Abstract

Primary central nervous system lymphoma is an aggressive extranodal lymphoma with poor prognosis, largely due to its capacity for immune evasion within the unique microenvironment of the CNS. Here, we investigated the interactions between macrophages and T cells in a syngeneic mouse model of PCNSL, manipulating macrophage/microglia populations and MHC class I expression on tumor cells to mimic patient-associated immune escape. We found that macrophages and microglia are indispensable for anti-tumor immunity and significantly enhance the efficacy of PD1 checkpoint blockade, particularly when tumor cells retain MHC-I expression. In contrast, depletion of these myeloid cells led to accelerated disease progression and diminished response to immunotherapy, highlighting the importance of both innate and adaptive immunity in PCNSL. Interestingly, MHC-I–deficient PCNSL did not respond to T cell–based therapies and was controlled exclusively by macrophages, rendering prognosis largely dependent on this alteration. Our findings support the need for therapeutic strategies that target both T cell and myeloid compartments and suggest that profiling MHC-I expression may help guide personalized immunotherapy approaches in this challenging disease.

Introduction

Primary Central Nervous System Lymphoma (PCNSL) is a rare and aggressive form of diffuse large B cell lymphoma (DLBCL) confined to the central nervous system (CNS), affecting the brain, spinal cord, leptomeninges, and/or eyes. It accounts for 4% of primary CNS tumors and 4-6% of extranodal lymphomas, with a median age at diagnosis of 67 years[1]. A high-dose methotrexate-based regimen followed by autologous stem cell transplantation is typically administered to fit patients, whereas whole-brain radiotherapy is often reserved for unfit patients. Despite these efforts, prognosis remains poor, with a median survival of 36 months, a five-year survival rate of 30%, and relapse occurring in 15-25% of cases, highlighting the urgent need for new therapies[2].

PCNSL belongs to the new term introduced in WHO-HAEM5 of primary large B cell lymphomas of immune-privileged sites[3]. Shared features include the activated B cell (ABC) subtype and frequent mutations in *MYD88* and *CD79B* as well as additional genetic alterations promoting immune evasion, which are hallmarks of the MCD/C5/MYD88 genetic subtype of DLBCL[4,5]. The brain is considered an immune-privileged organ due to the limited immune surveillance and unique microenvironment, which play a crucial role in the pathogenesis and progression of the disease[6]. Moreover, up to 70% of patients exhibit tumor genetic alterations involving deletion in the *HLA* locus (6p21) and loss of *B2M* (15q21.2), which leads to reduced MHC class I (MHC-I) surface expression[7,8]. These alterations contribute to low tumor antigen presentation and T cell recognition, preventing an efficient T cell-mediated anti-tumoral immune response[8]. Additionally, copy-number gain of CD274/PD-L1 (9p24.1) drives PD-L1 overexpression, which—together with MHC class I loss on lymphoma cells—enables immune evasion and is linked to poor clinical outcomes in PCNSL patients[9-11]. Given these immune checkpoint and antigen presentation defects, PD1 inhibitors like nivolumab have been explored clinically[12]. However, a phase II trial reported low response rates (ORR ~20-30%)[13], highlighting the need for further investigation.

Macrophages represent the predominant immune cells infiltrating PCNSL[14-17], and their abundance within the tumor microenvironment (TME) is associated with a favorable prognosis[16-18]. While the PD1/PD-L1 pathway has traditionally been considered a checkpoint regulating cytotoxic responses of activated T cells[19,20], recent studies have shown that tumor-associated macrophages (TAMs) can also express PD1, and its inhibition enhances their cytotoxic activity against malignant cells[21]. Additionally, MHC-I molecules on tumor cells can bind to LILRB1 on macrophages, delivering inhibitory signals that suppress phagocytosis[22]. For that reason, downregulation of MHC-I allows lymphoma cells to evade T cell recognition and cytotoxicity but simultaneously makes them more vulnerable to macrophage-mediated phagocytosis, particularly when inhibitory signals such as CD47 are effectively targeted[22]. Interestingly, macrophage immune checkpoints are strongly expressed in the tumor microenvironment of PCNSL patients[14,23]. Furthermore, our previous research using a PDX

preclinical model of PCNSL revealed high expression levels of both PD1 and SIRPα in tumoral infiltrating-macrophages[24]. This evidence highlights the strong interaction between malignant cells and macrophages in the brain and suggests that macrophages could serve as potent effector immune cells against PCNSL lacking MHC-I expression.

Herein, we assessed the infiltration and interaction of macrophages and T cells within the immune-evasive TME under immune checkpoint blockade. We achieved this using a PCNSL syngeneic mouse model by depleting macrophages and microglia, while simultaneously impairing cytotoxic T cell function through downregulation of MHC-I on malignant B cells. This intracerebral A20 implantation represents a robust preclinical model to study immunotherapies and tumor microenvironment in PCNSL, as demonstrated by others[24-26].

Methods

Additional details can be found in Supplementary data.

Cell Lines. The murine B cell lymphoma A20 cell line was obtained from ATCC and cultured in RPMI (ThermoFisher) supplemented with 10% FBS (ThermoFisher), 100 units/mL penicillin, 100 μg/mL streptomycin, and 292 μg/mL L-glutamine (ThermoFisher) and maintained in humidified incubators at 37ºC with 5 % CO_2. For stable luciferase expression, A20 cells were transfected with a luciferase-expressing vector (Fluc2 gene).

MHC-I downregulation. CRISPR-Cas9 was performed to generate downregulation of MHC-I expression in A20 cells (MHC-I KO A20) by disrupting *TAP1*. *TAP1* gRNA, Cas9 endonuclease and universal tracrRNA were obtained from Integrated DNA Technologies (IDT). The crRNA:tracrRNA complex was ensembled following the manufacturer's protocol and delivered by electroporation using the Neon™ Transfection System (ThermoFisher)[27].

Macrophage/Microglia depletion in mice. To achieve microglia depletion, mice were fed a chow diet supplemented with the CSF1R inhibitor pexidartinib (PLX3397, 290 mg/kg) for 21 days prior to intracerebral tumor implantation and maintained on this diet until endpoint. Systemic macrophages were depleted by intraperitoneal injections of clodronate liposomes at 50 mg/kg, administered daily for three consecutive days starting three days before tumor implantation, followed by twice-weekly maintenance dosing. Control groups received unsupplemented chow or PBS-containing liposomes.

***In vivo* modeling of PCNSL**. All experiments with animals were approved by the local Ethical Committee for the Use of Experimental Animals. Briefly, brains of eight-week-old BALB/c female mice were injected with 10^5 A20 cells expressing luciferase and tumor growth was monitored by bioluminescence imaging (BLI) using IVIS® Spectrum system and Living Image software (PerkinElmer).

