate is around 55%, median overall survival (OS) after intensive post-remission treatments, such as high dose cytarabine (HDAC) or haematopoietic stem cells transplantation, autologous (AUTO) or allogeneic (ALLO), is about 6 months. Cytogenetic is the principal prognostic factor influencing CR and survival.
Aims: Retrospective evaluation of data from AML pts ≥60 yrs of age who received an intensive treatment program at our Institute.
Methods: Period 2/2001 to 11/2015, 111 pts. Criteria for pts selection: PS (ECOG) ≤2, renal and hepatic parameters within normal ranges or<2 times normal values, no active infections and cardiac ejection fraction >50%.
Results: Median pts age was 68 (60-80). Diagnosis: secondary AML or AML with multilineage dysplasia in 64 cases (6 therapy-related), de novo AML in 47 cases. Cytogenetics: favourable (FAV) 4 cases, adverse (ADV) 15 (complex 11), intermediate (INT) 81, 57 of them were normal karytotype (NK), not evaluable (NE) 11 cases. Molecular analysis (56 pts): 10 NPM1 mut, 9 CEBPA mut, 7 FLT3ITD, 1 FLT3TKD, 1 RUNX1-RUNX1T1, 1 JAK2 mut, 27 negative. Overall, 79 pts (71%) obtained the CR after standard induction chemotherapy (CHT), cumulative incidence (CI) of post-induction treatment related mortality (TRM) was 7.5±4%, median OS was 386 days (12-4725), and 3y OS from diagnosis 29.6±9%, median DFS was 297 days (12-3704), and 3y DFS from diagnosis 20.2±8%. We compared the outcomes of 57 NK pts with 50 INT, UNFAV and

NE pts analysed together (noNK). CR rate after induction: 84% (48 pts) and 54% (27 pts) for NK and noNK pts, respectively, p=0.0008. Post-remission treatments (74 pts): 47 NK pts received HDAC in 16 cases, AUTO in 16, ALLO in 9 and CHT in 6, 27 noNK pts received HDAC in 14 cases, AUTO in 4, ALLO in 8 and CHT in 1. CI of post-remission treatment TRM was 13±7% (10 pts, 6 NK and 4 noNK), mostly after ALLO (6 pts). 3y relapse incidence: 55.8±15% for NK, 68.7±15% for noNK, p=0.282. Survival probability of NK pts was significatively higher than no-NK pts: 3y OS from diagnosis was 36.6±12% for NK (median 614 days), 19.4±10% for noNK (median 284 days), p=0.0006, 3y DFS from diagnosis was 27.5±11% for NK (median 453 days), 10.9±7% for noNK (median 219 days), p=0.002. Notably, age did not influence the outcomes: in particular, 3y OS from diagnosis was 46.5±15% if age<70 (median 795 days), and 22.3±13% if age ≥70 (median 467 days), p=0.246. Survival of NK pts remained significatively better than no-NK excluding from the analysis cases with FAV and ADV molecular abnormalities (p=0.0037 for OS, p=0.0013 for DFS).
Summary/Conclusions: Intensive approaches proved feasible in our pts and prolonged survival was observed for several of them. In particular, NK pts showed a survival advantage due to better CR rate after induction and a longer survival free from events, suggesting a higher chemosensitivity of leukemic blasts in absence of cytogenetic abnormalities. Molecular abnormalities and age did not significatively influence the outcome of NK pts. We conclude that absence of cytogenetic abnormalities *per se* probably defines in the elderly a AML subtype with favourable prognosis. Anyway, strategies to prevent disease relapse also in these pts should be explored.

E934

THE HOMOZYGOUS TP53 P72R SNP IS ASSOCIATED WITH NON-FAVORABLE CYTOGENETIC RISK GROUPS IN ACUTE MYELOID LEUKEMIA

E Schulz[1,*], K Lind[1], W Renner[2], BS Petersen[3], C Dill[4], S Hofer[1], R Lal[1], F Quehenberger[5], F Stölzel[4], H Sill[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria, [3]Institute of Clinical Molecular Biology, Christian-Albrechts-University, Kiel, [4]Department of Internal Medicine I, University Hospital Dresden, Dresden, Germany, [5]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria

Background: Previous results about a possible predisposition for acute myeloid leukemia (AML) in individuals with the *TP53* P72R SNP are conflicting.
Aims: We tested the hypothesis that the risk for AML development is increased in P72R carriers and that this SNP also influences survival of these patients.
Methods: We performed a case control study of 215 AML patients from Graz, Austria, and Dresden, Germany, and of 3759 controls from Graz and Kiel, Germany. Genotyping was accomplished with constitutional DNA using the TaqMan assay and direct sequencing. The presence of an Hardy-Weinberg equilibrium and the homogeneity of case and control genotypes as well as cytogenetic risk groups according to European LeukemiaNet were tested by the chi-squared test. Survival analyses according to different genotypes stratified for treatment centers were performed by the Kaplan-Meier method and the Wald-test of cox regression. The likelihood ratio test was used to assess the additive model of single alleles.
Results: Genotypes of cases and controls were in Hardy-Weinberg equilibrium (AMLs P=0.192, controls P=0.325; df=1). There was no difference in the genotype distributions between AML patients (PP n=20, PR n=78, RR n=117) and controls (PP n=249, PR n=1482, RR n=2028; P=0.262; df=2). This was also true for the recessive model PP/PR *versus* RR (P=0.949; df=1). Survival analyses of patients who received at least 3+7 induction therapy showed a trend for better overall survival (OS) in the combined group of patients with the PP/PR genotypes (HR=0.70, 95% CI, 0.46-1.1, P=0.091) whereas no difference was present between all three genotype groups. The additive model of Arginine alleles showed a trend for decreased survival (PP>PR>RR; 72R, HR=1.40, 95% CI, 0.99-1.90, P=0.061). There was no association with relapse free survival. Analyses of clinical parameters of all patients showed a significantly different distribution of cytogenetic risk groups with decrease of favorable cytogenetics in patients with the RR genotype (PP/PR, 15/90 [16.7%]; RR 6/112 [5.4%]; P=0.0171; df=1).
Summary/Conclusions: There is no association of the P72R genotype with AML development in this study. The RR genotype shows a trend for lower OS and a statistically significant association with non-favorable cytogenetic risk groups.

E935

FLAG-IDA REGIMEN AS SALVAGE THERAPY IN REFRACTORY/RELAPSED AML PATIENTS: A SINGLE-CENTER EXPERIENCE

M Delia*, D Pastore, P Carluccio, C Pasciolla, C Bitetti, A Franco, L Anelli, A Mestice, F Albano, G Specchia
Hematology - University of Bari, Bari, Italy

Background: Although treatment outcome in acute myeloid leukemia (AML) adult patient has improved over the past decade, relapse still occurs in up to 50-70% of cases. Furthermore, 15-30% of patients fail to achieve complete remission (CR) because of treatment-resistance. The management of primary refractory and/or relapsed disease remains challenging for clinicians. Although several different chemotherapy combinations are currently administered in refractory/relapsed AML patients, the prognosis is still poor, with a complete remission rate ranging from 30% to 40%.
Aims: In our study, we reviewed the outcome of 116 refractory and/or relapsed AML patients who underwent salvage therapy with the FLAG-Ida regimen between 2005 and 2015 at our institution. The study aim was to determine the efficacy of the FLAG-Ida regimen in order to clarify which variables (WHO PS, LDH, bone marrow, peripheral blood blasts and platelets counts, white blood cells (WBC), PMN, molecular-cytogentic risk, duration of response and relapsed or refractory disease), present before starting FLAG-Ida treatment, might have an impact both on CR and on overall survival (OS).
Methods: We analyzed 116 consecutive adult patients (56 males, 60 females; median age 48 years, range 17-72) with newly diagnosed acute myeloid leukemia refractory to standard induction regimens or relapsed after CR, who received the FLAG-Ida protocol as salvage therapy between January 2005 and December 2015. Sixty-eight of the 116 patients (58%) were in first relapse, forty-seven patients (42%) were refractory to conventional chemotherapy. Median WBC count before salvage therapy was 10.1 $x10^9$/l (range 0.56-88). Median bone marrow and peripheral blasts counts were 52 and 20%, respectively; median platelets count was 91x10e3/uL. According to the FAB classification, 14 patients had M0, 5 M1, 53 M2, 16 M4, 22 M5, 4 M6, 2 had Biphenotype Acute Leukemia. According to molecular-cytogenetic risk stratification 51(44%), 44 (38%) and 21 (18%) patients belonged to poor, intermediate and good risk group, respectively.
Results: Sixty-nine of 116 patients (59%) achieved complete remission (CR); forty-seven 41%) patients were refractory to the salvage therapy. In multivariable analysis, variables with positive impact on response rate were lower WBC counts (<10e3/uL, p=0.0047), higher platlets counts (>50x10e3/ul, p=0.046), molecular-cytogenetic risk (p=0.032), duration of response in relapsed AML (p=0.006) and relapsed rather than primary refractory disease (p=0.042), respectively. Median OS was 17 months (m). Cox regression analysis confirmed that both higher platlets counts, p=0.002 (17 (>50x10e3/ul) *vs* 11 m (<50x10e37uL), log Rank, p=0.05) and relapsed disease, p=0.041 (23 (relapsed) *vs* 17 m (refractory), Gehan-Breslow, p=0.021) correlated with better survival. Of note, molecular-cytogenetic risk evaluated before starting treatment was associated with CR, while no correlation was found with OS in multivariate model.
Summary/Conclusions: Our data seem to confirm the value of FLAG-Ida in relapsed AML rather than refractory disease, and may suggest its best usage as bridge-therapy in patients awaiting allotransplantation.

E936

DECITABINE COMBINED WITH HAAG AS INDUCTION CHEMOTHERAPY FOR NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

X Tang*, W Cui, Z Jin, J Cao, D Guo, A Sun, X Zhu, H Qiu, C Fu, Y Han, C Ruan, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Treatment of newly diagnosed acute myeloid leukemia (AML) remains challenging. Several host- and disease-related factors contribute to poor outcome in elderly patients or high risk patients with AML, including medical comorbidities, physical frailty, and increased incidence of poor-risk biologic features. Indicating an urgent need for alternative treatment strategies improving clinical outcome for these patients. It is confirmed that Decitabine has the synergistic reaction with daunomycin or cytarabine. Therefore, we investigated whether Decitabine combined with HAAG regimen might also be effective for the newly diagnosed of AML patients.
Aims: To evaluate the efficacy and toxicity of DAC combined with HAAG regimen as an induction therapy for newly diagnosed AML patients as well as compared with standard IA(IDA 12mg/m^2/d*3d) regimen.
Methods: 130 patients with AML were newly diagnosed in our center bewteen January 2014 and December 2015.The median age was 42□11-82□years. Among them,49 cases received DAC+HAAG regimen(DAC 20mg/m^2/d*5d combined with low dose of homoharringtonine 1mg/m^2/d*7-14d, cytarabine subcutaneously 10mg/m^2/q12h*7-14d, aclarubicin 10mg/d*4-8d and G-CSF priming). The other 81 patients received standard IA regimen (idarubicin 12mg/m^2/d*3d and cytarabine 100mg/m^2/d*7d).The outcomes of all the patients after one cycle of chemotherapy were evaluated.
Results: 1.The complete remission(CR) rate of DAC+HAAG group was superior than that of IA group(81.6% *vs* 74.5%, P=0.517), but with no statistically significant. While the overall response rate (ORR) of DAC+HAAG group was similar wiht IA group(87.8% *vs* 88.7%, P=0.786). 2. Median overall survival (OS) from the starting of DAC+HAAG chemotherapy and IA were 6.5(2-20) months and 8.5(0.5-25) months (P=0.384). Meanwhile, the estimated one-year survival of DAC+HAAG and IA group were 55.8%±8.9 and 77.9%±5.4% respectively (P=0.089).3. The survival of DAC+HAAG were not more prior than IA, but we found that the ages of DAC+HAAG were statistically older than the IA group(P=0.00). However, in DAC+HAAG group, there were 14 elderly (≥60 years old) that not any one in IA group(P=0.000). The CR rate of the old cases was 64.3% and the estimated 1-year survival was 73.4%±13.4%. 4. Treatment related mortality (TRM) was found in 1 case in DAC+HAAG group compared

with 2 cases in IA group. All patients presented cytopenias of grade 4. There were no differences on the recovery time of ANC ≥0.5*10^9/L,HB≥70g/L and PLT≥20*10^9/L after induction chemotherapy (P=0.969,0.392,0.225). 5. The incidence of adverse events including fever, nausea and vomiting, diarrhea were lower in DAC+HAAG group(P=0.024,0.024 and 0.028). While the happened of infection,bleeding,cardiovascular impact, liver dysfunction and renal insufficiency were similar. 6.For the two group, lower blast percentage as diagnosed were significantly associated with a higher OS rate (P=0.000 and P=0.000).
Summary/Conclusions: DAC+HAAG regimen as an induction chemotherapy for newly diagnosed AML patients could better effectively reduce tumor burden than IA regimen(no statistical significance) with mild toxicity. For naïve AML patients, DAC combined with HAAG regimen may be an optimal choice, especially for patients who cannot tolerate high dose of chemotherapy.

E937

AGE FACTOR ON REMISSION INDUCTION THERAPY FOR ADULT ACUTE MYELOID LEUKEMIA

H Kim[1,*], HJ Kim[2], YH Min[3], DS Hong[4], HJ Kim[5], J Park[6], HJ Shin[7], WS Lee[8], Y Park[9], SK Park[10]
[1]Division Of Hematology and Cellular Therapy, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, [2]Chonam National University Hwasun Hospital, Hwasun, [3]Yonsei University College of Medicine, [4]Soon Chun Hyang university Hospital, [5]St. Marry Seoul Hospital, Catholic University of Korea, Seoul, [6]Gachon University Gil Hospital, Incheon, [7]School of Medicine, Medical Research Institute, Pusan National University Hospital, [8]Inje University Busan Paik Hospital, Busan, [9]Korea University School of Medicine, Seoul, [10]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea, Republic Of

Background: Therapeutic goal for acute myeloid leukemia (AML) is the cure and usually it can be achieved by intensive chemotherapy. One of the most important factors to choose remission induction therapy is the patient's age.
Aims: We evaluated the impact of age on remission induction therapy for AML.
Methods: The Korean Society of Hematology AML/MDS Working Party built the adult AML registry. The registry collected 14 year or older patients; however this analysis included only 18 years or older patients as adult AML.

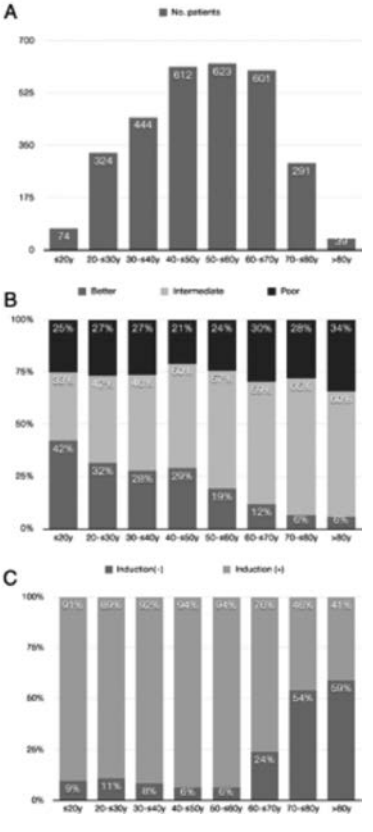

Figure 1.

Results: Total 3041 cases were collected in the registry and 3008 adult AML patients were included in this analysis. Enrolled number of patients were presented in Figure 1A. Risk groups based on karyotype showed strikingly different tendency among age groups. Poor risk group had a tendency of slight increase as patients were getting older (21-34%). However more dramatic change was decreasing better risk group instead of increasing intermediate risk group as ages increased (Figure 1B). Performing induction chemotherapy was similar below 60 years ago (89-94%), however it droped to 76% in age 60-70y, 46% in age 70-80y and only 41% in age older than 80y (Figure 1C). We selected 1935 patients who were older than 17y and not acute promyelocytic leukemia and received induction chemotherapy and known induction responses. The complete remission (CR) rates were decreasing as ages increased: 89.5% in age under 20y; 79% in 20-30y; 75% in 30-40y; 76% in 40-50y; 73% in 50-60y; 63% in 60-70y; 58% in 70-80y; 29% in 80y or older patients. When the analysis was focused on patients who had received cytababine-idarubicin (AI) or cytarabine-daunorubicin (AD) induction chemotherapy (n=1377), the CR rates were following: 86% in age under 20y; 77% in 20-30y; 75% in 30-40y; 76% in 40-50y; 73% in 50-60y; 68% in 60-70y; 62% in 70-80y; 50% in 80y or older patients. When analyzing the population according to risk group, the CR rates were similar in better risk group; 92.9% in age under 20y; 100% in 20-30y; 88.6% in 30-40y; 89.2% in 40-50y; 81.6% in 50-60y; 72.2% in 60-70y; 100% in 70-80y patients. In intermediate risk group, the CR rates were 84.6% in age under 20y; 78.9% in 20-30y; 74.1% in 30-40y; 79.4% in 40-50y; 77.6% in 50-60y; 74% in 60-70y; 59.5% in 70-80y; 66.7% in 80y or older patients. CR rates were dramatically dropped in elderly age with poor risk karyotypes; 77.8% in age under 20y; 66.7% in 20-30y; 70.9% in 30-40y; 59.7% in 40-50y; 61.6% in 50-60y; 54.5% in 60-70y; 44.4% in 70-80y; 0% in 80y or older patients. There was no difference of CR rate between AI and AD (p=0.542): p=0.685 in 30-40y; p=0.713 in 40-50y; p=0.452 in 50-60y; p=0.813 in 60-70y; p=1.000 in 70-80y; p=1.000 in age older than 80y. However there was significant higher CR rate among AI regimen in under 30y (p=0.033).
Summary/Conclusions: Age clearly impacts on outcome of induction chemotherapy. CR rates were similar in favorable risk group in all age groups. However CR rates of unfavorable risk group dramatically droped in elderly patients. There was no clear difference between AI and AD induction in terms of CR rates. Poor outcome in elderly AML can be resulted mainly from poor risk characteristics.

E938

DEFINING FRAILTY OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS

S Aydin[1], E Audisio[1], S D'Ardia[1], B Allione[1], B Nicolino[1,*], A Busca[2], CM Dellacasa[2], A Evangelista[3], G Ciccone[3], U Vitolo[1]
[1]Oncology and Hematology, [2]Oncology and Hematology, Stem Cell Transplant Center, [3]Unit of Cancer Epidemiology, CPO Piemonte, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy

Background: Acute myeloid leukemia (AML) is a disease of older adults, with a median age at diagnosis over 65 years. Evaluation of disease-related and patients specific factors in the context of clinic decision making has therefore been largely subjective. Several studies demonstrated improved survival for older patients receiving intensive induction chemotherapy compared to those receiving supportive care alone. Defining this subset of patients who are not eligible or "not fit" for intensive chemotherapy involves a great deal of subjectivity. Criteria yet have to be standardized across or within institutions.
Aims: Aim of this study was to investigate the validity of three validation scores for distinction of patient fitness at diagnosis in parallel to physician evaluation. Further patient outcome according the respective evaluation was compared.
Methods: A total of 69 clinically and molecularly well characterized consecutive elderly (>60 years) patients with newly diagnosed AML were treated from 2012 to 2015 according to age, performance status and co-morbidities in a single hematology center. Therapy response was defined according to ELN criteria. Therapy intensity decision was based on an initial haematologist evaluation followed by discussion in an interdisciplinary board. In parallel, the local geriatric G8 screening tool, the HCT-CI comorbidity score and the AML score proposed by the German Acute Myeloid Leukemia Cooperative Group, predicting probability of complete remission (CR) and early death (ED) were performed. Overall survival from diagnosis was compared between groups using the Cox model.
Results: Thirty-three patients (47,8%) were evaluated "fit" by the medical board and treated by intensive chemotherapy, whereas 26 patients (37,7%) underwent semi-intensive/experimental therapy and 10 patients (14,4%) received best supportive care. A total of 21 patients (31,4%) achieved a complete remission after induction chemotherapy, whereas 49% patients (25%) were non responders and 13 (19,4%) died. Overall, the median survival time was 5,2 months (95% CI 3,5-8,3). Primary physician care evaluation was able to define in a statistically significant manner a "fit" from an "unfit" patient. Median survival time from the "fit" patients was 8,3 moths (95%CI 6,1-11,2) compared to the "unfit" evaluated patients with 2,9 months (95%CI 1,3-4,4), p=0,004. Parallel evaluation of patients fitness using the G8, HCT-CI and AML scores discriminated significantly "fit" from "unfit" patients considering median survival time, p=0,001, p=0,032 and 0,021, respectively. The ability of the frailty scores on the prediction of fitness classification compared to the physician evaluation was analyzed by calculating the area under the curve (AUC) using a logistic regression model. In this approach an AUC of 1,0 denotes perfect prediction whereas and AUC of 0,5 is analogous to a coin flip. With this regard the AUC for the G8 Score was 0,73, whereas the HCT-CI was 0,72 and the AML score ED 0,78 and the AML CR 0,79 in the present cohort.
Summary/Conclusions: In conclusion, in the present cohort the applied frailty

scores at diagnosis correlated significantly regarding median overall survival. These results may encourage a following larger multi-centre analysis in order to verify the statistic power of the performed analysis.

E939

GENOTYPIC AND PHENOTYPIC CLONAL EVOLUTION IN RELAPSED FAVORABLE-ACUTE MYELOID LEUKEMIA PATIENTS

C Martinez Losada[1,*], J Serrano[1], N Noguera[2], E Garza[2], L Borgia[2], L Piredda[2], S Lavorgna[2], T Ottone[2], F Lo Coco[2], J Sanchez-García[1]
[1]Hospital Reina Sofia, Cordoba, Spain, [2]Tor Vergata University, Rome, Italy

Background: Despite high rates of cure with standard chemotherapy in patients with favourable-risk acute myeloid leukemia (AML) according to European Leukemia Net (ELN) classification, some patients will eventually relapse. It is currently unclear whether leukaemia relapse is due to intrinsic chemo resistance or to clonal evolution with acquisition of new driver mutations and clonal selection
Aims: Characterization of phenotypic and genotypic features at relapse compared to diagnosis in patients with molecular/cytogenetic favourable-risk AML presenting relapse after achieving complete remission (CR).
Methods: Retrospective study of 13 molecular/cytogenetic low risk AML patients (Non-M3) (CBF 3 NPM1 10) according to ELN classification criteria from Tor Vergata Hospital (Rome) and Reina Sofia Hospital (Córdoba). They were treated with intensive chemotherapy achieving CR and relapsed after a median of 12.2 months (4.4-255.9) (Table 1). NRAS, KRAS, DNMT3A, IDH1, IDH2 and TP53 genes were analyzed in marrow samples obtained at relapse by Sanger Sequencing using ABI 3130® Genetic Analyzer (Applied Biosystems Inc., Foster City, CA). When a mutation was found, the diagnosis sample for this mutation was screened using Sanger Sequencing also. A complete phenotypic profile was carried out using multiparametric flow cytometry with 3-laser FACSCanto II in both diagnosis and relapse samples. Additionally, all mutations were tested at diagnosis in 7 patients with favourable-risk AML achieving continuous CR (non-relapsing patients)
Results: In non-relapsing patients, only a case with IDH1 (R132H) was found. When analyzing relapse-diagnosis paired samples in 13 AML patients, three patterns of clonal evolution were found: Group A (8 patients): Genotypic (G) and phenotypic (P) persistence of the main clone. Two patients presented a mutation in DNMT3A gene: R882H mutation and c.2705_2706delTC (p.F902fs) mutation (not described so far) respectively. Both mutations were found in diagnosis and relapse samples and phenotypic profile remained unchanged. Group B (2 patients): Phenotypic profile evolution but no changes in genotype. One patient harboured a mutation in DNMT3A gene (R882H) in both diagnosis and relapse samples. Many importants phenotypic changes were observed: In diagnosis sample, CD65+, CD19-, CD15+, CD117+, DR+, CD56LOW, CD7-, CD13+, CD2+, CD11b+, CD14-, CD38+, CD34+, CD33+ were expressed in the main leukemic clone. In the relapse sample, CD15, DR, CD56, CD2 and CD11b not expressed. Group C: 3 patients presented phenotypic and genotypic clonal evolution. The mutations were detected in relapse but not in diagnosis samples: i) D876Y mutation in DNMT3A gene (not described so far), accompanied with phenotypic profile changes with acquisition of CD34 and CD117 and loss of CD15. ii) R140Q mutation in IDH2 gene and G105 mutation in IDH1 gene with a phenotypic evolution with acquisition of CD34 and loss of a suclone CD56 +. iii) G105 in IDH1 gene with a phenotypic evolution with increased of CD33 and acquisition of CD15. These mutations were studied by NGS in the diagnosis samples. IDH mutations were present in both patients, while DNMT3A gene remained wild type.

Table 1.

Summary/Conclusions: i). Driver mutations are found more frequently in patients with favourable-risk AML who relapse compared to those with sustained CR. ii). 3 patterns of relapse were detected: A). No P changes/G (N=8); B). P Changes/No G (N=2). C). P changes/G (N=3). These results highlight the importance of clonal evolution at relapse in favourable-risk AML patients.

DNMT3A MUTATIONS IN ACUTE MYELOID LEUKAEMIA WITH INTERMEDIATE-RISK KARYOTYPE - INCIDENCE AND CORRLEATION WITH OTHER GENE MUTATIONS

GF How[*], SJ Khoo, LT Tan, C Chuah
Haematology, Singapore General Hospital, Singapore, Singapore

Background: Acute myeloid leukaemia is an aggressive heterogeneous haematopoietic disease. It is characterized by an increased proliferation of haematopoietic progenitor cells that have lost the ability to differentiate. In the last 15 years, major advances have been made in the disease with the discovery of many genetic abnormalities affecting cell proliferation, differentiation, apoptosis or cell cycle regulation. Some of these molecular markers confer good prognosis while others have been found to be adverse prognostic factors. Of the molecular markers, DNMT3A (DNA N-methyltransferase 3A) gene mutation is found to be an independent poor prognostic marker in most studies.
Aims: In this study, we evaluated the mutation status of DNMT3A in AML patients with intermediate-risk cytogenetics, in particular, those with normal karyotype. The incidence of DNMT3A mutations was correlated with the mutation status of other genes like FLT3, NPM1, IDH1 and IDH2 which were also determined.
Methods: For the detection of DNMT3A mutations, exon 26 of the gene was PCR amplified and direct sequencing of the amplicons was performed to detect mutation hotspots in this exon in a cohort of 93 patients.

Table 1.

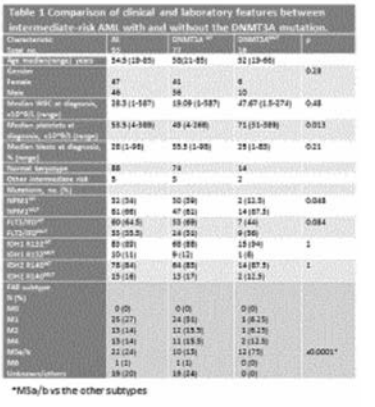

Table 1 Comparison of clinical and laboratory features between intermediate-risk AML with and without the DNMT3A mutation.

Characteristic	N	DNMT3A mut	DNMT3A wt	p
Total no.	93	17	76	
Age, median (range), years	54.5 (18-85)	58(21-85)	52 (19-66)	
Gender				0.28
Female	47	41	6	
Male	46	36	10	
Median WBC at diagnosis, x10^9/L (range)	28.3 (1-587)	19.09 (1-587)	47.67 (1.5-274)	0.48
Median platelets at diagnosis, x10^9/L (range)	53.5 (4-569)	49 (4-268)	71 (11-569)	0.013
Median blasts at diagnosis, % (range)	28 (1-96)	55.5 (1-96)	25 (1-85)	0.21
Normal karyotype	88	74	14	
Other intermediate risk	5	3	2	
Mutations, no. (%)				
NPM1^mut	32 (34)	30 (56)	2 (11.5)	0.048
NPM1^wt	61 (66)	47 (81)	14 (87.5)	
FLT3/ITD^mut	80 (64.5)	33 (69)	7 (44)	0.084
FLT3/ITD^wt	33 (35.5)	24 (31)	9 (56)	
IDH1 R132^mut	83 (89)	68 (88)	15 (94)	1
IDH1 R132^wt	10 (11)	9 (12)	1 (6)	
IDH2 R140^mut	75 (84)	64 (85)	14 (87.5)	1
IDH2 R140^wt	15 (16)	13 (17)	2 (12.5)	
FAB subtype N (%)				
M0	0 (0)	0 (0)	0 (0)	
M1	25 (27)	24 (51)	1 (6.25)	
M2	15 (14)	12 (15.5)	1 (6.25)	
M4	13 (14)	11 (15.5)	2 (12.5)	
M5a/b	22 (24)	10 (13)	12 (75)	<0.0001*
M6	1 (1)	1 (1)	0 (0)	
Unknown/others	18 (20)	18 (24)	0 (0)	

*M5a/b vs the other subtypes

Results: A total of 16(17%) patients were identified with R822 mutations in DNMT3A exon 26. R882H was the predominant mutation in these patients (n=10) while the remaining 6 had R822C. Of these 16 patients, 14 (87.5%) of them were also NPM1-mutated while 9 had FLT3/ITDs as well. The close association of DNMT3A mutations with NPM1 mutations was significant (*p=0.048*) while that with FLT3/ITDs was not quite statistically significant (and *p=0.084*). IDH mutations were detected in only 3 patients with R882 mutations (IDH1 R132H, n=1; IDH2 R140Q, n=2). The relation between DNMT3A mutations and other patient characteristics were determined by the Mann Whitney U test (continuous variables) and the Fisher exact test (categorical variables) (details in Table 1). The platelet counts were significantly higher in the DNMT3A -positive patients than in the patients without DNMT3A mutation (*p=0.0125*). DNMT3A mutations were also significantly enriched in patients with the FAB M5 subtype (12/22, 55%, *p=<0.0001*). Other clinical parameters showed no significant difference between the DNMT3A-positive group and the wild type group. Interestingly, in a patient who was separately investigated, FLT3/ITD^{mut}, NPM1^{mut} and DNMT3A R882C were detected at diagnosis but while FLT3/ITD was not detected on follow-up at relapse, an IDH2 R140Q was observed. The R882C status, however, remained unchanged. Previous larger study series have demonstrated the stability of DNMT3A during the course of disease.
Summary/Conclusions: Within the normal karyotype and other intermediate risk AMLs, we did not observe any significant correlation of DNMT3A mutations with white blood cell counts, FLT3/ITD or IDH mutations, contrary to what was observed in other studies which involved AMLs across all cytogenetic risk groups. We hope the findings from this preliminary study would help improve our understanding of the association of DNMT3A mutations with other gene mutations in intermediate risk AMLs. Further work is needed to investigate the significance of the DNMT3A exon 26 mutations, in particular, the R882 mutations, as a prognostic predictor and the role of screening of these mutations for further risk-stratification of intermediate risk AMLs, particularly in normal karyotype AML.

E941

CLINICAL CHARACTERISTICS OF ACUTE MYELOID LEUKEMIA PATIENTS FROM REGIONS CONTAMINATED BY DEPLETED URANIUM: 20 YEAR ANALYSIS

L Mehinovic[1], A Kozaric[1,*], A Dizdarevic[2], S Kurtovic[2]
[1]Pathology, Cytology, and Human Genetics, [2]Hematology, Clinical Center of the University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: During the war in Bosnia (1992-1995), ammunition with depleted uranium was used in several regions, including the town of Hadzici, where the United Nations have measured high concentrations of depleted uranium several years after the war. Depleted uranium (DU), a radioactive heavy metal, is used in military ammunition. Studies have shown the potential health risks of con-

tamination by DU by wounding, ingestion, and inhalation. *In vivo* and *in vitro* experiments showed the carcinogenic potential of DU by neoplastic transformation of human and mouse cells, leading to the development of myeloid neoplasms. It is assumed that the DU exposure induces genomic stability leading to carcinogenesis.
Aims: Increased numbers of patients with blood cancers in DU stricken area was noted by hematologists, so we systematically analyzed hematological patients from this region in the last 20 years, from 01.01.1996.-31.12.2015.
Methods: We systematically analyzed hematological patients from two region in the last 20 years, from 01.01.1996.-31.12.2015. One region had high concentrations of DU (Hadzici) and the other region (ilijas) was used as a control. Both regions have the same population size and same access to tertiary health care. Patient data was collected including age at diagnosis, sex, address, blood parameters, cytogenetics, therapy, and survival.
Results: In the 20 year analyzed period from 01.01.1996–31.12.2015, we found 717 patients with hematological conditions (437 from DU-stricken town *vs* 280 from control town). There were 74 patients with myeloid malignancies (54 *vs* 20), 55 patients with non Hodgkin lymphoma (26 *vs* 29), 21 patients with Hodgkin lymphoma (9 *vs* 12), and 6 patients with ALL (4 *vs* 2). Among the myeloid neoplasms, CML showed 6 fold increase in DU-stricken area and AML showed 3 fold increase. The median age at diagnosis for AML patients was 41 *vs* 73, and for CML patients was 62 *vs* 53. Male to female ratio was for AML 0.5 *vs* 1, and for CML 1 *vs* 7. For AML patients, 22% *vs* 67% of patients achived complete remission after first treatment. The median duration of remission was 10.5 v 17.5 months. OS at 24 months was 22% *vs* 50%.
Summary/Conclusions: Clinical parameters showed more severe course of acute myeloid leukemia patients in DU stricken area compared to the control and international data. Further investigation is needed to elucidate the possible causes of stark increase in myeloid neoplasms in Hadzici area.

E942

COMPARISON OF AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION TO INTENSIVE CONSOLIDATION CHEMOTHERAPY AND MONITORING MINIMAL RESIDUAL DISEASE IN CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA

HK Kim*, S Park, JH Jang, SJ Kim, WS Kim, K Kim, CW Jung
Division of Hematology-Oncology, Department of medicine, Samsung medical center, Seoul, Korea, Republic Of

Background: One third of patients with core binding factor (CBF) acute myeloid leukemia (AML) relapse and disease relapse is most common cause of treatment failure. For detecting relapse, quantitative RT-PCR of AML1-ETO or CBFB-MYH11 fusion transcript is used to evaluate minimal residual disease (MRD).
Aims: The purpose of this study was to compare the clinical outcome of post-remission therapy between autologous peripheral stem cell transplantation (ASCT) and intensive consolidation chemotherapy in CBF AML patients and to assess MRD in patients who accomplished first CR(CR1) after induction chemotherapy using quantitative RT-PCR of AML1-ETO transcript.
Methods: We retrospectively analyzed adult patients who diagnosed with CBF AML between March 1996 and July 2014, and achieved CR1 after induction chemotherapy at Samsung Medical Center. The patients were divided into two groups who received ASCT or 3 to 4 cycles of intensive consolidation chemotherapy as post-remission therapy. In addition, we also investigated the impact of MRD after induction chemotherapy using quantitative RT-PCR of AML1-ETO for patient with t(8;21). AML1-ETO transripts were normalized to ABL.

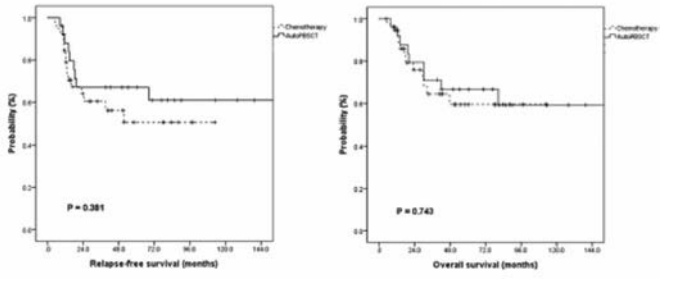

Figure 1.

Results: We identified 65 patients (Male=33, Female=32; t(8;21)=45, inv(16)=20) and the median age at diagnosis was 42 years(range 18-64). 26 patients (40%) received ASCT as postremission therapy and 40 patients were treated with 3 to 4 cycles of intensive chemotherapy. The ASCT group showed a better 5-year relapse free survival (RFS) rate (50.5% *vs* 67.0%, p=0.381) and similar 5-year overall survival (OS) rate (59.5% *vs* 66.6%, p=0.743) during median follow-up 96 months. The median value of AML1-ETO mRNA levels in bone marrow was higher in relapsed patients with t(8;21) than non-relapsed patients (425.79 *vs* 3.29, per ABL x 10^3, p=0.045). We determined cutoff for MRD as the median value of AML1-ETO transcript of all patients with t(8;21), 3.39 per ABL x 10^3. The 5-year RFS rates in the patients without and with MRD were 87.5% and 68.6%, respectively. (p=0.391).
Summary/Conclusions: This study demonstrated that ASCT as postremission therapy showed a better RFS than chemotherapy alone in patients with CBF AML, monitoring minimal residual disease by AML1-ETO mRNA levels as surrogate marker of patients with t(8;21) in CR1 was beneficial.

E943

PROGNOSTIC IMPLICATIONS OF THE IDH1 SINGLE NUCLEOTIDE POLYMORPHISM RS11554137 IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

E Petrova*, I Martynkevich, L Polushkina, L Martynenko, M Ivanova, N Cybakova, E Kleina, E Shabanova, A Chechetkin, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Saint-Petersburg, Russian Federation

Background: Several studies have shown that synonymous single nucleotide polymorphisms directly impact gene function through various translational or post-translational mechanisms, such as altering mRNA binding, protein folding, the spliceosome, mRNA stability, or expression in general. Mutations in 132 codon of *IDH1* gene are quite frequent event in acute myeloid leukemia (AML). Also, approximately 10% of AML patients were detected to have polymorphism rs11554137 in the 4th exon of *IDH1* gene. Data concerning the impact on prognosis of polymorphism rs11554137 is still controversial.
Aims: To investigate the frequency and prognostic value of polymorphism rs11554137 in *IDH1* gene, its combination with clinical hematological features and karyotype variant in AML pts.
Methods: The study included 112 pts with AML (median age - 55 years). In 103 pts (92.0%) was verified *de novo* AML and in 9 (8.0%) - secondary AML from preceding MDS or lymphoma. Cytogenetic analysis was performed on G-differentially stained chromosomes, so pts were divided into 4 groups: with normal karyotype (NK) - 52 (46.4%), favorable karyotype - 9 (8.0%), unfavorable karyotype - 16 (14.3%), with other chromosomal abnormalities - 35 (31.3%) pts. Screening of *IDH1* gene aberrations was performed by real-time PCR with further analysis of melting curves.
Results: Polymorphism rs11554137 in *IDH1* gene was detected in 7.1% (8 out of 112) of pts with AML. Distribution of pts with AML, depending on the morphological variants showed that polymorphism rs11554137 was more common in pts with M4 variant (5 of 20, p=0.005). All pts with polymorphism rs11554137 had *de novo* AML. The median age of pts with polymorphism rs11554137 (58 years) was significantly higher than in pts without it (55 years) (p=0.005). There was no significant differences when the number of white blood cells and platelets in PB, blasts in BM in pts with and without polymorphism rs11554137 was compared. Slightly more often polymorphism rs11554137 in *IDH1* gene occured in pts with NK (5 of 8 pts; p=0.334), 3 pts with polymorphism had unfavorable karyotype. None of the pts with favorable karyotype was detected to have polymorphism rs11554137. All pts with polymorphism rs11554137 in *IDH1* gene were screened for mutations in *FLT3*, *NPM1, NRAS, CKIT* and *DNMT3A* genes. Only in 2 pts polymorphism rs11554137 in *IDH1* gene was met singly. In the remaining pts (6 of 8) polymorphism rs11554137 was found simultaneously with mutations in other genes: *DNMT3A+, FLT3*-TKD+, *NPM1+, FLT3*-ITD+/*DNMT3A+, FLT3*-ITD+/*FLT3*-TKD+/*DNMT3A+* and in 2 pts polymorphism rs11554137 was detected in combination with *FLT3*-ITD. We also investigated the prognostic value of polymorphism rs11554137 in *IDH1* gene. Comparative analysis of median overall and relapse free survival in pts with and without polymorphism showed significant differences: 5.8 months and 12.8 months (p=0.046) and 4.2 months and 9.5 months (p=0.004) respectively.
Summary/Conclusions: Polymorphism rs11554137 in *IDH1* gene is quite frequent event in pts with AML. It is usually associated with M4 variant of AML and higher median age as compared with pts without polymorphism. Significant prognostic potential of polymorphism rs11554137 in *IDH1* gene allows to consider it as an unfavorable marker correlated with a high risk of relapse and poorer survival. Synonymous polymorphisms represent a special category of molecular aberrations that should be considered in the diagnosis and prognosis of AML pts.

LB2244

FRONT-LINE CENTRAL VASCULAR ACCESS DEVICES IN ACUTE LEUKEMIAS – PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) *VERSUS* TRADITIONAL CENTRAL VENOUS CATHETER(CVC): A PHASE IV RANDOMIZED TRIAL (NCT02405728)

C Cerchione*, M Di Perna, R Della Pepa, N Pugliese, V Caprioli, C Frieri, F Pane, M Picardi
Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: The use of PICC as an alternative to other CVC devices, particularly for prolonged infusions of cytotoxic agents, blood products and/or other

supportive therapy, is becoming very frequent in cancer patients. PICCs are easier to insert, and associated to a lower rate of complications than traditional CVC. However, in the setting of high-risk patients with acute leukemia there is limited information on the feasibility and safety of PICC as primary vascular access device. Our Hematology Department is conducting a Phase IV randomized trial. We compare PICC *versus* traditional CVC as front-line venous access device in patients with acute leukemias undergoing remission induction chemotherapy. This trial is registered on ClinicalTrials.gov, number NCT02405728 (ongoing).
Aims: Primary endpoint is the occurrence of catheter-related bloodstream infections and/or catheter-related thrombosis. Secondary endpoints are the occurrence of other complications, such as pneumothorax or catheter occlusion, and patient quality of life. Questionnaire covering functional status, sleep and hygiene disturbance had been given to assess patients'quality of life.
Methods: From April 2015 to February 2016, 152 patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B). Inclusion Criteria were: age >18 years, suspected survival >4 weeks, and need of central venous access device (long-term; >4 weeks). While exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by chest X-ray.
Results: 152 patients (130 AML, 22 ALL), median age 47 years (13-82), were randomized in the two arms. In Arm A, 76 PICCs were inserted in 76 hematological patients (median age 51.5 years, r.19-82, 17 females, 59 males) suffering from acute myeloid leukemia (AML: 70) or acute lymphoblastic leukemia (ALL: 6). Double lumen PICCs (5 Fr) were inserted in 70 patients, single lumen PICCs (4 Fr) were inserted in 5 patients, and triple lumen PICC (6Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs were inserted in other 76 hematological patients (44 males, 32 females) suffering from AML (60) or ALL (16). 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in jugular vein. Overall, the median duration of in situ catheter placement was 5 months. In the arm A, median duration of device was 6 months (r. 12-8), catheter-related thrombosis occurred in 8 patients (6 basilica vein, 2 brachial vein) and catheter-related bloodstream infections in 4 patients (2 methicillin-resistant, 1 coagulase-negative, 1 *staphylococci*). In the arm B, median duration of device was 3 months (r. 5-10), 20 cases of catheter-related thrombosis (7 subclavian vein, 13 jugular vein) and 15 cases of catheter-related bloodstream infections (3 methicillin-resistant, 2 coagulase-negative, 4 staphylococci, 6 *enterobacteriaceae*) were observed. Thus, PICCs were significantly associated with fewer major complications compared with traditional CVC (catheter-related thrombosis: 10.5% in the arm A *vs.* 26% in the arm B, P=0.01 by $\chi 2$ test; catheter-related bloodstream infections: 5% in the arm A *vs.* 19% in the arm B, P=0.007 by $\chi 2$ test).

Table 1.

	Arm A : PICCs	Arm B : CVCs
N° patients	76	76
Median age	51.5 (19-82)	42.5 (13-74)
M/F	59/17	44/32
AML	70	60
ALL	6	16
Median duration of device	6 months (r. 8-12)	3 months (r. 5-10)
Catheter-related thrombosis	10.5%	26%
Bloodstream infections	5%	19%

Summary/Conclusion: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improve of quality of life for patients with acute leukemia.

LB2245

EFFICACY AND SAFETY OF ETOPOSIDE IN COMBINATION WITH G-CSF, LOW-DOSE CYTARABINE AND ACLARUBICIN IN NEWLY DIAGNOSED ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

L Gao[1], YM Feng[1], HJ Yan[1], YQ Zhang[2], C Zhang, L Gao[1], PY Kong[1], Y Liu[1], LD Zhu[3], YJ Zeng[1], J Rao[1], Y Su[4], TH Yang[5], SB Wang[6], HM Li[7], SF Lou[8], X Zhang[1,*]
[1]Department of Hematology, Xinqiao Hospital, Third Military Medical University, [2]Department of Health Statistics, [3]Department of Hematology, Collage of Military Preventive Medicine, Third Military Medical University, Chongqing, [4]Department of Hematology, General Hospital of Chengdu Military Region of PLA,Sichuan, Chengdu, [5]Department of Hematology, Yunnan Provincial Peoples Hospital, Yunnan, [6]Department of Hematology, General Hospital of Kunming Military Region of PLA, Yunnan, [7]Department of Hematology, Yunnan Medical College, Kunmin, [8]Department of Hematology, Second Affiliated Hospital, Chongqing Medical University, Chongqing, China
Background: Chemotherapy for elderly patients with acute myeloid leukemia (AML) is still a great challenge. Although 50% AML patients could achieve complete remission (CR) after intensive 3+7 regimen, treatment-related toxicities (TRT) appeared particularly prominent in elderly patients. In 2013, a multicenter randomized controlled trial in southwestern China confirmed that 71.1% refractory or relapsed AML achieved CR after received etoposide combine with low-dose CAG (E-CAG) regimen, and TRT was low, with no mortality.
Aims: This prospective phase II, open label, randomized controlled study was designed to assess the efficacy and safety of E-CAG induction treatment for elderly patients with newly diagnosed AML.
Methods: The effect of E-CAG on the rate of CR was the main study endpoint. The median survival time and the toxicity of the E-CAG regimen were also evaluated.
Results: After induction chemotherapy, patients with E-CAG regimen had a similar CR rate than did patients who received DA regimen (55.1% *vs* 48.9%, P=0.158). The tolerability profiles of E-CAG regimen appeared better than DA regimen. Especially, gastrointestinal reaction and III-IV bone marrow suppression. The median survival time was extended for 4 months in E-CAG group (14.3 months *vs* 10.3 months, P=0.042). The two-year OS probability in E-CAG group and DA group was 24.2% and 11.3%, perspectively.
Summary/Conclusion: The E-CAG regimen seems promising and offers lower toxicity for the treatment of elderly patients with AML, and expected to become a bridge for non-myeloablative stem cell transplantation.

