Information for readers, authors and subscribers

Haematologica/The Hematology Journal (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community strictly following the World Association of Medical Editors (WAME) recommendations on publication ethics policies for medical journals (www.wame.org/pubethicrecom.htm).

Haematologica/The Hematology Journal publishes editorials, perspectives, research papers, decision making & problem solving papers, review articles, brief reports and scientific letters. Manuscripts should be prepared according to the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (ICMJE) and fully available online (http://www.icmje.org). Additional papers may be considered for the purely online journal (Haematologica/The Hematology Journal on Internet, eISSN 1592-8721). Because there are no space constraints online, Haematologica/The Hematology Journal will publish several items deemed by peer review to be scientifically sound and mainly useful as educational papers. These will include case reports, irreplaceable images, educational material from scientific meetings, meeting abstracts, and letters to the Editor.

Papers should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal's policy is reported in detail online (www.haematologica-thj.org/policy.html).

Galley Proofs and Reprints. Galley proofs should be corrected and returned by email, fax or express delivery within 72 hours. Minor corrections or reasonable additions are permitted; however, excessive alterations will require editorial re-evaluation and will be possibly charged to the authors. Papers accepted for publication will be printed without cost. The cost of printing color figures will be communicated upon request. Reprints may be ordered at cost by returning the appropriate form sent by the Publisher.

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Haematologica/The Hematology Journal is published in three printed editions: International (worldwide except Italy, Spain, Portugal and Latin America), Italian (Italy) and Spanish (Spain, Portugal and Latin America). Detailed information about subscriptions is available online: http://www.haematologica-thj.org/subscribe. While access to the online journal is free, online access to additional items of the website http://www.haematologica-thj.org will require either institutional or personal subscription.

Rates of the International edition for the year 2007 are as following:

	Institutional	*Personal*
Print edition (including full access to the online CME for personal subscribers)	*Euro 400*	*Euro 150*
Full access to the online CME only		*Euro 75*

To subscribe to the International edition, please visit our web site http://www.haematologica.org/subscribe or contact: Haematologica/the Hematology Journal Office, Strada Nuova 134, 27100 Pavia, Italy (phone +39.0382.531182, fax +39.0382. 27721, E-mail: office@haematologica.org).

Advertisements. Contact the Advertising Manager, Haematologica/The Hematology Journal Office, Strada Nuova 134, 27100 Pavia, Italy (phone +39.0382.531182, fax +39.0382.27721. E-mail: mikimos@haematologica.org).

12TH CONGRESS
JUNE 7 - 10, 2007
VIENNA

Words of welcome

On behalf of the Scientific Program Committee, we would like to welcome you to Vienna and to the 12th Congress of the European Hematology Association. We have put together an exciting programme with, we hope, an interesting balance of clinical and scientific topics ranging across the haematology disciplines. We invite you to participate in as many of the high quality Education Hematology-in-Focus Science-in-Progress and Plenary sessions as you can and to join in the challenging Lunch Debates and Clinical Trial Updates. We also have a number of highly expert 'Meet-the-Expert' sessions and encourage you to register early to grasp the opportunity to exchange information in a very informal and friendly atmosphere. As a new feature this year we have organized a Molecular Hematopoiesis Workshop on Friday June 8th. This will present cutting edge science in a new and exciting way and we hope to particularly attract scientists and young haematologists interested in a scientific career- please come along !

From the record number of abstracts we have also put together an interesting programme of simultaneous oral sessions and poster sessions. The 6 best abstracts will be presented during the Presidential Symposium. This year's joint EHA-ASH Symposium will take place on Saturday, June 9th and will address the very challenging and controversial topic of stem cell banking which is increasingly an issue in the lives of many haematologists- experts from the US (David Scadden) and Europe (Wim Fibbe) will provide stimulating and informative insight into practice on both sides of the Atlantic. A number of meetings of EHA Scientific Working Groups will be held on Thursday evening, which we hope will be of interest to many of you.

In addition, 26 Satellite Symposia will run on Super Thursday, covering the State-of-the-Art in experimental and clinical haematology. The Joint Symposium of the European School of Hematology (ESH) and EHA will again take place on Friday.

We would also like to welcome you to the Opening Ceremony which will take place on Friday, June 8th, directly followed by the presentation of the José Carreras Lecture by Professor Rogier Bertina. In the same session, the winners of the EHA-José Carreras Young Investigators Fellowship and the additional EHA Fellowships will be presented.

The congress program is accredited for continuing medical education (CME) by the EHA-CME System. The scientific program of the 12th Congress of the EHA has also been reviewed and approved for accreditation by the American Medical Association (AMA).

From a social point of view, we have the privilege to be here in Vienna with its rich historical and cultural attractions. On behalf of the EHA Board and the Scientific Program Committee of the 12th Congress: we are pleased to welcome you to this beautiful city and hope that this top hematology congress in Europe will provide you with fruitful and enjoyable interactions with your peers and induce new creative ideas for your work!

Acute lymphoblastic leukemia - Biology

0001

IDENTIFICATION OF PML AS NOVEL PAX5 FUSION PARTNER GENE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

K. Nebral,[1] R. Siebert,[2] M. König,[1] O.A. Haas,[3] S. Strehl[1]

[1]CCRI, Children's Cancer Research Inst., VIENNA, Austria; [2]Institute of Human Genetics, KIEL, Germany; [3]St. Anna Children's Hospital, VIENNA, Austria

Background. PAX5 encodes the B-cell lineage specific activator protein (BSAP) and is required for B-cell development and lineage maintenance. Pax5 fulfills a dual role by activating B-cell specific genes and simultaneously repressing lineage-inappropriate genes. In acute lymphoblastic leukemia (ALL) PAX5 is fused to ETV6 with a dic(9;12)(p13;p13) and is juxtaposed to the IGH locus in B-cell non-Hodgkin's-Lymphoma with t(9;14)(p13;q32). Recently, it has been shown that PAX5 can also fuse to FOXP1 (3p13), ZNF521 (18q11), and to ELN (7q11). *Aims and Methods.* In order to determine the overall incidence of PAX5 rearrangements in childhood ALL dual-color split-apart FISH assays using BAC clones flanking the PAX5 gene as well as PAX5 exon-specific cosmid probes were used. Novel fusion partner genes were identified by narrowing down the breakpoints on the respective partner chromosomes utilizing a panel of locus-specific FISH probes, and the presence of specific fusion genes was verified by RT-PCR. *Results.* In a retrospective study, 332 patients enrolled in the Austrian ALL-BFM 2000 study were screened for PAX5 rearrangements. Three patients showed a separation of the PAX5 FISH probes and 3 showed PAX5-3' deletions indicating PAX5 rearrangements. One of these cases has been previously identified as dic(9;12)(p13;q13)/PAX5-ETV6 positive, a fusion associated with a PAX5-3' deletion. In one patient cytogenetics revealed a 46,XX,add(9)(p13) and a separation of the PAX5 probes was observed. Subsequent 24-color FISH revealed a t(9;15), and the breakpoint was narrowed down to 15q24 by chromosome walking with appropriate FISH probes. Hybridization with a PML-specific probe resulted in a split signal providing compelling evidence that PAX5 was fused to PML. In a second case of childhood ALL (not included in the ALL-BFM 2000 series) a similar aberration, namely a t(9;15)(p21;q25) was detected. In both patients fusion gene-specific RT-PCR detected a chimeric PAX5-PML transcript and sequence analyses identified the same in-frame fusions between PAX5 exon 6 and PML exon 2. PAX5 consists of an N-terminal paired DNA-binding domain and a C-terminal proline-serine-threonine-rich region that harbors a transactivation domain. In the central region an octapeptide capable of recruiting corepressors and a partial homeodomain functioning as a protein-protein interaction motif are presented. PML is fused to RARA in the t(15;17)(q22;q12) in acute promyelocytic leukemia and is implicated in various cellular mechanisms. The PML protein consists of a *really interesting new gene* (RING) domain, followed by two zinc fingers (B Boxes), and a α-helical coiled-coil motif mediating protein-protein interaction. The putative chimeric PAX5-PML protein fuses the paired domain, the octapeptide and the partial homeodomain of PAX5 to almost the entire PML protein lacking only the 5' proline-rich region. *Conclusions.* Out of the 332 patients, three (0,9%) showed a PAX5 rearrangement including one with a PAX5-PML fusion, and two with yet unknown PAX5 partners. In addition, three (0,9%) displayed a PAX5-3' deletion, indicating fusion to a partner gene, among these one PAX5-ETV6 positive case. Although the incidence of PAX5 rearrangements seems rather low, the emerging variety of PAX5 fusion partners nevertheless underlines its important role in leukemogenesis.

ANALYSIS OF T(9;22) BREAKPOINTS INDICATES THAT P210 AND P190 BCR-ABL ARE FORMED BY DISTINCT MECHANISMS

J. Score,[1] M.J. Calasanz,[2] F. Pane,[3] O. Ottmann,[4] F.H. Grand,[1] N.C.P. Cross[1]

[1]Wessex Regional Genetics Laboratory, SALISBURY, United Kingdom; [2]University of Navarra, PAMPLONA, Spain; [3]Cardarelli Hospital, NAPLES, Italy; [4]Johann Wolfgang Goethe University, FRANKFURT, Germany

Chromosomal translocations that produce oncogenic fusion genes are common in haematological malignancies but the mechanism by which they are formed is incompletely understood. Analysis to date has indicated that translocations result from non-homologous end joining following two double stranded DNA breaks. In lymphoid disorders, DNA breaks may be a consequence of normal or aberrant RAG activity, whereas in myeloid disorders the reasons for breakage are unknown. The paradigm for fusions genes in leukaemia is BCR-ABL, produced as a consequence of the t(9;22). In chronic myeloid leukaemia (CML), breaks within BCR are located in the 5.8kb major breakpoint cluster region and a region of at least 200kb in ABL, resulting in a p210 BCR-ABL protein. In Philadelphia chromosome positive acute lymphoblastic leukaemia (Ph^+ ALL), however, the breaks within BCR are frequently located further upstream in the 70kb minor breakpoint cluster region, resulting in a smaller p190 protein. To determine if the mechanism giving rise to the Ph chromosome is different in CML vs ALL, or p210 vs p190, we have developed a FISH and long range PCR strategy to amplify and sequence t(9;22) genomic breakpoints. Thus far, forward breakpoints have been characterized for 19 cases with p190 ALL, 25 with p210 ALL and 32 with p210 CML with reciprocal breakpoints identified in a subset of these cases. Preliminary analysis has revealed some differences between the p190 and p210 breakpoints: perfectly balanced translocations occur in 26% of p190s but only 2% of p210s (p=0.001). Small insertions and/or deletions at the breakpoint occur in 63% of p190s compared to 35% of p210s (p=0.03) whereas large insertions and/or deletions occur in 11% of p190s vs 63% of p210s (p<0.001). This data supports the hypothesis that p190 and p210 are formed by distinct mechanisms.

0003

WNT16 AND BETA-CATENIN HAVE INDEPENDENT AND DISTINCT ROLES IN E2A-PBX1 POSITIVE PRE B ALL CELLS

M.K. Nygren, G. Døsen, H. Stubberud, E. Rian

Institute of Cancer Research, OSLO, Norway

Background. The t(1;19) chromosomal translocation is observed in approximately 5-6% of childhood early B-lineage acute lymphoblastic leukaemia (ALL). It results in the expression of the fusion protein E2A-PbX1, which has been shown to activate expression of Wnt16. Inhibition of Wnt16 may induce apoptosis in ALL-cells by blocking canonical Wnt signalling (Mazieres J *et al.,* 2005). Apart from this, little is known about Wnt16 and Wnt signalling pathways in ALL cells. *Aim.* We want to elucidate the roles of Wnt signalling pathways and β-catenin in pre-B ALL cells with activated Wnt16 expression. A particular focus is on interaction between leukaemia cells and the bone marrow stromal cells. *Methods.* PCR, proliferation studies, Western blotting, luciferase reporter assay, confocal microscopy, flow cytometry, siRNA transfection and adhesion assays. *Results.* We demonstrate that the cell lines 697 and RCH-ACV, both harbouring the t(1;19) translocation, express high levels of Wnt16B as well as β-catenin. We further found that high doses of the soluble Wnt inhibitor sFRP1 gave only a small reduction of proliferation, but no induction of apoptosis in these cells. However, we were not able to replicate this finding by treatment with the Wnt inhibitors Dkk1, Dkk4 or a specific Wnt16 antibody previously shown to induce apoptosis (Mazieres J *et al.,* 2005). Therefore, we suggest that Wnt16 does not have an important role in proliferation or survival of pre-B ALL cells. To study a possible link between canonical Wnt signalling and the high levels of Wnt16 and β-catenin, we measured the reporter gene (TOPflash) activity. Compared to other leukaemia cell lines and to induction with Wnt3A, the TOPflash acitivity in the Wnt16 expressing cell lines was

low. This was further confirmed by immonofluorescence demonstrating that β-catenin was localized in the cell membrane and not in the nucleus. In the cell membrane, β-catenin co-localized with N-cadherin. As we have shown that stromal cells protect several pre-B ALL cell lines from apoptosis during cytostatic treatment, we are currently investigating whether β-catenin in the cell membrane participates in the interaction between leukaemia cells and stroma cells. Using sFRP1 we are able to demonstrate a small reduction of β-catenin in Wnt16 expressing cells as well as a reduced protective effect of stromal cells during cytostatic treatment. The role of β-catenin, however, may be independent of Wnt16 and canonical Wnt signalling. These issues are currently being studied using siRNA and functional assays. *Conclusions.* Pre-B ALL cells harbouring the t(1;19) translocation express high levels of Wnt16 and β-catenin, but do not have constitutively active canonical Wnt signalling. The proposed role of Wnt16 in cell survival and proliferation of pre-B ALL cells was not confirmed. β-catenin is localized in the cell membrane, not in the nucleus of these cells, where it co localizes with N-cadherin and is likely to participate in cell-cell interactions. We are currently investigating whether the β-catenin level is independent of Wnt16 and other possible signalling pathways initiated by Wnt16.

0004

IGH, TCR GAMMA AND TCR DELTA GENE USAGE, FRAME CODING AND MUTATIONAL STATUS ANALYSIS IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA

L. Rai, L. Foroni

Royal Free & UCMS, LONDON, United Kingdom

Clonal antigen (Ag) receptor gene rearrangements are detected in ~75% of adult ALL patients and represent good targets for minimal residual disease monitoring. Association of specific Ag receptor gene rearrangement with outcome has been suggested by some investigators, at least in childhood ALL. *Aims*. The aims of this study were to investigate: 1) IgH, TCRg and TCRd gene usage in B and T lineage adult ALL; 2) the occurrence of in-frame (IF) and out-of-frame (OF) sequences and rate of mutation; 3) the correlation of these parameters with overall clinical outcome. *Patients and methods.* DNA from 176 *de novo* adult ALL patients (65F/111M) were obtained from diagnostic PB or BM samples. 312 clones were identified using primers for IgH, TCRg and TCRd loci in precursor B-ALL (242 clones from 133 patients) and T-ALL patients (37 clones from 24 patients). Median WBC was 18.1×10^9/L (range $0.25\text{-}653\times10^9$/L). Sixty three (70%) patients are, to date, in complete clinical remission (median follow up: 13.2 months; range: 0.49-158.3 months), 24 (26.7%) patients have relapsed (median time: 10.97 mo; range: 2.46-36.9 mo) and 3 (3.3%) patients showed resistant disease. Patients carrying the t(9;22) (no:39) and t(4;11) (no:14) translocations and those who received an allogeneic stem cell transplantation (no:59) were excluded when calculating relapse free survival to avoid bias towards bad and good performance, respectively. *Results*. 125 IgH clones from 97 patients, 117 TCRg clones from 92 patients and 70 TCRd clones from 59 patients were identified. In precursor B-ALL, usage of VH3, Vd2 and Vg2 followed by Vg9 and VH1 predominated. In T-ALL Vg10, Vg4 and Vd1 were predominantly used. In precursor B-ALL Vg4, Vg8 and Dd2 were associated with good prognosis while VH5 was associated with poor prognosis. In T-ALL Vg1, Vg2, Vg4, Vg5, Vg11, Vd2 and Dd2 were associated with good prognosis. When Ag receptor gene usage was analysed in the t(9;22) and t(4;11) ALL subgroups compared to non-translocation group, patients with t(9;22) used VH and TCRg genes across the length of respective loci while t(4;11) patients used downstream J proximal V genes (VH6, Vg10 and Vg11 genes) more frequently; indicative of prominent lineage immaturity of the latter. Majority of IgH (60%) and TCRg (64.9%) rearrangements were OF while 75% of Vd1 rearrangements were IF, with no association with clinical outcome in either types. DNA V-gene mutations ≥2% were observed in 15-20% of IgH rearrangements, 2-4% of TCRg and 0% of TCRd rearrangements without any impact on outcome compared to un-mutated germline rearrangements. *Conclusions.* In both adult precursor B-ALL and T-ALL specific IgH and TCR genes correlated with outcome. Gene usage pattern differs in t(9;22) and t(4;11) patients in line with cell origin of the two subgroups. Unlike observations made in other leukemias such as CLL, V gene mutations ≥2% does not appear to affect clinical outcome in our data set (p=ns).

0005

CELLULAR CHOLESTEROL MODULATES VEGFR-1 FUNCTION ON ACUTE LEUKEMIA CELLS

R. Fragoso, C. Casalou, S. Dias

Portuguese institute of Oncology, LISBON, Portugal

Vascular endothelial growth factor (VEGF) and its receptors play a crucial role in malignancy and in disease, regulating the survival, proliferation, and migration of several cell types, such as endothelium and also leukemia cells. Following our recent report on the role of VEGFR-1 (FLT-1) in ALL (Fragoso R *et al.,* 2006), in the present study we analyzed the molecular mechanisms whereby it modulates acute leukemia cell migration in response to VEGF/Placental Growth Factor (PLGF). First, we observed the formation of cell protrusions on ALL cells after VEGF/PLGF stimulation, with evidence for polymerized actin and FLT-1 co-localization (as determined by phalloidin, immunofluorescence staining, and confocal microscopy). Next, we investigated the mechanisms whereby FLT-1 and actin co-localize at the cell *leading edge* (protrusions), after VEGF/PLGF stimulation, and the relevance of such co-localization for cell migration. We addressed this question by impairing the formation of lipid rafts/caveolae using drugs that either sequester (nystatin) or deplete (methyl-β-ciclodextrin, MβCD) total cholesterol. Accordingly, co-treatment of leukemia cells with nystatin or MβCD and PLGF/VEGF blocked cell migration, an effect that was associated with a decrease in FLT-1 polarization and co-localization with actin filaments. Instead, FLT-1 was now found mostly in the cell cytosol. Given that leukemia cells have an increased rate of cholesterol up-take we sought to understand if increased cholesterol levels affected FLT-1 function in leukemia cells. Cholesterol enrichment enhanced leukemia migration in response to VEGF/PlGF (about 3 folds). This significant increase was associated with an increase in FLT-1 protein expression that resulted from increased protein translation in response to cholesterol enrichment. In order to address the *in vivo* importance of the cholesterol in modulating FLT-1 expression during leukemia onset and progression, we performed experiments using Nod-Scid mice subjected to high fat diet (that results in increased cholesterol levels in the BM and in the spleen) inoculated (or not) with leukemia cells. This metabolic condition worsened the disease, and significantly decreased the survival of leukemic mice. Very interestingly, this increased mortality was not associated to the early onset of extramedullary disease but rather to increased BM engraftment. This increased engraftment of leukemia in high fat diet was diminished by treating the mice with cholesterol lowering drugs (statins) and also with a FLT-1 neutralizing Ab, and was almost impaired by the synergistic use of the two drugs. These results shows clearly the importance of the BM micro-environment in modulating leukemia engraftment and progression and implicate for the first time the cholesterol metabolism in this process, which may be used to establish novel therapeutic approaches.

0006

IDENTIFICATION OF A NEW MECHANISM OF RESISTANCE TO IMATINIB AND DASATINIB IN PH-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA: OVEREXPRESSION OF ABERRANTLY SPLICED ONCOGENIC IKAROS ISOFORMS

I. Iacobucci,[1] S. Soverini,[1] S. Paolini,[1] P.P. Piccaluga,[1] M. Rondoni,[1] E. Ottaviani,[1] M. Amabile,[1] A. Poerio,[1] F. Castagnetti,[1] P. Giannoulia,[1] S. Colarossi,[1] A. Gnani,[1] D. Cilloni,[2] G. Saglio,[2] F. Pane,[3] G. Rosti,[1] M. Baccarani,[1] G. Martinelli[1]

[1]Dept. of Hematology/Oncology Seràgnol, BOLOGNA, [2]Dept of Clinical and Biological Sciences, ORBASSANO, TURIN; [3]CEINGE, University of Naples, NAPLES, Italy

Background. Pre-mRNA splicing is an important determinant of the protein repertoire in human cells but it is also a natural source of cancer-causing errors in gene expression. Spliced isoforms of Ikaros, a critical regulator of haematopoiesis, which lack the DNA-binding domain act as dominant negatives by binding long isoforms through the C-terminal zinc-finger domain, which allows for the homo-or heterodimerization of the proteins. Human leukemia has been shown to be heterogeneous for the pattern of Ikaros isoforms. Forced expression of short isoforms alters the differentiation capacities of haematopoietic progenitors and arrest lineage commitment. Despite imatinib or the second generation tyrosine kinase inhibitors induce a high complete remission rate in ALL patients carrying a BCR-ABL rearrangement, the disease often relapses due the occurrence of resistance. *Aim.* We sought to determine if the expression of aberrantly spliced oncogenic Ikaros isoforms could contribute to the resistance in Ph^+ acute lymphoblastic leukaemia (ALL) patients treated with imatinib and the novel dual Src/Abl inhibitor,

dasatinib. *Methods*. We studied Ikaros gene expression in bone marrow and peripheral blood samples from 29 patients with Ph+ ALL: 5 adult *de novo* patients, 16 patients resistant to imatinib and 8 resistant to dasatinib after imatinib failure. Reverse transcription-polymerase chain reaction (RT-PCR) using primers specific for exon 1 and exon 7 of Ikaros and nucleotide sequencing were performed to identify the specific isoforms. Genomic sequencing of the regions surrounding the predominant splice donor and acceptor sites at the exon-intron splice junctions was performed in search for mutations. BCR-ABL transcript levels were monitored in each patient by real-time quantitative PCR (RQ-PCR). *Results.* We detected expression of the full-length Ik1, Ik2 DNA binding isoforms in cells from healthy volunteers and in 3 (10%) Ph+ ALL patients (2 resistant to dasatinib and 1 to imatinib). In the 26/29 (90%) remaining patients the Ik6 isoform lacking all DNA-binding domains was detected and in 13/26 (50%) it was the predominant isoform, demonstrating its dominant activity. In 5/26 patients we detected also the Ik4 isoforms. Genomic sequencing of splice junction regions demonstrated no mutations. We confirmed the identification of a SNP that affects the third base of the triplet codon for a proline (CCC or CCA) in the highly conserved bipartite activation region of the exon 7. Bi-allelic expression pattern of the various Ikaros isoforms suggested that trans-acting factors were involved in the generation of the non-DNA binding isoforms. Molecular monitoring showed that the dominant negative Ik6 expression correlated with the BCR-ABL transcript levels suggesting that this alteration could depend on the Bcr-Abl activity. The majority of patients with Ik6 expression had also point mutations in the ABL kinase domain. *Conclusions.* The Bcr-Abl oncoprotein may induce the expression of aberrantly spliced oncogenic Ikaros isoforms which arrest the leukemic cells at the pre B-cell stage and contribute to the tyrosine kinase inhibitor resistance interfering with proteins in pathways that are normally regulated by the full-length Ikaros protein.

MLL TRANSLOCATION IN A MULTIPOTENT PROGENITOR CAUSING ACUTE LYMPHOBLASTIC LEUKAEMIA - TWO-STEP MODEL OF THE DISEASE

J. Zuna,[1] T. Burjanivova,[1] Z. Zemanova,[2] S. Horsley,[3] L. Kearney,[3] K. Muzikova,[1] C. Meyer,[4] E. Mejstrikova,[1] A. Houdkova,[5] S. Colman,[3] H. Ptoszkova,[6] R. Marschalek,[4] J. Stary,[1] M. Greaves,[3] J. Trka[1]

[1]CLIP, Charles Univ. Prague, 2nd Med. Sch, PRAGUE, Czech Republic; [2]Charles Univ. Prague, 1st Med. School, PRAGUE, Czech Republic; [3]Institute of Cancer Research, SUTTON, United Kingdom; [4]Univ. of Frankfurt, FRANKFURT/MAIN, Germany; [5]University Hospital Motol, PRAGUE, Czech Republic; [6]University Hospital Ostrava, OSTRAVA, Czech Republic

Background. Leukaemias with MLL gene rearrangement are usually considered prognostically unfavourable and the clinical symptoms typically follow the translocation formation rapidly. MLL rearrangement is thus thought to be a major hit in leukaemogenesis that is either sufficient to cause the disease or it is a very strong and rapid inducer of the subsequent hit(s) required for the malignant transformation. *Methods and Results*. We report an unusual presentation of secondary acute lymphoblastic leukaemia (sALL) with MLL rearrangement. Our patient was diagnosed originally with acute myeloid leukaemia (AML-M3) characterised by PML/RARα fusion and an internal tandem duplication of FLT3 (FLT3/ITD). After 30 months of complete remission of AML, she developed sALL with MLL/FOXO3A fusion gene. Bone marrow (BM) samples taken during AML therapy were analysed for the presence of these aberrations. Both the PML/RARα fusion and FLT3/ITD disappeared shortly after AML onset and did not reappear. However, FISH and quantitative RT-PCR showed the presence of the MLL/FOXO3A fusion 20 months before the diagnosis of sALL, present in 10-90% of BM cells. Morphological examination showed no blast infiltration of the BM at this time. Experiments combining FISH and morphology confirmed the presence of an MLL rearrangement in myeloid as well as lymphoid cells, indicating that the fusion arose in a multipotent progenitor. In order to identify potential secondary genetic events precipitating sALL in this patient, we used Affymetrix 50K single nucleotide polymorphism (SNP) array analysis on DNA from the diagnostic sALL sample versus the *preleukaemic* (remission AML) sample taken 16 months before. This analysis revealed a 10 Mb amplification on 19q13.32 in the sALL sample, not present in the preleukaemic sample: this was confirmed by FISH with a BAC from the amplified region. A difference between the preleukaemic and leukaemic cells is also demonstrated by the incomplete rearrangement of IgH gene (DH1/JH) present only at the diagnosis of sALL. There are about 450 genes in the amplified region on 19q and several of them might be involved in deregulation of the preleukaemic cell if overrepresented (e.g. FLT3 ligand, interleukin 11, Ras interacting protein 1, Stem cell growth factor, Aurora C). *Summary and conclusions.* The long latency period prior to the onset of the secondary leukaemia in our case resembles the mouse model of MLL/FOXO3A. However, in contrast to the animal model and also to the previous reports of MLL/FOXO3A patients (2 cases described so far, both secondary AMLs after Hodgkin's disease), our child developed leukaemia from the lymphoid lineage. Taken together, these results indicate that the MLL/FOXO3A fusion alone is not sufficient to cause leukaemia and that second hit is required to the onset of the disease. A responsible gene is possibly located on the telomeric part of the 19q.

V(D)J-MEDIATED TRANSLOCATIONS MORE EXCEPTION THAN THE RULE?

K. Vanura,[1] T. Le,[1] M. Marusic Vrsalovic,[2] R. Marculescu,[3] U. Jäger,[1] B. Nadel[4]

[1]Medical University of Vienna, VIENNA, Austria; [2]Dubrava University Hospital, ZAGREB, Croatia; [3]Rudolfstiftung Hospital, VIENNA, Austria; [4]CNRS-INSERM-Université de la Méditerrané, MARSEILLE, France

Background. Translocations of proto-oncogenes to the B-cell or T-cell antigen receptor loci (BCR and TCR) usually are accompanied by an overexpression of the proto-oncogene involved which leads to the development of lymphoid neoplasms. The mechanisms held accountable for these translocations are either V(D)J- or class switch recombination, depending on the receptor region the oncogene is translocated to. Arguments for one or the other mechanism range from a simple statement with no additional comments to very detailed discussions why the authors think that a particular mechanism is responsible for the translocation or not. In most cases, however, arguments are rather indiscriminating and do not take into account mechanistic definitions characteristic for the recombination mechanism. *Aims.* To assess the potential of cryptic sites in the proto-oncogenes LMO2/RBTN2, LCK/p56, HOX11/TLX1, and E2A/TCF3 to undergo illegitimate V(D)J recombination. LMO2, LCK, and HOX11 translocations to the TCR occur in 7, 4 and 1% of T-ALL, respectively. The E2A-PBX or E2A-HFL fusions are found in 25% of pre-B cell leukemias and in 5% of childhood and adult ALL. While not rearranged to one of the antigen receptor loci, cryptic sites have been found close to the breakpoints at E2A. *Methods.* An *ex vivo* recombination substrate assay was used to assess potential and efficiency of the cryptic sites to undergo V(D)J-recombination with a genuine TCR element. *Results.* LMO2 cryptic site, a site 1,3 kb downstream of a cryptic site that had been proven to function as a 12-RSS, appeared to be a 23-RSS target for V(D)J-recombination. Interestingly, this region contained additional cryptic sites which also engaged in V(D)J-recombination. While not as attractive a target as the 12-RSS site, these sites showed high recombinogenic efficiency in our assay. For LCK, two sites have been reported to be involved in translocations to the TCRβ locus. LCK site #1 functioned as a 12-RSS with high efficiency. Site #2, situated 30 kb upstream of site #1, only showed unspecific breaks scattered over the region used in our assay, indicating that it was not a direct target for V(D)J-recombination. The breakpoints of more than 6 patients were found close to a putative 23-RSS cyptic site 300 bp upstream of HOX11 exon 1. Recombination in our assay, however, resulted in unspecific breaks scattered over the region tested indicating that, as for LCK site #2, it was not a direct target for V(D)J-recombination. Finally, E2A contains two putative heptamers close to the breakpoint region found in translocations to PBX and HLF. These heptamers did not function as direct targets and recombination was unspecific in our experiments. *Conclusions.* While being potentially dangerous due to the initiation of DNA breaks, V(D)J-recombination is a tightly controlled mechanism that keeps the percentage of directly V(D)J-mediated chromosomal aberrations as low as possible. Other factors are involved causing doublestrand breaks which result in DNA ends that subsequently are incorrectly ligated to one of the immune receptor loci thus leading to overexpression of a proto-oncogene and the development of leukemia.

REFINEMENT OF THE REGIONS OF MINIMAL DELETION AT 6Q IN CHILDHOOD T-ALL BY BAC TILING PATH ARRAY CGH

M.P. Pisecker,[1] F. Erdogan,[2] R. Ullmann,[2] G. Mann,[1] S. Strehl[1]

[1]CCRI, Children´s Cancer Research Inst., VIENNA, Austria, [2]Max Planck Inst. for Molecular Genetics, BERLIN, Germany

Background. T-cell acute lymphoblastic leukemia (T-ALL) is a high-risk malignancy of thymocytes, and accounts for 10-15% of pediatric ALL cases. In T-ALL genetic analyses have elucidated an enormous heterogeneity in genetic abnormalities including chromosomal translocations, deletions, amplifications, and mutations. In particular, quantitative changes seem to play a crucial role in the pathogenesis and progression of the disease. Among these, deletions of the long arm of chromosome 6 have been found in 10-15% pediatric T-ALL. However, owing to the heterogeneity in the extent and the location of the 6q deletions, only one potential tumor suppressor gene, GRIK2, contributing to the pathogenesis of T-ALL has yet been identified in this region. *Aim and Methods.* This study was aimed at the refinement of the regions of minimal deletion (RMD) at 6q in childhood T-ALL by means of BAC tiling path array comparative genomic hybridization (CGH) with the final goal to identify novel genes possibly implicated in the development or progression of T-ALL. *Results.* Genomic DNAs extracted from 70 diagnostic bone marrow samples of childhood T-ALL patients were subjected to BAC tiling path array CGH. In 7 (10%) of the cases a del(6q) was detected, which is in accordance with formerly published incidences. Comprehensive data analysis allowed to determine two different potential RMDs on chromosome 6q14.1-15 and 6q16.2 corroborating the notion that not all cases with a del(6q) share a common RMD. The RMD at 6q14.1-15, which encompassed approximately 12 Mb was deleted in 6 of the cases, and apart from several other genes contained the previously described putative tumor suppressor gene GRIK2. The second, much smaller potential RMD at 6q16.2, spanned roughly 270 kb, and was also consistent with a common deleted region in 6 of the cases. This MRD contained only two genes, namely POU3F2 and FBXL4. POU3F2 (homeobox/POU domain protein 2) is a transcription factor, which is mainly expressed in fetal brain and melanocytes, and its expression is known to be altered in melanoma. The second gene, FBXL4, encodes a protein, which is a member of the F-box protein family and is probably involved in the phosphorylation-dependent ubiquitination of proteins, has so far not been shown to be implicated in any type of cancer. *Conclusions.* Analysis of hematopoietic diseases by BAC tiling path array CGH is an important tool to refine minimal regions of deletions and to delineate genes, which potentially play a critical role in leukemogenesis. Both genes, in particular FBXL4, located in the smallest region of RMD at 6q in T-ALL defined so far, may be crucial for tumor development or progression and warrant further investigations to elucidate their possible implication in T-cell disease.