Organ processing. Brains were collected in cold RPMI-1640 medium immediately after euthanasia. The two hemispheres were then separated with a razor blade. One hemisphere was dedicated to immunohistochemistry (IHC), while the other was processed for flow cytometry and RNA sequencing (RNA-seq). Single-cell suspensions from brains were obtained using the Tissue Neural Dissociation Kit (Papain) (Miltenyi Biotec) following the manufacturer's protocol[28].

Flow Cytometry. Cells were incubated with 1 μg IgG from rat serum (Sigma-Aldrich) per $1x10^6$ cells for 15 minutes at 4ºC, followed by staining with monoclonal antibodies for 20 minutes at 4 °C. Cells were acquired in a Navios™ cytometer (BeckmanCoulter) and data analyzed using FlowJo software (version 10.10).

Immunohistochemistry. Antigen retrieval, staining and counterstaining were performed at an Autostainer Link 48 (DAKO). Slides were scanned using NanoZoomer 2.0 HT Digital slide scanner C9600 and visualized using NDP.view 2 (Hamamatsu Photonics K.K).

Multiplexed Immunofluorescence and imaging analysis. Multiplex immunofluorescence (mIF) was performed on FFPE mouse brain sections using the Opal™ Multiplex IHC Assay (Akoya Biosciences). Slides from WT and MHC-I KO mice (IC and MMD PCNSL; NT and PD1–treated; day 15 post-implantation) were stained with a panel of purified rabbit anti-mouse antibodies (CD20, CD4, CD8, TMEM119, CD68, CD86, PD1, PD-L1, CD47). Fluorescent imaging was acquired on the Vectra Polaris™ system and analyzed in QuPath. Cell–cell interactions were defined as distances of 0.5–10 μm between segmented cells.

RNA sequencing. Total RNA was isolated from mice brains following tissue dissociation. RNA quantification was performed with Qubit™ RNA High Sensitivity kit (Invitrogen) in a Qubit™ fluorometer (Invitrogen). Samples were run on NovaSeq 6000 (Illumina) with a read length of 2 x 50bp paired end.

Statistical Analysis. The statistically significant differences between groups were assessed using the Mann-Whitney test or one or two-way ANOVA, and $P<0.05$ was considered significant. Survival curves were generated using the Kaplan-Meier method and statistically compared using the log-rank test. Analyses were performed using GraphPad Prism 6 software.

Results

***In vivo* primary central nervous system lymphoma modeling.** The detailed longitudinal timeline of the experimental procedure is presented in **Figure 1A**. To investigate the role of macrophages and MHC-I expression in PCNSL, we induced the disease in immunocompetent and macrophage-depleted 8-week-old BALB/c mice by intracerebrally injecting $1x10^5$

luciferase-expressing WT or MHC-I KO mature B cell lymphoma A20 cells[25]. Survival, tumoral growth, and immune cell characterization in the brain were assessed. In all models, tumor growth was monitored twice a week starting on day 7 post-tumor injection, with a total of six captures.

In our set up model, immunocompetent mice bearing WT PCNSL had a median survival of 45 days. Tumors were already detectable in some mice 7 days after brain injection (**Figure 1B**). At endpoint, anti-CD20 immunohistochemistry revealed multifocal tumor infiltrates affecting both cerebral hemispheres, predominantly the right hemisphere, with localization primarily in the brain parenchyma where lymphoma cells formed dense clusters. In some cases, the meningeal compartment was also involved (**Figure 1C**).

Intravenous treatment with anti-PD1, anti-CD47 or the combination of both was initiated seven days following the intracranial injection of tumor cells, with a dosage of 200 µg in 100 µL, administered twice per week. For survival experiments, mice received a total of seven injections (n=12 mice/group). Euthanasia was performed upon reaching humane endpoints, including weight loss, circling behavior, motor impairments, and increased head size. To investigate immune infiltration in the brain, the same groups were studied, and brains were harvested 15 days post-tumor inoculation (n=6 mice/group), following the administration of three treatment injections.

To study the role of macrophages in PCNSL, both systemic macrophages and brain microglia were depleted. Immunohistochemical staining for Iba-1 demonstrated complete depletion of systemic macrophages in the spleen and liver after three consecutive daily injections of clodronate liposomes prior to tumor induction (**Figure 2A**). Maintenance injections were given at the same concentration twice/week after tumor inoculation. In the same manner, partial microglia reduction in brain was achieved by continuously exposing mice to pexidartinib diet for 10 days, with complete depletion reached by day 21 (**Figure 2B**). At this point, PCNSL tumors were established with continuous exposure to pexidartinib diet until endpoint to ensure ongoing microglia depletion. We also assessed macrophage and microglia depletion in mice bearing PCNSL following this set up schedule. We evaluated CD11b expression by flow cytometry. Results showed a significant reduction in both myeloid cell populations in the TME at final point (**Figure 2C**), with only residual staining attributable to cellular debris, indicating significant depletion of both macrophages and microglia in the tumor-bearing brain at endpoint, which confirmed sustained depletion under the subsequent maintenance regimens (**Supplementary Figure 1A**).

To downregulate the surface expression of MHC class I on malignant cells, we employed CRISPR-Cas9 to target the *TAP1* gene. *TAP1* encodes a transporter involved in loading peptides onto MHC-I molecules[29] and its downregulation reduces surface MHC-I expression. Validation of the KO was performed through flow cytometry (**Figure 2D**) and Sanger sequencing (**Supplementary Figure 1B**).

Strong positive expression of PD-L1 and CD47 surface proteins in both WT and MHC-I KO A20 cells were detected by flow cytometry (**Supplementary Figure 1C**).

Lack of expression of MHC-I in primary CNS lymphoma induces a more aggressive disease and reduces overall survival.

To investigate the role of MHC-I expression in PCNSL, we induced the disease in immunocompetent mice by intracerebrally injecting luciferase-expressing WT or MHC-I KO A20 cells (n=12). Tumor progression was monitored by bioluminescence imaging, and survival was evaluated. Mice bearing MHC-I-negative tumors exhibited a more aggressive disease, with significant differences in tumor growth apparent as early as day 7 post-implantation, and continuing through later stages, compared to WT tumor growth (**Figure 3A**). To determine if the proliferative advantage of lymphoma cells was intrinsic to MHC-I downregulation, we cultured them *in vitro* under identical conditions; however, no significant differences in cell growth kinetics over time between WT A20 and MHC-I KO A20 cells were observed (**Figure 3B**). This faster-growing tumor translated into a significantly longer survival of WT tumor-bearing mice compared to MHC-I KO tumor-bearing mice (median survival: 39 days (WT, dark red line) vs. 26 days (MHC-I KO, light red line); P=0.002, Kaplan-Meier)) (**Figure 3C**). This suggests that MHC-I-negative lymphoma cells may possess a proliferative advantage *in vivo* within the brain microenvironment, where T cells are unable to recognize them and exert a cytotoxic effect. In this context of absence of the MHC-I-LILRB1 inhibitory signaling pathway, we hypothesize that macrophages may exhibit increased antitumoral activity. However, this potential increase in macrophage activation would not be reflected in the aggressiveness of MHC-I–negative PCNSL, possibly because, unlike T cells, macrophages may require additional stimulation. Consistent with this, MHC-II-deficient PCNSL exhibited comparable tumor growth and immune profiles to WT tumors in vivo (**Supplementary Figure 2**), emphasizing that MHC-I, rather than MHC-II, serves as a key determinant of immune control and a potential prognostic factor in PCNSL.