OUTCOMES WITH RITUXIMAB MONOTHERAPY *VERSUS* R-CHOP IN POST-TRANSPLANT LYMPHOPROLIFERATIVE DISEASE ARISING AFTER SOLID ORGAN TRANSPLANT: A UNITED KINGDOM MULTICENTRE STUDY

D Burns[1,2,*], C Klesham[3], YA Hodgson[4], L Fredrick[5], J Haughton[6], M Lannon[7], H Hussein[7], C Byrne[8], C McNamara[3], B Vydianath[9], A Lennard[7], R Johnson[6], J Wright[5], C Fox[4], K Cwynarski[3], S Chaganti[2]
[1]Institute of Cancer and Genomic Sciences, University of Birmingham, [2]Centre for Clinical Haematology, University Hospital Birmingham, Birmingham, [3]Department of Haematology, Royal Free Hospital, London, [4]Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, [5]Department of Haematology, Sheffield Teaching Hospitals, Sheffield, [6]Department of Haematology, St James's Institute of Oncology, Leeds, [7]Department of Haematology, Freeman Hospital, Newcastle upon Tyne, [8]Department of Renal Medicine, Nottingham University Hospital, Nottingham, [9]Department of Pathology, University Hospital Birmingham, Birmingham, United Kingdom

Background: Post-transplant lymphoproliferative disease (PTLD) remains an important complication of solid organ transplantation (SOT). There is currently a lack of data to guide selection between Rituximab monotherapy (R-mono) and R-CHOP as options for frontline therapy of B-cell PTLD.
Aims: To report outcomes and prognostic factors for patients with B-cell PTLD arising after SOT, comparing R-mono *vs* R-CHOP as initial therapy.
Methods: This retrospective study included adult patients from 6 centres in the United Kingdom diagnosed with biopsy-proven PTLD between 2000-2013. Median follow-up was 4 years 2 months.
Results: Of 116 cases of PTLD identified, 100 were categorised as B-cell PTLD and were included in this analysis. Histological subtypes were 67 DLBCL, 23 polymorphic and 10 B-cell PTLD otherwise unspecified. There were 62 renal, 30 liver, 7 cardiothoracic and 1 pancreatic transplant recipients. Median age at diagnosis was 48 years (range 16-84 years) and 65% of patients were male. Early onset disease, presenting ≤1 year after transplant, comprised 15% of cases. EBV-association was noted in 55/78 (71%) of evaluated cases and this was related to early onset disease (X^2 p=0.004). Initial therapy was R-mono in 26/100 (26%) and R-CHOP in 45/100 (45%). Use of R-CHOP was associated with monomorphic histology (OR 18.3, p=0.001), ≥2 extranodal sites (OR 4.5, p=0.03), late onset disease (OR 6.2, p=0.01) and lack of EBV association (OR 0.08, p=0.002). Of patients treated with R-mono, 25/26 (96%) completed at least 4 infusions of Rituximab 375 mg/m^2 weekly, with no treatment-related deaths. Of those treated with R-CHOP, 33/45 (73%) completed at least 6 cycles, although there were 4 treatment-related deaths. The overall response rate for R-mono was 20/26 (77%; 14 CR, 6 PR, 5 NR and 1 undetermined) compared to 36/45 (80%; 30 CR, 6 PR, 5 NR and 4 undetermined) for R-CHOP. Amongst patients treated with R-mono, 17/26 (65%) had no further therapy and remained disease free with median follow-up of 44 months; 6 other patients received R-CHOP for consolidation of response or relapsed/refractory disease. Overall survival (OS) was 71% and 61% at 3 years for R-mono and R-CHOP respectively (p=0.40; Figure 1A). Amongst all patients with B-cell PTLD, significant baseline predictors of inferior OS were age ≥50 years (HR 3.8, p<0.001), ECOG PS ≥2 (HR 1.9, p=0.04), elevated LDH (HR 2.0, p=0.08 borderline), stage ≥2 disease (HR 2.5, p=0.01) and ≥2 extranodal sites (HR 1.8, p=0.08 borderline). Overall response to R-mono or R-CHOP was also highly predictive of OS (HR 0.16, p=0.0001). B symptoms, onset time, extranodal disease, histology and EBV-association were not predictive. In multivariate testing, age ≥50 years (HR 5.3, p=0.0001) and advanced stage (HR 2.2, p=0.06 borderline) remained significant. Applying a 4 point modified prognostic index (comprising age ≥50 years, stage ≥2 disease, ECOG PS ≥2 and elevated LDH) to patients treated with R-mono or R-CHOP, those with low risk disease (0-1 points) had significantly improved survival compared to those with high risk disease (≥2 points), with 3 year OS of 87% *vs* 51% (p=0.001; Figure 1B). Amongst patients with high risk disease, 13 treated with R-mono had an inferior complete response rate compared to 21 treated with R-CHOP (23% *vs* 67%; OR 0.15, p=0.02), although a survival difference was not detected.

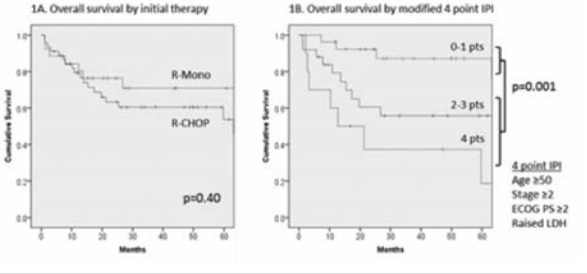

Figure 1.

Summary/Conclusions: We report outcomes for R-mono *vs* R-CHOP as initial therapy for PTLD arising after SOT. R-mono may deliver inferior response rates for patients with high risk disease. Using a modified prognostic index we identify a subset of patients with poor outcome for whom novel therapeutic strategies are required.

EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE OF ADVANCED STAGE: NKEA (NEXT-GENERATION THERAPY FOR NK/T-CELL LYMPHOMA IN EAST ASIA) PROJECT

R Suzuki[1,*], M Yamaguchi[2], M Oguchi[3], N Asano[4], N Tomita[5], J Amaki[6], T Ando[7], N Niitsu[8], N Sekiguchi[9], J Takizawa[10], K Miyazaki[2], N Katayama[2]
[1]Cancer Center, Shimane University, Izumo, [2]Hematology, Mie University, Tsu, [3]Radiation Oncology, Japanese Foundation for Cancer Research Cancer Institute Hospital, Tokyo, [4]Molecular Diagnostics, Nagano Prefectural Suzaka Hospital, Suzaka, [5]Hematology, Yokohama City University, Yokohama, [6]Hematology, Tokai University, Isehara, [7]Hematology, Saga University, Saga, [8]Hematology, Saitama Medical University, Moroyama, [9]Hematology, Shinshu University, Matsumoto, [10]Hematology, Niigata University, Niigata, Japan

Background: Treatment of extranodal NK/T-cell lymphoma, nasal type (ENKL) has proceeded and evolved. Concurrent chemoradiotherapy with platinum-containing regimen and L-asparaginase based chemotherapy such as SMILE (steroid, methotrexate, ifosfamide, L-asparaginase, and etoposide) are the current standard for limited- and advanced-stage ENKL, respectively. However, there are no large-scale study which analyzed the data of patients in general practice.
Aims: To understand the recent conditions of ENKL, we conducted a survey for new-generation therapy for NK/T-cell lymphoma in East Asia (NKEA). Patients with advanced-stage were analyzed in this study.
Methods: This cooperative study by hemato-oncologists and radiation oncologists in Japan (UMIN000015491) retrospectively analyzed data from patients with ENKL who were diagnosed between 2000 and 2013.
Results: Data of 358 patients with ENKL of all clinical stage were collected from 31 institutes. A total of 102 patients were in advanced stage (4 with stage III and 98 with stage IV). There were 64 males and 38 females. The median age was 59 years, ranging from 18 to 86 years old. A total of 27 patients were initially treated with CHOP-type regimen, 33 patients with DeVIC-type, and 30 patients with SMILE-type regimen, but 12 patients did not receive any chemotherapy. In total, 23 patients received additional radiotherapy (RT). The median dose of RT was 48 Gy. Thirty patients received hematopoietic stem cell transplantation (SCT, 10 autologous and 20 allogeneic). Patients who were initially treated with SMILE-type treatment more received SCT (50% *vs* 26% with CHOP-type or 24% with DeVIC-type). The overall response rate was 67% for SMILE-type, 45% for DeVIC-type, and 33% for CHOP-type regimens. The 5-year overall survival (OS) rate was 25% with a median follow-up of 5.8 yrs, and the 5-year progression free survival (PFS) rate of 17%. OS of patients who received SMILE-type, CHOP-type, and DeVIC-type regimen was 39%, 28%, and 19%, respectively (P=0.04). addition of RT did not affect the prognosis of advanced ENKL (5-year OS: 24% for patients without RT and 26% for patients with RT). Prognosis of patients who received SCT was better than those who did not (5-year OS: 55% *vs* 12%). The type of SCT (autologous *vs* allogeneic) did not affect the prognosis (5-year OS: 40% for autologous *vs* 62% for allogeneic). The international Korean Prognostic Indexes were not prognostic (P=0.54 and 0.30, respectively), but the PINK (Prognostic Index for NK) score was prognostic (P=0.03).

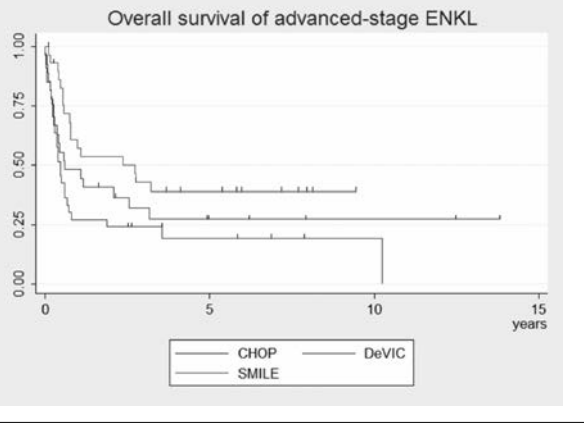

Figure 1.

Summary/Conclusions: The efficacy of SMILE-type chemotherapy for advanced ENKL was shown in this study, although there remains several limitations of retrospective nature. A novel prognostic index of PINK successfully

predicted the prognosis. The prognosis of advanced-stage ENKL has improved as compared with that in the previous-era, but further betterments are required.

E946

VALIDATION OF NCCN INTERNATIONAL PROGNOSTIC INDEX (NCCN-IPI) FOR DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL). THE ADDITION OF B2MICROGLOBULIN RESULTED IN GELTAMO-IPI THAT IS MORE ACCURATE

IRYCIS, [19]Pathology, MD Anderson Cancer Center Madrid, Spain, Madrid, Spain

Background: The NCCN International Prognostic Index (NCCN-IPI) for patients with DLBCL treated in the rituximab era showed enhanced discrimination in the original study, when compared to IPI. However, in our previous study (ASH 2015 #3955) it failed to identify patients with a real poor outcome.
Aims: In the present study we explore the prognostic effect of adding new factors to the variables of NCCN-IPI in a large series of patients.
Methods: This nation-wide retrospective study includes a final database of 1848 patients with de *novo* DLBCL diagnosed in 20 Spanish centers within the Grupo Español de Linfomas/ Transplante de Médula Osea (GELTAMO) network treated with standard chemotherapy and rituximab. To study the improvement of the prognostic effect of adding three new variables, normalized high serum β_2 microglobulin ($\beta_2$mcg), primary extranodal involvement and treatments more intense than R-CHOP, to the NCCN-IPI variables, the series was split in two cohorts. The training cohort (1230 patients) was used to develop a prognostic model using Cox regression models for Overall Survival and the final model was validated in an independent validation cohort (618 patients). The Kaplan Meyer method and log-rank test were used for OS and comparison of curves. The prognostic effect of this score was compared with NCCN-IPI and IPI with the reclassification calibration statistics (a modification of Hosmer–Lemeshow goodness of fit).
Results: The COX regression model in the training cohort, showed that distinct extranodal involvement (as included in NCCN-IPI), primary extranodal lymphoma and intense treatment achieved no significance. The final model included the rest of the variables, with points according with the hazard ratios: age (<65/0 pts; ≥65-79/1 pt; ≥80/2 pts), PS(0-1/0 pts ; 2/1 pt ;≥2/2 pts), high LDH, Stage III-IV and high $\beta_2$mcg, with 1 point each, resulting in a score (GELTAMO-IPI) with a maximum of 7 points that separated significantly four risk groups: LR (0 points), LIR (1-3 pts), HIR (4 pts), HR (≥5) with significantly different 5-yOS that was subsequently confirmed in the validation cohort. Using all the patients in the series with available data (n=1672), GELTAMO-IPI discriminates better (5-yOS rates of LR: 93%, LIR 79%, HIR 66%, HR 39%) than NCCN-IPI (93%, 83%, 67%, 49%, respectively) and IPI (88%, 77%, 68%, 51%, respectively); both NCCN-IPI and IPI failed to identify a population with a 5-yOS substantially lower that 50%. Similar results were obtained for 5-yFFS. In the reclassification calibration statistics GELTAMO-IPI was more accurate than NCCN-IPI and IPI.

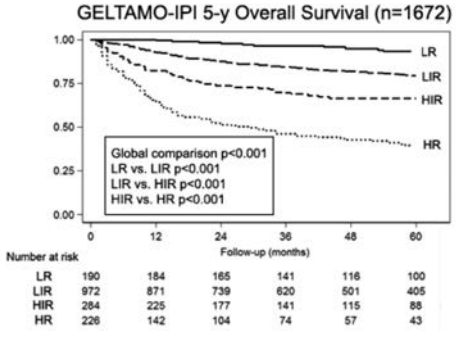

Figure 1.

Summary/Conclusions: GELTAMO-IPI including $\beta_2$mcg along all the variables of NCCN-IPI (excluding selective extranodal involvement) is more accurate than NCCN-IPI and IPI for the prognosis of DLBCL. Additionally, it can be used in primary nodal and extranodal lymphoma and in patients with intense treatment and, most important, identifies a poor prognostic group with 5y-OS of 39%.

E947

EVALUATION OF A PROGNOSTIC MODEL FOR CNS RELAPSE WITHIN THE UK NCRI R-CHOP-14 *VS* 21 TRIAL

G Mary[1,*], D Cunningham[1], N Chadwick[2], N Counsell[2], EA Hawkes[3,4], A McMillan[5], KM Ardeshna[6,7], A Jack[8], P Smith[2], P Mouncey[2], C Pocock[9], J Radford[10], J Davies[11], D Turner[12], A Kruger[13], P Johnson[14], J Gambell[2], D Linch[7]

[1]The Royal Marsden, London and Surrey, [2]Cancer Research UK and UCL Cancer Trials Centre, UCL Cancer Institute, London, United Kingdom, [3]Dept Oncology and Clinical Haematology, Austin Hospital, [4]Eastern Health, Melbourne, Australia, [5]Nottingham City Hospital, Nottingham, [6]Mount Vernon Cancer Centre, Northwood, [7]University College London, London, [8]St James' Institute of Oncology, Leeds, [9]East Kent Hospitals, Canterbury, [10]University of Manchester and the Christie NHS Foundation Trust, Manchester, [11]Western General Hospital, Edinburgh, [12]Torbay Hospital, Torquay, [13]Royal Cornwall Hospital, Truro, [14]Cancer Research UK Centre, Southampton, United Kingdom

Background: Central Nervous System (CNS) relapse of Diffuse Large B-cell Lymphoma (DLBCL) is associated with a poor prognosis. CNS prophylaxis is administered to patients deemed to be at high risk of CNS relapse but the indications for prophylaxis are not standardized. The German High-Grade Non-Hodgkin Lymphoma Study Group (DSHNHL) recently proposed a new 6-factor prognostic model incorporating the 5 International Prognostic Index (IPI) factors in addition to kidney/adrenal gland involvement to determine the risk of CNS relapse in patients with aggressive B-cell lymphoma. This model stratified patients into 3 risk groups: low [0-1 factors, 2 yr CNS relapse risk=0.6% (95% CI 0.0-1.2)]; intermediate [2-3 factors, 2 yr CNS relapse risk=3.4% (95% CI 2.2-4.6)] and high risk [4-6 factors, 2 yr CNS relapse risk=10.2% (95% CI 6.3-14.1)] (Schmitz et al, Lugano 2013); which was subsequently validated in an independent cohort of R-CHOP-treated patients with DLBCL at the British Columbia Cancer Agency (BCCA) (Savage et al, ASH 2014).
Aims: In this analysis we applied the DSHNHL prognostic model to the UK NCRI prospective R-CHOP-14 v 21 trial cohort to determine if similar risk groups could be identified.
Methods: The randomised phase III UK R-CHOP-14 *vs* 21 trial assessed rituximab, cyclophosphamide, doxorubicin, vincristine, prednisolone (R-CHOP) given 2 weekly *versus* 3 weekly in 1080 DLBCL patients accrued between 2005-2008 (Cunningham et al, 2013). Administration of CNS prophylaxis was at the discretion of investigators but recommended for patients with involvement of bone marrow, peripheral blood, nasal/paranasal sinuses, orbit and testis (12.5mg intrathecal methotrexate (IT MTX) for the first 3 cycles of treatment or according to local guidelines). Details of CNS prophylaxis were retrospectively collected from participating sites using case report forms.

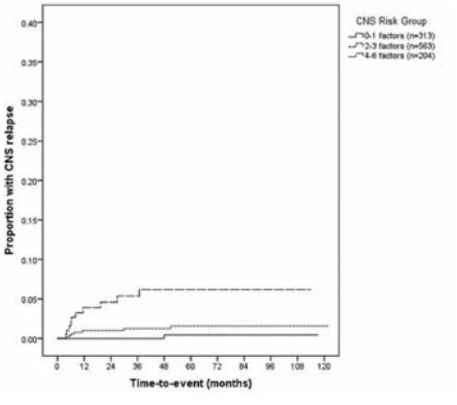

Figure 1.

Results: With a median follow-up of 6.5 years the incidence of CNS relapse in our cohort was 1.7% (18/1,080). 17.3% (170/982) of patients in the R-CHOP-14 *vs* 21 trial received CNS prophylaxis: IT MTX=94.0%, high-dose intravenous MTX=1.3%, prophylaxis type unknown=4.5%. We have previously reported that the incidence of CNS relapse for patients receiving prophylaxis was 3.5% which may suggest some benefit of this therapy (Gleeson et al, ASH 2014). The 6-factor DSHNHL model stratified patients into 3 risk groups for CNS relapse at 2 years: low (0-1 factors)=0%; intermediate (2-3 factors)=1.0% (95% CI 0.2-1.8) and high risk (4-6 factors)=4.6% (95% CI 1.5-7.7) [Figure 1]. Patients developing CNS relapse (n=18) were divided into the following DSHNHL risk groups: low n=1/313, intermediate n=7/563 and high-risk n=10/204. The proportion of patients receiving CNS prophylaxis was 15.3%, 14.2% and 31.4% for low, intermediate and high-risk groups respectively.

Summary/Conclusions: The overall incidence of CNS relapse within the R-CHOP-14 *vs* 21 trial cohort was low (1.7%). The DSHNHL model identified 3 risk groups for CNS relapse at 2 years in the R-CHOP-14 *vs* 21 cohort, with patients in the high-risk group demonstrating a 2-year incidence of CNS relapse of 4.6%. We observed a lower rate of CNS relapse than that reported by both the DSHNHL and BCCA groups. This may have been influenced by population differences, as the DSHNHL cohort included patients with aggressive B-cell non-Hodgkin lymphoma and the BCCA cohort is a population-based dataset. In addition the proportion of patients receiving CNS prophylaxis may have differed between patient cohorts.

E948

SAFETY AND CLINICAL ACTIVITY OF TEMSIROLIMUS IN COMBINATION WITH RITUXIMAB AND DHAP IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA-PRELIMINARY RESULTS OF THE STORM TRIAL

M Witzens-Harig[1,*], U Keller[2], A Viardot[3], C Buske[3], E Hönig[4], A Crombe[4], J Brandt[1], J Meissner[1], A Ho[1], P La Rosee[5], R Marks[6], M Dreyling[7], G Hess[8]
[1]University of Heidelberg Hospital, Heidelberg, [2]TU, Munich, [3]University Hospital, Ulm, [4]IZKS, Mainz, [5]University Hospital, Jena, [6]University Hospital, Freiburg, [7]LMU, Munich, [8]University Hospital, Mainz, Germany

Background: Prognosis of diffuse large B-cell lymphoma (DLBCL) has improved with the advent of Rituximab. However, there is increasing evidence that treatment of patients with relapsed and refractory disease is challenging.
Aims: The purpose of this trial is to evaluate the safety, tolerability and efficacy of the combination of the mTOR inhibitor Temsirolimus and a standard salvage regimen (R-DHAP) in patients with relapsed or refractory DLBCL.
Methods: This is a prospective, multicenter, phase II, open-label study. Patients with relapsed or refractory DLBCL with a maximum of two prior treatment lines were eligible. The STORM regimen consisted of Rituximab 375mg/m^2 (day 2) and DHAP (Dexamethasone 40mg day 3-6, Cisplatine 100mg/m^2 day 3, Cytarabine 2x2g/m^2 day 4) with Temsirolimus added on day 1 and 8 of a 21 d cycle, with 2-4 cycles planned. In part I, dose levels for the mTOR inhibitor Temsirolimus from 25, 50, 75 and 100 mg were predefined. Based on the observed toxicity profile, the independent data safety committee recommended a Temsirolimus dose of 25mg given on day 1 and 8 for the part II extension cohort of the trial.
Results: In part I of this clinical trial 15 patients were included - 8 patients in the 25 mg cohort and 7 patients in the 50 mg cohort. Median age was 70 (range 49-76) years and median number of prior regimen was 1. Two DLTs (one venous thrombosis in the 25 mg cohort, one esophagus infection in the 50 mg cohort) were observed. The most frequent non-hematologic side effects were nausea (9 pts, 60%), epistaxis (7 pts, 47%), fatigue (6 pts, 40%), increased ALT (6 pts, 40%) and increased creatinine (6 pts, 40%). Frequent grade 3/4 events (n>2) in both cohorts (25mg|50mg) included leukopenia (11 pts, 73% - with a mean duration of 4.4 days | 6.7 days), thrombocytopenia (11 pts, 73% - with a mean duration of 4.6 days | 11.9 days), lymphopenia (6pts, 40%), anemia (5 pts, 33%), neutropenia (3 pts, 20%), renal failure (3 pts, 20%) and infections (4 pts, 27%, bladder infection, esophagus infection, central venous access infection, soft tissue infection, mucositis). All but one evaluable patient responded (10/11 pts, 91%), with two CRs and one CRu (27%). Four patients could not be evaluated for response at the time of the first report. After a median follow up of 12 (range 5-22) months, no relapse had been documented (1 pt lost to follow up); since then, progression of disease has occurred in three patients and led to these patients' death. However, only for one of these patients participation in the study ended prematurely because of progressive disease under therapy, while the other two had already dropped out due to adverse events. As far as the extension cohort of part II is concerned, preliminary data of 17 patients are reported below. Median age was 61 (range 42-74) and median number of prior regimen was one. Out of these 17 patient data sets, two could not be evaluated for response. The response rate of the remaining 15 patients was 87% (13/15 pts). Two therapy-related deaths occurred (one patient died from sepsis during neutropenia, another from cerebral bleeding, both events occurring after cycle 3). After a median follow up of 7 months for the total study population, median PFS and OS have not been reached.
Summary/Conclusions: Temsirolimus can be safely added to DHAP and Rituximab with promising activity. This conclusion drawn from part I of the study has been confirmed by the preliminary data of part II. Recruitment of the part II of the trial is continuing.

Background: Prognostic factors (PFs) have not been extensively studied in PMLBCL and prognostic models specifically applicable to this entity have not been developed, mainly due to its rarity. R-CHOP provides very good results in PMLBCL, minimizing failure rates. High IPI and serous effusions emerged as adverse prognostic factors in 181 Japanese patients treated with RCHOP±RT (selected among broader population with heterogenous treatment), while serous effusions, B-symptoms and age were identified in 96 RCHOP±RT-treated patients in a 2012 abstract from Vancouver. Given that more intensive chemotherapy (R-da-EPOCH) might be better than R-CHOP, the applicability of various PFs needs to be urgently evaluated in the Rituximab era in order to define subgroups of patients at high risk for treatment failure and death.
Aims: The identification of PFs for the outcome of patients with PMLBCL treated with RCHOP± RT.
Methods: 213 patients with PMLBCL were treated in a multicenter setting with RCHOP±RT (usually 6-8 cycles). The following potential prognostic factors were evaluated: Age (median 31; range 17-82; >60 years only 4%), gender (female 64%), B-symptoms, stage III/IV, infradiaphragmatic disease, extranodal involvement (either stage IV or stage E), pleuritis, pericarditis, performance status (PS) ≥2, LDH levels, anemia, leukocytosis ≥10x10^9/L, ESR ≥30mm/h, albumin <4g/dL, bulky disease (≥10cm), age-adjusted IPI (aaIPI; ≥2 in 21%). A modified version of aaIPI was also analyzed, attributing 1 point to either stage III/IV or E-disease instead of stage III/IV only (aaIPI-mod).
Results: With 52 failures recorded (51 within 17 months from diagnosis), the 3-year freedom from progression (FFP) was 75%. With 24 deaths recorded (excluding 2 unrelated deaths), the 5-year overall survival (OS) was 87%. aaIPI≥2 identified a minority of patients (21%) with a 5-year FFP of 64% *vs* 79% for those with aaIPI 0-1 (p=0.04) and 5-year OS of 76% *vs* 91% (p=0.0095). The aaIPI-mod was more effective in predicting the outcome and indentified a larger poor prognostic group (41% of total): The 5-year FFP was 61% *vs* 86% for those with aaIPI-mod 0-1 (p<0.0001), while 5-year OS was 75% *vs* 97% (p<0.0001). Many of the examined variables had a significant (p<0.05) or borderline (p<0.15) association with both FFP and OS (extranodal disease, LDH, PS, abdominal disease, bulky disease, serous effusions, anemia). In multivariate analysis of FFP, extranodal involvement and bulky disease were independent PFs (p=0.006 and p=0.04). None, 1 or 2 of these factors were present in 29%, 42% and 30% of the patients. FFP at 5 years was effectively predicted being 88%, 79% and 59% for patients with 0, 1 or 2 PFs respectively, while 5-year disease specific survival was 100%, 91% and 72%.
Summary/Conclusions: In the largest patient series reported so far, RCHOP±RT provided satisfactory results in PMLBCL with long-term FFS of 75% and excellent OS of 87%. The aaIPI was moderately predictive of the outcome but a modified version performed better. Either the aaIPI-mod or the combination of extranodal involvement and bulky disease defined a subgroup comprising ~40% and ~30% of patients respectively with a ~40% risk of failure and ≥25% risk of death, who might be suitable for trials of treatment intensification.

Antonio e Biagio e Cesare Arrigo di Alessandria, Alessandria, [2]Cancer Epidemiology, Città della Salute e della Scienza, Torino, [3]Medical Oncology, University of Modena e Reggio Emilia, Modena, [4]Hematology II, Città della Salute e della Scienza, Torino, [5]Hematology and Bone marrow Transplantation, Regional Hospital S. Maurizio of Bolzano, Bolzano, [6]Hematology, Hospital Businco of Cagliari, Cagliari, [7]Hematology, IRCCS CRO of Aviano, Aviano, [8]Hematology, Ospedale Maggiore Policlinico of Milan, University of Milan, Milano, [9]Diagnostic, Clinical and Public Health Medicine, University of Modena, Modena, [10]Hematology, Hospital S. Bortolo, Vicenza, Italy

Background: Recent studies show that the risk of VTE in Non Hodgkin Lymphoma (NHL) patients (pts) is similar to that observed in high risk solid tumors (i.e. pancreatic, ovarian cancer). VTE in NHL occurs in most cases within 3 months from diagnosis and can have substantial impact on treatment delivery and outcome as well as on quality of life. However few data are available on potential predictors.
Aims: To better clarify the epidemiology of early (within 6 months from treatment start) VTE in NHL pts we conducted a pooled data analysis of 12 clinical trials from FIL. Our analysis included basic demographic features, lymphoma-related characteristics as well as the Khorana score KS (based on histology, body mass index BMI, platelets count PLTs, white blood cells count WBC and hemoglobin values Hb) which is extensively used in solid tumors to predict VTE risk.
Methods: From Jan. 2010 to Dec. 2014 all pts with B-cell NHL enrolled in prospective clinical trials from FIL for frontline treatment were included. For 9 studies the study period included the entire trial population. The analysis was conducted based on CRFs as well as pharmacovigilance reports. VTE definition and grading was stated according to standard criteria of toxicity (CTCAE V4.0). Cumulative incidence of VTE from study enrollment was estimated using the method described by Gooley et al. accounting for death from any causes as a competing risk. The Fine & Gray survival model was used to identify predictors of VTE among NHL pts. Factors predicting the grade of VTE were investigated using an ordinal logistic regression model. This pooled data analysis was approved by local IRB.
Results: Overall, 1717 pts belonging to 12 studies were evaluated. 8 studies were phase I/II or II (25% of pts) and 4 phase III (75% of pts). M/F ratio was 1.41, median age was 57 (IQ range IQR 49-66). Histologies were: diffuse large B-cell lymphoma DLCL-B 34%, follicular lymphoma FL 41%, mantle cell lymphoma MCL 18%, other 6%. Median BMI was 25 (IQR 22-28). Median Hb, WBC and PLTs counts were 13g/dl (IQR 11.5-14.2), 7,1x10^9/l (IQR 5.6-10.3) and 224x10^9/l (IQR 169-298) respectively. In 1189 pts was assessed KS: 58% low risk, 30% intermediate risk, 12% high risk. Human erytropoetin support was given to 9% of pts. All pts received Rituximab. Planned therapeutic programs included autologous stem cells transplantation in 27% of pts, conventional chemotherapy in 67% and conventional chemotherapy plus lenalidomide in 6%. Overall 59 any grade VTE episodes occurred in 51 pts (2.9%), including 21 grade III-IV VTEs (18 pts). None was fatal. Median time from study enrollment to VTE was 63 days (IQR: 35-110). Considering death as a competitive event the 6 months cumulative incidence of VTE was 2,2% (95%IC: 1.1-3.3) in low risk, 4.5% (95%IC: 2.3-6.7) in intermediate and 6.6% (95%IC: 2.4-10.8) in high risk KS (p=0.012). KS was predictive also for grade III-IV VTEs as they were 0,7% (95%IC:0.1-1.4) in low risk and 2% (95%IC:0.8-3.3) in intermediate-high risk (p=0.048). Results were similar also after excluding lenalidomide containing studies. Fine and Gray multivariate analysis, adjusted for age and stage, showed that KS (intermediate risk adjHR=1.96; 95%IC: 0.84-4.56 and high risk adjHR=3.81; 95%IC: 1.51-9.58) and DLCL-B histotype (adjHR=2.58; 95%IC: 1.01-6.55) were independently associated to an increased risk of VTE. Moreover an ordinal logistical regression model indicated that the increase of 1 point in the KS resulted in an increased risk of VTE (OR=1.85; 95%CI: 1.23-2.79).

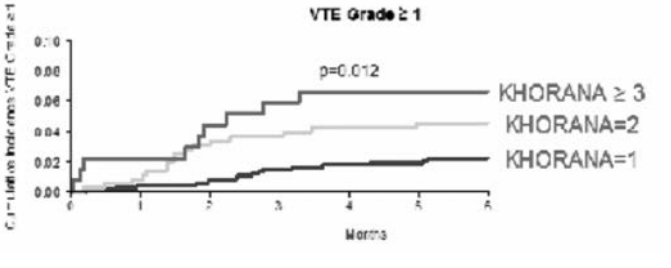

Figure 1.

Summary/Conclusions: Our results suggest that DLCL-B hystotype and KS are predictors of VTE in NHL. The latter might become a simple and effective tool to assess the risk of VTE in NHL. Prospective validation including also pts not eligible for clinical trials is needed.

HEMOGLOBIN LEVEL IMPROVES THE ABILITY OF THE NATIONAL COMPREHENSIVE CANCER NETWORK INTERNATIONAL PROGNOSTIC INDEX TO PREDICT OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA A POPULATION BASED COHORT STUDY

MR Clausen[1,*], M Nørgaard[2], F d'Amore[1]
[1]Department of Hematology, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Prognosis and treatment options for patients with diffuse large B-cell lymphoma (DLBCL) has for the last 20 years been conveyed on the basis of The International Prognostic Index (IPI). Improving IPI by adding biomarkers is, however, an ongoing discipline. The National Comprehensive Cancer Network IPI (NCCN-IPI) adds to the classical IPI factors more refined age and lactate dehydrogenase (LDH) strata and weighs extranodal disease according to the involvement or not of high risk organs such as bone marrow, CNS, liver/GI tract or lung. The NCCN-IPI was derived and validated on two cohorts with a mean age of 57- and 62-years, respectively, *i.e.* slightly younger than one would expect in a population-based DLBCL cohort. In Denmark, the universal healthcare system is tax funded and free of charge for all inhabitants ensuring a broad coverage of high quality healthcare. For lymphoma, a national group elaborate management guidelines and a prospective collection of patient-related data stored in the group's database (LYFO).
Aims: i) To validate the NCCN-IPI in a population-based cohort of de-novo DLBCL patients treated with anthracycline-based chemotherapy; (ii) to analyze, in a multivariate model, whether adding information on pre-therapeutic hemoglobin level improves on the ability of the NCCN-IPI to predict outcome.
Methods: All patients were diagnosed with de novo DLBCL between 2000 and 2012 and treated with anthracycline-based chemotherapy with or without rituximab (R). Patients with indolent- or composite lymphoma were excluded, as were patients with primary CNS-lymphoma. Clinical data were obtained from LYFO and biochemical data were retrieved partly from LYFO and from hospital laboratories. Data on vital status were obtained from the Danish Civil Registration System. Patients were followed from the date of biopsy until death or the end of study (December 10, 2015). Overall survival was described using Kaplan-Meier curves according to NCCN-IPI, treatment and hemoglobin values. Univariate and multivariate analysis were performed using Cox proportional hazard model including NCCN-IPI group, anemia and treatment as covariates with mutual adjustment. Anemia was defined as hemoglobin<7.3 mmol/l l for women and<8.3 mmol/l for men. The proportional hazard assumption was evaluated graphically using log-log plots. The study was approved by the Danish Data Protection Agency (no. 1-16-02-562-13).
Results: A total of 3654 patients fulfilled the inclusion criteria and had a median follow-up of 1888 days. Median age was 65 years (range 15-98), 2033 (56%) were men, 2081 (57%) had Ann Arbor stage III-IV, and 712 (19%) had a performance score ≥2. The pre-therapeutic LDH ratio (measured *vs* max reference value) was >1 in 2225 (61%). Anemia was present in 1784 (49%) patients. The NCCN-IPI separated our cohort in low (8%), low intermediate (35%), high intermediate (39%), and high risk (18%) patients. For R-chemo treated patients, the four NCCN-IPI risk groups (low, low-intermediate, high-intermediate, high) revealed 5-year OS values of 0.96 (CI95%, 0.92-0.98), 0.81 (CI95% 0.77-0.83), 0.60 (CI95% 0.56-0.63), and 0.30 (CI95% 0.26-0.37), respectively (Figure 1A). When hemoglobin level was added to the model it showed a significant impact on OS for both intermediate risk groups. Estimated 5 year overall survival in anemic *vs* non anemic patients with high-intermediate risk NCCN-IPI was 0.53 (95%CI 0.48-0.58) and 0.69 (95%CI 0.63-0.73) (Figure 1 B) and for low-intermediate 0.74 (95%CI 0.68-0.79) and 0.84 (95%CI 0.80-0.87). Patients with anemia as defined had a HR of 2.46 (95%CI 2.08-2.90).). After adjusting for NCCN-IPI factors, the HR remained significant (1.51; 95%CI 1.29-1.83).

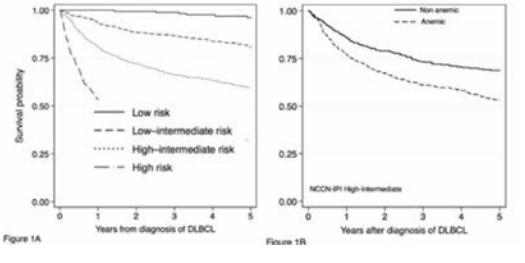

Figure 1.

Summary/Conclusions: In a population-based cohort of de novo DLBCL patients, we found that pre-therapeutic anemia was present in 49% of the patients and had independent prognostic impact also when adjusted for NCCN-IPI risk factors, and stratified for rituximab treatment. The adverse prognostic value of pretherapeutic anemia was independent of gender and age strata. Our patient cohort was older than the ones of the original NCCN-IPI publications (median age 65 yrs *vs* 54 yrs), which probably explains the difference in the proportion of high-risk patients (18% in our cohort *vs* 8% and 14% in the two original NCCN-IPI cohorts).

E953

ROUTINE IMAGING FOR PERIPHERAL T-CELL LYMPHOMA IN FIRST COMPLETE REMISSION DOES NOT IMPROVE SURVIVAL: A DANISH SWEDISH POPULATION-BASED STUDY

H Cederleuf[1,*], L Hjort Jakobsen[2,3], F Ellin[4], P de Nully Brown[5], T Stauffer Larsen[6], M Boegsted[2,3], T Relander[1], M Jerkeman[1], TC El-Galaly[2,3]
[1]Department of Oncology, Skåne University Hospital, Lund, Sweden, [2]Department of Hematology, Aalborg University Hospital, [3]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark, [4]Department of Internal Medicine, Kalmar County Hospital, Kalmar, Sweden, [5]Department of Hematology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, [6]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Routine surveillance imaging plays a limited role in detecting lymphoma relapse and a recent Danish-Swedish study showed that imaging-based follow-up practice was not associated with better outcome for diffuse large B-cell lymphoma (DLBCL) patients.
Aims: Using a similar approach, we evaluated the outcome of Danish and Swedish patients with nodal peripheral T-cell lymphoma (PTCL) in first CR for whom traditions for routine imaging have been different.
Methods: Patients from the Danish and Swedish lymphoma registries were selected by the following criteria: a) newly diagnosed nodal PTCL from 2007 to 2012, b) age ≥18 years, and c) CR after CHOP or CHOEP therapy with or without consolidating high-dose therapy (HDT). Follow-up for Swedish patients included symptom assessment, clinical examinations and blood tests at 3- to 4-month intervals for 2 years, with longer intervals later in follow-up. The national Swedish guidelines only recommended imaging when relapse was clinically suspected. Follow-up for Danish patients was similar but included routine imaging, usually computed tomography (CT) every 6 months for 2 years and at some centers annual CT from the 3rd till the 5th year of follow-up as well.
Results: In total, 109 Danish patients and 123 Swedish patients with nodal PTCLs were included. PTCL not otherwise specified (NOS) was diagnosed in 95 patients, anaplastic large cell lymphoma (ALCL) in 88 patients, and angioimmunoblastic T-cell lymphoma (AITL) in 49 patients and with similar subtype frequencies for Danish and Swedish patients. The baseline demographic characteristics were also fully comparable between Danish and Swedish patients (Table 1). The OS estimates for Danish and Swedish patients in CR following frontline therapy were similar for all patients (P=0.6, Fig 1) and in PTCL subtype specific analyses. The most important adverse predictor of OS following CR was age >60 (Hazard Ratio [HR], 3.73; 95% CI, 2.08 to 6.66, P<0.01). The 2-year probability of relapse was similar for Danish and Swedish patients (25%; 95% CI 16-33% *vs* 29%; 95% CI 19-38%, P=0.53). The post-relapse OS was similar for Danish and Swedish patients overall (P=0.8) and in PTCL subtype specific analyses.

Table 1. Demographic and clinicopathological information on Danish and Swedish patients with nodal PTCL.

	DK (n=109)	SWE (n=123)	Missing (DK/SWE)	P-value
Median age (years)	61 (21-89)	64 (20-87)	0/0	0.29
Male-female ratio	1.27	1.51	0/0	0.59
IPI > 2, n (%)	31 (29.8)	36 (30.0)	5/3	1.00
ECOG >= 2	14 (13.0)	16 (13.2)	1/2	1.00
Induction chemo CHOP	77 (70.6)	72 (58.5)	0/0	0.07
Induction chemo CHOEP	32 (29.4)	51 (41.5)	0/0	0.07
ALCL	42 (39)	46 (37)	0/0	0.33
AITL	27 (25)	22 (18)	0/0	0.33
PTCL NOS	40 (37)	55 (45)	0/0	0.33

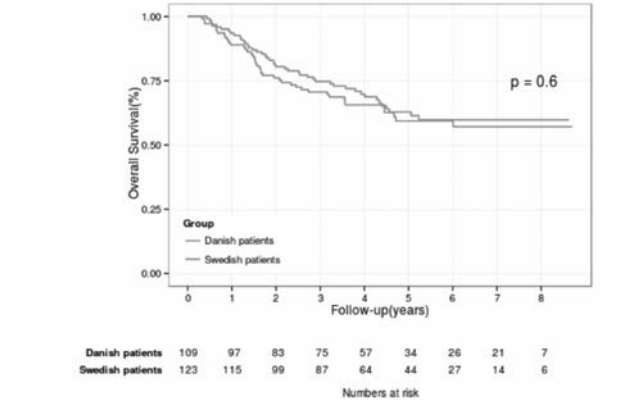

Figure 1.

Summary/Conclusions: Relapse following frontline treatment for PTCL is typically associated with a poor prognosis and an imaging based follow-up practice did not translate into better survival for Danish patients. Thus, a follow-up strategy without routine surveillance imaging appears safe and equally effective to a FU strategy with imaging for patients with nodal PTCL in first CR.

E954

REAL-TIME CELL-OF-ORIGIN SUBTYPE IDENTIFICATION BY GENE EXPRESSION PROFILE IN THE PHASE 3 ROBUST TRIAL OF LENALIDOMIDE+R-CHOP *VS* PLACEBO+R-CHOP IN PREVIOUSLY UNTREATED ABC-TYPE DLBCL

U Vitolo[1,*], A Chiappella[1], TE Witzig[2], M Spina[3], RD Gascoyne[4], L Zhang[5], J Flament[5], J Repici[5], E Conlin[5], K Delissio[5], GS Nowakowski[2]
[1]Division of Hematology, Città della Salute e della Scienza Hospital and University, Torino, Italy, [2]Division of Hematology, Mayo Clinic, Rochester, United States, [3]Division of Medical Oncology, National Cancer Institute, Aviano, Italy, [4]Pathology and Lymphoid Cancer Research, British Columbia Cancer Agency, Vancouver, BC, Canada, [5]Celgene Corporation, Summit, United States

Background: Gene expression profiling (GEP) represents a gold standard in identifying patients with activated B-cell–like (ABC) DLBCL, a subtype associated with inferior outcomes. Until recently, real-time identification of patients with ABC DLBCL as an integrated biomarker and inclusion criterion was not feasible due to technology limitations. The randomized, double-blind, global phase 3 ROBUST study (NCT02285062) compares lenalidomide+R-CHOP (R^2-CHOP) with placebo+R-CHOP in patients with previously untreated ABC-type DLBCL with participating sites in Asia, Australia, Europe, New Zealand, and North America.
Aims: Explore the real-world feasibility of GEP screening to determine DLBCL cell of origin (COO) in a global phase 3 study and quantify turnaround time and the percentage of screened patients having ABC-subtype DLBCL.
Methods: ROBUST methods have been described (Nowakowski, ASCO 2015). Patients must provide written informed consent. A key entry criterion is previously untreated, histologically confirmed ABC-type CD20+ DLBCL. Formalin-fixed paraffin-embedded excisional/surgical or core needle biopsy samples (Storhoff, Blood 2015) are analyzed by central pathology using the NanoString Lymphoma Subtyping Test (LST; Wallden, JCO 2015), based on the Lymph2Cx GEP assay (Scott, Blood 2014). Turnaround time is defined as number of days between central pathology sample receipt and results being provided to the study site.
Results: As of 11 Jan 2016, 357 patients were screened for ROBUST using the LST. Samples were analyzed in 2 central pathology labs in the US and UK. COO was ABC and non-ABC in 118 (33%) and 212 (59%), respectively. 27 patients (8%) had samples that could not be processed for technical reasons (incorrect/insufficient slides or blocks, or low tissue RNA concentration and/or purity). Mean turnaround time was 2.25 days (range, 0-9). 86 patients have met all inclusion criteria and were enrolled in ROBUST.
Summary/Conclusions: Real-time COO assessment is feasible in a multicenter, global phase 3 DLBCL study with short turnaround time. The percentage of patients with ABC-type DLBCL was similar to that reported in the literature. Our findings have important implications for the design and size estimation of both current and future studies in newly diagnosed DLBCL utilizing COO as a biomarker, promising a significant step forward in precision medicine. Updated results will be presented.

E955

MYD88 (L265P) MUTATION IS ASSOCIATED WITH AN UNFAVORABLE OUTCOME OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

K Hattori[1,*], M Sakata-Yanagimoto[1,2], Y Okoshi[2,3,4], Y Goshima[5], S Yanagimoto[6], R Nakamoto-Matsubara[1], T Sato[7], M Noguchi[7], S Takano[8], E Ishikawa[8], T Yamamoto[8], A Matsumura[8], S Chiba[1,2]
[1]Hematology, Graduate School of Comprehensive Human Sciences, [2]Hematology, Faculty of Medicine, University of Tsukuba, [3]Ibaraki Clinical Education and Training Center, University of Tsukuba Hospital, Tsukuba, [4]Hematology, Ibaraki Prefectural Central Hospital, Ibaraki, [5]School of Medicine, University of Tsukuba, Tsukuba, [6]Division for Health Service Promotion, The University of Tokyo, Bunkyo-ku, Tokyo, [7]Pathology, Faculty of Medicine, [8]Neurosurgery, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

Background: Primary central nervous system lymphomas (PCNSL) typically show an immunophenotype resembling that of activated B-cell-like diffuse large B-cell lymphoma (ABC-DLBCL). Somatic mutations in *MyD88, CD79B*, and *CARD11* were shown to activate the NFκB signaling pathway in ABC-DLBCL. These mutations are reported to be strongly over-represented in PCNSL. Nonetheless, clinical relevance of these mutations remains unclear. On the other hand, the several specific clinical parameters, such as MSKCC and IELSG prognostic score systems, were reported to predict the treatment outcome of PCNSL patients. Recently advanced genetic knowledge, however, is not incorporated in any of these proposals.
Aims: We conducted this study to elucidate the impact of gene mutations on clinical outcome of PCNSL.
Methods: We analyzed 42 immuno-competent patients suffering from newly diagnosed PCNSL who were aged over 60 years, or aged 55-60 years if they had poor performance status, and in whom enough material for DNA extraction was available. They were treated with modified version of the EORTC protocol, consisted of systemic administration of intermediate-dose methotrexate (MTX), lomustine, procarbazine, and methylprednisolone, and intrathecal chemother-

apy with MTX and cytarabine (Taoka K., et al., Int J Hematol 2010; Lee SY., et al., Oncol Res Treat 2014), at the University of Tsukuba Hospital between March, 2005 and May, 2015. Targeted deep sequencing was performed by using Ion Ampliseq technology for 12 genes, including *MyD88*, *CD79B*, *PIM1*, *TBL1XR1*, *BTG2*, *PRDM1*, *TNFAIP3*, *CARD11*, *B2M*, *TOX*, *TMEM30A*, and *PRKCD*. All candidate mutations were validated by genomic PCR followed by Sanger sequencing. Overall survival (OS) and progression-free survival (PFS) were estimated using the Kaplan-Meier method, and compared by the peto-peto generalized Wilcoxon test.