IDENTIFICATION OF NOVEL RECURRENT GENOMIC ABERRATIONS BY ARRAY-CGH IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

A. Viardot,[1] C. Schwaenen,[1] N. Gökbuget,[2] D. Hoelzer,[2]
M. Witzens-Harig,[3] H. Döhner,[1] S. Weßendorf,[1] M. Schmid1

[1]Klinik für Innere Medizin III, ULM; [2]Medizinische Klinik III, FRANKFURT; [3]Medizinische Klinik und Poliklinik V, HEIDELBERG, Germany

Background. In acute lymphoblastic leukaemia (ALL), genomic aberrations like translocations t(4;11) or t(9;22) are associated with an adverse prognostic impact and play an important role in the development of risk adapted treatment strategies. So far, chromosomal banding analysis is the standard cytogenetic procedure for routine diagnosis. Genomic array-comparative genomic hybridization (aCGH) has become a useful technique for genomic screening allowing a more precise delineation of small genomic aberrations. *Methods.* We analyzed 54 patients with ALL, which were treated within the GMALL trials, by aCGH analysis using a genomic 2,8K chip. *Results.* Forty-seven patients had a B-precursor-ALL including 14 patients with t(9;22) and 4 patients with t(4;11); 7 patients had a T-ALL. We found genomic aberrations in 37 out of 54 patients (69%). The most frequent aberrations were deletions on chromosome bands 9p21 (12 cases; 22%), 7q35 (9 cases; 17%) and 13q14 (8 cases; 15%); as well as gains on chromosome X, on chromosome arms 1q and 11q 13 (5 cases each, 9%). The consensus region of the 9p21 deletion was narrowed down to a size of 420 kilobasepairs. This region covers 3 different genes with potential tumor suppressor gene (TSG) function: p14ARF, p15INK4B/p10 and p16INK4A. Further consensus regions could be delineated which contains candidate gene of possible biologic importance: gains on chromosome bands 8q24 (C-MYC), 9q34 (ABL-1) and 11q13 (CyclinD1), deletions on chromosome bands 12p13.1 (CDKN1B) and 16q22 (TRADD). In the group of B-precursor-ALL, there was a tendency to a higher number of aberrations per case in the standard risk group (that means no t(9;22) and t(4;11)) in contrast to the t(9;22) positive group (2.2 vs. 1.2 aberrations per case). Deletions on 9p21 and 12p13 seems to be more frequent in the standard group than in the t(9;22) group (9p21: 10/27 vs. 1/14, p=0.06; 12p13: 5/27 vs. 0/14; p=0.14, Fisher´s exact test). *Conclusions.* aCGH analysis is useful for the identification of recurrent genomic aberrations which are not detectable using standard cytogenetic techniques.

Development of a secondary leukemia after chemotherapeutic treatment for childhood acute leukemia is associated with rearrangements of the MLL gene on chromosome 11q23 and characteristically results in acute myeloid leukemia (AML). We identified the NOTCH co-activator Mastermind-like 2 as novel MLL fusion partner in two cases of pediatric therapy-related leukemia. The MLL-MAML2 fusion results from a cryptic inv (11)(q21q23). With a latency of twenty months after initial diagnosis of MLL negative AML and five years after precursor B acute lymphoblastic leukemia, respectively, both patients developed a therapy-related T-cell acute lymphoblastic leukemia. MAML2 is the first MLL fusion partner involved in human NOTCH signaling and was only recently identified as recurrent translocation fusion partner in a subset of salivary gland tumors. The genomic MLL breakpoint shows similar localization and sequence features described for etoposide induced t-AML. The growth dynamic between primary and secondary disease was quantified using the individual genomic fusion sequence and Ig/TCR rearrangements as clonal markers. Whole genome expression profiles demonstrated involvement of target genes downstream of NOTCH, which suggests a modulatory role of the MAML2 transcriptional activation domain in MLL leukemogenesis and lineage assignment induced by the MLL-MAML2 fusion protein.

CHARACTERISTICS OF MESENCHYMAL STROMAL CELLS FROM BONE MARROW OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

H. Dimitriou, C. Perdikogianni, G. Martimianaki, D. Choumerianou,
E. Stiakaki, S. Genitsari, M. Kalmanti

University of Crete, HERAKLION, CRETE, Greece

Background. The effect of several chemotherapeutic agents on mesenchymal stromal cells (MSC) has been tested *in vitro* and it was found that MSC are sensitive to different cytotoxic drugs. In the only existing *in vivo* study assessing MSCs properties from bone marrow (BM) of adult patients under chemotherapy though, such an effect was not observed. *Aim.* To detect a) any effects of the acute lymphoblastic leukemia on the morphology and functional characteristics of MSCs in children, b) alterations in MSC characteristics that could be attributed to chemotherapy and c) the possible bone marrow microenvironment restoration, if damaged, and the time point that this occurs. *Material and Methods.* BM mononuclear cells (MNC) from children with ALL [diagnosis (ALL_d, n=12), 15th day (d15, n=6), 33rd day of therapy (d33, n=9), maintenance (n=26) and end of therapy (ALL_end, n=11)] were cultured under conditions that favor MSC growth, for six passages (1-6). The cell doubling time (DT), the development of CFU-F colonies and surface antigen expression were evaluated in each treatment phase and in P2, P4 and P6. Moreover, apoptosis by 7AAD staining (flow cytometry) was assessed. Selected samples from each group were cultured under the appropriate conditions for adipocyte, osteocyte and chondrocyte differentiation.

Expression of the oncogene H-Ras and the tumor suppressor genes p53, p16 and Rb was assessed in both MSC_P2 and P6 and MNC of diagnosis. *Results.* MNC of diagnosis required more days to reach confluency (23.9±2.09) compared to MNCs from the groups corresponding to different stages of treatment, which required 16.9±0.6 days. DT, which at diagnosis had the highest value, (4.26±0.88 vs 2.34±0.32 d15, 2.95±0.45 d33, 3.52±0.54 remission, 2.94±0.31 ALL_end) increased with the progression of passages. The immunophenotypic analysis showed a homogenous cell population with MSC characteristics appearing as early as P1 (CD73, CD105, CD146>90%) and simultaneous absence of hemopoietic markers. The CD95 expression was found to be high (95.8±2.7% ALL_d, 95.6±3.6% ALL_end) whereas the rate of apoptosis was low (<3%) in serial passages, indicating a cell population able to survive in a long term culture. The CFU-F /105 MNC count was lower at diagnosis (1.4±0.4), compared to the rest phases of therapy 3.5±0.9 d15, 6.4±0.6 remission and 9.3±0.8 ALL_end ($p<0.05$) and remained lower in all passages. In addition, the CFU-F decreased with progression of passages in all groups. At all the studied phases, MSCs had the ability of trilineage differentiation. MSCs at P2 expressed higher levels of p53, Rb and H-Ras and lower levels of p16 in comparison to MNCs in the group used as control, but in ALL samples the expression levels were similar between MNCs and MSCs at P2. No differences were observed in expression levels between passages P2 and P6. *Conclusions.* ALL affects the clonogenic and proliferative potential of MSCs and this could be attributed to BM blast infiltration and/or qualitative differences in the BM microenvironment. Chemotherapy does not seem to have any effect as MSC characteristics are re-established early in the course treatment and remain stable throughout treatment and after the end of it.

0013

IDENTIFICATION OF POTENTIAL THERAPEUTIC TARGETS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA BY PROTEIN KINASE GENE EXPRESSION PROFILE AND *IN VITRO* FUNCTIONAL TESTS

M. Messina, S. Chiaretti, S. Tavolaro, N. Peragine, R. Maggio, I. Della Starza, A. Vitale, C. Ariola, A.D. Negulici, L. Elia, A. Guarini, R. Foà

University La Sapienza, ROME, Italy

Background. Rational drug discovery and tailored targeted therapies represent a promising alternative in the treatment of adult ALL. In this context, PK have emerged as one of the most attractive targets since they often display an aberrant activation in cancer. Aims. We sought to assess if PK genes showed an altered expression pattern and might be regarded as potential therapeutic targets in adult ALL. Methods. We studied the gene expression profile of PK in 133 adult ALL samples with newly diagnosed ALL by oligonucleotide arrays (HGU133 Plus 2.0, Affymetrix). Ninety-one leukemia samples were of B-lineage affiliation and included, according to molecular assessments, 4 subgroups: BCR/ABL$^+$ (40 pts), ALL1/AF4$^+$ (5 pts), E2A/PBX$^+$ (3 pts) and B-lineage ALL without known molecular abnormalities (43 pts), defined as B-NEG. Leukemic cells from the remaining 42 samples were of T-cell origin. The comparison between the 5 ALL subgroups was primarily performed by ANOVA, using a list of 1324 probesets coding for PK; then the genes identified were further selected to focus on distinguishing PK genes. Real-time quantitative PCR (Q-PCR) was used to validate the oligonucleotide array expression values of 13 genes identified by ANOVA. *in vitro* proliferation experiments were performed on cell lines harboring the BCR/ABL, ALL1/AF4 and E2A/PBX transcripts - namely, SUP B15, RS4;11 and ACV - as well as on the Jurkat T-cell line after treatment with increasing doses, from 0.01 μM to 100 μM, of the TK (tyrosine kinase) inhibitors imatinib and dasatinib. *Results.* ANOVA provided a list of 290 probesets differentially expressed among the 5 ALL subsets considered. The stringent selection criteria applied highlighted the PK genes significantly distinctive of each group. T-ALL and E2A/PBX+ ALL showed the highest number of specific PK genes, namely 18. In particular, ZAP-70, LCK, ITK, EPHB6, FGFR1 and RYK distinguished the T-ALL group. The E2A/PBX+ samples were characterized by high expression levels of MERTK, BLK, TNK2 and ROR1. In the ALL1/AF4$^+$ group 15 genes were specifically overexpressed, including FLT3, ILK and LTK. Only 8 genes satisfied the selection criteria in the BCR/ABL$^+$ set; apart from ABL, FYN was selected. A consistent number of PK genes was overexpressed, though not exclusively, in B-NEG samples. Q-PCR analysis confirmed the array results, with a median Pearson correlation coefficient of -0.73. As expected, *in vitro* experiments showed a marked proliferation decrease of the BCR/ABL$^+$ cell line when exposed to TK inhibitors. Furthermore, we observed a significant and dose-dependent reduction in the proliferation of Jurkat and ACV cells following treatment with TK inhibitors, even at the lowest concentrations used. On the other hand, the RS4;11 proved insensitive. *Conclusions.* These data document a distinctive PK signature for different ALL subgroups. T-ALL, E2A/PBX$^+$ and B-NEG cases show a prevalence of TK. Thus, TK inhibitors may be effective not only in BCR/ABL$^+$ patients, but also in the aforementioned ALL subsets, as corroborated by preliminary *in vitro* experiments on leukemic cell lines. Functional studies are currently ongoing on primary cells to establish the role of the available TK inhibitors in the management of adult ALL.

0014

IDENTIFICATION AND CHARACTERISATION OF MLL-AF4-REGULATED CELLULAR PROCESSES

J. Greil,[1] M. Thomas,[1] A. Gessner,[1] P. Garrido-Castro,[1] L. Büchler,[1] O. Heidenreich[2]

[1]University Children's Hospital, HEIDELBERG, Germany; [2]University of Tuebingen, TUEBINGEN, Germany

Background. The translocation t(4;11)(q21;q23) marks an infant acute lymphoblastic leukaemia with a particularly dismal prognosis. We have recently shown that the der11, MLL-AF4, is indispensable for maintaining the leukaemic phenotype in part by interfering with apoptotic programmes. *Aims.* We examined the effects of RNAi-mediated depletion of MLL-AF4 on cell proliferation and gene expression in t(4;11)-positive leukaemia cell lines. *Methods.* t(4;11)-positive cell lines SEM and RS4;11 were electroporated with preformed siRNAs. Changes in gene expression levels were analysed by real time RT-PCR and by immunoblotting. Proliferation and apoptosis was examined by cell counting, MTT assays, cell cycle analysis, CFSE, and annexin V staining. DNA methylation and binding was studied by bisulfite sequencing and chromatin immunoprecipitation. *Results.* In previous experiments we showed that transient suppression of MLL-AF4 by siRNAs impairs clonogenicity, but not proliferation in suspension culture. However, prolonged MLL-AF4 depletion by repetitive siRNA transfections abolishes cell expansion. This inhibition is mainly caused by the induction of apoptosis and not so much by the inhibition of cell proliferation, as CFSE labelling studies indicate ongoing proliferation in spite of prolonged MLL-AF4 suppression. On the molecular level, two classes of putative target genes can be distinguished. The first class consisting mainly of homeotic genes such as HOXA7 is affected within 48 hours after MLL-AF4 siRNA transfection. The expression levels of a second class containing genes such as FGFR1, CDH2, DNMT1, DNMT3A, TERT (all downmodulated), DAAM1 and SEPT4 (ARTS, all upregulated) are only substantially affected by prolonged MLL-AF4 depletion. Inhibition of apoptosis by the general caspase inhibitor zVAD does not prevent changes of SEPT4 and TERT expression, suggesting that caspase-dependent apoptotic processes are not responsible for the observed expression changes. Furthermore, the DNMT inhibitor Aza-dC causes similar changes in TERT and SEPT4 expression as MLL-AF4 siRNAs, which is also reflected by very similar changes in the DNA methylation pattern of the TERT promoter. Current experiments address the role of these MLL-AF4 target genes in the MLL-AF4-dependent regulation of apoptosis. Furthermore, we are examining how MLL-AF4 controls these putative target genes. *Conclusions.* We have identified several MLL-AF4 target genes, which may contribute to the regulation of cell survival by MLL-AF4. The analysis of target gene functions may open up new treatment options for this therapy resistant infant leukaemia.

EFFECTIVE CELL KILLING OF PRIMARY ACUTE LYMPHOBLASTIC LEUKEMIA CELLS BY THE BCL-2 ANTAGONIST ABT-737

A. Tafuri,[1] M.R. Ricciardi,[1] C. Gregorj,[1] F. De Cave,[1] S. Santinelli,[1] P. Bergamo,[1] S. Decandia,[1] A. Vitale,[1] M.T. Petrucci,[1] M. Milella,[2] R. Foà[1]

[1]Hematology, ROME; [2]Medical Oncology A, Regina Elena Nationa, ROME, Italy

Background. Studies on the treatment of adult acute lymphoblastic leukemia (ALL) have shown only modest improvements over the last two decades, with the actual cure rate remaining in the range of 30-40%. Novel treatment modalities have been directed toward inappropriately activated cell-signaling pathways associated with the abnormal proliferation and/or apoptosis escape of leukemic blasts. Further studies on cell signaling may allow the identification of novel therapeutic targets for adult ALL. Proteins in the B cell leukemia/lymphoma 2 (Bcl-2) family are important regulators of the commitment to apoptosis at the mito-

chondrion level and are frequently found aberrantly expressed, particularly in lymphoid malignancies. The role of Bcl-2 overexpression in tumorigenesis and chemoresistance prompted us to investigate whether the inhibition of the antiapoptotic function may result also in ALL in an attractive therapeutic strategy. *Aims.* We investigated the cell cycle and apoptotic effects of the ABT-737 (kindly provided by Abbott Laboratories), a Bcl-2 (BH3) inhibitor, on primary adult and childhood LAL primary cells. *Results.* The lymphoid leukemia cell line CEM was exposed to increasing concentration of ABT-737 (from 0.1 to 1 μM) up to 72 hours. A dose- and time-dependent cell growth arrest and induction of apoptosis was found. In fact, measuring the subG0/1 peak at 48h, levels of apoptosis increased from 14.1% in DMSO to 34.4%, 64.5%, 86.5% and 98.6% at ABT-737 concentrations of 0.1, 0.25, 0.5 and 1 μM, respectively. The effects of ABT-737 were then examined on primary blasts from 6 untreated ALL patients (4 adults and 2 pediatrics). Bone marrow aspirates with a blast percentage infiltration (>70%) were obtained from patients broadly characterized for clinical and biological parameters, as well as therapeutic response. ALL cells were cultured *in vitro* with ABT-737 (at increasing concentrations from 0.01 to 1 μM) for 24 hours. A significant decrease in viability was observed at 0.01 μM (p=0.039) with a remarkable dose-dependent increase of apoptosis. In fact, Annexin V-positive cells increased from a mean baseline value of 16.3±9.9% up to 39.1±21.4% (p=0.04), 69.1±25.45% (p=0.005), 70.3±26.9% (p=0.05), 74.6±18.9% (p=0.03) and 80.8±11.8% (p=0.0001) in the presence of ABT-737 at 0.01, 0.1, 0.25, 0.5 and 1μM, respectively. A significant cell killing was demonstrated in 6/6 samples, including Ph-positive leukemias. No significant cell cycle changes were instead detected even at higher concentration of ABT-737. *Summary.* This study shows, for the first time at our knowledge, in primary adult and childhood ALL samples a potent growth-inhibitory and pro-apoptotic activity of the Bcl-2 antagonist ABT-737 at nanomolar concentrations. These results prompt to further extend pre-clinical studies in the different biologically-defined subset of ALL and suggest a potential clinical development of ABT-737 in this disease.

Acute lymphoblastic leukemia - Clinical

E2A/PBX, T(1;19) IS THE PREDOMINANT TRANSLOCATION IN PRECURSOR- B PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN EGYPT WITH NO SPECIAL ASSOCIATION WITH PRE B PHENOTYPE

A. Kamel,[1] Y. El-Nahass,[1] I. Sidhom,[1] K. Girtman,[2] H. Moussa,[1] D. Yassin,[1] N. El-Sharkawy,[1] K. Shaaban,[1] H. Hussein,[1] S. Aboul-Naga,[1] W. Zekry,[1] E. Ebeid,[1] M. Zamzam,[1] A. El-Haddad,[1] S. Shurtleff[3]

[1]NCI, Cairo University, CAIRO, Egypt; [2]St Jude Children Research Hospital, MEMPHIS, TENESSEE, United States of America; [3]St. Jude Children Research Hospital, MEMPHIS, TENESSEE, United States of America

Background. Molecular genetics of pediatric ALL is essential for risk stratification. Egyptian data in this field are sporadic. *Aim.* To determine the relative incidence of the 4 most common fusion genes of pediatric precursor B-ALL in a cohort of Egyptian patients and study their possible impact on clinical outcome. *Patients and Methods.* The study comprised 134 children (<18 years) newly diagnosed precursor B ALL patients presented to the Pediatric Oncology Department, NCI, Cairo University in the period 2003-2004. Cases were diagnosed according to standard methods including morphology, cytochemistry and immunophenotyping. Accordingly they were classified as CALL (74 patients, 55.2%), Pre B ALL (47 patients, 35.1%) and Pro B ALL (13 patients, 9.7%). Patients were risk stratified according to age, total leucocyte count, immunophenotyping, and early response to therapy (BM day 14). Patients were tested for the 4 major fusion gene transcripts frequently associated with ALL namely t(1;19) E2A/PBX1, t(12;21)TEL/AML1, t(4;11) AF4/MLL and t(9;22) BCR/ABL p190 and p210. Fusion genes were identified by both conventional and real-time RT-PCR using cell lines as positive controls. *Results.* t(1;19) was encountered in 24 patients (17.9%) while t(12;21) was encountered in 13 patients (9.7%). t(9;22) and t(4;11) were encountered in 2 patients each (1.5%). One case (CALL) showed double translocation t(1;19) and t(12;21). The remaining 93 patients (93/134, 69.4%) were negative for all fusion genes tested. None of the fusion transcripts correlated with any particular immunophenotype. t(12;21) was found in CALL and pre B subtypes while t(1;19) was distributed among the 3 precursor B subtypes including 11 CALL cases, 10 pre-B and 3 pro-B. The 2 cases with t(9;22) were CALL. The 2 cases with t(4;11) included one pro-B and one pre-B. Myeloid marker expression was encountered in 1/13 cases with t(12;21). Nor was there any significant association with DNA ploidy. However the majority of cases (11/13) with t(12;21) showed 2N DNA; the other 2 cases showed DNA index of 1.1 and 1.21. No statistically significant correlation was encountered between t(1;19), t(9;22) or t(4;11) on one side and any of the prognostic parameters on the other side. However, 9/13 (69.2%) cases with t(12;21) were classified as low risk (p 0.019) . The other 4 would have been classified as low risk if the translocation status was known upfront. The disease free survival (DFS) and event-free survival (EFS) at 30 months of all studied patients was 88.5±3.5% and 70.6±5.2%, respectively. DFS and EFS at 30 months of all groups together after excluding t(4;11) and t(9;22) was 100% and 90.9±8.7% for t(12;21), 90.9±8.7% and 69.3±10.7% for t(1 ;19), and 85.8±4.4% and 67.9±6.3% for cases without translocations (p=0.42. *Summary and conclusions.* Our study reports, probably for the first time, the incidence of the 4 specific fusion genes occurring in pediatric precursor B ALL Egyptian population in the same cohort of patients. t(1;19) proved to be the most common among our series followed by t(12;21); another feature in our patients that is different from western countries.

0017

ROLE OF ERYTHROPOIETIN RECEPTOR IN T(12;21) POSITIVE LEUKEMIA

A. Inthal,[1] G. Krapf,[1] E. Csinady,[1] D. Beck,[1] O. Orel,[1] G. Mann,[2] R. Panzer-Grümayer1

[1]Children's Cancer Research Institute, VIENNA, Austria; [2]St. Anna Kinderspital, VIENNA, Austria

Background. The chromosomal translocation t(12;21)(p13;q22) resulting in the TEL/AML1 (also known as ETV6/ RUNX1) fusion gene is the most frequent translocation in childhood B cell precursor (BCP) ALL. This particular type of ALL is, like the other genetic subtypes, associated with a specific pattern of differentially expressed genes, among which

is the gene for the erythropoietin receptor (EpoR). So far, it is not known, which effects EpoR overexpression has on the t(12;21) positive leukemia, nor which signaling pathways, potentially different from those used in erythroblasts, are activated. *Aim.* The aim of this study was to evaluate the effects of EpoR signaling on survival and proliferation in t(12;21) positive leukemias and to investigate the apoptosis-modulatory potential of Epo. We further planned to explore relevant signaling pathways, linked to the respective effects and thereby elucidating mechanisms that might be essential for cell survival. *Material and Methods.* As model system for TEL/AML1 positive ALL the only available human BCP ALL cell line REH was used. Controls included the t(12;21) negative leukemic cell lines Nalm6, K562 and the Epo-dependent cell line UT7. Proliferation was measured by 3H-Thymidine incorporation assays. Cell viability and apoptosis rates were evaluated by MTT assay and Annexin V/ propidium iodide staining, respectively. Activated members of signaling pathways were detected by Western blotting using appropriate anti-phospho-antibodies either after immunoprecipitation or from whole cell lysates. *Results.* REH cells exhibited a dose dependent increase in proliferation when cultured with Epo (10, 50, 100U/mL) for 72 hours. Upon addition of blocking anti-EpoR antibodies these effects were negated. Epo-induced proliferation was also abolished when cells were co-cultured with AG490, a JAK2 inhibitor. We could, however, not detect an Epo-induced phosphorylation of proteins involved in the EpoR/JAK2/STAT5 cascade. This observation has been already described in several non-hematopoietic cancers and suggests that other members of the JAK/STAT pathway compensate for this specific lack of activation. REH cells further showed an impaired glucocorticoid (GC)-induced apoptosis in the presence of Epo. We thus evaluated whether signaling pathways implicated in survival of tumor cells exposed to apoptotic stimuli play a role in this rescue mechanism. Preliminary data indicate that the NF-kB as well as the PI3K/Akt pathway is triggered by Epo. Since cell lines may have intrinsic changes which could affect their signaling pathways, we are currently evaluating whether the observed results can also be reproduced in primary leukemic cells. First results suggest that also primary t(12;21) positive ALL may exhibit a superior survival and reduced apoptosis rate to GC in the presence of Epo. *Summary and Conclusions.* Our data indicate that in t(12;21) positive leukemias binding of Epo to its receptor leads to enhanced survival *in vitro* and negatively affects the sensitivity to GCs. andrea.inthal@ccri.at

FLOW CYTOMETRY ANALYSIS OF THE CO-EXPRESSION OF T- AND B-CELL MARKERS IN BLASTS FROM PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G. Shubinsky, T. Yermiahu, M. Van den Akker, I. Dulman, I. Levy, J. Kapelushnik

Soroka University Medical Center, BEER SHEVA, Israel

Analysis of genes encoding Ig- and T-cell receptors (TCR) in acute lymphoblastic leukemia (ALL) demonstrated frequent lineage infidelity of blast cells. Rearranged Ig-genes were found in 50-95% cases of T-cell ALL, and rearranged T-cell receptor genes were found in 70-82% cases of B-cell ALL. It remains, however, unclear whether the infidelity of lymphoblasts may be defined at the study of antigenic properties of blasts. We used multiparameter flow cytometry to test the expression of CD3/TCR ε'chain and B-cell receptor α-chain (CD79a) in the cytoplasm of electronically separated (gated) blasts from 51 pediatric and 16 adult patients with ALL. T-ALL was diagnosed in 16 pediatric and 5 adult patients, and B-ALL in 35 pediatric and 11 adult patients. Two arbitrary cutoff thresholds, above the 10% and above the 20% of positive cells within gated lymphoblasts, were used to define the co-expression of T- and B-cell markers in blast cells. Statistical analysis of data was performed using the Fisher exact probability test. At 10% cutoff threshold, the expression of CD79a was determined in 7 of 21 cases (33%) of T-ALL with CD3ε+ blasts. The expression of CD3ε was found in 13 of 46 cases (28%) of B-ALL with CD79a+ blasts. Totally the blasts with co-expression of T- and B-cell markers were found in 30% patients with ALL. Thirteen from 20 patients (65%) with CD3ε+/CD79a+ double-positive blasts had either pre-B or late cortical subtype of ALL. At 20% cutoff threshold for positive cell count, double-positive blasts were identified in 8 patients (12%) with ALL. Two of these patients had pre-B, and 5 had late cortical subtype of ALL, indicating more frequent finding of biphenotypic blasts in patients with these immunologic subtypes of ALL than in patients with other subtypes of ALL (p=0.01). The proportion of cases with biphenotypic blasts was higher in patients with T-ALL than in patients with B-ALL (p<0.01). The study of intracellular expression of VpreB (CD179a) fragments of surrogate light chains in 3 cases of T-ALL with CD79a+ blasts showed a strong expression of CD179a in blast cells. Blasts from one patient with CD3ε+ T-ALL displayed high level of intracellular TCRβ, CD79a, and CD179a markers. The patients with T/B biphenotypic lymphoblasts demonstrated a slightly lower rate of residual disease during induction therapy than the patients without biphenotypic blasts. Obtained data showed that T/B biphenotypic blasts may be found in 12-30% cases of ALL. Biphenotypic appearance of lymphoblasts is apparently associated with relatively mature immunologic subtypes of T- and B-ALL. Analysis of intracellular expression of CD179a and TCRβ seems to be useful for the detection of ALL with T/B biphenotypic lymphoblasts. Clinical significance of ALL with biphenotypic blasts remains unclear and requires further investigation.

EPIGENETIC THERAPY WITH 5-AZACITIDINE IN A TREATMENT SCHEDULE OF FIVE DAYS EVERY 4 WEEKS INDUCES HEMATOLOGIC RESPONSES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA REFRACTORY TO OR NOT ELIGIBLE FOR INTENSIVE CHEMOTHERAPY

H.K. Al-Ali, S. Schwind, R. Krahl, C. Becker, S. Leiblein, C. Mueller, D. Niederwieser

University of Leipzig, LEIPZIG, Germany

Epigenetic alterations such as DNA methylation within gene promoter regions and histone modification are prevalent in cancer. Reversal of epigenetically inactivated genes by the nucleoside analogue 5-azacitidine is an effective treatment in MDS. In the current study, the safety and efficacy of azacitidine in patients with AML refractory to or not eligible for chemotherapy were assessed at the University of Leipzig. *Patients and Methods.* Since August, 2005, 25 patients with AML (14m/11f), median age was 69 (range 32-80) years, received a 5 days treatment schedule with 75 mg/m^2 azacitidine sc every 4 weeks mostly in an outpatient setting. Secondary AML was present in 15 (60%) patients. Abnormal cytogenetics were found in 9 (36%) patients [8 with complex aberrations and one with trisomy 8]. Azacitidine was given as first-line therapy in 10 (40%) patients not eligible for chemotherapy. The remaining 15 (60%) were treated because of relapsed or refractory AML including 6 patients who relapsed after allogeneic hematopoietic cell transplantation (HCT). Median pre-treatment marrow blasts, WBC, ANC and platelets were 24% (range 21-88%), 5.7 (range 0.5-82)×10^9/L, 1 (range 0-27.7)×10^9/L and 32 (range 3-1520)×10^9/L respectively. Hematological response was assessed according to the International Working Group Criteria for AML. For non-hematologic toxicity, the NCI CTC and for hematologic toxicity the NCI CTC hematology criteria for leukemia studies or bone marrow infiltrative/myelophthisic processes were used. *Results.* To date, 92 treatment cycles with a median of 3 (range 1-8) cycles/patient were applied. Leukopenia and thrombocytopenia > grade III occurred in 9 (36%) and 12 (48%) patients respectively. ANC and platelet nadirs occurred day 21 (range 5-23) and 14 (range 10-27) respectively. Non-hematologic side effects were constipation grade I, n=7, liver toxicity grade I, n=7, nephrotoxicity grade I, n=2, parasthesia grade I, n=1, fever grade II, n=1. Hospitalisation because of grade IV liver toxicity, arthritis grade III, and pneumonia were required in three patients. After a median follow-up of 15 (range 3-78) weeks, 18 (72%) patients responded [CR, n=7 (39%), PR, n=2 (11%), hematologic improvement, n=4 (22%), stable disease, n=5 (28%)]. Two (22%) complete cytogenetic remissions were achieved. Responses occurred after a median of 6 (range 2-16) weeks after treatment. Median response duration amounts to 36 (range 3-not reached) weeks. Median survival time in responding patients is 57 (range 9-not reached) weeks compared to 16 (range 4-29) weeks in refractory patients (p<0.0001). Two Patients in CR received HCT after RIC [200cGy TBI+ fludarabine 30 mg/m^2 on 3 days] from a MUD. Engraftment with 50% marrow donor T-cell chimerism day 28 after HCT occurred in both patients. Azacitidine given to patients with relapsed AML after HCT was also feasible with no negative impact on donor chimerism. *Conclusions.* Azacitidine applied in a 5 days schedule every 4 weeks is well tolerated and induces remarkable hematologic responses even in patients with refractory AML. HCT after RIC seems feasible after azacitidine therapy. Azacitidine could also be safely given in relapsed patients with AML after HCT. A phase II study is currently underway to confirm these data.

MRD BY MULTIPARAMETER FLOW CYTOMETRY IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: PROGNOSTIC IMPACT OF EARLY RESPONSE PARAMETERS ON THE MRD-STATUS AT THE END OF INDUCTION PHASE I

R. Ratei,[1] M. Dworzak,[2] P. Rhein,[1] G. Basso,[3] M. Veltroni,[4] G. Gaipa,[5] M. Schrappe,[6] W.-D. Ludwig,[1] L. Karawajew[1]

[1]HELIOS klinikum Berlin Buch, BERLIN, Germany; CCRI, St. Anna Kinderspital, VIENNA, Austria; [3]Department of Pediatrics, University of, PADUA, Italy; [4]3Department of Pediatrics, University of, PADUA, Italy; [5]Tettamanti Research Center,University o, MILANO, Italy; [6]Department of Pediatrics, University Ho, KIEL, Germany

Background. Multiparametric flow cytometry (MFC) offers the unique possibility of quantitative monitoring of therapy response at early stages of treatment. *Aims.* In the present study we analyzed the predictive impact of early blast reduction kinetics measured by MFC on the minimal residual disease (MRD) status of the BM at day 33, an important time point for later therapy stratification. *Methods.* Standardized MFC-MRD quantification was performed for 197 patients within the AIEOP-BFM ALL MRD study. Relation between BM MRD status at d33 and blast reduction rates at day 8 in pb (BRRd8) and day 15 in bone marrow (BRRd15) was investigated using a a binary logistic regression model. Cut-off values for BRR were chosen according to ROC-curve calculations. Crosstable calculations were used for estimation of odds ratios. *Results.* BRR at d8 and d15 were significantly lower in patients with a positive FCM-MRD status than in patients with a negative FCM - MRD status on day 33. Furthermore, BRRd8 and BBRd15 were significantly contributing variables relating to the MRD status with a specificity of 83.5%. The incidence for a positive MRD status was higher for patients with a BRRd8<96% compared to a BRRd8 > 96% (44.9% vs. 23.4%; odds ratio, 2.67; 95 percent confidence interval [CI], 1.43-4.9; p=0.002) and for patients with BRRd15<99.5% (incidence, 37.7% vs.10.9%; odds ratio, 4.9; 95% CI, 2.4 -10.3; p<0.001). Combination of both blast reduction parameters defines two subgroups of patients with a high and low incidence of a positive MRD- status (incidence, 75% vs. 25%; odds ratio, 8.9; 95% CI, 3.2-24,6 p<0.001). *Summary.* Quantitative MFC assessment of early response parameters, in particular their complementary application, has a predictive impact on the MRD status after induction phase I of the AIEOP-ALL-BFM 2000 protocol.