Macrophages control the tumoral growth in PCNSL and prolong mice overall survival.

To uncover the role of macrophages and microglia in PCNSL, we also injected WT or MHC-I KO A20 lymphoma cells into the brains of macrophage-depleted mice (n=12 per group) and assessed tumor growth and survival. Results demonstrated that both WT and MHC-I KO tumors exhibited a faster tumoral growth in the absence of macrophages in the tumor microenvironment compared to the same tumors growing in immunocompetent mice (**Figure 3D**). Accordingly, survival analysis also showed significant differences in immunocompetent mice compared to those without macrophages (**Figure 3C**). In macrophage-depleted mice, both WT (dark green line) and MHC-I KO (light green line) PCNSL had approximately the same short median survival rates (25 vs. 21 days; p=0.04), meaning that the absence of

macrophages and microglia cells is sufficient to induce a very aggressive disease, even in WT tumors.

To understand the aggressiveness of MHC-I KO tumors, it is important to note that survival of mice bearing MHC-I KO PCNSL with a fully intact immune cell compartment (light red line) closely mirrored that of mice carrying WT tumors growing in the absence of macrophages and microglia (dark green line) (26 vs. 25 days). This suggests that macrophages and/or microglia may play a critical role in controlling the initial tumoral growth of CNS lymphoma cells in the brain and supports the observation of limited T cell activity in MHC-I KO tumors, highlighting the necessity of stimulating the myeloid compartment to enhance an anti-tumoral immune response in this setting.

PD1-blockade immunotherapy is more effective when macrophages are present in the tumor microenvironment.

The loss of MHC-I surface expression in malignant cells resulted in more aggressive disease in our syngeneic mouse model of PCNSL. Recognizing the critical role of macrophages in controlling malignant cell growth within this microenvironment, we hypothesized that anti-PD1 treatment may exert anti-tumoral effects by enhancing macrophage phagocytic activity, even in the context of MHC-I downregulation. To investigate the roles of macrophages and T cells in the response to checkpoint inhibitors, we utilized both immunocompetent and macrophage-depleted mice bearing either WT or MHC-I KO PCNSL tumors. For each model, 48 mice were used and divided into two cohorts based on tumor type (WT A20 cells or MHC-I KO A20 cells; n=24 per cohort). Each cohort was then split into two treatment groups: vehicle control or anti-PD1 antibody (n=12 per group). Anti-PD1 therapy was initiated seven days after tumor induction and administered intravenously twice weekly for a total of seven doses.

Results showed that in WT CNS lymphoma, significant differences in tumor growth between treated and non-treated groups became apparent starting at day 14 post-tumor injection in immunocompetent mice (**Figure 4A,** dashed dark red line vs. solid dark red line). In contrast, in MHC-I KO CNS lymphoma, no significant differences in tumor growth were observed between anti-PD1-treated mice and the vehicle group at any timepoint, although a modest response to treatment was noted (**Figure 4A,** dashed light red line vs. solid light red line).

To evaluate the specific role of macrophages in the therapeutic activity of PD1 blockade, we compared vehicle-treated and anti-PD1 treatment groups in macrophage-depleted mice. As shown in **Figure 4B**, no significant differences were observed between control and anti-PD1 treatment in any group, indicating that a robust anti-PD1 treatment response is achieved when macrophages are present in the TME. In terms of survival, PD1 blockade significantly prolonged survival in immunocompetent mice bearing both WT PCNSL (dashed dark red line vs. solid dark red line; undefined vs. 39 days; P=0.0005) and MHC-I KO PCNSL (dashed light red line vs. solid light red line 43.5 vs. 26 days; P=0.0002) (**Figure 4C**). Notably, the survival

of IC mice with MHC-I KO tumors treated with anti-PD1 was comparable to that of non-treated mice bearing WT tumors (dashed light red line vs. solid dark red line; 43.5 vs. 39 days). Interestingly, in the absence of macrophages and microglia, only those bearing WT PCNSL tumors had a significant survival advantage from treatment (dashed dark green line vs. solid dark green line; 50 vs. 25 days; p=0.005). MHC-I KO tumor-bearing mice did not respond to anti-PD1 treatment in macrophage-depleted mice (dashed light green line vs. solid light green line; 19 vs. 21 days) (**Figure 4D**).

Overall, anti-PD1 treatment is less effective in the absence of macrophages and microglia in both genetic scenarios, suggesting myeloid cells actively participate in the anti-tumoral response to the treatment in PCNSL. We confirm that MHC-I-negative CNS lymphomas can only be controlled by macrophages. However, PD1 blockade alone is insufficient to reduce the aggressiveness of MHC-I KO CNS tumors, indicating that disrupting the PD1/PD-L1 interaction does not fully engage macrophages to eliminate the tumors.

Blocking CD47- SIRPα immunecheckpoint pathway is not enough to engage a complete macrophage anti-tumoral response in MHC I-negative CNS lymphomas.

To explore immunotherapies that can further potentiate macrophage anti-tumoral activity in MHC-I-negative CNS lymphomas, we next treated mice bearing WT or MHC-I KO tumors with either anti-CD47—targeting the key macrophage immune checkpoint CD47-SIRPα pathway—alone or in combination with anti-PD1. Interestingly, significant improvement in survival was observed only in MHC-I-negative PCNSL mice compared to controls (dashed light purple line vs. solid light purple line; 37 vs. 26 days; p=0.0017) (**Figure 5A**), suggesting that macrophages are more active against MHC-I KO tumors under CD47 blockade (**Supplementary Figure 3A**). However, MHC-I KO PCNSL presented general lower responses than WT PCNSL to anti-PD1, anti-CD47 and combination treatments (**Supplementary Figure 3B)**. We observed no synergistic effect of the combination across tumor types (**Figure 5B**), which we confirmed *in vitro* by co-culturing SG+ MHC-I KO A20 cells with BALB/c macrophages and quantifying tumor growth over 7 days (**Supplementary Figure 3C**). Treatment with the combination showed no enhanced phagocytosis or further reduction in tumor cell growth.