Results: At least one mutation was detected in 38/42 cases (90.4%). Frequencies of mutations of 12 genes were similar to those of the previous reports (*MyD88*, 79%; *CD79B*, 52%; *PIM1*, 69%; *TBL1XR1*, 24%; *BTG2*, 29%; *PRDM1*, 24%; *TNFAIP3*, 12%; *CARD11*, 19%; *B2M*, 11.9%; *TOX*, 11.9%; *TMEM30A*, 4.8%; *PRKCD*, 4.8%). The median follow-up time was 26 months (range, 1-105 months), with OS at 3 years of 46% and PFS at 3 years of 26%. By univariate analysis, age >75 (P=0.0105) and altered mentation (P=0.0202) were significantly associated with inferior OS. Regarding PFS, CrCl >90 (P=0.0286) and altered mentation (P=0.0473) were significant factors. In addition, *MyD88* L265P mutation showed a tendency to be associated with inferior OS and PFS, although statistically non-significant (OS: P=0.127, PFS: P=0.0872, Figure1). When adjusted to a multivariate Cox regression analysis, *MyD88* L265P mutation remained as a significant risk factor for death (hazard ratio (HR), 2.9; 95% confidence interval (CI), 1.0–8.3, P=0.0470), together with altered mentation (HR, 4.7; 95% CI, 1.5-14.7, P=0.0072). Regarding PFS, only *MYD88* L265P mutation (P=0.0303) was significantly associated with a higher risk of progression.

Summary/Conclusions: This is the first study that provides evidence that elderly PCNSL patients with *MyD88* L265P mutation show an unfavorable prognosis. Given that *MyD88* L265P mutation was reported to be also associated with an unfavorable outcome of DLBCL, not otherwise specified and cutaneous DLBCL of leg type, dysregulated cellular program by this mutation may be an important determinant for the prognosis of DLBCL in general. These findings open new perspectives in the utility of *MyD88* L265P mutation in the clinical sequencing settings of PCNSL.

SUBCUTANEOUS *VERSUS* INTRAVENOUS RITUXIMAB ADMINISTRATION IN FIRST-LINE DIFFUSE LARGE B-CELL LYMPHOMA AND FOLLICULAR LYMPHOMA: PREFMAB STUDY OF PATIENT PREFERENCE AND SATISFACTION IN 19 COUNTRIES

M Rummel[1,*], TM Kim[2], P Jensen[3], WV Pereira[4], F Re[5], M Mendoza[6], S Osborne[6], R Smith[6], A Grigg[7]

[1]University Hospital Giessen and Marburg, Giessen, Germany, [2]Seoul National University Hospital, Seoul, Korea, Republic Of, [3]Aalborg University Hospital, Aalborg, Denmark, [4]Universidade Federal de Santa Maria, Santa Maria, Brazil, [5]Universitaria di Parma, Parma, Italy, [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [7]Austin Hospital, Heidelberg, Australia

Background: A subcutaneous (SC) formulation of rituximab has been developed with comparable clinical activity to rituximab intravenous (IV), but a shorter administration time (~5 min *vs* 1.5-6 hrs). The SC administration route has been shown to reduce healthcare resource burden and has potential to reduce patient treatment burden compared with rituximab IV. In PrefMab, patients preferred rituximab SC over IV when given with chemotherapy, and reported higher levels of convenience and satisfaction with the rituximab SC administration route. However, in a large, international study, regional differences in patient preference due to local variations in clinical practice or culture may not be clear in the overall data.

Aims: To evaluate country-specific patient preference and satisfaction with rituximab SC *vs* IV.

Methods: PrefMab (NCT01724021) is a randomized, open-label, crossover phase 3b study. Patients were aged 18-80 years and had: previously untreated CD20+ diffuse large B-cell lymphoma (DLBCL; international prognostic index [IPI] 1-4 or 0 with bulky disease) or follicular lymphoma (FL; FLIPI grade 1-3a); at least 1 bi-dimensionally measurable lesion ≥1.5cm at its largest dimension; and ECOG performance status ≤3. All patients gave informed consent. Patients received 8 cycles of rituximab according to 2 schedules: 1 cycle rituximab IV (375mg/m^2) and 3 cycles rituximab SC (1400mg) then 4 cycles rituximab IV; or 4 cycles rituximab IV (375mg/m^2) then 4 cycles rituximab SC (1400mg). Patients also received 6-8 cycles of chemotherapy (CHOP [cyclophosphamide, doxorubicin, vincristine, prednisone], CVP [cyclophosphamide, vincristine, prednisone], or bendamustine as per standard local practice). A Patient Preference Questionnaire (PPQ) was completed at cycles 6 and 8. A Rituximab Administration Satisfaction Questionnaire (RASQ) was completed at cycles 4 and 8; domains were scored 0 (least)-100 (best). The current analysis included countries with data for ≥10 patients.

Results: At the primary data cut-off (January 19, 2015), 743 patients had been randomized to treatment in 32 countries. The median age was 60 years, most patients had DLBCL (63% *vs* 37% FL) and baseline characteristics were balanced between arms. Nineteen countries (listed in Figure) with data available for ≥10 patients were eligible for and included in the analysis. At cycle 8, most patients preferred rituximab SC to IV, with the median score ranging from 60-100% (Figure); similar results were seen at cycle 6. Preference was not substantially impacted by underlying disease. Patient satisfaction was higher for the SC administration route. Compared with the IV route, median RASQ scores were ≥10 points higher for SC in: 0/19 countries in the physical impact domain; 8/19 countries in the psychological impact domain; 16/19 countries in the impact on activities of daily living domain; 15/19 countries in the convenience domain; and 14/19 countries in the satisfaction domain. In 18/19 countries most patients (>70%) thought the time taken to administer rituximab SC was "just right", although 53% of patients in Brazil felt it was "too short". In all countries, most patients (>50%) felt they had "more than enough time" to discuss their illness with their nurse and/or doctor, regardless of administration route, although in Germany, Brazil and Canada >50% patients felt the SC route impacted on this time.

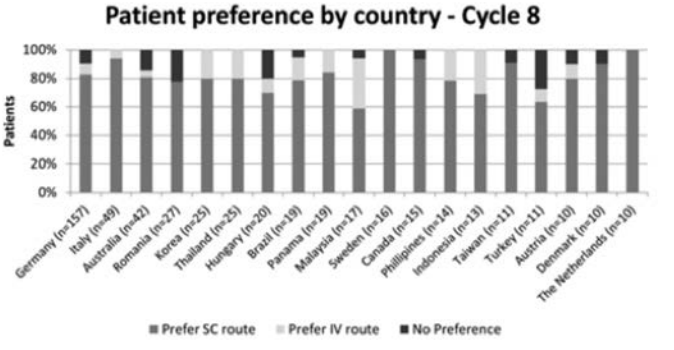

Figure 1.

Summary/Conclusions: Patient preference and satisfaction was higher with rituximab SC *vs* IV, and did not vary substantially by the country in which treatment was received.

E957

EXTRACORPOREAL PHOTOPHERESIS: SAFE AND EFFECTIVE FOR THE TREATMENT OF MYCOSIS FUNGOIDES

E Atilla[1,*], P Ataca Atilla[1], S Civriz Bozdag[1], SK Toprak[1], BN Akay[2], H Sanli[2], P Topcuoglu[1], H Akan[1], G Gurman[1], O Ilhan[1]

[1]Ankara University School of Medicine Department of Hematology, [2]Ankara University School of Medicine Department of Dermatology, Ankara, Turkey

Background: Primary cutaneous T-cell lymphomas (CTCL) are second most common extranodal non-Hodgkin lymphoma with an yearly incidence of 0.45 per 100,000 person. The treatment of mycosis fungoides (MF), the most frequent CTCL, is determined by disease extent, prognostic factors and patient characteristics. Extracorporeal Photopheresis (ECP) was approved by the US Food and Drug Administiration for the palliative treatment of MF since 1988.

Aims: The aim of this study is to analyze the clinical activity, toxicities, response and outcome rates of ECP; compare with combination therapies in the treatment of patients with MF.

Methods: We retrospectively included 50 MF patients who have diagnosed at our center. ECP was given empirically in cycles of 2 consecutive days in every 2 to 4 weeks at any time during their follow-up.

Table 1.

Patients (n=50)	
Median age, years (range)	55 (25-79)
Sex,n (M/F)	43/7
Stage at diagnosis, n (%) Stage 1-2 Stage 3-4	 17 (34%) 33 (66%)
Treatments prior to ECP, n (%) < 3 lines ≥ 3 lines	 25 (50%) 25 (50%)
Number of average ECP cycles, n (range)	39 (2-161)
Combination therapy with ECP, n (%)	36 (72%)

Results: The patient characteristics is shown in table. Treatments prior to ECP were; topical retinoids (bexarotene), topical corticosteroids, phototherapy (PUVA), Narrowband ultraviolet B light (NBUVB), Interferons, Metotrexate (MTX), CHOP (cyclophosphamide, daunorubicin, vincristine, prednisolone). ECP is combined with gemcitabine, PUVA, MTX, Bexaroten, IFN or Vorinostat up to patient characteristics. Overall response rate (ORR) was 42% (21/50)

with median time to response 11 months (range, 3-48 months). 15 of the responded patients (71%) were in stage III and IV at diagnosis. 10 of the responders (48%) had 3 or over treatment lines prior to ECP. 29 patient had not responded (58%) and 3 patients underwent (6%) allogeneic hematopoietic stem cell transplantation during follow-up. 8 patients (16%) had adverse events related with ECP; catheter related infection, headache, fever, shivering, nausea. Overall survival (OS) rate for 50 patients were 72 months (range, 3-211). The number of cycles in ECP responder patients were 32, and 44 for non-responders. Stage 3 and 4 patients had received average of 31 cycles compared to 55 cycles in stage 1 and 2 patients (P=0.006). The increased number of ECP is not correlated with the response (P=0.203). There were no statistically difference in OS in early stage *vs* late stage patients (77 *vs* 69 months, P=0.077). Time to response in early stage disease were 14 months and 8 months with late stage disease (P=0.267). Combined treatment with ECP statistically had improved OS (84 months *vs* 62 months, P=0.005).

Summary/Conclusions: The overall survival has improved in combined treatment with ECP patients. ECP may be a preferred treatment alternative due to low risk of adverse events. There is a conflicting data on treatment schedule and continuation. Prospective controlled clinical trials which are conducted on same ECP protocol and duration will better document the efficacy of this therapeutic modality.

E958

R-DA-EPOCH WITHOUT RADIOTHERAPY IN PRIMARY MEDIASTINAL LYMPHOMA PATIENTS RESULTS IN SIMILAR OUTCOME IN COMPARISON WITH A HISTORICAL COHORT TREATED WITH RADIOTHERAPY BASED REGIMENS

A Guidetti[1,2,*], L Devizzi[1], L Pappalettera[1], G Perrone[1], A Mussetti[1], N Cieri[1], L Pettine[1], L Farina[1], A Dodero[1], P Corradini[1,2]
[1]Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, [2]Hematology and Hemato-Oncology, University of Milano, Milano, Italy

Background: Historically, patients with Primary Mediastinal B Cell Lymphoma (PMBCL) have been treated with chemotherapy according to R-CHOP or R-VACOP-B regimen followed by radiotherapy with favorable outcome. Omission of radiotherapy in treatment of PMBCL represents a challenge due to the long-term toxicity observed in young people affected by this disease. Recently, Rituximab Dose Adjusted EPOCH (R-DA-EPOCH) regimen based on continuous drugs infusion not followed by radiotherapy demontrated to be an attractive alternative treatment for these patients.

Aims: We retropsectively compared the outcome of R-DA-EPOCH without radiotherapy with R-CHOP, R-VACOP-B or high dose sequential therapy followed by radiotherapy in newly diagnosed PMBCL patients treated at Istituto Nazionale dei Tumori in Milano from 2002.

Methods: Clinical, laboratory and imaging data of patients with PMBCL at diagnosis have been retrospectively collected and analyzed for clinical characteristics, response rate, progression free survival (PFS) and overall survival (OS).

Results: Overall, 67 newly diagnosed PMBCL patients have been treated between 2002 and 2016, 26 patients treated after September 2009 received 6 cycles of R-DA-EPOCH (R-DA-EPOCH group), whereas from 2002 to 2009, 31 patients received 6 cycles of R-CHOP (n=15), 12 weeks of R-VACOP-B (n=13) or high dose sequential therapy supplemented with rituximab (n=3), followed by radiotherapy (RT group). Ten patients treated without Rituximab were excluded from this analysis. Median age at diagnosis was 30 years in both groups (range, 18-61 and 21-55). With the exception of an higher proportion of stage III/IV patients in RT group (42% *vs* 11%) (p=0.01), other clinical characteristics were similar: extranodal disease in 11% and 35%, elevated LDH in 65% and 48% and presence of bulky disease (diameter >10 cm) in 77% and 68% of patients in R-DA-EPOCH and RT group respectively (p=ns). Eighteen patients (69%) completed R-DA-EPOCH without radiotherapy, 4 patients received radiotherapy because of residual disease at PET (Deauville Score 4), whereas 4 patients progressed. No patients relapsed after a median follow-up of 21 months (range, 3–79). In RT group, 24 patients (77%) completed the treatment with radiotherapy whereas 7 (22%) patients experienced disease progression before radiotherapy. Overall, 6 patients (19%) relapsed after a median of 7 months (range, 4-19). Eight out of 13 relapsed and refractory patients underwent autologous transplant and 5 of them are in complete remission. Median follow-up for RT patients was 73 months (range, 5-155). One patient developed a secondary malignancy 3 years after R-VACOP-B, whereas until today no secondary tumors have been observed among R-DA-EPOCH patients. 3-yrs OS and PFS for the whole population were 80% and 66%. In R-DA-EPOCH group 3-yrs PFS was 82% and in RT group was 57% (p=0.07); 3-yrs OS was 88% and 76% in R-DA-EPOCH and RT group, respectively (p=ns). 3-yrs PFS was 46%, 76% and 82% in R-CHOP, R-VACOP-B and R-DA-EPOCH (p=0.02), whereas 3-yrs OS was 62%, 92% and 88% in the three subgroups respectively (p=ns).

Summary/Conclusions: Omitting radiotherapy is feasible in patients treated with R-DA-EPOCH regimen. At the present, no significative differences in PFS and OS have been observed when R-DA-EPOCH patients are compared with a retrospective cohort treated with chemotherapy and radiotherapy. A longer follow-up of R-DA-EPOCH patients could assess significativity of the slighty advantage observed in term of PFS and will allow a proper assessment of long-term toxicity.

E959

COMPARISON OF BONE MARROW ASPIRATE FLOW CYTOMETRY AND TREPHINE IMMUNOHISTOCHEMISTRY IN STAGING OF PATIENTS WITH LYMPHOMA

G Shah[1,*], A Dunlop[1], R García-Consuegra[2], C Rea[3], D Cardosa[4], R Ireland[1], D Yallop[1], S Kassam[1]
[1]Haematology Department, King's College Hospital, London, [2]Haematology Department, Maidstone and Tunbridge Wells NHS Trust, Maidstone, [3]Haematology Department, Eastbourne District General Hospital, Eastbourne, [4]Haematology Department, Darent Valley Hospital, Dartford, United Kingdom

Background: Accurate staging of lymphoma is essential for guiding management and predicting outcome. Bone marrow biopsies are performed as part of routine staging for patients with lymphoma and immunohistochemistry on the trephine biopsy is considered the gold standard. Multiparameter Flow Cytometry (MFC) is increasingly sensitive at detecting small clonal B-cell populations and abnormal T-cell phenotypes on bone marrow aspirate samples but it is not clear that this adds additional clinically relevant information.

Aims: To compare results of MFC on bone marrow aspirates with immunohistochemistry on trephine biopsies for patients with T- and B-cell lymphomas to assess whether MFC is of additional clinical utility.

Methods: Results of lymphoma staging marrows received by the King's College Hospital Haematological Malignancy Diagnostic Centre between June 2014 and June 2015 were retrospectively reviewed. All aspirate samples had MFC performed using the following antibodies; CD19, CD5, CD4, CD8, CD2, CD20, CD23, CD10, CD79b, CD49d, CD38, FMC7, kappa and lambda.

Results: 117 patient samples were received. The lymphoma diagnoses included diffuse large B-cell lymphoma (DLBCL; n=63), follicular lymphoma (FL; n=29), primary central nervous system lymphoma (n=9), marginal zone lymphoma (n=6), high grade transformation of low grade lymphoma (n=4), mantle cell lymphoma (n=2), post-transplant lymphoproliferative disorder (n=2) and T-cell lymphoma (n=2). The concordance rate between trephine histology and MFC was 86.3% (n=101). Both were negative in 89 cases (76.1%) and positive in 12 cases (10.3%). Three cases (2.6%) were detected by MFC alone but not apparent on the trephine histology. The diagnoses in these cases included primary central nervous system lymphoma (3% CD5-/CD10- clonal B-cells; n=1), mantle cell lymphoma (2% clonal B-cells; n=1) and DLBCL (4% CD5-/CD10- clonal B-cells; n=1). In these three cases the clinical management was not altered by knowledge of the MFC results. Ten cases (8.5%) were histologically positive but negative by MFC. The diagnoses in these cases were FL (n=4), DLBCL (n=2), T-cell lymphoma (n=1) and FL transformed to DLBCL (n=3). There were three cases (2.6%) with suboptimal trephines. One of which was a case of DLBCL in which MFC was positive (5% CD5-/CD10- clonal B cells).

Summary/Conclusions: As reported in other series, the concordance between multiparameter flow cytometry and the trephine biopsy is high. Rarely, MFC can detect low-level bone marrow involvement not detected by immunohistochemistry. However, these results are unlikely to alter clinical management. In resource stretched health care systems, MFC on lymphoma staging marrows may not be justified.

E960

EVALUATION OF THE NEW PROGNOSTIC SCORE IN HIV RELATED NON HODGKIN LYMPHOMA. EXPERIENCE IN UNIVERSITY HOSPITAL SON ESPASES

S Ruiz[1,*], L Garcia[1], L Bento[1], MD Bea[2], F Serra[3], I Herráez[1], M Garcia[1], R Del Campo[3], J Bargay[3], A Sampol[1], A Gutierrez[1]
[1]Hematology, [2]Microbiology, Hospital Universitario Son Espases, [3]Hematology, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: The use of the International Prognostic Index (IPI) in aggressive lymphoma is widespread in the context of HIV infection. However recently it has been reported a new index tailored to patients infected with human immunodeficiency virus (HIV) which takes into account the characteristics of immunosuppression, viral load and evolutionary status of HIV infection: the AIDS-related lymphoma International Prognostic Index (ARL- IPI).

Aims: To evaluate this new index inside the Balearic Lymphoma Group in comparison with other prognostic scores used in aggressive lymphomas.

Methods: We identified all aggressive lymphomas diagnosed between 2002 and 2015 based on the records of the Service of Pathology contrasted with their HIV status. After that, the characteristics of their HIV infection (CD4 counts, viral load and AIDS-defining illness) with the main prognostic factors, treatment and evolution of the lymphoma were subsequently collected. Survival analysis was performed using Kaplan - Meier curves with the log -rank test.

Results: Table 1 shows main characteristics of the patients (n=50). Median age was 41 years, most with advanced disease (84% Ann Arbor (AA) stage III-IV) and poor prognosis factors: 70% a-IPI >1 and 71% TS>2. Seventy-two per-

cent of cases had a prior history of AIDS; while 46% had CD4 counts lower than 200 / microL and 54% VIH viral loads higher than 10000 copies/mL. ARL-IPI showed 26%, 42% and 26% of patients respectively in the low, intermediate and high risk subgroups. Overall response (p=0.002) and CR rates (p=0.012) were significantly different in these three risk subgroups: respectively low risk (92% and 77%), intermediate risk (74% and 65%) and high risk (31% and 23%). Median follow-up was 53 (0-167) months. PFS and OS at 4 years was 53% and 51%, respectively. Univaried survival analysis showed several factors significantly associated to worse PFS (ECOG PS>1, p=0.001; III-IV AA stage, p=0.018; a-IPI 2-3, p=0.01; R-IPI 1-2 or 3-5, p=0.029; TS>2, p=0.006; intermediate and high ARL, p=0.002 and lower CD4 count, p=0.019) and OS (ECOG PS>1, p<0.001; bulky disease, p=0.043; a-IPI 2-3, p=0.041; intermediate and high ARL-IPI, p=0.001 and lower CD4 count, p=0.001) (Image 1).

Table 1.

Sex (M/F)	45 (90%) / 5 (10%)
ECOG PS > 1	16 (32%)
B symptoms	29 (58%)
High LDH	32 (64%)
High Beta-2-microglobuline	40 (91%)
> 1 extranodal site	12 (24%)
Bulky disease	5 (10%)
Diagnosis:	
- DLBCL	31 (62%)
- Plasmablastic lymphoma	10 (20%)
- Burkitt lymphoma	7 (14%)
- Peripheral T-cell lymphoma	2 (4%)
a-IPI:	
- 0-1	15 (30%)
- 2-3	35 (70%)
R-IPI:	
- Low risk (0)	4 (8%)
- Intemediate risk (1-2)	32 (64%)
- High risk (3-5)	14 (28%)
LRS-IPI:	
- Low risk	13 (26%)
- Intermediate risk	24 (48%)
- High risk	13 (26%)
CD4 count:	
- <50	5 (10%)
- 50-199	18 (36%)
- 200-499	12 (24%)
- >500	15 (30%)

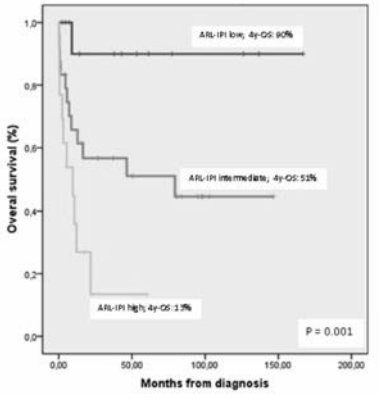

Figure 1.

Summary/Conclusions: In our study ARL-IPI showed a very good definition of prognostic groups in terms of response and survival. Interestingly, ARL-IPI identifies a high risk subgroup with a very poor prognosis. Our results validate the usefulness of this new prognostic index in the HIV population with aggressive lymphoma.

E961

SERUM IL-10 LEVEL PREDICTS POOR PROGNOSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA: RESULTS OF A SINGLE CENTER COHORT STUDY

SJ Kim[1,*], JS Ham[2], KJ Ryu[3], YH Ko[4], WS Kim[1], SH Kim[5]
[1]Medicine, [2]Samsung Medical Center, [3]Samsung Biomedical Research Institute, [4]Pathology, [5]Laboratory Medicine, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Angioimmunoblastic T-cell lymphoma (AITL) is derived from T-follicular helper cell, and tumor cells are often outnumbered by admixed reactive inflammatory cells. Accordingly, the secretion of various cytokines and their interaction with tumor microenvironment has been more studied compared to other subtypes of PTCL. Interleukin-10 (IL-10) is one of T-helper cell-associated cytokine and promotes M2 macrophage inhibiting the anti-tumor action of non-neoplastic T-cells. Thus, serum IL-10 level might be associated with treatment outcome of AITL patients.

Aims: The primary objective is to evaluate whether serum IL-10 level at diagnosis could predict survival outcome of AITL patients. The secondary objectives are the comparison of serum cytokine profiles according to subtypes of PTCL and their interaction with clinical and laboratory features.

Methods: Patients were from two prospective cohort studies of our institution: the first study (NCT#00822731) and the second study (NCT#01877109). Patients were diagnosed with AITL, peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS), ALK-negative and positive anaplastic large cell lymphoma (ALCL) between September 2008 and December 2014 according to the pathology criteria of the World Health Organization. Serum samples at diagnosis after we obtained written informed consent were collected and stored at -80°C until analysis. Procarta cytokine profiling kit (Panomics, CA, USA) with Bio-Plex Cytokine Assay System (Bio-Rad Laboratories, Herucules, CA, USA) was used to measure different cytokines, including IL-2, IL-4, IL-5, IL-10, IL-12, IL-13, and interferon-γ. Survival status and disease status were updated in February, 2016.

Results: A total of 97 patients were analyzed: AITL (n=37), PTCL-NOS (n=40), ALK-negative ALCL (n=11), and ALK-positive ALCL (n=9). All patients were treated with CHOP (cyclophosphamide, doxorubicin, vincristine and prednisone) or CHOP-like regimens after diagnosis. The response to the first-line treatment was as follows: complete response (n=64), partial response (n=11), and progressive disease (n=22). With the median follow-up of 42 months, 58 patients experienced relapse, progression, or any kinds of death, and 44 patients died. The 3-year overall survival of AITL patients (66%) was superior to that of PTCL-NOS (43%) and inferior to ALK-positive ALCL (75%) in consistent with previous reports. Among measured cytokines, serum levels of IL-10 and IL-12 were significantly higher in AITL patients than other subtypes (P<0.05), and other cytokines did not show any significant association with subtypes. The cutoff for serum IL-10 and IL-12 was determined by the ROC curve, and high serum IL-10 (>1.845 pg/mL) was significantly associated with poor overall survival (P=0.012, figure). All patients with high serum IL-10 showed disease progression after CHOP chemotherapy. This association was only found in AITL patients not other subtypes. In addition, other cytokines including IL-4,5, and 12 did not show a significant association with survival outcomes in AITL patients as well as other subtypes.

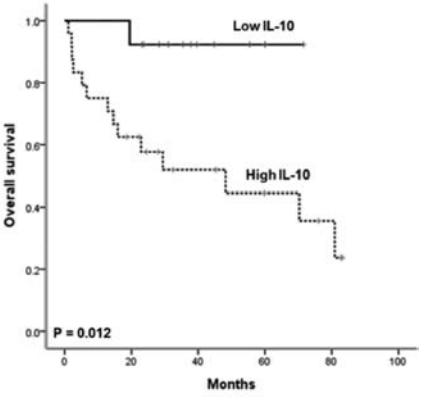

Figure 1.

Summary/Conclusions: Serum IL-10 level at diagnosis might be a useful biomarker for predicting survival outcome in patients with AITL. Our findings should be confirmed by a future study with larger population.

E962

REDUCED RCHOP FOR ELDERLY PATIENTS WITH DLBCL

L Vidal[1,*], S Lando[1], I Vaxman[1], P Raanani[1], R Gurion[1], A Gafter-Gvili[2]
[1]Davidoff Cancer Center, Hematology, [2]Internal Medicine A, Rabin Medical Center, Petah Tikva, Israel

Background: RCHOP regimen is considered the standard of care for patients with diffuse large B-cell lymphoma (DLBCL). Elderly patients often have comorbidities, worse performance status, less hematologic reserve and are more prone to changes in pharmacokinetics, which lead to higher rates of toxicity. Therefore it was suggested that elderly patients should be treated with reduced intensity RCHOP regimen. Very few studies examined regimens of reduced intensity RCHOP.

Aims: To evaluate the effect of dose reduction of RCHOP on survival, disease control and toxicity in patients 70 years or older with DLBCL.

Methods: We performed a retrospective cohort study including patients with DLBCL treated with RCHOP at the Rabin Medical Center between the years 2004-2014. We excluded patients with transformation or CNS involvement. We collected age, sex, performance status (PS), B symptoms, bone marrow involvement, number of extranodal involvement sites, Ann Arbor stage, international prognostic index (IPI), bulky disease, Charlson comorbidity index (Charlson), hemoglobin (Hb), LDH, neutrophil, lymphocyte, monocyte, and

platelet count, creatinine, albumin, CRP, cardiac ejection function, RCHOP dose (for each drug separately) and treatment date, response, and survival. We defined full, standard dose (SD) as 90% and above of standard adriamycin dose, and reduced dose (RD) as less than 90% in the first cycle. OS was compared using Kaplan-Meier survival analysis. Variables potentially associated with mortality were entered into a Cox regression multivariate analysis.
Results: 140 patients were eligible. Median dose reduction was by 88%. Median age was 80 years in the RD group, and 76 years in SD group (p<0.001). Patients in the RD group were older, had a worse PS, and a higher IPI and Ki67, and lower albumin, Hb, and lymphocyte count. There were no differences between the groups regarding sex, B symptoms, bone marrow involvement, number of extranodal involvement sites, stage, bulky disease, Charlson, LDH, neutrophil, monocyte, and platelet count, creatinine, and CRP. 3% of patients had cardiac ejection function<45%. Patients treated with RD RCHOP had statistically significant lower risk of achieving complete response (CR) (HR for in a univariate model of OS RD group (HR 2.53, 95% CI 1.57-4.07, p=0.0001), older age, advanced stage, more than 1 extranodal site involvement, performance status more than 1, higher IPI, lower albumin and Hb levels had negative prognostic effect on survival. In multivariate model 1 including age, sex, Charlson, and Hb the negative effect of RD treatment remained statistically significant compared to SD (HR 1.93, 95% CI 1.18-3.15, p=0.01) as well as age and Hb. In model 2 including treatment group, age, sex, PS, IPI, LDH, and albumin there was a trend towards worse survival with RD RCHOP compared to SD (HR 1.64, 95% CI 0.96-2.82, p=0.069). Age, sex, IPI, and albumin remained prognostic in this model. There was no statistically difference in the rate of any infection between the groups (p=0.623). Patients treated with RD RCHOP were hospitalized more than patients treated with SD RCHOP (median 4 *vs* 1 day, respectively).
Summary/Conclusions: Based on retrospective data, dose reduction of adriamycin in the first cycle of R-CHOP may reduce the chance to achieve CR and impair OS. This should be further evaluated in randomized trials. We will further explore the effect of dose intensity and density in all cycles of RCHOP on PFS and OS.

E963

A PREDICTIVE SCORE FOR CNS DISSEMINATION AND ITS EFFECT ON CNS PROPHYLAXIS IN A MONO-INSTITUTIONAL SERIES OF 242 PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) TREATED IN THE RITUXIMAB ERA

AJ Ferreri[1,*], T Calimeri[1], C Cecchetti[1], A Vignati[1], M Foppoli[1], L Scarfò[1], M Sassone[1], M Ponzoni[2], F Caligaris-Cappio[1]
[1]Department of OncoHematology, [2]Pathology Unit, San Raffaele Scientific Institute, Milan, Italy

Background: CNS dissemination is a lethal event in DLBCL. Early detection and effective CNS prophylaxis may reduce related mortality. However, risk predictors reported in the rituximab era exhibits a low diagnostic sensitivity and the most effective prophylaxis remains to be defined.
Aims: We analysed these two unmet clinical needs in a retrospective series of 242 pts with DLBCL treated in the rituximab era.
Methods: Consecutive HIV-neg adults with DLBCL without CNS involvement treated with R-CHOP or similar were considered. CNS, mediastinal and leg-type DLBCL, high-grade transformed lymphomas and pts registered in prospective trials were excluded. Following institutional guidelines, no DLBCL pt diagnosed before 2007 received CNS prophylaxis; after 2007, CNS prophylaxis, consisting of 3-4 cycles of methotrexate 3 g/m^2±intrathecal liposomal cytarabine (IT) was indicated in pts with high CNS recurrence risk. IT was delivered one dose per R-CHOP course, and methotrexate was delivered after R-CHOP treatment. CNS dissemination risk was defined by involvement of the testis, kidney/adrenal, spine, skull, paranasal sinuses, orbit, and/or breast or by the simultaneous presence of advanced stage and high serum LDH. In the present study, CNS dissemination risk was defined as low in pts without involvement of high-risk extranodal organs and with an International Prognostic Index (IPI) of 0-3; intermediate in pts without involvement of high-risk extranodal organs and with an IPI of 4-5; and high in pts with involvement of above-mentioned high-risk extranodal organs and with any IPI.
Results: 242 pts were analysed (median age 66, range 18-89). According to the proposed model, CNS dissemination risk was low in 148 (61%) pts, intermediate in 29 (12%) and high in 65 (27%). Pts with low and intermediate risk were managed without prophylaxis, whereas this strategy was indicated in 45 high-risk pts: 35 pts received intravenous±IT chemotherapy, 10 pts receive only IT chemotherapy due to MTHFR polymorphisms, comorbidity or old age. CNS prophylaxis was well tolerated; unexpected toxicity and interruptions due to toxicity were not recorded. At a median follow-up of 51 months (12-171), 11 (4.5%) pts experienced CNS relapse: in the brain parenchyma in 6 cases, in the meninges in the others. CNS relapse rate was<1% (1/148) in low-risk pts, 10% (3/29) in intermediate-risk, and 11% (7/65) in high-risk pts. Eight of these pts died of CNS progressive lymphoma after 7-37 months (median 12). In the high-risk subgroup, CNS relapse rate was 25% (5/20) in pts who did not receive CNS prophylaxis, 20% (2/10) in pts treated IT chemotherapy alone and 0% (0/35) in pts who received intravenous±IT chemotherapy (p=0.004). Overall, 18 high-risk pts experienced relapse, and CNS was the most commonly involved site (7/18). Moreover, the addition of intravenous CNS prophylaxis was associated with a significantly improved PFS (3-yr: 80% *vs* 42%; p=0.001) and OS (3-yr: 86% *vs* 43%; p=0.00007).
Summary/Conclusions: With all the limitations of a retrospective series, this study suggest that pts with DLBCL and involvement of certain extranodal organs and/or high IPI should receive CNS prophylaxis with intravenous high-dose methotrexate and IT liposomal cytarabine. This strategy shows a relevant effect on survival of high-risk pts as CNS is a common relapse site, associated with a high mortality.

A PHASE I STUDY IN T CELL LYMPHOMA PATIENTS TREATED WITH ANTI-CD70 SIMPLE ANTIBODY™ ARGX-110

JM Michot[1,*], M Maerevoet[2], P Aftimos[2], S Rottey[3], C Rolfo[4], F Offner[3], L Van Rompaey[5], M Moshir[5], H de Haard[5], K Silence[5], M Bagot[6], P Pauwels[7], K Zwaenepoel[7], A Awada[2], D Bron[2], V Ribrag[1]
[1]Hematology, Gustave Roussy Institute, Villejuif, France, [2]Hematology, Jules Bordet Institut, Bruxelles, [3]Hematology, Ghent University Hospital, Ghent, Belgium, [4]Hematology, Universitair Ziekenhuis Antwerpen, Antwerpen, Bahrain, [5]arGEN-X BVBA, Ghent, Belgium, [6]Dermatology, Saint Louis APHP, Paris, France, [7]Hematology, Universitair Ziekenhuis Antwerpen, Antwerpen, Belgium

Background: CD70 is a cell surface marker transiently expressed on activated B, T cells and dendritic cells. The interaction via its receptor CD27 results in survival, proliferation and lymphocyte differentiation. In a large number of solid tumours types, CD70 is overexpressed but without receptor co-expression. As overexpression of CD70 is paralleled by high expression of its receptor CD27 in TCL, the CD70/CD27 axis appears critical for proliferation and survival of malignant cells in T-cell lymphoma.
Aims: ARGX-110 is a novel glycoengineered monoclonal antibody targeting CD70 and blocking CD27 signaling, leading to a direct mode of action lysing CD70$^+$ tumor cells (via CDC, ADCP and enhanced ADCC) and indirect anti-tumor restoring immune surveillance.
Methods: (NCT01813539) A phase I trial was initiated with ARGX-110, dose escalated to investigate safety, clinical pharmacology and determine the RP2D, in refractory or relapsed solid tumors and hematological malignancies on patients with CD70+tumors (defined by IHC >10%+). ARGX-110 was given to 65 patients at doses from 0.1 to 10 mg/kg intravenously every 3W.
Results: *Preclinical data:* Immunohistochemistry on TCL patient samples confirmed overexpression of CD70 (>10% CD70+ tumor cells) in 40/73 PTCL (55%) and 15/21 CTCL (71%) samples. Serum soluble CD27 levels were elevated in TCL patients compared to healthy subjects (670±1096 *vs* 192±44 IU/ml, respectively, p= 0.0062). *Phase 1 heme results:* Nine patients received ARGX-110 for a TCL. Histological TCL types were 3 Cutaneous TCL (CTCL) and 6 Peripheral TCL (PTCL). ARGX-110 was well tolerated with no grade >3 adverse events related to the study drug. A clinical and/or biological response was observed in 4/9 of T-cell Lymphoma patients; CTCL (n=3) and PTCL-AITL (n=1) patients. Response consisted in 2 patients with CTCL Sezary syndrome (treated at 0.1 and 10 mg/kg, respectively) in a >90% reduction in the circulating malignant clone, with a clinical partial response in the skin in one patient. The other patient with CTCL T_{FH} lymphoma (treated at 5 mg/kg) achieved a PR. One patient with PTCL with Angioimmunoblastic T-cell Lymphoma (AITL) reached a PR (5 mg/kg dose) and had a resolution of lymphoma associated auto-immune hemolytic anemia.
Summary/Conclusions: In the TCL patients treated with ARGX-110, a signal of clinical and/or biological anti-tumor activity was observed. These preliminary results support further investigation of ARGX-110 in TCL.

E965

DOUBLE PROTEIN LYMPHOMA PATIENTS OF THE NON-GCB SUBTYPE HAVE AN INFERIOR PROGNOSIS WHEN TREATED WITH CHEMOIMMUNOTHERAPY

K Troppan[1,*], C Beham[2], H Greinix[1], A Deutsch[3], P Neumeister[1]
[1]Hematology, Internal Medicine, [2]Pathology, [3]Internal Medicine, Graz, Austria

Background: Diffuse large B-cell lymphoma (DLBCL) can be stratified by cell of origin (COO) derivation into the prognostically favorable germinal center B-cell (GCB)–like and unfavorable activated B-cell (ABC) or non-GCB-like subtype based on gene expression signatures or immunohistochemical determination. Double-hit lymphoma (DHL) were identified as a subgroup of aggressive lymphomas with both MYC and BCL2 gene rearrangements, characterised by a rapidly progressing clinical course and short survival. Recently, DLBCL patients with an immunohistochemical coexpression of MYC and BCL2 also demonstrated inferior prognosis suggesting that concurrent expression of MYC/BCL2, termed double-protein-expression lymphoma (DPL), rather than cell-of-origin classification, is a better predictor of prognosis in patients treated with R-CHOP.
Aims: We determined the frequency of DPL in a large single center cohort of DLBCL uniformely treated with R-CHOP and evaluated patients' outcome in contrast to "standard" DLBCL not exhibiting concurrent expression of MYC/BCL2.

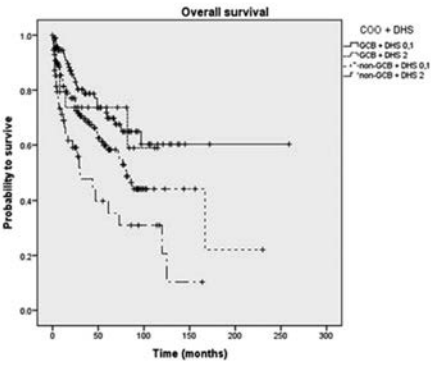

Figure 1.

Methods: We evaluated retrospectively the appearance of DPL in 440 patients with DLBCL, consecutively diagnosed and treated between 2004 and 2014 at our institution. To determine the double-hit score, immunohistochemistry for c-MYC and BCL2 was performed on diagnostic samples. Furthermore, the Choi algorithm was used to subclassify samples by cell-of-origin. On the basis of immunohistochemical MYC and BCL2 expression, a double-hit score (DHS) was assigned to all patients with DLBCL. The DHS-2 group was defined by high expression of both MYC and BCL2 protein.
Results: A GCB subtype was found in 162 patients, whereas 223 samples were classified as non-GCB subtype. For 55 patients, no classification according to cell-of-origin could be performed. Of 440 DLBCL, 289 patients were evaluable, 58 of them showed a double-hit score of 0, 168 patients had a DHS of 1, and 63 a DHS of 2, respectively. Twenty-one of 76 patients with a DHS of 2 could be classified as GCB, whereas 42 patients exhibited a non-GCB subtype. Using Kaplan-Meier curves and log-rank tests, we could demonstrate a significant inferior outcome for DLBCL patients with the non-GCB subtype as compared to the GCB subtype (, p<0.001). Further, DPL patients had also a shorter overall survival (OS) (p=0.05). Combining the cell-of-origin classification with the DHS, we were able to further discriminate a subgroup of patients with an even worse clinical outcome to standard treatment (median OS 81 *vs* 44 months, p<0.001) (Figure 1).
Summary/Conclusions: In this large single center cohort, we could demonstrate a significant negative effect on OS for DLBCL patients coexpressing MYC and BCL2. We could further define a particular subgroup of patients within the non-GCB cohort demonstrating double hit positivity (DHS of 2) that is associated with a particular short survival. These non-GCB-, DHS positive DLBCL patients are candidates for novel therapeutic strategies.

E966

A CLINICO-PATHOLOGIC AND IMMUNOHISTOCHEMICAL ANALYSIS OF ORAL AND EXTRA-ORAL PLASMABLASTIC LYMPHOMA IN SOUTH AFRICA

S Meer[1,*], Y Perner[2], P Willem[3]
[1]Faculty of Health Sciences, Department of Oral Pathology, [2]Faculty of Health Sciences, Department of Anatomical Pathology, [3]Faculty of Health Sciences, Department of Hematology and Molecular Medicine, University of the Witwatersrand, Johannesburg, South Africa

Background: Plasmablastic lymphomas (PBLs) are a group of aggressive non-Hodgkin lymphomas originally described to be exclusive to the oral cavity in patients with immunodeficiency. This group of uncommon lymphomas, which shows morphologic, phenotypic and molecular features of terminally differentiated B-cells is increasingly being described in many extra-oral sites as well, in both HIV and non-HIV infected patients. Data relating to age, gender, HIV status and immunophenotypic profile have been published in case reports, case series and systemic reviews. To date there are no data on extra-oral PBLs in South Africa where HIV is higly endemic. We present a series of 101 oral (55) and extra-oral (45) PBLs which forms the largest global series described to date in a region of Africa where HIV is endemic.
Aims: To characterize the clinical, morphological and immunological features of oral and extra-oral plasmablastic lymphomas in a defined South African population.
Methods: This is a retrospective study on archival cases of extra-oral and oral PBLs diagnosed over the period 2006 to 2015 in the Department of Anatomical Pathology, University of the Witwatersrand, Johannesburg, South Africa. Clinical parameters analyzed included patients age, gender, HIV status and site of tumor presentation. Each case was reviewed histologically to confirm the diagnosis and assessed immunohistochemically with CD45 (LCA), CD20, CD79a, PAX5, CD138, MUM1, BLIMP1, VS38c, Ki-67, BCL6, CD10, and HHV8 using standard immunohistochemistry protocols. The presence of EBV-encoded early nuclear RNAs (EBER1 and EBER2) was assessed by chromogenic *in-situ* hybridization. Ethical clearance was obtained from the University of the Witwatersrand human research ethics committee.
Results: Forty-six patients were diagnosed with extra-oral PBLs and 55 patients with oral PBLs. These included all adult patients, except for one case of a nine-year old child. The age ranged from 9 to 59 years (mean:35.5; median:35) for extra-oral cases and 22 to 78 years for oral PBLs (mean:41.1; median:41). Of the 18 and 34 patients with extra-oral and oral PBLS with known HIV status, 17 (95%) and 33 (97%) patients respectively were infected with HIV. None of the patients had systemic disease at presentation. The overall male:female ratio was 1.9:1 (67 males and 34 females), with 66% of PBLs occurring in males. The male:female ratio for extra-oral and oral PBLs was 1.4:1 (27 males (59%) and 19 females) and 2.7:1 (40 (73%) males and 15 females) respectively. The anus was the favoured extra-oral site of presentation (13 of 46 cases, 28%), followed by soft tissue (11 of 46 cases, 24%). The favoured oral site for PBL was the maxilla (16 of 55 cases, 29%) followed by the palate (11 of 55 cases; 20%). The histomorphology in both oral and extra-oral PBLs was similar showing both plasmablastic and plasmacytic features. The immunohistochemical profile of all PBLs in the study recapitulated that found for both oral and extra-oral PBL in the literature, except for CD45 (leucocyte common antigen), which signalled positively in a higher percentage of cases. Overall 73 of 80 cases (91%) were positive for CD45; 36 of 42 extra-oral cases (85.7%) and 37 of 38 oral cases (97%). The positive membrane signal for CD45 was of variable intensity, between 5 and 100% of tumor cells. EBV was positive by *in-situ* hybridization in 71 of 74 cases (96%), *i.e.* in 37 of 40 (93%) extra-oral cases and all 34 oral PBLs (100%).
Summary/Conclusions: Extra-oral PBL was identical to its oral counterpart in gender and age distribution, HIV status, morphological appearances, immunophenotypic profile and association with EBV. The high association with EBV as assessed by *in-situ* hybridization studies mirrors that of extra-oral and oral PBLs reported in the literature. A peculiarity observed within this case cohort was the high level of expression of CD45. This has been reported to be of low or near absent in most cases of PBL, as defined by the WHO 2008 and recorded in the literature. Although the HIV status was only known for approximately half of these cases, HIV associated PBL manifested as a single disease in both oral and extra-oral forms, and should be regarded as the same tumor.