CYTOREDUCTION RATES ARE ASSOCIATED WITH BCL-2 PROTEIN EXPRESSION IN ALL BLASTS PERSISTING DURING INDUCTION THERAPY

P. Rhein,[1] R. Ratei,[1] R. Mitloehner,[1] A. Moericke,[2] C. Hagemeier,[3] K. Seeger,[3] R. Kirschner-Schwabe,[3] R. Spang,[4] M. Schrappe,[2] W.-D. Ludwig,[1] L. Karawajew[1]

[1]Robert-Rossle-Clinic, HELIOS, Charite, BERLIN, German;, [2]University Hospital Schleswig-Holstein, KIEL, Germany; [3]Charite Medical School, BERLIN, Germany; [4]University of Regensburg, REGENSBURG, Germany

Background. In childhood acute lymphoblastic leukemia (ALL), leukemic cell reduction rate during therapy is of crucial prognostic significance. Recently, we investigated gene expression changes during the first week of induction glucocorticoid (GC) therapy and identified a common set of genes differentially expressed in blasts at day 8 (d8) and at diagnosis (d0). The hallmark of mRNA expression changes in d8 cells was a downregulation of BCL-2, the antiapoptotic factor critically involved in the regulation of both normal B cell lymphopoiesis and GC-specific apoptosis. Moreover, BCL-2 is frequently overexpressed in ALL cells at diagnosis, but its expression levels do not correlate with rates of cytoreduction. *Aims.* Investigation of expression changes of BCL-2 protein during induction therapy in a large series of ALL patients and evaluation of its impact on leukemic cell reduction. *Methods.* Blood samples (d0; d8) from patients with B cell precursor ALL enrolled in the multicenter ALL-BFM 2000 study were acquired prospectively (n=100). BCL-2 expression in leukemic blasts was assessed using multiparameter flow cytometry. BCL-2 expression in ALL cell lines was downregulated by transfection with BCL-2 specific siRNAs. *Results.* BCL-2 protein expression decreased after 1 week of therapy in the majority of cases (86%, mean fold change 0.6, p<0.001). Comparison of BCL-2 reduction rates with therapy-induced cytoreduction revealed a tendency towards positive correlation (p=0.059), and absolute levels of BCL-2 at d8 (but not at d0) inversely correlated with the cytoreduction (p=0.002). In experimental cell systems (B-lineage ALL cell lines), downregulation of BCL-2 was a common event in GC sensitive lines and a pre-requisite for GC-induced apoptosis. Downregulation of BCL-2 alone was sufficient to induce apoptosis in the absence of GC treatment. Moreover, cytoreduction rates and expression levels of BCL-2 protein inversely correlated in BCL-2 siRNA transfected cells (p=0.05). *Conclusions.* BCL-2 acts as an antiapoptotic threshold in ALL blasts which is targeted by GC treatment. An inability of GCs to downregulate BCL-2 or an insufficient decrease of BCL-2 levels results in a worse therapy response.

0022

DIFFERENTIAL EXPRESSION OF VALOSIN-CONTAINING PROTEIN (VCP, P97) IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS WITH AND WITHOUT GLUCOCORTICOID TREATMENT

N. von Neuhoff,[1] S. Junk,[1] G. Cario,[2] N. Wittner,[1] M. Schrappe,[2] B. Schlegelberger,[1] M. Lauten[2]

[1]Medical school Hannover, OE 5120, HANNOVER, Germany; [2]Department of Paediatrics, University, KIEL, Germany

Background. The response to initial glucocorticoid therapy in childhood acute lymphoblastic leukaemia (ALL) reliably predicts the response to multiagent chemotherapy. Patients resistant to glucocorticoids (prednisone poor responders (PPR)) have a poorer event-free survival compared to glucocorticoid-sensitive patients (prednisone good responders (PGR)). In a case control study to investigate differential protein expression in leukaemic blasts, catalase, RING finger protein 22 α, VCP and a G-protein coupled receptor (family C, group 5, member D (GPRC5D)) were overexpressed in PPR. *Aims.* In this study the functional consequences of glucocorticoid treatment of ALL cell lines on the RNA and protein expression of the valosin-containing protein (VCP) was investigated with respect to VCP expression on the RNA and Protein level. Moreover, the study was extended to primary bone marrow samples of patients with childhood ALL. *Methods.* Human B cell precursor leukaemic cell lines MHH cALL 2 (PPR) and MHH cALL 3 (PGR) were studied after induction with glucocorticoids (3 µg/mL Solu-DecortinH®) for 96 hours, according to one doubling time of the cell lines. Incubated cells were sampled every 24 hours for protein isolation, RNA extraction and immunfluorescence. Western blot analysis using an anti-p97 antibody was performed on whole cell lysates, nuclear, membrane and cytosolic fractions separated by differential detergent fractionation with the Qproteome Cell Compartment Kit (Qiagen, #37502). The amount of expressed VCP RNA was analysed by Lightcycler analysis after for each time point. The results were further evaluated using mononuclear cells from bone marrow samples from five PGR and five PPR patients with childhood ALL in a matched-pair design. *Results.* After glucocorticoid induction for 24h, 48h and 72h, VCP RNA expression was increasing. However, in the PPR cell line VCP was upregulated 2.8 fold compared to the PGR cell line after 96h of glucocorticoid induction. In agreement with these findings, VCP protein expression was also overexpressed in the PPR cell line compared to the PGR cells . The results of the immunfluorescence analysis supported these findings, but revealed no differences in the localization of the target protein. On average, VCP RNA expression was increased about 0,56 times in three of five PPR samples (5,1'6,5) in comparison to the PGR (3,1-3,3). Results were normalized with the housekeeping gene TBP. VCP protein expression was slightly increased about 0,71 in the PPR group in comparison to the PGR group. *Conclusions.* The results of this study indicate that the deregulation of the proteasome-ubiquitin degradation pathway with valosin-containing protein (VCP) as part of it may determine multi-agent chemotherapy resistance and treatment outcome in childhood ALL patients.

SAFETY AND TOLERABILITY OF INTRATHECAL LIPOSOMAL CYTARABINE AS CNS PROPHYLAXIS IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

P.N. Neumeister,[1] M. Pfeilstöcker,[2] W. Linkesch,[1] A. Rohn1

[1]Division of Hematology, GRAZ, Austria; [2]3.Medical Dept Hanusch Hospital, VIENNA, Austria

Background. Meningeal recurrence in acute lymphoblastic leukaemia (ALL) occurs in up to 15% of patients and depends on intensity of front line systemic and CNS directed therapy and subtype of ALL. Meningeal recurrence not only adds significant morbidity for the individual patient but also is frequently associated with poor outcome. Liposomal Cytarabine (DepoCyte) is a sustained release formulation of Ara-C with a more homogeneous distribution throughout the neuroaxis and a prolonged half life maintaining cytotoxic concentrations in the CSF for more than 14 days. *Aims.* The purpose of our study was to evaluate the efficacy and

safety of a slow-release liposomal formulation of cytarabine for intrathecal (IT) meningeal prophylaxis in patients suffering from ALL. *Patients and Results.* From 7/2004 to 01/2007 17 patients aged 20 to 65 years (median= 37) were preventively treated with a total of 44 (range:1-6) single doses containing 50 mg of liposomal cytarabine on a compassionate use basis. Diagnoses consisted of Pro-B-ALL (n=6), c-ALL (n=2), T-ALL (n=6), and Pre-B-ALL (n=3). All patients were treated according to the risk adapted German Multicenter Protocol/ GMALL 07/2003 including 24 Gy irradiation to the neurocranium as constituent component of CNS directed therapy. 4 patients expressed the bcr-abl fusion oncogen and were concomitantly treated with imatinib mesylate as outlined in the study protocol. All patients received dexamethason for 3'5 days in order to prevent chemical arachnoiditis. Except for headache grade 2 in one patient no specific toxicity attributable to IT liposomal cytarabine application was noted. So far, after an observation period of 11 months (1-27) 6 patients died, 5 of disease recurrence and one of sepsis. 2 patients show a refractory course of disease. 9 patients are in complete remission, one after successful salvage therapy of first relapse and 5 after allogeneic stem cell transplantation. Only one patient experienced a combined medullary - leptomeningeal disease recurrence 6 month after primary diagnosis. None of the surviving ALL patients developed neurological symptoms or unexpected long term neurological side effects. *Conclusions.* IT liposomal cytarabine therapy at a dose of 50 mg with concomitant dexamethasone appears to be feasible and well tolerated. However, since all patients received concurrent systemic chemotherapy and CNS directed irradiation the efficacy of liposomal cytarabine cannot be assessed separately. Further studies are warranted to determine the exact schedule for IT prophylaxis in adult patients with ALL.

0024

GENE EXPRESSION PROFILING IN E2A-PBX1-SILENCED T(1;19)+ LEUKEMIA CELLS

G. Casagrande, G. Basso

University of Padova, PADOVA, Italy

Background and Aims. The translocation t(1;19)(q23;p13) is one of the most common ones in childhood pre-B acute lymphoblastic leukemia and usually results in the chimeric gene E2A-PBX1. Through extensive studies, E2A-PBX1 has been shown capable of transformation in fibroblast, myeloid, and T lineage cells, but its role during leukemogenesis is not yet fully understood (Fu X, Kamps MP. Mol Cell Biol 1997; Kamps MP, Baltimore D. Mol Cell Biol 1993; Dedera DA, *et al.* Cell 1993). We initially silenced E2A-PBX1, achieving an efficient downregulation of this fusion in several pre-B leukemia cell lines and obtaining as consequence a strong downregulation of the Wnt16b and EB-1 genes. The presented project aims to clarify the mechanism of E2A-PBX1 in leukemia cells also through the elucidation of its interactions with a panel of gene involved in tumorigenesis and transformation, based on differential gene expression array in pre-B acute lymphoblastic leukemia cell lines (in normal conditions as well as during RNAi silencing). *Methods.* The transfection of small interfering RNAs (siRNAs) was monitored by fluorescence microscopy and FACS analysis. The specific mRNA expression of the fusion gene was measured using TaqMan real-time quantitative PCR, while the reduction of the correspondent protein levels was assessed by Western Blot. To better understand the role of E2A-PBX1 in human pre-B cell leukemogenesis, the study focused also on genes whose expression invariantly accompanies the t(1;19) translocation, and their transcripts were detected by SYBR Green PCR. The expression profiles were obtained through PCR arrays, considering eighty-four genes representative of different biological pathways. *Results and Conclusions.* The downregulation induced by anti-E2A-PBX1 siRNA in the fusion gene expressing cells reduced the specific transcript expression by 85-90% (ABL-normalized levels were measured 24 hours after transfection). In particular, the fusion gene depletion downregulated other two genes: EB-1, which encodes for a protein that could contribute to the transformed phenotype of pre-B ALL, and Wnt16b (not the Wnt16a isoform of the Wnt16 gene); their aberrant expression may therefore be a key-step in leukemogenesis in t(1;19)-positive pre-B leukemia. The roles of E2A-PBX1 target genes was characterized through differential gene expression PCR arrays, investigating genes involved in tumorigenesis, transformation, growth regulation, proliferation, and allowed to focus on the most significant pathways and on the interactions of E2A-PBX1 with specific signal trasduction molecules, transcription factors and target genes.

TOLERANCE TO METHOTREXATE THERAPY IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA: IMPORTANCE OF GENETIC POLYMORPHISMS IN FOLATE METABOLIC PATHWAY

E. Oliveira,[1] S. Quental,[2] F. Ferreira,[3] S. Alves,[4] V. Gomes,[1] A. Amorim,[2] M.J Prata[2]

[1]IPATIMUP, PORTO, Portugal; [2]IPATIMUP/FCUP, PORTO, Portugal; [3]Hospital S. João, Hematologia Clinica, PORTO, Portugal; [4]Instituto de Genética Médica, PORTO, Portugal

Background. Present days, approximately 80% of children diagnosed with acute lymphoblastic leukemia (ALL) are cured. Almost all therapeutic protocols use methotrexate (MTX) as antifolate agent and this drug is administred in high doses (5 g/m^2) during interval therapy. It has been observed that only some patients experience therapy-related toxicity, developing intolerance to MTX such as hepatic toxicity and/or mucositis. MTX targets several critical aspects of folate metabolism inhibiting enzymes in the folate cycle and leading to the decrease of folate pool. The folate metabolic pathway is crucial in purine and pyrimidine synthesis, as well as in the provision of methyl groups for DNA, RNA and protein methylation. SNPs in genes encoding enzymes involved in methotrexate metabolism have been implicated in relapse or toxicity in ALL patients. *Aims.* We hypothesized that toxicity to MTX could be influenced by genetic polymorphisms in the folate-metabolizing pathway because MTX induces a low folate state. In this work we investigated how seven genetic polymorphisms in five genes encoding enzymes involved in folate metabolism (Methylenetetrahydrofolate Reductase - MTHFR, Thymidylate Synthase - TYMS, Methionine Synthase - MS, Methionine Synthase Reductase - MTRR and Serine Hydroxymethyltransferase - SHMT), influence the response to MTX in childhood ALL therapy. *Methods.* Using PCR/RFLP and direct sequencing based methods, we characterized DNA sample from 34 children diagnosed with ALL, and retrospectively analyzed their clinical histories. All children were following the same protocol for ALL therapy. Intolerance to MTX was defined as the occurrence of hepato-toxicity (increase in liver transaminases - TGO/TGP) and mucositis. *Results.* The MTRR C524T variant was found to be significantly associated with a decrease of mucositis during MTX administration and an over-representation of the MTHFR C677T allele in the group of patients who developed mucositis was also observed although not reaching statistical significance. *Conclusions.* While these results seem to indicate that pretherapeutic testing of MTRR and MTHFR may predict toxicity reactions to MTX treatment in children undergoing ALL therapy, enlargement of sample sizes (which is currently ongoing) is needed to validate these preliminary observations.

DASATINIB INDUCES RAPID AND DURABLE RESPONSES IN PATIENTS WITH PH+ ALL RESISTANT OR INTOLERANT TO IMATINIB: UPDATED RESULTS FROM CA180015 (START-L) TRIAL

O. Ottmann,[1] A. Hochhaus,[2] G. Saglio,[3] R. Paquette,[4] B. Simonsson,[5] K. Porkka,[6] J.M.A. Van Tornout,[7] A.M. Apanovitch,[7] P. Rousselot[8]

[1]Johann Wolfgang Goethe Universitaet, FRANKFURT MAIN, Germany; [2]University Heidelberg, MANNHEIM, Germany; [3]Universita di Torino, ORBASSANO-TORINO, Italy; [4]Universite de Montreal, MONTREAL, Canada; [5]Uppsala University Hospital, UPPSALA, Sweden; [6]University of Helsinki, HELSINKI, Finland; [7]Bristol-Myers Squibb Co., WALLINGFORD, USA; [8]Hôpital Saint-Louis, PARIS, France

Background. Relapsing patients with Ph$^+$ ALL who have previously received treatment with imatinib and/or chemotherapy have a particularly poor prognosis. Dasatinib is a novel multi-targeted kinase inhibitor of BCR-ABL and SRC family kinases, with *in vitro* potency some 325-fold greater than imatinib against BCR-ABL and proven efficacy in this patient population. *Aims.* This study was designed to assess the efficacy and safety of dasatinib. *Methods.* Phase-II, open-label, international, multicenter study where patients with Ph$^+$ ALL with resistance or intolerance to imatinib were treated with dasatinib 70 mg BID, administered orally. Dose escalation to 100 mg BID was allowed for inadequate response, and dose reduction to 50 mg or 40 mg BID for adverse events. All patients provided written informed consent. *Results.* From January through July 2005, 46 patients (median age 48 years; 59% male) enrolled and received treatment, 96% of whom were imatinib-resistant; 46% had received doses of >600 mg/d per day, and 52% had received imatinib therapy for ≥12 months. Median time from initial diagnosis of Ph$^+$ ALL was 18 months and 37% of patients had undergone prior stem-cell

transplantation (SCT). BCR-ABL mutations were present at baseline in 78% of patients. With follow-up extending to 18.5 months, the overall major hematologic response rate was 41%. Major cytogenetic response (MCyR) was achieved for 57% of patients; this was complete in all but one of these patients (54%). Response rates were consistent irrespective of pre-existing BCR-ABL mutations. Responses were durable with a positive impact on survival; median overall survival (OS) was 8.0 months and 22% of patients remained alive and progression-free after 1 year of treatment. Outcome was favorable for patients with prior SCT: median OS of 9.0 months (5.8 months for patients without prior SCT). Grade 3-4 thrombocytopenia and grade 3-4 neutropenia both occurred in 78% of patients. Most frequent non-hematologic side-effects included diarrhea in 33% of patients (grade 3-4, 9%), pleural effusion in 24% (grade 3-4, 7%), nausea in 22% (no grade 3-4), and pyrexia in 22% (grade 3-4, 2%). The dasatinib dose was reduced in 30% of patients and interrupted in 43%, primarily due to non-hematologic toxicities. The average median daily dose was 143 mg. *Summary and conclusions.* Dasatinib continues to show impressive efficacy in this difficult-to-treat population post-imatinib failure.

0027

OUTCOME OF ADULT PATIENTS WITH RELAPSED ACUTE T-LYMPHOBLASTIC LEUKEMIA (T-ALL) CAN BE IMPROVED WITH SEQUENTIAL SALVAGE THERAPIES AND SCT IN SECOND CR

N. Goekbuget,[1] R. Arnold,[2] A. Böhme,[1] R. Fietkau,[3] M. Freund,[3] A. Ganser,[3] M. Kneba, T. Lipp,[4] W.-D. Ludwig,[3] G. Maschmeyer,[5] D. Messerer,[6] H. Rieder,[3] E. Thiel,[2] D. Hoelzer[1]

[1]J.W.Goethe University, FRANKFURT AM MAIN, Germany; [2]University Hospital Charité, BERLIN, Germany; [3]University Hospital, ROSTOCK, Germany; [4]Krankenhaus Schwabing, MÜNCHEN, Germany; [5]Klinikum Ernst von Bergmann, POTSDAM, Germany; [6]IBE, University, MUNICH, Germany

Outcome of newly diagnosed T-ALL which was formerly an unfavourable subgroup has improved considerably. With current regimens CR rates >80% and an overall survival (OS) >50% can be achieved in adults by chemotherapy and risk adapted stem cell transplantation (SCT). However few data on outcome of relapsed T-ALL are published and prognostic factors at relapse are unknown. This is a retrospective analysis of 155 pts with 1st relapse of T-ALL. All pts had been treated at first diagnosis in the German Multicenter Study Group (GMALL) studies 05/93 (N=88) and 06/99-07/03 (N=67). At relapse treatment decision was at the discretion of the physician and generally consisted of intensive salvage regimens e.g. modified induction, HDMTX or HDAC combinations. Since treatment approaches are different for CNS and BM relapse the outcome analysis will focus on BM relapse (N=117). Patient characteristics did not differ significantly (sign.) between both studies (Table 1).

Table 1. Paient Characteristics and outcome of relapsed T-ALL.

		Study 05/93	Studies 06/99-07/03
N		88	67
Age	Median (Range)	28 (15-63) yrs	31 (17-62) yrs
Subtype	Early	22%	12%
	Mature	34%	15%
	Thymic	44%	70%
Time to relapse	Median (Range)	12 (1-47) mo	11 (1-35) mo
	Early (< 18 mo)	70%	73%
Localisation	BM ± Other (no CNS)	76%	75%
	CNS ± Other	19%	13%
	Other only	5%	12%
CR rate		39%	30%
Survival		6%	24%

The CR rate with 1st approach was 35% (33% in early and 39% in late relapse). OS was 12% and significantly higher in study 06 (24%) compared to 05 (6%) (p=0.0001). Overall 56% of the patients were referred to SCT, more in study 06-07 (72%) versus 05 (43%). Survival after any SCT vs no SCT was 9% vs 4% in study 05 and 30% vs 0% in study 06-07 (p<0.0001). Results were sign. better for SCT performed in 2nd CR compared to SCT in relapse. In study 06-07 more pts were treated with several subsequent approaches incl. experimental drugs. Thus a CR-rate of 41% was achieved with Nelarabine in 94 pts with refractory relapse of T-ALL. 1 of 5 patients achieved a CR with MabCampath monotherapy. The most sign. prognostic factor for OS ' also confirmed in multivariate analysis - was achievement of CR with first attempt (23% vs 6%; p=0.0001) and realisation of SCT (19% vs 3%; p=0.0001). Immunophenotype was a prognostic factor for CR-rate and survival, with better results for thymic compared to early/mature T-ALL (24% vs 0%; p=0.04). Duration of first remission and relapse localisaton had no sign. impact on survival. In this large cohort of pts with relapsed T-ALL with first intensive therapy approach the CR rate was 35% and the OS 12%. Achievement of 2nd CR, realisation of SCT and subtype were sign. prognostic factors. Survival improved in the recent study 06-07 which may be partly attributed to more intensive attempts to achieve CR even with experimental approaches, higher SCT rates and improved outcome after SCT. Since pts with relapsed T-ALL are generally young several subsequent attempts to achieve CR and perform SCT in CR are reasonable. The GMALL has activated sequential studies with T-cell specific drugs including Nelarabine, MabCampath and Forodesine. If proven successful the next step is integration of these drugs in front-line therapy.

0028

L-ASPARAGINASE HYPERSENSITIVITY IN CHILDHOOD ALL - ISRAEL EXPERIENCE

A. Moser, S. Santo-Zohar, J. Kapelushnik

Soroka Medical Center, BEER SHEVA, Israel

Asparaginase (ASP) is an effective antileukemic agent. However, hypersensitivity and allergic reactions are reported in 2.5-45% of recipients and are a major limitation in its clinical use. The risk of developing sensitivity to ASP increases with higher doses, *E. coli* preparation, IV (vs. IM), continuous and repeated treatment after a prolonged abstinence. We surveyed the rate of hypersensitivity in pediatric ALL in Israel, while trying to identify factors of significance. *Methods.* Data gathered from medical records of 245 children diagnosed with ALL during the years 2000-2005 from 4 Pediatric Hematology-Oncology wards comprising 70% of all children treated. Drugs were uniformly administered in all children on the Israel National leukemia Study, modified from BFM protocols *E. coli* L-ASP was to be substituted with PEG or Erwinase in case of allergy or hypersensitivity. The definition and severity of allergy was defined by the professional opinion of the treating medical team. *Results.* Forty-eight (19.6%) of patients developed an allergic reaction. A wide range was noticed between the treating centers (6.4%-29.4%). A significantly higher number of patients with allergic reactions were treated on the high-risk arm (39.1% vs. 14.6% in the overall group), including 10 with severe reactions. A higher incidence was noticed at the start of the second cycle, occurring after 8 initial doses and a 4 month break in ASP treatment with 15 (31.2%) of the allergic patients developed the reaction to ASP on the second cycle's first dose, and 8 (16.6%) on the second dose, 3 days later. PEG ASP had significantly more allergic reactions vs. E. coli L-ASP treatments (8/145; 5.5% vs. 37/2610; 1.4%). PEG was also associated with allergies of higher severity, (8/9; 88.9% vs. 43.6%). Ewrina product was discontinued during the study period. A careful analysis revealed no differences between the allergenic and non-allergenic groups in relation to sex, age, mortality and/or chromosomal abnormality. *Conclusions.* The overall allergy rate (with noticed wide variations) and the high incidence at the beginning of the second cycle are within the described literature. The findings regarding the PEG were unexpected. We report here a relationship between the higher risk group and the development of the allergy and the severity of the allergy. We believe that the differences observed between treating wards are due to unclear definitions of reaction or severity .We have noticed a wide variability in executing the supporting treatment. We recommend that the ASP treatment should be preceded with a period of steroids at the beginning of all treatment cycles.

0029

OUTCOME OF THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA USING A PEDRIATRIC PROTOCOL

S. Haiat, A. Vekhoff, C. Marzac, O.A. Calendini, S. Lapusan, Z. Marjanovic, B. Rio, J.P. Marie, O. Legrand

Hopital Hotel Dieu, PARIS CEDEX 04, France

Background. Adult acute lymphoblastic leukemia (ALL) still have poor outcome compared with childhood ALL, with an expected long time survival of less than 40%. Adolescents aged from 15 to 20 years have improved complete remission (CR) and event free survival (EFS) rates when treated with pediatric protocol instead of adult one. *Aims.* In a pilot study, we have tested the feasibility and the efficiency of the French pediatric protocol FRALLE 2000 to treat adult ALL aged up to 55 years. *Methods.* 20 consecutive adults Philadelphia negative ALL aged from 15 to 55 years received treatment courses according to the French pediatric protocol FRALLE 2000 from 2001 to 2006. After a prednisone prephase and a four-drugs induction (prednisone, daunorubicin, vincristine and 9 infusions of L-asparaginase), patients in CR received a consolidation course, two delayed intensifications with L-asparaginase separed by an interphase, a CNS irradiation and a maintenance chemotherapy during two years. Results were compared with the outcome from 20 consecutive patients treated in our institution with the historic EORTC ALL-4 adults protocol from 1998 to 2001. Median age, WHO performans status, white blood count at diagnosis, phenotype and cytotogenetics risk groups were statistically similar in both groups. *Results.* Cortico-sensitivity and chemo-sensitivity was assessed for 15 and 17 patients respectively and CR rate was 85% after FRALLE induction, and 100% after a salvage therapy with high doses cytarabine. All patients who achieved cortico and chemo-sensitivity were in persistant CR with a median follow-up of 26 months. Minimal residual disease (MRD) study was available for 12 patients, using IgH/TCR rearrangement or E2A/PBX1 transcript. Among the 10 patients with an indetectable MRD at D90, no one experienced relapse. Overall, with a median follow-up of alive patients of 26 months, the 4-years EFS and overall survival are 80±10% vs 47±12%, (p=0.04) and 87±9% vs 35±16%, (p=0.03) respectively. This better outcome is not explained by significant differences in patients characteristics nor by a better CR rate but rather by a lower relapse rate in the pediatric treatment group (more than two-fold lower). This indicates a major role of the drugs indication and the dose intensity, especially in L-asparaginase administration. No treatment related mortality and no severe side effect were observed during treatment with supportive cares including parenteral nutrition, granular growth factor, infectious prophylaxis, and antithrombine III infusions. *Summary and conclusions.* This pilot study shows that adults up to 55 years with Ph negative-ALL have a dramatically better outcome when there are treated with childhood ALL protocol without any major side effect. This therapeutic strategy has to be confirmed by the current prospective study performed by the EORTC group.

Acute myeloid leukemia - Biology I

0030

EXPRESSION OF ANGIOPOIETINS AND VASCULAR ENDOTHELIAL GROWTH FACTORS AND ITS CLINICAL SIGNIFICANCE IN ACUTE MYELOID LEUKEMIA: ANG-2 EXPRESSION IS AN INDEPENDENT PROGNOSTIC FACTOR FOR OVERALL SURVIVAL

H.-A. Hou, W.-C. Chou, L.-I. Lin, J.-L. Tang, M.-H. Tseng, C.-F. Huang, M. Yao, C.-L. Chen, S.-Y. Huang, C.-Y. Chen, B.-S. Ko, W. Tsay, Y.-C. Chen, H.-F. Tien

National Taiwan University Hospital, TAIPEI, Taiwan

Background and Aims. Concerted expression of angiopoietins, their receptor Tie2 and vascular endothelial growth factor (VEGF) family, most specific inducers of angiogenesis secreted by leukemia blasts, are known to play an essential role in normal and pathologic angiogenesis. We therefore evaluate the clinical implication of angiogenic factors in patients with acute myeloid leukemia (AML). *Methods and Patients.* We investigated the RNA expression of genes encoding angiopoietin-1 (Ang-1), angiopoietin-2 (Ang-2), the receptor Tie2, VEGF-A and VEGF-C by real-time quantitative polymerase chain reaction (RQ-PCR) in a cohort of 126 patients with newly diagnosed de novo AML at National Taiwan University from June 1995 to Feb 2006. The results were correlated with clinical features and outcome of the patients. *Results.* Expression of Ang-1, Ang-2 and VEGF-A was significantly higher and that of VEGF-C was lower in AML patients than in normal controls. RNA expression level correlated well with the results of immunocytochemical staining in the selected patients studied. Patients with high Ang-1, Ang-2, or Tie2 expression had significantly shorter relapse-free survival than those with low expression (8 months versus 14 months, p=0.029; 9 months versus 14 months, p=0.01; 8.5 months versus 14 months, p=0.01, respectively) by univariate analysis, but the significance disappeared by multivariate analysis. On the other hand, high expression of Ang-2 and Tie2, but not other angiogenic factors, was correlated with a shorter overall survival (15.7 months versus 38 months, p=0.005; 14 months versus 26 months, p=0.043, respectively). In multivariate analysis, only karyotype and Ang-2 expression were independent prognostic factors, with a hazard ratio of 2.19 (95%CI, 1.27-3.77, p=0.005) and 2.05 (95%CI, 1.20-3.52, p=0.009), respectively. Furthermore, the prognostic relevance of Ang-2 expression became even more pronounced in the patients with intermediate-risk karyotype (p=0.004). Subgroup analysis showed that the prognostic impact of Ang-2 expression was only evident in the patients with low Ang-1 or low Tie2 levels, but not those with high levels, and in the patients high VEGF-A or high VEGF-C levels, but not those with low levels. *Conclusions.* These results provide evidence that high pre-treated levels of Ang-2 in the bone marrow indicate an unfavorable prognosis in AML. Further research into interaction of concerted angiogenic factors in AML is warranted.

0031

MUTATED NUCLEOPHOSMIN (NPM1) IS ASSOCIATED WITH INCREASED SPONTANEOUS APOPTOSIS AND FAVORABLE PROGNOSIS IN FLT3-ITD NEGATIVE ACUTE MYELOID LEUKEMIA (AML)

G. Del Poeta, E. Ammatuna, S. Zaza, F. Buccisano, T. Ottone, M.I. Del Principe, S. Lavorgna, G. Catalano, F. Luciano, L. Maurillo, L. Ottaviani, A. Bruno, A. Venditti, P. De Fabritiis, S. Amadori, F. Lo-Coco

University Tor Vergata, ROME, Italy

Nucleophosmin (NPM1) is a multifunctional protein that interacts with p53 and its regulatory molecules (ARF, Hdm2/Mdm2), thus controlling cell proliferation and apoptosis (Falini et al, 2007). Mutations in NPM1 occur in up to 50% to 60% of normal karyotype acute myeloid leukemia (AML) patients and are associated with more favorable response to therapy. Moreover, genes and proteins involved in apoptosis have been shown to be relevant in response to treatment and prognosis in AML (Del Poeta *et al.,* 2003). We analysed NPM1 mutational status and the expression of apoptosis proteins (bcl-2 and bax) in 188 pts affected by de novo non-M3 AML. Median age was 61 yrs (range 21-82) and patients received treatment according to the GIMEMA-EORTC cooperative groups protocols. The aims of our study were: 1) to correlate the NPM1 status with bax/bcl-2 ratio levels, as a measure of spontaneous apoptosis, and 2) to assess the prognostic significance of NPM1 and FLT3 status in relation to the bax/bcl-2 ratio. Bcl-2 and bax proteins were determined by multicolor flow cytometry and bax/bcl-2 ratio was obtained by dividing mean fluorescence intensity (MFI) of bax/MFI bcl-2. The threshold of positivity was set at the median value >0.3. NPM1

mutations and FLT3-ITD were detected by multiplex PCR and capillary gel electrophoresis. One hundred-one/188 (54%) pts were bax/bcl-2 ratio positive. NPM1 and FLT3 mutations were detected in 21.3% and in 20.9% of cases, respectively. There was a significant correlation between higher WBC counts (>100×10^9/L) and NPM1 mutations (p=0.001). A normal karyotype was found in 25/32 (78%) NPM1 mutated pts (p=0.003) and 35/40 NPM1 mutated cases were CD34 negative (p<0.0001). A positive bax/bcl-2 ratio was significantly associated with NPM1 mutations (28/40; p=0.02) and 15 of 21 (78%) NPM1+FLT3-ITD negative cases showed higher bax/bcl-2 ratio. As concerns clinical outcome, significantly lower complete remission (CR) and overall survival (OS) rates were found in NPM1+FLT3-ITD+ vs NPM1+FLT3-ITD negative pts (27% vs 63%; p=0.04 and 0% vs 36% at 9 months; p=0.006, respectively). Bax/bcl-2 ratio and NPM1 showed additive prognostic impact, since higher bax/bcl-2 ratio plus mutated NPM1 in absence of FLT3-ITD identified AML pts at better prognosis with regard to disease free survival ([DFS] 76% vs 0% at 4 months; p=0.015). Of note, within the poor prognostic subgroup NPM1+FLT3-ITD+, higher bax/bcl-2 ratio was able to distinguish pts at better prognosis with regard to CR (60% vs 0%; p=0.04) and OS (50% vs 0% at 3 months; P=0.017). There were no significant differences between NPM1+ and NPM1 negative pts with regard to CR, OS and DFS. In multivariate analysis, only bax/bcl-2 ratio and WBC counts resulted to be independent prognostic factors with regard to OS (p=0.0001 and p=0.03, respectively) and DFS (p=0.009 and p=0.001, respectively). Therefore, we confirm that NPM1 mutations in the absence of FLT3-ITD identifies a subgroup of pts with favorable prognosis and in pts with both mutations FLT3-ITD dominates the leukemic phenotype conferring a poor outcome. We demonstrate that NPM1-mutated/FLT3-ITD negative pts exhibit high levels of spontaneous apoptosis, thus explaining their more favorable response to therapy.