Overall, these results indicate that MHC-I KO CNS lymphomas remain highly aggressive under CD47 blockade, and that this immune checkpoint inhibition is insufficient to improve outcomes in mice bearing these tumors. An important observation from these results is that macrophages respond, at least partially, to these immunotherapies, indicating their potential as effector immune cells in treating MHC-I-negative CNS lymphomas. Additional immunotherapies need to be explored to fully activate macrophage-mediated cytotoxicity against these tumors.

Macrophages and microglia drive immune suppression and modulate T cell infiltration.

To further characterize macrophages and T cells participating in the antitumor response, we

harvested brains on day 15 after tumor induction and analyzed the infiltrating immune cell populations by flow cytometry, IHC and multiplexed IF. Our analyses revealed a significant association between the abundance of myeloid cells in the tumor microenvironment and the expression of immune checkpoints on tumor cells.

By immunohistochemistry, we observed a stronger infiltration of $CD3^+$ T cells in WT PCNSL tumors compared with MHC-I KO tumors in immunocompetent mice (**Figure 6A, Supplementary Figure 4).** This difference was also maintained in macrophage-depleted tumors, although overall infiltration levels were markedly lower, confirming that macrophages are required to sustain a full T cell infiltration and effective immune response. Multiplexed immunofluorescence confirmed that tumor-infiltrating T cells were exclusively $CD8^+$ cytotoxic T cells, indicating that antitumor immunity in PCNSL primarily depends on MHC-I rather than MHC-II pathways.

Interestingly, expression of PD-L1 and CD47 on tumor cells were markedly reduced in the absence of macrophages and microglia (**Figure 6B**). This finding correlates with the diminished infiltration of $CD8^+$ T cells observed in macrophage-depleted tumors, indicating impaired T cell activation compared to immunocompetent mice. In contrast, immunocompetent tumors exhibited a coordinated immune response characterized by high infiltration of $CD86^+$ macrophages and $CD8^+$ T cells in the tumor core, where interactions between immune cells (macrophages in orange and $CD8^+$ T cells in green) and tumor cells (purple) were highly evident (**Figure 6C**). Notably, T cells were absent from non-tumoral regions, highlighting their specific recruitment to the tumor site.

We hypothesize that myeloid cells may actively shape an “immune-hot” microenvironment, which promotes upregulation of immune checkpoints on lymphoma cells as an adaptive response to immune pressure. In a setting with intact macrophages, tumor cells expressing higher levels of PD-L1 and CD47 are likely preferentially selected, as these molecules inhibit macrophage-mediated phagocytosis and thereby protect lymphoma cells from clearance.

Interestingly, this pattern was reversed in the MHC-I–deficient setting, where PD-L1 and CD47 expression on lymphoma cells was reduced (**Figure 6B**). In this MHC-I-deficient context, we consistently observed reduced T cell infiltration and activation (**Figure 6A,C; Supplementary Figure 4**), reflecting a lower adaptive antitumor immunity due to failed antigen presentation and cytotoxic T lymphocyte priming. These data reveal that T cells—rather than macrophages alone—serve as the dominant upstream regulators of checkpoint upregulation within the lymphoma tumor microenvironment. Specifically, CD8+ T cells would provide the primary IFNγ signal that transcriptionally induces PD-L1 (via JAK1/STAT1/IRF1) and CD47 (through parallel STAT1 and IRF1 activation) as an adaptive resistance mechanism, creating a feed-forward loop where initial tumor recognition paradoxically amplify immune inhibitory ligands. Macrophages would amplify this circuit secondarily via TNFα/IL-6 but cannot independently sustain it without T cell-derived IFNγ, explaining why both MHC-I loss (eliminating T cell

activation) and macrophage depletion (removing amplification) independently attenuate checkpoint expression on lymphoma cells.

Overall, in our experiments, a robust antitumoral response was only observed when lymphoma cells expressed MHC-I, enabling effective T cell activity that synergized with macrophage function. Conversely, loss of either T cell–mediated recognition (through MHC-I deficiency) or macrophage activity (through cell depletion) is associated with lower immune checkpoint expression and a more aggressive tumor phenotype, highlighting that macrophages alone, in the absence of T cell help or therapeutic intervention, are insufficient to control MHC-I–deficient lymphoma.

In the myeloid compartment, microglia were the most prevalent non-tumoral immune cells throughout the brain parenchyma, and macrophages had already infiltrated the TME by day 15. As previously demonstrated in a preclinical model of PCNSL[24], these cells were highly concentrated in proximity to $CD20^+$ tumoral cells, suggesting a direct interaction with the tumor (**Figure 6D**).

Both microglial cells and macrophages ($Iba1^+$ cells) located within the tumor displayed enlarged cell bodies and more complex branching compared to those in non-tumoral regions, where Iba1 staining was weak. Such morphological activation has previously been associated with improved outcomes in CNS lymphoma patients[16-18]. To determine whether microglia contribute to the antitumor response, we assessed TMEM119 expression by immunofluorescence and found that these exhibited activated, enlarged morphologies specifically when in contact with tumor cells, supporting their role in the local immune response (**Figure 6E**). This pattern was consistently observed across all tumor settings in which microglia were present, indicating that these resident immune cells can respond to the tumor independently of tumor type or therapeutic strategy.

The percentage of macrophages among total $CD11b^+$ cells was higher in MHC-I KO tumors, suggesting increased infiltration of these cells, potentially due to the aggressiveness of the tumor (**Figure 6C,F**). Immunofluorescence analysis revealed that most infiltrating macrophages expressed CD86, consistent with an activated phenotype. Moreover, PD1 expression in macrophages was significantly higher in WT PCNSL (**Figure 6G)**. This suggests that higher PD-L1 expression in WT tumor cells likely leads to greater macrophage engagement through PD1, triggering increased PD1 expression on macrophages as a feedback mechanism. A slight but not significant decrease of SIRPα was also observed.

PD1 blockade triggers a T cell–dependent antitumor response that requires MHC-I expression in PCNSL.

Because the absence of an effective antitumor response in MHC-I-negative tumors was not due to the absence of major immune cell subsets in the brain, we first examined PD1 expression on T cells as a marker of activation in untreated tumors. We found a significantly

lower frequency of $PD1^+$ $CD3^+$ T cells within MHC-I KO tumors compared to WT tumors (**Figure 7A**), confirming that T cell activation and antitumor effector function are reduced in the absence of MHC-I in PCNSL. Upon anti–PD1 treatment, WT tumors exhibited a pronounced increase in T cell infiltration within the tumoral area (**Figure 7B**), accompanied by a strong upregulation of PD1 on T cells and elevated PD-L1 expression on tumor and immune cells (**Figure 7C, Supplementary Figure 5**), consistent with an active, IFN-γ–driven immune response. In contrast, this treatment-induced T cell infiltration and immune activation were largely absent in MHC-I KO tumors, indicating that effective T cell recognition through MHC-I is necessary to mount a productive response to checkpoint blockade. As expected, CD47 blockade failed to promote T cell recruitment into the tumor microenvironment. Interestingly, in macrophage-depleted mice, anti–PD1–induced T cell infiltration into WT tumors was maintained (**Figure 7B**).