E967

A NGS IGK ASSAY FOR THE DETECTION OF CLONALITY AND THE MONITORING OF MINIMAL RESIDUAL DISEASE

Z Xie[1,*], K Hutt[1], J Panganiban[1], W Huang[1], S Zheng[1], D Duong[1], A Jacobsen[1], G Pawlowsky[2], J Thorne[1], M Arcila[3], J Miller[1], T Stenzel[1]
[1]Invivoscribe, San Diego, United States, [2]LabPMM, Martinseried, Germany, [3]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: During B-cell development, functional immunoglobulin genes are assembled from individual V, D, and J gene segments to generate V-D-J combinations of length and sequence that are unique for each cell. Rearrangements within *IGH* occur first, followed by *IGK*. In addition to V-D-J rearrangement, the *IGK* Kde locus can rearrange to Vk gene and to an isolated RSS in the Jk-Ck intron (INTR). Leukemia and lymphomas originating from the malignant transformation of individual lymphoid cells generally share one or more of these cell specific or “clonal” gene rearrangements. Assays that identify clonal lymphocyte populations in clinical specimens are used on a routine basis to assist in the diagnosis of lymphoproliferative disease. The clinical relevance of minimal residual disease (MRD) detection in lymphoproliferative disease has been demonstrated by many studies. However, allele-specific primers are required for the qPCR-based MRD monitoring. The emergence of cost-effective, next-generation sequencing (NGS) platforms and development with associated bioinformatics tools have resulted in powerful new approaches for clonality detection and MRD monitoring without the requirement of allele-specific designs.
Aims: To establish an *IGK* NGS assay that, combined with an *IGH* NGS assay, will increase the chance of identifying clonal populations and provide easy tracking of identified clonal population for MRD in lymphoid malignancies.
Methods: Genomic DNA from cell line, peripheral blood, bone marrow aspirates, and FFPE were tested for *IGK* rearrangements using the LymphoTrack® *IGK* MiSeq® Assay (Invivoscribe Inc., San Diego, USA). The *IGK* libraries were run individually or in combination with *IGH* and or *TRG* libraries. The sequencing data was analyzed using LymphoTrack® bioinformatics software, which performs the separation of *IGK*, *IGH*, and *TRG* data as necessary, and generates frequency distributions and identifies the rearranged DNA sequences for each target. Total of 198 peripheral blood samples were also tested by the capillary electrophoresis (CE) based IdentiClone® *IGK* assay.
Results: Data generated with the *IGK* NGS assay and bioinformatics software identified clonality and corresponding DNA sequences of *IGK* Vk-Jk, Vk-Kde, and INTR-Kde gene rearrangements. Excellent linearity of the *IGK* NGS assay was obtained from contrived cell line DNA in the range of 2.5-20% when running individually (R^2=0.9897) or in combination with *IGH* and *TRG* assays (R^2=0.9905). The concordance between the 198 samples tested by *IGK* NGS and CE assays was 77%. There were 43 samples indentified to be clonal out of 198 samples tested by both *IGK* and *IGH* NGS assays. Among those samples, 31 and 25 samples were clonal for *IGK* and *IGH*, respectively, and 18 samples were clonal for both *IGK* and *IGH*. It was demonstrated that the NGS

assay allows for easy tracking of clonal populations at the sensitivity of 10^{-4} or at even lower limits of dectection, provided sufficient amount of DNA is tested.
Summary/Conclusions: A comprehensive assay has been developed for the MiSeq® platform that identifies clonal *IGK* rearrangements and the associated specific DNA sequences. The *IGK* assay, in combination with the *IGH* assay, increased the detection of clonality by 72% comparing to *IGH* alone. The assay can be used both to detect clonality and monitor the identified clonal populations in MRD.

E968

DE NOVO TRANSFORMED FOLICULAR LYMPHOMA. OUTCOMES AND ROLE OF AUTOLOGOUS STEM CELL TRANSPLANTATION

M Alcoceba*, S Alonso, L Magnano, M García-Álvarez, M Andrade, G Rodríguez, S Mercadal, JM Sancho, A Salar, R Arranz, MJ Terol, A Rodríguez, S González de Villambrosia, L López, S Monsalvo, S Novelli, E de Cabo, MS Infante, E Pardal, M Canales, M González, A Martín, A López-Guillermo, MD Caballero
Hematologia, Spanish Group of Lymphoma and Autologous Stem Cell Transplantation (GELTAMO), Spain

Background: The role of histologic transformation (HT) on survival of follicular lymphoma (FL) in the rituximab era has been recently analyzed in several studies. However, there is no information about the outcome of patients with simultaneous presence of FL and diffuse large B cell lymphoma (DLBCL) in the same initial diagnostic biopsy (*de novo* transformed FL; dn-tFL).
Aims: We examined clinical characteristics, survival following transformation (SFT) and impact of intensive regimens (including ASCT) in a group of patients diagnosed of dn-tFL, and compared them with a group of FL patients who developed HT (tFL).
Methods: We recruited 1809 patient candidates from a retrospective series in 18 centres from the Spanish Group of Lymphoma and Autologous Stem Cell Transplantation (GELTAMO). Of them, 75 patients were diagnosed of dn-tFL, and the other 1734 of FL grade 1-3a, from which 106 developed HT. Treatment at HT consisted in rituximab containing regimens.
Results: Clinical variables were not significantly different between tFL and dn-tFL. 5-year SFT was significantly higher in dn-tFL as compared to tFL patients (75% *vs.* 25%, p<0.0001; Figure 1A). Variables influencing 5-year SFT in dn-tFL were complete response (CR) to front line therapy (90% *vs.* 41%, p<0.001; Figure 1B), and low-risk FLIPI score (100% *vs* 58%, p=0.018). In the multivariate analysis, only CR to front line therapy (HR 6.5, 95% CI: 2.0-20.7) had an independent influence on 5-year SFT. In the conventional tFL comparison cohort, achievement of CR (47% *vs* 5%, p<0.001; Figure 1B), but not low-risk FLIPI (40% *vs.* 27%, p=0.2) influenced 5-year SFT. A total of 19 dn-tFL patients did not achieve CR to first-line therapy, and received salvage therapy, which was followed by ASCT as consolidation therapy only in 4 cases. 5-year SFT in the ASCT group was higher (67% *vs.* 42%, p=0.07). However, these groups were not comparable since patients receiving ASCT were significantly younger than those not receiving ASCT (median 54 years *vs.* 71 years, p=0.031).

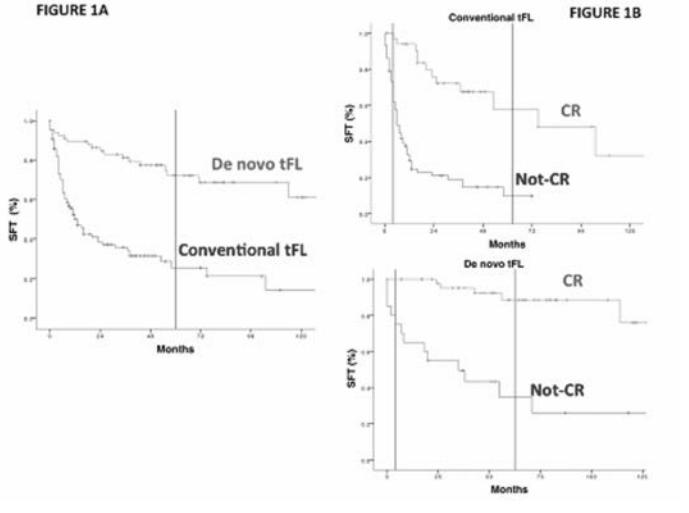

Figure 1.

Summary/Conclusions: De novo tFL patients have better SFT than patients that develop HT after FL diagnosis. Although differences are evident in terms of general SFT, both groups are characterized by a decisive influence of therapy response in SFT. Interestingly, although FLIPI score is not the standard index to evaluate aggressive lymphoma, it accurately stratified composite FL+DLBCL and not the conventional tFL. In our series, ASCT shows a potential benefit as a rescue therapy in those dn-tFL patients not responding to first-line treatment.

E969

LOW EXPRESSION OF MIR-155 IN VINCRISTINE RESISTANT DIFFUSE LARGE B-CELL LYMPHOMA

H Due[1,2,*], A Amanda Schönherz[1], L Bechmann Krogh[3], J Støve Bødker[1], A Schmitz[1], R Froberg Brøndum[1], H Erik Johnsen[1], M Bøgsted[1], J Giehm Mikkelsen[3], A Stidsholt Roug[4], K Dybkær[1]
[1]Department of Hematology, Aalborg University Hospital, Denmark, Aalborg, [2]Clinical Medicine, Aarhus University, [3]Department of Biomedicine, Aarhus University, [4]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: Vincristine is a key chemotherapeutic drug of first line therapy R-CHOP in Diffuse Large B-cell Lymphoma (DLBCL). The clinical course for DLBCL patients has great variability and an unfavorable outcome is observed in more than 40% of cases due to intrinsic or acquired treatment resistance. Accordingly, identification of molecular resistance mechanisms and early prediction of drug specific resistance is an urgent clinical need.
Aims: This study investigates the potential of miRNAs as predictive biomarkers of vincristine resistance and the involvement of miRNAs in the resistance mechanisms.
Methods: Systematic vincristine dose-response screen was performed on 12 DLBCL cell lines to identify 50% growth inhibition dose (GI_{50}) for the individual cell lines. Ranking of GI_{50} allowed trichotomisation into groups of drug specific sensitive (n=3), intermediate (n=6), or resistant (n=3) cell lines. Based on global miRNA expression profiles of each cell line in untreated condition, class comparison was performed and 13 differentially expressed miRNAs were identified between sensitive and resistant cell lines (fold-change>|2|, p-value<0.05). Especially, miR-155 showed significant association between low expression and increased vincristine resistance having 33.5 fold decreased expression in resistant cell lines (p=0.0005). Based on gene expression profiles, 66 DLBCL patients biopsied at time of diagnosis were classified into the prognostic molecular subclasses ABC/GCB and B-cell associated gene signatures (BAGS), reflecting naturally occurring B-cell subsets of naïve, centroblast, centrocyte, memory, and plasmablast cells as cell of origin. Additionally, resistance gene signature (REGS) for vincristine was assigned to the clinical samples giving each case a likelihood of predicted response to vincristine. Expression levels of miR-155 were determined in the DLBCL samples by RT-qPCR.
Results: A significantly higher expression of miR-155 was observed in the prognostic adverse ABC subclass compared to GCB (n=66, p-value=0.0373) indicating miR-155 as an unfavorable marker. However, using BAGS classification clinical samples assigned into the prognostic favorable centrocyte subclass had higher miR-155 expression compared to the prognostic adverse centroblast subclass (n=59, p-value=0.003). Observations further supported when BAGS classification was stratified into ABC and GCB subclasses. Within the GCB subclass centrocyte DLBCL cases had significantly higher miR-155 expression compared to centroblast cases (n=27, p=0.0223). Within the ABC subclass no difference between the BAGS subclasses was detectable. Thus, using the prognostic BAGS classification system within the GCB subclass low miR-155 expression is an unfavorable marker. REGS stratification of clinical samples did not show significant miR-155 expression differences between REGS classes. However, assigning REGS to ABC and GCB subclasses, separately, a significant difference between low miR-155 expression and vincristine resistance was observed within the GCB subclass (n=27, p-value=0.051) but not within the ABC subclass (n=26, p-value=0.99). This supports the *in vitro* observations of low miR-155 expression and vincristine resistance within the GCB subclass.
Summary/Conclusions: In conclusion, we observed different miR-155 expression patterns between ABC and GCB subclasses. Moreover, a significant association between low miR-155 expression and vincristine resistance was demonstrated within GCB assigned cases. To unravel the biological mechanism determining miR-155 impact on vincristine resistance functional studies including expression manipulation in DLBCL cells with lentiviral vector system are ongoing.

E970

RITUXIMAB AND HIGH DOSE CYTARABINE WITH AUTOLOGOUS TRANSPLANTATION FOR MANTLE CELL LYMPHOMA

S Burrows[1,*], D Tucker[1], G Naylor[2], K Wardrope[3], S Bolam[4], P McKay[3], A Forbes[2], S Rule[1]
[1]Haematology, Derriford Hospital, Plymouth Hospitals Trust, Plymouth, [2]Haematology, Royal Cornwall Hospital, Truro, [3]Haematology, Gartnavel General Hospital, Glasgow, [4]Haematology, Musgrove Park Hospital, Taunton, United Kingdom

Background: Mantle cell lymphoma (MCL) is an aggressive and incurable form of non-Hodgkin lymphoma (NHL), typically presenting at a late stage, often with extra nodal involvement, and with a preponderance for older males. Front-line therapy incorporating rituximab and high-dose cytarabine (R-HDAC), often in combination with other drugs or alternating with another regimen, followed by autograft in first response is standard of care for younger, fitter patients. Reported overall response rates (ORR) and progression free survival (PFS) are typically 70-90% and 50-60% respectively.

Aims: To explore the tolerability and efficacy of rituximab and single-agent R-HDAC prior to autologous stem-cell transplant in patients with untreated MCL.
Methods: We studied 45 unselected, transplant eligible patients with MCL treated upfront with R-HDAC alone across four UK centres between February 2010 and August 2015. The median age was 60, the majority were male (84%), and the majority had advanced disease (91% Stage III/IV). None had central nervous system (CNS) involvement at presentation. All patients received at least one cycle of R-HDAC. The median number of cycles of R-HDAC given was 5, and 89% received at least three cycles. Only two patients stopped R-HDAC therapy early due to toxicity; one due to PJP pneumonia after the first cycle who was stepped down to Bendamustine based treatment, and one due to severe sepsis after the second cycle who stopped therapy at this point having already achieved a partial response. One further patient completed five cycles of R-HDAC but was felt unfit for autograft at that point.
Results: Nine patients (20%) progressed on R-HDAC, of whom only three (33%) achieved a remission with second line therapy, two of whom subsequently died of progressive disease. In total 31 patients (69%) have now undergone transplantation; 28 (62%) received an autograft (the majority BEAM conditioned), two had an allogeneic transplant and one a syngeneic transplant. Two patients are currently completing R-HDAC treatment and will undergo BEAM autograft thereafter. Transplant related mortality was within expected limits, with one patient dying as a result of sepsis due to BEAM autograft toxicity. Median duration of follow up of the entire cohort was 38 months. Overall response rate for R-HDAC with or without transplantation was 35/45 (78%), with most patients achieving a complete remission (CR) (n=30, 67%). Median OS and PFS were not reached. The OS at 4yrs is 78% (18/23); and PFS at 4yrs is 61% (14/23). Eight patients relapsed after achieving CR1 with HDAC +/- transplantation, five (63%) have subsequently achieved a second remission. The most commonly employed strategies amongst patients who required subsequent treatment were Ibrutinib (47%), Bortezomib (35%), CHOP (29%) and Bendamustine (17%) based therapies. CNS involvement was seen at relapse/progression in four cases.

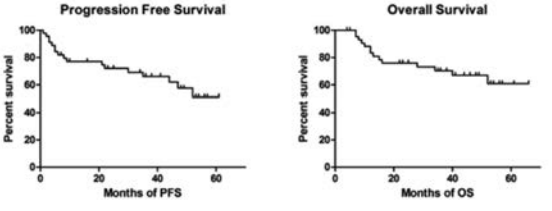

Figure 1.

Summary/Conclusions: This study confirms that induction with R-HDAC, consolidated with stem cell transplantation where appropriate, is a safe and effective upfront treatment strategy in MCL, and compares favourably with other induction regimens in terms of toxicity and duration of response. By avoiding the use of other agents as part of upfront treatment excess toxicity is avoided. Using R-HDAC upfront also leaves a greater range of therapies available for use at subsequent relapse, with good remission rates after second line therapy shown in this study. However, direct comparison with other upfront treatment strategies has not been made, and a prospective randomised controlled trial is needed.

E971

TREATMENT OF INITIAL CENTRAL NERVOUS SYSTEM INVOLVEMENT IN SYSTEMIC AGGRESSIVE LYMPHOMA WITH HIGH DOSE METHOTREXATE AND R-CHOP

M Nijland[1,*], A Jansen[2], J Doorduijn[3], R Enting[4], J Bromberg[5], H Kluin-Nelemans[1]
[1]Hematology, University Medical Center Gronigen, Groningen, [2]Neurology, Canisius-Wilhelmina Hospital, Nijmegen, [3]Hematology, Erasmus University Medical Center Rottedam, Rotterdam, [4]Neurology, University Medical Center Gronigen, Groningen, [5]Neurology, Erasmus University Medical Center Rottedam, Rotterdam, Netherlands

Background: Central nervous system (CNS) involvement in systemic aggressive B-cell non Hodgkin lymphomas (B-NHL) at initial diagnosis is uncommon. Two recent studies suggest a beneficial effect of intensive chemotherapy followed by autologous stem cell transplantation (ASCT) for these patients, but since ASCT was only offered to patients in complete remission optimal treatment remains unclear.
Aims: We investigated the outcome of patients with concomitant systemic and CNS B-NHL (sCNS B-NHL) at diagnosis treated with high dose methotrexate (HD-MTX) and R-CHOP, but no ASCT.
Methods: We performed a retrospective cohort study of patients with sCNS B-NHL at diagnosis identified from the electronical databases of 2 referral centers in the Netherlands. Patients had histological proven aggressive B-NHL and stage 4 disease according to Ann Arbor classification with concomitant paryncymal CNS involvement. Patients were treated according to one of two regimens: either 6 alternating cycles of HD-MTX and R-CHOP, or four cycles of HD-MTX followed by 6 cycles of R-CHOP. In the latter MTX was part of the MBVP regimen which also includes teniposide (VP16) and carmustine (BCNU). Primary endpoints were progression free survival (PFS) and overall survival (OS).

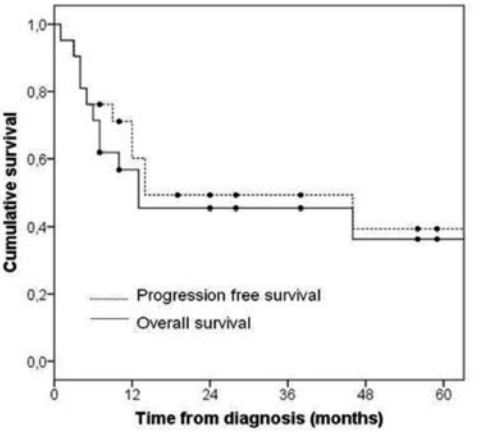

Figure 1. Overall and progression free survival.

Results: From 2001-2015 21 patients with sCNS B-NHL were identified. Median follow-up was 28 months. Characteristics at diagnosis: median age 54 years (range 19-71); WHO performance ≥2: 33%; IPI-score 0-1: 9%, 2-3: 66%, 4-5: 25%. Histological B-NHL types: diffuse large B-cell lymphoma: 66%; iatrogenic immunodeficiency B-NHL: 14%; transformed marginal zone lymphoma: 10%; intravascular B-NHL: 10%. Systemic organ involvement: testicular: 44% of patients at risk; breast: 17% of patients at risk; bone: 38%; kidney: 19%. Concomitant spinal fluid localization occured in 43% of patients. Fifteen out of 21 patients completed therapy as planned. The median number of MTX cycles at a dose of 3 g/m^2 was 4 (range 1-8). Sixty-two percent of patients also received intrathecal MTX. The median number of R-CHOP cycles was 6 (range 0-8). Whole brain radiotherapy was given to 33% of patients in partial remission. Besides the additional VP16 and BCNU in patients treated with MBVP, there was no difference between the two regimens. 3-year PFS and OS for the entire cohort were 45% (95%CI 34-56%) and 49% (95%CI 38-60%) respectively. The treatment related mortality (TRM) was 24% (5/21). No significant difference in OS was found between the two regimens (HR OS 1.25, 95%CI 0.38-4.2 p 0.72). The 3 patients with IPI-score 0-1 were alive at the last control, whereas all 4 patients with IPI-score 4-5 died within 2 years after diagnosis. There were 6 relapses (28%): 2 systemic, 2 in CNS, and 2 both systemic and in CNS.
Summary/Conclusions: In this second largest cohort described to date, the outcome of patients with sCNS B-NHL treated with HD-MTX and R-CHOP was comparable to that of more intensive regimens. Prospective studies are needed to define the optimal treatment for these patients.

E972

FEASIBILITY AND EFFICACY OF DHAOX REGIMEN AS SALVAGE AND MOBILIZING THERAPY IN RELAPSED /REFRACTORY LYMPHOMAS

E Coviello*, L Giannoni, G Pastori, L Mitscheunig, D Avenoso, P Minetto, F Guolo, M Miglino, M Clavio, RM Lemoli, G Marco, F Ballerini
Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genoa, Italy

Background: As already known, cisplatinum containing regimens for the management of relapsed-refractory lymphomas are complicated by different adverse events, mainly renal impairment. Since 2004 we used oxaliplatinum instead of cisplatinum, in association with cytarabine and dexamethasone (DHAOX).
Aims: The aim of the present study was to perform a retrospective analysis on feasibility and efficacy of this salvage regimen in patients with R/R lymphomas.
Methods: We retrospectively analyzed the outcome of 83 patients with R/R lymphomas who received DHAOX regimen from October 2004 to January 2016. The median age was 59 (22-79) and the median follow up is 56 months. Our series includes 41 patients with Diffuse Large B cell Lymphoma (DLBCL, 49%), 10 with Hodgkin Lymphoma (HL, 12%), 13 with Mantle Cell Lymphoma (MCL,16%), 15 with Indolent Lymphomas (18%), 4 with Peripheral T cell Lymphoma (5%). DHAOX schedule contains dexamethasone (40 mg/die on days 1-4), oxaliplatinum (130 mg/sqm on day 1) and cytarabine (2 g/sqm bid on day 2). In the majority of patients DHAOX was used as second line therapy. All patients received prophylactic G-CSF to reduce neutropenia. We analyzed overall survival (OS) and relapse free survival (RFS) in the whole cohort and then in DLBCL and HL patients. We evaluated haematological and non haematological adverse events (AEs).
Results: Non haematological AEs of grade >2 were observed in 27 patients (33%). The most frequent were: oral mucositis and other gastrointestinal events (6 patients, 8%), FUO (17 patients, 21%), sepsis (3 patients, 4%), paresthesias

(5 patients, 6%), and other different AEs in 4 patients (gout, atrial fibrillation, hypocalcemia and pleural effusion). 13 patients (16%) needed transfusional support. No patients experienced renal impairment. In 39 patients DHAOX regimen was utilized as mobilizing therapy to collect CD34+ cells for autologous stem cell transplantation (ASCT). In 32/40 patients (83%) more than $4x10^6$ CD34+ cells/kg were collected following G-CSF stimulation (5 mcg/Kg/die from day 5), in 1 patient associated with plerixafor. Median OS was 84 months. The projected OS at 12, 24, 36 months was 74.5%, 64.3% and 54.5%, respectively. Forty-one patients with DLBCL have been treated (median age 55 yy, range 22-79), 33 in second line (81%), 8 in third or subsequent line (19%). CR was obtained in 22 cases (60%), PR in 4 cases (11%). Eleven patients did not respond (29%). ORR was 71%. The median OS was 33 months and the projected OS at 12, 24 and 36 months was 66.3%, 57.9%, 45.5% respectively.
Ten patients with HL were treated (median age 44, range 28-74), 7 in second or third line (70%), 3 in fourth or subsequent lines (30%). CR and PR were obtained in 3 (30%) and 1 patients (10%), respectively. ORR was 40%. Considering only patients in second or third line, the ORR was 29%. Stem cell harvest was attempted in 2 patients, reaching the stem cell goal in both cases. The median OS was 84 months. The projected OS at 12, 24 e 36 months was 88.9%, 77.8%, 66.7% respectively.

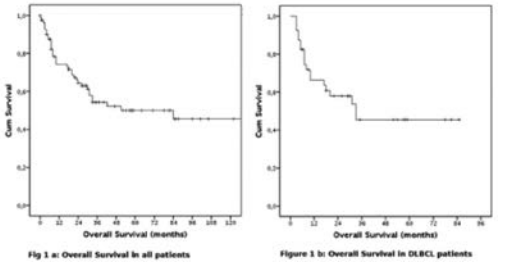

Figure 1.

Summary/Conclusions: DHAOX regimen was generally well tolerated, with acceptable toxicity profile and no documented significant renal impairment. By reducing days of hospitalization and the need of supportive care, we obtained a significant saving of economic resources despite the higher cost of oxaliplatinum. Stem cell mobilization with DHAOX resulted feasible and a successful apheresis was achieved in most patients. In conclusion, DHAOX regimen showed a good efficacy and a safe profile in the setting of relapsed/refractory non Hodgkin Lymphomas, mainly DLBCL; on the contrary, we experienced poor results in relapsed/refractory HL, suggesting that other schedules might be better in these patients.

OUTCOMES OF 34 PRIMARY BREAST DIFFUSE LARGE B-CELL LYMPHOMA IN RITUXIMAB ERA AT A SINGLE INSTITUTION

N Nishimura[1,*], Y Kusano[1], A Takahashi[1], N Inoue[1], M Gunji[1], H Nitta[1], K Ueda[1], Y Mishima[1], M Yokoyama[1], N Tsuyama[2], K Takeuchi[3], Y Terui[1], K Hatake[1]
[1]Hematology/Oncology, [2]Division of Pathology, [3]Pathology Project for Molecular Targets, The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Primary breast lymphoma (PBL) is a rare subtype of lymphoma accounting for 1 to 2% of extra-nodal lymphomas with the most subtype of diffuse large B cell lymphoma (DLBCL), thus the data of pathology and outcome is limited.
Aims: To elucidate the clinicopathological features and the outcomes including incidence of central nervous system (CNS) relapse in Rituximab-era.
Methods: Data were collected on patients with PBL diagnosed between January 1992 and 2016 at the Cancer Institute Hospital of JFCR, retrospectively. Patients with stage III and IV were excluded. Female DLBCL with stage I / II were also collected as a control in the matched case-control study.
Results: A total of 34 patients; 9 treated with CHOP-like regimens (CHOP group), 10 treated with rituximab-CHOP (R-CHOP group), and 15 treated with R-CHOP and intrathecal (IT) prophylaxis, were analyzed. Median age was 57 years. All patients were female with 21 patients (70.5%) of presenting with right breast tumor. Non-GC type defined by Hans algorithm had a higher proportion of 14 out of 24 analyzable patients (58.3%) without poor prognostic value. In comparison with early stage DLBCL treated with R-CHOP with or without IT prophylaxis except for breast, younger age (57 years v.s. 66 years) and higher CNS relapse rate (8.8% v.s. 0%) had significant difference between two groups. Then 1: 3 pair-matched case-control study limited in patients with stage I / II, female, and rituximab use, adjusted with age was carried out. Non-GC had higher rate in PBL than early stage DLBCL (66.7% v.s.44.4%), however, with no significant difference. On survival analysis with a median follow-up of 63months, PBL did not have poor prognosis with a 3-y-PFS (89.2% *vs* 90.2%, p=0.55) and 3-y-OS (90.0% *vs* 94.5%, p=0.87). Among patients with PBL, after a median follow-up of 47.5 months (range 1-286 months), the 3-year Progression free survival (PFS) and overall survival (OS) according to three groups; CHOP group, R-CHOP group, and IT+R-CHOP group were 55.6%, 80%, and 100% (p=0.058), and 55.6%, 80%, and 100% (p=0.06), respectively. CNS relapse had occurred in 3 out of 34 patients: all were stage II, one in CHOP group and two in R-CHOP group. Notably IT+ R-CHOP group had no relapse to date.

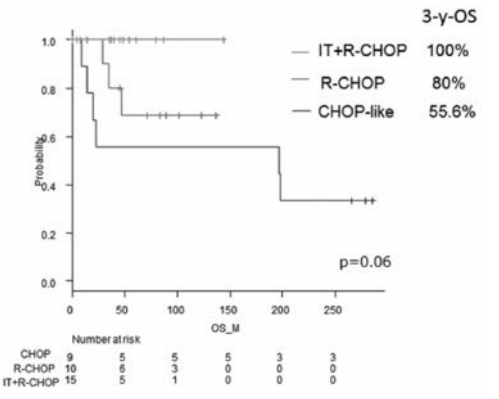

Figure 1.

Summary/Conclusions: PBL patients are younger than early stage DLBCL, and still considered as a high-risk for CNS relapse in Rituximab era. Nevertheless, IT added to R-CHOP potentially improve outcomes including CNS relapse.

E975

PATIENTS WITH PRIMARY CNS LYMPHOMA OR PRIMARY TESTICULAR DIFFUSE LARGE B-CELL LYMPHOMA HAVE AN INFERIOR PROGNOSIS WHEN CO-EXPRESSING C-MYC AND BCL2

K troppan[1,*], C Beham[2], H Greinix[1], A Deutsch[1], P Neumeister[1]
[1]Hematology, Internal Medicine, [2]Pathology, Graz, Austria

Background: Primary central nervous system lymphomas (PCNSLs) and primary testicular lymphomas (PTLs) are extranodal diffuse large B-cell lymphomas (DLBCLs) exhibiting a similar genetic signature and are characterised by an inferior response to current treatment regimens. DLBCL can be stratified by cell of origin (COO) derivation into the prognostically favorable germinal center B-cell (GCB)-like and the unfavorable activated B-cell (ABC) or non-GCB-like subtype based on gene expression signatures or immunohistochemical determination. The majority of PCNSL or PTL lymphoma derives from the non-GCB subtype. Recently, DLBCL patients with an immunohistochemical co-expression of c-MYC and BCL2 demonstrated inferior prognosis suggesting that concurrent expression of MYC/BCL2, termed double-protein-expression lymphoma (DPL), is a predictor of prognosis. Up to now there are no data, investigating the impact of DHL in patients with PCNSL or PTL.
Aims: We determined the frequency of DPL in a single center cohort of PCNSL or PTL and evaluated patients' outcome in contrast to "standard" DLBCL not exhibiting concurrent expression of MYC/BCL2.

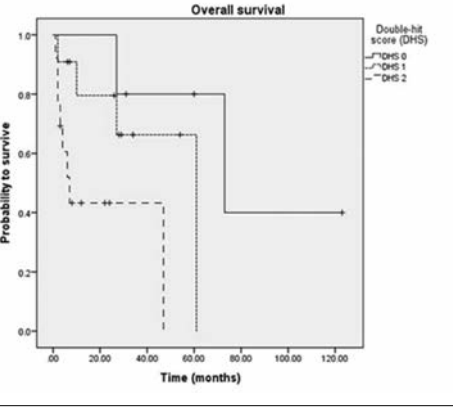

Figure 1.

Methods: We evaluated retrospectively the appearance of DPL in 42 patients with CNS or testicular DLBCL, consecutively diagnosed and treated between

2004 and 2014 at our institution. To determine the double-hit score, immunohistochemistry for c-MYC and BCL2 was performed on diagnostic samples. Furthermore, the Choi algorithm was used to subclassify samples by cell-of-origin. On the basis of immunohistochemical c-MYC and BCL2 expression, a double-hit score (DHS) was assigned to all patients with DLBCL. The DHS-2 group was defined by high expression of both MYC and BCL2 protein.
Results: Except for 3 samples, all patients were classified as non-GCB subtype. For 7 patients, no classification according to cell-of-origin could be performed. Of 42 primary extranodal DLBCL (PCNSL, n=28, PTL, n= 14), 29 patients were evaluable, 5 of them showed a double-hit score of 0, 11 patients had a DHS of 1, and 13 a DHS of 2, respectively. Using Kaplan-Meier curves and log-rank tests, probably due to small sample size, we could not demonstrate a significant different outcome for PCNSL or PTL patients with the non-GCB subtype as compared to the GCB subtype (*p*=0.74). However, we could clearly demonstrate a significant impaired outcome for patients with DHS of 2 (OS 61 *versus* 7 months, *p*=0.01) (Figure 1). Particularly, for patients with non-GCB subtype, we were able to further discriminate a subgroup of patients with an even worse clinical outcome to standard treatment (*p*=0.007).
Summary/Conclusions: In this single center cohort, we could demonstrate a significant negative effect on OS for PCNSL or testicular large cell lymphoma patients co-expressing MYC and BCL2. We could further define a subgroup of patients within the non-GCB cohort demonstrating double hit positivity (DHS of 2) that is associated with a particular short survival. These non-GCB-, DHS positive DLBCL patients are candidates for novel therapeutic strategies.

E976

CENTRAL NERVOUS SYSTEM (CNS) INVOLVEMENT IN DIFFUSE LARGE B-CELL LYMPHOMA. A SINGLE CENTER ANALYSIS OF THE RISK FACTORS AND THE IMPACT OF CNS PROPHYLAXIS IN THE RITUXIMAB ERA

M Ansuinelli[1,*], A Di Rocco[1], A Fama[2], F De Angelis[1], V Maiuri[1], C Minotti[1], F Robin[1], M Martelli[1]
[1]Department of Cellular Biotechnologies and Hematology, Institute of Hematology, Sapienza University, Rome, Italy, Rome, [2]Hematology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

Background: Central nervous system (CNS) relapse is a serious and generally fatal complication of diffuse large B-cell lymphoma (DLBCL) occurring in almost 5-7% of patients in the pre-rituximab era. The median time from diagnosis to detection of CNS disease is less than 1 year, suggesting that seeding in the CNS occurs early in the course of disease, with the exception of primary testis lymphoma in which it can occur up to 10 years after diagnosis. Up to date, there is no general consensus on how to define high-risk patients and what is the optimal CNS prophylaxis. The addition of rituximab to CHOP chemotherapy (RCHOP) has improved the clinical outcome of DLBCL. Nevertheless, the impact of rituximab on the incidence of CNS complications is still unclear.
Aims: This retrospective study aimed to analyze the predictive factors of CNS relapse and the impact of CNS prophylaxis in DLBCL patients treated at our Institute over a 12-years period.
Methods: We collected 393 patients with DLBCL diagnosed between 2002 and 2014. The patients with all stage of disease, regardless of the IPI score, were eligible and all received RCHOP every 14 or 21 days for at least 4/6 cycles. Patients with HIV or CNS involvement at diagnosis were excluded. Prophylaxis with intrathecal methotrexate (IT-MTX) was administered in patients with a high risk of CNS relapse according to the Italian Society of Hematology's guidelines. The diagnosis of CNS relapse was based on CT/MRI assessment and/or cerebrospinal fluid cytology.
Results: The median age was 58 years (IQR 47-68), 54% were males; 212/393 patients (54%) had stage III-IV, a bone marrow (BM) involvement was found in 51/393 patients (13%), while 49 (12%) had an involvement of more than 1 extranodal site, testis involvement was in 20/393 patients (5%). B symptoms were experienced by 100/393 patients (25%) and an elevated LDH was present in 115/393 patients (29%). According to the IPI score, 197/393 patients (50%) had a IPI<2 and 196/393 (50%) a IPI>2. Twelve/393 patients (3%) experienced a CNS relapse: 7 of them had a brain mass, 2 had a leptomeningeal involvement and 3 had both.CNS prophylaxis was carried out in 81/393 patients (21%): 27 with a IPI<2 and 54 (67%) with a IPI≥2. In the low risk group, only 1 patient with a primary testis involvement developed a CNS relapse 26 months from diagnosis, despite prophylaxis. In the high risk group according to IPI, 11 patients experienced a CNS relapse; only 4 of them had received IT-MTX[R1]. At univariate analysis: gender (p=0.029), advanced stage (p=0.004), PS>2 (p=0.009), presence of B symptoms (p=0.000), elevated LDH (p=0.006), involvement of >1 extranodal sites (p=0.000), BM involvement plus elevated LDH (p=0.003), testis localization (p=0.019) and IPI>=2 (p=0.000) were associated with an increased risk of CNS relapse. At multivariate analysis, only PS>2 (p=0.031, 95%CI: 0.009-0.189), testis involvement (p=0.001, 95%CI: 0.048-0.2) and BM involvement plus elevated LDH (p=0.016, 95%CI: 0.021-0.2) were predictive factors of high risk of CNS relapse. The 2-year overall survival of the CNS relapsed patients was 9%, with a median follow-up of 8 months from diagnosis (IQR 4-28).
Summary/Conclusions: CNS relapse remains a fatal event for patients with DLBCL even in the rituximab era. Poor PS, testis and BM involvement combined with elevated LDH represent the most important prognostic factors for CNS relapse. In our experience, single IT-MTX prophylaxis did not reduced CNS.

E977

SURVIVAL IMPACT OF SERUM ALBUMIN (SA) IN PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) RELATED NON-HODGKIN'S LYMPHOMAS

J Clara[1,2,*], S Dalia[3], B Shah[2], C Bello[2], P Chervenick[2], LM Juarez Salcedo[2], MA Kharfan-Dabaja[2], L Sokol[2], E Sotomayor[4], J Chavez[2]
[1]Internal Medicine, University of South Florida Morsani College of Mecdicine, [2]Malignant Hematology, Moffitt Cancer Center, Tampa, [3]Hematology/Oncology, Mercy Clinic, Joplin, [4]Hematology/Oncology, George Washington University, Washington D.C., United States

Background: Despite effective combination antiretroviral therapy for HIV, there is still increased incidence of Acquired Immunodeficiency Syndrome (AIDS) related Non-Hodgkin lymphomas (NHLs). AIDS related NHLs represent a challenge for the practicing oncologist. Prognostic factors have been shown to be useful to risk stratify the disease.
Aims: Here we examine potential prognostic indicators that may improve the performance of current prognostic systems in AIDS related NHLs.
Methods: Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2014 at Moffitt Cancer Center. Patients with and primary central nervous system lymphoma were excluded. Clinical data including CD4 count, HIV viral load (VL) and opportunistic infections (OI) were included. Survival curves analyzed using the Kaplan Meier method and statistical significance was assessed using the log-rank test. A p<0.05 was considered statistically significant.
Results: A total of 85 patients were included. The male:female ratio was 6.7. Median age was 44.3 years (range 25-65). The median time from HIV to NHL diagnosis was 29 months (0-284). Seventy-eight percent presented with stage III/IV disease. The Eastern Cooperative Oncology Group performance (ECOG) status was >1 in 62%. The most common histologies were Diffuse Large B Cell Lymphoma (DLBCL) and Burkitt's lymphoma with 49 and 34%, respectively. Bulky disease was present in 27.3%, elevated LDH in 61.5%, and CD4 count<100/mL at diagnosis in 29.5% patients. The mean Hb, SA and CD4 count were 3.6 g/dL, 11.8 g/dL and 205.9 k/uL, respectively. A serum albumin (SA)<3.7 g/dL and Hb<10 g/dl were present in 33% and 23.2% of patients, respectively. Forty-six percent had had cART at time of diagnosis. The cohort's median OS was 5.9 years. KM curves showed poor median OS with SA<3.7 g/dl (OS=3.9 y, p=0.021), Hb<10 g/dl (0.7 y, p= 0.001) and OI (OS= 1.0 y, p=0.018), There was a trend with worse OS with NCCN-IPI score >3 (OS=1.1 y, p= 0.165). MV analysis showed that SA<3.7 retained statistical significance (HR: 2.45, CI: 1.03-5.84, p=0.042).

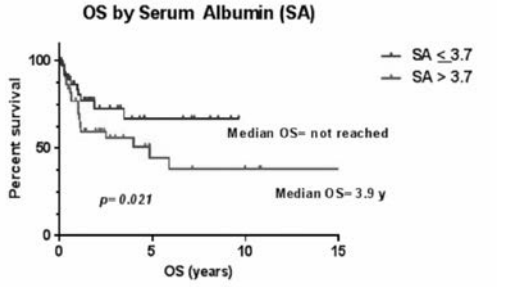

Figure 1.

Summary/Conclusions: New prognostic scoring systems have improved the risk stratification of AIDS-related lymphomas (Barta el al, Haematologica 2014). SA<3.7 is associated with worse OS in this study. SA could improve the stratification of AIDS related lymphomas in the cART era. A validation of the role of SA should be performed in larger cohorts.

E978

OUTCOME FOR PATIENTS WITH RELAPSED/REFRACTORY LYMPHOMA TREATED WITH GEMCITABINE AND OXALIPLATIN WITH OR WITHOUT RITUXIMAB

V Dhanapal[1,*], M Gunasekara[1], L Chia[1], P Patten[2], R Marcus[2], S Devereux[2], D Yallop[2], D Wrench[3], P Fields[3], C De Iord[2], S Bowcock[2], S Kassam[2]
[1]Haematology, Medway Maritime Hospital, Kent, [2]Haematology, Kings College Hospital, [3]Haematology, Guys & St Thomas Hospital, London, United Kingdom

Background: Relapsed/refractory aggressive lymphoma remains challenging to treat. There is no standard salvage chemotherapy regimen. Studies suggest that the outpatient combination of Gemcitabine, Oxaliplatin (Gem-Ox) with Rituximab (R) achieves similar response rates (RR) with less toxicity than intensive inpatient regimens[1].

Aims: To review outcomes for patients with refractory/relapsed aggressive lymphoma treated with Gem/Ox+/-R.
Methods: This retrospective study analysed clinical data on patients with relapsed/refractory aggressive lymphoma treated with Gem/Ox with or without R between 2010 and 2015 at 3 teaching hospitals in London, UK. The treatment schedule was Gemcitabine 1000mg/m^2 and Oxaliplatin 100mg/m^2 +/- Rituximab 375 mg/m^2 on day 1 and repeated every 15 days for up to 8 cycles.
Results: 44 patients, 26 male, with a median age of 66 years (range 22-83) were included. 30 (68%) patients had DLBCL; 27 had received prior R. 6 had T-cell lymphoma, 3 Hodgkin lymphoma and 5 had high grade transformation of low grade B-cell lymphoma. The median number of prior treatments was 1 (range 1-6). 7 patients had received an autologous transplant, 1 of whom had also received an allogeneic transplant. Remission duration (RD) to the prior treatment regimen was<12 months in 26 (59%) patients. 26 (75%) patients received R with Gem-Ox. The median number of cycles received was 4 (range 1-6). Response was assessed by CT scan in 19 PET/CT in 19, MRI in 2 and by clinical evaluation in 4. The overall response was 43% (n=19) with a complete response (CR) of 29% (n=13). CR was achieved in 11/18 (61%) patients with a prior RD ≥12 months compared to 2/26 (8%) patients whose prior RD was<12 months (p=0.0002). 27/44 (61%) patients were transplant eligible, 7 of whom had received a prior autologous transplant. The overall response in transplant eligible patients was 44% (n=12) 8/27 (30%) went on to receive a stem cell transplant; 4 autologous and 4 allogeneic transplants. At a median follow up of 6 months (range 0.5-33), the median overall survival (OS) is 8 months. For the 19 responding patients the median RD has not been reached. Median OS was significantly better in patients who had had a ≥12 month response to their prior treatment regimen; 13 *vs* 4.5 months, p=0.02 (Fig 1). Toxicity data were available for 36 patients. 17(47%) patients experienced grade 3/4 haematological toxicity. 8 (22%) had at least one febrile episode requiring hospitalisation. There were 4 (11%) grade 3/4 non-haematological toxicities, including diarrhoea, vomiting, peripheral neuropathy and bowel perforation. Dose reductions were required in 5 patients. 33 (75%) patients have died, 26 (60%) from lymphoma. Other causes of death include 1 old age, 2 post transplant graft *vs* host disease, 1 treatment-related sepsis 3 unknown.

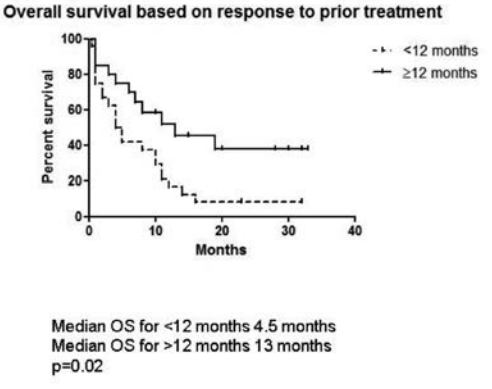

Figure 1.

Summary/Conclusions: In this study of 'real world' patients, Gem-Ox+/-R is a well-tolerated, outpatient regimen achieving good response rates in patients with chemo-responsive disease. Responses are comparable to more toxic, inpatient, platinum-based regimens. It can also successfully bridge patients to stem cell transplantation. Best responses are achieved in patients who have had a prior remission of at least 1 year.

E979

DOSE-ADJUSTED ETOPOSIDE-PREDNISONE-VINCRISTINE-CYCLOPHOSPHAMIDE-DOXORUBICIN-RITUXIMAB (DA-EPOCH-R) FOR PRIMARY MEDIASTINAL B-CELL LYMPHOMA (PMBCL) AND OTHER VERY HIGH-RISK OR ADVANCED LYMPHOMAS

F Carobolante[1,*], AM Scattolin[1], P Viero[1], M Dozzo[1], R Sancetta[1], A Pascarella[1], F Dei Rossi[2], A Dorigo[3], P Donisi[4], R Bassan[1]
[1]Hematology, [2]Nuclear Medicine, [3]Pharmacy, Ospedale dell'Angelo and SS. Giovanni e Paolo, Venezia Mestre, [4]Pathology, Ospedale SS. Giovanni e Paolo, Venezia, Italy

Background: Dose-adjusted etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin and rituximab (DA-EPOCH-R) is highly effective in PMBCL (Wilson W et al. NEJM 2013;368:1408) and is adopted in very aggressive lymphomas with encouraging results. While it is commonly used in US, experience in European countries is limited.
Aims: DA-EPOCH-R was used at Venice hospitals to treat adult patients with PMBCL and aggressive lymphoma variants associated with a poor response to R-CHOP.
Methods: DA–EPOCH-R consists of 6-8 cycles q21d with escalating doses of etoposide, cyclophosphamide and doxorubicin. Etoposide, vincristine (fixed dose 0.4mg/m^2/d) and doxorubicin are given by continuous IV infusion over 96 hours (dd 1-4). Drug level 1 is with etoposide 50, doxorubicin 10 and cyclophosphamide (d5) 750mg/m^2/d. A 20% dose escalation after each cycle and up to level 6 is prescribed to patients who do not develop a neutropenia <500/µl. The dose is reduced by 20% if neutropenia lasts >1 week or platelets fall <25.000/µl. Concomitant drugs are prednisone 60mg/m^2/bd (dd 1-5), rituximab 375mg/m^2 d1, and G-CSF from d6. Complete remission (CR, CRu [unconfirmed]) is defined according to standard criteria and PET/CT assessment after a minimum of 4 cycles.
Results: Thirty-three patients were treated between august 2013 and january 2016. Twenty-eight patients were treated frontline for PMBCL (n=14), non-GCB/highly proliferative (Ki67 ≥80%) diffuse large B-cell lymphoma (DLBCL) (n=5), double-hit DLBCL (n=6), plasmablastic lymphoma (n=2, one without R), and EBV+ lymphomatoid granulomatosis (n=1). Five patients were treated at salvage after 1-2 prior lines for DLBCL (n=3), Burkitt lymphoma (n=1) and Hodgkin disease (n=1, without R). Median patient age was 57.5 years (range 17-74 years), 61% were male, 73% had ECOG PS >1, 64% had stage III-IV disease and 58% had intermediate-high/high IPI. Altogether, the 33 patients received 158 courses, without change in dose level in 5 salvage patients. Twenty-six of 28 untreated patients had 2 or more cycles and are evaluable for dose level increments. Dose level could not be increased in 8 patients (31%), reached level 2 in 5 (19%), level 3 in 7 (27%), level 4 in 5 (19%), level 5 in 1 (4%) and level 6 in none. Toxicity consisted of severe neutropenia and thrombocytopenia in 67% and 10% of the cycles, respectively, neutropenic fever with admission to hospital (n=5, 15%), vincristine-related neuropathy (n=3, 9%), and thromboembolism (n=3, 9%). Due to poor clinical conditions, treatment was stopped after cycle 1 in a DLBCL patient (aged 65) with concurrent lung cancer, and switched to R-CHOP after 2 and 4 cycles in 2 patients (aged 74 and 61, respectively) with double-hit DLBCL, both remaining well and alive. Twenty-five patients completing 4 courses with PET/CT-based restaging are evaluable for response (Table). CR and ORR rate was high in patients treated frontline, particularly in PMBCL (ORR and PFS 100%). Response rate was appreciable in double-hit and very aggressive lymphomas as well, but was instead poor in patients treated at salvage.