0032

ACUTE MYELOID LEUKEMIA IS PROPAGATED BY A LEUKEMIC STEM CELL WITH LYMPHOID CHARACTERISTICS IN A MOUSE MODEL OF CALM/AF10 POSITIVE LEUKEMIA

A. Deshpande,[1] M. Cusan,[2] V.P.S. Rawat,[2] H. Reuter,[3] A. Krause,[2] C. Pott,[4] L. Quintanilla-Martinez,[5] P. Kakadia,[2] F. Kuchenbauer,[2] F. Ahmed,[2] E. Delabesse,[6] M. Hahn,[3] P. Lichter,[3] M. Kneba,[4] W. Hiddemann,[2] E. MacIntyre,[6] C. Mecucci,[7] W.D. Ludwig,[8] R.K. Humphries,[9] S.K. Bohlander,[2] M. Feuring-Buske,[2] C. Buske[2]

[1]GSF, MUNICH, Germany; [2]GSF Hematology and Klinikum Grosshadern, MUNICH, Germany, [3]German Cancer Research Center, HEIDELBERG, Germany; [4]University Hospital Schleswig-Holstein, KIEL, Germany; [5]Institute of Pathology, GSF, NEUHERBERG, Germany; [6]Laboratoire d'Hématologie, Tour Pasteur, PARIS, France; [7]University of Perugia, PERUGIA, Italy, [8]Robert-Rossle-Klinik, BERLIN, Germany; [9]The Terry Fox Laboratory, VANCOUVER, Canada

Background. The demonstration that most, if not all cancers are sustained by a small population of malignant clones within the tumor with stem cell properties has rendered the identification of cancer stem cells in leukemia critical to the understanding of the pathogenesis of this disease. *Aim.* The aim of this study was to identify the leukemic stem cells (LSCs) in acute myeloid leukemia (AML) associated with the CALM/AF10 (C/A) fusion gene. *Methods.* Mice (n=13) were transplanted with BM cells retrovirally engineered to express the C/A fusion gene. For human C/A$^+$ patient samples, IGH DJ analysis, immunostaining, FISH and CFC assays were performed. *Results.* We demonstrate that AML can be propagated by LSCs with lymphoid characteristics (Deshpande et al. Cancer Cell, Nov 2006). All mice injected with C/A$^+$ cells succumbed to AML showing IGH DJ rearrangements. In the leukemic mice only a minor fraction, (avg. 6.7%) cells in the BM displayed the B220 lymphoid antigen and lacked myeloid markers (avg. 9.4%). The majority of cells expressed myeloid markers (avg. 82.9% Mac1+ cells). Additionally, an average of 26.0% of these cells co-expressed B220 and Mac1, compared to 2.1%, in controls. Surprisingly, when injected into secondary mice, the B220+/Mac1' cells showed the highest frequency of leukemia propagation (>1 in 36 cells) as compared to the Mac1$^+$/B220$^-$ bulk population population (1 in 19717) and the B220$^+$/Mac$^+$ cells (1 in 437). Moreover, at a single cell level, the leukemic IGH DJ rearranged B220$^+$/Mac1$^-$ cells could give rise to the B220$^+$/Mac1$^+$ as well as the Mac1$^+$/ B220$^-$ populations with clonal DJ rearrangements, and induce identical leukemias demonstrating its capacity to give rise to the myeloid leukemic bulk at the single cell level. Depletion of the B220$^+$ cells from the leukemia before secondary transplantation effectively prevented leukemia development in mice. This murine model closely recapitulated C/A$^+$ human AML; BM cells of a majority of patients (7 of 9) displayed clonal IGH DJ rearrangements and in 3 of 3 patients tested, a significant proportion of C/A$^+$ IGH rearranged CD45RA$^+$ (B220) cells could be detected. *Conclusions.* These results indicate that LSCs can have surface markers different from both normal stem cells and the tumor bulk, which might be useful for specific targeting of such LSCs while sparing the normal stem cell pool.

0033

IDENTIFICATION OF HEME OXYGENASE 1 (HO-1=HSP32) AS A CRITICAL SURVIVAL FACTOR AND NEW THERAPEUTIC TARGET IN AML

M. Kneidinger,[1] K. V. Gleixner,[1] R. Kondo,[1] P. Samorapoompichit,[1] A. Vales,[1] M.-T. Krauth,[1] M. Mayerhofer,[1] A. Gruze,[1] W. F. Pickl,[1] K. Greish,[2] A. Böhm,[1] W. R. Sperr,[1] H. Maeda,[2] P. Valent[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]Graduate School of Medical Sciences, KUMAMOTO, Japan

Background. Heat Shock Protein 32 (Hsp32), also known as Heme Oxygenase 1 (HO-1), has recently been identified as a stress-related survival molecule that acts anti-apoptotic and cytoprotective in inflammatory reactions. Recent data suggest that Hsp32 is also expressed in neoplastic cells in various malignancies. Methods and *Results.* In the present study, we provide evidence that Hsp32 is constitutively expressed in primary leukemic cells in patients with acute myeloid leukemia (AML, n=17) and in various AML cell lines such as HL60, KG1, KG1a, and U937. Expression of Hsp32 mRNA was demonstrable by RT-PCR, and the Hsp32 protein by immunocytochemistry and Western blotting. In addition, we were able to demonstrate expression of Hsp32 mRNA and of Hsp32 protein in the CD34$^+$/CD38$^-$ progenitor/stem cell fraction in the leukemic clone in patients with AML. The Hsp32-inducing compound hemin (10 μM) was found to promote expression of Hsp32 in AML cells. Incubation with the Hsp32-targeting drugs pegylated zink protoporphyrin (PEG-ZnPP) or styrene maleic acid-conjugated ZnPP (SMA-ZnPP), resulted in a dose-dependent inhibition of growth of leukemic cells at pharmacologic concentrations (IC50: 5-30 μM for cell lines and primary AML cells). The SMA-ZnPP-induced growth-inhibition of AML cells were found to be associated with induction of apoptosis as evidenced by light microscopy, electron microscopy, and by a Tunel assay. In consecutive experiments, combination experiments were performed using SMA-ZnPP and AML cell lines. In these experiments, SMA-ZnPP was found to synergize with cytarabine in producing growth inhibition in all AML cell lines tested. *Conclusions.* Hsp32 is a novel survival factor and interesting target in AML. The clinical significance of this observation remains to be determined in forthcoming trials.

0034

ABSENCE OF JNK ACTIVATION IS A PREDICTOR OF ANTHRACYCLINE RESISTANCE IN AML

E.D. Lagadinou,[1] P. Ziros,[1] O. Tsopra,[1] K.S. Dimas,[2] E. Thanopoulou,[1] A. Kouraklis-Symeonidis,[1] M. Karakantza,[1] P. Pantazis,[3] N.C. Zoumbos[1]

[1]University Hospital of Patras, PATRAS, Greece; [2]Foundation for Biomedical Research, ACADEMY OF ATHENS, ATHENS, Greece; [3]University of Miami, MIAMI, CORAL GABLES,FL, USA

Standard chemotherapy is often unsuccessful in AML. Besides other extensively studied causes of treatment failure, as MDR, defective apoptosis emerges as an important mechanism of drug resistance. Anthracyclins are reported to activate the JNK signaling pathway in drug-sensitive AML cell lines, including U937 cells. In U937 derivative drug-resistant cells (URD) we have shown absence of basal and anthracycline-induced activation of JNK. As we have observed that URD cells are remarkably less susceptible to anthracycline-induced apoptosis compared to parental U937 cells, the different pattern of JNK response may account for their resistant phenotype. *Aims.* To investigate the impact of JNK on the apoptosis induction and the resistance to standard chemotherapy in AML cell lines and in primary AML blasts. *Methods.* We performed siRNA inhibition of JNK in U937 cells and we evaluated apoptosis susceptibility after treatment with the anthracycline Daunorubicin(DNR), (1 μM). DNR-induced apoptosis was also examined in URD cells transfected with a constitutively active form of SEK1 (SEK-ED), an upstream activator of JNK (URD/SEKED cells). Bone marrow blasts from 30 AML patients at diagnosis and without any previous therapy were exposed *in vitro* to anthracycline treatment (1 μ DNR, 16hr) and the basal levels as well as the inducibility of JNK activity were correlated with the

drug-induced apoptotic response of blast cells. Experimental results were also associated with patient clinical data. *Results.* RNA silencing of JNK in U937 cells resulted in a 57,4% decrease in DNR-induced apoptosis compared with wild type and cells transfected with empty vector (annexin V+ve cells=26.46±2.02% vs 62.12±0.28%). Additionally, URD/SEKED cells, characterized by active JNK, became more susceptible to DNR and underwent drug-induced apoptosis (annexin V+ve cells=21.6±1.7% vs 6.42±2% in control cells). 44.2% of primary AML samples exhibited increased basal JNK activity levels, but they were not correlated with sensitivity to DNR. In 46% of AML samples a drug-induced upregulation of basal JNK activity preceded the induction of significant apoptosis, in relation to untreated controls. (p=0,00048<0,05). The pattern of JNK activation in these patients was similar to that detected in U937 drug-sensitive cells. On the contrary, in the remaining 54% of AML samples basal JNK activity remained immutable in response to drug treatment, and this was accompanied by a failure of DNR to induce significant apoptosis (p=0,4697>0,05). Moreover, the latter cohort of patients shared clinical features indicative of a poor response to treatment, such as older age (mean=78,6 years vs 57,16 years in the JNK activation group, p=0,0036<0.05) and antecedent hematological disorders, mainly myelodysplasia (61,53% vs 16,6% in the JNK-activation group). CR1 rates were significantly lower in these patients (28,57% vs 77,7% in the JNK-activation group). *Conclusions.* Our findings suggest that JNK is a critical proapoptotic mediator of Daunorubicin and impaired activation of JNK is associated with a failure of DNR to induce apoptosis in AML. In accordance with that point of view, restoration of JNK activity may increase chemotherapy effectiveness in AML. Moreover, the activation levels of JNK may serve as a marker reflecting differences in disease biology which affect treatment outcome in AML.

0035

DEFINED NICHE CONDITIONS AND A STEM CELL PHENOTYPE BOTH CONTRIBUTE TO THE *IN VITRO* RESISTANCE OF PRIMARY AML CELLS TO A FLT3 TYROSINE KINASE INHIBITOR

M. Pallis,[1] C.H. Seedhouse,[2] N.H. Russell,[2] U. Mony,[2] M. Jawad[2]

[1]Nottingham University Hospitals, NOTTINGHAM, United Kingdom, [2]University of Nottingham, NOTTINGHAM, United Kingdom

Background. Relapse in acute myeloid leukaemia is considered to be mediated by the survival of leukaemic stem cells and by protection of blasts in the bone marrow niche following remission induction chemotherapy. *Aims.* The aim of this study was to study the differential response of both bulk cells and CD34+CD38-CD123+ leukaemic stem and progenitor cells (LSPC) to *in vitro* FLT3 inhibition under different culture conditions. *Methods*. We devised a flow cytometric chemosensitivity assay to allow 48 hour culture of leukaemic blasts with and without defined niche conditions (fibronectin, IL-3, SCF, IL-6, Ang-1) followed by enumeration of the viable (7-amino-actinomycin D negative, forward scatter high) LSPC. The FLT3 inhibitor AG1296 was applied to 11 AML samples, of which 9 had internal tandem duplications of the FLT3 gene (FLT3 ITDs). *Results.* 3/11 samples were very sensitive (>50% kill) and 5 were quite sensitive (10-50% kill) to AG1296 in bulk suspension culture without niche support. However when niche conditions were used and the LSPC compartment was analysed, the concentration of LSPC was enhanced rather than inhibited by AG1296 treatment. *Conclusions.* We conclude that LSPC from samples with FLT3 ITDs are resistant to AG1296 under defined niche conditions. Whilst pharmacological FLT3 inhibitors may be more effective than AG1296, we suggest that it would be useful to assay the effects of such agents on LSPC under niche conditions, since the current study does not provide a rationale for the clinical use of single agent FLT3 inhibitors to target residual LSPC post chemotherapy.

0036

ANTITUMOR ACTIVITY OF BORTEZOMIB ALONE AND IN COMBINATION WITH TRAIL IN HUMAN ACUTE MYELOID LEUKEMIA

C.M.S. Conticello,[1] L. Adamo,[1] L. Vicari,[1] R. Giuffrida,[1] G. Iannolo,[1] G. Moschetti,[1] G. Anastasi,[1] G.A. Palumbo,[2] R. De Maria,[1] R. Giustolisi,[2] F. Di Raimondo,[2] M. Gulisano[1]

[1]Istituto oncologico del Mediterraneo, VIAGRANDE, CATANIA; [2]Dipartimento di Scienze Biomediche, Sezi, CATANIA, Italy

Background. acute myeloid leukemia (AML) is a malignant disease characterized by abnormal proliferation of clonal precursor cells. Although different strategies have been performed to obtain complete remission, disease progression actually occurs in about 60-70% of patients. Therefore, new alternative strategies are urgently required. The proteasome inhibitor Bortezomib has a documented antitumor activity in multiple myeloma and other lymphoid malignancies. Tumor Necrosis Factor Related Apoptosis Induced Ligand (TRAIL) is a member of the TNF family that induces apoptosis in tumor cells while sparing normal cells. *Aims.* we examined the sensitivity to Bortezomib alone or in combination with TRAIL of bone marrow cells from newly diagnosed or relapsed/refractory AML patients (34 patients: 25 newly diagnosed, 4 relapsed, 5 refractory patients). *Methods.* cell viability was determined using the CellTiter 96 AQueous One Solution Cell Proliferation Assay. Immunohistochemistry or immunofluorescence were performed using a monoclonal mouse anti-human p65 (Rel A) to evaluate the cellular localization of NF-κB. *Results.* in each sample Bortezomib was able to induce cell death of AML blasts. The cytotoxic effect was dose and time-dependent (concentration of Bortezomib ranging from 0.001 to 10 μM for 24 and 48 hours) and was associated with downregulation of Bcl-xL and Mcl-1, with an upregulation of TRAIL-R1, TRAIL-R2 and p21 and the activation of executioner caspases. NF-κB was in the nucleus of AML blasts and do not translocate after Bortezomib exposure. Moreover, low doses of Bortezomib were able to prime TRAIL-resistant AML cells for enhanced TRAIL-mediated killing. *Conclusions.* the combination of proteasome inhibitors and TRAIL is effective for treatment of AML patients even though refractory to conventional chemotherapy.

Background. Ionizing radiation is established as a cause of leukemia in humans. However, little is known about the molecular mechanisms by which radiation induces the leukemia. *Aims.* The aim of this study was the identification of molecular leukemia markers that are associated with exposure to ionizing radiation. *Methods.* The cohort of patients consisted of 154 unselected adult acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) patients, diagnosed between 1988 and 2006 in Ukraine. Of these patients, 84 had experienced radiation exposure due to the Chernobyl accident (radiation-associated cases), and 70 developed spontaneous AML and served as controls. Fifty-one and 59 AML samples were analyzed for the presence of AML1 and MLL abnormalities respectively using fluorescent in-situ hybridization and/or reverse transcription polymerase chain reaction (PCR). AML1 mutations were screened in 6 radiation-associated cases of MDS or AML following MDS by direct sequencing of genomic DNA. Using Affymetrix high-density single nucleotide polymorphism 10K mapping arrays, we performed a whole-genome loss of heterozygosity (LOH) and DNA copy number changes analysis of 19 radiation-associated AML cases. The conventional comparative genomic hybridization (CGH) was done on 25 radiation-associated and 12 spontaneous AML samples. One hundred and twenty four patients (71 radiation-associated and 53 spontaneous AML cases) were examined for the presence of FLT3 internal tandem duplications (ITD) by genomic PCR. *Results.* Translocations involving AML1 fused to ETO but no other translocation partner was found to be significantly less frequent in radiation-associated AML (1/24) than in spontaneous cases (9/29, p=0.02). No difference in MLL translocations frequency was found between radiation-associated and spontaneous AML cases (0/27 and 1/32 respectively). An AML1 point mutation was detected in 1 out of 6 MDS/AML following MDS patients. The hexanucleotide duplication of CGGCAT in exon 8, inserted after base position 1502 was found in a patient who developed MDS following an acute radiation syndrome. Most significant was a high frequency of LOH at 5q and/or 7p, and 7q detected in 8 cases (42%) of radiation-associated AML and their combination with DNA loss at 5q and/or 7q and 7p (10/26 in radiation-associated vs. 1/12 in spontaneous cases, p=0.06). There was no significant difference in the prevalence of FLT3 ITD between patients with (8/71) and without history of radiation exposure (9/53, p=0.4). Six out of 17 patients with ITD were found to harbor more than one FLT3 mutant alleles. Multiple duplications were found in 5 of the 8 Flt3 mutated radiation-associated AML, but in 1 of the 9 spontaneous cases (p=0.0498). *Conclusions.* Chromosomal translocations of the AML1 and MLL genes are not common among the AML patients exposed to ionizing radiation. Radiation may contribute to the development of leukemia through

AML1 gene point mutation. We hypothesize that LOH/DNA loss at 5q and/or 7 constitutes an important genetic mechanism involved in leukemogenesis following accidental radiation exposure. The higher prevalence of multiple ITD alleles in radiation-associated AML cases with FLT3 mutations may reflect an underlying radiation-induced genetic instability.

INHIBITION OF SDF-1/CXCR4 AXIS AFFECTS SURVIVAL AND DIFFERENTIATION OF HUMAN AML CELLS

S. Tavor,[1] M. Eisenbach,[2] J. Jacob-Hirsch,[3] S. Kay,[2] S. Baron,[2] K. Ben-Zion,[2] N. Amariglio,[3] V. Deutsch,[2] E. Naparstek,[2] G. Rechavi[3]

[1]*Sourasky Medical Center, TEL-AVIV, Israel;* [2]*Department of Hematology and BMT, Tel Av, TEL AVIV, Israel;* [3]*Cancer Research Center, Sheba M.C., Tel-, RAMAT-GAN, Israel*

A number of recent studies showed that the chemokine stromal cell-derived factor-1 (SDF-1) and its receptor CXCR4 participate in the retention of human acute myeloid leukemic (AML) cells within the bone marrow (BM) microenvironment, and their release into the circulation. We have also showed that AML cells constitutively express and secrete SDF-1 dependent cell surface elastase, which regulates their migration and proliferation. To elucidate the molecular events and genes regulated by SDF-1/CXCR4 axis and elastase in AML cells, we examined gene expression of U937 AML cell line treated with neutralizing anti-CXCR4 or elastase inhibitor (EI) compared to untreated cells, using DNA microarray technology. Unsupervised hierarchical clustering analysis showed very similar gene expression profiles of anti CXCR4 mAb and EI treated cells, both differ significantly from the untreated control. 230 of the 8400 genes investigated were repressed, and 164 were induced after culturing AML cells in the presence of anti CXCR4 mAb or EI compared to untreated cells. Inhibition of CXCR4 or elastase was accompanied by down regulation of the transcripts of primary granule proteins. Functional classification of SDF-1/CXCR4 axis or elastase regulated genes revealed down-regulation of HOXA9, HOXA10, ETS2, as well as other transcription factors that are over expressed in AML, and are important for the development of leukemia. In contrast, transcriptional factors and regulators known to be induced during myeloid differentiation like C/EBPα, ID1, RUNX3 and HHEX were up-regulated in the treated cells. In addition, interleukin receptors, growth factors (G-CSFR and GM-CSF), complement component (C1QR1) were up-regulated in the treated cells. These data were confirmed by real time PCR for selected marker genes of myeloid cells differentiation. Interestingly, many of the differentially expressed genes were common to the transcriptional program of normal terminal granulocytic differentiation (Theilgaard- Monch & Borregarrd 2005. Blood 105:1785), suggesting that inhibition of SDF-1/CXCR4 axis may induce myeloid differentiation in AML cells. We further analyzed the effect of CXCR4 pathway inhibition on AML cell differentiation and growth. Treatment of AML cell lines with the SDF-1 antagonist AMD3100 triggered a proliferative arrest and mimicked myeloid differentiation, including morphologic changes and increased expression of myeloid differentiation antigens. In summary, our study showed that inhibition of SDF-1/CXCR4 axis or elastase in AML cells affects similar pathways related to differentiation and malignant transformation, implying a critical role for those molecules in regulating leukemic development. Repression of SDF-1/CXCR4 decreases survival and induces differentiation of AML cells, suggesting a potential new therapeutic approach for AML.

RETROVIRAL INSERTIONAL MUTAGENESIS SCREEN IN A C/EBPALPHA PROLIFERATIVE GENETIC BACKGROUND

M.S. Hasemann,[1] A.B. Sorensen,[2] F.S. Pedersen,[2] C. Nerlov,[3] B.T. Porse[1]

[1]*Copenhagen University Hospital, COPENHAGEN O, Denmark;* [2]*University of Aarhus, AARHUS, Denmark;* [3]*EMBL, MONTEROTONDO, Italy*

The CCAAT enhancer binding protein α (C/EBPα) transcription factor plays a key role in the regulation of growth and differentiation of the granulocytic lineage in the hematopoietic system and CEBPA (encoding C/EBPα) is often mutated or deregulated in AML patients. Consistently, mice lacking C/EBPα have no mature neutrophils and die within a few hours. However, homozygous knockin mice in which wild type Cebpa has been replaced with a mutant allele (BRM2), which abolish the growth-repressing ability of C/EBPα, are viable, but at 8 weeks of age they display myeloid dysplasia with absence of neutrophil granulocytes. Strikingly, in older CebpaBRM2/ BRM2 knockin mice the myeloid dysplastic phenotype progress into other myeloid malignancies such as myeloid proliferative syndrome and acute myeloid leukemia-like malignancy. This strongly suggests that secondary mutations in other loci must occur when developing leukemia in the CebpaBRM2/BRM2. In order to identify genes that cooperate with Cebpa mutations in the development of leukemia in CebpaBRM2/BRM2 mice a so-called retroviral insertion mutagenesis screen was performed. Inbred newborn CebpaBRM2/BRM2 and wildtype mice were injected with SRS19-6 retrovirus, which incorporated into the genome and resulted in activation of oncogenes and leukemic progression. When leukemia was evident the mice were euthanized and analyzed. As expected the CebpaBRM2/BRM2 mice had a shorter latency than wildtype mice (186 vs. 276 days). The mice had enlarged spleen, thymus, and/or lymph nodes and were thoroughly investigated by histology, flow cytometry and southern in order to determine the leukemic phenotypes. Most of the CebpaBRM2/BRM2 mice developed an AML-like phenotype, whereas T cell leukemias were most prominent in wildtype mice, showing that mutating Cebpa specifically directs leukemic progression towards a myeloid direction. Finally, the retroviral insertion loci were identified through a splinkerette-aided PCR strategy. This led to the identification of several novel putative and previously unexplored oncogenes, which might collaborate with mutated Cebpa in the development of AML.

Background. Abnormal activation of kinases may promote leukemogenesis by conferring cell proliferation and survival advantage in acute myeloid leukemia (AML). New targeted therapies are currently developed to disrupt such activation, to improve the long term prognosis of AML patients. However, the prognosis impact of kinase activation on AML patients was only rarely evaluated. The most important studies related to FLT3 activating mutations, which implied an adverse outcome. Recent reports suggest that PI3 kinase (PI3K) activation may confer a poor survival to AML patients. *Methods.* Primary bone marrow blast cell samples from 92 patients registered for the LAM2001 trial of the GOELAMS were analyzed at diagnosis and PI3K constitutive activation was correlated with outcome. As previously reported (V Bardet, Haematologica, 2006, 91, 757-764), PI3K activation was established with the status of AKT phosphorylation on Ser 473, determined using either Western Blot analysis (in samples >90% blasts) or flow cytometry in the CD45Low positive population of blast cells, after 4 hours of cytokine and serum starvation. In such conditions, two groups of patients were defined, one with constitutive activation of PI3K ($PI3K^+$), contrary to the second ($PI3K^-$). *Results.* Median age at diagnosis was 46 (17,3-64,5) years. 42 patients were males and 50 were females. Leukocytosis was 12000/∝L (range 400-251800). Patients were classified in low, standard and high-risk cytogenetic subgroups in 16%, 61% and 23%, respectively. 17/79 (21,5%) had FLT3-ITD mutation, 9/60 (15%) had Ras (N-Ras or K-Ras) mutations and 18/72 (25%) had NPM mutations. 46 of 92 (50%) patients had constitutive PI3K activation ($PI3K^+$ group). In univariate analysis, no difference was observed between the two groups for all previously described parameters, except concerning FLT3 mutational status: 5/40 (12,5%) $PI3K^+$ patients had FLT3-ITD versus 12/39 (30%) in the PI3K- (p=0,048). All patients received one course of induction chemotherapy (3+7 regimen), and 31 (34%) a second induction course at day 15. Complete remission was obtained in 74 patients (80%) with no difference between the two groups (p=0,60). Among responders, 30 (41%) had autologous stem cell transplantation, 24 (32%) had allogenic bone marrow transplantation and 16 (22%) had consolidation chemotherapy. With a median follow-up of 26 months (range 3 days-37 months), 48 patients died. Overall survival was 56% in the $PI3K^+$ group and 33% in the $PI3K^-$ group (p=0.007). Among responders, 30 patients relapsed. Relapse free survival was 72% in the $PI3K^+$ group and

41% in the PI3K- group (p=0.001). In multivariate analysis, the PI3K activation plays a significant prognostic role on overall and relapse free survival, after adjustment for FLT3 status (p<0.01 and p=0.0073 respectively) and cytogenetics (p=0.033 and p=0.0075 respectively). *Conclusions.* Thus constitutive PI3K activity detected in leukemic cells at diagnosis confers a better prognosis in AML. As we observed significantly more relapses in PI3K- patients, we can make the assumption that PI3K activity may confer a particular sensitivity to chemotherapy in AML. Furthermore, targeting PI3K signalling in AML may be harmful and a better understanding of downstream effectors is needed.

LS104, A NOVEL KINASE INHIBITOR, INDUCES APOPTOSIS, SYNERGIZES WITH CYTOSTATIC DRUGS AND IS TARGETING THE RECEPTOR TYROSINE KINASE FLT3

S. Kasper,[1] F. Breitenbuecher,[1] T. Kindler,[2] F. Heidel,[1] D.B. Lipka,[1] J. Elliot,[3] Ch. Huber,[1] T. Fischer[1]

[1]3rd Medical Department, MAINZ, Germany; [2]Howard Hughes Medical Institut, BOSTON, USA; [3]LymphoSign, inc, TORRONTO, Canada

Background. Fms-like tyrosine kinase 3 (FLT3), a member of the class III tyrosine kinase receptor family, is expressed in up to 90% of adult acute myeloid leukemia (AML). Internal tandem duplications (ITD) of the juxtamembrane domain are found in approximately 35% of AML-cases, are associated with poor clinical outcome and are considered to represent an attractive target for molecular therapy. LS104 is a novel small molecule substrate inhibitor. *Aims.* To characterize biologic activity of the novel kinase inhibitor LS104 in FLT3 ITD-positive leukemic cells. *Methods.* As a cellular model to investigate FLT3-ITD specific activity we employed 32D myeloid cells stably transfected with FLT3-ITD or wt-FLT3. In addition, we used the human myeloid-leukemia derived MV4;11 cell line harbouring FLT3-ITD and the human lymphoid-leukemia derived RS4;11 cell line expressing wt-FLT3. *Results.* In MTT assays, pronounced inhibition of cell growth was seen at nanomolar concentration (IC_{50}=50 nM) which could be partially rescued by addition of IL3. LS104 at a concentration ranging from 3-10 µM readily induced apoptosis as evaluated by cell cycle analysis, annexin-V assays and PARP cleavage. Similar results were observed using primary AML-blasts. Throughout the experiments, FLT3-ITD expressing cells showed significantly higher sensitivity towards LS104 than cells expressing wt-FLT3. Interestingly, efficacy of LS104 to induce apoptosis was significantly reduced in 32D cells transfected with a FLT3-ITD isoform (N676K) previously reported to be associated with clinical resistance of FLT3-ITD to the kinase inhibitor PKC-412 (Heidel-F *et al.,* Blood 2006). These results strongly suggest that the mechanism of action of LS104 is inhibition of FLT3 kinase activity rather than inhibition of other kinases targeted by LS104. Immunoblot and phosphoprotein-FACS analysis demonstrated inhibiton of tyrosine phosphorylation of FLT3-ITD and of its downstream target S6 ribosomal protein in transfected 32D cells and primary AML blasts. To estimate non-specific toxicity we tested the effects of LS104 on differentation and proliferation of normal bone marrow cells in colony assays. Upon incubation of up to 10 ∝M LS104, bone marrow mononuclear cells showed normal differentiation to CFU-GMs with only slight reduction in colony numbers. Using the intrinsic fluorescence activity of the novel compound, a rapid and dose dependent cellular uptake lasting up to 24h could be demonstrated by FACS analysis and fluorescence microscopy. Combination of LS104 with the cytostatic drugs cytosine arabinosid (Ara-C) and daunorubicin (DNR) showed synergistic and additive effects in induction of apoptosis in cell-lines and primary AML blasts, respectively. *Conclusions.* Our data show that LS104 inhibits signalling of FLT3-ITD kinase activity and induces apoptosis in cell lines and primary AML blasts harbouring FLT3-ITD. CFU-GM growth of bone marrow mononuclear cells from normal controls was only slightly inhibited. Together, this indicates a therapeutic window which provides a preclinical framework for clinical testing of LS104 in FLT3-ITD-positive AML. A phase I trial for patients with refractory hematologic malignancies is currently in preparation.

0042

CHROMOSOME 21-ENCODED MIR-125B AND ITS ROLE IN THE LEUKEMOGENESIS OF MYELOID LEUKEMIAS IN CHILDREN WITH TRISOMY 21

K. Janikova, J.H. Klusmann, D. Reinhardt

Medical School Hannover, HANNOVER, Germany

Background. Children with Down Syndrome (DS) have a 20 to 40 fold increased risk of developing acute myeloid leukemia (ML-DS), primarily the megakaryoblastic subtype (AMKL). Approximately 10% of newborns with DS show a transient myeloproliferative disorder (TMD) and more than 20% of the neonates with TMD suffer ML-DS within the first years of their life. Recently, acquired mutations of the transcription factor GATA1 have been identified in leukemic blasts from virtually all DS patients with ML or TMD. The factors on chromosome 21 that predispose to TMD or ML-DS are still unknown. So far four miRNAs (miR-99a, miR-125b, miR-155 and let-7c) which are localized on chromosome 21 are known. *Aims.* We hypothesized that there might be a role of miRNAs in the development of TMD and ML-DS. *Patients and Methods.* The expression levels of miRNAs were analyzed in sorted cells from patient samples [ML-DS (n=4), TMD (n=4), AMKL (n=4)], and megakaryocytes from healthy donors (n=3) by qRT-PCR. CMK, a TMD derived cell line, served as standard reference. For normalization, ribosomal 5S was used as housekeeping gene. Myeloid progenitor cells (MPC, CD34pos, CD33pos) were retrovirally transduced with MIGR1 containing miR-99a, miR-125b-2, miR-155 or let-7c, respectively (MPCmiR125b MPCmiR155 MPCmiR99a/let7c / MPCMIGR1). Green fluorescent protein (GFP) gene was used for selection of successfully transduced cells. MegaCult®-C (StemCell Technologies) and CollagenCultTM (Stem Cell Technologies) were used for the evaluation of proliferation and differentiation capacity. A cocktail of cytokines (FLT3 ligand, stem cell factor, thrombopoietin and interleukin 6) was added to stimulate proliferation. Expression of putative target genes of the analyzed miRNAs has been obtained by Gene Set Enrichment Analysis (GSEA) of recently reported gene expression profiles (Bourquin *et al.,* PNAS 2006), using the databases for the prediction of miRNA targets (Targetscan/ Pictar). Specific target genes of miRNA 125b such as CD61, CD34, and NCAM, were quantified by immunophenotyping. *Results.* miR-125b was clearly overexpressed in ML-DS (10.0 fold), TMD (5.6 fold) and AMKL (3.2 fold) compared to normal megakaryocytes (p patients vs. control <0.003). Comparable results were obtained with miR-155 (DS-ML 3.4fold; TMD 2.2fold; AMKL 2.3fold; p patients vs. control <0.02). By contrast, let-7c and miR-99a expressions did not differ from controls. In the colony assays the number of colonies of MPCmiR125b was significantly higher than from MPCMIGR1 (1.8 to 7 fold, χ^2=0.0004). Furthermore, MPCmiR125b were less differentiated than MPCMIGR1, analyzed by morphology (numbers of CFU-GM 0 vs. 9) and immunophenotyping (percentage CD34/CD33 26% vs 9%). GSEA revealed a significant decrease of the expression of miR-125b target genes. By contrast, MPCmir155 and MPCmiR99a/let7c revealed a strong inhibition of proliferation. *Conclusions.* MPC transduced by miR-125b revealed a high proliferation and reduced differentiation, which supports the hypothesis, that at least miR-125b is involved in the leukemogenesis of megakaryoblastic leukemias.