Multiplex immunofluorescence analysis of cellular interactions revealed that the number of close contacts between $CD8^+$ T cells and $CD20^+$ tumor cells was significantly increased in anti–PD1–treated WT tumors compared to non-treated controls (**Figure 7D**).

Infiltration of Iba1+ myeloid cells (macrophages and microglia) within the tumor microenvironment was comparable across groups in immunocompetent mice (**Figure 7E**). Also, multiplexed IF revealed similar microglia distributions across samples, and elevated CD86+ macrophage infiltration in MHC-I KO PCNSL tumors; however, the small sample size precludes strong conclusions.

T cell-to-macrophage ratios were higher in WT PCNSL tumors, particularly under anti-PD1 treatment (**Figure 7F**), which indicates T cell dominance, and is generally associated with improved prognosis in cancer[30]. This spatial organization supports enhanced T cell–tumor engagement crosstalk following PD1 blockade, further highlighting the dependence of an effective antitumor immune response on MHC-I–restricted T cell recognition.

RNA-seq analysis highlights MHC-I-dependent T cell activation and immune surveillance in PCNSL.

To investigate differences in gene expression, we performed RNA-seq on brains extracted from mice 15 days after tumor induction. Using supervised analysis, we compared the gene expression profiles of IC mice and macrophage-depleted mice. This analysis revealed significant differential gene expression between the two groups. In mice bearing WT PCNSL tumors, 1534 genes were upregulated and 1284 were downregulated in IC conditions compared to macrophage-depleted conditions (**Supplementary Table 1).** Similarly, in mice bearing MHC-I KO PCNSL tumors, 414 genes were upregulated and 323 were downregulated under the same comparison (**Supplementary Table 2**).

To understand the biological roles of these differentially expressed genes, we conducted Gene Set Enrichment Analysis (GSEA) using the mouse Reactome database. In WT PCNSL tumors

we observed a significant upregulation of pathways associated with MHC-I signaling, PD1, and CD3/TCR phosphorylation in immunocompetent mice compared to their counterparts in macrophage-depleted mice (**Figure 8A**). These findings suggest that in the absence of macrophages and microglia, compensatory T cell activation occurs, which slows tumor growth. In contrast, in MHC-I KO PCNSL tumors, the absence of T cell activation led to significantly more aggressive tumor growth. This is driven by the upregulation of pathways associated with proliferation, mitosis, and cytokine/interleukin signaling, highlighting the critical role of immune surveillance in controlling tumor progression (**Figure 8B**).

We further interrogated the dataset by directly comparing the transcriptional effects of anti-PD1 treatment and MHC-I depletion. PD1 blockade led to upregulation of immune activation and interferon response pathways in WT PCNSL tumors, in both immunocompetent and macrophage-depleted mice, consistent with enhanced immune effector activity (**Supplementary Figure 6A,B; Supplementary Table 3 and 4**). This was not observed in MHC-I KO PCNSL tumors. In contrast, MHC-I deficiency was associated with upregulation of DNA repair, replication stress, and chromatin remodeling pathways, indicating activation of proliferative and genome-stabilizing programs in MHC-I-deficient tumors (**Supplementary Figure 6C; Supplementary Table 5**).

These findings emphasize the important role of MHC-I in immune-mediated tumor control and reveal distinct transcriptional responses to PD1 blockade which are dependent to MHC-I expression in the TME.

Discussion

Our research highlights the dynamic interplay between malignant cells, macrophages, and T cells within the TME of primary CNS lymphoma. We demonstrate that macrophages play a crucial role in the pathogenesis of primary CNS lymphoma as well as in the anti-tumor response to immune checkpoint blockade.

In many solid tumors, tumor-associated macrophages frequently adopt an immunosuppressive M2-like phenotype that facilitates tumor progression and diminishes the efficacy of immune checkpoint blockade. To counteract this, agents such as pexidartinib are being investigated for their capacity to deplete or reprogram these macrophages, with promising results in shifting them toward a pro-inflammatory, anti-tumoral M1-like phenotype[31]. This strategy has also shown encouraging effects in preclinical lymphoma models—including DLBCL, follicular lymphoma, and Burkitt lymphoma—by enhancing macrophage-mediated anti-tumor responses[32]. However, Gao et al. demonstrated that CSF1R inhibition using pexidartinib after PCNSL induction in mice paradoxically accelerated tumor progression[17]. This divergence likely reflects the distinct immunologic landscape of the CNS, where infiltrating macrophages and resident microglia exhibit context-dependent functions. In our experimental model, depletion of these myeloid populations prior to tumor implantation similarly resulted in

a more aggressive disease phenotype. Herein, we confirmed that macrophages and microglia serve as anti-tumoral effectors in PCNSL. Microglial cells, in particular, may act as the first immune cells to engage tumor cells in the CNS, shaping the subsequent immune landscape and influencing the timing and extent of macrophage and T cell infiltration. Consistent with our findings, several studies have demonstrated that macrophages robustly infiltrate the brain in human PCNSL and constitute a major component of the tumor microenvironment[15-18]. Komohara et al.[15] analyzed tumor samples from 43 PCNSL patients and showed by IHC that $CD86^+$ macrophages constitute a predominant population within the tumor microenvironment. Nam et al.[16] examined 104 PCNSL specimens and observed significant infiltration of macrophages, with higher $CD86^+$ cell densities correlating with improved PFS. Gao et al.[17] analyzed 62 diagnostic specimens from immunocompetent PCNSL patients and found that lower density and smaller size of CD68+ TAMs significantly correlated with shorter OS. Interestingly, strong TAP1 expression independently predicted improved PFS, supporting the protecting role of tumor-associated macrophages against PCNSL progression. Moreover, Pollari et al.[18] further characterized macrophage subpopulations and found that a high proportion of $PD\text{-}L1^+CD68^+$ macrophages was associated with improved overall and disease-specific survival.