Table 1.

	CR	CRu	CR/CRu	PR	ORR	NR	Progression-free (m.)
1st line							
PMBCL (n=12)	8 (66.6%)	2 (16.6%)	10 (83.3%)	2 (16.6%)	12 (100%)	0	12 (100%) at 15.5 (2-29+) mos.
Double hit (n=6)	3 (50%)	1 (16.6%)	4 (66.6%)	1 (16.6%)	5 (83.3%)	1 (16.6%)	5 (83.3%) at 9.5 (3-14+) mos.
Others (n=7)	5 (71.4%)	1 (14.3%)	6 (85.7%)	0	6 (85.7%)	1 (14.3%)	6 (85.7%) at 11 (1-21+) mos.
>1st line							
All (n=5)	2 (40%)	0	2 (40%)	0	2 (40%)	3 (60%)	0 (0%) at 4 mos.

PR, partial remission; ORR, overall response rate; NR, no response

Summary/Conclusions: DA-EPOCH-R proved globally feasible and safe in this aged patient population, and highly active in PMBCL as observed in the original study. The small patient number and the limited follow-up period do not allow definite conclusions, although the regimen would be useful in PMBCL (avoiding mediastinal irradiation) and potentially useful in very aggressive B-cell lymphomas at risk of failing standard R-CHOP therapy.

E980

ELDERLY AGE IS NOT EXCLUSION FACTOR FOR INTENSIVE THERAPY BY SCHEME R-DA-EPOCH/R-HMA FOR PATIENTS WITH UNTREATED HIGH-GRADE DIFFUSE LARGE B-CELL LYMPHOMA

O Gavrilina[1,*], E Zvonkov[1], E Parovichnikova[1], V Troitskaya[1], N Gabeeva[1], L Kuzmina[1], I Toropova[2], V Lapin[2], V Kanin[3], A Gubkin[4], S Kulikov[1], V Savchenko[1]
[1]National Research Center for Hematology, Moscow, [2]Regional hospital, Yaroslavl, [3]Regional oncology center, Khabarovsk, [4]Clinical hospital named N.A. Semashko, Moscow, Russian Federation

Background: Median of age for patients with diffuse large B-cell lymphoma (DLBCL) is 60. Approximately 50% of DLBCL are defined as high-grade by IPI and these forms are characterized by aggressive course and poor response to standard chemotherapy (CT). High-dose methotrexate courses, as example Hyper-CVAD/HMA or mNHL-BFM-90 protocols are applied for patients with high risk DLBCL. But for elder patients this approach usually is not employed due to the extreme toxicity. Addition of R-HMA to R-DA-EPOCH favourably changes the outcome in patients with untreated high-grade diffuse large B-cell lymphoma [ASH 2015 # 2708].
Aims: To evaluate the efficacy and toxicity of R-DA-EPOCH/R-HMA protocol in patients with untreated high-grade diffuse large B-cell lymphoma depending on age.
Methods: 35 untreated DLBCL patients from 4 centers were enrolled in a prospective study between August 2013 - Jan 2016; stage II-IV; ECOG 0-3; median age 55 years (27-76); age ≥60y/<60y 50%/50%; M/F 60%/40%; IPI: 63% high-intermediate and 37% high risk; 20% with bone marrow involvement. All patients underwent 4-8 courses (2-4 cycles) of chemotherapy: R-DA-EPOCH (standard dose and scheme), R-HMA (R 375 mg/m^2 d1, MTX 1000 mg/m^2 24 hours d 2, AraC 3000 mg/m^2 q 12 hrs d 3-4). For patients older than 60 year dose of R-HMA was reduced (R 375 mg/m^2 d1, MTX 500 mg/m^2 24 hours d 2, AraC 1000 mg/m^2 q 12 hrs d 3-4) and R-EPOCH were applied with-

out dose adjusted. In 4 cases of DLBCL with bone marrow involvement BEAM conditioning and autologous stem cell transplantation were applied.

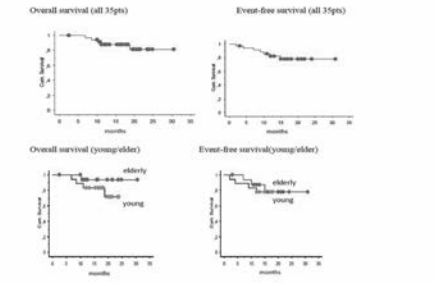

Figure 1.

Results: The median follow-up is 16 months (3-31). There was no mortality associated with toxicity. The main non-hematological toxicities of R-HMA were infections (mucositis, pneumonia, sepsis, enteropathy) grades 1-2 and 3-4 in 90% and 10%, respectively. Hematological toxicity grade 4 for less than 4 days we observed only after courses R-HMA. Complete remission (CR) was achieved in 31 (88,6%) patients. In group of young patients we observed 2 progressions of the disease after first cycle of chemotherapy, 2 cases with partial remission after 2-3 cycles and following progression of disease. There are three failures in patients older than 60 years: two relapses (after 5 and 13 month CR) and one death after 7 month CR by reasons not related with DLBCL. With a median follow 16 months overall and event-free survival of 35 patients constituted 81,6% and 78,2%, respectively. There is no difference in elderly and young groups: OS was 93,3% *vs* 71,4% (p=0,2), EFS was 77,8% in both. So the combination of R-DA-EPOCH/R-HMA may be considered as optimal intensive approach in elder patients.
Summary/Conclusions: The R-DA-EPOCH/R-HMA protocol demonstrated acceptable toxicity and high efficacy in patients with high-grade DLBCL. This protocol has shown optimistic results in the elderly patients and it could be recommended for further investigation in that group.

E981

FREQUENCY AND CLINICAL IMPLICATIONS OF SOX11 EXPRESSION IN BURKITT LYMPHOMA

T Wästerlid[1,*], L Nordström[2], M Pedersen[3], P Nørgaard[3], AO Gang[4], P Brown[5], M Jerkeman[1], S Ek[2]
[1]Department of Oncology, Lund University and Skåne University Hospital, [2]Department of Immunotechnology, CREATE Health, Lund University, Lund, Sweden, [3]Department of Pathology, Herlev University Hospital, Herlev, [4]Department of Hematology, Herlev University Hospital, [5]Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background: The transcription factor SOX11 is normally expressed during embryogenesis in humans. Several studies have shown that SOX11 is aberrantly expressed in various types of haematopoetic and solid malignancies, and appears to affect clinicopathological characteristics. In mantle cell lymphoma, SOX11 serves as a diagnostic antigen and has been shown to be associated with superior outcome (Nordström *et al.* British Journal of Haematology 2014), although its role as a prognostic indicator remains controversial. In chronic lymphocytic leukemia, SOX11 was associated with inferior overall survival (Roisman *et al.* Tumor Biol 2015), whereas SOX11 expression correlated with superior outcome in epithelial ovarian cancer (Sernbo *et al.* BMC Cancer 2011). Various possible target genes and transcriptional programs have been identified, by which SOX11 may exert both repressive, and exaggerative, functions on proliferation (Kuo *et al.* Oncogene 2015, Vegliante *et al.* Blood 2013). In Burkitt lymphoma (BL), two small series have reported expression of SOX11 in 30-50% of cases (Mozos *et al.* Haematologica 2009, Dictor *et al.* Haematologica 2009). As of yet, no study has been performed specifically to evaluate the implication of SOX11 expression in BL.
Aims: The aim of this study was to investigate the frequency of SOX11 positive BL cases in a larger joint cohort from Denmark and Sweden, and correlate its expression to clinical and pathological parameters.
Methods: 45 BL cases were collected from Sweden and Denmark. Samples were analyzed for expression of SOX11 and other immunohistochemical markers. Clinical data were obtained from the Danish Lymphoma Database (LYFO) and the Swedish Lymphoma Registry. Additionally, 9 pediatric BL cases were analyzed for SOX11 expression, but with no clinical data available.
Results: In the adult study population, 14/45 (31%) expressed nuclear staining of SOX11. The SOX11 positive subgroup had a higher median age (53 compared to 41), as well as a larger proportion with elevated LDH. Other prognostic factors were equally distributed between the groups. Although a similar proportion of patients received high-intensive chemotherapy in both subgroups, 3 (21%) received no treatment in the SOX11 positive cohort. There was no significant difference in immunohistochemical characteristics between SOX11 positive and negative cases. Five-year overall survival (OS) in the SOX11 positive group was 57%, compared to 77% in the SOX11 negative cohort. When adjusting for treatment and and prognostic factors in multivariable analysis, no significant difference in outcome was seen between groups (hazard ratio: 1.5, 95% confidence interval: 0.3-6.3, p=0.6). In the pediatric cohort, 5/9 (56%) expressed SOX11.
Summary/Conclusions: SOX11 expression was found in a minority of BL cases, and was associated with higher age in the adult BL cohort. In contrast to SOX11 expression in other malignancies, SOX11 expression showed no significant impact on outcome, in our study, when adjusting for prognostic factors and treatment.

E982

LONG-TERM FOLLOW-UP OF PRIMARY GASTRIC DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH MNHL-BFM-90

E Zvonkov[*], N Gabeeva, A Morozova, O Gavrilina, A Sidorova, D Koroleva, A Kovrigina, E Parovichnikova, V Savchenko
National Research Center for Hematology, Moscow, Russian Federation

Background: R-CHOP chemotherapy can induce favorable result for localized-stage primary gastric diffuse large B-cell lymphoma (PG-DLBCL) patients. But the presence of adverse factors (AF) and advanced stage decrease the efficacy of this therapy: 3-year progression-free survival (PFS) and overall survival (OS) are 43% and 64% respectively. The optimal treatment strategy for this pts still remains unknown.
Aims: Efficacy and safety assessment of the modified chemotherapy protocol NHL-BFM-90 (m NHL-BFM-90) in the treatment of the PG-DLBCL with AF.
Methods: Forty previously untreated pts with PG-DLBCL underwent m NHL-BFM-90 treatment between January 2004 and December 2015; mean age 47 years (range 37-72); age ≥60 years 9 pts (22,5%); M\F=23\17; stage >I 27 pts (68%); all pts had one or more AF. None of the patients received surgical treatment before chemotherapy and no consolidation radiotherapy. NHL-BFM-90 program (2 courses A and 2 courses B) was modified for PG-DLBCL in the following way: doxorubicin (50mg\m^2) was added on the third day of course A. Twenty one (52%) pts received rituximab on day 0 prior to each course of therapy.
Results: The overall response rate (ORR) was 100%. Complete remission was achieved in 38 (95%) pts. From 2 pts with partial remission one died from progression of disease, one received salvage therapy. With a median follow-up of 74 months (range 3-146) disease-free and overall survival of 40 pts constituted 87,5% and 92,5%, respectively. All but one treatment failure belonged to the group without rituximab. Hematologic toxicity of grade 3 and 4 was observed in 80% of pts. Severe complications became the reason for subsequent switch to CHOP therapy after 2 courses in 6 cases. There was no treatment-related mortality.
Summary/Conclusions: The mNHL-BFM-90 demonstrated acceptable toxicity and high efficacy in patients with PG-DLBCL with AF.

E983

PRIMARY BONE MARROW LYMPHOMA: A HEMATOLOGICAL EMERGENCY IN ADULTS WITH FEVER OF UNKNOWN ORIGIN

HY Wang[1,*], CF Yang[2], TJ Chiou[3], SH Yang[4], JP Gau[1], YB Yu[1], PM Chen[1], CH Tzeng[1], CY Tsai[5], HC Hsu[6], FD Wang[7], JH Liu[1], LT Hsiao[1]
[1]Division of Hematology and Oncology, Department of Medicine, [2]Department of Pathology and Laboratory Medicine, [3]Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, [4]Division of Oncology and Hematology, Department of Medicine, National Yang-Ming University Hospital, Ilan, [5]Division of Allergy, Immunology, and Rheumatology, Department of Medicine, [6]Division of General Medicine, Department of Medicine, [7]Division of Infectious Disease, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ROC

Background: Primary bone marrow lymphoma (PBML) denotes non-Hodgkin lymphoma (NHL) arising primarily in the bone marrow (BM) without any lymphadenopathy. It is often masked by prolonged fever leading to delayed diagnosis and notorious for various definitions adopted by previous studies.
Aims: This study aimed to lighten clinical panorama of PBML and to identify potentially warning parameters of PBML.
Methods: Two cohorts of PBML patients were enrolled. Cohort I consisted of 163 PBML cases from 16 case series and 23 case reports for meta-analysis of clinical characteristics. Cohort II comprised 221 adults with fever of unknown origin (FUO) from Taipei Veterans General Hospital who underwent a BM study, and 52 cases of them were finally diagnosed of NHLs, including 26 PBML cases. The latter cohort was used to identify warning parameters of PBML by comparing data upon admission between all FUO patients with and without a subsequent PBML diagnosis.
Results: In cohort I, PBML had heterogenous histology and could be clinically separated into two distinct entities: lymphoma limited entirely to the BM, liver, and/or spleen (i.e. BLS-type, n=79), and isolated BM lymphoma (i.e. IBM-type, n=84). Two third (67%) of PBML patients initially manifested with fever, and one third (31%) complicated with hemophagocytic lymphohistiocytosis (HLH). The BLS-type cases were mainly reported from the countries in Eastern Asia, more often presented as FUO and HLH at diagnosis, and suffered from a poorer prognosis (median overall survival of BLS-type *vs* IBM type=272 *vs* 580 days,

P<0.001). For 26 PBML patients of the cohort II, 89% were classified as BLS-type; median overall survival revealed dismal 9 days, with 54% having early mortality within 30 days. Compared to non-PBML NHL in the cohort II, PBML is an independent risk factor of both early mortality and overall survival. Among 221 FUO adults in cohort II, 4 warning parameters able to alert underlying PBML were independently identified, including serum alkaline phosphate >2× UNL, serum immunoglobulin G<0.67× UNL, cytopenia ≥2 lineages, and leuco-erythroblastosis in the peripheral blood.

Table 1. Univariate and multivariate analyses of warning parameters for primary bone marrow lymphoma in 221 adults with fever of unknown origin.

Warning parameters for PBML	Univariate		Multivariate	
	OR (95% CI)	*P*	OR (95% CI)	*P*
Bicytopenia or pancytopenia	22.844 (6.572–79.404)	<0.001	20.559 (3.101–136.279)	0.002
Leucoerythroblastosis in PB smear	1.390 (1.193–1.619)	<0.001	1.384 (1.008–1.901)	0.045
LDH >500 IU/L (2x UNL)	15.693 (4.543–54.212)	<0.001	4.956 (0.832–29.511)	0.079
IgG <1000 (0.67x UNL)	4.912 (2.015–11.972)	<0.001	5.086 (1.046–24.728)	0.044
ALP >200 U/L (2x UNL)	6.000 (2.473–14.556)	<0.001	5.857 (1.179–29.085)	0.031
PT >12 sec (1x UNL)	6.416 (2.551–16.133)	<0.001	4.457 (0.939–21.161)	0.060

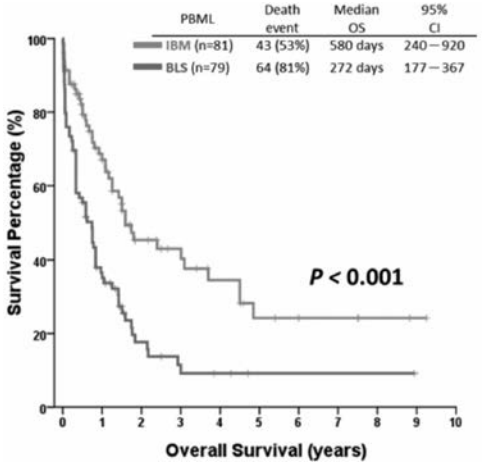

Figure 1.

Summary/Conclusions: As a particular clinical phenotype of NHL, PBML is often masked by prolonged fever and should be regarded as a hematological emergency when approaching patients with FUO. Our study provided additional diagnostic clues to early recognize FUO adults with underlying PBML.

E984

CHEMOTHERAPY OF 40 PRIMARY MEDIASTINAL B-CELL LYMPHOMA PATIENTS

J Mangasarova[1,*], A Magomedova[1], A Misyurina[1,2], E Nesterova[1], L Gorenkova[1], A Gilenko[1], E Baryakh[3], V Vorobiev[3], S Kravchenko[1]
[1]National Research Center for Hematology, [2]LLC "GeneTechnology", [3]State clinical hospital N°52, Moscow, Russian Federation

Background: Primary mediastinal B-cell lymphoma (PMBCL) amounts from 0,9 to 4% of Non-Hodgkin Lymphomas. Predominantly suffer young women. All relapses in PMBCL occur as early events. Taking into account unfavorable prognosis in case of relapse or progression of PMBCL (2-year overall survival (OS) is about 15% [Kurvilla J., 2008]), it's necessary to achieve a complete remission (CR) in first line treatment.
Aims: To evaluate an efficacy of R-DA-EPOCH therapy+R-DHAP№2 and autologous peripheral blood stem cell transplantation (autoSCT) with BEAM conditioning regimen in treatment of PMBCL pts.
Methods: In 40 pts (14 males, 26 females) diagnosis of PMBCL was established according to WHO criteria. All pts had stage II of disease according to Ann Arbor classification. Median age of pts was 27 years old (from 19 to 67 years old). Increased LDH concentration was revealed in 34 from 40 (85%) pts. Bulky mediastinal disease was in 31/40 (77.5%) pts. In case of CR after 6 courses according to computer tomography and PET scanning treatment was completed. In case of PR pts underwent 2 R-DHAP courses with autoSCT (BEAM conditioning regimen). All cases of treatment failure occurred till one year of observation. Kaplan-Meier method was used to calculate OS and OFS.
Results: After 6 R-DA-EPOCH therapy CR was achieved in 32/40 (80%) pts, 8/40 (20%) pts had PR and underwent 2 R-DHAP courses followed by auto-SCT (BEAM). 2- OFS and OS was 96% and 100%. Early relapse occurred in 1/40 (2,5%) patient. Median follow up was 20 months (3-32).
Summary/Conclusions: R-DA-EPOCH allows getting high efficacy of primary mediastinal B-cell lymphoma therapy. Although future analysis will show distant results of R-DA-EPOCH chemotherapy. Taking into account unfavorable prognosis in case of relapse or progression of PMBCL autoSCT in first line therapy might have benefit in patients with partial remission after R-DA-EPOCH.

E985

VITREORETINAL LYMPHOMA: A DESCRIPTIVE STUDY OF A VERY RARE OCCURRENCE FROM A SINGLE INSTITUTION IN ITALY

A Ferrari[1,*], L Cimino[2], F Ilariucci[1], A Fama[1], I Alvarez[1], A Ruffini[1], CC Chan[3], S Luminari[1], F Merli[1]
[1]Ematologia, Dipartimento Oncologico e Tecnologie avanzate, [2]Oculistica, Chirurgia Generale e Specialistiche, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy, [3]Section on Immunopathology, Laboratory of Immunology, National Eye Institute, National Institutes of Health, Bethesda, Maryland, United States

Background: The vitreoretinal lymphoma is a rare subset of primary central nervous system lymphoma (PCNSL) with a poor prognosis. Because of its rarity and the difficult of collecting tumor simples, this entity remains poorly understood and the optimal management is still unknow.
Aims: to describe a single insitution experience with Vitreoretinal lymphomas.
Methods: The 2011-2015 archives of the hematology and oftalmology units of the Reggio Emilia Hospital Lymphoma were searched for cases with vitreoretinal lymphoma. Cases were classified as primary vitreoretinal lymphoma (PVRL) of systemic lymphomas with concurrent Vitreoretinal involvement (CVRL). We defined stage IE as mono or bilateral involvement of the vitreum. We provide a complete description of pathological, clinical, and therapeutic findings.
Results: We identified 7 patients with either PVRL (3) or with CVRL (4). Four patient were female, the median age at diagnosis was 62 years (range 45-74), three had a stage IE and four a stage IVA. All patients were HIV negative. Among the 4 CVRL 2 patients showed brain involvement, one patient nodal involvement, one patient gastric involvement. All patients were initially referred with ocular symptoms mimicking uveitis. The median time between the onset of the ocular symptoms and the lymphoma diagnosis was 13 months (range 2-30 months). All patients underwent a diagnostic vitrectomy. The cytopathological analysis was positive in five cases and uncertain in two cases (CVRL). The immunoistochemical analysis showed atypical CD20+ lymphocytes in three cases. Vitreous supernatant was submitted for IL-10 and IL-6 measurement by ELISA using the IL-10 to IL-6 ratio as a diagnostic marker. Elevation of IL-10 levels and IL-10:IL-6 ratio greather than 1 was found in all cases. Molecular analysis of the specimens detected IgH gene rearrangements in 4 cases. Notably the three PCR negative samples displayed a sharp unbalanced IL-10:IL-6 ratio and atypical CD20+ lymphoid large cells. Cerebral Spine Fluid (CSF) analysis was negative in all patients. All patients were treated as CNS lymphomas and received combined high-dose systemic chemotherapy with Rituximab, High dose ARA-C and High dose Methotrexate, and intravitreal methotrexate iniection (Intravitreal methotrexate 400 microg/0,1 ml twice weekly for 4 weeks, once weekly for 8 weeks, and then once montly for 9 months for a total of 25 injection). All 7 patients achieved a complete remission (CR) at the end of therapy. Four patients underwent autologous stem cell transplant (ASCT) in first remission.m The median observation period was 16 months (range, 2-48 months). All patients were alive at this time point except for one patient who relapsed four months after ASCT and died one month later.
Summary/Conclusions: This single center retrospective series highlights the insidious onset of both PVRL and CVRL and the difficulties in diagnosing this particularly rare lymphoma occurrence.

E986

RCHOP *VS* -CHOP CHOP IN DIFFUSE LARGE CELL FOLLICULAR EPIDEMIOLOGICAL OF PATIENTS WITH LYMPHOMA LYMPHOMA TREATED IN CARACAS, VENZUELA FOR 14 YEARS

A Muller[*]
Hematology, Clinica El Avila, Caracas, Venezuela

Background: Few epidemiological Venezuelan Lymphoma patients data are found in the literature to compare survival and the current standard treatment with chemoinmunotheraphy with Lymphoma patients from developed countries.
Aims: The purpose of this paper is to present epidemiological data of patients with lymphoma treated by the Commission of lymphoma IOH and some private clinics in Caracas during the past 14 years and compare the efficacy of treatment of RCHOP *vs* CHOP
Methods: Materials and Methods A total of 1812 patients with lymphoma, of which 1214 were classified as non-Hodgkin lymphoma and 598 as Hodgkin's lymphoma were treated, and of these 1117 patients with lymphoma were studied from the pto epidemiologically between 1996- 2010 Lymphoma diagnosis was made based on clinical history, X-rays, CT, lymph and tissue biopsy (depending on the case), immunohistochemistry studies when required.
Results: Results Patients with lymphoma were classified into Hodgkin and non-Hodgkin 390 cases 827 cases. Hodgkin's lymphoma (HL) is subclassified in Nodular Sclerosis 62.6%, 27.7% mixed cellularity, lymphocyte-predominant 4.3% 5.4% Depletion Lymphocytic The age and sex of the patients were Nodular Sclerosis: 32.45 years (18-65), 129 female and 115 male, Mixed cellularity: 22.3

years (18-56), 37 female and 72 male, predominantly lymphocytic 22.6 years (18-67), 6 female and 11 male, depletion Lymphocytic 22 years (20-42) female and 15 maleThe stages were stage I: 5,5%, stage II: 44%, stage III: 31.1% stage IV: 19.4%.HL patients were treated with different chemotherapy protocols: MOPP, ABVD, STANDFORD V, HYBRID, COPP / ABVD, COPP / EBVD, BEA-COPP and in some cases radiotherapyNon Hodgkin Lymphomas were subclassified by 36.4% Diffuse Large Cell, Follicular 24.1%, 10% Maltoma, 5.5% of peripheral blood cells, 3% mantle cell lymphoma, 20.8% other types of lymphoma such as mycosis Mycosis, immunoblastic Anaplastic, Lymphoblastic, Burkitt, Cutaneous B cell 45% of patients with follicular lymphoma had a high score FLIPI and 60% of diffuse large cell lymphoma had a high intermediate score with high-risk prognostic factors and only 15% of these were low-risk DLB-CLNHL were treated with different protocols according to the year of admission and stage of CHOP disease, CHOP Bleo, MACOB B, ATT, Hyper-CVAD, CHOP MTX and from 2005 to 2010 55 patients were treated with R-CHOP and year 1999-2004 29 patients were treated with CHOP resulting overall survival in DLB-CL with RCHOP 92.1% *vs* 67.9% and 89.5% LF *vs* 50%, event-free survival of 90% DLBCL with RCHOP CHOP *vs* 44% (p 0.002) and LF with CHOP *vs* 89.8 RCHOP age influenced patient survival (p 0.56). Other variables such as sex, type of lymphoma, stage had no impact on the EFS.

Summary/Conclusions: Conclusion: 1117 patients with lymphoma were studied retrospectively. Patients were classified in 34.9% and 65.1% non -Hodgkin lymphoma. The most common subtype of LH was nodular sclerosis (62.57%) and was more common in women and young adults of mixed cellularity HL was the second most common and the prevalence in lymphocytes and lymphocyte depletion constituted only 6.8% and 8 7%% the most common was the NHL diffuse large cell and the second Follicular NHL. The Venezuelan population is made up of a mixture of different indigenous races, Caucasian, Negroid, but it seems that this disease follows the same patterns reported in other populations Overall survival, event-free survival of DLBCL and LF was statistically significant in favor of RCHOP, which should be the treatment of choice in these pathologies.

E987

IS THAT MALE GENDER AN ADVERSE RISK FACTOR ONLY IN YOUNG PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA?

T Faiza[1,*], B SALAH[1], D malika[1], G yamina[1], S mohamed[1], T mohamed el habri[2], B mohamed[2], A fatma zohra[1]
[1]Hematology, [2]Radiology, central hospital of the army, ALGER, Algeria

Background: The International Prognostic Index (IPI) is the most important clinical tool for determining prognosis in diffuse large B-cell lymphoma (DLBCL). It incorporates five adverse risk factors: age above 60 years; Ann Arbor stage III or IV; elevated serumnlactate dehydrogenase (S-LDH); Eastern Cooperative Oncology Group (ECOG) performance status of 2 or higher; and involvement of two or mor extranodal sites. GUSTAF HEDSTRÖM was published in Acta Oncologica (in April 2015), one of the largest population-based studies of DLB-CL presented (7166 patients were included), he found male gender to be a significant adverse risk factor compared to fertile women, without msurvival differences between genders in the older sub-population. According Nurith H, the reduced rate of NHL among females may be explained by direct effects of estrogens on lymphoma cell proliferation or by its effect on anti-tumor immune response: the influence of sex hormones on lymphoid malignancies has been the subject of clinical and *in vitro* research. Epidemiological studies highlighting the association between sex hormones and NHL have provided some clues. Lee and colleagues reported that an increasing number of pregnancies and live births is associated with a decreasing trend in the risk of DLBCL.

Aims: The primary objective of this study was to analyze the impact of gender on age in patients with newly diagnosed DLBCL.This retrospective study included 95 patients with diffuse large B cell lymphoma who were treated the Medical Hematology Department, HCA during the time period from 2000 to 2015.

Methods: We conducted a retrospective cohort study of all DLBCL patients diagnosed between 2000 and 2015, to evaluate the impact of gender for survival from DLBCL. Survival curves n were estimated according to the Kaplan-Meier method and associated log rank, a Cox model was used to evaluate the prognostic impact of clinical risk factors (age<vs≥52 y, ECOG≤VS>2, stage I-II *vs* III-IV, LDH normal *vs* high, extranodal sites, IPI (0-5), IPI-a (0-3).

Results: In total, 95 patients were included for analysis, clinical caracteristics of our patients are summarized in Table I. Data collected were: year of diagnosis, age, gender, Ann Arbor stage, ECOG performance status, extranodal sites, S-LDH, IPI, age adjusted IPI (aaIPI). When patients older (52 years or older), or younger than 52 years, were analysed separately, the same risk factors remained no significant. Sex was not found to be significantly correlated with adverse outcome in univariate analysis according to the Kaplan-Meier method and associated log rank tests: women have a comparable overall survival to that of men in the same age group (75% *vs* 88,5% ; P=0,332). **n**In a relative survival multifactorial model adjusted for stage, ECOG performance status, serum lactate dehydrogenase and two or more extranodal sites, male gender was not found to be an adverse risk factor for patients younger than 52 years (RR 0.893, 95% CI 0.641-1.244). However, the impact of the above-mentioned prognostic factors was significantly correlated with age. In effect, using multiple regression Cox model, we found that Ann Arbor stage III and IV, as well as extranodal involvement of two or more sites, IPI are correlated to worse outcome, with 0.024 *vs* 0.087, 0.009 *vs* 0.844, 0.0001 *vs* 0.687 respectively, P (for age ≥*vs*<52 years), see Figure 1-6.

Table 1.

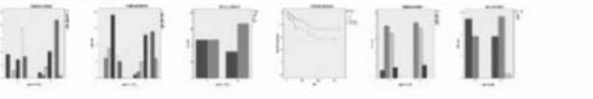
aaIPI, age adjusted IPI, DLBCL, diffuse large B-cell lymphoma, ECOG PS, Eastern Cooperative Oncology Group performance status, Extranodal, involvement of 2 or more extranodal sites, IPI, International Prognostic Index, NA, not available, S-LDH, serum lactate dehydrogenase, Stage, Ann Arbor stage.



Summary/Conclusions: our study clearly demonstrates the impact of age on the survival of patients with LGDB, however gender does not appear to influence patient outcomes.

Bleeding disorders (congenital and acquired)

E988

INCIDENTAL FINDINGS BY TARGETED EXOME SEQUENCING USED TO DIAGNOSE RARE INHERITED BLEEDING DISORDERS-PATIENT'S CHOICES ON INFORMATION AND OUTCOME

EB Leinoe[1,*], M Rossing[2], O Østrup[2], P Kampmann[1], N G Andersson[3], E Zetterberg[3]
[1]Haematology, [2]Center for Genomic Medicine, Rigshospitalet University Hospital, Copenhagen, Denmark, [3]Coagulation Unit, University Hospital Skaane, Malmoe, Sweden

Background: Whole exome sequencing (WES) has the ability to identify numerous mutations within a genome, many of which are not related to the phenotype in question, but they may have clinical ramifications. Incidental findings (IF) are pathogenic alterations in genes, that are not apparently relevant to the diagnostic situation, for which, the sequencing was intended. Scientific and ethics boards recommend, that the informed consent process ensures, that patients understand the possibility that IF will be detected and indicate which (if any) information on IF, they wish to receive. We have implemented WES to diagnose patients with inherited bleeding disorders. Our exome sequencing panel for bleeding disorders only examines specific genes, but with the additional use of search terms (thrombocytopenia, thrombocytopathia and bleeding) incidental findings may occur. Mutations associated with inherited thrombocytopenia may also be associated with haematological cancers. No previous study has described the outcome of IF in this diagnostic setting.
Aims: To examine patient`s choice on information regarding IF and to report the rate of IF.
Methods: Patients were examined by ISTH-BAT score and standard coagulation testing. Prior to WES analysis, patients were given oral and written information concerning the risk and possible seriousness of IF. The pretest information on IF included risk of detecting mutations associated with cancer or brain disease. Patients from Copenhagen were asked to make a pretest written choice of whether they wanted information on: A. All genetic results of clinical significance, including IF. B. No information on IF. C. Provision of IF with known clinical significance and the possibility of treatment or prevention of disease. Patients from Malmoe were asked to make a pretest written choice of whether they wanted information on: A. All genetic results of clinical significance, including IF. B. No information on IF. The Illumina HiSeq 2500 platform was used for targeted exome sequencing. Sequencing was performed on the HiSeq 2500 as paired end (PE) sequencing, 2x101 bases, resulting in approximately 100 M PE reads. Variants were called with a minimum of 10x coverage and exported as.vcf format with approximately 220,000 variants prior to upload in Ingenuity Variant Analysis (Qiagen). Common SNPs were subtracted.
Results: A total of 91 genes associated with bleeding were examined in 107 patients from Copenhagen and 37 patients from Malmoe. The following IF were made: 1. A heterozygous variant in *Telomerase reverse transcriptase (TERT)* (His412Tyr) in a 34-year female with macro-thrombocytopenia. The variant had previously been reported to be associated with reduced telomerase activity, dyskeratosis congenital and aplastic anemia. A telomer analysis performed by an outside lab, showed that leukocytes did not have short telomeres or low telomerase enzymatic activity. It was concluded, that the variant was a non-pathogenic polymorphism and the patient informed correspondently. 2. A heterozygous missense mutation in *SERPINC1* (Pro73Leu) in a 40-year female without thrombosis. It was previously described as a founder mutation in the Finnish population, associated with type II antithrombin (AT) deficiency and increased risk of thrombosis. Her AT III level was normal; no additional function testing was done. It was concluded that due to her haemorrhagic diathesis, she was not at high risk of thrombosis and informed correspondently. 3. A heterozygous *GATA2* mutation (Pro41Ala) previously associated with myelodysplasia and skin cancer in a 36-year female. Several relatives had a history of skin cancer and her aunt had leukemia. She was informed of the increased risk of skin and haematological cancer, offered regular follow-up and advised on skin protection.

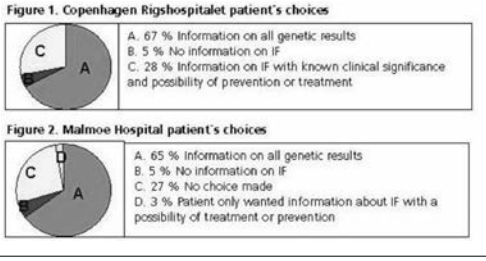


Figure 1.

Summary/Conclusions: IF were discovered in 3/148 (2%). In two separate cohorts of patients from Copenhagen and Malmoe, the choices on information were comparable. Ninety-nine patients (66%) wanted information on all genetic results and 7 patients (5%) declined all information regarding IF. The remaining 42 patients (29%) did either not make a choice or only wanted information, when a disease could be treated or prevented. Targeted exome sequencing of rare inherited bleeding disorders may disclose IF with major impact and/or require additional consultation/validation by an external laboratory or expert. It is of outmost importance that patients understand the consequences of IF, before giving informed consent to WES:

E989

HEMORRHAGIC EVENTS AND PRIMARY HEMOSTASIS DISORDERS DURING TREATMENT WITH IBRUTINIB

N Acedo, J Loscertales, B Aguado*, Y Paz, E Jiménez-Barral, S Rodrigo, S Almero, I Santamaría, A Alegre
Hematology, Hospital Universitario de La Princesa, Madrid, Spain

Background: Ibrutinib is a first-in-class Bruton kinase inhibitor (BTK) registered for the treatment of Chronic Lymphocytic Leukemia (CLL), mantle cell lymphoma (MCL) and Waldenström Macroglobulinemia (WM). Increased risk of bleeding events are associated with ibrutinib, mostly grade ≤2. Probable mechanism for this risk could be the role of BTK in platelet activation via GPIb, GPVI and FVW.
Aims: To present our experience regarding hemorrhagic events and hemostasis tests alterations in CLL patients (pts) treated with ibrutinib.
Methods: 10 pts with relapsed CLL were started on ibrutinib between december/2012 and march/2016. Median age was 69 years (range: 42-83 years). 8 of them were male. Median exposure to the drug was 17 months (range 1-38). After 9 to 36 months from initiation of treatment (median 22 months) 6/10 were thoroughly interviewed about personal history of bleeding events and the following laboratory work was performed: factor VIII level, FvW antigen and activity, platelet function analysis (PFA-100^{TM}) with ADP and epinephrine, and aggregation studies with collagen, ADP and arachidonic acid (AA). Along this tests all patients had blood counts with platelets more than 100 x 10e9/L.
Results: 2 out of 10 pts had bleeding events (grade 1 or 2), consisting in spontaneous bruising, in the first weeks of treatment. 4 pts underwent minor invasive procedures with no complications, withholding the drug at least 3 days before and after. 2 pts were on concomitant antiplatelet (1) or anticoagulant (1, LMWH, due to AF) and had no bleeding events. All pts tested (6/6) had normal or slightly elevated levels of F VIII, FvW:Ag and FvW:ristocetin cofactor activity. 2 pts had abnormal PFA-100^{TM} and abnormal aggregations with every agonist. One case had normal PFA-100 ^{TM} while aggregations with collagen and AA were mildly altered.
Summary/Conclusions: Our limited experience shows a moderate risk of minor bleedings consisting with a platelet disfunction. Despite the fact that we have no baseline tests done, alterations in primary hemostasis tests, including PFA-100^{TM} and specially aggregometry could be expected early on after exposure to ibrutinib.

E990

REGULATION OF CD72 EXPRESSION ON CD19+CD27+ MEMORY B CELL BY CD40L IN PRIMARY IMMUNE THROMBOCYTOPENIA

M Lyu*, Y Li, Y Hao, C Lyu, W Liu, S Wang, Y Guan, H Li, R Yang
Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, Tianjin, China

Background: CD72, a co-receptor of B cell receptor, regulates B cell activation and is involved in B cell-related autoimmune diseases. Despite the knowledge that expression of CD72 on peripheral B cell is aberrant in patients with some autoimmune diseases, it is uncertain whether this aberrant expression is restricted to specific B cell subsets in primary immune thrombocytopenia (ITP). Furthermore, the mechanisms that regulate CD72 expression on peripheral B cell in ITP are unknown.
Aims: This study aimed to examine CD72 expression on subsets of B cells and uncover the regulatory mechanisms of CD72 expression on peripheral B cell in ITP.
Methods: Frequencies of B cell subsets and expression of CD72 and CD40L were determined by flow cytometry in patients with active ITP, patients in remission and health controls. To activate B cells, the following reagents were added at the initiation of culture in vitro, anti-IgM, CD40L, LPS. The following cytokines were used to evaluate their effect on CD72 expression: interleukin-4 (IL-4), IL-10, IL-21, B-cell-activating factors (BAFF). The level of CD72 mRNA was assessed by real-time PCR. The concentration of plasma CD40L was measured by ELISA. Specific anti-platelet autoantibodies were measured by the Pak Auto method.
Results: Patients with active ITP had a significantly higher frequency of CD19+B cells, CD19+CD27+ memory B cell and lower frequency of CD19+CD27- naive B cells than did controls and patients in remission. The mean fluorescence intensity of CD72 on circulating B subcells is upregulated in active ITP patients compared to that recorded in controls and patients in remission. In active ITP patients, the expression of CD72 on CD19+ CD27+B cells was inversely corre-

lated with platelet counts, but there is no difference among groups with different age and gender. Patients with anti-platelet autoantibodies had significantly higher expression of CD72 on CD19+CD27+B cells. In vitro, analysis of B cell activation revealed that the CD40L could induce CD72 significant upregulation on B cells and CD19+CD27+ B cells both in patients and controls. The mRNA levels of CD72 in peripheral blood mononuclear cells activated by CD40L were increased. When used in combination with CD40L, IL-10 and BAFF further enhanced the expression of CD72 on CD19+CD27+B cell, whereas IL-21 reduced CD72 upregulation. CD40L expression on CD4 T cells and plasma CD40L levels were significantly higher in active ITP patients compared to controls. Significant increases in plasma CD40L were correlated with CD72 expression on CD19+CD27+ B cell in ITP patients.
Summary/Conclusions: These data provide evidence that active ITP patients have higher CD72 expression on increased CD19+CD27+ memory B cells, which is associated with platelet counts and autoantibody. Soluble higher CD40L found in active ITP patients might contribute to the increased levels of CD72 on CD19+CD27+ B cell.

E991

THROMBIN GENERATION AND WHOLE BLOOD VISCOELASTIC ASSAYS IN THE MONITORING OF HAEMOPHILIA WITH INHIBITORS

M Serban[1,*], E Ursu[1], L Cernat[2], D Poenaru[3], J Patrascu[3], C Jinca[3], W Schramm[4], S Talpos[3], S Arghirescu[3]
[1]Hemato-oncology, [2]Laboratory, Emergency Children's Hospital "Louis Turcanu", European Haemophilia Center, [3]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [4]"Ludwig-Maximilians" University, München, Germany

Background: During the past decade numerous studies using thrombin generation (TGA) and viscoelastic tests (TEG) have been introduced in clinical laboratories, looking for a new perspective on monitoring patients with severe haemophilia complicated with inhibitors.
Aims: We attempted to obtain a more reliable image on global hemostasis of patients with haemophilia A (HA) and high titre inhibitors treated with bypassing agents (BPAs) by using these two new laboratory tools, TGA and TEG.
Methods: Seven persons with HA and high titre inhibitors treated with by passing agents during 12 bleeding episodes, 5 of them in invasive surgical conditions have been evaluated. Reaction time (R), kynetics (K) and maximal amplitude (MA) on thrombelastograph System 5000, and lag time, peak, time to peak (ttpeak), endogenous thrombin potential (ETP), start tail and velocity index have been the focused parameters, interpreted also in connection with the clinical outcomes. The same procedure was performed on 15 healthy volunteer control group.
Results: While traditional coagulometric assay failed giving information on the global hemostatic potential, TEG displayed significantly prolonged R and K ($p<0.01$), with prompt improvement after BPAs administration. The thrombogram revealed also significantly low values ($p<0.001$) for peak and velocity index and prolonged time to peak and start tail, also, with significant ($p<0.01$) long lasting (more than 4 hours) improvement after BPAs administration.
Summary/Conclusions: In our modest experience, the combined use of TEG and TGA has been a useful source for surrogate markers, able providing more informative and reliable data on the impact of BPAs on the hemostatic results in an attempt of a more safe and effective personalised therapy in haemophilia complicated with inhibitors.

E992

ACQUIRED HAEMOPHILIA: A MALAYSIAN OUTLOOK

V Selvaratnam[1,*], J Suriar[1], T Sen Mui[1], O Tee Chuan[1], C Kian Meng[1], J Sathar[2]
[1]Haematology, [2]Hospital Ampang, Malaysia, Selangor, Malaysia

Background: Acquired Factor VIII inhibitor is a very rare bleeding condition due to the spontaneous development of autoantibodies directed against factor VIII.
Aims: To identify at the demographics, presenting features and bleeding characteristics of patients with Acquired Hemophilia referred to the Haematology Unit at Ampang General Hospital, over a 10 year period.
Methods: The list of patients with acquired factor VIII inhibitor who were treated from June 2005 to May 2015 was identified and their case notes were then retrieved from the medical records of the hospital.
Results: Between 2005 and 2015, 28 patients from Kuala Lumpur were diagnosed with acquired factor VIII inhibitors. The population of Kuala Lumpur is 1,501,800 (Population Statistics 2003) giving an incidence of 1.8 cases /million/year.The patient demographics are shown in Table 1.Ten patients (36%) had an underlying associated disease. One was postpartum with history of psoriasis, two had systemic lupus erythematosus, three with bullous pemphigoid, two with thyroid disease, one rheumatoid arthritis and one with a malignant lung nodule. In the remaining 18 patients (64%) were idiopathic. All patients had abnormal bleeding with a total of 54 haemorrhagic episodes. 14 patients had life or limb threatening bleeding: postpartum haemorrhage, iliopsoas haematoma, compartment syndrome, arterial puncture, gastrointestinal bleed and intracranial bleed.

Table 1. Demographics of patients with acquired FVIII inhibitor.

Age(yrs) Mean (range)	58.5(27-80)
Gender Male / Female	16 /12
Inhibitortitre(BU)Median(range)	31.5(1.1-1404)
Median Inhibitor titre (BU) in life/limb threatening bleed	9.7
Median Inhibitor titre (BU) in subcutanoues bleed	51.5

Table 2. Sites of Haemorrhages on Presentation.

Site of bleeding	No. of haemorrhages	Percentage (%)
Ecchymoses	28	52
Soft Tissue Haematomas	5	9
Haematuria	3	5
Intracrannial Bleed	1	2
Iliopsoas Hematoma	3	5
Other Intramuscular hematoma	3	5
Compartment Syndrome	1	2
Postpartum Haemorrhage	1	2
GI Bleeding	5	9
Bleeding post procedure / arterial puncture	3	5
Bleeding from injury	1	2

Summary/Conclusions: Over a 10-year period we treated 28 patients with acquired hemophilia with an estimated incidence of 1.8/million/year. The median age of was 58.5 years, with a male preponderance(57%). It was associated with an underlying disease in 36% of cases. Life or limb threatening haemorrhages were seen in 50% of patients. Factor VIII level and inhibitor titre at presentation did not predict severity of bleeding.Mortality rate was 15%; all patients died of complications related to bleeding and treatment. It is important to recognize and diagnose this disorder, as appropriate treatment will give a favorable outcome; failing which it can be fatal.