0043

FUNCTION AND CLINICAL APPLICATION OF EMBRYONIC GENE NANOG IN CANCER

T.H. Lipscomb,[1] L. Zhang,[2] M.A. Karajannis,[2] S. Rafii,[2] D.K. Jin[2]

[1]Yorktown High School, YORKTOWN HEIGHTS; [2]Weill Medical College, Cornell University, New York, USA

Background and Aims. Each year about 9,000 people die from acute myeloid leukemia (AML), a form of malignancy affecting the hematopoietic stem cells in the bone marrow. The average age of a patient with AML is 65 years old. Overall, the survival rate in adults under 65 is about 33%, but it is 4% for people over 65. The division of normal cells is a regulated process, but when that regulation breaks down, cells become cancerous and divide out of control. Only a few cancer cells have the ability to replicate indefinitely. They are called cancer stem cells, and they are responsible for cancer's long-term growth and possibly metastasis. The embryonic gene Nanog is responsible for maintaining the embryonic stem cells (ESCs) in an immature state to maintain their self-renewal capability and allow long-term proliferation. Our aim was to determine if decreasing Nanog expression could decrease proliferation in HL60 cancer cells as it does in embryonic stem cells. *Methods and Results.* Polymerase Chain Reaction (PCR) shows that Nanog is expressed in an AML cell line HL60, SA726 AML cells primary human AML cells, and circulating mononuclear cells from a patient diagnosed with glioblastoma, the deadliest and most common type of brain cancer. Nanog expression did not decrease when the SA726 AML cells were subjected to all-trans retinoic acid differentiation factor for a week. Trypan blue staining shows that cell proliferation decreased when HL60 was subjected to 25 micromolars of sodium orthovanadate. Real-time PCR suggests a decrease in Nanog expression after HL60 AML cells were subjected to 25 micromolars of sodium orthovanadate for 72 hours. Nanog and other embryonic genes may be highly specific cancer molecular biomarkers for new diagnosis and therapeutic targets. Possible cancer treatments

in the future may target Nanog and its signaling pathways using small molecule inhibitors or gene-based therapy by delivering shRNAi- or Zinc Finger Nuclease-plasmids to target cancer stem cells. Also, two suspended blastocyst-like clusters (Figure 1) were found on day 7 of SA726 AML cell culture on Mouse Embryonic Fibroblast feeder cells in Minimum Essential Medium 10% Fetal Calf Serum. These are indicative of embryonic behavior of the cancer cells.

Figure 1. Suspended blastocyst-like SA726 AML cell clusters.

Conclusions. These preliminary results suggest that a decrease in the cancer cell population happens concurrently with a decrease in Nanog expression. This may justify a future study to investigate a possible causal relationship.

Suspended blastocyst-like SA726 AML cell clusters

0044

THE CYTOSOLIC SEQUESTRATION OF NF-KB INDUCED BY DELOCALIZED NPM1 MAY REPRESENT ONE OF THE MECHANISM RESPONSIBLE FOR THE BETTER CHEMOSENSITIVITY OBSERVED IN NPM1 MUTATED AML PATIENTS

D. Cilloni, V. Rosso, F. Messa, E. Messa, S. Carturan, I. Defilippi, F. Arruga, R. Catalano, C. Boveri, C. Bittoto, P. Nicoli, E. Bracco, G. Saglio

University of Turin, TURIN, Italy

Background. Mutations in NPM1 exon 12 and the resulting shift of NPM1 into the cytoplasm are the most specific and frequent events in acute myeloid leukaemia patients with normal karyotype. Cytoplasmatic NPM1 is associated with responsiveness to chemotherapy, although its role in predicting outcome remains to be defined. The aim of the study was to identify the molecular mechanism responsible for chemosensitivity in leukemic cells carrying the mutation of NPM1(NPM1M). NF-κB is a transcription factor involved in many intracellular pathways including apoptosis. NF-κB is a heterodimer of p50 and p65 subunits sequestered in the cytoplasm in its inactive form through interaction with inhibitory IKB proteins and activated in the nucleous after degradation of IKB. The activation of NF-κB is responsible for chemoresistance to different drugs including anthracyclines. *Aims.* The aim of the study was to analyze the possible cytoplasmatic interaction between the mutated form of NPM1 and NF-κB. METHODS The NF-κB DNA binding activity was analyzed in 72 BM samples collected from AML patients carrying the NPM1 mutations (n=35) and NPM1 wild type (NPM1WT) (n=37) using EMSA and ELISA methods. Immunofluorescence analysis and Western blot using NPM1 and p65 antibodies were performed to identify the amount and localization of both proteins. Co-immunoprecipitation assay was perform to study the interaction of the two proteins. To study the *in vitro* chemosensitivity, etoposide incubations were performed in both NPM1WT and NPM1M cells and apoptosis was evaluated. Downstream genes transcriptionally activated by NF-κB have been evaluated by RT-PCR and RQ-PCR. *Results.* NPM1M cells were more sensitive *in vitro* to etoposide induced apoptosis as compared to NPM1WT (p=0,004). We found a significant lower DNA binding activity in NPM1M cells when compared to the NPM1WT cells (p=0,001). Immunofluorescence analysis confirmed the cytoplasmatic localization of NPM1M protein and the prevalent nuclear localization of NPM1WT. In addition, immunofluorescence analysis shows different pattern of NF-κB localization in NPM1M cells when compared to NPM1WT cells. In particular, in NPM1M cells NF-κB is mainly localized in the cytoplasm in the inactive form and in NPM1WT cells is mainly nuclear localized. These data were confirmed by Western blot. The cytosolic interaction of NPM1M and NF-κB was demonstrated by co-immunoprecipitation studies. Furthermore, the expression levels of genes activated by NF-κB such as bcl2 were significantly deregulated in NPM1M cells. Finally, TNFα, a potent stimulus for NF-κB activation was unable to activate NF-κB in NPM1M cells. *Conclusions.* We demonstrated that p65 and NPM1 interact with each other within the cytoplasm and this interaction results in the sequestration of NF-κB within the cytoplasm. The cytosolic localization of the inactive form of NF-κB explains the reduced NF-κB DNA binding activity observed in NPM1M patients. These data may provide a possible explanation for the chemosensitivity observed in NPM1M patients. Furthermore, since NF-κB is involved in the transcription of many genes which regulate proliferation and differentiation processes, the disruption of NF-κB function may represent one of the mechanism of leukemogenesis induced by NPM1 mutated proteins.

0045

THE HOMEOBOX A9 GENE (HOXA9) IS REQUIRED FOR SURVIVAL OF HUMAN MLL-REARRANGED ACUTE LEUKEMIAS

J. Faber,[1] A. Krivtsov,[1] M. Stubbs,[1] R. Wright,[2]
M. Van den Heuvel-Eibrink,[3] C. Zwaan,[3] A. Kung,[2] S.A. Armstrong1

[1]Children's Hospital Boston, BOSTON, United States of America; [2]Dana Farber Cancer Institute, BOSTON, United States of America; [3]Sophia Children's Hospital, ROTTERDAM, Netherlands

Background. Leukemias that harbor translocations involving the mixed lineage leukemia gene (MLL) possess unique biological characteristics and often have an unfavorable prognosis. Gene expression analyses demonstrated a unique profile for MLL-rearranged leukemias with consistent high-level expression of select Homeobox (HOX) genes including HOXA9, implicating an important role for HOX genes in MLL-translocation associated leukemias. *Aims.* In this study we aimed to elucidate the role of aberrant HOXA9 expression in human MLL-rearranged and non-rearranged leukemia's utilizing RNAi mediated knockdown. *Methods.* To establish efficient knockdown, 6 different shRNA constructs targeting human HOXA9 were synthesized applying the BROAD Institute (Cambridge, USA) selection algorithm to minimize off-target effects. The shRNA constructs were then stably introduced into a panel of 17 AML/ALL cell lines (7 MLL-rearranged, 10 non rearranged) and primary AML patient cells utilizing a pLKO.1 lentiviral vector system. The shRNA constructs which showed highest knockdown efficiency (75-80% knockdown) as measured by quantitative PCR and Western Blot analysis and no induction of interferon response genes were used for further experiments. *Results.* Initial analysis of phenotypic effects after HOXA9 knockdown in (9;11) MOLM-14 cells revealed sustained inhibition of cell proliferation 48h after transduction as determined by MTT assay followed by a progressive induction of apoptosis starting at 72h. This effect was almost completely rescued by introducing an exogenous HOXA9 expression vector. To investigate if the HOXA9 knockdown related effects are specific for MLL-rearranged cells, cell growth and viability were next analyzed in the 17 AML/ALL cell line panel. Interestingly, impaired cell proliferation and induction of apoptosis was significantly higher in the MLL-rearranged cell lines than in the non-rearranged cells (mean viability at 72h: 51% vs. 91%: p=0.007) and significantly correlated with the baseline HOXA9 mRNA expression before knockdown, with the greatest effect in high-level HOXA9 expressing cells (R=0.8, p=0.00017). Analysis of MLL-rearranged and non-rearranged primary human AML cells demonstrated a similar induction of apoptosis after HOXA9 knockdown with a higher effect on viability in association with the presence of an MLL translocation (p=0.004) and high-level HOXA9 expression. Expression analysis after HOXA9 knockdown revealed concomitant downregulation in a gene set previously found to be aberrantly expressed in human MLL-AML and also associated with *self-renewal* in a recently defined murine MllAf9 leukemia stem cell model, including HOXA5, HOXA10, MEIS1, RUNX2 and MEF2C. To assess the *in vivo* effects of HOXA9 knockdown, luciferase-expressing SEMK2 (t4;11) cells were transduced with HOXA9 shRNA or GFP control shRNA and transplanted into SCID-beige mice. Engraftment and leukemia burden was monitored by subsequent *in vivo* bioluminescent imaging. There was a significantly lower leukemia burden in the HOXA9 group when compared to controls with a peak difference at day 15, shortly before the control group animals succumbed to overt leukemia. At this point, all mice in the HOXA9 group were still clinically healthy. *Conclusions.* Our data implicates an important role for aberrant HOXA9 expression in the survival of human MLL-rearranged leukemias and suggests targeting HOXA9 or downstream programs may be a novel therapeutic approach which warrants further exploration.

Acute myeloid leukemia - Clinical I

0046

PROGNOSIS OF ACUTE MYELOID LEUKEMIA IN FIRST RELAPSE: IMPORTANCE OF THE HOVON/SAKK INDEX

F. Costa, A. Botelho de Sousa

Hospital dos Capuchos, LISBON, Portugal

Background. The outcome of adults with acute myeloid leukemia (AML) in first relapse is highly unsatisfactory, as very few patients achieve durable second complete remissions (CR) with intensive reinduction chemotherapy (CT). Breems et al recently proposed a Prognostic Index (PI) to be applied to patients ≤ 60 years in first relapse, which may prove to be a major tool in therapeutic decisions. Aim. To evaluate the reproducibility of this PI in a cohort of uniformely treated patients at a single center. Methods. Of 151 consecutive new patients (age 17-60 years) with de novo or secondary AML (excluding promyelocytic leukemia) treated from May 98 to April 06, 107 achieved CR1, among whom 55 had relapsed as of June 06. The 50 patients who received intensive reinduction CT are the object of this analysis. Patients were stratified into the 3 risk groups of the PI according to the following parameters: length of CR1, cytogenetics at diagnosis, age at relapse, and whether previous stem cell transplantation had been performed. Overall survival (OS) from relapse was compared between the 3 groups. *Results.* Forty two percent of the patients achieved CR2. The median OS was 5 months; the overall 1-year survival rate was 25%. The PI defined 3 groups with significantly different 1-year OS: 100% for the favorable group (comprising 8% of the patients) 40% for the intermediate-risk group (42% of the patients) and 4% for the poor-risk group (50% of the patients) [$p<0.05$]. *Conclusions.* The distribution of our patients among the 3 prognostic groups is remarkably similar to the original HOVON/SAKK cohort. This index is simple, reproducible, and segregates subsets of patients with very different outcomes at relapse. It should be used to identify candidates to conventional salvage CT vs investigational strategies or palliative support.

IMPAIRED NUTRITIONAL STATUS AMONG RUSSIAN AND NORWEGIAN PATIENTS RECEIVING INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA

P.O. Iversen,[1] J.M. Tangen,[2] E. Ukrainchenko,[3] F. Wisløff,[4] B. Afanasyev[3]

[1]University of Oslo, OSLO, Norway; [2]Dept. of Hematology, Ulleval UnivH, OSLO, Norway; [3]BMT Clinic, Pavlov University, ST. PETERSBURG, Russian Federation, [4]Dept. Hematology, UllevaalUnivH, OSLO, Norway

Background. The 5-year survival rarely exceeds 50% for patients with acute myeloid leukemia (AML) treated with intensive chemotherapy. During treatment repeated and prolonged hospitalisations, often in isolation wards, are necessary. Our clinical experience is that body weight is reduced and the patients experience nausea, loss of appetite and fatigue, indicating that during treatment the nutritional status of the patients deteriorates. However, these alterations have not been quantified or systematically studied. Such documentation is necessary in order to give recommendations concerning nutritional supplements. *Aim.* In this prospective study we investigated the nutritional status in AML patients receiving intensive chemotherapy treatment. *Methods.* From 2004-2006 we recruited newly diagnosed adult AML patients consecutively admitted to either Pavlov University (n=26, mean age 60 years) or to Ullevaal University Hospital (n=14, mean age 46 years). Written, informed consent was obtained from all patients, and the protocol was approved by ethics committees in both countries. The patients were treated with induction chemotherapy consisting of cytarabin and daunorubicin followed by 3-4 courses of consolidation therapy with cytarabin every 3-4 weeks. Nutritional status was monitored at diagnosis, at start of each chemotherapy course, and finally 9 months after diagnosis, or until they died or underwent allogeneic stem cell transplantation. Measurements included body mass index (BMI), skinfold thickness (a marker of fat tissue), hand grip strength (a marker of muscle mass) and blood samples. *Results.* Among the Russian patients 20 (64%) did not survive beyond the induction therapy, and 6 (19%) completed the study. The corresponding numbers among the Norwegian patients were 14 (100%) and 8 (57%). The Table 1 shows significant and similar reductions in both country-groups of markers of anthropometry as well as decreased levels of albumin and transferrin, sex-hormones and fat-soluble vitamins. Intriguingly, the gonadotrophines and vitamin A remained low nine months after diagnosis. Neither BMI, thyreoid status nor the plasma levels of water soluble vitamins (B12, B6 and C) changed in either country-group during follow-up. *Summary.* For a successful outcome of AML treatment, repeated intensive chemotherapy courses are necessary. Such treatment apparently leads to a catabolic condition characterized by decreased fat and muscle mass, lowered fat soluble vitamin levels, and hypofunction of the pituitary-gonadal axis. Whether nutritional support is warranted during this treatment requires intervention studies aimed at improving the nutritional status among AML patients.

Table 1.

0048

FRACTIONATED DOSES OF GEMTUZUMAB OZOGAMICIN (3,3,3 REGIMEN) IN ADDITION TO ESCALATED DOSES OF DAUNORUBICIN AND CYTARABINE FOR THE REINDUCTION TREATMENT OF RELAPSED AML: A PHASE 1/2 STUDY OF THE ALFA GROUP

H. Farhat,[1] N. Boissel,[2] O. Reman,[3] N. Contentin,[4] S. Corm,[5] E. Raffoux,[2] S. De Botton,[5] P. Rousselot,[1] C. Preudhomme,[5] F. Pousset,[1] S. Chevret,[2] H. Dombret,[2] S. Castaigne[1]

[1]Hopital de Versailles, LE CHESNAY; [2]Hopital Saint Louis, PARIS; [3]Hopital Georges Clemenceau, CAEN; [4]Centre Henri Becquerel, ROUEN; [5]Hopital Claude Huriez, LILLE, France

Gemtuzumab Ozogamicin (GO, Mylotarg®) used as a single agent at a dose of 9 mg/m^2 for 2 doses given 14 days apart was shown to induce a 26% response rate (RR) in patients (pts) with relapsed AML. However grade 3-4 liver toxicity was observed in 20% of patients with a risk of VOD. To avoid excessive toxicity lower dosage of GO are proposed in trials combining GO in addition to conventional induction chemotherapy for untreated AML pts . The MRC AML15 trial used a dose of GO of 3 mg/m^2 on day 1 of induction course with DA, DAE or FLAG-IDA with promising results in terms of DFS. The ongoing SWOG study is using a dose of GO of 6 mg/m^2 on day 1 with DNR: 45 mg/m^2×3 days (d) and Ara-C 100 mg/m^2 × 7d. We adressed the question of the possibility of using a higher cumulative dosage of GO in addition with a 3+7 regimen. In a previous phase 2 study in 57 relapsed AML patients we demonstrated that fractionated doses of GO: 3 mg/m^2 on days 1,4 and 7 (3,3,3 GO regimen) had a good efficacy/safety profile without excessive hematological and liver toxicities (no grade 3-4 liver toxicity).[1] Thus, we designed a phase 1/2 trial to assess the safety and activity of escalated doses of DNR and AraC in addition to the 3,3,3 GO regimen. Three dose levels of a 3+7 chemotherapy regimen were tested: level 1: DNR: 45 mg/m^2 + AraC: 100 mg/m^2; level 2: DNR: 60 mg/m^2 + AraC: 100 mg/m^2; level 3: 60 mg/m^2 + AraC: 200 mg/m^2. Inclusion criteria were relapsed AML patients over 50 years. To date, 11 patients have been treated: 5 in the first dose level, 4 in the second, 2 in the third. Median age was 65 years (range: 55-75). During the induction period, grade 3-4 adverse events included: sepsis in 3 patients (dose level 1, 1 pt; dose level 2, 2 pts), bleeding in 1 patient (dose level 1), diarrhea in 2 patients (1 pt in first and second dose level), pneumonia in 2 pts (1 pt in first and second dose level). No grade 3-4 elevated liver function tests nor hyper-

bilirubinelia were observed and no pts developped VOD. 3 pts died during the induction period. Causes of death were disease progression in 2 pts (dose level 2) and sepsis in 1 pt (dose level 2). 5 pts achieved complete remission (dose level 1, 2 pts, dose level 2, 1 pt and dose level 3, 2 pts). Median duration of neutropenia <0.5 10^9/L was 25 days and median duration of thrombocytopenia <50.10^9/L was 28 days for responding patients. We conclude that combining a 3,3,3 GO regimen with conventional doses of DNR and AraC regimen is feasible. Inclusions in level 3 cohort are ongoing.

ADDING LOW DOSE GEMTUZUMAB OZOGAMICIN TO FLUDARABINE ARA-C AND IDARUBICIN MAY IMPROVE DFS AND OS IN ELDERLY PATIENTS WITH NON M3 AML: RESULTS OF A PROSPECTIVE, PILOT, TRIAL AND COMPARISON WITH A HISTORICAL COHORT OF PATIENTS

M. Clavio,[1] L. Vignolo,[1] A. Albarello,[1] R. Varaldo,[1] G. Catania,[1] A. Ghiso,[1] C. Ghiggi,[1] F. Olcese,[1] I. Pierri,[1] M. Miglino,[1] A. Manna,[2] E. Balleari,[1] A.M. Carella,[1] M. Sessarego,[1] M.T. Van Lint,[1] A. Bacigalupo,[1] M. Gobbi[1]

[1]Clinica Ematologica Univ. Genova, GENOVA; 2Dept. Oncology, LA SPEZIA, Italy

Background. Elderly AML patients and patients with AML evolved from MDS or therapy related display a very poor prognosis. In the last decade the association of fludarabine, Ara-C and anthracycline proved to be an effective and well tolerated induction regimen for this group of patients and, more recently, the introduction of gemtuzumab ozogamicin (GO) has opened new perspectives in the treatment of AML. *Methods*. We report here final results of a prospective multicentre trial testing the combination of chemotherapy (Fludarabine 25 mg /sqm, Ara-C 1 g /sqm, idarubicin 5 mg / sqm all for 3 days) followed by gemtuzumab ozogamicin (3 mg/sqm at day 4), for induction treatment of patients with CD33+ acute myeloid leukaemia (AML). Responding patients received the same regimen as consolidation therapy. *Patients*. Forty-six consecutive patients were treated between May 2004 and September 2006. The median age was 66 years (60-80), the karyotype was unfavourable in 12 patients (26%), intermediate in 33 (71%) and favourable in 1 (3%). *Results.* Neutrophil (N>0.5×10^9/L) and platelet (Plt > 25×10^9/L) recovery required a median of 17 days (range 10-26) and 16 days (range 7-30) from the end of therapy, respectively. There was one early death during induction. Eleven major infectious complications were recorded (sepsis in 6 patients, pneumonia in 1, pleuritis in 1, aspergillosis in 3). Non-haematological toxicity was very mild. In particular, none of the patients experienced grade 3 or 4 hepatic toxicity, but 4 patients had transient elevation in liver function tests (specifically bilirubin). No evidence of VOD or sinusoidal obstructive syndrome was documented. Of the 45 evaluable patients 24 achieved a complete remission (52%), 66% and 33% in good-intermediate /poor karyotype patients, respectively. Median duration of CR is 8 months (3-26). The cumulative incidence of relapse is 37% with an actuarial 3 year survival of 54%. These results were compared with 47 patients matched for age and karyotype who received the same treatment (FLAI), without GO. The proportion of patients achieving CR was comparable. However, patients with de novo AML receiving GO (n=26) had a significantly lower risk of relapse at 2 years when compared to patients not receiving GO (n=35) (40% vs 80%, p=0.01) and significantly better overall 2 years survival (40% vs 14% p=0.02). Patients with secondary AML had comparable outcome whether or not they were given GO. *Conclusions.* this GO based induction chemotherapy can be given to elderly patients with AML with a good toxicity profile. In keeping with a recent prospective randomised trial, the addition of GO seems to reduce the risk of relapse and therefore to prolong disease free survival.

0050

AN ANTHRACYCLINE FREE REGIMEN BASED ON CONTINUOUS SEQUENTIAL INFUSION OF FLUDARABINE AND CYTARABINE FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA. RESULTS FROM A PHASE II STUDY ON 100 PATIENTS

F. Ferrara,[1] M. D'Arco,[2] G. Mele,[1] M. De Simone,[1] D. Laudati,[1] C. Califano,[2] C. Copia,[1] A. Fasanaro,[1] M. Pedata,[1] S. Palmieri[1]

[1]Cardarelli Hospital, NAPLES; [2]Umberto I Hospital, NOCERA INFERIORE, Italy

New approaches are needed for elderly patients with acute myeloid leukemia (AML). The combination of fludarabine (F) with cytarabine (ARA-C) ± G-CSF has been proven to be effective in refractory or relapsed AML. However, little is known as concerns continuous sequential infusion of the two drugs in newly diagnosed patients. In a phase II study, we investigated the efficacy and toxicity of a regimen including F + ARA-C administered as sequential continuous infusion (CI-FLA) in a series of untreated non-M3-AML patients aged more than 60 years. F at loading dose of 10 mg/sqm over 15 min at day 0, and after three hours and half ARA-C at a loading dose of 390 mg/sqm over 3 hours were given; at the end, F at 20 mg/sqm/ci/24 hours for a total of 72 hours and ARA-C at 1440 mg/sqm/ci/24 hours for a total of 96 hours were started. G-CSF was added at day +15 at a dose of 5 microg/kg. Patients achieving CR were programmed to receive an additional course of CI-FLA. After consolidation, G-CSF at 10 microg/kg was given from day 15 in order to mobilize $CD34^+$ cells. Between June 2001 and June 2006, 100 patients received the treatment. Median age was 68 years (range 61-81). In 42 patients (42%) an antecedent myelodysplastic syndrome preceded overt AML. Cytogenetic analysis showed normal karyotype in 50 patients, complex karyotype or other unfavourable chromosomal abnormalities in 38 cases, no mitoses in 12 cases. Finally, 65 patients were affected by one or more concomitant diseases requiring specific treatment. Overall, 63 (63%) patients achieved CR, all but one following one course of CI-FLA. There were 18 induction deaths (18%), while 19 patients (19%) were refractory to induction treatment. The median number of days to neutrophil > 0.5×10^9/L and platelet > 20×10^9/L was 19 (7-34) and 19 (9-38), respectively. Patients needed a median of 3 platelet units (0-19) and 7 blood units (1-38), respectively. Most patients required broad spectrum empiric antibiotic therapy, while 19/100 cases (19%) needed intravenous antifungal treatment. Documented infections occurred in 15 cases (15%). Forty-four patients out of 63 (70%) were eligible for the programmed consolidation course. Five of the first 20 consolidated patients died from infectious complications during subsequent pancytopenia; therefore, the remaining last 24 patients received reduced consolidation with F+ARA-C at 48 and 72 hours, respectively. Forty-four patients were monitorized for the mobilization of $CD34^+$ cells, collection being successful in 33 (75%). Median number of $CD34^+$ cells/kg collected was 6.8×10^6 (2-60.3), median number of apheresis being 2 (1-2). Overall, 27 (27%) patients received autologous stem cell transplantation (ASCT). Disease free survival and overall survival are 11 and 13 months, respectively. Survival at 5 years is projected to 25%. In conclusion, this study demonstrates that CI-FLA is an effective and well-tolerated regimen for elderly patients with AML. Therapeutic results are extremely encouraging as to CR achievement, $CD34^+$ cell collection and ASCT feasibility and compare favorably with conventional anthracycline/ARA-C based therapy.

0051

FACTORS INFLUENCING THE COLLECTION OF PERIPHERAL BLOOD STEM CELLS IN ACUTE MYELOID LEUKEMIA IN FIRST COMPLETE REMISSION

F. Ferrara, M. Annunziata, M.R. D'Amico, S. Palmieri, C. Copia, M. De Simone, F. Pollio, P. Correale, F.P. Tambaro, A. Viola, G. Mele

Cardarelli Hospital, NAPLES, Italy

Several studies have investigated factors influencing peripheral blood stem cell (PBSC) mobilization in patients with non myeloid malignancies; conversely, there are very few reports on low number of patients concerning the efficiency of PBSC mobilization in patients with acute myeloid leukemia (AML). We analyzed the effects of different potentially influential variables on successful mobilization of CD34 positive ($CD34^+$) from a series of 160 consecutive patients with AML in first complete remission (CR1). Data were collected from a cohort of 160 consecutive patients with AML in CR1. The median age was 52 years (14-78). There were 134 patients with de novo AML (84%) and 26 patients (16%) with secondary AML (s-AML). According to MRC criteria, cytogenetic findings at diagnosis were classified as favourable in 11%, intermediate in 69% and adverse in 20% of patients. Patients up

to 60 years (n=116, or 72%) received anthracycline + cytarabine + etoposide as induction, followed by consolidation including intermediate dose cytarabine + mitoxantrone, while those aged more than 60 (n=44, 28%) were treated in induction/consolidation with fludarabine/cytarabine given as continuous sequential infusion. Consolidation therapy followed by G-CSF at 10 microg/sqm given from day 15 to the last apheresis was used as mobilization regimen. The following variables were analyzed: age > vs 60 years, de novo vs s-AML, anthracycline vs fludarabine based induction treatment, cytogenetics at diagnosis, presence of FLT3 mutations (either ITD or D835 mutation), WBC at diagnosis (more or less than 50×10^9/L), number of courses (i.e. 1 or 2) needed for achievement of CR. The above parameters were correlated to successful mobilization (defined as collection of $>2\times10^6$/L). Overall, 137 patients (86%) had a successful mobilization of stem cells, while 23 (14%) failed to mobilize. The median number of $CD34^+$ cells collected was 6.9×10^6/L (range 2.1-25). Either univariate or multivariate analysis (see Table 1) failed to demonstrate significant influence on successful mobilization for any of parameter which were considered into the study. More in detail, no effect was observed as median number of $CD34^+$ cell collection, median number of apheresis, peak of SC in PB and median number of $CD34^+$ cells collected per single apheresis were concerned. In addition, none of the above parameters was significantly related to hematopoietic reconstitution after autologous stem cell transplantation in terms of WBC and platelet recovery, while hematopoietic recovery was significantly related to the number of $CD34^+$ infused cells. We conclude that successful mobilization in AML is unpredictable by using the variables analyzed in our study.

Table 1. Multivariate analysis of different paramenters on mobilization.

0052

THE DETERMINATION OF LEUKEMIC PHENOTYPE AND MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA BY USING FLOW CYTOMETRY

P. Topcuoglu, K. Dalva, S. Meric, S. Sahin, M. Arat, M. Beksac

Ankara University, ANKARA, Turkey

The hematological remission in acute leukemia is defined as the achievement of complete hematological recovery in peripheral blood and the a decrease of leukemic blasts below 5%. The persistency of malignant cells below this threshold level (<5%) is called as minimal residual disease (MRD). A number of publications have reported that the presence of MRD after the treatment(s) might predict relapse of the underlying disease. One of the covinient methods used for the detection of MRD is immunophenotyping with flow cytometry (FCM). In this study we aimed to evaluate both the leukemic cell immunophenotype at the diagnosis and the amount of MRD at the follow-up in AML patients (using FCM events). 166 patients diagnosed as AML between January 2004 and June 2006 in our center were analyzed retrospectively. Median age was 49 years. Male/Female was 104/62. Method: Immunophenotyping at the period of diagnosis was performed by using the monoclonal antibodies specific for CD45, HLA-DR, CD34, CD33, MPO, CD15(CD16), CD13, CD24, CD11b, CD117, CD64, CD10, CD2, CD19, TdT and (CD4)(CD7). The data were collected in FC500 (Beckman Coulter, France) flow cytometer and were analyzed using the RX-P software program. We usually analyzed approximately 10.000 cells at the diagnostic samples and at least 500.000 cells at the follow-up samples for the detection of MRD. The classification of MRD was evaluated in four groups according to Kern et al recommendations (Crit Reviews Oncol/Hematol 2005). *Results.* The diagnostic samples in AML patients for FCM were obtained from bone marrow (n=133) or peripheral blood (n=33). The median value of immature cell ratio was 63% (21-98%). We detected leukemia associated immunophenotype (LAIP) in one and/or more than one categories at the diagnosis (Table 1).

Table 1.

Clssification	*LAIP*	*The detected parameter*	*%*
Cross-lineage (n=55 patients)	CD2+,CD19+, CD4+, CD7+ etc	61	7.05
Asynchronous (n=148 patients)	CD117/34/33±13 CD11b+/CD117+/CD34+ CD34+/CD15+/CD33+/±CD13+ etc	289	33.4
Lack of expression (n=patients)	CD15+/CD33+/CD13- HLA-DR+/CD34-/CD13+ OR CD33+ CD11b+/CD24-/CD34+ OR CD117+ etc	298	34.5
Overexpression (n=111 patients)	CD11b-/CD117+/CD34+(+) CD15+/CD13++/CD33++ HLA-DR++/CD33++/CD34++ ect	217	25.1
Total		865	100

In summary The 55 of the diagnostic samples, were positive for cross-lineage expression of lymphoid antigen, 148 show asynchronous expression of antigens, 155 present a lack of myeloid antigen expression and 111 have had myeloid antigen overexpression. The most frequent LAIP in the diagnosis was the persistency of immature myeloid antigen during the maturation (33.4%) or the lack of expression of myeloid antigen (34.5%). Only 73 patients were able to be analysed for MRD on day of 14th to 54th following remission induction therapy. We could not evaluate 17 patients (23%) for MRD at the follow-up in which hematological remission was not achieved after a remission-induction therapy. Eighty-nine percent of 56 patients in the remission had any LEIP permitting for the evaluation of MRD. The amount of MRD was 0.1% to 10% in different follow-up periods. We observed relapse within six months in 36% of 55 patients having MRD. *Conclusions.* We found less myeloid-antigen associated abnormal immunphenotype (7.65%) in the diagnostic samples compared with the previous published studies (10-24%). However, the ratio of leukemic immunophenotype was detected as 92.6%. Evaluation of MRD with regular follow-up of FCM events may allow us to predict the probability of relapse.