In our macrophage-competent PCNSL mouse models, PD1 blockade was significantly more effective than in macrophage-depleted models, highlighting a crucial and non-redundant role for macrophages and microglia in the response to anti-PD1 therapy, besides the expected role of cytotoxic T lymphocytes. This effect was further enhanced in tumors retaining intact MHC-I expression. Together, our findings suggest that effective T cell activation in PCNSL depends on the coordinated involvement of both macrophages and microglia, emphasizing the importance of antigen cross-presentation in linking innate and adaptive anti-tumor immunity within the CNS microenvironment. Preclinical and clinical studies provide a strong biological rationale for targeting PD1 in PCNSL[12,25]. Early-phase clinical trials have shown promising initial responses in relapsed or refractory PCNSL patients[12]; however, these are often short, with most patients eventually experiencing relapse. A major factor limiting the durability of PD1 blockade is the loss of MHC-I expression in tumor cells, as also demonstrated in our findings. Consistent with this, few studies have corroborated the loss of HLA class I expression in patients, associated with outcome[8-10]. Riemersma et al.[10] reported total loss of HLA-A expression in 60% of extranodal lymphomas—including primary CNS and testicular lymphomas, both considered immune-privileged sites—compared with only 10% in nodal cases. Interestingly, Geng et al.[7] correlated genomic lesions at the HLA class I locus with clinical outcomes in PCNSL. In their cohort of 78 patients, 6p CN-LOH/6p21.3 homozygous deletions affecting HLA-A, -B, and -C in 16 cases defined a high-risk subgroup with significantly shorter progression-free and overall survival. Furthermore, Alame et al.[9] observed that lower HLA gene expression is associated with an immune-poor TME correlated with bad prognosis in patients. This establishes impaired HLA class I–mediated antigen presentation as a major prognostic factor clinically associated with poorer outcomes in PCNSL patients.

While loss of HLA class I expression in lymphomas arising in immune-privileged sites such as PCNSL may appear to be a redundant immune evasion benefit given the low baseline immune surveillance in these compartments, it remains to be investigated whether such genomic alterations represent a positive selection feature. These mutations might allow tumor cells to proliferate in these sites without triggering any unwanted immune response, potentially facilitating tumor growth through subtle modulation of local immunity rather than overt immune evasion.

A limitation of our study is the use of the intracerebral A20 model. Although this model is robust and widely employed to investigate pathogenesis and evaluate novel therapeutic strategies in PCNSL, it does not fully recapitulate the natural clinical origin or B cell tropism observed in human disease. Accordingly, caution is warranted when extrapolating these findings to patients. Despite these limitations, the model remains a valuable tool for dissecting CNS-specific immune mechanisms within a controlled experimental setting.

Collectively, therapeutic strategies must go beyond T cell reinvigoration and include targeting of the macrophage–microglia compartment. Such combinatorial approaches could bypass the need for MHC-I–dependent immune recognition and address the immune resistance observed in PCNSL.

Quantification of tumoral growth and survival curves are represented. **C,** CD20 immunohistochemical staining of mouse brain sections with PCNSL. Presence of lymphoma cells within the brain parenchyma and meninges is indicated by red arrows. Whole-brain images are displayed at 0.6x magnification, while higher-resolution images focusing on the parenchyma and meninges are shown at 10x magnification.

Figure 2. Macrophage/microglia depletion and MHC-I knockout set up. A,B, Microglia and macrophage staining. IHC of Iba-1-stained macrophages in FFPE spleen and liver sections from mice treated with clodronate liposomes, comparing control (day 0) and different timepoints. Images were captured at 10x magnification (**A**). IHC of Iba-1-stained microglia in FFPE brain sections from mice treated with the anti-CSF1R drug pexidartinib (PLX3397) at baseline (day 0), day 10, and day 21 post-treatment (**B**). **C,** Detection of CD11b+ macrophages and microglia by flow cytometry after PCNSL induction. Macrophages identified as $CD45^{high}CD11b^{+}$ cells (left graph) and microglia identified as $CD45^{low}CD11b^{+}$ cells (right graph) in brain tissue. Plots show percentages of cells (out of singlets) in PCNSL-induced immunocompetent mice (red) and macrophage-depleted mice (green). Significant differences are indicated by **p-value < 0.01 and ****p-value < 0.0001, as determined using the Mann-Whitney test. **D,** Validation of MHC-I knockout by CRISPR-Cas9 using flow cytometry. Dot plots and histogram showing surface expression of MHC-I in A20 cells. Constitutive expression in WT A20 is shown, as well as expression after the CRISPR.

Figure 3. Tumoral growth and survival of immunocompetent and macrophage-depleted mice bearing either WT or MHC-I KO PCNSL. A, *In vivo* growth of WT and MHC-I KO A20 cells in brains of immunocompetent mice. Sample size is n = 12 per group. Data are presented as mean BLI intensity (ph/s) ± SEM. Significant differences are indicated by **p-value < 0.01 and ***p-value < 0.001, as determined using the Mann-Whitney test. **B,** *In vitro* growth of WT and MHC-I KO A20 cells. Proliferation was assessed by counting viable cells every 24 hours using flow cytometry with counting beads. Data are presented as the mean of two replicates ± SEM. Dark red represents WT cells, while light red indicates MHC-I KO cells. **C,D,** Results are organized into two groups comparing immunocompetent (IC) and macrophage-depleted mice. Within each group, mice were induced with either WT PCNSL (dark red for IC and dark green for macrophage-depleted mice) or MHC-I KO PCNSL (light red for IC and light green for macrophage-depleted mice). Kaplan-Meier survival plot represents the probability of survival

over 80 days, with median survival days indicated for each group. Numbers at risk for days 20, 40, 60 and 80 are shown. Significant differences in survival are shown by p-values determined using the Log-rank test (**C**). Tumor growth curves are displayed as mean bioluminescence intensity ± SEM for each group over time until day 21. Mann-Whitney tests were conducted to compare tumor types growing in macrophage-depleted mice with their respective tumor types in IC mice at each timepoint, with significant differences indicated by *$p < 0.05$ and **$p < 0.01$ (**D**). IC = Immunocompetent mice; MD = Macrophage-depleted mice.

Figure 4. Anti-PD1 treatment effect on tumoral growth and survival in PCNSL mouse models. A,B, Tumoral growth in mice bearing PCNSL treated with anti-PD1. Tumor growth curves are shown for each group over time, up to day 21 or 28 (until last timepoint with all mice alive), in immunocompetent mice (**A**) and macrophage-depleted mice (**B**), bearing either WT or MHC-I KO PCNSL. Solid lines represent non-treated groups, while dashed lines represent groups treated with anti-PD1. Sample size is n=12 mice/group. Data is presented as mean bioluminescence intensity ± SEM. The legend provides color-coded lines for the different groups. **C,D,** Kaplan-Meier survival curves of mice bearing PCNSL. Survival plots illustrating the probability of survival over 80 days for immunocompetent mice (**C**) and macrophage-depleted mice (**D**), bearing either WT or MHC-I KO PCNSL. Median survival days for each group are indicated below the curves. Solid lines represent non-treated groups, while dashed lines represent groups treated with anti-PD1. Numbers at risk for days 20, 40, 60 and 80 are shown. Significant differences in survival are represented by p-values determined using the Log-rank test. CTL=Control (Vehicle)

Figure 5. Anti-CD47 and combination treatments effect on survival in immunocompetent PCNSL mouse models. A,B, Kaplan-Meier survival curves of mice bearing PCNSL. Survival plots illustrating the probability of survival over 80 days for IC mice with WT PCNSL and MHC-I KO PCNSL. Mice were treated with anti-CD47 treatment (**A**), or combination of anti-PD1 and anti-CD47 treatments (**B**). Median survival days for each group are indicated below the curves. Significant differences in survival are represented by p-values determined using the Log-rank test. CTL=Control (Vehicle).