E993

CONTRIBUTION OF HEMODILUTION, FIBRINOLYSIS, ACIDOSIS, AND HYPOTHERMIA TO DERANGEMENT OF CLOT FORMATION IN THE *IN VITRO* MODEL OF TRAUMA-INDUCED COAGULOPATHY

I Budnik[1,*], B Shenkman[2], U Martinowitz[2]
[1]Department of Pathophysiology, Sechenov First Moscow State Medical University, Moscow, Russian Federation, [2]National Hemophilia Center and Institute of Thrombosis and Hemostasis, Sheba Medical Center, Tel Hashomer, Israel

Background: Trauma-induced coagulopathy (TIC) develops often after major trauma and may be diagnosed before any therapeutic intervention is provided. Pathophysiology of TIC includes tissue injury and severe hypoperfusion which cause endothelial activation of the protein C pathway and release of tissue plasminogen activator (tPA) resulting in systemic anticoagulation and hyperfibrinolysis. Subsequent hemodilution due to massive transfusions as well as hypothermia and acidosis exacerbate the hemostatic derangement and may lead to uncontrollable postoperative hemorrhage in severely traumatized patients.
Aims: To investigate the relative contribution of hemodilution, fibrinolysis, acidosis, and hypothermia to the derangement of clot formation in the in vitro TIC model.
Methods: The study was approved by the local research ethics committee. Citrated venous blood was obtained from adult healthy volunteers who signed an informed consent form. The in vitro TIC model included hemodilution combined with hyperfibrinolysis, acidosis, and hypothermia. Hemodilution (40%) was produced by mixing the blood with TRIS/saline solution. Fibrinolysis was induced by treating the blood with 165 ng/mL tPA. Acidosis (pH 7.0–7.1) was produced by treating the blood with 1.2 mg/mL lactic acid. Hypothermia (31°C) was achieved by setting the appropriate temperature while running the test. Intact blood tested at 37°C served as control. Clot formation was evaluated using rotational thromboelastometry (ROTEM) device (Pentapharm, Germany). Clotting time (CT, s), maximum clot firmness (MCF, mm) and lysis onset time (LOT, s) were measured using the EXTEM test with 1:50 pre-diluted reagent and presented as Mean±SD.
Results: In control, CT was 349±66 s, and none of the factors (hemodilution alone or in combination with tPA-induced fibrinolysis, hypothermia, and/or acidosis) affected this parameter. In control, MCF was 64±3 mm. Hemodilution reduced MCF to 54±4 mm ($P<0.001$ *vs* control). Combination of hemodilution and hypothermia produced the same effect. Combination of hemodilution and hyperfibrinolysis reduced MCF to 46±7 mm ($P<0.001$ *vs* hemodilution alone). Combination of hemodilution, hypothermia, and hyperfibrinolysis had the greatest inhibitory effect on MCF reducing it to 38±8 mm ($P<0.001$ *vs* combination of hemodilution and hyperfibrinolysis). Acidosis did not modify the effect of the other factors on MCF. No clot lysis was observed in control. Hemodilution did not lead to clot lysis unless hyperfibrinolysis was induced; in these conditions, LOT was 1766±324 s. When additionally combined with hypothermia, LOT was prolonged to 2380±530 s ($P<0.001$). Acidosis had no effect on LOT at either blood temperature.
Summary/Conclusions: Differential effect of TIC constituents on clot formation is revealed. Latent processes that precede clot formation (CT) were not affected by any of the factors studied. Clot strength (MCF) was reduced in the presence of hemodilution, further reduced if combined with hyperfibrinolysis, and maximally reduced if additionally combined with hypothermia. tPA-initiated clot lysis was delayed by hypothermia. Acidosis had no effect on clot formation. The data presented may be helpful to better understanding the pathogenesis of TIC and elaboration of individually-tailored treatment strategy.

E994

DIRECT ORAL ANTICOAGULANTS THERAPY AFTER INTRACRANIAL HAEMORRHAGE WHILE ON VITAMIN K ANTAGONISTS

E Gómez, P García-Ramirez, A Zabalza*, M Redondo, I Quispe, P Arregui, MC Montoya, M Alvarellos, DP Millacoy, MJ Paloma
Servicio de Hematología, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Restarting antithrombotic therapy after an intracranial haemorrhage while on vitamin K antagonists (VKA-ICH) treatment is challenging in many cases. When cardioembolic risk is high (CHADS2-Vasc ≥3) antithrombotic therapy should be offered to these patients. The lower rate of intracranial bleeding of direct oral anticoagulants (DOACs) compared to warfarin reported in recent phase III randomized trials for patients diagnosed of non valvular atrial fibrillation (NVAF), probably make these drugs a safer option to treat VKA-ICH patients.
Aims: The objective of this retrospective, observational study is to evaluate the efficacy and safety of restarting oral anticoagulation treatment with DOACs in NVAF patients with a high cardioembolic risk and a previous VKA-ICH episode.
Methods: From October 2012 until January 2016 a total of 23 patients at the Complejo Hospitalario de Navarra were treated with DOACs after a VKA-ICH episode while on treatment with the VKA acenocoumarol (sintrom®). We analysed the following variables: INR on admission, the time in the therapeutic range (TTR), the rate of spontaneous or posttraumatic ICH, the use of reversal drugs on admission, the median days to restart oral anticoagulation, and the cumulative incidence of a second ICH following the restart of anticoagulation treatment.
Results: 23 patients with intracranial hemorrhage during treatment with VKA restart anticoagulation with a DOAC at our institution. The median age was 78 (68-89), 56.5% were male. All patients had been treated with a VKA antagonist for NVAF with a median CHADS2VASc score of 4 (2-7) and a median HASBLED of 3 (1-5). The mayority of ICH events ocurred spontaneously (65.2%). In contrast, 34.8% ICH occurred after trauma. Only one patient in our cohort had a lobar ICH. International normalized ratio (INR) on admission was infratherapetic in 26% (n=6), therapeutic in 52.2% (n=12) and supratherapetic in 21.7% (n=5). The mayority of cases were managed at the Emergency room with non activated prothrombin complex concentrate (PCC) (73.9%) as reversal agent with a median dose of 24.6 UI/kg (9.68-37.5) in combination with 10 intravenous mg of vitamin K. (Table 1). The median days to restart oral anticoagulation with a DOACs after an ICH was 42 (4-521). 17.4% rivaroxaban (n=5), 4.3% dabigatran (n=1) and 73.9% apixaban (n=17). With a median follow up of 32.88 months (3-88.58) the cumulative incidence of a second ICH was 7.1% (standard error 6.9%). Only 2 patients in our cohort had recurrent spontaneous ICH, one under rivaroxaban 15 mg once daily and a second one while on apixaban 2.5 mg bid, at 19 and 43 months after restarting DOACs, respectively. No thromboembolic event was recorded during the follow up in our cohort. (Table 2).

Tables.

Table 1: Patient characteristics

	ICH (n=23)
Sex, male (%)	13 (56.5%)
Age , median (range)	78 (68-89)
CHADS2 VASc, median (range)	4 (2-7)
2-3 points (%)	10 (43.5%)
≥ 4 points (%)	13 (56.5%)
HASBLED, median (range)	3 (1-5)
INR on admission, range	2.15 (1.6 - 3.5)
Therapeutic values (%)	12 (52.2%)
Infratherapeutic values (%)	6 (26%)
Supratherapeutic values (%)	5 (21.7%)
TRT	
≥ 65% (%)	13 (56.5%)
< 65% (%)	4 (17.4%)
Trauma (%)	8 (34.8%)

Table 2: DOAC treatment

Switch to (%)	
Rivaroxaban	5 (17.4%)
Dabigatran	1 (4.3%)
Apixaban	17 (73.9%)
Therapeutic doses (%)	18 (78.3%)
Restart of DOAC, days, median (range)	42 (4- 521)

Summary/Conclusions: The use of direct oral anticoagulants after an ICH is a safe option for long-term anticoagulation treatment in patients with non-valvular atrial fibrillation at high risk of ischaemic stroke. However, further studies are required to assess longer-term efficacy and safety of DOAC after an ICH.

E995

BEVACIZUMAB AS TREATMENT IN REFRACTORY HEREDITARY HAEMORRHAGIC TELANGIECTASIA

E Castillo[1,*], J Prada-Arismendy[2]
[1]Unidad de Oncología y Hematología, Hospital Manuel Uribe Ángel, [2]Grupo de Investigación e Innovación Biomédica, Instituto Tecnológico Metropolitano, Medellin, Colombia

Background: Hereditary Hemorrhagic Telangiectasia (HHT) is a dominantly inherited vascular disorder characterized by recurrent epistaxis, cutaneous telangiectases and visceral arteriovenous malformations (AVMs) that affect many organs: lungs, gastrointestinal tract, liver and brain. Diagnosis is definitive if at least 3 of the following are fulfilled: spontaneous and recurrent epistaxis, telangiectasia, family history and visceral lesions. Although the disease is highly penetrant, during the first years of life, only 50% of individuals have symptoms. Although 80% of patients have gastric or small bowel telangiectases, only 25-30% of patients develops symptomatic gastrointestinal bleeding. Treatment of these patients is based on iron therapy and secondary use of medications such as Hormone Replacement Therapy, antifibrinolytic, tamoxifen, interferon, sirolimus and endoscopic cauterization. There are few clinical studies that clarifies therapeutic measures in these patients, and that is why the best available scientific evidence is based on case reports.
Aims: This is the case of a patient with refractory HHT, who presented severe gastrointestinal bleeding, which was successfully treated with Bevacizumab
Methods: A 67 year-old man with history of Chronic Obstructive Pulmonary Disease, hypertension, diabetes mellitus, hypothyroidism, right-sided heart failure and HHT which was diagnosed 11 years ago. HHT was initially characterized by epistaxis, skin telangiectases and occasional events of gastrointestinal bleeding. The patient had received repeated nasal and esophagogastric cauterizations, but there was scarce response and it was necessary recurring blood transfusions. Diagnosis was confirmed, and multiple palate, esophagus, stomach and duodenum bleeding angiodysplasias were found. Laboratory tests demonstrated iron deficiency and anemia. The patient was on parenteral iron supplementation every week, without obtaining any benefit.
Results: The patient was admitted every week in emergency service with hemorrhagic shock (Hemoblobin (Hb) levels between 3.5 to 6 g/dL), receiving between 3-4 blood units every week. The patient received oral thalidomide 200 mg/day during 2 months with no benefit, persisting low Hb levels despite numerous transfusions, and he was diagnosed with hepatic and pulmonary AVMs. Bevacizumab was initiated 5 mg/kg every 14 days for 6 doses. Hb rose to14 g/dl during the first week of treatment and it has been stable since then, the patient has been independent of blood transfusions for 8 months, decreasing hepatomegaly and right heart failure.
Summary/Conclusions: Bevacizumab is a humanized recombinant monoclonal antibody against VEGF, which plays an important role in angiogenesis. It inhibits endothelial cell proliferation thus preventing vessel growth and causing regression of existing vessels. HHT is characterized by high serum and tissue levels of VEGF, that is why Bevacizumab is a reasonable agent to consider for the treatment of HHT. To our knowledge, this is one of the first cases reported of intractable HHT with gastro-intestinal hemorrhage efficiently treated using bevacizumab. Some cases of epistaxis with anemia successfully treated with bevacizumab has been reported. Others works have reported that administration of bevacizumab in patients with HHT associated with severe hepatic AVMs and high cardiac output, was associated with reversal of high-output cardiac failure related to hepatic shunting. Nevertheless, longer follow-up studies are necessary to determine the duration of HHT efficacy and whether maintenance therapy is required.

E996

PREDICTION OF INHIBITORS IN UKRAINIAN HAEMOPHILIA PATIENTS

O Stasyshyn*
Surgery, SI "Institute of blood pathology and transfusion medicine of UNAMS", Lviv, Ukraine

Background: Replacement therapy in hemophilia patients (pts) is complicated by the factor VIII (IX) inhibitors among 30% of hemophilia A pts and 3-5% of hemophilia B pts. The treatment of bleeding and elimination of inhibitors is complicated, costly and not always successful.
Aims: To develop a simple score that stratifies hemophilia pts according to their risk of developing inhibitors.
Methods: 135 pts with hemophilia A and B was divided into two groups: I -74 pts with inhibitor and II –61 pts without inhibitor. We analyzed 16 risk factors to develop inhibitor: type of hemophilia (A or B), severity, age, age at diagnosis, hereditary or sporadic, family history of inhibitors, intensive treatment at initial treatment- days of exposure (ED) /1 episode), age at first exposure to FVIII/IX, reason for first treatment with FVIII, FVIII/IX product type, prophylaxis or "on demand" treatment, factor concentrate switching, significant and life-threatening bleeding localization; surgery: I-urgent or selective; II - major or minor, the purulent complications. To examine the relationship between risk factors and the likelihood of inhibitor development, we used regression models of discrete choice. Specifically, we estimate the range of one factor binomial choice models to study the individual effects of each factor on the probability of inhibitor development. In addition, we analyze the joint impact of risk factors using multiple logit regression that allows to explore the effects and importance of each factor, controlling for the presence of other factors. Adequacy of logit models was conducted using chi-square test, and the significance of regression coefficients was based on Student Wald statistics. Finally, we calculated the theoretical values of probability of an inhibitor development for each patient and ranges (95% CI) of predicted risk of inhibitor development in pts with the value of the dependent variable "yes" and "no".

Results: The first model includes the following factors: age, clotting factor concentrate switching, FVIII/IX product type, purulent complications and the number of ED / 1 episode of bleeding. At 5% significance level, the type of surgery (minor/major) as well as positive "inhibitory" history are added. At the 10% significance level, the model additionally contains a variable characterizing the urgency of surgery (urgent or planned). In this approach, the factors that determine the type of hemophilia, age, diagnosis and life-threatening bleeding are not significant and therefore, we do not include them in the final multivariate regression. The number ED / 1 episode has the highest impact on the probability of inhibitor development: if it increases, the likelihood of inhibitor development increases by 27%. For patients who changed the type of concentrates, the likelihood of inhibitor development increases by 23%. The effect of the FVIII/IX product type, the age and the type of the surgery - is negative and significant, while purulent complications and "inhibitory" history result in the increase in the likelihood of inhibitor development by 21% and 12%, respectively. This multivariate logit model allows to predict the likelihood of developing an inhibitor for a pts based on the information about the values of each of these factors.
Summary/Conclusions: According to our model, the factors associated with treatment have the highest impact on the probability of inhibitor development. Based on the results, reducing the frequency of inhibitors can be achieved by changing the approaches to the treatment of pts with hemophilia.

E997

ACQUIRED ISOLATED PROTHROMBIN DEFICIENY IN A PATIENT WITH FOLLICULAR LYMPHOMA SUCCESSFULLY TREATED WITH IMMUNOCHEMOTHERAPY

K Müller[1,*], G Eiling[1], C Schröder[1], B Oldenkott[1], E Langer[2], KM Derwahl[1], F Nolte[1,3]
[1]Internal Medicine, St. Hedwig Hospital, [2]Laboratory Berlin, Charité Vivantes GmbH, Berlin, [3]Medical Faculty Mannheim of the University of Heidelberg, Mannheim, Germany

Background: Acquired haemophilia is rare bleeding disorder, that is caused by autoantibodies against clotting factors. Approximately 50% of cases are associated with either malignancies, autoimmune diseases or pregnancy, respectively. However, half of the cases remain idiopathic. While in the vast majority autoantibodies are directed against factor VIII leading to acquired haemophilia A, acquired prothrombin (factor II) deficiency is a rare event and information on treatment outcome is scarce.
Aims: Here we report on a case of a patient with follicular lymphoma and an acquired isolated prothrombin deficiency suffering from severe bleeding complications, who was successfully treated with immunochemotherapy.
Methods: A 73-year old female patient was diagnosed with a grade I-II asymptomatic follicular lymphoma stage IV (intermediate risk according to FLIPI) in July 2015. In November 2015 the patient was admitted to our hospital due to macro haematuria and pain in the distal right thigh. The patient did not remember any trauma but MRI showed an intramuscular haematoma. Laboratory testing revealed decreased Quick values (32%) and a prolonged activated partial thromboplastin time (aPTT: 64 sec.) as compared to August 2015 (Quick 100%; aPTT 26 sec.) Since the patient received no anticoagulant treatment and diet-related vitamin K deficiency could be ruled out, single factor analyses were performed and showed an isolated prothrombin deficiency, which was confirmed by repeated analyses. Lupus anticoagulants were negative, as were analyses with regard to von-Willebrand-Jürgens syndrome. Moreover, the patient developed a haemoglobin relevant gastrointestinal bleeding with gastroscopy showing a diffuse bleeding in the fundus reflecting the haemorrhagic diathesis due to the coagulopathy. The patient received repetitive prothrombin substitution with prothrombin complex concentrates leading to transient stabilization of the coagulation system. Eventually she was subjected to successful surgical revision of the muscular haematoma. Although inhibitory antibodies were not detectable we assumed an association of the coagulopathy with the concomitant FCL and initiated an immunochemotherapy with rituximab and bendamustine in December 2015.

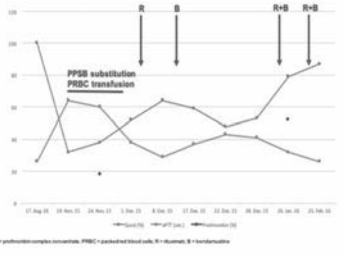

Figure 1.

Results: Repetitive evaluation of coagulation parameters and prothrombin activity showed a successive improvement of the respective parameters after the first cycle of treatment (Figure 1). Since December 2015 no prothrombin substitution was necessary and prothrombin activity increased from 18% in November 2015 to 52% by January 2016. Currently, the patient has no signs of haemorrhage or relapse of the coagulopathy with continuous improvement of the global coagulation parameters.
Summary/Conclusions: Although rare events, isolated clotting factor deficiencies should be considered in cases of unexplained coagulopathy in patients with malignancy in general and malignant lymphoma in particular. Treatment of the underlying lymphoma by immunochemotherapy can reverse the haemophilic state in patients with NHL.

E998

THE BLEEDING SPECTRUM OF 21 EGYPTIAN PATIENTS SUFFERING FROM CONGENITAL AFIBRINOGENAEMIA: A 10-YEAR RETROSPECTIVE STUDY

M Abdelwahab[1,*], A Casini[2]
[1]Pediatric Hematology, Cairo University Pediatric Hospital, Cairo, Egypt, [2]University Hospitals and Faculty of Medicine of Geneva, Switzerland, Geneva, Switzerland

Background: Congenital afibrinogenaemia has an estimated prevalence of one in 1,000000. The afibrinogenemic patients' phenotype is mainly characterised by bleeding but thromboses, bone pain and delayed wound healing have also been reported
Aims: To describe the phenotypic spectrum and bleeding incidence of an Egyptian afibrinogenaemic cohort
Methods: All patients with a confirmed congenital afibrinogenaemia (based on fibrinogen levels and genotype) were included. Patients were followed regularly every 1-12 months over a period of 1 to 10 years. All bleeding episodes and fibrinogen replacements were recorded.
Results: Twenty-one patients (13 males, 8 females) with a mean age of 12.9 years from 15 consanguineous families were included.They were followed for a median period of 9 years.The bleeding phenotype was characterized by umbilical bleeding (65%), oral bleeding and epistaxis (45%), central nervous system haemorrhage (25%), joint bleeds (25%), hematochezia (10%), peritoneal bleeding (10%), hematuria (5%), spinal hemorrhage (5%), muscle bleeds (5%). Most women in child bearing period reported menorrhagia (75%). In addition, 15% of patients experienced a delayed wound healing and all had post-traumatic bleeding. Half of patients (57%) had atypical bleeds in the form of spontaneous unexplained severe bone pain in forearms and lower limbs, relieved by fibrinogen replacement. Overall, the incidence of severe bleeding varied from 1 to 5 bleeds/pt/years although one patient had weekly hemorrhages. No patients had arterial or venous thrombosis. All patients were on demand therapy but one with recurrent cerebral bleeding on biweekly prophylaxis. Replacement fibrinogen included cryoprecipitate 15-20 mg/kg/d for mild to moderate bleeds and 30mg/kg/12-24 hours for severe/serious bleeds for a period ranging from 1-5 days.
Summary/Conclusions: Our cohort showed a wide phenotypic spectrum with high prevalence of cerebral bleeding. The absence of thrombosis is possibly explained by the young age of patients. We confirmed that bone pain is a frequent complication of afibrinogenaemia. Optimal management of this symptom require further investigations.

E999

HEALTH RELATED QUALITY OF LIFE IN GREEK CHILDREN WITH HAEMOPHILIA AND THEIR CAREGIVERS

A Papagianni[1,*], M Economou[1], A Teli[1], H Platokouki[2], H Pergantou[2], D Niakas[3], A Varaklioti[3,4]
[1]1rst Pediatric Department, Ippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, [2]Haemostasis Unit, Haemophilia Centre, "Aghia Sophia" Childrens' Hospital, Athens, [3]Faculty of Social Sciences, Hellenic Open University, Patras, [4]Blood Center and National Centre for Congenital Bleeding Disorders, Laiko General Hospital, Athens, Greece

Background: Health-related Quality of Life(HRQoL) has become an important outcome in every day clinical practice.
Aims: The aim of the study was the assessment of health-related quality of life (HRQoL) in children with haemophilia and their caregivers in Greece, using a disease-specific questionnaire and the investigation of demographic and clinical factors that affect their HRQoL.
Methods: The study was conducted in two national pediatric haemophilia centers, in Thessaloniki and Athens [and included 45 children and their parents] The Greek version of the Hemophilia-Specific Quality of Life Index (Haemo-QoL) questionnaire was administered to 45 pediatric patients aged 4 to 16 years and their parents. The latter filled in a questionnaire with demographic data (child's and parent's age, residence, number of siblings-whether sick or not, marital status, education level, employment) and clinical data of the patient, namely type of haemophilia, severity, presence or history of inhibitor, type of treatment, number of haemarthrosis over last 12 months, presence of chronic pain). Statistical analysis of the results was performed using SPSS 19.0.
Results: Overall, patients and caregivers had a mean age of 10.46±4.3 and 39.51±7.4 years respectively. 86.7% of patients had haemophilia A and 77.8%

were on prophylaxis treatment. HRQoL scores were found to be widely below 40 for children and below 50 for their caregivers in all dimensions. "Family" and "Treatment" had the highest scores (mean scores 57.7 and 46.2 respectively), suggesting reduced quality of life in these dimensions in age group 4-7. The most impaired domain of Haemo-QoL in age group 8-12 was "Perceived Support" (mean score 40.63), while the older children were more impaired in "Family" and "Treatment", but much less so than the younger ones (mean scores 36.1 in both domains). The least impaired dimensions were "Self-view", "Other people" and "Relationships" among the three groups. Cronbach's alpha coefficient was assessed for every subscale and in total, suggesting sufficient/very good internal consistency reliability of the Greek version of Haemo-QoL. Among Haemo-QoL subscales, "Perceived Support" in age group 8-12 and "Sports/School" and "Relationships" in the adolescent group were found strongly associated with the number of haemarthrosis over the previous 12 months.

Summary/Conclusions: The use of a disease specific QoL tool showed that children and their caregivers report a relatively good quality of life, with "family" and "treatment" being the most impaired especially in the younger age group. The number of haemarthrosis over the previous year is a clinical characteristic which impairs some of the aspects of quality of life, especially in the adolescent group. These data are important for the future planning of treatment regimens as well as the psychological support of patients and their families.

E1000

ANTIPHOSPHOLIPID ANTIBODIES IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

S Sahinkaya, H Tokgoz*, U Caliskan
Pediatric Hematology and Oncology, Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey

Background: Presence of antiphospholipid antibodies (APAs) has been observed in children with immune thrombocytopenic purpura (ITP), but their role for the outcome of disease is controversial.

Aims: The aim of this study was to evaluate the relation between APAs and the clinical course, labarotory findings, response to treatment and prognosis of ITP in childhood.

Methods: The cross-sectional study included to patients with newly diagnosed ITP aged between 0-18 years, in the period of time between March 2014 and March 2015, at our centre. Clinical and laboratory findings, medical treatments, and the course of the diseases were recorded for all patients. At the time of diagnosis, anti-phospholipid antibodies including lupus anticoagulant, anticardiolipin antibodies (aCL), anti-beta-2 glycoprotein I antibodies were studied. The patients who have positive results for APAs at diagnosis were examined again for APAs at 12th week of follow-up period.

Results: Forty children (21 (52.5%) females and 19 (47.5%) males) with newly diagnosed with ITP were enrolled the study. APA levels were positive at 12 patients (30%) at the time of diagnosis. Among the APA positive patients, only one patient had all of three APAs, one patient had both aCL IgM and LA, 10 patients had single positive results for APAs (figure 1). Among APA positive patients, the positivity of anti beta 2 glycoprotein I, aCL and LA were 58.3%, 16.7%, and 8.3% respectively. After 12 week, only 3 of these 20 cases were still positive for APA. One of them was positive both LA and anti beta 2 glycoprotein I, and two of them were positive for anti beta 2 glycoprotein I IgG. There was not a significant difference between APA positiveness (at the time of diagnosis and control) and gender groups, platelet counts, IgG levels or course of disease. At the time of diagnosis, mean age of APA positive patients was significantly higher than in APA negative patients ($p<0.05$). According to age interval; there was three patients aged between 0-1 year and none of them were APA positive. At the time of diagnosis, APA positiveness was found in 7 of 28 (25%) patients aged between1-9 years, and 5 of 9 patients (55.5%) aged between 9-18 years. There was no relationship between APAs and treatment response or outcome of disease.

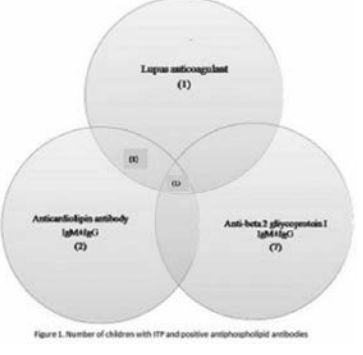

Figure 1. Number of children with ITP and positive antiphospholipid antibodies

Figure 1.

Summary/Conclusions: Unlike in adults, pediatric studies about APAs and ITP are limited. APAs may be present in children with ITP. It may be related to underlying viral infections or idiopathic, and more common in adolescence. The persistence of APAs may contribute to thrombotic complications in the future. More comprehensive studies are needed to determine the relationship between APAs and İTP.

E1001

FUNCTIONAL PLATELET ACTIVITY ANALYSIS IN CHILDREN WITH BLEEDING

P Zharkov*, I Demina, M Panteleev
Federal Research Clinical Centre Of Pediatric Hematology Oncology And Immunology N.A. D. Rogachev, Moscow, Russian Federation

Background: Diagnosis in a bleeding child without thrombocytopenia or clotting factor deficiency is always challenging. In these cases using a platelet flow cytometry (PFC) method might be helpful because it can detect several glycoprotein deficiencies on platelet surface and confirm the diagnosis of platelet dysfunction. Here we present a case series of patients with bleeding due different platelet disorders, established by a modification of PFC method-functional platelet activity analysis (FPAA).

Aims: to asses the role of a modification of platelet flow cytometry (PFC) method-functional platelet activity analysis (FPAA) in children with bleeding.

Methods: 32 patients (1-17 yo) with mild to severe bleeding without von Willebrand disease, factor XIII deficiency, or other coagulopathy were included. Whole blood platelets were studied by FC either in native or activated with collagen-related peptide (0.18 µg/ml) and thrombin receptor activating peptide (12.5 µM). Fluorescencently labeled antibodies against CD42b, CD61 and PAC-1, phosphatidylserine (PS) and CD62p were used; dense granule (DG) release was studied using loading with mepacrine.

Results: After FPAA from 32 children 2 pts were excluded because of normal results and 1 because of preanalytical issues. From those 29, 4 pts were diagnosed with CD61 deficiency, and 25-with different granule defects. Isolated deficiency or mobilization defect of dense and alpha granules was found in 9 and 4 children, respectively. Combined storage pool deficiency/mobilization defect (CSPD/MD) was diagnosed in 8, while we found 1 combination of CSPD/MD and PAC-1 deficiency, and 3 combinations of CSPD/MD and PS deficiency.

Summary/Conclusions: Different platelet disorders could be found in up to 93,5% of patients with bleeding without clotting factor deficiency. Most of the alterations include storage alpha/dense granule pool deficiency/mobilization defect or CSPD/MD.

E1002

SAFETY AND EFFICACY OF B-DOMAIN DELETED 3RD GENERATION RECOMBINANT FACTOR VIII (GREENGENE FTM) IN KOREAN PATIENTS WITH HAEMOPHILIA A: DATA FROM A POST-MARKETING SURVEILLANCE STUDY

SK Kim[1,*], SK Park[2], KY You[3], TJ Hwang[3], YM Choi[4]
[1]Dept. of Pediatrics, Inha University Hospital, Incheon, [2]Dept. of Pediatrics, Ulsan University Hospital, Ulsan, [3]Dept. of Pediatrics, [4]Internal Medicine, Korea Hemophilia Foundation, Seoul, Korea, Republic Of

Background: New B-domain deleted 3rd generation recombinant factor VIII (GreenGene F™, beroctocog alfa) was launched in 2010.

Aims: This clinical trial evaluated the safety and efficacy of GreenGene F™ in patients with haemophilia A over a period of 12 months.

Methods: From July 2010 to July 2014, a total 136 hemophilia A patients were enrolled in the post marketing surveillance (PMS) study and were analyzed for safety of the drug. Among them, 114 patients were analyzed for efficacy. Subjects with differing haemophilia A severities and medical histories were monitored during 12 months of prophylactic and/or on-demand therapy. Efficacy was rated by their doctors with 4 scales as excellent, good, moderate, or no effect.

Results: Among 135 evaluable subjects, 85 (63.0%) had severe haemophilia, 35 (25.9%) had moderate haemophilia and 15 (11.1%) had mild haemophilia. Excellent/good efficacy rate was 91.3% for hemostasis and 89.4% for hemorrhage prevention. Twelve subjects reported 13 adverse drug reactions (ADRs), which were recovered without sequelae. The frequent ADRs were gastrointestinal disorders, nervous system, vascular disorders and general disorders. In 113 previously treated patients (PTP), two patients (1.8%) developed inhibitors after intensive FVIII treatment for surgery and hematuria, respectively.

Summary/Conclusions: The results of this PMS study support that GreenGene F™ is safe and efficacious in the treatment and prevention of patients with hemophilia A. The results of this study are consistent with the previously published GreenGene F™ studies.

E1003

FACTOR XI DEFICIENCY IN PREGNANCY: THREE CASE REPORTS

A Poz[1], M Turello[2], A Bertone[2], G Barillari[2,*]

[1]Department of medical and biological sciences (DSMB), University of Udine, [2]Center for Hemorragic and Thrombotic Diseases, University Hospital of Udine, Udine, Italy

Background: Management of pregnant women with factor XI deficiency (F11D) poses a challenge to the clinician because of both the variabile uterine bleeding during labor and the risk associated with factor replacement. Hemoleven® is a factor eleven (FXI) concentrate processed by deep filtration and ion exchange chtomatography, with double viral inactivation performed using solvent detergent and nanofiltration. It represents a good treatment for protecting against bleeding, but the potential risk of thrombosis shoul be considered.
Aims: We present the cases of three women with F11D and a history of bleedings, where the efficacy and safety of Hemoleven® treatment was assessed during pregnancy and labor.
Methods: During labor, the drug was administered together with tranexamic acid.
Results: In case 1 the woman was diagnosed as F11D when she was 10, with a plasma FXI level less than 1% and an omozygote phenotype. The 34 year old primagravidae had an uneventful pregnancy, and she was admitted at 39+1 weeks of gestation. When cutting the umbelical cord, antihaemorragic prophylaxis was performed with 1 g of tranexamic acid, intravenously injected, and 1000 UI of Hemoleven. 1 g of tranexamic acid was then administered every 8 hours, from the first to the eighth day post-partum, while 1000 UI of Hemoleven were given during the second and the fifth day post-partum.In case 2, a 26 year old primagravidae had an uneventful pregnancy, but she was admitted at 38+4 weeks of gestation due to a very big condylomatosis. She was diagnosed as F11D at the age of 17, with a plasma FXI level of 42% and an heterozygote phenotype. Despite FXI level, she had an hemorragic phenotype. Caesaren section was planned and performed at the day of admission, in general anesthesia. 30 minutes before the delivery started, 1000 UI of Hemoleven were infused, and 1 g of tranexamic acid was administered intravenously ad the beginning of the procedure. After caesarean section, 1 g of tranexamic acid was given every 8 hour till the seventh day.In case 3, a 36 year old woman had an uneventful second pregnancy, and she was admitted at 39 weeks of gestation. She was diagnosed as F11D at the age of 31, with a plasma FXI level of 30%. Vaginal delivery was induced with oxitocin. After umbelical cord excision, 1000 UI of Hemoleven were infused and 1 g of tranexamic acid was given intravenously. Subsequently, 1 g of tranexamic acid was then administered every 8 hours, from the first to the seventh day post-partum.
Summary/Conclusions: Neither post-partum haemorragy nor thrombotic events were evident in all the three cases, thus confirming safety and efficacy of clotting factor eleven concentrate. Hemoleven® dose and duration of treatmen was alway carefully decided before delivery, with a management plan shared between haemostasis experts, obstetrics, and the patients. Considering our experience, the benefit/risk ratio of Hemoleven® should be weighted and management tailored to each individual patient.

E1004

SERUM CYTOKINE AND CHEMOKINE LEVELS IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA

A Komitopoulou[1,*], A Bartzeliotou[2], E Pergantou[1], I Farakla[2], I Papassotiriou[2], H Platokouki[1]
[1]Hemophilia Center and Hemostasis Unit, [2]Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, Athens, Greece

Background: Immune thrombocytopenia (ITP) is an acquired immune disorder derived from disruption of platelet production and removal from blood circulation, usually as a consequence of autoantibody and cytotoxic T-lymphocyte development against them, which ultimately results to the phagocytosis of the trapped platelets from monocytes. Onset of ITP in children is often triggered by viral infections, infectious diseases or vaccination. In pediatric patients with ITP, as in adults, impaired immunity by deregulation of the balance of Th1/Th2 (T-helper) and of Tregs (regulatory T cells) is referred. The cytokines which are secreted by activated lymphocytes control the immune system either by stimulating or inhibiting the activity of cells but simultaneously they are involved in the production of antiplatelet antibodies or other cytokines and/or chemokines.
Aims: The aim of our study was to determine the serum levels of specific Th cytokines and chemokines in children with ITP and to correlate them with clinical parameters.
Methods: The group of patients consisted of 18 children with ITP (8 male,10 female) of a mean age at investigation 5.46 years. ITP was chronic in 6/18 children, while acute/persistent was in 12/18 (duration of thrombocytopenia>12 or<12 months, respectively). None but one patient had received any treatment during the last 3 months. The control group was constituted by 37 children of preschool age. Serum levels of cytokines IL-1a, TNF-a, IL-1b, IL-10, IL-12p40, hsIL-6 and chemokines of macrophages such as IL-8 (CXCL8) and MCP-1 (CCL2) were measured in patients and controls using the cytokine-chemokine-MAP technology which is a bead based multiplex assay using the Luminex. Inform consent was obtained from the parents of both groups.
Results: There was no significant difference in the concentrations of IL-1a, Il-1b, IL-10, IL12p40 and the chemokine IL-8 among the two groups, except of the concentration of TNF-a which was found quite lower among patients and controls. Furthermore, only the levels of TNF-a differed remarkably between children with acute/persistent compared to children with chronic ITP ($p<0.05$). A significant reduction of hsIL-6 (1.0±0.2 *vs* 1.6±0.2pg/mL, $p<0.05$) and MCP-1 (252.7±20.0 *vs* 408.5±22.2pg/mL, $p<0.001$) was noticed in children with ITP.
Summary/Conclusions: The current study did not seem to confirm the hypothesis of the overall increase of proinflammatory cytokines in children with ITP. The higher values of TNF-a in the initial phase of the disease could be interpreted as a response to inflammation. The finding of the dramatically reduced chemotactic protein MCP-1 (CCL2), possibly reveals deficient response in the ability to control inflammation, a conclusion reinforced by a recent study in murine models of human ITP[1]. The exact role of various cytokines/chemokines in the deregulation of the immune system, sush as occurs in autoimmune diseases, remains to be investigated, particularly in children which are often on inflammatory process. Well-designed studies with a larger number of children with ITP and larger subsets of patients at different stages of the disease, as well, which will investigate a wider range of cytokines, may provide useful answers in the future.

COMBINED DEFICIENCY OF FACTOR V AND VIII CAUSED BY TWO NOVEL MUTATIONS AT MCFD2 GENE

Q Li*, R Zhou
The Affiliated Nanjing Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Combined deficiency of coagulation factor V and VIII (F5F8D) is a rare autosomal recessive disorder characterized by a mild-to-moderate bleeding tendency with the reduction of the two factors in plasma. Mutations in LMAN1 and MCFD2 gene account for all F5F8D patients.
Aims: To identify the molecular mutation causing F5F8D in a Chinese pedigree.
Methods: The activated partial thromboplastin time(APTT), prothrombin time (PT) and coagulate activities of coagulation factors of the proband and her parents were detected for diagnosis. PCR was used to amplify the exons and intron/exon boundaries of LMAN1 and MCFD2 genes . The amplicons were sequenced directly and aligned with software chromas 2.
Results: The proband's APTT, PT, FV:C and FVIII:C was 75s, 17s, 9.9% and 5.9%, respectively, while those parameters of her parents were all within the normal range. Sequencing the 13 exons of the LMAN1 gene and 4 exons of the MCFD2 gene from the patient revealed two novel missense mutations. The first one was a heterozygous mutation: g.35T>A, causing the Leu12Glu in exon2 of MCFD2. The second one was a homozygous mutation: g.398A>T, leading to the Asp133Val in exon 4 of MCFD2. The two mutations Leu12Glu and Asp133Val were identified in the compound heterozygous state in her parents.
Summary/Conclusion: The two novel mutations might be the molecular pathological mechanism causing F5F8D in this pedigree.

FALSE HOMOZYGOUS HLA GENOTYPING RESULTS DUE TO LOSS OF HETEROZYGOSITY IN ACQUIRED APLASTIC ANAEMIA

B Heyrman*, A De Becker, S Verheyden, C Demanet
UZ Brussel, Brussels, Belgium

Background: The pathogenesis of acquired aplastic anaemia is driven by T cell-mediated destruction of hematopoietic progenitors. Clonal evolution is known to occur in around 70% of patients. This includes around 12% with loss of heterozygosity (LOH) of chromosome 6p, involving the human leukocyte antigen (HLA) locus. Loss or down-regulation of HLA class I antigens is a way to escape cytotoxic T-cell surveillance. LOH can appear even without previous therapy. In acquired aplastic anaemia it is well studied as a biological phenomenon. LOH appears to have no impact on the course of the disease nor does it predict response to treatment, as results are contradictory in this matter.
Aims: The aim of this case report is to draw attention on possible false HLA genotyping in acquired aplastic anaemia prior to allogeneic hematopoietic stem cell transplantation.
Methods: Repeated HLA genotyping was performed on peripheral blood using flow multiplex DNA typing and sequence-based typing.
Results: We report false HLA genotyping results due to loss of heterozygosity in a 59-year-old female patient of Caucasian origin, presenting with very severe aplastic anaemia. At diagnosis we obtained heterozygous results (A*24, A*33, B*07, B*14, C*07, C*08, DRB1*13, DRB1*15, DQB1*03, DQB1*06). Bone marrow karyotype was normal. After treatment with rabbit anti-thymocyte globulin+cyclosporine, not reaching a partial response at 6 months, we repeated HLA genotyping in order to search for an unrelated donor, because there was no HLA compatible sibling. This time we obtained homozygous results (A*24:02, B*07:02, C*07:02, DQ*06:02,DR*15.01). Repeated testing confirmed loss of HLA genotype heterozygosity. New bone marrow karyotype didn't show alterations in chromosome 6. Monosomy 7 was found, compatible with development of high risk myelodysplastic syndrome-associated cytogenetic abnormalities.
Summary/Conclusions: When homozygous HLA genotype results are obtained in acquired aplastic anemia, confirmatory testing on other somatic cells (eg. buccal swab) is needed to avoid hematopoietic stem cell transplantation with an unmatched donor.

E1006

PREVALANCE OF CHROMOSALLY-INTEGRATED HERPESVIRUS 6 IN PATIENTS WITH APLASTIC ANEMIA

M Bakker[1,*], C Van Leer-Buter[2], M Nijland[1]
[1]Hematology, [2]Microbiology, University Medical Center Groningen (UMCG), Groningen, Netherlands

Background: Aplastic anemia (AA) is a rare heterogeneous bone marrow failure syndrome. It is hypothesized that in most cases AA is an immune-mediated disease. One third of patients, especially those who do not respond to immunosuppressive therapy, have shortening of telomeres in there leucocytes. Mutations in genes responsible for telomere repair proteins are present in some of these patients. Human herpesvirus 6 is one of the herpesviruses which establish latent infection. It is shown that reactivation of latent HHV-6 can have direct suppressive effects on hematopoietic progenitors which can be the cause of bone marrow suppression after hematopoietic stemcell transplantation. Besides latent infection, HHV-6 can integrate in the human DNA at the telomeric region which results in germ-line transmission of the HHV-6 genome. Chromosomally integrated HHV-6 (ciHHV-6) can be found in less than 1% of the population.
Aims: We performed an exploratory study to investigate the prevalence of ciHHV-6 in patients with AA in order to determine whether ciHHV-6 represents a risk factor for developing AA.
Methods: Between 2008 and 2015 101 patients were treated for AA at the University Medical Center Groningen in The Netherlands. Whole blood samples of 53 of these patients that were initially used for clinical purposes were available for analysis by quantitative PCR (qPCR) for the presence of HHV-6 DNA.
Results: Of the 53 samples 11 patients had detectable HHV-6 DNA. Ten patients had a low HHV-6 viral load with median concentration of $1.9x10^2$ copies/ml (range $1.2x10^6$-$2.3x10^4$ copies/ml). One patient had a high viral load with $5.2x10^6$ copies/ml suggestive of ciHHV-6. Viral chromosomal integration was subsequently proved by demonstrating HHV-6 DNA in hair follicles of this patient. In our cohort the prevalence of ciHHV-6 was 1.9%, which is not above the expected incidence of the general population.
Summary/Conclusions: The prevalence of ciHHV-6 in patients with AA is similar to that of the general population. It is therefore unlikely that ciHHV-6 is a risk factor for AA.

Bone marrow failure syndromes incl. PNH - Clinical

Background: Although consensus guidelines have been proposed in 2010 for the diagnostic screening of paroxysmal nocturnal hemoglobinuria (PNH) by flow cytometry (FCM), so far no study has investigated the efficiency of such medical indications in multicentric *vs.* reference laboratory settings.
Aims: To evaluated the efficiency of the current consensus medical indications for diagnostic screening of PNH by FCM
Methods: Overall, information about 3,938 samples from an identical number of individuals prospectively submitted between January 2011 and December 2014 for diagnostic screening of PNH by flow cytometry was collected at 24 flow cytometry laboratories in Spain which participate in the PNH-External Quality Assurance Program of the Iberian Society of Cytometry (1,718 samples) plus one reference laboratory in Sao Paulo, Brazil (2,220 samples). The following GPI-associated markers were analyzed: FLAER (analyzed in 87% of the cases), CD14 (98%), CD16 (37%), CD24 (93%), and/or CD157 (5%). In those cases with GPI-deficient mature neutrophils and monocytes, expression of CD59 (100% of cases) was also analyzed on red blood cells.
Results: Overall, diagnostic screening based on consensus medical indications was highly efficient (567 PNH^+/3,938 screened cases; 14% PNH^+ samples) both in the multicenter setting in Spain (10%) and reference laboratory in Brazil (16%). Although GPI-deficient cells were found within all age groups, a significantly higher frequency of PNH^+ cases was observed among the screened PB samples from individuals ≤40 years *vs.* older cases (18% *vs.* 11%; $p<0.001$) Estimated annual incidence of new PNH cases was be of ≈2.5 cases/million individuals per year. When patients with previously diagnosed hematological associated disorders (mostly AA and MDS) were excluded from the analysis, the annual incidence of PNH was of 0.6 cases per million individuals per year. The highest frequency of PNH^+ cases was observed among patients screened because of bone marrow (BM) failure syndrome (33%), particularly among those with mainly aplastic anemia (243/541; 45%) and to a less extent also myelodysplastic syndrome (26/266; 10%). Among the other individuals studied, the most efficient medical indications for PNH screening included: hemoglobinuria (35/73; 48%), unexplained cytopenias including anemia (88/393; 22%), non-immune hemolytic anemia (71/382; 19%), and thrombosis associated to (non-hemolytic) anemia and/or another cytopenia (10/73; 14%). PNH^+ cases was less commonly observed among patients with chronic myeloproliferative neoplasms (1/21; 4.8%), unexplained cytopenias in the absence of anemia (39/772; 5.1%) or unspecified anemia (17/468; 3.6%). In contrast, only a minor fraction of the patients who had been submitted for PNH testing because of unexplained thrombosis in the absence of cytopenia were positive (3/800; 0.4%).
Summary/Conclusions: In summary, our results demonstrate that the current medical indications for PNH screening by FCM are highly efficient, although

improved screening algorithms are needed for patients presenting with thrombosis and normal blood cell counts.

E1008

POSSIBLE RISK FACTORS FOR THROMBOSIS IN CHINESE PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

Z Long*, Y Du, B Han
Department of Hematology, Peking union medical college, Beijing, China

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease caused by an acquired mutation of the X-linked PIGA gene on the hematopoietic stem cell. The most common cause of morbidity and mortality in PNH is thrombosis, but the exact mechanisms involved in thrombus formation are still unknown, and predisposing factors for thrombosis in PNH patients have yet to be defined.
Aims: To identify high risk factors and susceptibility genes leading to thrombotic formation in PNH.
Methods: Totally, 95 patients with PNH diagnosed between 2009 and 2015 were enrolled in the study. Clinical data like sex, age, hemoglobin level, reticular cell percentage, white blood cell and platelet count, LDH level, CD59- and FLAER-granulocytes percentage, thrombophilia risk factors like level of protein C, protein S, antithrombin III, APC resistance, blood fat, phospholipid antibody were evaluated. Samples from patients were genotyped for the reported 28 alleles in 21 genes including MTHFR, PROC, PROS, F2, F5, prothrombin and other genes which are reported as high risk factors for venous thromboembolism (VTE) by polymerase chain reaction fragment length polymorphism methods (PCR-RFLP).
Results: Of the 95 PNH patients, 19 (20%) patients had at least 1 episode of thrombotic event. Only 3 patients had arterial thrombosis and 16 patients had venous thrombosis. The medium age of patients with thrombosis was 42-year-old, similar to those without (42-year-old, p=0.9947). Male: female ratio was 1.71 in thrombosis group, 1.17 in non-thrombosis group (p=0.6072). Patients with thrombosis had the same disease pattern compared to those without. Although there was no difference in level of hemoglobin (p=0.2512), white blood cell count (p=0.4681), platelet count(p=0.6185), reticular cell count (p=0.6296)and LDH level (p=0.4511) between patients with thrombosis and those without, patients with thrombosis showed higher percentage of CD59-granulocytes (p=0.038)and FLAER- granulocytes (p=0.036) compared to those without. The routine thrombophilia screening tests did not show any difference either between PNH patients and normal controls, or between patients with or without thrombosis. Patients with the TC genotype (rs2519093 in the ABO gene) were approximately 18.5 folds prone to thrombus formation than those with the CC genotype (p<0.0001). In addition, the T allele was found to be a significant risk factor for thrombosis (OR 6.447, 95%CI 2.815-14.76, p<0.0001). No association was detected between other SNPs and risk to thrombosis.
Summary/Conclusions: Compared with non-thrombotic patients, PNH thrombotic patients have similar clinical features except that they have bigger PNH clone. And for the first time, our results suggested that the rs2519093 in the ABO gene confers risk to thrombosis in PNH. Therefore, rs2519093 polymorphism may represent a potential genetic biomarker in PNH patients for thrombus formation.