0053

WILMS' TUMOUR 1 MUTATION IN NORMAL KARYOTYPE AML

P. Virappane,[1] R.E. Gale,[2] R.K. Hills,[3] I. Kakkas,[4] K. Summers,[5] J. Stevens,[5] C.L. Green,[2] C.G. Allen,[2] H. Quentmeier,[6] H. Drexler,[6] A.K. Burnett,[3] D.C. Linch,[2] D. Bonnet,[7] T.A. Lister,[5] J. Fitzgibbon[5]

[1]Institute of Cancer, LONDON, United Kingdom; [2]University College London, LONDON WC1E 6HX, United Kingdom; [3]University of Wales College of Medicine, CARDIFF, CF14 4XN, United Kingdom; [4]Evaggelismos Hospital, ATHENS, Greece; [5]Barts and the London School of Medicine, LONDON, United Kingdom; [6]DSMZ, BRAUNSCHWEIG, Germany; [7]Cancer Research, HSC laboratory, LONDON WC2A 3PX, United Kingdom

Background. Our recent studies demonstrated that the Wilms' tumour 1 (WT1) gene represents an important mutational target in normal karyotype (NK) Acute Myeloid Leukemias (AML) (Fitzgibbon *et al.,* 2005; Summers *et al.,* 2007). In this study, we have set out to determine the potential clinical relevance of these mutations. *Methods.* Diagnostic NK AML patient DNA samples (n=285: de novo 272, secondary 13) were obtained from previously conducted Medical Research Council AML 10 and 12 trials and AML cell lines (n=67) from the DSMZ-German Collection of Microorganisms and Cell Cultures. Mutation analysis for WT1 was performed using standard PCR-based direct sequencing and high-resolution Capillary Electrophoresis (CE) of exons 7 and 9. FLT3 and NPM mutation status were obtained using standard approaches. Statistical analysis was performed using the Mantel-Haenszel test for initial response, and log-rank test for long term outcomes. *Results.* Mutation of WT1 was observed in 32/285 (11%) NK AMLs. These occurred predominantly in exon 7 (26/32) with the vast majority being frameshift mutations (30/32 cases) arising as a result of insertions or deletions (range 1-28 bps). Two non-synonymous substitutions, D396N and H397Y of

unknown significance were identified in single cases. Mutations could be separated into 3 distinct patterns based on CE mutant quantification: low (6 cases < 30% mutant), intermediate (15 cases 30-60% mutant) and high (9 cases > 70% mutant) mutation load. There was no significant difference in the frequency of FLT3-ITD (47% Vs 34%) and NPM mutation (50% vs 62%) between WT1(M) and WT1(WT) cases. Patients with mutations in WT1 had an inferior initial response to therapy (Complete Remission [CR] WT1(M) 75% Vs WT1(WT) 90%, Odds Ratio [OR] 4.04, Confidence Intervals [CI] 1.30-12.5; p=0.02) and a higher rate of Resistant Disease [RD] (RD WT1(M) 16% Vs WT1(WT) 5%, OR 5.85, CI 1.29-26.4; p=0.02). Although Overall Survival (OS 34% vs 47%) and Disease Free Survival (DFS 33% vs 47%) were lower in the WT1(M) Vs WT1(WT) cases, this did not reach statistical significance. CE mutation analysis in 67 AML cell lines yielded mutation in the UF-1 (PML-RARA) and CTS (MLL-AF6) cell lines suggesting that WT1 mutations are likely to occur in other cytogenetic risk groups. *Conclusions.* WT1 mutations occur in 11% of NK AML at diagnosis. Mutations result in insertion or deletions in the DNA binding domain of the protein and have the potential to interfere with WT1 derived minimal residual disease detection. The locations of the common epitopes used for immunotherapy locate outside of the mutated region. WT1 mutations are associated with a lower CR rate and a higher rate of RD. Although OS and DFS are lower in the mutated group, this did not reach significance. Additional cases are being investigated to determine whether WT1 mutation status warrants inclusion as a poor risk marker in AML.

0054

ANALYSIS OF NPM1 MUTATIONS USING A SIMPLIFIED DNA-BASED PCR APPROACH DEMONSTRATES THAT ONE THIRD OF YOUNGER ADULT PATIENTS WITH NORMAL KARYOTYPE CARRY A MUTATION

D. Rund, M. Safrai, M. Kedmi, S. Bar Cohen

Hebrew University-Hadassah Hospital, JERUSALEM, Israel

Background. There is a need for guidelines to improve risk stratification of patients with AML who have a normal karyotype. In 1999, it was discovered that rearrangements of the FLT3 gene confer a poor prognosis in AML. These were found in around 25% of AML, mostly in patients with a normal karyotype. In 2005, it was discovered that mutations in the NPM1 gene conferred a favorable prognosis. Analysis of these two mutations greatly improves prognostic ability for normal karyotype AML. The analysis of NPM1 mutations has generally been performed using histochemistry, sequencing of DNA, or RNA-based methods (RT-PCR) however many laboratories do not have the facilities to perform these analyses. Furthermore, as FLT3 analysis is performed on DNA, it is advantageous to have a DNA-based method to study these two aberrations in parallel. *Aims.* To establish and test a DNA-based method of NPM1 analysis. *Methods.* We have developed a DNA-based method for NPM1 analysis using PCR and melting temperature which gives rapid clearcut results which demonstrate the presence of a mutation. Although this method does not detect the specific type of mutation, this does not influence prognosis, and it is not crucial to determine it. We have used this method to analyze 154 patients with AML (primary and secondary) for both NPM1 and FLT3 mutations. 60 of these had a normal karyotype. FLT3 length mutations were analyzed by PCR and acrylamide gel electrphoresis. *Results.* Figure 1 shows a typical result of such an analysis. The tracing with a single peak represents normal DNA. The tracing with two peaks represents an AML patient sample which carries an NPM1 mutation.

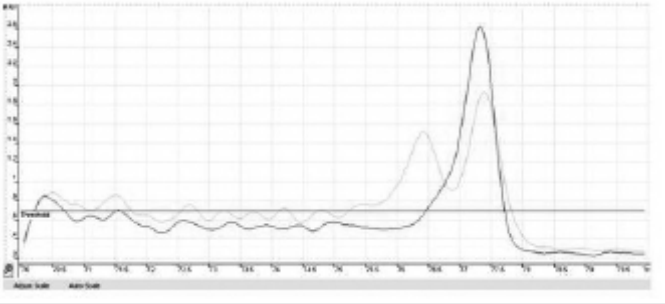

Figure 1. Melting curve analysis for NPM1 mutations.

In total, we found that 21 patients had NPM1 mutations, of whom 20 had a normal karyotype, representing 33% of normal karyotype AML patients. Of these, 10 patients also had FLT3 rearrangements, whereas 10 had only NPM1mutations without FLT3 rearrangements. Although our sample is small, our findings were in accordance with the literature: patients with NPM1 mutations had a longer survival than those without such mutations, but only if FLT3 rearrangements were not present. Two thirds of the NPM1 positive patients were female. Our percent of normal karyotype/NPM1 positive patients (33%) is somewhat lower than that reported in the literature [45.7% (Theide, 2006) to 50-60% (Falini, 2006))]. The slightly lower percent could be due to a number of factors, such as the small sample size of our group. Alternatively, it could be due to the younger age of our patient population. The mean age of our patients positive for NPM1 mutations was 46 years (range 17-79) as compared to 48 (17-87) without NPM1 mutations. Falini (2005) reported that the NPM1 positive patients were significantly older (51.8 years) than NPM1 negative patients (41.9 years) (Falini, 2005). Thiede (2006) also reported a slightly older age for NPM1 positive compared to negative patients, in a population whose median age was 60 years. Summary and *Conclusions.* We conclude that melting temperature DNA-based NPM1 analysis is useful in rapid determination of NPM1 status. Patient age may influence the development of NPM1 mutations.

ARE COMORBIDITY SCORES USEFUL DECISION MAKING TOOLS FOR INTENSIVE CHEMOTHERAPY IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA?

H. Dombret,[1] J.V. Malfuson,[2] A. Etienne,[3] P. Turlure,[4] T. De Revel,[2] D. Bordessoule,[4] N. Vey,[3] C. Gardin[5]

[1]Hopital Saint-Louis, PARIS; [2]Hopital Percy, CLAMART; [3]IPC, MARSEILLE; [4]CHU, LIMOGES; [5]Hopital Avicenne, BOBIGNY, France

Aim. We have recently reported results of standard intensive chemotherapy in 416 patients with AML aged 65 years or more (median, 72 years) treated in the ALFA-9803 trial. We report here on the impact of pretreatment comorbidities on mortality before day 100 (d100 mortality, 22% in the whole patient population) and survival in this large cohort of patients. *Methods.* For each patient, we calculated the original Charlson Comorbidity Index (CCI) (Charlson, J Chron Dis 1987) and the refined Hematopoietic Cell Transplantation Comorbidity Index (HCT-CI) (Sorror, Blood 2005). *Results.* As expected, both scores correlated pretty well (CCI 0/1/2=353/57/6; HCTCI 0/1/2/3+ = 268/85/42/21; p<0.001). Due to usual inclusion criteria which represent a first important selection step including notably the absence of heart or renal failure, only 5 comorbidities were observed in at least 5% of patients : coronary artery disease (10%), arythmia (8%), infection (8%), diabetes (7%), and chronic pulmonary disease (5%). Neither CCI or HCTCI correlated with advanced age in this patient population. Performance Status (PS) correlated strikingly with initial WBC but not with HCTCI, making it more a characteristic of AML impact on host status than purely host-related. In multivariate analysis, the HCTCI influenced d100 mortality (p=0.01) and overall survival (p=0.008) more significantly than the original CCI. Other independent factors were age, PS, and cytogenetics. Such an additive weighted score is, however, of relatively limited interest for decision making at the individual patient level. An HCTCI>1 demarcated only 15% of high-risk patients with a d100 mortality rate of 35% and higher HCTCI levels only 5% of patients or less. In addition, the predicted d100 mortality was 21% in a patient with HCTCI>1 due to cardiac abnormality and/or diabetes and/or obesity versus 47% in a patient with HCTCI=1 due to infection only, indicating that some HCTCI items did not impact on outcome. Further analysis of the prognostic impact of each comorbidity or combination led us to propose only four independent criteria (pre-treatment documented infection, chronic pulmonary disease, PS>1 if age>74y, and high-risk cytogenetics) to consider a patient as unfit for intensive chemotherapy, even if he/she fulfilled all usual inclusion criteria. This 4-criteria non-additive tool was associated with a higher decisional value allowing to demarcate 28% of patients with a d100 mortality rate of 43% and a specificity of 86%. This new definition of unfit patients was validated in a set of patients from one independent French institution.

0056

PROGNOSTIC SIGNIFICANCE OF FLT3/ITD MUTATION IN PATIENTS WITH AML1/ETO ASSOCIATED ACUTE MYELOID LEUKEMIA

Y.-K. Kim,[1] H.N. Kim,[2] I.K. Lee,[2] D.Y. Jo,[3] J.H. Won,[4] J.H. Choi,[2] S.R. Lee,[1] H.J. Shim,[1] J. S. Ahn,[1] D.H. Yang,[1] J.J. Lee,[1] H.S. Park,[4] H.J. Kim[1]

[1]Chonnam National University Hwasun Hosp, JEOLLANAM-DO; [2]GRCHD, Chonnam Natl. Univ. Hwasun Hosp., JEOLLANAM-DO; [3]Chungnam National University Hospital, DAEJEON; [4]Soonchunhyang Univ. College of Med., SEOUL, South-Korea

Background. AML1/ETO fusion gene in acute myeloid leukemia (AML) usually predicts a good response to chemotherapy with a high remission rate and a relatively long median survival. An internal tandem duplication of the FLT3 gene (FLT3/ITDs) is known to be associated with poor outcome in AML patients. In these days, animal study showed that the dual presentation of AML1/ETO fusion gene and the FLT3 length mutation collaborate in inducing acute leukemia in mice. *Aims.* To determine the prognostic role of FLT3/ITD mutation in patients with AML1/ETO positive AML. *Methods.* FLT3/ITD mutation status was evaluated by performing DNA polymerase chain reaction assays on 38 bone marrow samples obtained at initial diagnosis from the patients with AML1/ETO fusion gene positive AML. GeneScan analysis was performed to confirm the FLT3/ITD mutation and to measure mutant levels. *Results.* Of total 38 patients, 9 patients (23.7%) demonstrated the aberrant FLT3/ITD mutations. The median age of patients was 37 years (range, 18-75 years). There were 23 males (60.5%) and 15 females (39.5%). There was no statistically significant difference in age, gender, leukocyte count, hemoglobin level, platelet count and percentage of peripheral or bone marrow blasts between the patients with FLT3/ITD and the patients without FLT3/ITD. To analyze the response to or outcome of therapy, we evaluated 33 patients who received intensive induction chemotherapy containing cytarabine. In univariate analysis, there was no significant difference in complete response rate (100% vs. 95.8%, p=0.53). However, the presence of FLT3/ITD was associated with higher relapse rate in these patients (77.8% vs. 30.4%, p<0.05). A trend for shorter leukemic-free survival (LFS) was observed in patients with FLT3/ITD compared with those without FLT3/ITD, but there was no statistical significance (8.7±2.7 ms vs. 18.9±7.9 ms, p=0.26). Also, there was no significant difference in median duration of overall survival (p=0.79). *Conclusions.* This study demonstrates that the presence of FLT3/ITD mutations is a significantly higher relapse rate in AML1/ETO positive patients. Therefore, a stratified treatment plan such as stem cell transplantation may be warranted for the AML1/ETO positive AML harvoring FLT3/ITD mutation.

0057

HAEMORRHAGE AND THROMBOSIS IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS: RELATION TO THROMBOTIC MARKERS

A. Falanga,[1] D. Balducci,[1] L. Russo,[1] A. Vignoli,[1] M. Marchetti,[1] J.H. Morrissey,[2] T. Barbui[1]

[1]Ospedali Riuniti di Bergamo, BERGAMO, Italy, [2]University of Illinois, URBANA, IL, USA

Background. APL patients present with laboratory signs of disseminated intra-vascular coagulation. Clinical manifestations include both severe haemorrhage and thrombosis. Remission induction therapy with all-trans retinoic acid (ATRA) has produced high rates of complete remission and a rapid resolution of the APL-associated coagulopathy. *Aim.* In this study, in newly diagnosed APL patients, we prospectively evaluated: 1. The rate of haemorrhage and thrombosis; 2. The plasma levels of thrombotic markers before and after starting remission induction therapy; 3. The predictive value of these markers. *Methods.* Forty-four consecutive patients with APL (F/M = 20/24; age range = 8-84 years) were enrolled at our Centre from January 2000 to January 2007. All patients received induction therapy with Idarubicin + ATRA (GIMEMA AIDA 2000 protocol) and were prospectively monitored for thrombo-haemorrhagic episodes for 8 weeks. Blood samples were obtained from 18 of the 44 patients, at baseline (before ATRA = T0), and at days 7 (T7), 15 (T15), and 25 (T25) after starting ATRA. Control samples were from 25 healthy subjects. Plasma levels of clotting activation markers were measured by ELISA, including: D-dimer, thrombin-antithrombin complex (TAT), tissue factor pathway inhibitor (TFPI), and activated factor VII-antithrombin complex (FVIIa-AT). *Results.* At disease onset, among the 44 patients, 8 had haemorrhages (18%), including 3 (6.8%) fatal intracranial bleeding (1 before starting ATRA, and 2 after 1 and 3 days ATRA, respectively) and 5 non-fatal major bleedings (11.3%) at days 1-3 of therapy; furthermore 3 patients (6.8%) presented with thrombosis, including 1 fatal Budd-Chiari syndrome (2.2%), and 2 non-fatal events (4.5%). During induction therapy, 3 patients (9.0%) developed thrombosis at day 9, 15 and 40, respectively. The study of plasma markers in the subgroup of 18 patients showed that at T0, the levels of D-dimer, TAT, TFPI, and FVIIa-AT were all significantly (p<0.05) higher in APL patients than controls. During ATRA therapy the thrombotic marker levels declined. However, after a week (T7), D-dimer and TAT were significantly (p<0.05) reduced compared to T0, whereas TFPI and FVIIa/AT levels persisted elevated. Thereafter, TFPI level significantly decreased at T15 (vs T0, p<0.05), and last, FVIIa-AT showed a significant reduction at T25 (vs T0, p<0.05). Three of the 18 subjects of this sub-group had thrombosis, after 1, 9, and 15 days of ATRA, respectively, none had major haemorrhages. Among all markers, the pre-treatment TFPI levels > 74.9 showed a significant predicting value for thrombosis by the Fisher's exact test (RR= 5.14; CI = 85.34-60.81, p<0.05). *Summary and Conclusions.* These data confirm a significant rate of early deaths in APL due to the coagulopathy, in the ATRA era. The analysis of coagulation markers shows for the first time persistent elevated levels of TFPI and FVIIa/AT, possibly due to persistent APL cell TF expression, which suggests a role for these markers in the follow up of these patients. Finally, TFPI levels at diagnosis may be a promising marker of increased thrombotic risk, although this needs to be tested by large prospective clinical studies.

0058

FLOW-CYTOMETRIC ASSESSMENT OF MINIMAL RESIDUAL DISEASE DISCRIMINATES CATEGORIES OF RISK AMONG ADULT AML PATIENTS WITH INTERMEDIATE KARYOTYPE

F. Buccisano,[1] L. Maurillo,[2] V. Gattei,[3] G. Del Poeta,[2] M.I. Del Principe,[2] P. Panetta,[2] D. Fraboni,[2] M. Irno Consalvo,[2] S. Campagna,[2] L. Franceschini,[2] L. Ottaviani,[2] C. Sarlo[2] E. Ammatuna,[2] F. Lo Coco,[2] S. Amadori,[2] A. Venditti[2]

[1]Policlinico Tor Vergata, ROME; [2]University Tor Vergata, ROME, Italy; 3Centro di Riferimento Oncologico, AVIANO (PN), Italy

Background. According to the prognostic classifications of karyotypic abnormalities of AML (MRC and SWOG), the intermediate group includes patients either lacking good and poor karyotype or with normal karyotype. Therefore, it represents, by definition, a miscellaneous group for which the evaluation of the better treatment strategy is difficult due to its heterogeneity. Moreover, patients belonging to this intermediate group account for the large majority of AML cases enrolled into clinical trials. *Aims.* The aim of our study was to analyze the factors specifically affecting the outcome of patients bearing intermediate risk karyotypic abnormalities in a group of 121 AML cases entered into the EORTC/GIMEMA protocols AML10/AML12 (age <61yrs) or AML13/AML15 (age >61 yrs), consisting in intensive induction and consolidation cycles. *Methods.* The clinico-biological variables evaluated in our model included age, FAB, WBC count, MDR1 phenotype, FLT3 mutations and level of post-consolidation bone marrow residual leukemic cells (BMRCL), assessed by multiparametric flow-cytometry (MPFC). By applying the maximally selected log-rank statistics, the threshold discriminating MRD negative from positive cases was set at 3.5×10^{-4} BMRLC, a level that allowed the identification of distinct subgroups of MRD^- and MRD^+ patients at post-Cons time-point.

Figure 1.

Results. Patients with $<3.5\times10^{-4}$ BMRLC at the end of consolidation therapy were considered MRD- and showed a better outcome, patients whose level of MRD were $>3.5\times10^{-4}$at the end of consolidation were considered MRD+ and showed a poor prognosis. Using the MRC classification, 17/121 patients (14%) had a good-risk cytogenetics, 97/121 (80%) an intermediate-risk and 7/121 (6%) a poor-risk. When we restricted the analysis to cases with intermediate-risk karyotype we found that: 1) patients in the MRD- and MRD+ group differed significantly in terms of relapse free survival (RFS), overall survival (OS) and relapse rate ($p<0.001$, 0.003 and <0.001, respectively); 2) Intermediate karyotype MRD' patients had an outcome comparable to those bearing good risk karyotype whereas intermediate karyotype MRD+ patients showed a dismal outcome comparable to adverse karyotype patients (Figure 1). *Conclusions.* These results suggest that the inclusion of MPFC assessment of MRD in patients with intermediate risk karyotype may be particularly useful in discriminating subgroups with different outcomes. This may allow clinicians to design risk-based therapeutic programs in a group of AML where karyotype does not represent a clear prognosticator likely due to the underlying molecular heterogeneity.

PROGNOSTIC SCORE INCLUDING SERUM β-2 MICROGLOBULIN LEVELS TO STRATIFY PATIENTS WITH ACUTE MYELOID LEUKEMIA: ANALYSIS OF 1293 PATIENTS

A.M. Tsimberidou, H.M. Kantarjian, S. Wen, M.J. Keating, S. O'Brien, J. Cortes, S. Pierce, M. Brandt, E.J Freireich, E. Estey

U. T. M. D. Anderson Cancer Center, HOUSTON, USA

Background. Serum β2 microglobulin (β2M) levels reflect renal function and membrane turnover. *Aims.* The aim of this study was to evaluate the prognostic significance of β2M in acute myeloid leukemia (AML). *Methods.* Among 2,014 patients who presented to M. D. Anderson Cancer Center with newly diagnosed AML (> 20% myeloblasts) from 1990 to 2005, pretreatment β2M levels were determined in 1,293 patients using a radioimmunoassay (Pharmacia Diagnostic, Uppsala, Sweden)(normal values, 0.7-2.0 mg/L). Survival analyses were performed considering 38 covariates. Pretreatment parameters that remained independently significant were used to design a model to predict an individual patient s risk of death: the AML score. *Results.* The median age of patients was 61 years (range, 16-89 years). Cytogenetic risk was poor in 29%, intermediate in 60%, and favorable in 7%. Zubrod performance status (PS) was > 1 in 27%. The median follow-up of surviving patients was 27 months (range, 1-145 months). Overall, 96% received chemotherapy and 91% received ara-C-based induction therapy. In the multivariate analysis of the 2,014 patients, lack of β2M measurements was an adverse independent factor predicting survival. Since patients > 60 years are sometimes offered less intensive therapy and have shorter survival than younger patients, we performed separate multivariate analyses for these groups. β2M levels were among the top three independent prognostic factors for patients > 60 years, but not for younger patients. We then performed multivariate analyses in 1293 patients with β2M measurements. A training sample of 862 patients (2/3) was randomly selected.

Figure 1.

The following factors had independent adverse significance for survival: worse-risk cytogenetics, older age, poorer performance status, higher β2-microglobulin levels, lower hemoglobin levels, secondary (vs. *de novo*) AML, longer prothrombin time, and higher LDH levels. The prognostic factor model was then applied to a validation sample of the remaining one third of patients (415/1293), with complete data on the eight specified variables. The model was equally predictive in the validation sample. Based on the relative risks associated with each of the top four independent risk factors (cytogenetics, age, performance status, 'β2M level), we designed the AML score. Patients with poor-risk cytogenetics were given a score of 2, those with intermediate risk a score of 1, and those with favorable cytogenetics a score of 0. Each of the following factors was given a score of 1: age > 60 years, β2M > 3 mg/L, PS >1. The risk of death could be determined by summing the above scores present at diagnosis and ranged from 0 to 5. At 2 years, 74%, 51%, 36%, 19%, and 6% of patients with scores of 0, 1, 2, 3, 4-5, respectively, are expected to be alive (Figure 1). *Conclusions.* This large study strongly supports the utility of uncorrected serum β2M levels as an independent prognostic factor for survival in patients with newly diagnosed AML who are 60 years or older, regardless of cytogenetics and PS. The proposed score defines the key prognostic features in newly diagnosed AML and provides a refined stratification of risk assessment.

0060

MUTATION PROFILE AND PROGNOSIS OF ADULT ACUTE MYELOID LEUKEMIA WITH INVAGINATED *CUP-LIKE* NUCLEI

A. De Labarthe,[1] O. Nibourel,[2] A. Renneville,[2] V. Biggio,[2] M.T. Daniel,[1] C. Parmentier,[1] J.M. Cayuela,[1] X. Thomas,[3] H. Dombret,[1] C. Preudhomme,[2] N. Boissel[1]

[1]Hopital Saint-Louis, PARIS; [2]Hopital Calmette, LILLE; [3]Hopital Edouard Herriot, LYON, France

Background : Acute myeloid leukemia with the most frequent recurrent cytogenetical abnormalities (t(15;17), t(8;21), inv(16)) display well recognized cytological features. In contrary, few morphological characteristics allow to predict the mutation profile (NPM1, FLT3, CEBPA) in AML. Recently, AML with prominent nuclear invaginations were successively shown to be associated with FLT3/ITD and NPM1 mutations (Kussick, Leukemia 2004; Chen, Blood, 2006). These AML also display a particular phenotype with a low expression of CD34 and HLA-DR. The aim of this study was to precise the mutation profile of these AML with invaginated cup-like nuclei. *Methods.* AML in 92 patients aged 15-50 years and treated in the ALFA-9802 protocol were investigated for the presence of cup-like nuclei, NPM1 mutation (NPM1m), FLT3 internal tandem duplication (FLT3/ITD), FLT3/D835 mutation and CEBPA mutation (CEBPAm). The criterion for this morphological feature was the presence of 10% ore more blasts with nuclear invagination embossing at least 25% of the nucleus. R*esults.* The incidence of NPM1m, FLT3/ITD, FLT3/D835 and CEBPAm were respectively 28%, 20%, 11% and 7%. Both NPM1m and FLT3/ITD were found in 12% AML. AML with cup-like nuclei (CL-AML) were found in 17/92 patients (18%) : 6 FAB-M1, 6 M2 and 5 M4. CL-AML were associated with a higher WBC (76 vs 25 G/L, $p= 0.07$) and a higher marrow blast rate (88% vs 70%, $p=0.02$). CL-AML mostly displayed a normal karyotype (81% vs 46%, $p=0.01$). All CP-AML presented with either a NPM and/or a FLT3 mutation. In this subgroup, NPM1m and FLT3/ITD were significantly more frequent (NPM1m : 76% vs 17%, FLT3/ITD : 71% vs 8%, $p<0.0001$) but no difference was observed concerning FLT3/D835 or CEBPAm ($p=0.99$). Among the 11 patients with both NPM1 and FLT3/ITD, 9 (82%) presented with CL-AML ($p<0.0001$). In our cohort, the sensitivity and the specificity of this morphological feature to predict the presence of concomitant mutations were respectively 82% and 89%. Complete remission rate was not different for CL-AML patients (89% vs 92%, $p=0.7$). However CL-AML was associated with a shorter survival in the whole population (3y-OS:30% vs 53%, $p=0.05$) or in the cytogenetical intermediate risk group (3y-OS:45% vs 67%, $p=0.09$). *Conclusions.* CL-AML consist in a relatively homogeneous group displaying a high frequency of both NPM1m and FLT/ITD rates and a poor outcome. Gene expression profiling may be useful to understand and to corroborate this observation.

Anemia and Bone marrow failure

0061

GRANULOCYTE TRANSFUSION IN THE MANAGEMENT OF PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND SEVERE INFECTION

H. Cherif,[1] U. Axdorph,[2] M. Kalin,[2] M. Björkholm[2]

[1]Karolinska University Hospital, STOCKHOLM; [2]Karolinska University Hospital and Ins., STOCKHOLM, Sweden

Background. Infection associated with chemotherapy induced neutropenia continues to be a major cause of morbidity and mortality in patients treated for hematological malignancies. The role of granulocyte transfusion (GT) in this clinical setting has not been established. *Aims and Methods.* We retrospectively analysed clinical characteristics and outcome in a cohort of patients with hematological malignancies receiving GT during neutropenia and severe infection. *Results.* A total of 30 patients with a median age of 46 years (range 3-82) who had received one or more GT, achieved from community donors after stimulation with G-CSF and corticosteroids, were included. Acute leukemia (80%) and non-Hodgkin lymphoma (17%) predominated as underlying hematological malignancy. All patients had severe (absolute neutrophil count $<0.1\times10^9$/L) and prolonged (median 16 days; range 6-63) neutropenia. In 28 patients (97%) neutropenia was induced by chemotherapy and 6 of those had received allogeneic stem cell transplantation. The etiology of febrile neutropenia was microbiologically verified in 20 patients (66%) and 19 of those had bacteremia. The major reasons for GT were persistent fever and clinical deterioration despite adequate antibiotic therapy in combination with progressive pneumonia (n=16), neutropenic enterocolitis (n=6), and soft tissue infections (n=3). GT were given daily for a median of 4 days (range 1-14). An increment in neutrophil counts after GT occurred in 62% of patients and median time to fever defervescence after GT was 5 days (range 1-33). In 11 patients resolution of fever and all signs of infection could directly be related to GT and 3 of those patients were long term survivors (>5 years). Mortalities at 30-days and 6-months post GT were 40% and 72%, respectively. GT was well tolerated and only 2 patients needed antihistamines/corticosteroids to avoid reactions. *Conclusions.* A substantial proportion of severely ill patients with complicated febrile neutropenia benefited from GT. Despite high mortality, the presence of long time survivors motivates further evaluation using well designed randomised prospective trials to evaluate the efficacy of this intervention in patients with hematological malignancies.

0062

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FROM MATCHED RELATED DONORS IN FANCONI ANEMIA PATIENTS: THE TUNISIAN EXPERIENCE WITH TWO CONDITIONING REGIMENS

L. Torjemane

Centre National de Greffe de Moelle Osse, TUNIS, Tunisia

We transplanted twenty-four patients with Fanconi anemia (FA) using matched related donors (MRD) between January 1999 and June 2006. The patients were assigned to the following groups according to the conditioning regimen: group 1 (N=17), low-dose cyclophosphamide (CY; 40 mg/kg)-busulfan (BU; 6 mg/kg) conditioning regimen; group 2 (N=7), low-dose CY- Fludarabine (120 mg/m^2) conditioning regimen. Median age at transplantation was 10 years (range:3-22 years). Graft-versus-host disease (GVHD) prophylaxis included cyclosporine A and methotrexate (MTX; 5mg/m^2 at day 1, 3, 6). Twenty-three patients engrafted (for an absolute neutrophil count $>0.5\times10^9$/L) after a median time of 12 days (range,10-16 days). Eighteen patients (78%) had sustained grafts, whereas five others of the group 1 (29%) rejected grafts between day +39 and 22 months after transplantation. Four of them are still alive after successful second PBSC transplantation and one died. All of the group 2 patients had sustained grafts without major toxicity. Acute and chronic GVHD occurred, respectively, in 17% and 9% of only group1 patients. After a median follow-up of 53 months (range, 9-93 months), nineteen patients are alive. The Kaplan-Meyer survival is 79% at 7 years. We conclude that, in FA patients, fludarabine-based conditionning allowed engraftment with low toxicity.

0063

ALEMTUZUMAB PLUS CYCLOSPORIN A FOR TREATMENT OF PATIENTS WITH BONE MARROW FAILURE SYNDROME

H. Kim, J.-H. Park, S.-J. Shin, Y.J. Min

Ulsan University Hospital, ULSAN, South-Korea

Patients with bone marrow failure syndrome are suffered from cytopenia and resulting requirement of transfusion. Allogeneic hematopoietic stem cell transplantation (alloHSCT) is the standard therapy for severe aplastic anemia (AA) with suitable sibling donor. However, it is true in many cases that alloHSCT can not be performed even in very severe AA due to no suitable donor. In that regards, immunosuppressive therapy (IST) is another option for those patients. Alemtuzumab (ALM) targets not only B-cell but also Tcell, which is known to play an important role in pathogenesis of bone marrow failure syndrome (BMFS). Although there were several reports of ALM for immune cytopenia and pure red cell aplasia, no report were published regarding ALM for BMFS. We studied the feasibility of ALM and cyclosporine A (CsA) for patients with BMFS. Inclusion criteria were transfusion-dependent BMFS including AA, MDS, PNH. Prior IST or other drugs for BMFS except for ALM were not excluded. ALM was infused for 3 days (10 mg on day 1, 20 mg on day 2, and 30 mg on day 3) along with CsA for at least 6 months. Prophylactic ciprofloxacin, acyclovir, and bactrim were given for first 2 months. Without partial response (PR) or more within 6 months, subsequent alloHSCT or antithymoglobulin therapy was allowed. Total 12 patients were enrolled. Female were 9 (75%). Median age was 43 (16-74) years. Disease were 9 severe AA, 2 moderate AA and 1 hypoplastic MDS. All patients were transfusion-dependent. Median amount of transfused red cell, platelet concentrate and platelet apheresis prior to ALM-CsA were 2, 2 and 7 units, respectively. Prior therapy were none in 9 (75%), anti-thymoglobulin in 2 (16.7%), and danazol in 1 (8.3%). Only 1 patient could not receive full scheduled CsA because the patient underwent alloHSCT. Median follow-up was 326 (140-466) days. Response to ALM-CsA were none response in 7 (58.3%), PR in 4 (33.3%), and CR in 1 (8.3%). Therefore, overall response rate was 4/12 (41.7%). Median time to response was 47 (24-71) days (Figure 1). PR was converted to CR in 1 patient at 12 months after treatment. Neither fever nor skin rash during treatment did not affect the possibility of response to ALM-CsA (p=0.523, p=0.523, respectively). Toxicity during ALM was fever in 3 (25%), skin rash in 3 (25%), G1 ALT elevation in 7, G1 AST elevation in 4, and hyperbilirubinemia in 3 (G1 in 2, G3 in 1). There were no anaphylaxis, serum sickness or CMV reactivation. In spite of small number, AML-CsA showed comparable response rate within 3 months after treatment. Therefore in conclusion, ALM-CsA is feasible and tolerable therapy for BMFS.

Figure 1. Time to response.