Figure 6. Characterization of immune cell infiltration in mouse brains with PCNSL. A, Percentages of infiltrating CD3+ T cells were quantified in the tumoral area of IHC slides using QuPath (number of CD3+ cells / number of CD20+ cells × 100). Five vehicle-treated samples per group were analyzed (n=5). Significant differences between groups were assessed using the Mann-Whitney U test. **B,** Surface expression of PD-L1 and CD47 on tumor cells. Data is represented by MFI. Purple represents WT PCNSL, while maroon represents MHC-I KO PCNSL. Significant differences between groups were determined using the Mann-Whitney U

test, with p-values indicated. **C,** Representative images of the tumor microenvironment from multiplexed immunofluorescence (IF) staining (rabbit anti-mouse CD20, CD86, and CD8) in vehicle-treated mouse brains. Images derive from immunocompetent and macrophage-depleted mice bearing WT or MHC-I KO PCNSL tumors. Top row: 100–500 µm scale; bottom row: 50 µm zoom-in. **D,** Immunohistochemistry of brain tissue stained for CD20+ tumor cells. The same region stained for Iba-1, showing the distribution of macrophages and microglia. High infiltration of macrophages and the increased size of both macrophages and microglia in areas with a high concentration of tumor cells is shown. Brains were extracted from immunocompetent mice bearing either WT or MHC-I KO PCNSL. 100 µm scale. **E,** Representative images of TMEM119-stained tumoral and non-tumoral areas, highlighting microglia. Scale bar, 20 µm. **F,** Percentage of macrophages out of $CD11b^+$ cells by flow cytometry. Purple represents WT PCNSL, while maroon represents MHC-I KO PCNSL. Significant differences between groups were determined using the Mann-Whitney test, with p-values indicated. **G,** Expression of PD1 and SIRPα, represented by MFI, in macrophages. Expression of markers was performed by flow cytometry of brain samples from WT or MHC-I KO tumor-bearing immunocompetent mice. Significant differences between groups were determined using the Mann-Whitney test, with p-values indicated.

Figure 7. Effect of immunecheckpoint blockade treatment in immune cell infiltration in mouse brains with PCNSL. A, MFI expression of PD1 in T cells. Expression was checked in non-treated immunocompetent and macrophage-depleted mice bearing WT and MHC-I PCNSL. **B,** Percentages of infiltrating CD3+ T cells were quantified in the tumoral area of IHC slides using QuPath (number of CD3+ cells / number of CD20+ cells × 100). Samples from immunocompetent and macrophage-depleted mice bearing WT or MHC-I KO tumors—treated with vehicle, anti-PD1, or anti-CD47—were analyzed (n=5 per group). Significant differences between groups were determined using the Mann-Whitney U test. **C,** Representative images of the tumor microenvironment from multiplexed immunofluorescence (IF) staining (rabbit anti-mouse CD20, CD86, and CD8 in the top row, and DAPI, PD1 and PDL1) in vehicle-treated mouse brains. Images derive from immunocompetent and macrophage-depleted mice bearing WT or MHC-I KO PCNSL tumors. Top row: 100–500 µm scale; bottom row: 50 µm zoom-in. **D,** Percentage of CD20+ tumor cells interacting with CD8+ T cells within the tumoral area in vehicle- and anti-PD1–treated mice bearing WT or MHC-I KO PCNSL. Interactions were defined as cell–cell proximity <15 µm using QuPath. **E,** Percentages of infiltrating Iba1+ cells quantified in the tumoral area of IHC slides using QuPath (number of Iba1+ cells / number of CD20+ cells × 100). Samples from immunocompetent and macrophage-depleted mice bearing WT or MHC-I KO tumors—treated with vehicle, anti-PD1, or anti-CD47—were analyzed (n=5 per group). **F,** T cell/macrophage ratios were calculated as CD3+/Iba1+ cell numbers in the same groups as in Figure 7E.

Figure 8. Pathway enrichment analysis comparisons between groups A,B, Bar plots representing normalized enrichment scores (NES) from Gene Set Enrichment Analysis (GSEA) using the Reactome database, comparing immunocompetent (IC) mice to macrophage-depleted mice bearing either WT PCNSL (**A**) or MHC-I KO PCNSL (**B**). The x-axis displays the enriched pathways, while the y-axis shows the NES values. Pathways are colored according to their statistical significance, indicating adjusted p-values.

Supplementary Methods

Cell lines. For luciferase expression, cells were electroporated, using the Neon™ Transfection System (Thermo Fisher) in the presence of 5pM of pGL4_Luc2_CMV_neo plasmid. Forty-eight hours post-electroporation, G418 (800 µg/mL) was added to the culture medium for selection. After two weeks, luciferase activity was assessed by bioluminescence imaging (BLI) following luciferin addition, using the IVIS® Spectrum system and Living Image software (PerkinElmer).

MHC-II downregulation. CRISPR-Cas9 was performed to generate downregulation of MHC-II expression in A20 cells (MHC-II KO A20) by disrupting *CIITA. CIITA* gRNA, Cas9 endonuclease and universal tracrRNA were obtained from Integrated DNA Technologies (IDT). The crRNA:tracrRNA complex was ensembled following the manufacturer's protocol and delivered by electroporation using the Neon™ Transfection System (ThermoFisher)[1].

Mouse macrophage isolation. Murine bone marrow–derived macrophages (BMDMs) were generated from BALB/c mice as described[2]. Briefly, bone marrow cells were ACK-lysed, cultured in M-CSF (20 ng/mL; Peprotech) for 7–21 days, detached with TrypLE (Invitrogen), and used for experiments.

Long-term co-culture assays: Tumoral growth curves in long-term co-cultures of BALB/c murine macrophages and SG+ A20 lymphoma cells. Co-cultures were established in 384-well plates with 1×10^4 macrophages and 2×10^3 target cells (4:1 E:T ratio) ±anti-PD1, anti-CD47, or combination (10 µg/mL final). Whole-well phase contrast and green-channel imaging was performed every 8 h for 156 h (~6.5 days) using an Incucyte S3 (Sartorius), with automated analysis via Incucyte software.