E1009

POLYMORPHISM OF THE COMPLEMENT RECEPTOR 1 GENE IN CHINESE PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

Y Du, Z Long, J Zhuang, M Chen, B Han*
Department of Hematology, Peking union medical college, Beijing, China

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired genetic disorder of the bone marrow, eculizumab is an effective monoclonal antibody inhibits terminal complement activation through block the distal complement pathway, but the hematologic response to eculizumab is variable. Previous report showed patients with PNH who have rare allele (L) of the *complement receptor 1* (*CR1*) gene, either heterozygotes (H/L) or homozygotes (L/L), displayed more sub-optimal responder to eculizumab compared with common allele (H/H).
Aims: We investigate polymorphism of the *CR1* gene in Chinese patients with PNH in order to determine its potential impact on eculizumab efficiency.
Methods: DNA was extracted from peripheral blood mononuclear cells from 95 Chinese patients with PNH. Rs2274567 and rs3811381 in *CR1* gene were genotyped by polymerase chain reaction fragment length polymorphism methods (PCR-RFLP). Hemolysis factors including hemoglobin level and LDH level were investigated and thrombotic percentage was evaluated between different genotypes.
Results: Of the 95 patients, frequencies of the rare rs2274567 allele (12%) is much lower than Caucasian PNH population previous reported (31%, P<0.0001), and rare allele frequencies of rs3811381 is also significantly lower (12% *vs* 29%, P<0.0001) in Chinese patients. 72(76%) patients were H/H, while 23 (24%) patients were H/L genotype for rs2274567 polymorphism. There were no difference between the two genotypes in hemoglobin level (83.7g/L *vs* 72.8g/L, p=0.0917) and LDH level (1312U/L *vs* 1022U/L, p=0.2682). As for the rs3811381 genotype, there were 71 (75%), 22 (23%) and 2 (2.1%) patients with H/H, H/L, L/L genotype separately. There was no difference among the different genotype groups in the hemoglobin level (83.2g/L, 74.8g/L and 75.5g/L, respectively, p=0.4278) and LDH level (1312U/L, 997U/L,1233U/L, respectively, p=0.5171), either. Although not significantly, the thrombotic percentage tent to increase from H/H to H/L (17% to 30%, p=0.2288) for rs2274567 polymorphism and H/H to H/L to L/L genotype (17%, 27%, 50%, respectively, p=0.3201) for rs3811381 genotype.
Summary/Conclusions: Very rare H/L or L/L genotype of *CR1* was found in Chinese people with PNH. Frequencies of Chinese rare alleles in *CR1* gene were significantly lower than that of Caucasian population, which may indicate a favorable response to eculizumab treatment. No difference of hemoglobin level or hemolysis was found among different genotype groups, but the percentage of thrombosis seemed to increase from H/H, H/L to L/L.

E1010

EPIDEMIOLOGIC OVERVIEW OF CONGENITAL DYSERYTHROPOIETIC ANEMIA-UPDATED DATA FROM THE GERMAN CDA REGISTRY

M Bommer[1,*], R Javorniczky[1], U Keppler[2], K Holzwarth[2], R Leichtle[2], F Theis[2]
[1]Hematology, Oncology and Infectious diseases, Alb-Fils Kliniken Göppingen, Göppingen, [2]Hematology, Oncology, Rheumatology and Infectious diseases, University of Ulm, Ulm, Germany

Background: Congenital dyserythropoietic anemia is a very rare hereditary disorder, leading to ineffective hematopoiesis, anemia and secondary hemochromatosis. According to the classification of Heimpel and Wendt (1968) at least four subtypes (CDA I-III, CDA variant) can be distinguished. Diagnosis is based upon morphological examination of blood and bone marrow. Genetic testing can confirm the diagnosis in many cases: CDA I-CDAN1, C15ORF41; CDA II - SEC23B; CDA III-KIF23; variant-KLF 1, GATA-1. Familial cases are autosomal recessive (CDA I, CDA II), autosomal dominant (CDA III) or variable (CDA variant).
Aims: The aim of this study was to analyze the prevalence of this very rare inherited anemia.
Methods: The German CDA registry was initiated in 1990 by Heimpel and coworkers and includes cases from all over the world. All patients known to the study group since 1967 have been documented. Data analysis is based upon an ACCESS database. Diagnosis was confirmed using the criteria published previously by Heimpel and Anselstetter (2003). From a minority of patients results from genetic testing are available. We analyzed the prevalence of CDA-subtypes in different continents. CDA IV is summarized within the CDA variant group.
Results: At the reporting date (13.02.2016) a total of 989 cases from 811 families were registered. Geographical analysis shows 751 patients are registered in Europe, 90 in America, 21 in Oceania (Australia, New Zeeland), 57 in Africa/near east (including Israel) and 70 in Asia. The most frequent subtype is CDA II, followed by CDA I. Most cases are reported in Italy, Spain, Great-Britain, Germany and Israel (data not shown). Detailed information is given in table 1.

Table 1.

Region	CDA I	CDA II	CDA III	Variant	Total
Europe	145	437	32	137	751
America	12	38	13	27	90
Oceania	8	10	0	3	21
Asia	27	32	3	8	70
Africa/Near East	37	18	0	2	57
Σ	229	535	48	177	989

Summary/Conclusions: Prevalence of congenital dyserythropoietic anemia in the different countries is very heterogeneous, reflecting the rarity and the lack of awareness of the disease. Nevertheless the diagnosis is under reported due to numerous cases with only mild symptoms misdiagnosed as myelodysplastic syndrome or unclassified hemolytic anemia.

E1011

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) SCREENING IN PATIENTS WITH UNEXPLAINED ANEMIA: A SINGLE INSTITUTION EXPERIENCE

J England[1,*], B Dalal[2], H Leitch[3]
[1]Internal Medicine, University of British Columbia, [2]Division of Laboratory Hematology, Vancouver General Hospital, [3]Hematology, St. Paul's Hospital, Vancouver, Canada

Background: Referral to hematology for work up and management of anemia is common. Paroxysmal nocturnal hematoglobinuria (PNH) is a clonal disorder in which cells deficient in glycosylphosphatidyl inositol (GPI) anchor are lysed by complement. PNH can present with direct antiglobulin test (DAT) negative

hemolysis, thrombosis, unexplained cytopenias, and iron deficiency secondary to ongoing hemolysis. Evaluation for PNH clones is recommended for patients with DAT negative hemolysis or cytopenias that remain unexplained after thorough work up. PNH screening is important to identify patients who could benefit from eculizumab therapy, which improves quality of life and overall survival while reducing hemolysis, transfusion requirement, and thrombosis.
Aims: This study sought to evaluate how frequently patients with unexplained anemia were being screened for PNH.
Methods: The study looked at patients with unexplained anemia referred to hematology at St. Paul's Hospital between 2010 and 2015. Demographic information, clinical features (including history of arterial/venous blood clots and history of red blood cell [RBC] transfusion), and list of key investigations such as bone marrow biopsy (BMBx) were collected for each patient. Baseline laboratory data relevant to hemolysis were obtained including lactate dehydrogenase (LDH), bilirubin, reticulocyte count, haptoglobin, and DAT testing. Flow cytometry for expression of FLAER, CD24, CD14, and CD59 on neutrophils, monocytes, and RBC was used as high resolution testing of PNH.
Results: A total of 540 patients were included in the study. The study group was comprised of those with anemia not yet diagnosed (NYD, n=318, including 9 with DAT negative hemolysis and 92 with unexplained iron deficiency despite endoscopic gastrointestinal investigation), pancytopenia NYD (n=49), and anemia of chronic disease (n=173). Of these patients 112 (20.7%) underwent BMBx, 48 (8.9%) had a history of RBC transfusion, and 24 (4.4%) had prior thrombosis. For hemolysis investigations, 445 (82.4%) patients had testing done for LDH, 459 (85.0%) for total bilirubin, 425 (78.7%) had reticulocyte counts, and 219 (40.6%) patients had haptoglobin levels done. A total of 131 (24.2%) patients had a suggestion of possible hemolysis based on these measurements. PNH testing was done in 56 (10.4%) patients, corresponding to 12.3% of anemia NYD, 44% of DAT-negative hemolysis, 21.7% of unexplained iron deficiency, 20.4% of pancytopenia NYD, and 4.0% of anemia of chronic disease. One patient with anemia NYD had a positive PNH screen with a small (0.017%) detectable clone of uncertain significance. Compared to those who did not undergo PNH testing, those who were screened for PNH were more likely to have a history of thrombosis (16.1% *vs* 3.1%, p=0.0003), underwent BMBx (44.6% *vs* 18.0%, p=0.0001), received RBC transfusions (21.4% *vs* 7.4%, p=0.0018),and to have elevated reticulocytes (26.8% *vs* 7.6%, p=0.0001), LDH (25.0% *vs* 12.2%, p=0.0126), and low haptoglobin (21.4% *vs* 2.9%, p=0.0001).
Summary/Conclusions: Anemia is a common referral to hematology, but initial investigations may not uncover a cause. Although hemolytic parameters are evaluated in most patients with unexplained anemia, PNH is tested for only in a minority of cases (10.4%) despite potential indicators of hemolysis in 24.2% of those with unexplained anemia. As effective therapy for PNH is now available, increased screening could identify patients who would benefit from treatment and should be considered.

E1012

EFFICACY AND SAFETY OF DEFIBROTIDE FOR TREATMENT OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) IN ADULT AND PEDIATRIC PATIENTS FOLLOWING CHEMOTHERAPY

N Kernan[1], P Richardson[2,*], A Smith[3], B Triplett[4], S Grupp[5], J Antin[6], L Lehmann[7], Y Messinger[8], W Liang[9], R Hume[9], A Hannah[9], R Soiffer[6]
[1]Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, [2]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [3]Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, [4]Bone Marrow Transplantation and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, [5]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [6]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, [7]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [8]Cancer and Blood Disorders Program, Children's Minnesota, Minnesota, [9]Jazz Pharmaceuticals, Palo Alto, United States

Background: Veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is typically thought of as an unpredictable and potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT) conditioning, but also may occur following primary chemotherapy (CT) without HSCT. Severe hepatic VOD/SOS (associated with multi-organ dysfunction [MOD]) may be associated with >80% mortality. Endothelial cell (EC) damage is a critical pathophysiologic factor; preclinical data suggest that defibrotide (DF) stabilizes ECs with direct, as well as EC-mediated, restoration of the thrombo-fibrinolytic balance. DF is approved in the European Union for treatment of severe hepatic VOD/SOS in adult and pediatric patients post-HSCT. In the United States (US), a new drug application was accepted for priority review in 2015. DF has been available in the US on an investigational basis via a treatment protocol (T-IND) study.
Aims: To assess the efficacy of DF for treatment of VOD/SOS in pediatric and adult subgroups following primary CT with MOD or without MOD (off-label), from the T-IND program.
Methods: Eligibility for the T-IND program initially required VOD/SOS diagnosed by Baltimore criteria, with MOD, following HSCT. The protocol was amended to include patients with VOD/SOS without MOD, following CT, or as diagnosed by modified Seattle criteria (using a 5% weight gain threshold). All patients provided informed consent and received open-label defibrotide as a 2-hour intravenous infusion at 6.25 mg/kg every 6 hours (25 mg/kg/day) for a recommended ≥21 days. Survival at Day+100 following CT was measured using Kaplan-Meier (KM) estimates.
Results: Among 857 T-IND patients with VOD/SOS who received ≥1 dose of DF as of April 18, 2015, 101 (11.8%) had undergone primary CT (without HSCT), of whom 54.5% were male, 66.3% were white, and median (range) age was 7.0 (0, 69.0) years. This group included 81 (80.2%) pediatric patients (aged ≤16 years; 59 [72.8%] aged 2–11 years) and 19 (18.8%) adults (aged >16 years) (age not available for 1 patient); 48 (47.5%) patients had MOD (40 [49.4%] pediatric patients and 8 [42.1%] adults), and 52 (51.5%) did not have MOD (41 [50.6%] pediatric patients and 11 [57.9%] adults). For all patients and for the subset without MOD, the most commonly used chemotherapy agents included vincristine, cytarabine, and cyclophosphamide. KM-estimated Day+100 survival is reported in the Table. Overall, 62 (61.4%) patients reported ≥1 adverse event (AE), including 22 (21.8%) with AEs judged at least possibly related to DF, most commonly (≥3.0%) hypotension (4.0%) and nausea (3.0%). Two deaths (pleural hemorrhage and pulmonary hemorrhage plus hypotension) were possibly related to DF.

Table 1.

Day+100 Survival, % (95% confidence interval)	All Ages*	Pediatric (≤16 years)	Adult (>16 years)
All VOD/SOS	77.0% (67.5%, 84.1%) N=101	81.3% (70.9%, 88.3%) n=81	63.2% (37.9%, 80.4%) n=19
With MOD	71.4% (56.6%, 82.0%) n=49	72.5% (55.9%, 83.7%) n=40	75.0% (31.5%, 93.1%) n=8
No MOD	82.3% (68.7%, 90.4%) n=52	90.0% (75.5%, 96.1%) n=41	54.5% (22.9%, 78.0%) n=11

*Age not available for 1 patient, included in All Ages only.

Summary/Conclusions: KM-estimated survival rates at Day+100 post-CT for patients treated with DF were 81% in pediatric patients and 63% in adults, which were clinically encouraging findings. As has been observed in post-HSCT patients, pediatric patients may have higher survival rates than adults post-CT. DF was generally well tolerated in this study and had a safety profile consistent with previous studies. Support: Jazz Pharmaceuticals

LB2247

ALXN1210, A LONG-ACTING C5 INHIBITOR, RESULTS IN RAPID AND SUSTAINED REDUCTION OF LDH WITH A MONTHLY DOSING INTERVAL IN PATIENTS WITH PNH: PRELIMINARY DATA FROM A DOSE-ESCALATION STUDY

JW Lee[1,*], E Bachman[2], R Aguzzi[2], JH Jang[3], JS Kim[4], ST Rottinghaus[2], L Shafner[2], J Szer[5]
[1]The Catholic University of Korea, Seoul, Korea, Republic Of, [2]Alexion Pharmaceuticals, Inc., New Haven, CT, United States, [3]Samsung Medical Center, [4]Yonsei University College of Medicine, Seoul, Korea, Republic Of, [5]Royal Melbourne Hospital, Melbourne, Australia

Background: ALXN1210, a rationally designed humanized monoclonal antibody to C5, was engineered for an extended duration of complement inhibition. A previous study in healthy volunteers showed immediate, complete, and sustained inhibition of C5. The half-life (t½) of ALXN1210 was >30 days-substantially longer than eculizumab-which facilitates an extended dosing interval of ≥1mo.
Aims: ALXN1210-PNH-103 is a Phase 1b, multicenter, open-label, intrapatient dose-escalation study (NCT02598583), evaluating the safety, tolerability, and efficacy of 2 IV maintenance dosing regimens of ALXN1210 in patients (pts) with paroxysmal nocturnal hemoglobinuria (PNH) never treated with a complement inhibitor.
Methods: In this interim analysis, 2 cohorts of pts ≥18 y were investigated: pts in Cohort 1 (C1) received either 400- or 600-mg induction doses followed by a 900-mg maintenance dose q4w; pts in Cohort 2 (C2) received 600- and 900-mg induction doses, followed by an 1800-mg maintenance dose q4w. The primary objective was to assess safety and tolerability of ALXN1210. The primary efficacy outcome was change in lactate dehydrogenase (LDH) level. Other endpoints included change in blood transfusions and in hematologic parameters related to PNH.
Results: A total of 13 pts consented and enrolled (Table). Median duration of exposure was 3.7 mo for C1 (n=6) and 1.8 mo for C2 (n=7). All pts showed rapid reductions in LDH levels, which were observed at the first evaluable time point (day 8). Decreases in LDH were sustained over 4-mo dose intervals, as shown by mean reductions from baseline in LDH of 85.6% in C1 on day 113

and 83.8% in C2 on day 57, the latest evaluable time points (Figure). Among 5 pts with ≥1 transfusion in the year before treatment (2 in C1, 3 in C2), only 1 patient (in C1, who had received 12 units of packed red blood cells in the prior 6 mo) received a transfusion (2 units) while on ALXN1210. Multiple doses of ALXN1210 resulted in no serious adverse events (SAEs), no infusion site reactions, and no drug discontinuations or AEs leading to withdrawals. The most common treatment-emergent AE (TEAE) was headache (2 pts). Investigators judged 69% of TEAEs to be unrelated to treatment. All related AEs resolved with ongoing ALXN1210 treatment.

Table 1. Baseline demographics and disease characteristics.

		Cohort 1 n=6	Cohort 2 n=7	Overall n=13

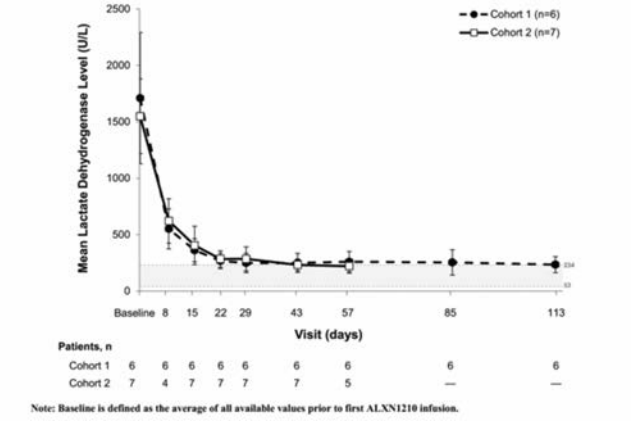
LDH=lactate dehydrogenase; RBC=red blood cell; xULN=multiples (fold) of the upper limit of normal.



Note: Baseline is defined as the average of all available values prior to first ALXN1210 infusion.

Figure 1. Mean (SD) LDH values over time, by cohort.

Summary/Conclusions: ALXN1210-PNH-103 is the first study to demonstrate safety and efficacy of ALXN1210 in pts with PNH. ALXN1210 treatment resulted in rapid reductions in LDH levels in 100% of pts, which were sustained through 2-4 monthly dosing intervals, consistent with the extended t½ of ALXN1210. There was a notable decrease in the need for blood transfusions. These preliminary LDH data suggest that rapid, complete, and sustained complement inhibition with ALXN1210 results in highly effective blockade of intravascular hemolysis. A Phase 2 study examining monthly and longer dosing intervals of ALXN1210 is ongoing.

LB2248

12 WEEKS SAFETY AND EFFICACY RESULTS OF A NOVEL C5 INHIBITOR COVERSIN IN PNH WITH RESISTANCE TO ECULIZUMAB DUE TO COMPLEMENT C5 POLYMORPHISM

S Langemeijer[1,*], W Weston Davies[2], M Nunn[2], JI Nishimura[3], Y Kanakura[3], N Blijlevens[1], M Nijziel[1], P Muus[1]
[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Akari Therapeutics Plc, London, United Kingdom, [3]Osaka University Graduate School of Medicine, Osaka, Japan

Background: Paroxysmal Nocturnal Haemoglobinuria (PNH) is a rare acquired life-threatening disease characterized by complement induced haemolysis and its sequelae and a high incidence of thrombosis. The monoclonal antibody eculizumab binds to C5 and prevents its activation and cleavage into C5a and C5b and is an established treatment for PNH and aHUS. However, for patients with the rare amino acid polymorphism p.Arg885His or pArg885Ser, which interferes with the binding and efficacy of eculizumab (Nishimura et al, 2014, Langemeijer et al, 2015), there is still no effective treatment. A new small protein complement inhibitor named Coversin is in Phase 1-2 clinical development. Coversin also prevents cleavage and activation of C5 but binds to C5 at different site than eculizumab. In vitro Coversin inhibits C5 activation in both wild type C5 and C5 with a polymorphism at the Eculizumab binding site. Coversin studies in healthy volunteers proved safe and demonstrated inhibition of terminal complement activation.
Aims: We report pharmacokinetics (PK), pharmacodynamics (PD), safety and preliminary efficacy data of the novel C5 inhibitor Coversin in a severely haemolytic PNH patient with a C5 polymorphism.
Methods: Coversin was administered by s.c. injection at an ablating dose of 0.57 mg/kg on day 1, followed by a maintenance dose of 0.14 mg/kg per day thereafter. Peripheral blood samples were drawn for PK/PD. Protocol specified doubling of the dose and /or shortening of the dose interval were allowed on the basis of clinical symptoms and CH50 levels to achieve adequate and sustained complement inhibition.
Results: The patient is a 30 year old male with PNH, (granulocyte clone size: 90%) and severe haemolysis (LDH 3 to 17 x UNL), transient renal failure, extreme fatigue and symptoms of muscle dystonia and no history of thrombosis. He remained severely haemolytic during eculizumab treatment despite adequate drug levels and no antidrug antibodies. Other causes of haemolysis were excluded. The patient was shown to have a p.Arg885Ser polymorphism rendering him resistant to eculizumab therapy. There was a good initial response to an ablating dose of 0.57mg/kg Coversin with CH50 levels decreasing below 8 U Eq/ml, which is the lower limit of qualification of the ELISA assay. Clinical symptoms and laboratory markers of haemolysis improved during the maintenance treatment of 0.14mg/kg every 24 hours. However, 6 days into the treatment, the patient again experienced haemolysis-associated symptoms with dark urine hours before the next s.c. injection and no further decrease of his LDH. The same occurred after doubling of the dose to 0.29 mg/kg per day. Dividing the dose into 0.14 mg/kg injections Q 12 hours resulted in stable complement inhibition with CH50 levels <8 U Eq/ml and no breakthrough symptoms. The LDH decreased to approximately 1.5xUNL. For the first time since he was diagnosed with PNH in 2009 the patient feels well with no symptoms of fatigue and no muscle dystonia. There have been no further haemolytic episodes. Twelve weeks after start of treatment, our patient did not have any drug-related adverse events, except occasional local and transient irritation at the injection site.
Summary/Conclusions: Over a period of 12 weeks Coversin has proven safe and effective in the first PNH patient treated with the drug.

LB2249

A PHASE 1 MULTIPLE-DOSE CLINICAL STUDY OF RA101495, A SUBCUTANEOUSLY ADMINISTERED SYNTHETIC MACROCYCLIC PEPTIDE INHIBITOR OF COMPLEMENT C5 FOR TREATMENT OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

JM Johnston[1,*], A Ricardo[1], M Arata[1], J Lickliter[2], SJ DeMarco[1], R Fahrner[1], RP Hammer[1], B Newstat[1], D Roychowdhury[1], S Tobe[1], D Winslow[1], D Treco[1]
[1]Ra Pharmaceuticals, Cambridge, United States, [2]Nucleus Network, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, acquired, clonal hematopoietic stem cell disorder caused by a deficiency in glycosylphosphatidylinositol (GPI)-linked proteins on cell surfaces. Patients with mutations in the phosphatidylinositol glycan class A gene are unable to produce functional, protective, GPI-linked proteins, resulting in the accumulation of specific complement proteins on the surface of red blood cells (RBCs) and subsequent RBC lysis by the membrane attack complex (MAC). Inhibition of complement activation at the level of complement C5 is a clinically validated approach for the treatment of PNH. RA101495, a synthetic macrocyclic peptide, binds to C5 at a unique site not targeted by currently available therapies and allosterically inhibits C5 cleavage into C5a and C5b, preventing production of a key component of the MAC. RA101495 also inhibits the assembly of MAC by blocking the interaction between C5b and C6.
Aims: A Phase 1 multiple-dose clinical pharmacology study in healthy human volunteers designed to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of RA101495 following once daily subcutaneous (SC) injections over 7 days.
Methods: The study was single-center (Australia), randomized, double-blinded, and placebo (PBO)-controlled. After obtaining written informed consent, all subjects received daily SC doses of 0.2 mg/kg RA101495 or matching PBO for 7 days while housed in a clinical pharmacology unit. Safety was assessed by intensive clinical monitoring, and daily blood samples were obtained at -15 minutes, 3 hours, and 6 hours relative to each day's dose for determination of RA101495 concentrations by liquid chromatography/high resolution mass spectroscopy and ability to inhibit complement-mediated RBC lysis in an *ex vivo* antibody-sensitized sheep erythrocyte hemolysis assay. All subjects received prophylaxis for *N. meningitides* infection with ciprofloxacin and vaccination.
Results: A total of 6 subjects were enrolled into the study (4 RA101495 and 2 PBO). Plasma concentrations showed a steadily increasing exposure over the 7 days of dosing in the 4 RA101495-treated subjects (see Figure). From these

data, the half-life of RA101495 appears to be 7 days. Preliminary results show that, for the subjects with measurable plasma levels of RA101495, the mean percent inhibition of hemolysis compared to baseline reached ≥95% beginning at the first time point, 3 hours after dosing on Day 1, and continued throughout the 7 days of dosing; all individual subjects showed ≥90% reduction of hemolysis at all time points (Figure). The only safety finding noted was mild cutaneous injection site erythema in 2 of the 4 RA101495-treated subjects; there was no associated pain, tenderness, swelling, or induration and all events resolved rapidly following dosing.

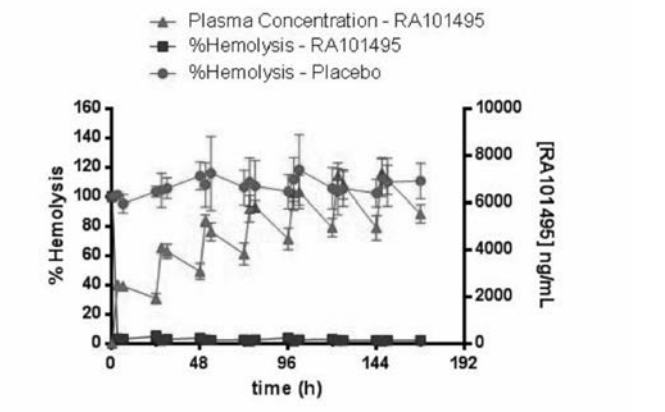


Figure 1.

Summary/Conclusions: RA101495 is a novel synthetic macrocyclic peptide inhibitor of C5-mediated hemolysis that is being developed as an alternative to intravenous monoclonal antibody therapy for the treatment of PNH. RA101495, currently being investigated for daily at-home SC self-administration, shows a rapid onset of activity, and appears to be safe and well tolerated. These preliminary data suggest low daily doses will achieve steady-state levels suitable for complete and sustained inhibition of complement and suppression of hemolysis, and, given the long half-life, that once-weekly dosing is possible.

LB2250

AN ORALLY ADMINISTERED SMALL MOLECULE FACTOR D INHIBITOR (ACH-4471) FOR TREATMENT OF PNH AND COMPLEMENT DISEASES: PRELIMINARY PHASE 1 RESULTS IN HEALTHY VOLUNTEERS

RB Ellis-Pegler[1,*], C Schwabe[1], I Ajari[2], H Robison[2], R Sorensen[2], J Lahey[2], W Yang[2], M Huang[2], J Hui[2], H Kocinsky[2], M Geffner[2], D Apelian[2]
[1]Auckland Clinical Studies Ltd, Aukland, New Zealand, [2]Achillion Pharmaceuticals, Inc, New Haven, United States

Background: ACH-4471 is a novel, small molecule complement factor D (fD) inhibitor; to our knowledge, this represents the first clinical data reported for an oral inhibitor of this target. ACH-4471 prevents cleavage of complement factor B into Ba and Bb in the alternative pathway of the complement cascade, leading to blockade of C3 convertase production. Hence, unlike C5 inhibitors, ACH-4471 also prevents C3 fragment deposition on PNH cells and may confer a pharmacological advantage by protecting PNH cells from both intravascular and extravascular hemolysis.
Aims: To assess the safety and tolerability of single ascending oral doses of ACH-4471 in healthy volunteers and to evaluate its pharmacokinetic (PK) and pharmacodynamic (PD) profile and PK/PD relationship as measured by the serum AP activity *ex vivo*.
Methods: In this Phase 1a study, ACH-4471 was given as a single oral dose to healthy volunteers. Dose group 1 enrolled 6 active and 6 placebo subjects, while subsequent groups enrolled 6 active and 2 placebo subjects each. Each group was studied for 28 days after dosing. Active treatment subjects in the first 2 groups received 200 and 600mg ACH-4471 QD, respectively. Inhibition of serum AP activity was evaluated using the AP Wieslab assay, which tests ACH-4471 under stringent conditions in the presence of bacterial endotoxin (LPS), a potent AP activator. To date, 20 subjects (Groups 1 and 2) have been dosed and evaluated (19 males, 1 female) with a median age of 23.9 years (range 21.0 - 54.2). For both groups, all subjects were followed for AEs/SAEs through the last scheduled visit at Day 28. Blood samples were collected at predefined time points from Days 1 to 4 to determine plasma concentrations of ACH-4471.
Results: There have been no drug-related SAEs, TEAEs leading to study discontinuation, or study-drug related Grade 3/4 TEAEs. PK data indicate that peak plasma concentrations (C_{max}) are achieved by 1 to 2.5 hours after a single 200- or 600-mg dose, with the majority of exposure (measured as AUC) occurring over the first 24 hours. The terminal phase begins 16 hours after dosing and the mean terminal half-life is approximately 9 hours. PD data from the *ex vivo* evaluation of serum AP activity indicate rapid and nearly complete inhibition of AP activity after single 200- or 600-mg doses. Mean plasma concentrations of ACH-4471 necessary to achieve >80% or >90% AP inhibition were approximately 180 and 230ng/mL, respectively. Simulations indicate that these steady-state C_{trough} levels could be maintained by twice daily (BID) dosing with the current capsule formulation; ongoing formulation development efforts may allow for once daily dosing. Plasma Bb concentration, an *in vivo* biomarker for the inhibition of fD activity by ACH-4471, decreased dose-dependently with a nadir 9 hours after dosing and a gradual recovery to original levels by 48 hours. Taken together, these results indicate that administration of ACH-4471 results in potent inhibition of AP activity.
Summary/Conclusions: ACH-4471 was well-tolerated at the single dose levels examined to date with no safety trends. PD results indicate that ACH-4471 potently inhibits AP activity. PK modeling predicts that the current formulation of ACH-4471 will provide sustained suppression of AP activity with BID dosing, and future formulations may be effective with QD dosing. A 14-day multiple ascending dose study of ACH-4471 is planned to start in 2Q2016.

Chronic lymphocytic leukemia and related disorders - Biology

E1013

THE PI3K DELTA SELECTIVE INHIBITOR, IDELALISIB, MODULATES CYTOKINE PRODUCTION IN INNATE IMMUNE CELLS STIMULATED THROUGH TOLL-LIKE RECEPTORS

L Grosmaire, A Yahiaoui, S Tannheimer*
Gilead Sciences, Inc., Foster City, United States

Background: Idelalisib (IDELA) is an oral, selective PI3Kd inhibitor approved for the treatment of relapsed chronic lymphocytic leukemia (CLL). A subset of patients develop severe diarrhea/colitis which requires interruption of IDELA therapy and in some instances, corticosteroid treatment (Coutre et al., Leuk Lymphoma, 2015). Toll-like receptors (TLR) play a critical role in innate immunity by detecting pathogen associated molecular patterns (PAMPs). Responses to signaling through TLR drive not only an immediate innate cell response to pathogens, but also enable cells of the innate immune system to shape an adaptive immune response. PI3Kd has been shown to modulate signal transduction through TLR4 and TLR1/2 in murine bone marrow derived dendritic cells (Aksoy et al., Nat Imm, 2012). Additionally, PI3Kd has been shown to modulate TLR2, TLR4, TLR5, and TLR9 signaling in murine bone marrow derived macrophages (Plevy et al., Gastroenterology, 2010). Mice with a targeted inactivating mutation in the p110d subunit of PI3Kd spontaneously develop colitis at 8 weeks of age, and bone marrow macrophages from these mice secreted significantly more inflammatory cytokines (Plevy et al., Gastroenterology, 2010).
Aims: Evaluate the effects of clinically relevant concentrations of IDELA on TLR signaling in human monocyte derived macrophages (MDMs) as a potential mechanism contributing to clinically observed adverse events.
Methods: We utilized MDMs skewed to either a M1 or M2 phenotype by culture for six days in GM-CSF or M-CSF, respectively. MDMs stimulated with a TLR1/2 (PAM3CSK4), TLR4 (LPS), or TLR5 (flagellin) agonist in the presence of clinically relevant concentrations of IDELA were examined for cytokine production at early and late time points (MesoScale Discovery). Additionally, nCounter Human Inflammation Kit V2 (NanoString) was used to assess the effects on gene expression and Peggy Sue (Protein Simple) was used to analyze changes in protein expression on MDMs.
Results: Cytokine analysis revealed that both MDM1 and MDM2 cells produced inflammatory IL-12p40 when stimulated with TLR agonists. However, IL-12p40 production by MDM2 cells when stimulated with TLR1/2, TLR4 or TLR5 agonists was significantly increased in the presence of IDELA (Fig. 1A). Inflammatory cytokine upregulation was not seen in MDM1 cells. MDM2 cells produced immunosuppressive IL-10 in response to TLR1/2, TLR4 or TLR5 agonist stimulation. The IL-10 production was inhibited in the presence of IDELA (Fig. 1B). MDM1 cells produced little to no IL-10 in this context. IDELA exerted a differential effect on gene expression in MDM2 *versus* MDM1 cells. CXCR2 ligands were upregulated in MDM2 cells in the presence of IDELA plus TLR agonists to a much greater extent than MDM1 cells, while the anti-inflammatory IL-1RA was downregulated.

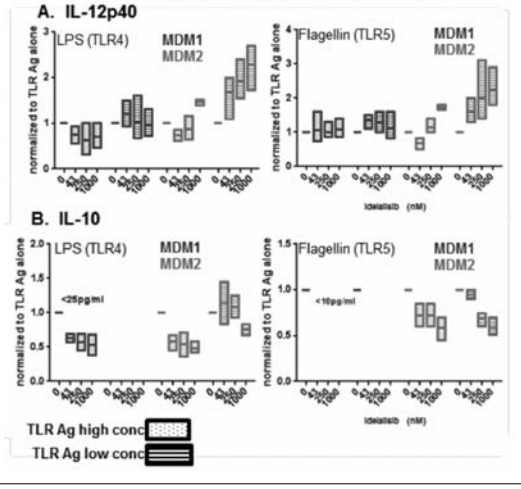

Figure 1.

Summary/Conclusions: The immunological challenge of the mucosal environment of the intestine is maintaining a balance between a tolerogenic state with the commensal microbiota and an ability to aggressively respond to potential pathogens. Under normal conditions, TLR signaling by enteric bacteria is protective (Rakoff-Nahoum et al., Cell, 2004). Here we show that IDELA modulates TLR signaling in MDMs, resulting in MDM2 cells producing higher amounts of inflammatory cytokines, and less immunosuppressive IL-10. This dysregulation of the tolerogenic cytokine balance and subsequent perturbations of the innate/adaptive immune system is consistent with proinflammatory cytokine imbalance which may result in colitis in PI3Kd deficient animal models.

E1014

MUTATIONS IN SF3B1 GENE ARE SELECTED INDEPENDENTLY ON ATM/TP53 STATUS AND REDUCE THE TIME TO FIRST TREATMENT IN CLL PATIENTS

M Hlozkova*, J Figulova, V Navrkalova, J Malcikova, J Smardova, N Tom, Y Brychtova, M Doubek, J Mayer, S Pospisilova, M Trbusek
University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Significant proportion of chronic lymphocytic leukemia (CLL) patients manifests abnormalities in the DNA damage response pathway (DDR) through defects in *TP53* or *ATM* gene. Interestingly, recurrent mutations in splicing factor 3 subunit b1 (*SF3B1*) have also been shown to partially impair DDR in CLL patients. Whilst *ATM* dysfunction seems to typically occur early in CLL pathogenesis, mutations in *TP53* and *SF3B1* have been reported to be mostly subclonal events originating later during the disease course.
Aims: (a) to assess whether *SF3B1* mutations' occurrence associates with adverse genetic lesions in *TP53* and *ATM* genes, (b) to determine the impact of all three types of defects on time to first treatment (TTFT) and overall survival (OS), and (c) to analyze changes in *ATM* and *SF3B1* mutation status during the disease course.
Methods: We used the yeast functional analysis FASAY coupled to Sanger sequencing for the identification of *TP53* mutations (analyzing thus exons 4-10), the next generation sequencing (NGS) on MiSeq instrument (Illumina) for the whole *ATM* gene screening (62 coding exons with splicing sites), and direct Sanger sequencing for the analysis of mutational hot-spot exons 14-16 in *SF3B1* gene. The median coverage in the NGS analysis was ~4000 reads, and we set up a uniform sensitivity of 10% for all three methodologies.
Results: We analyzed unfavorable cohort of 205 patients consisting predominantly (86%) of *IGHV* unmutated patients, with 64% of the patients being treatment-naïve. The *TP53* dysfunction was identified in 53/205 patients (26%), while both *ATM* and *SF3B1* mutations occurred in 49/205 cases (24%). In line with the expectations, we observed the frequent co-occurrence of *ATM* mutations with del(11q) (P<0.001), and the strong mutual exclusivity of *ATM* and *TP53* mutations (co-occurring in only one patient). By contrast, there was no significant association or mutual exclusivity between *SF3B1* mutations´ presence and *ATM* or *TP53* mutational status, neither among untreated patients nor in the whole cohort. For the TTFT and OS analyses, we firstly employed a hierarchical classification of *TP53* and *ATM* mutations and did not consider *SF3B1* mutational status; in addition, we limited this analysis to only *IGHV* unmutated patients. Compared to TP53-wt/ATM-wt patients having median of 18 months (m), the TTFT was apparently reduced in both *TP53*-mutated (6 m; P=0.002) and *ATM*-mutated patients (7 m). However, the latter group exhibited heterogeneous impact of mutations leading to only non-significant TTFT reduction (P=0.130). The OS analysis then showed a prominent (P<0.001) negative impact of *TP53* mutations (38 m) and a borderline significance of *ATM* mutations (67 m; P=0.058) compared to wt patients (90 m). As a sub-analysis, we assessed the effect of single *SF3B1* mutations: these led to reduced TTFT (11 m; P=0.029 compared to 18 m in wt patients), while did not show an impact on OS. The analysis of *ATM* and *SF3B1* throughout the disease course involving at least one relapse then disclosed that (a) 27/28 repeatedly analyzed *ATM* mutations (median time between analyses 40 m) and (b) 29/30 analyzed *SF3B1* mutations (33 m) were identified in both samplings. In addition, 7 out of 72 repeatedly analyzed *SF3B1*-wt samples showed a new mutation in this gene.
Summary/Conclusions: Mutations in *SF3B1* occur regardless of the ATM/p53 pathway dysfunction in CLL and can be selected by therapy. Their presence results in early therapy need but not in shorter survival. Supported by projects no. 65269705, TA0 TE02000058 and MUNI/A/1028/2015.

BIOLOGICAL AND CLINICAL FEATURES OF IMMUNOSUPPRESSIVE THERAPY IN PATIENTS AFFECTED BY LARGE GRANULAR LYMPHOCYTE LEUKEMIA

A Teramo[1,2,*], M Leoncin[1,2], G Barilà[1,2], G Calabretto[1,2], C Ercolin[1,2], A Cabrelle[2], E Boscaro[1], S Teolato[1], E Pagnin[1], M Facco[1,2], L Trentin[1,2], G Semenzato[1,2], R Zambello[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, University School of Medicine, [2]Venetian Institute of Molecular Medicine (VIMM), Padua, Italy

Background: Large Granular Lymphocyte Leukemia (LGLL) is a rare and heterogeneous lymphoproliferative disorder characterized by the chronic proliferation of clonal Large Granular Lymphocytes (LGLs) with cytotoxic activity. Recently, activating STAT3 mutations have been discovered in 30-40% of T-LGLL patients. The treatment of LGLL is based on immunosuppressive drugs, such as Methotrexate (MTX), Cyclophosphamide (CTX) and Cyclosporin A (CyA), used

at low doses. These therapies have limited efficacy and the Overall Response Rate (ORR) is near 50%. Furthermore, *in vitro* studies on the molecular effects of these drugs on leukemic lymphocytes are not available in the literature and the biological rational of LGLL treatment has yet not been investigated.
Aims: The aim of this study was to analyze the *in vivo* efficacy of treatment on a cohort of patients referred to the Hematology Unit at Padua University. In addition, we performed *in vitro* study of the molecular effect of these drugs on pathological LGLs in order to better understand their efficacy/specificity, in particular considering their effect on STAT3 pathway.
Methods: Clinical characteristics and treatment response were collected from 17 LGLL patients. For *in vitro* analysis a cohort accounting 35 patients was studied. Cell cultures of patients' peripheral blood mononuclear cells (PBMCs) were set up with CTX (5μM), CyA (10μM) or MTX (100μM). On collected culture cells apoptosis by Annexin V assay and phosphorylation of STAT3 by Western Blot were investigated.
Results: Clinical results demonstrated that ORR for each drug ranged from 35.7% to 57.1%, CTX treatment showing the higher ORR independently from the therapy line. Fifteen out of the 17 treated patients were STAT3 mutated, indicating a strong correlation between STAT3 mutation and symptomatic disease. Interestingly, consistent with literature data, patients carrying Y640F STAT3 mutation showed a better ORR on MTX treatment as compared with patients with different STAT3 mutation (66% *versus* 14.2%). *In vitro*, CTX and CyA showed a strong increase of LGL apoptosis, leading to the complete disappearance of LGL clone within 3-6 days of culture. Anyway, concerning the specificity of the killing leukemic LGL cells, while sparing non leukemic PBMCs, our data showed that both CTX and CyA were also partially toxic for non-LGLs population. As regards MTX treatment, no increase of apoptosis was revealed, but, interestingly, we observed that MTX induced apoptosis when LGL were stimulated to proliferate by IL-15, suggesting a predominant effect on activated cells. Considering the key role of STAT3 activation in leukemic LGL survival, we observed a decrease of STAT3 phosphorylation levels only after CyA treatment. Finally, adding autologous plasma (10%) to cell culture the cytotoxic effect of drugs was partially reduced (~50%), suggesting that plasma might contain cytokines preserving LGL survival.
Summary/Conclusions: In summary, CTX showed a good efficacy *in vivo* and *in vitro*, even if in this last setting the compound did not exhibit a good LGL specificity. MTX might be more efficient when LGLs are proliferating and when LGLs carry activating mutations, even if it does not affect STAT3 activation. Finally, we demonstrated that CyA expresses its cytotoxic effect through a mechanism that down-modulates STAT3 activation. Our results contribute to get insights into the molecular mechanisms of immunosuppressive drugs used in LGLL treatment and suggest that STAT3 mutation/activation might represent a suitable target for therapy.

CD49D IS A BETTER PREDICTOR OF OVERALL SURVIVAL THAN THE NOVEL RECURRENT MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS FROM AN ITALIAN MULTI-CENTER COHORT

M Dal Bo[1], P Bulian[1], R Bomben[1], A Zucchetto[1], FM Rossi[1], F Pozzo[1], E Tissino[1], D Benedetti[1], T Bittolo[1], P Nanni[1], I Cattarossi[1], E Zaina[1], H Chivilò[1], M Degan[1], F Zaja[2], G Pozzato[3], A Chiarenza[4], F Di Raimondo[4], MI Del Principe[5], G Del Poeta[5], D Rossi[6], G Gaidano[7], V Gattei[1,*]
[1]Clinical and Experimental Onco-Ematology Unit, Centro di Riferimento Oncologico, I.R.C.C.S., Aviano, [2]Clinica Ematologica, Centro Trapianti e Terapie Cellulari "Carlo Melzi" DISM, Azienda Ospedaliera Universitaria S. Maria Misericordia, Udine, [3]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, [4]Division of Hematology, Ferrarotto Hospital, Catania, [5]Division of Hematology, S. Eugenio Hospital and University of Tor Vergata, Rome, [6]Division of Hematology-Department of Translational Medicine –, [7]Division of Hematology-Department of Translational Medicine –, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: CD49d, the alpha-chain of VLA-4 integrin, was identified among the strongest predictors of overall survival (OS) in chronic lymphocytic leukemia (CLL), along with *IGHV* status and the 17p deletion (Bulian et al, JCO, 2014). In addition to *TP53*, the clinical relevance of mutations of *NOTCH1*, *SF3B1* and *BIRC3* recently emerged.
Aims: To test the clinical relevance of CD49d in subgroups defined by *NOTCH1*, *SF3B1*, *BIRC3* alterations.
Methods: The cohort was of 778 unselected CLL (treated cases, n=356, median follow-up 80 months with 173 deaths), all characterized for CD49d expression (CD49d^{high}, ≥30% positive cells by flow cytometry, n=229), *IGHV* status (unmutated, UM, n=262), karyotype abnormalities (5% cut-off, 13q-, n=308; +12, n=103; 11q-, n=64), at diagnosis, along with *TP53* mutations/deletions (hereinafter, disruption, n=84, including 58 17p-), *NOTCH1* mutations (n=81), *SF3B1* mutations (n=54), *BIRC3* disruption (n=59). Recurrent mutations were investigated by Sanger sequencing before therapy (at diagnosis in 65% of cases).
Results: i) CD49d^{high} associated with age ≥65 years (p=0.0001), Rai stage ≥I (p<0.0001), UM *IGHV* status (p>0.0001), absence of 13q- (p=0.0001), presence of +12 (p<0.0001), *NOTCH1* mutations (p<0.0001). **ii**) By univariate analysis, CD49d^{high} had impact as OS predictor (hazard ratio/confidence interval, HR/CI=2.62/1.94-3.54; p<0.0001). In multivariate analysis, CD49d^{high} was confirmed as independent prognosticator (HR/CI=1.88/1.36-2.60, p<0.0001), along with age≥65 years (HR/CI=3.90/2.68-5.67), Rai stage ≥I (HR/CI=1.80/1.30-2.51, p=0.0005), UM *IGHV* (HR/CI=1.84/1.31-2.60, p=0.0005), 11q- (HR/CI=2.21/1.39-3.51, p=0.0008), *TP53* disruption (HR/CI=3.65/2.15-5.30, p<0.0001), *NOTCH1* mutations (HR/CI=1.79/1.17-2.73, p=0.0068). Conversely, +12, *SF3B1* mutations, *BIRC3* disruption were all excluded from the final model. **iii**) The variable importance (VIMP) of biological markers as OS predictors was evaluated by a random forests approach. CD49d (VIMP=0.0410) was ranked among the most important OS predictors, followed by *IGHV* status (VIMP=0.0388), *TP53* disruption (VIMP=0.0352) and *NOTCH1* mutations (VIMP=0.0168); conversely, *SF3B1* mutations (VIMP=0.0002) and *BIRC3* disruption (VIMP=-0.0024) had no importance as OS predictors. iv) Post-treatment survival was evaluated to explore the impact of prognosticators as therapy response predictors. CD49d^{high}, UM *IGHV*, *TP53* disruption but not *NOTCH1* mutations were able to split cases into groups with significant different treatment responses (see Figure). This observation was confirmed by multivariate analysis where CD49d^{high} (HR/CI=1.55/1.08-2.23, p=0.0192), UM *IGHV* (HR/CI=1.70/1.17-2.49, p=0.0060), *TP53* disruption (HR/CI=2.67/1.79-4.00, p<0.0001) were maintained and *NOTCH1* mutations were excluded. iv) In Rai stage 0 cases (n=389), CD49d^{high} had impact as Time-to-First-Treatment predictor (HR/CI, 2.68/1.78-4.05, p<0.0001) by univariate analysis. In multivariate analysis, CD49d^{high} again emerged as independent prognosticator (HR/CI=1.61/1.01-2.56, p=0.0442), along with UM *IGHV* (HR=2.66/1.72-4.12, p<0.0001), +12 (HR/CI=3.36/2.00-5.62, p<0.0001), *TP53* disruption (HR/CI=1.97/1.03-3.78, p=0.0419), *BIRC3* disruption (HR/CI=2.70/1.24-5.89, p=0.0127), whereas age, *NOTCH1* mutations, 13q-, 11q-, were excluded.