0064

INCREASED EXPRESSION OF TOLL-LIKE RECEPTOR-4 AND -9 IN THE BONE MARROW OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA MAY CONTRIBUTE TO THE INFLAMMATORY MARROW MICROENVIRONMENT

H. Papadaki, M. Velegraki, K. Pyrovolaki, M. Ximeri, H. Koutala, C. Kalpadaki, G. Gvazava, G. Samonis, G.D. Eliopoulos

University of Crete School of Medicine, VOUTES, HERAKLION, Greece

Background. Chronic idiopathic neutropenia (CIN) is an acquired bone marrow (BM) failure syndrome characterized by Fas-mediated apoptosis of the BM $CD34^+/CD33^+$ granulocytic progenitor cells. An inflammatory BM microenvironment consisting of activated myelosuppressive T-lymphocytes, pro-inflammatory cytokines such as Tumor Necrosis Factor-α (TNFα), Interferon-γ (IFNγ) and Interleukin-6 (IL-6) and pro-apoptotic mediators such as Fas-Ligand (FasL) are mainly implicated in the pathogenesis of the disease. Recent evidence suggests that activation of Toll-like-Receptors (TLRs) on antigen presenting cells (APCs) by a variety of microbial and/or host-derived ligands, may induce the production of pro-inflammatory cytokines by APCs. *Aims.* To evaluate the expression of TLRs in the BM of CIN patients looking for possible relationships between TLR induction and pro-inflammatory cytokine production in CIN BM. *Methods.* BM was obtained from 16 patients with CIN and 14 healthy controls. All patients fulfilled the diagnostic criteria for CIN as we have previously published (Blood 2003; 101: 2591-2600). Surface TLR-1, TLR-2, TLR-4 and intracellular TLR-3 and TLR-9 expression was evaluated by flow-cytometry in the $CD14^+$ BM cell fraction. TLR flow-cytometric analysis was also performed in the $CD45^+$ and $CD45^-$ cell fraction of trypsinised adherent cell layer of confluent (week-3) long-term BM cultures (LTBMCs), representing an approximation of BM microenvironment cells, in patients and controls. *Results.* Increased proportion of TLR-4+ and TLR-9+ cells was found in the $CD14^+$ BM cell fraction of CIN patients (6.48±5.29 and 40.36±26.31, respectively) compared to healthy controls (1.87±1.27 and 21.10±14.17, respectively; $p<0.05$ and $p<0.05$, respectively). A trend towards increased expression of TLR-1, TLR-2 and TLR-3 was also observed in patients (7.58±7.41, 56.14±15.68, 14.42±15.70, respectively) compared to controls (4.01±3.89, 43.36±24.57, 5.73±4.82, respectively); however the obtained differences were not statistically significant. Increased proportion of TLR-4+ and TLR-9+ cells was also observed in the CD45- fraction of patient LTBMC adherent layers (18.42±12.41 and 42.27±20.14, respectively) compared to controls (4.43±0.81 and 3.93±3.35, respectively; $p<0.05$ and $p<0.05$, respectively). *Summary and Conclusions.* CIN patients display increased proportion of $TLR\text{-}4^+$ and $TLR\text{-}9^+$ cells in the BM $CD14^+$ cell compartment and in marrow microenvironment. A degree of TLR up-modulation might be due to the presence of pro-inflammatory cytokines in patients BM. Alternatively, that specific up-regulation of TLR-4 by intrinsic stress proteins and TLR-9 by incorporated DNA from the apoptotic granulocytic progenitor cells may represent a contributory pathogenetic mechanism in CIN by further increasing the pro-inflammatory cytokine production in patients' BM.

BLOCKADE OF INTRAVASCULAR HEMOLYSIS IN PNH WITH THE TERMINAL COMPLEMENT INHIBITOR ECULIZUMAB UNMASKS LOW-LEVEL HEMOLYSIS POTENTIALLY OCCURRING THROUGH C3 OPSONIZATION

A. Hill,[1] R.P. Rother,[2] A.M Risitano,[3] D.S. Cole,[4] M.J. Cullen,[1] S.J. Richards,[1] C. Selleri,[3] P. Ricci,[3] B. Rotoli,[3] L. Luzzatto,[3] P. Hillmen[1]

[1]Leeds General Infirmary, LEEDS, United Kingdom; [2]Alexion Pharmaceuticals, Inc., CHESHIRE, USA; [3]Federico II University of Naples, NAPLES, Italy; [4]University Hospital of Wales, CARDIFF, United Kingdom

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hemolytic anemia characterized by intravascular hemolysis, often resulting in the need for red blood cell (RBC) transfusions. PNH RBCs lack two complement regulatory molecules - CD59, a terminal complement inhibitor, and CD55, a C3 convertase inhibitor. Eculizumab, a humanized monoclonal antibody that inhibits terminal complement by binding to C5, effectively controls intravascular hemolysis as determined by a dramatic reduction in lactate dehydrogenase (LDH) to levels in or just above the normal range. Control of intravascular hemolysis in these patients led to a reduction in, or cessation of, RBC transfusions. During eculizumab treatment, a majority of patients demonstrate evidence of residual, low-level hemolysis; LDH levels remain slightly elevated, haptoglobin levels are low or undetectable, and bilirubin levels are above normal. We hypothesized that this low-level residual hemolysis may be due to clearance of PNH RBCs through a C3b-mediated mechanism. *Aims.* To investigate C3 deposition on RBC in PNH patients before and on eculizumab. *Methods.* C3 deposition was investigated using a direct antiglobulin test (DAT) using monoclonal anti-C3d and two-color flow cytometric analysis with anti-CD59 and anti-C3. *Results.* The DAT was positive in 29 out of 39 PNH patients on eculizumab. Of these 29 DAT-positive patients, who were all receiving transfusions, 25 had DAT testing prior to eculizumab therapy and only one of these was positive. DAT was negative in all of 8 normal volunteers. By two-color flow cytometric analysis, the majority of patients on eculizumab demonstrated three distinct RBC populations: (i) $CD59^+/C3^-$ (normal RBCs); (ii) CD59-/C3- (PNH RBCs without C3 coating); and (iii) $CD59^-/C3^+$ (PNH RBCs coated by C3). No $CD59^+/C3^+$ RBCs were observed. Of 21 DAT positive eculizumab treated patients tested, the median proportion of total RBCs that were C3b positive was 17.6%. 18 of 29 [62%] eculizumab patients with a positive DAT received at least one transfusion during eculizumab therapy compared with 1 of 10 [10%] for DAT negative patients ($p=0.01$), although even patients who did not become transfusion independent during eculizumab treatment showed a marked reduction in transfusion requirement. The median hemoglobin value for the 29 DAT positive eculizumab patients was 9.8 g/dL compared with 11.3 g/dL in the 10 DAT negative eculizumab patients ($p=0.08$). No apparent relationship between LDH and DAT positivity was observed. *Summary.* It is proposed that resolution of intravascular hemolysis in PNH patients on eculizumab results in deposition of C3b on the surface of PNH RBCs which may explain, at least in part, the residual low level hemolysis occurring in some patients. This appears to be a previously undescribed mechanism of RBC clearance in PNH, most likely obscured by the rapidity of intravascular hemolysis in the absence of eculizumab therapy. Despite the low-level residual hemolysis, patients continue to receive significant benefit from eculizumab treatment.

HIGH DEFINITION CONTRAST-ENHANCED MR IMAGING IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA SUGGESTS A HIGH FREQUENCY OF SUBCLINICAL THROMBOSIS

A. Hill,[1] S.A. Reid,[1] R.P. Rother,[2] M.T. Gladwin,[3] P.O. Collinson,[4] D.C. Gaze,[4] A. Lowe,[1] A. Guthrie,[1] M.U. Sivananthan,[1] P. Hillmen1

[1]Leeds General Infirmary, LEEDS, United Kingdom; [2]Alexion Pharmaceuticals, Inc., CHESHIRE, USA; [3]NIH, BETHESDA, USA; [4]St. George's Hospital, LONDON, United Kingdom

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired disorder characterized by intravascular hemolysis and venous thrombosis. Thrombosis is the most feared complication in PNH and is reported to occur in more than 40% of patients. Proposed mechanisms of thrombosis include depletion of the coagulation regulator nitric oxide (NO) by intravascular hemolysis and increased sensitivity of PNH platelets to activation due to deficiency in complement regulatory molecules, particularly CD59. The occurrence of subclinical thrombosis in PNH patients has not been previously studied using modern imaging techniques. B-type natriuretic peptide (BNP) has been shown to increase in proportion to right ventricular dysfunction in pulmonary hypertension. *Aims.* To evaluate the incidence of subclinical thrombosis in PNH. *Methods.* PNH patients were evaluated with a comprehensive state-of-the-art MRI protocol (which included the use of both blood pool and conventional Gadolinium based contrast agents) for the detection of subclinical thromboses and its sequelae. The detailed protocol consisted of: (a) lung perfusion and pulmonary MRA, (b) cardiac MR - including quantitative studies of both ventricles, right heart flow dynamics and delayed enhancement for the detection of left ventricular damage, and (c) abdominal MR for the assessment of hepatic and portal venous systems and kidneys. Plasma BNP levels were measured directly by immunoassay. *Results.* 10 PNH patients (median age 31.5 yrs) with large PNH clones but without previous clinical evidence of venous or arterial thrombosis underwent imaging. Five (50%) of the patients were on primary anticoagulant prophylaxis with warfarin. There was evidence of significant renal hemosiderosis, which was distributed throughout the cortices, in 9/10 patients. Two patients had small myocardial scars suggestive of previous unsuspected ischemic damage. Six patients had subsegmental perfusion defects mainly distributed in the peripheries of the lung fields indicative of previous small pulmonary emboli. No such subclinical thromboses would be anticipated in an age-matched control population. 8 patients had mildly reduced right ventricular ejection fractions (mean 42.2±1.8%; normal range 48-63%). The plasma BNP level was high in all 10 patients (median 29.4 pmol/l; range 18.7-373.90; normal subjects 4.89±1.00 pmol/l). No intra-abdominal defects were iden-

tified with the current protocol. *Summary.* we identified abnormalities suggestive of previous subclinical thromboses in 6 of 10 hemolytic PNH patients by high-resolution MR imaging, including in patients on primary prophylaxis with warfarin. Effective prevention of thrombosis is an important aspect of the therapy in PNH.

0067

THE INCIDENCE AND PREVALENCE OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) AND SURVIVAL OF PATIENTS IN YORKSHIRE

A. Hill,[1] P.J. Platts,[2] A. Smith,[2] S.J. Richards,[1] M.J. Cullen,[1] Q.A. Hill,[1] E. Roman,[2] P. Hillmen[1]

[1]Leeds General Infirmary, LEEDS; [2]University of York, YORK, United Kingdom

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired clonal stem cell disorder characterized by the expansion of a population of blood cells deficient in glycosylphosphatidylinositol (GPI) linked proteins. This results in the classical clinical features of intravascular hemolysis and thrombosis. PNH is known to be a rare disorder, but its incidence and prevalence have so far been poorly defined with very few studies. *Aims.* To better define the incidence and prevalence of PNH. *Methods.* Survival data was collected on all patients diagnosed with PNH in the strategic health authorities of North and East Yorkshire, Northern Lincolnshire and West Yorkshire between January 1991 and July 2006. All patients were diagnosed by flow cytometry for GPI-linked antigens on red cells and neutrophils at a single reference laboratory (HMDS). *Results.* The population of the study region is 3,742,835 (based on the 2001 census of Britain). 76 PNH patients were diagnosed during this time period giving an incidence of 0.13/100,000/year. Based on incidence and survival rates, the estimated 15 year prevalence of PNH is 1.59 per 100,000 resulting in a predicted prevalence of 59 patients in the study region. We have previously demonstrated that a neutrophil clone size >50% is a predictor of increased thrombotic risk; the current study predicts that 25% of patients will have >50% PNH neutrophil clone size, 43% with >10%, and 82% with >1%. Platelet count $>100\times10^9$/L has been used as a criteria to consider primary prophylactic anticoagulation in PNH patients with substantial hemolysis if the neutrophil clone size is >50%. In the current study, the platelet count is $>100\times10^9$/L in 32% of patients and <30 x 109/L in 27%. The primary clinical manifestation of PNH is intravascular hemolysis and although levels of hemolysis vary considerably between patients even those with relatively small PNH clones will have some degree of hemolysis. Levels of LDH (a sensitive marker of hemolysis) were elevated above the upper limit of the normal range in 82.5% of patients. Of the 59 patients in the study region, 33% reported hemoglobinuria. Overall survival was 78% with a median follow-up of 6.25 years (range 0 to 15 years). Survival was compared between patients with a) hemoglobinuria (89%) vs. those without (76%); b) neutrophil clone size 50% (81%) vs. <50% (80%) and c) Platelet counts $<30\times10^9$/L (61%) vs. 30×10^9/L (86%) by univariate analysis. Hazard ratios and 95% confidence intervals were estimated using Cox s proportional hazards model adjusted for age and sex. Worse survival was only significantly predicted by a platelet count $<30\times10^9$/L (log rank test, p=0.008). *Conclusions.* With a population of 57,105,375 (2001 census of Britain), Great Britain should have an estimated 75 new cases of PNH per year and a predicted prevalence of 908 patients. The USA will therefore have 4713 cases of PNH based on its July 1, 2005 census bureau population estimate of 296,410,404. This study is the first to accurately report the incidence and prevalence of PNH in a given population in a well-defined geographical area.

THIOL-DEPENDENT FORMATION OF LECTIN-INDUCED NEUTROPHIL AGGREGATES

G. Gusakov,[1] I.V. Gorudko[2]

[1]Institute of Applied Physics Problems, MINSK, Republic of Belarus; [2]Belarusian State University, MINSK, Rebublic of Belarus

Background. Recruitment of circulating leukocytes to vascular endothelium requires multistep adhesive and signaling events including selectin-mediated attachment and rolling, leukocyte aggregation and activation and others. *Aims.* To evaluate the significance of thiol-dependent signaling for stable aggregate formation, the aggregation/dissociation of neutrophils initiated by two crosslinking plant lectins, namely Viscum album agglutinin (VAA) and by potato lectin Solanum tuberosum (STA) in the presence of sulfhydryl agent N-ethylmaleimide (NEM) were comparatively studied. *Methods.* Cell aggregation/disaggregation was measured with the methods of light transmission and optical microscopy. For analysis of mechanisms of cell aggregate formation by lectins we used the method of haptenic-sugar-resistant (HSR) intercellular contacts identification.[1] *Results.* It was found that despite intimate cell contacts in the neutrophil aggregates by N-acetyl-D-glucosamine-specific lectin STA and galactose-specific lectin VAA only the later led to establishment of HSR complexes. NEM concentration-dependently inhibites VAA-induced HSR-contacts in cell aggregates. The treatment of neutrophils by NEM increases in a dose-dependent manner rate and degree of STA-induced aggregation and induces the formation of HSR-contacts in neutrophil aggregates by STA. *Conclusions.* The ability of NEM to modify lectin-dependent formation of neutrophil aggregates supports the importance of thiol-dependent signaling for this process. The obtained differences in the mechanisms of action of NEM are determined apparently by type of glycoreceptor involved in the adhesion interactions.

HLA-DRB AND DQB1 GENES IN PREDISPOSITION TO APLASTIC ANEMIA

E. Khamaganova, L. Murashova, Y. Zaretskaya

Research Centre for Hematology, MOSCOW, Russian Federation

Background. Aplastic anemia (AA) is considered to be an autoimmune disease with active destruction of blood-forming cells by lymphocytes. Most cases of AA can be pathophysiologically characterized as T-cell-mediated, organ-specific destruction of bone marrow hematopoietic cells. Immunogenetic studies have reported about a strong association between AA and antigen HLA-DR2 (DRB1*15) in different populations, although the exact role of HLA-DR2 in the immune mechanisms of AA remains unclear. Genomic organization of HLA-DR region includes a few group haplotypes (DR51, DR52, DR53, DR1, DR8), which differ not only by encoded products but also in a number of expressed genes (one or two). The aims of present work have been to define the role of different HLA-DRB specificities and the expression of second DRB gene (DRB3, DRB4 or DRB5) in predisposition to AA. *Methods.* 38 AA patients were HLA-A, -B, -C, -DRB1 (3, 4, 5) and -DQB1 typed (2n=76). 328 unrelated donors of blood components were taken as controls (2n=656). HLA class II genes were typed by PCR-SSP. Statistical analysis was performed using exact Fisher's test. The strength of association between HLA specificities and disease was estimated by evaluation of relative risk (RR). *Results.* In AA patients we have found insignificantly increased frequency of HLA-DRB1*15 (0.25 vs 0.128 in controls, RR=2.27) and significantly increased frequency of HLA-DQB1*06 (0.382 vs 0.213 in controls, p<0.05, RR=2.28). The frequencies of HLA-DRB1*01 and HLA-DQB1*0501 were decreased (0.013 vs 0.131 in controls, p<0.01, RR=0.09 and 0.013 vs 0.137, p<0.001, RR=0.08, accordingly). The presence of second expressed DRB gene (DRB1+DRB3 or DRB4, or DRB 5), i.e. group haplotypes DR51+DR52+DR53, was revealed in AA patients more often than in controls (0.973 vs 0.793, p<0.001), and the absence of second expressed DRB gene (in DR1 and DR8 group haplotypes) took place in AA patients rarely than in controls (0.026 vs 0.155, p<0.01). In case of two expressed DRB genes in one DR group haplotype RR of AA development was increased to 9.4 and in case of absence of second expressed DRB gene RR was diminished to 0.14. *Conclusions.* Although DRB1*15 and DQB1*06 contribute to the development of AA, the increased number of expressed DRB genes also can play an important role in predisposition to AA development.

0070

EXPRESSION OF CD203C ON NEOPLASTIC MAST CELLS IN SYSTEMIC MASTOCYTOSIS: COMPARISON TO NORMAL MAST CELLS AND UPREGULATION BY CROSS-LINKING OF THE FCγRI

A. Hauswirth,[1] L. Escribano,[2] R. Nunez,[2] S. Florian,[1] K. Sonneck,[1] G.-H. Schernthaner,[1] W.R. Sperr,[1] A. Vales,[1] A. Orfao,[3] P. Valent[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]Hospital Ramón y Cajal, MADRID, Spain, [3]University of Salamanca, SALAMANCA, Spain

Background. In patients with systemic mastocytosis (SM), several activation-linked cell surface antigens such as CD2 or CD25, are *overexpressed* on neoplastic mast cells (MC) compared to normal MC, and thus can be employed as diagnostic parameters. The ectoenzyme E-NPP3 (CD203c) is a novel activation-linked basophil antigen that is expressed at low levels on normal MC. *Methods.* Using multicolor flow cytometry,

we examined the expression of CD203c on bone marrow MC in 85 patients with SM, in normal bone marrow (n=38), and in primary lung MC (n=3). Lung MC or neoplastic MC were incubated with an anti-IgE antibody or stem cell factor before being examined for CD203c expression. In patients with ASM or MCL, we examined expression of CD203c-mRNA in highly purified FACS sorted MC by RT-PCR. *Results.* In patients with SM, MC expressed significantly higher levels of CD203c compared to normal bone marrow. There were no significant differences in expression of CD203c among the SM variants analyzed, although slightly lower amounts of CD203c were detected in those with SM-AHNMD. As assessed by RT-PCR, purified neoplastic MC as well as HMC-1 cells were found to express CD203c mRNA. Incubation of lung MC or neoplastic MC with anti-IgE resulted in upregulation of expression of CD203c. However, in patients with SM with anaphylaxis, MC did not exhibit higher baseline levels of CD203c compared to SM patients without anaphylaxis. *Conclusions.* CD203c is a novel activation-linked MC antigen, that is upregulated in response to IgE receptor cross-linking and is overexpressed on neoplastic MC in SM.

0071

RESULTS OF IMMUNOSUPRESSIVE THERAPY IN CHILDREN WITH SEVERE APLASTIC ANAEMIA. REPORT POLISH PAEDIATRIC LEUKAEMIA AND LYMPHOMA STUDY GROUP

K. Pawelec,[1] M. Matysiak,[2] E. Niewiadomska,[2] J. Stefaniak,[3] J. Kowalczyk,[3] E. Zalecka-Czepko,[3] W. Balwierz,[3] K. Szmyd,[3] A. Chybicka,[3] H.B. Bubala,[3] D. Sonta-Jakimczyk,[3] A. Krauze,[4] A. Kurylak,[3] M. Wysocki,[3] M. Kaczmarczyk-Kanod,[3] J. Wachowiak,[3] I. Karolczyk,[3] M. Stolarska,[3] J. Pergud-Pogorzelski,[3] T. Urasinski,[3] E. Leszczynska,[3] M. Krawczuk-Rybak,[3] M.W Wlazlowski,[3] A. Balcerska[3]

[1]Medical University, WARSAW; [2]Dep of Paediatric Hematology/Oncology, WARSAW; [3]Department of Paediatric Hematology and, LUBLIN; [4]Department of Paediatric Pulmonology, WARSAW, Poland

Introduction. Bone marrow transplantation from HLA identical family donors is the treatment chosen for children with severe aplastic anaemia (SAA). When no donor is available, combined immunosuppressive therapy is given. *Aim.* evaluation of results immunosupressive therapy in children with severe aplastic anaemia. *Material and Methods.* SAA was recognised in 85 children (31 girls, 54 boys) aged 2-17,5 years in the eleven centre Polish Paediatric Leukaemia and Lymphoma Study Group (PPLLSG) in Poland between 1993-2003 years. All patients received protocol according Severe Aplastic Anaemia Working Party of the Europe Bone Marrow Transplant (EBMT) protocol: antilymphocyte globulin or antithymocyte globulin, cyclosporin A, prednisolon and granulocyto- or granulocytomacrophagic-cell stimulation factor was additionally administered during deep neutropenia. Haematological response was evaluated on 84, 112 or 180 day of the therapy. *Results.* complete remission occurred in 43 patients (50,5%), partial remission in 22 (25,4%), no response was obtained in 20 children (23.7%) in 180 day of the therapy. Period of observation was from 12 months to 10.5 years. During this time relapse occurred in 6 patients (7%). We observed 16 deaths: 7 early during the first 3 months of immunosupressive therapy (IS) and 9 after the first 3 months of IS. *Conclusions.* The actuarial survival at 10-years after immunosupressive therapy is 81,2% in our group. Transformation to leukaemia or myelodysplastic syndrome (MDS) was not observed in none of our patients. We notice one case with paroxysmal nocturnal hemoglobinuria (PNH).

0072

PHASE II STUDY OF THYMOGLOBULIN, CYCLOSPORINE, AND G-CSF FOR THE INITIAL TREATMENT OF APLASTIC ANEMIA AND LOW RISK MYELODYSPLASTIC SYNDROME

F. Ravandi, S. Faderl, A. Ferrajoli, G. Borthakur, M. Beran, S Pierce, C. Koller, J. Cortes, H. Kantarjian

University of Texas, M.D. Anderson Cance, HOUSTON, USA

Background. Treatment of aplastic anemia (AA) often involves the use of equine anti-thymocyte globulin (ATG) in combination with cyclosporine. Hematological responses occur in 40% to 50% of patients treated with equine ATG alone. With the addition of cyclosporine, response rates of up to 65%, and 5-year survival rates of over 80% have been reported. Rabbit ATG (Thymoglobulin) is commonly used to treat refractory or relapsing AA patients because of its demonstrated efficacy and a desire to minimize the risk of potentially life-threatening allergic reactions associated with re-administration of equine preparations. It has been previously demonstrated that most patients who received Thymoglobulin after unsuccessful treatment with equine ATG achieved response (Di bonna E, Br J Haematol, 1999). High response rates achieved with Thymoglobulin have also been reported in patients with relapsed AA (Scheinberg P, Br J Haematol, 2006). The efficacy of Thymoglobulin in AA may also be extended to myelodysplastic syndrome (MDS), as several lines of evidence suggest that the underlying autoimmune mechanisms leading to the development of AA may overlap with the disease process in at least a subset of patients with MDS. *Aims and Methods.*We investigated the efficacy and tolerability of the combination of Thymoglobulin, cyclosporine, and G-CSF as a first-line therapy for patients with AA or low-risk MDS. Thymoglobulin 3.5 mg/kg (or 2.5 mg/kg if patients were 55 years or older) was initially administered daily for 4 days. After treatment of the first 10 patients resulted in an acceptable safety profile, the study was amended to allow administration of Thymoglobulin 3.5 mg/kg for 5 days in all AA patients and MDS patients younger than 55. Methyl prednisone (1 mg/kg intravenously) was administered daily for 5 days and was followed by a tapering dose of oral prednisone. Cyclosporine (5 mg/kg), and G-CSF (5 μg/kg) were also administered daily and were continued for up to 3 to 6 months, at the discretion of the treating physician. All patients received prophylactic broad-spectrum antibiotics. *Results.* To date, we have enrolled 17 patients, and 15 (8 with AA and 7 with MDS) have received treatment. The median age was 61 years (range 45-73 years) for AA patients, and 60 years (range, 41-71 years) for MDS patients. The median absolute neutrophil count (ANC) for AA patients was 0.74×10^9/L (range, 0.1-1.0 $\times10^9$/L) and 0.5×10^9/L (range, 0.2-2.5$\times10^9$/L) for MDS patients. The median Hgb for AA patients was 6.9 g/dL (range, 3.9-7.9 g/dL) and for MDS patients was 8.1 g/dL (range 6.4-10.7 g/dL). The median platelet count for AA patients was 10×10^9/L (range, 0-153$\times10^9$/L) and for MDS patients was 10×10^9/L (range, 6-16$\times10^9$/L). Flow cytometry for a PNH clone was negative in all patients. Seven patients (4 with AA and 3 with MDS) were positive for HLA-DR15. All AA patients had diploid cytogenetics; 5 MDS patients were diploid and 2 had cytogenetic abnormalities (-18 and add{18p}). Seven of 8 (87.5%) patients with AA have responded including 3 CRs, 3 PRs and 1 HI. One patient with MDS had a CR. Cytopenias and neutropenic fever were the only grade 3 or 4 side-effects observed. Other side-effects (grade 1 and 2) included infusion-related reactions, rash, myalgias, hypomagnesemia, elevation of serum creatinine, and hyperbilirubinemia. *Conclusions.* The combination of Thymoglobulin, cyclosporine and G-CSF is safe and effective in the first-line treatment of AA and has activity in low-risk MDS.

0073

LEAD-INDUCED ANEMIA CAUSED BY THE SAME AYURVEDIC FORMULATION IN BELGIAN PATIENTS

L. Creemers,[1] M. Van den Driessche,[1] M. Moens,[1] A. Van Olmen,[1] M. TSyen,[2] J. Verschaeren,[2] J. Moerman[1]

[1]Imelda Hospital, BONHEIDEN, Belgium; [2]St. Jozef Hospital, TURNHOUT, Belgium

Background. An almost forgotten, but still existing cause of normochromic normocytic anemia is intoxication by lead. Heavy metals, in particular lead, have been a regular constituent of traditional formulations like Indian Ayurvedic medications. Since the renewed public interest in complementary and alternative medicines, cases of lead poisoning are emerging around the world. To our knowledge, these are the first reported cases in Belgium. *Case report.* Two Belgian women, both about 40-years old, presented at the emergency department of their hospital with abdominal discomfort. Laboratory investigation showed a normochromic normocytic anemia with hemoglobin levels of 10.0 and 8.1 g/dL respectively. No explanation for the anemia and abdominal pain was found after extensive clinical, endoscopic and radiological investigation. Suspicion of a lead intoxication was based on the prominent basophilic stippling of erythrocytes, both observed in the peripheral blood smear and the bone marrow aspirate. Both patients' blood lead levels were dangerously high, 80 and 75 μg/dL respectively. Despite the risk to develop an encephalopathy and nephropathy at these levels, no clinical abnormalities could be found. Upon further questioning both patients admitted to take some Ayurvedic medications. Toxicological analysis revealed that, in both, the same orange-red pills contained a remarkable high amount of lead, namely 31 mg per tablet. *Discussions.* Traditional remedies have become more and more popular in industrialised countries. One of the patients recently travelled to India where Ayurvedic medications are widely available. However, in both cases, the lead intoxication was caused by the same Ayurvedic formulation, prescribed in Belgium by an Indian *healer*. The Belgian Federal Agency for the Safety of the Food Chain has been notified. Subsequently, three

new cases of lead poisoning due to the same medication also were reported. *Conclusions.* Health care workers should be aware of the potential health risks posed by some traditional or folk remedies. Although in general, these products are believed to be safe, they may contain hazardously toxic amounts of heavy metals, particularly lead. Also patients have to know that not all substances found in nature are harmless. Under-reporting of consumption of these *herbal* medicine products may be substantial indicating how important it is for physicians to include questions about traditional remedies. Furthermore, governments should take measures to protect the public from potentially harmful products like Ayurvedic formulations.

0074

STROMAL CELLS ALTERED FUNCTION IN PATIENTS WITH APLASTIC ANEMIA

I. Nifontova, V. Petrova, A. Michaylova, J. Drize

National Hematology Reseach Centre, MOSCOW, Russian Federation

Background. The cause of hematopoiesis dysfunction during aplastic anemia (AA) is not fully known. A few assumptions were made to explain the alterations occurred. Ineffective hematopoiesis could be caused both by disordered interactions between hematopoietic stem cells (HSC) and stromal cells and alterations in HSC or stromal microenvironment itself. *Aims.* The goal of this investigation was to characterize stromal precursors (CFU-F) and mesenchymal stem cells (MSC) of AA patients. *Methods.* CFU-F frequency was calculated using standard assay. Mononuclear bone marrow cells from donors and AA patients were plated into the 25 cm^2-cultivation flasks (106, 5×10^5 and $2{,}5\times10^5$ cells per flask) in α-MEM with 20% of fetal calf serum. Two weeks later the colonies were stained with crystal violet dye. MSC were isolated by cultivating $2{,}5\times10^6$ mononuclear cells from the bone marrow in the 25 cm^2-cultivation flasks in α-MEM with 10% of fetal calf serum Cells were passaged leaving one third on average once in 10 days. To induce adipogenic differentiation MSC were cultivated with isobutyl-1-methylxanthine, dexametasone, indomethacin and insulin. *Results.* There were no CFU-F detected in the bone marrow of 3 out of 15 tested AA patients; 2 out of 15 contained regular-sized colonies, equal to the ones of the donors and in 10 cases the formed colonies were much bigger than the donors' ones judging by size (28,7±1,3 mm^2 versus 9,1±0,5 mm^2 , $p<0.001$). CFU-F frequency in the bone marrow of AA patients was twice as large as in the donor bone marrow (63,5±18.3 and 29,7±5,7 correspondingly), however the difference is insignificant. Total cell production was also more intensive in MSC cultures derived from the bone marrow of AA patients than in the donors' ones. First 4 passages in donor cultures resulted in total $50{,}8\pm1{,}27\times10^5$ cells from one cultivation flask and took 30-60 days, while in AA patients cultures - $60{,}98\pm23{,}9\times10^5$ cells in 30-40 days. After the adipogenic induction MSC from AA patient unlike the donor's one doesn't show changed morphology and an increased number of lipophylic granules. The latter has even decreased in some cases. Obviously there are some alterations of MSC response depending on the type of inductor. *Conclusions.* The data obtained display apparent changes in stromal cells function from the bone marrow of AA patients. The increase in CFU-F frequency and size of the colonies could be a consequence of alterations in the expression level of such genes as FGF, BMP4, HGF etc, and needs further investigation. The depression of hematopoiesis often leads to negative changes in the stromal microenvironment. Observed improvement in MSC growth in culture together with its differentiation potential distortion might be an evidence of both the initial damage of stromal cells and it's secondary alteration due to profound bone marrow aplasia. In any case when analyzing the pathogenesis of aplastic anemia one should necessarily take into the consideration the changes occurred in stromal microenvironment of the patients.

ALTERATIONS IN OSTEOBLASTIC AND VASCULAR NICHES REVEALED IN ADHERENT CELL LAYERS OF LONG-TERM BONE MARROW CULTURES FROM PATIENTS WITH APLASTIC ANEMIA

T. Petrova

National Haematology Research Centre, MOSCOW, Russian Federation

Background. Up to date the exact pathogeneic mechanism of acquired aplastic anemia (AA) is still unknown. Beside immune-mediated destruction of marrow hematopoietic progenitor/stem cells (HSC) recent scientific data suggest that disturbed interaction between bone marrow (BM) stromal microenvironment and HSC may cause this disorder. In our previous studies we have shown that expression of genes regulating BM niches is changed in adherent cell layers (ACLs) of AA patients as compared with donors. Expression of Ang-1 - one of genes regulating self-renewal and quiescence of HSC in osteoblastic niche in BM was decreased in ACLs of AA patients. Expression of genes regulating vascular niche was also altered. Expression of VCAM-1 was decreased whereas expression of VEGF was increased in cultures of AA patients. Moreover futher cultivation led to normalization of expression of genes described here in ACLs of AA patients. *Aims*. The aim of this study was to find out whether normalization of gene expression in ACLs of AA patients during long-term cultivation was due to the absence in cultures of inhibiting factors existing in AA patient's organism. *Methods*. Long-term bone marrow cultures (LT-BMC) were established from 5 donors. Blood serum was obtained from 13 AA patients. Serum from healthy donor was used as a control. Serum from different AA patients was added for 3 weeks of cultivation in LT-BMC of donors in amount of 10% from the total media volume once a week. Gene expression analysis was made after 3 and 6 weeks of cultivation of donor cultures. To characterize alterations in the expression of several genes in ACLs after serum administration semi-quantitative analysis of RT-PCR products was performed using PhosphoImager Cyclone, Packard Bell (USA) after Southern blot hybridization with appropriate sequences. The expression level of β-actin was used as a normalization factor. *Results.* 7 of 12 samples of blood serums derived from AA patients significantly decreased the expression of Ang-1 in ACL's of donors administered with these serums separately. Expression of VCAM-1 also decreased in donor cultures treated for 3 weeks with 9 of 12 serum samples. Moreover expression of VEGF increased in ACL's of donors administered with 12 of 13 serum samples separately. Tendency in changes of gene expression in this experiment coincided with our previous studies of gene expression in ACL's of AA patients. *Summary/Conclusions*. Serum of AA patients contains some factors that change functioning of BM stroma *in vivo* and correspondingly gene expression in ACL of donors administered with AA patient's serum *in vitro*.