Macrophage/Microglia depletion in mice. Pexidartinib (PLX3397; Selleckhem) was incorporated into a purified diet (D20031201; Research Diets, Inc.) at 290 mg/kg, corresponding to an approximate weekly exposure of 7 mg/kg per mouse assuming average food consumption of 3.5 g/day[3]. Clodronate liposomes were obtained from Liposoma, Inc. and prepared according to the manufacturer's instructions[4].

***In vivo* modeling of PCNSL**. Mice were anesthetized with isoflurane (1-2%), followed by subcutaneous injection of meloxicam (5 mg/kg) for analgesia. A total of $1x10^5$ A20 cells in 5 µl of PBS were injected intracerebrally into eight-week-old BALB/c female mice, using a Hamilton syringe with a 26-gauge needle at a rate of 1 µl/min, guided by stereotactic coordinates (1 mm anterior, 1.8 mm lateral right to the bregma, and 2.5 mm deep from the dura) on a Stoelting Just For Mouse™

stereotaxic platform. Tumor growth was monitored by BLI using an IVIS® Spectrum system (PerkinElmer) once a week. Tumoral size was quantified using Living Image software (PerkinElmer), and the total photons per second (ph/s) were recorded.

Organ processing. Briefly, brain tissue was enzymatically digested using papain for 30 minutes at 37°C, with gentle agitation. The cellular suspension was filtered through a 70 µm cell strainer to remove debris. Cells were washed and resuspended in PBS supplemented with 0.5% BSA for further analysis.

Flow Cytometry. The following antibodies were used for the identification of lymphoma cells, 42 macrophages and T cells: anti-mouse/human CD11b-PerCP Cy5.5 (Clone M1/70), anti-mouse CD45-43 BV510 (Clone 30-F11), anti-mouse CD206-PE/Cy7 (Clone C068C2), anti-mouse CD279-PE (PD-1, 44 Clone 29F.1A12), anti-mouse F4/80-APC/Cy7 (Clone BM8), anti-mouse Gr1-FITC (Clone RB6-8C5), 45 anti-mouse CD20-APC (Clone SA275A11), anti-mouse H-2Kd-PE (Clone SF1-1.1), and anti-mouse 46 CD3-AF700 (Clone 17A2) were all purchased from Biolegend; anti-mouse CD172a-APC (SIRPα, 47 Clone P84), anti-human/mouse CD47-FITC (Clone B6H12) and anti-human/mouse CD274-PE (PD-48 L1, Clone MIH1) were obtained from eBioscience. Dead cells were excluded using the LIVE/DEADTM 49 Fixable Violet Dead Stain Cell kit (Invitrogen). Lymphoma cells were identified as CD45+CD20+. Mouse 50 TAMs were identified as CD45+ Gr1low/- CD11b+ F4/80+; CD206 expression was also assessed to 51 evaluate macrophage polarization. T cells were identified as CD45+CD3+. Gates were set using 52 fluorescence minus one (FMO) or isotype controls.

Immunohistochemistry. Antibodies against mouse CD20 (LS-B12186-50, LSBio) for tumoral B cells, mouse CD3 (Clone SP7, ThermoFisher) for T cells, and mouse Iba-1 (Clone EPR16588, Abcam) for macrophages and microglia were used.

RNA sequencing. RNA integrity was checked by Agilent Bioanalyzer-2100 equipment (Agilent 57 Technologies) using Agilent RNA 6000 Pico Kit (Agilent Technologies). RNA-seq data was processed 58 using the nf-core/rnaseq pipeline (v3.14.0)5, with the option using STAR aligner6 and RSEM7 for 59 quantification. Trimming step was performed with specified arguments of length at 35 and stringency 60 at 10. Reads were mapped against Mus musculus reference genome (GRCm39) and genes were 61 quantified using version M36 of the annotation. Differential expression analysis was performed with 62 limma v3.54.2 R package8, using TMM normalization. The voom function9 was used to estimate mean-63 variance relationship and to compute observation-level weights. The linear model was fitted with the 64 65 voom-transformed counts and contrasts of the different groups were extracted. A gene set enrichment 66 analysis (GSEA) was performed with the R package fgsea

v1.12.010 using, for each comparison, the 67 list of pre-ranked genes by a t-statistic against the mouse Reactome database.

Supplementary figure legends

Supplementary Figure 1. Validation of *in vivo* macrophage depletion, MHC-I knockout and maker expression on WT and MHC-I KO A20 lymphoma cells. A, Sanger sequencing chromatograms show the 5' to 3' nucleotide sequence of the *TAP1* gene region targeted by Cas9 in WT and MHC-I KO A20 cells. The Cas9 cut site is indicated by a black dashed line. Peaks represent he four bases (A, T, C, G), with colors for adenine (green), cytosine (blue), guanine (yellow), and hymine (red). Sequence edits at the cut site are compared between the two cell lines. **B,** Histogram plots show the surface expression of PD-L1 and CD47 in WT and MHC-I KO A20 cells by flow cytometry. Red peaks represent isotype control, while blue peaks indicate the expression of PD-L1 or CD47.

Supplementary Figure 2. Tumoral growth and survival of immunocompetent and macrophage-depleted mice bearing MHC-II KO PCNSL. Tumoral growth over 28 post-tumor injection and Kaplan-Meier survival curves over 80 days of immunocompetent and macrophage-depleted mice bearing MHC-II KO PCNSL. Significant differences in survival are represented by p-values determined using the Log-rank test. Number at risk are shown.

Supplementary Figure 3. In vitro and in vivo tumor growth and survival in PCNSL models under immunotherapy. A, Tumoral growth of WT and MHC-I KO PCNSL tumors in immunocompetent mice treated with vehicle, anti-CD47 or combination treatments. BLI intensity (ph/s) Mean ± SEM of n=12 mice/group is shown. **B,** Survival plots comparing treated immunocompetent mice bearing either WT or MHC-I KO PCNSL. Data show the effects of each treatment regimen on survival in WT and MHC-I KO PCNSL models (left graph: anti-PD-1 vs. combo; right graph: anti-CD47 vs. combo). **C,** Growth of SG+ MHC-I KO A20 lymphoma cells in co-culture with BALB/c macrophages under vehicle, anti-PD1, anti-CD47 and combination treatments. Curves are the mean of three individual co-culture wells ± SEM.

Supplementary Figure 4. CD3+ T cell infiltration in PCNSL mouse brain IHC slides. Representative IHC images of CD3+ T cell infiltration in tumoral areas of brains bearing WT or MHC-I KO PCNSL from immunocompetent or macrophage-depleted mice. Bottom rows are zoom-in views.

Supplementary Figure 5. Pathway enrichment analysis comparison between groups. A-C, Gene Set Enrichment Analysis (GSEA) using the Reactome database, across different comparisons. Displayed are the enriched pathways and the NES values.