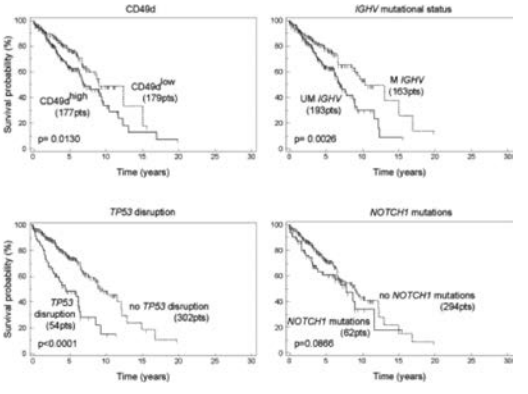

Figure 1.

Summary/Conclusions: CD49d, along with *IGHV* status, is the most powerful independent negative OS prognosticator in CLL also when *NOTCH1*, *SF3B1*, *BIRC3* alterations were evaluated. CD49d, *IGHV* status and *TP53* disruption may also have a role as therapy response predictors.

E1017

COMBINED SYK AND JAK INHIBITION BY CERDULATINIB INDUCES APOPTOSIS IN CLL AND OVERCOMES RESISTANCE TO IBRUTINIB

A Guo[1], P Lu[1], G Coffey[2], P Conley[2], A Pandey[2], L Wang[1,*]
[1]University of Chicago, Chicago, [2]Portola Pharmaceuticals, S. San Francisco, United States

Background: Despite recent advances in the treatment of chronic lymphocytic leukemia, robust and durable complete responses enabling extended periods of time off-therapy are not achieved. One possible reason for this may be explained pre-clinically; agents like ibrutinib and idelalisib induce cell cycle arrest, but not apoptosis, in CLL cells treated in vitro. Consistently, when cells from ibrutinib-treated patients are analyzed, no significant apoptosis is seen even after 3 months of therapy. CLL tumor cells receive growth and survival signals from not only the BCR, but also a variety of cytokine receptors which primarily utilize Janus kinases (JAK) to initiate the signaling cascade, culminating in the upregulation of BCL2 family members and preventing apoptosis. We have therefore been exploring the utility of combining BCR pathway suppression via SYK with JAK/STAT pathway suppression using a novel small molecule inhibitor, cerdulatinib. Cerdulatinib is a selective and potent inhibitor of SYK, JAK1, JAK3, and TYK2, currently in a phase I dose escalation study in patients with B cell malignancies.
Aims: The aim of these studies was to determine the anti-tumor activity of cerdulatinib in primary CLL co-cultures as well as molecular correlates of response.
Methods: Using a repository of previously-banked viable CLL primary tumors (n=60), we evaluated cell death in the presence of cerdulatinib on stromal cell supported CLL cultures. Viability assays were performed by evaluating PARP cleavage and propidium iodide uptake. Western blotting or FACS analysis was

used to determine cerdulatinib-impact on survival signaling networks and BCL2 family expression.
Results: In general, tumor specimens were sensitive to cerdulatinib, especially in cases with poor prognosis (e.g. mutation status, ZAP70 expression, cytogenetics). Importantly, sensitive tumor cells actually underwent apoptosis, which was not observed in direct comparisons with ibrutinib. The mechanism of apoptosis induction was demonstrated by western blotting to be cerdulatinib-induced down-regulation of MCL-1, which was associated with induction of tumor PARP cleavage. Apoptosis was induced by this agent irrespective of co-culture with known survival factors, including different stromal cell lines, or media supplementation with IL4, CD40 ligand, anti-IgM, or a combination of the three. Cerdulatinib anti-tumor activity significantly correlated with inhibition of pAKT S473 and pERK T202/Y204 within the tumor cells, and was associated with decreased BCR, JAK/STAT, and NF-kB pathway activation. Moreover, primary CLL samples resistant to ibrutinib remained sensitive to cerdulatinib.
Summary/Conclusions: The data suggest an alternate mechanism by which apoptosis may be induced in CLL, and provide a justification to continue clinical studies with cerdulatinb in this disease. Cerdulatinib has the potential to deliver a higher rate of complete responses in CLL, as well as provide another therapeutic option for patients who either did not respond to or relapsed on ibrutinib.

DNA REPLICATION CONTROL MECHANISMS INVOLVED IN CHEMORESISTANCE OF CHRONIC LYMPHOCYTIC LEUKEMIA

G Srdana[1,2,*], P Montilla-Perez[1,2], A Bradbury[3], L Berquet[1], L Yseabert[1,2,4], G Laurent[1,4], A Quillet-Mary[1,2], JS Hoffmann[1,2]
[1]UMR 1037 INSERM Université Paul Sabatier ERL 5294 CNRS, Cancer Research Center of Toulouse, [2]Laboratory of Excellence Toulouse Cancer LABEX TOUCAN, Toulouse, France, [3]Newcastle University, Newcastle, United Kingdom, [4]Departement of Hematology, Institute Universitaire du Cancer, Toulouse, France

Background: Chronic lymphocytic leukemia (CLL), the most common leukemia in the Western hemisphere, is characterized by clonal expansion of B lymphocytes co-expressing CD5 and CD19 that arise from the lymph nodes and accumulate in patient's peripheral blood and bone marrow. Historically, standard first line treatment of CLL patients has been based on a DNA targeting agent, cyclophosphamide, nucleoside analogue, fludarabine and an anti-CD20 antibody, rituximab. Although the chemotherapeutic regime results in high rate of complete response, majority of CLL patients, nevertheless, relapse.
Aims: CLL genomes are characterized by, both, chromosome aberrations affecting the karyotypic integrity and elevated frequencies of nucleotide point mutations. Altered DNA replication, repair and recombination (3R) mechanisms may account for chromosomal instability and mutator phenotype that propels the development of chemoresistance towards genotoxic therapies. Here, we aimed to determine the expression of 3R genes and decipher their functional role in CLL.
Methods: For this purpose we assessed complete 3R gene expression profiles in 140 peripheral blood (PB) samples obtained from clinically annotated CLL patients and correlated the obtained data with patients' clinical outcomes. Next, in order to investigate the DNA replisome of the cycling CLL cells, we used an *in vitro* approach based on interleukin-2 (IL-2) and CpG-oligonucleotide stimulation to obtain proliferative primary patient leukemic cells. To determine the chemotherapeutic implication of the 3R gene of interest (GOI), we performed drug sensitivity screens in presence of fludarabine on two CLL cell lines established successively from the same patient that differed in the expression of the 3R GOI. Also, we used a mouse embryonic fibroblast (MEF) cell line and its heterozygous and homozygous knock-outs for the 3R GOI to confirm the obtained results. We characterized chemoresistance profiles using cellular viability screens, cell cycle and DNA synthesis analysis. In order to decipher the molecular basis of chemoresistance driven by our 3R GOI, we used drugs that partially recapitulate the mechanism of action (MOA) of fludarabine, namely, hydroxyurea (HU), an inhibitor of the ribonucleotide reductase (RNR) and aphidicolin, an inhibitor of replicative DNA polymerases.
Results: Our qRT-PCR data revealed deregulated expression of several 3R genes among which, alternative DNA polymerase nu (*POLN*). Interestingly, we observed that relatively high expression of *POLN* correlates with a shorter progression free survival (PFS) in patients that received the chemotherapeutic treatment. In addition, *in vitro* proliferation assays showed that primary CLL lymphocytes that were stimulated to enter the cell cycle and divide, exclusively upregulated *POLN*. Drug screens in two independent cellular models showed that upregulation of *POLN* contributed to fludarabine chemoresistance in terms of cellular viability and sustained DNA synthesis. Our chemoresistance data demonstrated that, unlike *POLN* knock-out cells, *POLN* expressing cells are able to continue synthesizing DNA in presence of fludarabine. These results support observed clinical correlation between *POLN* expression and PFS. In terms of the molecular mechanism of *POLN* driven chemoresistance, differential DNA synthesis profiles obtained in presence of fludarabine were recapitulated when cells were treated with hydroxyurea but not aphidicolin.
Summary/Conclusions: Finally, our data reveal deregulated expression of 3R genes in CLL, among which that of a specialized DNA polymerase nu (*POLN*). We show that *POLN* overexpression correlates with worse clinical outcome in CLL patients upon receiving therapy. Moreover, our *in vitro* results clearly show that upregulation of *POLN* observed in cycling CLL cells can drive fludarabine chemoresistance. In conclusion, we propose that, on the molecular level, *POLN* contributes to chemoresistance by sustaining the DNA synthesis and preserving cellular viability in presence of a low dNTP pool imposed by fludarabine.

ARSENICTRIOXIDE REGULATES CHRONIC LYMPHOCYTIC LEUKEMIA PROLIFERATION BY TARGETING XPO1/SURVIVIN PATHWAY SIGNALLING

XH Zhang[1,*], R Feng[2], JM Zhang[1], SM Yang[1], Q Jiang[1], H Jiang[1], J Lu[1], YZ Qin[1], LP Xu[1], KY Liu[1], XJ Huang[1]
[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Departments of Hematology, Beijing Hospital, Beijing, China

Background: Chronic lymphocytic leukaemia(CLL) is characterized by the progressive accumulation of clonal mature B-cells in the blood, bone marrow, and lymphoid organs and by a highly variable clinical course. Elevated expression of exportin 1 (XPO1/CRM1) has been reported in CLL and correlated with a poor prognosis and resistance to therapy. Inhibition of XPO1 can result in CLL cell death in vitro and increased survival in a CLL mouse model. The efficacy of XPO1 inhibitor for the treatment of diffuse malignant peritoneal mesothelioma may rely on interference with the function of survivin. Our previous work showed that arsenic trioxide(As_2O_3) induced apoptosis in a CLL cell linetogether with up-regulation of p53 and down-regulation of survivin. Taken together, these findings raise the question of whetherAs_2O_3 might inhibit CLL by inducing apoptosis via the suppression of XPO1/survivin pathway signalling.
Aims: We sought to investigate whether XPO1/survivin pathway signalling might be involved in the anti-CLL effect induced by As_2O_3.
Methods: The expression of XPO1 in the MEC1 cell line and primary peripheral blood cells from CLL patients was assessed by qPCR and compared with the expression in purified peripheral normal B-cells. XPO1 siRNA was used to knockdown XPO1 expression in MEC1 cells. XPO1 plasmid transfection was used to overexpress XPO1. Thesurvival and apoptosis rates of MEC1 cells induced by As_2O_3were determinedby 7-AAD,Annexin V-PI and caspase3/7 analysis. The expression of various genes associated with apoptosis, including Bax, PUMA, survivin, BCL-2, BCL-x and XIAP, were assessed by real-time PCR.XPO1 normal and XPO1 knockdown MEC1 cells were inoculated intravenously intoNOD/scid/γc^{null}(NSG) mice to establish a human leukaemia xenograft model. We assessed tumour characteristics, including organ infiltration, apoptosis, andexpression of survivin, ki67 and XPO1, as well as survival in our xenograft model. Next, we used this model to study the effects of As_2O_3 *in vivo*.
Results: XPO1 was expressed in the MEC1 cell line and in CLL patients. Expression data suggested that XPO1 was up-regulated inCLL patients compared with normal controls. As_2O_3 could inhibit the proliferation and induced apoptosis in MEC1 cells, and it down-regulated the expression of XPO1 and survivin in MEC1 cells.XPO1 suppressed by $As_2O_3$was associated with enhanced mRNA expression of the pro-apoptotic genes Bax, PUMA and survivin, and suppression of the anti-apoptotic genes BCL-2, BCL-x and XIAP.Overexpression of XPO1 in MEC1 decreased As_2O_3 -induced apoptosis.Inhibition of XPO1 by selinexorin MEC1 cellsresulted in increasedAs_2O_3 -induced apoptosis.Furthermore, siRNA knockdown of XPO1 strongly impaired *in vivo* engraftment of MEC1 cells following transplantation in NSG mice, conferring a survival benefit compared with mice transplanted with control cells.As_2O_3 could inhibit tumour growth and significantly increased the survival of mice bearing MEC1-derived xenografts by inhibiting XPO1 and survivin.
Summary/Conclusions: This is the first report to demonstrate thatAs_2O_3can induce apoptosis and inhibit proliferation in CLL. The mechanistic effect of As_2O_3 on CLLresults from the down-regulation of XPO1/survivin pathway signalling.

IBRUTINIB STIMULATES IL-10 SECRETION BY NLCS, MEDIATING A PARTIAL PROTECTION OF CLL CELLS FROM APOPTOSIS

S Fiorcari[1,*], R Maffei[1], V Audrito[2], S Martinelli[1], E ten Hacken[3], P Zucchini[1], C Quadrelli[1], S Benatti[1], L Potenza[1], M Luppi[1], JA Burger[3], S Deaglio[2], R Marasca[1]
[1]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, [2]Department of Medical Sciences, University of Turin and Human Genetics Foundation, Turin, Italy, [3]Department of Leukemia, MD Anderson Cancer Center, Houston, United States

Background: In lymphatic tissues, CLL cells establish intimate contact with accessory cells, such as nurse-like cells (NLCs). NLCs have a pivotal role in CLL clone maintenance and support CLL cell survival, proliferation and protection from drug-induced apoptosis. Ibrutinib is a potent inhibitor of Btk kinase, able to counteract the pro-survival effects in CLL cells provided by microenvironment. A peculiar effect of ibrutinib includes reduced retention and homing of CLL cells to tissue compartments and a mobilization from microenvironmental niches into the peripheral blood.
Aims: Here, we investigated the biological effects and mechanism mediated by ibrutinib on CLL- NLCs crosstalk.

Methods: CLL-PBMCs were cultured in complete medium for 12 days and then treated with 1μM ibrutinib. NLC phenotype was analyzed upon ibrutinib exposure. IL-10 production was tested by real time PCR and CSA in NLCs. CD19+ CLL cells viability and analysis of signaling pathways in presence of IL-10 stimulation were evaluated after treatment with ibrutinib.
Results: First, we found that CLL cells cultured without NLCs are more sensitive to ibrutinib-induced apoptosis if compared to CLL cultured with NLCs. Indeed ibrutinib does not completely hamper the protective effect mediated by NLCs on leukemic cells when both CLL and NLCs are exposed to the drug ($p<0.05$ at 24h, 48h and 72h). Among the plethora of factors potentially involved in CLL desensitization to ibrutinib effect, NLCs were characterized by a strong up-regulation of IL10 and NAMPT known to be involved in CLL protection from apoptosis ($p<0.05$). We focused our attention on IL-10 and we demonstrated that treatment with ibrutinib for 24h improves NLCs secretion of IL-10. CD19+ CLL cells stimulated with IL-10 in a dose escalation experiment (from 0.1 ng/ml to 100 ng/ml) show good protection from apoptosis at different doses at different time-points. We then analyzed the ability of ibrutinib to abrogate the pro-survival signal induced by IL10 stimulation (1 ng/ml) in CD19+ CLL cells after 24-48h of culture. Ibrutinib does not completely antagonize the ability of IL-10 to protect CLL cells from apoptosis and to activate pSTAT3 and pERK signaling pathways. In accordance, ibrutinib is able to potentiate the immunosuppressive and permissive profile of NLCs stimulating the expression of CD163, CD206 and the activation of pSTAT6 with a concomitant inhibition of pSTAT1.
Summary/Conclusions: The ability of ibrutinib to effectively disrupt the crosstalk between CLL cells and NLCs is still unclear. Our data demonstrate that ibrutinib may also target NLCs, potentiating their permissive features through the secretion of unwanted survival factors such as IL-10.

LEUKEMIC CELL/MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA: ROLE OF JAK2/STAT3 AXIS IN THE SURVIVAL OF NEOPLASTIC CLONE

F Severin[1,2,*], F Fezzato[1,2], V Martini[1,2], V Trimarco[1,2], F Raggi[1,2], L Martinello[1], A Visentin[1,2], E Scomazzon[1], M Facco[1,2], G Semenzato[1,2], L Trentin[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padua, [2]VIMM (Venetian Institute of Molecular Medicine), Padova, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is characterized by the accumulation of mature clonal CD19+/CD5+/CD23+ B lymphocytes in peripheral blood, bone marrow, and lymphoid tissues. Despite their *in vivo* prolonged lifespan due to intrinsic defects, CLL leukemic cells rapidly undergo spontaneous apoptosis *in vitro*, highlighting the need of extrinsic signals delivered by the microenvironment. Several molecules, including those released by mesenchymal stromal cells (MSCs), signal through JAK (Janus Kinases)/STAT (Signal Transducers and Activators of Transcription) pathways. Constitutive activation of JAKs and STATs occurs at very high frequency in various hematopoietic malignancies and solid tumors. STAT3 tyrosine (Tyr) phosphorylation at residue 705 is known to be critical for the activation of JAK2/STAT3 pro-survival signaling, while the role of STAT3 Serine (Ser) phosphorylation at residue 727 has not yet been well described. In CLL, STAT3 is constitutively phosphorylated at Ser727 with respect to normal B lymphocytes, but the phosphorylation status at Tyr705 still remains unresolved.
Aims: We are aimed to evaluate JAK2/STAT3 pathway involvement in leukemic B cell survival and to study the cross-talk between JAK/STAT and BCR/Lyn axes. With the identification of new targets implicated in this cross-talk, and through the analysis of leukemic cell resistance to drug-induced apoptosis, we plan to counteract the favorable pro-leukemic cell stimuli.
Methods: B cells were collected from 34 controls and 76 CLL patients. Purified cells ($2x10^6$ cells/ml) were cultured, with/without mesenchymal stromal cells (MSCs), and treated with AG490 (10, 50 and 100μM) and Stattic (5, 7.5, and 10μM), specific inhibitors of JAK2 and STAT3 respectively, for 24, 48 and 72h. STAT3 expression and phosphorylation were evaluated by Western Blotting (WB) and Flow Cytometry (FC), and its localization was analyzed by confocal microscopy and subcellular fractionation. CLL and normal B cell viability was tested by FC with Annexin V/PI test. Lyn and SHP-1 phosphorylation was assessed by WB.
Results: We demonstrated that STAT3 is overexpressed in malignant B cells (Student's *t* test, $p<0.001$) and the protein is higher phosphorylated at Tyr705 with respect to the normal counterpart (Student's *t* test, $p<0.05$), thus showing its constitutive activation in CLL. We also found that the *in vitro* incubation of leukemic B cells with AG490 and Stattic, specific inhibitors of JAK2 and STAT3, respectively, induces a dose-dependent apoptosis of CLL B cells. We demonstrated that these inhibitors are able to induce apoptosis in CLL B cells reverting the resistance to cytotoxic agents induced by the MSCs, bypassing the provided pro-survival stimuli. In addition to JAK2/STAT3 inhibition, we showed that AG490 treatment on CLL cells can mediate the activation of SHP-1, decreasing its phosphorylation at Ser591, thus leading to inactivation of Lyn protein, by de-phosphorylation in its active site at Tyr396. Lyn, a Tyr-kinase, and SHP-1, a Tyr-phosphatase, are both involved in the prolonged lifespan of neoplastic CLL cells.
Summary/Conclusions: Bypassing the pro-survival stimuli provided by the tumor microenvironment, the ability of AG490 and Stattic to induce apoptosis in leukemic B cells, represents a starting point for the development of new therapeutic strategies in CLL. These findings also provide new insights on the cross-talk between JAK/STAT and BCR/Lyn axes in CLL.

E1022

LINKING PROTEOME AND GENOME FOR BIOMARKER DISCOVERY IN CLL-ESTABLISHMENT OF A CLL PROTEIN DATABASE

G L Eagle[1,*], J Zhuang[1], R Jenkins[2], N Kitteringham[2], M Oates[1], K Park[2], A Schuh[3], S Devereux[4], P Hillmen[5], A Pettitt[1]
[1]Department of Molecular & Clinical Cancer Medicine, [2]MRC Centre for Drug Safety Science, Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, [3]Department of Oncology, University of Oxford, Oxford, [4]Department of Haematological Medicine, Kings College Hospital NHS Foundation Trust, London, [5]Faculty of Medicine and Health, University of Leeds, Leeds, United Kingdom

Background: Chronic Lymphocytic Leukaemia (CLL) is notable for its clinical variability, suggesting a role for precision medicine. Attempts at understanding the biological basis of this variability have mainly focussed on genomic alterations and gene expression at the mRNA level. However, the molecular basis of CLL variability remains incompletely understood. We speculate that this is because the clinical phenotype is ultimately determined by gene expression at the protein level. We have therefore embarked on a global proteomic study of a large number of CLL trial samples for which whole genome sequencing data will be available through the Genomics England Ltd (GEL) CLL Pilot Project. We anticipate that our study will bridge the gap in our understanding between genotype and clinical phenotype.
Aims: Recently developed mass spectrometric approaches to highly parallel, label-free protein quantification provide a new opportunity to develop diagnostic, prognostic and predictive biomarkers. SWATH (Sequential Windowed Acquisition of all THeoretical fragments) is a data-independent approach which generates a mass spectral library of fragment ions from all detectable peptide precursors. The composite MS/MS spectra are deconvoluted by alignment with a high quality and exhaustive, tissue specific database, whereupon patient samples may be stratified based on the quantitative expression profile of thousands of proteins. Here, we describe generation of a CLL-specific protein database that will provide a permanent reference source for all future trial samples, as indicated in Figure 1.
Methods: Protein extracts were prepared from CLL cells from 14 individual patients in various stages of the disease. Lysates were pooled and digested before being subjected to cation exchange chromatography. Forty fractions were delivered into a TripleTOF 6600 mass spectrometer (SCIEX) via an Eksigent nanoLC 415 system (SCIEX). Data dependent acquisition was performed using 25 MS/MS per cycle to optimise for quality and 30 MS/MS per cycle to optimise for coverage, and the combined data were searched using ProteinPilot 5.0 (SCIEX) against the SwissProt database (Nov 2015, 20,193 human entries). Proteins lying within a 1% global false discovery rate were included in the database.
Results: The new CLL-specific database contains 7773 proteins. The database covers 50% of all human UniProtKB/SwissProt entries which have evidence at the protein level. Pathway analysis of B cell receptor (BCR) signalling based on the GeneGo pathway maps in the MetaCore database (version 6.14, build 61508; Thomson Reuters) showed that this CLL database covers over 87% of the proteins involved in BCR signalling. The quality of the database entries is further underlined by high representation in the Human Genome database (20,814 entries) in aspect of Gene Ontology biological processes and molecular functions, as determined by PANTHER over-representation tests.

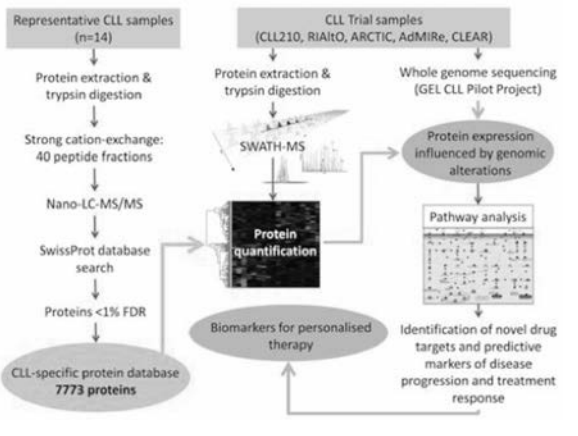

Figure 1.

Summary/Conclusions: Our global protein expression database for CLL cells is thus the most complete database of its type. By combining advanced computational biology to relate protein expression to whole genome sequencing data, the database will provide a framework for elucidating the effect of genomic alterations on protein expression. The construction of this comprehensive CLL database also provides the platform for applying SWATH/MS-based analysis of individual patient samples to identify novel drug targets and predictive biomarkers of disease progression and treatment response.

E1023

THE IMPACT OF THE TUMOUR MICROENVIRONMENT ON B-CELL RECEPTOR (BCR) EXPRESSION AND SIGNALLING IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL)

R Dobson*, M Blunt, M Aguilar-Hernandez, M Larrayoz-Ilundain, L Smith, J Strefford, M Cragg, F Forconi, F Stevenson, G Packham, A Steele
University of Southampton, Southampton, United Kingdom

Background: Chronic lymphocytic leukaemia (CLL) is thought to be driven following antigen engagement of the B cell receptor (BCR). This has been highlighted further by the BCR Kinase inhibitors Ibrutinib and Idelalisib, which have proved instrumental in the treatment of CLL. However, these inhibitors appear to only suppress the disease without being curative. A number of patients have developed resistance to ibrutinib following mutation of the *BTK* or *PLCγ2* gene, whilst other patients are unable to tolerate these drugs due to adverse events or progress whilst on therapy for unknown reasons. B-cell activating factor (BAFF) and interleukin-4 (IL-4) are known to increase CLL cell viability *in vitro*, and are thought to be present within CLL lymph nodes. Therefore we have investigated the role of BAFF and IL-4 in regulating BCR signalling in CLL cells and promoting resistance to ibrutinib and idelalisib.
Aims: To understand how IL-4 and BAFF regulate BCR pathway inhibition by ibrutinib and idelalisib.
Methods: Experiments were carried out using primary CLL cells. All isolates used contained >85% $CD19^+CD5^+$ cells. Protein expression was evaluated by flow cytometry or immunoblotting and signalling capacity was detected by calcium flux analysis in response to soluble αIgM by flow cytometry. Cell viability was assessed using annexin v/propidium iodide staining.
Results: As previously shown CLL cells treated with BAFF (500 ng/ml) or IL-4 (10 ng/ml) only for 48h significantly protected against basal apoptosis. This anti-apoptotic effect was further augmented when cells were treated with BAFF and IL-4 in combination. CLL cells treated *in vitro* with ibrutinib and idelalisib induced approximately 24.3% and 28.8% apoptosis respectively following treatment for 48h. However, apoptosis induced by the BCR-kinase inhibitors was reversed following pre-treatment with IL-4 or BAFF. CLL cells incubated *in vitro* with IL-4 for 24h significantly augmented sIgM expression and αIgM induced phosphorylated ERK and calcium flux. These IL-4 induced effects on sIgM expression were more prominent in Unmutated(U)-CLL samples, and could be reversed using the JAK3 inhibitor tofacitinib (CP-690550). Whilst, IL-4 had little effect on sIgD. Interestingly pre-treating CLL cells with IL-4 significantly reversed the ability of ibrutinib (1 μM) and idelalisib (1 μM) to inhibit αIgM-mediated signalling at 24h. In contrast BAFF treatment showed no clear effect on sIgM expression and downstream signalling. However, in a proportion of CLL samples treated simultaneously with BAFF and IL-4, BAFF reduced IL-4 specific increases in sIgM augmentation. Next we pre-treated CLL cells with tofacitinib (10 μM) for 1 hr prior to IL-4 treatment. Tofacitinib significantly reversed the effects observed with IL-4 and restored the ability of ibrutinib and idelalisib to inhibit αIgM induced signalling. This effect was specific to the inhibition of IL-4 since tofacitinib (≤10 μM) did not induce CLL cell death. Finally we showed that BAFF, and IL-4 to a greater extent, resulted in an increase in miRNA155 expression which has previously been shown to be associated with more progressive disease and enhanced BCR signalling.
Summary/Conclusions: Our data suggests that IL-4 augments sIgM recovery and down-stream signalling in CLL, which may compromise the effectiveness of BCR kinase inhibitors. However these effects were not observed for BAFF. Furthermore, co-treatment of BCR-kinase inhibitors in combination with tofacitinib may indicate a promising treatment strategy for the treatment of CLL.

Of Oncology, University of Turin,San Luigi Gonzaga Hospital, Orbassano, [5]Department of Molecular Biotechnology and Health Sciences, University of Turin, Torino, Italy, [6]Department of Medicine and Pathology, Beth Israel Deaconess Medical Center, Harvard Medical School, Cancer Genetics Program, Beth Israel Deaconess Cancer Center, Boston, United States

Background: Standard immune-chemotherapy allows to achieve 60-70% response rate in CLL patients, but complete remission remains uncommon. Unsatisfactory therapeutic options still exist for higher risk groups, and in particular those harboring *TP53* mutations or deletion.
Aims: We propose USP7, a known de-ubiquitinase with multiple roles in cellular homeostasis, as a potential therapeutic target in CLL.
Methods: Primary CLL cells were enriched in $CD19^+$ fraction using the Milteny anti-CD19 kit and were used to investigate USP7 levels. P5091 (USP7 inhibitor) efficacy was tested in CLL cell lines and patients. Proliferation and apoptosis were evaluated respectively with CTG technology and Annexin V-FITC/Propidium PE detection by flow cytometry. The specificity of the USP7 inhibitor was verified with a pool of 5 different siRNAs able to efficiently silence USP7.
Results: Our data show that the de-ubiquitinase USP7 is aberrantly expressed in CLL. In particular, USP7 is over-expressed in about 70% of CLL $CD19^+$ lymphocytes, both at the mRNA and protein levels. We also analyzed USP7 expression levels in an expansion cohort of a publicly available CLL patients (n=217) and 12 normal samples, where USP7 was over-expressed in CLL when compared to normal samples (****$p<0.0001$). We proved that USP7 is regulated at post-transcriptional level by miR-338-3p and functionally activated by Casein Kinase 2 (CK2) through phosphorylation at serine 18 residue. USP7 inhibition by P5091 as well as by specific siRNA, induces cell growth arrest and apoptosis mediated by the restoration of the nuclear pool of PTEN. Notably in primary CLL cells, P5091 treatment strongly promoted apoptosis. Moreover, USP7 inhibitor treatment of primary CLL was associated with increases ubiquitination of endogenous PTEN and consequently PTEN relocalization into the nucleus. Strikingly, TP53 deleted CLL samples and cells lines were equally subject to P5091 apoptosis induction, confirming that the USP7 inhibitor acts in a p53 independent manner. These data showed potent activity of P5091 against primary CLL.
Summary/Conclusions: We demonstrate the efficacy of a small molecule inhibitor of USP7, P5091, *in vitro* in cell lines and *ex vivo* in primary CLL samples in a P53-independent manner. Our preclinical study therefore, supports the evaluation of USP7 inhibitor as a potential CLL therapy.

DIRECT AND INDIRECT MODULATION OF MACROPHAGES IN THE TUMOR MICROENVIRONMENT UPON GENOTOXIC STRESS ALTERS PHAGOCYTIC FUNCTION

D Vorholt*, T Erlikh, N Nickel, M Hallek, C Pallasch
Department I for Internal Medicine, Centre for Integrative Oncology CIO, University Hospital of Cologne, Cologne, Germany

Background: Resistance against chemotherapy is a central problem in the current treatment of B cell malignancies. Up until now, little is known about the impact of the tumor microenvironment on therapeutic outcome. This microenvironment consists of many different kinds of cells varying between tumors, significantly manipulating malignancy and enabling relapses after treatment. Macrophages are present in the microenvironment of most tumors-designated as tumor associated macrophages (TAM)-and are often correlated to a poor prognosis. We postulate that macrophages and their reprogramming are an essential element in the malignant progression of tumors and their response to DNA damage as occurring in chemotherapeutic treatment and are a promising target to improve therapy response.
Aims: We aim to define the functional characteristics of macrophages in their cross talk with malignant B cells and characterize their role for disease progression and antitumor therapy. Our particular interest lies on the investigation of the functional mechanistic and kinetics underlying macrophage repolarisation. Here, we intend to identify key regulators and their upstream signaling pathways by focusing on the DNA damage pathway.
Methods: To assess macrophage leukemia cell interaction we established *in vitro* and *ex vivo* co-cultures of macrophages and leukemic cells, specifically investigating macrophage antibody dependent cellular phagocytic (ADCP) capacities. Leukemic cell clearance and macrophage phenotype characterization are determined by flow cytometry. We addressed both primary CLL patient cells as well as humanized mouse model of BCL2/MYC double hit lymphoma.
Results: Functionally we prove that low dose application of the *in vitro* equivalent of Cyclophosphamide, Mafosfamide significantly increases the phagocytic function of macrophages. Besides this direct effect on macrophages, a combination of cyclophosphamide and alemtuzumab was demonstrated to induce a macrophage based increase in tumor clearance by cytokine secretion of stressed malignant B cells. Here, we could determine IL10 as an inducer of increased phagocytosis in tumor associated macrophages. Moreover we show that IL10 modulates differentiation of macrophages which strongly increases their ADCP compared to classical M1/M2 differentiated macrophages. Analyzing the functional contribution of the DNA-damage pathway we could identify pronounced secretion of IL10 in p53-deficient leukemia cells. We show *in vitro* that the DNA damage pathway plays an important role in the ASAP mechanism as a down regulation of various DNA damage key players in the leukemic cells diminishes the stimulating effect of Cyclophosphamide and antibody combinations.
Summary/Conclusions: Repolarisation of macrophages towards increased phagocytosis is essential in immunochemotherapies. We demonstrate that the DNA damage pathway is important for this stimulating effect and that the mech-

anism involves a complex interplay between macrophages and leukemic cells. The DNA damage of the genotoxic chemotherapy is increasing the phagocytosis activity of the macrophages directly as well as indirect by a cytokine secreted from stressed leukemic cells.

Background: In CLL cells STAT3 is constitutively phosphorylated on serine 727 residues whereas phosphorylation of STAT3 on tyrosine 705 residues cells is inducible. Cytokines, such as IL-6, or IgM antibodies that activate CLL cells' BCR, induce tyrosine phosphorylated (p) STAT3. However, while IL-6 induces tyrosine pSTAT3 within 15 minutes, IgM induces pSTAT3 within 2-4 hours. The reason for the delayed IgM-induced phosphorylation is unknown. Like STAT3, the transcription factor NF-κB is constitutively activated in CLL cells and stimulation of the BCR further activates NF-κB. Whether BCR stimulation upsurges NF-κB's transcriptional activity. Specificallhas not been elucidated.In CLL cells STAT3 is constitutively phosphorylated on serine 727 residues whereas phosphorylation of STAT3 on tyrosine 705 residues cells is inducible. Cytokines, such as IL-6, or IgM antibodies that activate CLL cells' BCR, induce tyrosine phosphorylated (p) STAT3. However, while IL-6 induces tyrosine pSTAT3 within 15 minutes, IgM induces pSTAT3 within 2-4 hours. The reason for the delayed IgM-induced phosphorylation is unknown. Like STAT3, the transcription factor NF-κB is constitutively activated in CLL cells and stimulation of the BCR further activates NF-κB. Whether BCR stimulation upsurges NF-κB's transcriptional activity. Specificallhas not been elucidated.
Aims: 1) To describe the BCR dependent, NF-κB-mediated gene expression profile of CLL cells. 2) To confirm our hypothesis that prolonged stimulation with IgM antibodies induces tyrosine pSTAT3 via NF-κB-mediated induction of IL-6 in CLL cells.
Methods: We incubated peripheral blood CLL cells in the presence or absence of IgM antibodies or IL-6, and harvested the cells at different time points. Total RNA was extracted using TRIzol, cDNA was synthesized with Super Script First synthesis System for RT-PCR, and NF-κB-target gene expression was quantified using RT-PCR. To measure the levels of tyrosine pSTAT3 we used flow cytometry and to assess binding of NF-κB (p65) to DNA we utilized an electromobility shift assay (EMSA) using an NF-κB-binding site labelled DNA probe.
Results: To study the transcriptional activity of NF-κB we used a PCR array that profiles the expression of 83 NF-κB-target genes. To reduce the 'noise' from stochastic variability in gene expression we first identified a core of genes that are expressed in cells from all patients' samples. To that aim we ranked the Ct values in each array and considered all genes that were amplified earlier than the cycle in the 75th percentile. Using this approach we identified 35 genes (42% of genes represented in the array) that were amplified in all 6 patients' samples. Annotation analysis revealed that the key pathways common to these 35 genes included 'Positive regulation of the NF-κB cascade', 'Inflammation' and 'Negative regulation of apoptosis'. Applying stringent criteria we identified 5 genes common to all cases that were amplified prior to the cycle representing the 25th percentile. Most amplified genes detected in all samples prior to stimulation (28/35, 80%) were also detected after 4 h of IgM stimulation, confirming that NF-κB is constitutively activated in CLL cells. However, 19 addition genes (19/83, 23% of the genes in the array) were detected in all IgM-stimulated but not in unstimulated cells. Remarkably, *IL-6* was detected in all cases only after IgM stimulation. Furthermore, observed an IgM-induced time-dependent increment in *IL-6* and *IL-8*, suggesting that IL-6 expression is dependent on stimulation of the BCR. Indeed IL-6 neutralizing antibodies significantly reduced the levels of tyrosine pSTAT3 in CLL cells incubated for 18 h with IgM antibodies. In addition, EMSA of CLL cells from 4 different patients showed that stimulation of the BCR with IgM antibodies increased the binding of NF-κB to DNA in a time-dependent manner. Furthermore, the JAK2 inhibitor Ruxolitinib attenuated the NF-κB-DNA binding, suggesting that 2-4 hour exposure to IgM antibodies induces activation of NF-κB, a process mediated in part by IL-6 that activates the JAK2/STAT3 pathway.
Summary/Conclusions: It has been well established that the BCR of CLL cells is stimulated in the bone marrow and lymph nodes. However, whereas the immediate effects of BCR stimulation have been excessively studied, the successive effect of BCR stimulation is poorly understood. We found that stimulation of the BCR induces tyrosine phosphorylation of STAT3 via NF-κB-mediated induction of IL-6, a process that requires protracted BCR stimulation. Although NF-κB is constitutively activated in CLL cells, continuous activation of the BCR further activates NF-κB. These findings suggest that agents, such as Ruxolitinib, that inhibit the successive effects of the BCR activation, would become effective therapeutic agents in CLL.

DIFFERENTIAL EXPRESSION PROFILE OF H/ACA RIBONUCLEOPROTEIN COMPONENTS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

P Dos Santos[1,*], J Panero[1], C Stanganelli[2], V Palau Nagore[1], R Bezares[3], I Slavutsky [1]
[1]Laboratorio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimental-CONICET-Academia Nacional de Medicina, [2]División Patología Molecular, Instituto de Investigaciones Hematológicas-Academia Nacional de Medicina, [3]Servicio de Hematología, Hospital Teodoro Alvarez, Buenos Aires, Argentina

Background: Chronic lymphocytic leukemia (CLL) is a clinically heterogeneous disease. Telomere dysfunction has been proposed as an emerging prognostic factor in this pathology. Telomeres are essential to maintain chromosomal integrity and genome stability. They progressively shorten with repeated cell division, leading to telomere dysfunction and contributing to tumorigenesis. Telomerase is a ribonucleoprotein complex containing an internal RNA template (TERC) and a catalytic protein with telomere-specific reverse transcriptase activity (TERT). The human TERC gene consists of three major domains; among them the H/ACA domain is essential for telomere biogenesis. H/ACA ribonucleoprotein (RNP) complex is composed of four evolutionary conserved proteins, including dyskerin (DKC1), NOP10, NHP2 and GAR1. The first three proteins form a core trimer that directly binds to H/ACA RNAs. They are interdependent upon each other for stability and also regulate stability of the bound RNAs. GAR1 binds only to DKC1 and is needed for proper functioning of the H/ACA RNPs, but its absence does not reduce stability of the RNA.
Aims: In this study, we have evaluated the expression profile of the H/ACA RNP complex: *DKC1*, *NOP10, NHP2 and GAR1*, as well as *TERT* and *TERC* mRNA levels, in patients with CLL. Results were correlated with telomere length (TL), genetic alterations, mutational status of *IGHV* (immunoglobulin heavy chain variable region) genes, and clinico-pathological characteristics of the disease.
Methods: The study was performed on mononuclear cells isolated on a Ficoll-Paque Plus density gradient from peripheral blood samples of 60 patients with CLL at diagnosis (34 males; mean age: 66.8 years; range: 44-88 years) and 14 normal controls. All individuals gave their informed consent and the study was approved by the local Ethics Committee. Gene expression and absolute TL measurement was carried out by real-time quantitative PCR. *IGHV* gene rearrangements and mutational status were analyzed by RT-PCR and bi-directional sequencing. Cytogenetic and FISH analysis were also performed.
Results: Gene expression analysis showed increased mRNA levels of *TERT, NHP2 and GAR1,* as well as decreased expression of *TERC, DKC1* and *NOP10* in CLL patients compared to controls (p=0.043). A significant correlation between *GAR1-NHP2*, *GAR1-NOP10* and *NOP10-NHP2* transcription levels (p=0.0001) was detected, supporting a strong interaction among them. Patients with short TL had higher expression of *TERT* (p=0.033) and *DKC1* (p=0.02) than those with long telomeres. The analysis taking into account cytogenetic and FISH alterations showed higher mRNA levels of *GAR1* and *NHP2* in patients with two or more anomalies (p=0.02) compared to those with no/one alteration. An upregulation of *TERT, TERC, GAR1 and NOP10* expression in unmutated *IGHV* CLL patients was also observed. No association between gene expression and clinical parameters was found. However, a tendency to a short treatment free survival in patients with increased *TERT* expression was detected.
Summary/Conclusions: Our findings show a global modification in the expression of telomere associated genes in CLL, being, to our knowledge, the first analysis of *TERC, NOP10, NHP2 and GAR1* in this pathology. Their association with higher number of genetic alterations and unmutated *IGHV* mutational status suggests a role for these telomere-associated genes in genomic instability and telomere dysfunction in CLL.

REDOX SIGNALING HYPERSENSITIVITY DISTINGUISHES CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH FAVORABLE PROGNOSIS

C Cavallini[1], O Perbellini[2], R Chignola[1], M Cordani[1], E Zoratti[1], E Mimiola[1], C Laudanna[1], M Donadelli[1], G Pizzolo[1], MT Scupoli[1,*]
[1]University of Verona, Verona, [2]San Bortolo Hospital, Vicenza, Italy

Background: Chronic lymphocytic leukemia (CLL) patients exhibit a variable clinical course, with some patients having indolent disease and others experiencing a more accelerated course, treatment resistance and dismal outcome. The B-cell receptor (BCR) signaling is a key determinant of heterogeneous clinical behavior of CLL and is a target for therapeutic interventions. Endogenously produced H_2O_2 is thought to fine tune the level of BCR signaling by reversibly inhibiting phosphatases. However, relatively little is known about how CLL cells sense and respond to such redox cues.
Aims: In this study, we used phospho-specific flow cytometry to compare BCR signaling responses to H_2O_2 in prognostic groups of CLL patients.
Methods: The phosphorylation levels of five proteins downstream of the BCR signaling, namely SYK, NF-κB p65, ERK1/2, p38 and JNK, were analyzed at the single-cell level in 26 CLL cell samples using phospho-specific flow cytom-

etry. In accordance with the Declaration of Helsinki, all patients provided written informed consent for the collection and use of their samples for research purposes. The local Ethics Committee (Comitato Etico per la Sperimentazione, AOUI) approved sample collection. Protein phosphorylation was measured in the basal condition and following stimulation with H_2O_2. Circulating B cells from healthy individuals were analyzed as controls. The two-sample Wilcoxon's rank sum test was used to compare protein phosphorylation in groups of patients. Time to first treatment (TTFT) was calculated from the date of diagnosis to the date of initial therapy. TTFT curves estimated using the Kaplan- Meier method for the respective groups of patients were compared using the log-rank test.
Results: In CLL cells, stimulation with H_2O_2 induced a statistically significant increase in phosphorylation of all analyzed signaling proteins with the exception of SYK. Moreover, the extents of responses to H_2O_2 were significantly higher in CLL than normal B cells for all signaling proteins but SYK. Comparison of H_2O_2 signaling response in prognostic groups of patients defined by *IGHV* mutational status, CD38 or ZAP-70 expression, showed that median phosphorylation response of ERK1/2 to H_2O_2 was significantly higher in the patient subset defined by the mutated *IGHV* status (M-CLL) (*P*=0.031). No significant correlations were observed between H_2O_2 responsiveness of BCR signaling proteins and ZAP-70 or CD38 expression. Kaplan-Meier curves showed statistically significant slower progression (longer time to first treatment, TTFT) in patients with higher p-ERK1/2 and p-NF-□B p65 responses to H_2O_2, indicating that lower responsiveness of these signaling proteins to H_2O_2 correlated with more rapid progression [median TTFT was 41.6 and 115 months for patients with lower and higher NK-kB p65 responsiveness to H_2O_2, respectively (log-rank test *P*=0.0011); median TTFT was 38.7 and 117.0 months for patients with lower and higher ERK1/2 responsiveness to H_2O_2, respectively (log-rank test *P*=0.0008)] (Figure 1). Interestingly, the ability of H_2O_2 responsiveness signaling to define prognostic groups is comparable to that of *IGHV* mutational status (log-rank test *P*=0.0003).

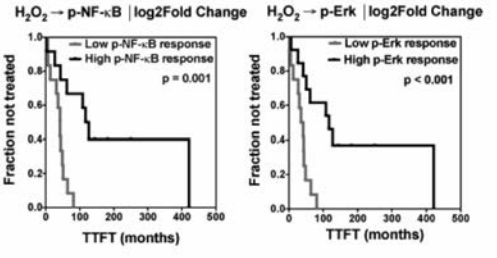

Figure 1. Kaplan-Meier curves of TTFT for subgroups of patients defined by response to H_2O_2.

Figure 1.

Summary/Conclusions: This study reveals that a novel H_2O_2 signaling response distinguishes a prognostic group of CLL patients with favorable prognosis. Specifically, higher H_2O_2 responsiveness of ERK1/2 or NF-kB is predictive of longer TTFT, thus highlighting ERK and NF-kB as biologically and clinically relevant signaling nodes in CLL.
Funding. This study was funded by Fondazione Cassa di Risparmio di Verona, Vicenza, Belluno e Ancona and Associazione Italiana Ricerca sul Cancro (AIRC) (grant #6599).