FURTHER CHARACTERIZATION OF THE CYTOKINE PROFILE IN ACQUIRED APLASTIC ANEMIA

J. Svahn,[1] C. Dufour[1] E. Ferretti,[1] M. Van Lindt,[2] D. Longoni,[3] M. Pillon,[4] A.P. Iori,[5] F. Bagnasco,[1] U. Ramenghi,[6] A. Bacigalupo,[2] A. Locasciulli,[7] A. Misuraca,[8] M. Lanciotti,[1] S. Pigullo,[1] V. Pistoia,[1] V. Pistoia,[1] A. Corcione[1]

[1]Gaslini Childrens Hospital, GENOVA; [2]San Martino Hospital, GENOVA; [3]San Gerardo Hospital, MONZA; [4]University of Padova, PADOVA; [5]La Sapienza University, ROMA; [6]Regina Margherita Hospital, TORINO; [7]San Camillo Hospital, ROMA; [8]Pausillipon Hospital, NAPOLI, Italy

Background. Myelosuppressive cytokines TNF-α and IFN-γ act as final effectors of apoptosis in haematopoietic cells in Acquired Aplastic Anemia (AAA). Combined Immunosuppression (IS) with ATG and CyA improves haematopoiesis in most patients but has a relapse rate of about 30%. *Aims.* To characterize the role of TNF-α, IFN-γ and IL-4 in the clinical course of AAA treated with combined IS. *Methods.* A first group of 59 subjects, 42 in Active Disease (AD) (onset, relapse, never responding to IS) and 31 in Non Active Disease (NAD) (responding to IS), median age 15 years (range 2-56 years) was tested for TNF-α, IFN-γ and IL-4 expression in $CD3^+$ and in $CD14^+$ marrow cells. Twentynine subjects (18 AD and 19 NAD) were also tested for BFU-e growth after block of TNF-α and/or IFN-γ in culture system. A second group including 21 patients, median age 10 years (range 2-32) was prospectively tested for TNF-α, IFN-γ and IL-4 expression in $CD3^+$ marrow cells at diagnosis and at response evaluation time (RET) after IS. *Results.* First group= IFN-γ and IL-4 were not differently expressed in $CD3^+$ and in $CD14^+$ marrow cells of NAD vs AD patients. TNF-α was more expressed in CD3+ and in $CD14^+$ cells of AD than of NAD patients without significant difference. After blocking TNF-α and IFN-γ in culture systems BFU-e incremented in AD patients and, significantly ($p<0.05$), in NAD patients, while not incrementing in normal controls, thus suggesting that a residual TNF-α and IFN-γ activity was still present particularly in the marrow of patients responding to IS. This finding led us to investigate prospectively the kinetics of these cytokines in a second group of AAA patients. *Second group.* The expression of TNF-α and IFN-γ at diagnosis was not different in patients who at RET were Responders vs patients who were Non Responders to IS. The expression of TNF-α and IFN-γ (median absolute number of $CD3^+$ marrow cells expressing cytokine in the cytoplasm) was significantly lower at RET (443 for TNF-α and 590 for IFN-γ) vs Diagnosis (1368 for TNF-α, 1028 for IFN-γ) in Responders (p 0.02). No

significant difference was found at RET vs Diagnosis in Non Responders. IL4 was significantly lower at RET (1324) vs Diagnosis (4748) (p 0.003) in Non Responders but not in Responders. *Conclusions.* 1.TNF-α and IFN-γ were confirmed to be over-expressed in marrow of both AD and NAD AAA patients. 2. TNF-α and IFN-γ decline more in patients Responding vs Non responding to IS. 3. Myelosuppressive cytokines remain in the marrow also of patients who respond to IS. This smouldering activity may contribute to relapse in case of immune attack reactivation. 4. The reduced expression of IL-4 in may contribute to the disease by not counterbalancing the Th1 polarization in Non Responding patients. Overall these data indicate TNF-α and IFN-γ as crucial effectors of marrow damage in AAA and suggest to strengthen IS with targeted anti cytokine treatments that may reduce the risk of relapse after IS.

0077

HIGH PREVALENCE OF ANAEMIA AMONG FRENCH HOSPITALIZED CANCER PATIENTS: A ONE-DAY CROSS-SECTIONAL SURVEY

S. Castaigne,[1] J.M. Tourani,[2] S. Delaloge,[3] C. Hennequin,[4] M. Zureik,[5] E. Lemarié[6]

[1]Hôpital de Versailles, LE CHESNAY; [2]Hôpital La Miletrie, POITIERS; [3]Institut Gustave Roussy, VILLEJUIF; [4]Hôpital Saint Louis, PARIS; [5]INSERM U700, PARIS; [6]Hôpital Bretonneau, TOURS, France

Objective. To evaluate the prevalence of anaemia (haemoglobin [Hb] <12.0 g/dL) among hospitalized cancer patients in France. *Material and Methods.* A written invitation to participate in a one day survey of anaemia among hospitalized French cancer patients on November 14, 2006, was sent to all practicing hospital-based French oncologists, haematologists and pulmonary specialists (n=4165). 255 physicians provided data. Age, gender, cancer type and treatment, Hb value, type of anaemia and treatment for anaemia were recorded. Unless otherwise specified, data are presented as mean±standard deviation. *Results.* 4,161 patients (mean age, 62.2±14.6 years; males, 53.2%) from 255 hospitals were described. The patients were admitted for chemotherapy (CT) (57.6%), initial staging and follow-up (19.6%), radiotherapy (5.2%), supportive care (22.6%), and/or other (20.6%). 57.8% of patients had a hospital stay >24 hours. 76.9% of patients received cancer treatment (recurrent disease: 44.2%); 42.7% of patients had a performance status of ≥2. 23.8% of patients had haematological malignancies (including lymphoma, 8.9%; and acute leukaemia, 6.3%) and 76.2% had solid tumours (including lung cancer 15.9%; colorectal cancer 14.4%; and breast cancer 12.8%). 57.6% of solid tumours were metastatic. Hb levels ranged from a minimum of 4.2 to a maximum of 18.9 g/dL (11.2±1.9). 63.8% of patients had anaemia (77.3% among patients with haematological tumours; 59.5% in patients with solid tumours). 57.8% of anaemia cases were considered to be related to cancer treatment. 59.1% of patients receiving CT were anaemic. 47.4% of anaemic patients were not being treated for their anaemia. Among patients receiving 1 or more treatment for anaemia, the treatments included transfusion (28.5%), erythropoietin stimulating protein (27.0%), and nutritional supplements (iron and/or vitamins) (19.1%). Further analysis of patients not treated for anaemia is underway. *Conclusions.* These results confirm the findings of ECAS, a large European survey of anaemia in cancer patients. Better identification of the causes of anaemia in cancer patients may optimize patient care. Detailed data on haematological patients will be presented.

0078

INTRAVENOUS IRON IMPROVES RESPONSE RATES TO RECOMBINANT HUMAN ERYTHROPOIETIN IN ANAEMIC PATIENTS WITH HAEMATOLOGICAL MALIGNANCY ON CHEMOTHERAPY WHICH IRON PARAMETERS TO USE?

P. Greaves,[1] S. Agrawal,[1] C. Lim,[1] C. Poole[2]

[1]St Bartholomew's Hospital, LONDON; [2]Threesixtydegree Research Ltd, CARDIFF, United Kingdom

Background. Recombinant human erythropoietin (rhEpo) may be used to avoid transfusion and improve quality of life in the anaemia of cancer. Poor response rates to rhEpo are a factor contributing towards its poor uptake in clinical practice. Supplementation with intravenous iron improves response rates to rhEpo. Biochemical markers of iron status may guide rational use of iron supplementation, but they are often unreliable, being altered by the same factors that disrupt iron metabolism and contribute to the anaemia of malignancy. Functional iron deficiency (FID) is a status whereby iron stores are adequate by biochemical parameters but rendered inaccessible to erythropoiesis, perhaps through cytokine dysregulation. *Aims.* ASH/ASCO-based guidelines and a protocol-based approach to the use of intravenous iron and rhEpo in the treatment of non-myeloid haematological malignancy have been used in our centre for the last 4 years. Monitoring of several biochemical iron status markers was integral to the protocol. The aim was to determine which iron parameters most consistently predicted FID and hence the need for intravenous iron. *Methods.* A prospective audit was carried out of patients with non-myeloid haematological malignancy on chemotherapy and who were anaemic and receiving rhEpo. Intravenous iron supplementation was based on the following iron parameters: haemoglobin, mean corpuscular haemoglobin, serum ferritin, transferrin saturation, zinc protoporphyrin (ZPP), reticulocyte count and reticulocyte haemoglobin concentration (CHr). Measurements were made at baseline, weeks 4 and 8, then as indicated by a suboptimal haemoglobin (Hb) response. The data were examined to determine which measures most frequently triggered the addition of intravenous iron at baseline (indicating FID) and which measures most frequently indicated the development of FID during rhEpo therapy, leading to later addition of intravenous iron. *Results*. The iron status indices of 54 patients receiving rhEpo were analysed. 68% had myeloma, 17% CLL, 6% Waldenstrom's macroglobulinemia and 9% other non-Hodgkin's lymphoma. Their mean baseline haemoglobin was 9.2 g/dL. 50% of patients received intravenous iron. Abnormal baseline ZPP was most frequently the iron-deficiency trigger for commencing intravenous iron supplementation on first instigating rhEpo therapy. In patients started on rhEpo alone, the development of functional iron-deficiency during rhEpo-driven erythropoiesis was best monitored by changes in transferrin saturation and serum ferritin, leading to commencement of intravenous iron. However, in some patients, intravenous iron was instituted in spite of biochemical parameters not themselves indicating iron deficiency, because of downward trends in transferrin saturation and serum ferritin. Intravenous iron commencement enabled rhEpo maintenance doses to be reduced and even discontinued. With this approach, the overall response rate was 90% (81% > 2g/dL Hb increase) and mean Hb increment was 3.25 g/dL. *Summary and Conclusions*. Rational use of intravenous iron to support rhEpo therapy in haematological malignancy is possible with readily available, inexpensive biochemical parameters of iron status. ZPP most frequently reflects initial iron depletion, while transferrin saturation and serum ferritin trends best reflect development of functional iron deficiency during rhEpo therapy.

0079

SEQUENTIAL MONITORING OF ERYTHROCYTE HEMOGLOBINIZATION AND IRON MARKERS DURING R-HUEPO THERAPY IN ANEMIC PATIENTS WITH MULTIPLE MYELOMA AND LYMPHOMA

E.K. Katodritou,[1] E. Verrou,[1] D. Kapetanos,[1] A. Banti,[1] C. Kartsios,[1] D. Mihou,[1] V. Gastari,[1] D. Markala,[1] S. Effraimidou,[1] A. Lazaridou,[1] E. Terpos,[2] K. Zervas[1]

[1]Theagenion Cancer Center, THESSALONIKI; [2]251 General Airforce Hospital, ATHENS, Greece

Background. Recombinant human erythropoietin (r-HuEPO) stimulates erythropoiesis and increases iron demands in the erythroid marrow leading to functional iron deficiency (FID). The development of FID is an important cause of r-huEPO unresponsiveness in anemic patients with multiple myeloma (MM) and lymphoma. Close monitoring of sensitive markers of erythrocyte hemoglobinization and iron status are useful in recognizing FID early in the course of r-huEPO treatment. *Aims.* The aim of this study was to monitor the sequential alterations in erythrocyte hemoglobinization (EH) and iron markers in order to recognize the development of FID early in the course of r-huEPO treatment, in anemic patients with MM and lymphoma. *Methods.* Fourty-one patients with a median age of 71 years (range 18-84) with symptomatic MM or lymphoma and disease related anemia, were enrolled. All patients received epoietin β at a dose of 30.000IU/wk for 6 consecutive weeks. The evaluated parameters of iron status and EH, were: serum ferritin, transferrin saturation (TSAT%), soluble transferrin receptor (sTfR), the ratio of sTfR to the logarithm of ferritin (sTfR-F index), the percentage of hypochromic erythrocytes (HYPO%) and reticulocyte haemoglobin content (CHr). These parameters were evaluated in serial measurements at baseline and on weeks 1, 2 and 6. The gradual development of FID during sequential weeks was indicated by an increase in HYPO% and sTfR-F index and a reduction in CHr and TSAT%. Statistical analysis was performed with paired samples Wilcoxon test and correlations with the Spearman's test. *Results.* HYPO% and sTfR-F index gradually increased during all sequential measurements showing statistical signif-

icance, from baseline to week 6 (p<0.001). CHr was significantly decreased between baseline and weeks 2 and 6, as well as between week 1 and 6. In contrast, TSAT% was significantly decreased from baseline to week 6 and from weeks 1 and 2 to week 6 (p<0.001). HYPO% and sTfR-F index changes between baseline and week 6 were positively correlated (p<0.01) whereas CHr was negatively correlated with HYPO% and sTfR-F index (p<0.01). *Conclusions.* These results indicate that FID is gradually observed early in the course of r-HuEPO treatment in anemic patients with MM and lymphoma. Sequential monitoring of sensitive erythrocyte hemoglobinization (CHr and HYPO%) and iron status markers (sTfR-F index and TSAT%) is very useful for the early recognition of FID during r-huEPO therapy. This could help to optimise r-huEPO treatment by using intravenous iron in a rational manner, avoiding the risks of inappropriate iron co-administration.

RIBOSOMAL PROTEIN S24 GENE ANALYSIS IN DIAMOND BLACKFAN ANEMIA IN ITALY

P. Quarello,[1] E. Garelli,[2] M.F. Campagnoli,[2] A. Carando,[2] A. De Fanti,[3] R. Caruso,[4] I. Dianzani,[5] U. Ramenghi[2]

[1]University of Torino, TORINO; [2]Pediatric Dept, University of Torino, TORINO; [3]Hematology Dept, University of Parma, PARMA; [4]Hematology Dept, Bambin Gesù Hospital, ROMA; [5]University of Eastern Piedmont, NOVARA, Italy

Background. Diamond Blackfan anemia (DBA; MIM 105650) is a rare, pure red cell aplasia of childhood due to an intrinsic defect in erythropoietic progenitors. Somatic malformations are present in about 40% of patients. Although the vast majority of cases are apparently sporadic, 10-20% show an autosomal dominant pattern of inheritance. DBA is clinically heterogeneous, and within the affected families anemia may be mild or absent; some patients may show only increased mean corpuscular volume (MCV) and/or elevated erythrocyte adenosine deaminase activity. Approximately 25% of patients carry heterozygous mutations in the RPS19 gene which encodes for a structural ribosomal protein. Recently, Gazda et al. identified mutations in ribosomal protein S24 (RPS24) in 2% of patients. These data strongly suggest that DBA is a ribosomal disease. *Aims.* Our aim was to analyze the RPS24 gene in Italian DBA patients. *Methods.* We have collected DNA of 110 Italian unrelated patients with DBA; in 25 of them we documented a RPS19 mutation. So far we have sequenced exons and intron-exon boundaries of RPS24 in the 85 patients without a mutation in RPS19. Enzymatic digestion was performed to search for the mutation in all the available family members of one mutated patient and in 50 healthy subjects. *Results.* We found 2 new changes in the RPS24 gene. A missense mutation (371nt A>G) in exon 4 causes a non-conservative amino acid substitution that results in replacement of an asparagine with a serine at codon 124. The patient shows lip and palate cleft, short stature and is steroid-dependent. The mutation was inherited from her healthy father, and it was also found in a healthy sister. Incomplete penetrance has been reported also for RPS19 mutations. The second mutation is a deletion of codon 22 in exon 2 (64-66delCAA). The patient does not show somatic malformations or short stature; he is now transfusion dependent. No other members of his family have been analyzed so far. The mutations were not identified in 100 normal chromosomes. *Conclusions.* We have identified 2 new mutations in RPS 24 in Italian DBA patients. The prevalence of RPS 24 mutations in the population matches that found in US patients by Gazda *et al.* 2006. Although these mutations are not a common polymorphisms further data are needed to demonstrate their role in the pathogenesis of DBA.

0081

APLASTIC ANAEMIA: MANAGEMENT CONSTRAINS IN ZARIA, NIGERIA

A. Babadoko,[1] S. Ahmed[2]

[1]University Teaching Hospital, ZARIA; [2]Department of Histopathology, AHMADU BELLO, Nigeria

Background. Aplastic Anaemia (AA) is one of the bone marrow failure syndromes characterized by pancytopenia with a hypocellular marrow, often *empty bone* marrow in the absence of foreign cells. It can be inherited or acquired and definitive treatment consists of allogeneic hemopoietic stem cell transplantation (HSCT) or immunosuppression. *Aim.* To assess some diagnostic and treatment constrains in a resource limited setting with a view to raising awareness towards the formulation of an AA policy and consequent establishment of stem cell transplantation facility in Nigeria. *Methods.* Over a 4 year period (March 2002 to December 2006), a total of 309 patients had bone marrow studies out of which only 14 had Clinical and bone marrow histological features consistent with AA. Prospective clinic based assessment of patients was carried out. Blood cell count was carried out by standard manual methods (no automated haematology analyzer). All the patients were seronegative for transfusion transmissible viruses (HIV, Hepatitis B and Hepatitis C). Bone marrow studies include both aspiration cytology and trephine biopsy, normal marrow cytogenetics and immunophenotying could not be determined. Bone marrow microvascular density could not be done due lack of expertise on such diagnostic tool. Ferrokinetic studies were also not done due to lack of radiolabelled isotopes. The modality of specific treatment was the use of steroids and cyclosporin, other immunosuppressive agents such as Antilymphocyte Globulin, Androgens, Erythropoietin and haemopoietic growth factors were not available. Achieving cure with HSCT is still far from our reach. *Results.* Adult male patients predominate, with a male to female ratio of 1.6:1. Patient's ages range from 18 to 67 years. One childhood AA was reported in a 5 year old boy. Transfusion dependence was the commonest mode of presentation in 85.7% of the patients while the remaining 14.3% presented with epistaxis. The mean haematological parameters at presentation were packed cell volume of 0.14L/L, white cell count of 2.2×10^9/L, platelet count of 78×10^9/L and a corrected reticulocyte count of 0.02%. Management consists largely of supportive care with blood transfusions; packed red cells for anaemia and fresh whole blood when platelets are required in bleeding patients as there are no cell separators to produce platelet concentrates. Specific therapy was with prednisolone in 3 patients, high dose methylprenisolone (HDMP) in 7 patients, 1 patient had a combination of HDMP with cyclosporin and non in the remaining 3 patients. One patient achieved bone marrow recovery and still alive as at the time of this report, 1 patient had an unstable aplasia, after 1 year she developed a low grade bone marrow lymphoma and died in the following year, 5 patients were lost to follow up and 6 patients had a progressive aplasia with death ensuring within 4 months of diagnosis. Management is hampered by ignorance, poverty, lack of some diagnostic tools and inability to afford the recommended choice of therapeutic agents in a country with a Gross Domestic Product (GDP) per capita of $ 330-348 where 70.2% of the population subsists on less than $ 1 per day. *Conclusions.* Improved outcome might be achieved by health education, provision of basic diagnostic tools, availability/reduction in the cost of standard therapeutic agents and HSCT centre as is obtained in other countries.

Bleeding disorders

0082

ACQUIRED HEMOPHILIA IN URUGUAY (1977–2007) IN MEMORIAM PROF. ROBERTO DE BELLIS

J. Novoa, R. De Bellis

Ministry of Health, MONTEVIDEO, Uruguay

Background. acquired factor VIII inhibitor in a non-hemophiliac patient (acquired hemophilia A), is a rare life-threatening bleeding disorder. Treatment is an emergency and must control hemorrhagic manifestations and ultimate suppression of antibody production. Current management is challenging with the availability of novel agents, but immunosupression could lead the patient to fatal infectious complications. The experience of thirty years in the diagnosis and treatment of this patients in Uruguay is presented. *Methods.* 21 patients were studied from 1977 to 2007 in three medical institutions in Uruguay. Gender: 12 women and 9 men. Age: from 18 to 87 years old (median age 78). To dosage of factor VIII inhibitors we employed in the first years Carol Kasper's tecnique and in the last three years Nijmejen & Kasper technique. *Results.* the underlying condition in these cases were: idiopathic 9, lymphoproliferative disorders (non Hodgkin's lymphoma, chronic lymphoid leukemia, multiple myeloma) 4, PAR 2, puerperal conditions 2, hepatic transplantation 1, lupus erithematosus 2 and metastatic cáncer 1 patient. All of them presented with severe spontaneous haemorrhage. The main areas of bleeding were: central nervous system, calf haematoma, gastrointestinal, cellular subcutaneous, hematuria and oropharinx. Prolonged APTT, and reduced factor VIII:C level was detected. The factor VIII inhibitor titre ranged from 4,5 to 160 Bethesda Units (BU). All received high dose steroids and factor VIII concentrates (cryoprecipitate or recombinant human factor VIII). 7 patients received cyclofosfamide intravenous, and 14 of them intravenous immunoglobulin. One patient received rituximab 375 mg/m^2 during 4 weeks with excelent outcome. Other patient received factor rVII in two oportunities, with very good outcome too. 9 patients died of bleeding complications and 1 ot them of septic shock with normal values of factor VIII: C, in remission. *Conclusions.* Our experience confirms that significant clinical bleeding is the major presenting symptom of acquired hemophilia A. On this serie the most frecquent condition was idiopathic, affecting mainly elderly patients and associated with high mortality due to bleeding or immunosupression. Factor rVII and rituximab were two new options for succesfull treatment but have a very high cost. Treatment must be individualiced in order to obtain the fastest resolution of bleeding but avoiding the consequences of immunosupression that can lead the patient to fatal infections.

0083

EXCLUSION OF HAEMOPHILIA A BY DIRECT MUTATION DETECTION IN TRIGEMINI PREGNANCY

A. Bors, H. Andrikovics, K. Hajdu, J. Bátorfi, M. Török, L. Nemes, A. Tordai

National Medical Center, BUDAPEST, Hungary

Haemophilia A (HA) and haemophilia B (HB) are common X-linked bleeding disorders resulting from the inherited deficiency of coagulation factors VIII (fVIII) and IX (fIX), respectively. Female relatives of patients with haemophilia may be carriers and many of them request carrier status determination and prenatal diagnosis. In the framework of the molecular diagnostics service for haemophiliacs as a tertiary national referral center, since 1998, prenatal diagnostics was required in 42 cases out of 153 HA and 2 cases out of 31 HB affected families (28 male and 16 female fetuses). In cases of male fetuses, cycle sequencing or large gene inversion detection as direct mutation analysis, (in 2 and 12 cases respectively) and linkage analysis using intragenic polymorphisms in 14 cases was used as a method for prenatal diagnosis. Overall, 19 healthy and 9 haemophilia affected male fetuses were diagnosed. Furthermore, we hereby report an unusual case, a 33-year-old obligate HA-carrier woman (fVIII gene, intron 22 inversion carrier) who conceived three embryos during an *in vitro* fertilisation procedure and requested prenatal diagnosis. Transabdominal chorion-villus sampling was performed on the 9th week of pregnancy with successful sample acquisition form all three embryos. Long-distance PCR for intron 22 inversion detection indicated two healthy boys and one carrier girl. Knowing that all of the fetuses are free of HA-manifestation, the couple desisted from reduction. On the 35th week of pregnancy a caesarean section was performed on the bases of comlex indications and a 1950 g and a 2200 g boy and a 2350g premature girl were born. Our results further confirm, that molecular genetic investigations play an important role in haemophilia prenatal diagnostics.

0084

HAEMOSTATIC THERAPY DURING SURGICAL OPERATIONS TO HAEMOPHILIA PATIENTS WITH INHIBITOR

T. Polyanskaya, Y. Zorenko, E. Karpov

Hematological Scientific Center, MOSCOW, Russian Federation

Introduction. We present our experience surgical treatments of haemophilia patients with inhibitor. Haemostatic therapy is one of the leading problems in treatment of haemophilia patients with inhibitor. *Patients and Methods.* In total in our department there were 67 surgical operations to patients with inhibitor. All patients were with sever haemophilia. 68% of them were patients with high responding inhibitors, usually greater than 10 BU. All of them were HCV+. The majority of surgical operations were a high degree of risk, there were: total knee and hip replacement (6), extirpation of pseudotumour (10), osteosynthesis (6), synovectomy (16), ectomy of iliopsoas hematomas with intra-abdominal bleeding (3) and others. To all patients with a high titer before operation carried out plasmapheresis for decrease until inhibitor was not reduced up to 2 BU or lower. We used different hemostatic treatment. The last 3 years haemostatic therapy during the operation realized by preparation Novo Seven - from 120 mkg/kg each two hours per day of operation up to 90 mkg/kg each 4 hours for 9 day, then FEIBA 50 U/kg 2 times day till 14 days. *Results.* In 75% of cases there were good results (positive functional and anatomic results). 12% of cases have become complicated by bleedings. Most of them have been connected with insufficient hemostatic treatment and the expressed local inflammation. Fatal outcomes were not. The best results were when the hemostatic treatment was carried out by recombinant activated factor VII (rFVIIa-NovoSeven) during the operation and the first days after and then by activated protrombin complex concentrate (FEIBA). *Conclusions.* Modern hemostatic therapy in a complex with additional methods allows carrying out the haemophilia patients with inhibitor of surgical operations of any complexity. It is necessary to provide a good hemostasis both during operation, and in the first days after operation. At operative interventions of a high degree of risk hemostatic therapy is better for carrying out NovoSeven or FEIBA.

0085

MANAGEMENT OF HEMOPHILIA IN THREE PREMATURE NEONATES

P. Brons,[1] K. Kraft,[2] R. Verlaak,[3] A. van Heijst[1]

[1]Radboud Univ. Nijmegen Medical Centre, NIJMEGEN; [2]Rijnstate Hospital, ARNHEM; [3]Canisius Wilhelmina Hospital, NIJMEGEN, Netherlands

We describe the management and outcome of hemophilia in three premature infants. Only 3 other patients have been described in literature thus far. Two twins born at 33 weeks of gestation with moderate hemophilia A (factor VIII activity of 2%) were treated with prophylactic factor VIII replacement because of prematurity and the associated increased risk of intracranial hemorrhage. We preferred minimal blood sampling to avoid the insertion of a central venous catheter (CVC). The first born twin received a CVC for only two days for temporary difficult venous access during a clinical suspicious but non proven infection at day 9. He received prohylactic treatment for 17 days and no bleeding complications were observed. Recovery of factor VIII was 94%. No presence of factor VIII inhibitors were found for up the age of 18 months. The second twin developed respiratory distress and an infection with staphylococcus aureus. No bleeding episodes and no cranial hemorrhage were observed until day 7. On day 8 the infant became septic with bacteremia caused by enterobacter cloacae with rapid deteoriation. In the final phase of the septic shock a pulmonary bleeding occurred and a cranial ultrasound showed a intraventricular bleeding. He died on day 8. The third child was a premature infant born at 31 weeks of gestation with prolonged bleeding form a scalp pH-measurement. He was diagnosed with hemophilia B and started with prophylactic factor IX replacement 17 hours after birth. A grade II intraventricular bleeding was found on day 2 and he received intensive replacement therapy to achieve a through factor IX level of 70% for 17 days. A central venous catheter was inserted to avoid continuous access. The mean recovery of factor IX was 46% (range 28%-69%) and the half life time was 5,8 hours. A cerebral ultrasound on day 17 showed no signs of intracerebral hemorrhage and he was discharged at our hospital at day 28. No presence of factor VIII inhibitors were found for up the age of 16 months.

THROMBELASTOGRAPHIC CHART RELIABLE REFLECTION OF HEMOSTATIC IMPACT OF ITP IN CHILDREN

M. Serban,[1] S. Arghirescu,[1] M. Bataneant,[1] M. Lelik,[2] C. Jinca,[1] E. Boeriu,[1] L. Stana,[1] A. Oprisoni[1]

[1]University of Medicine and Pharmacy, TIMISOARA; [2]Spitalul Clinic de Urgenta pt Copii, TIMISOARA, Romania

Background. Immune Thrombocytopenic Purpura (ITP) in children continues to be confronted with life threatening bleedings despite its generally accepted benign evolution. This risk is dependent primarily on the hemostatic efficiency of platelets, rather than the platelet count. *Aims.* Therefore, looking for a supplementary information about hemostatic consequence of thrombocytopenia and taking into account the multiple targets of platelets, we aimed a bedside evaluation of the whole dynamic process of hemostasis by means of thrombelastography (TEG) in ITP patients. *Method.* Our study included 34 patients: 35,29% with severe, 26,47% with moderate, and 14,70% with mild ITP. We analyzed TEG parameters: r (reaction time), k (clot kinetics to reach 20 mm amplitude), Angle α (clot strengthening), MA (maximum aplitude), G (clot strength) in correlation with platelet count and some hemostatic explorations: bleeding time (BT), clot retraction rate (CRR), prothrombin consumption ratio (PCR) and APTT. *Results.* In our study, we assessed the following hemostatic abnormalities ascribed to thrombocytopenia: PCR (p<0,01), CRR (p<0,01), BT (p<0,03); APTT wasn't changed in a significant manner (p=0,3). TEG was very sensitive, reproducible and specific revealing a defining reduction of MA (X=32,32 mm) (p<0,001) and G(X = 2,76) (p<0,001) and a slight prolongation of k (p<0,1). This simple point of care investigation succeded to draw the attention on risky situation even in moderate or mild ITP. *Conclusions.* Minimal tissue factor triggered whole blood TEG provided a valuable bed side tool for the follow-up of the kinetics of hemostasis in ITP patients.

0087

EHLERS-DANLOS SYNDROME A NOT SO UNCOMMON CAUSE OF BLEEDING

S. Dukka, A. Parapia

Bradford royal infirmary, BRADFORD, United Kingdom

Background. Ehlers-Danlos syndrome (EDS) is a group of connective tissue dysplasias which comes to the attention of a hematologist as an unexplained bleeding disorder. The hemorrhagic manifestations can be mild with easy bruising to severe fatal arterial ruptures. *Aims and Methods.* From the year 1986 to 2006, seventy patients with EDS from the haematology database at Bradford Centre for Haemophilia and Thrombosis were reviewed with the aim of analyzing their bleeding manifestations and to correlate the symptoms with any pathological abnormality in the tests for haemostasis. A retrospective analysis of the case notes and the results of the laboratory tests which included Bleeding Time (BT) by Ivy method, Prothrombin Time (PT), Activated Partial Thromboplastin Time (APTT), Platelet Aggregation studies by standard methods and PFA100, VWD screen and coagulation factor assays when appropriate were done. *Results.* Sixty seven of these patients were referred for evaluation of bleeding tendencies and three were detected during screening. All the patients were of Caucasian origin. The age at presentation ranged from eleven to sixty five years (mean age 36.9 years). Majority of them belonged to EDS type I. Bleeding manifestations recorded included easy bruising (39), epistaxis(15), menorrhagia(14), bleeding post dental procedures(7), post trauma(5), post surgical procedures(3).There were 4 major bleeds requiring blood transfusions including post partum haemorrhages(3) and gastrointestinal bleeds(1). The laboratory investigations revealed prolonged PT in two cases and APTT prolongation in one patient. Five out of twenty-nine had a prolonged bleeding time. Platelet aggregometry was done in fifteen patients with reduced aggregation detected in six-one with arachidonic acid and five with collagen. PFA 100 analysis was abnormal with collagen epinephrine in two of the six patients which was not corrected with platelet transfusion .They were found to have normal nucleotides on further evaluation. Three patients had type l VWD. Management of these patients involved supportive treatment with Tranexamic acid. One patient needed factor VIIa for controlling a nasal bleed. The three mild VWD patients responded to DDAVP. *Conclusions.* EDS accounts for a substantial number of patients with bleeding diathesis. In Bradford, Type I EDS, especially the milder variants is the most common form seen. Interestingly, none of the patients in our series were Asians though they contribute to 15% of population. The bleeding tendency is usually mild with easy bruising being the most common. Major bleeds requiring transfusions were rare and there were no fatalities.84% of the patients with EDS had normal haemostasis test results and the few abnormalities found were nonspecific. Three patients had type 1 VWD.Treatment is supportive with Tranexamic acid and avoiding elective surgeries. DDAVP may be helpful and factor VIIa may be needed for severe bleeds.

0088

SUCCESSFUL MANAGEMENT OF AN INFANT WITH KASABACH-MERRITT SYNDROME USING ARTERIAL EMBOLIZATION AND SYSTEMIC DRUG THERAPY

E. Kurekci,[1] B. Ustunsoz,[2] A.A. Atay,[1] N. Balamtekin,[3] D. Hacihamdioglu,[3] Y. Egin[4]

[1]Gulhane Military Medical Academy, ANKARA; [2]Department of Radiology, ANKARA; [3]Department of Pediatrics, ANKARA, Turkey; [4]Department of Molecular Hematology, ANKARA, Turkey

Kasabach-Merritt syndrome (KMS) is a rare life-threatening disorder in which significant thrombocytopenia and consumption coagulopathy are accompanied by rapidly expanding hemangiomas of trunk, extremities and/or abdominal viscera, sometimes associated with bleeding anemia. Many treatments have been tried for this difficult syndrome. These include systemic treatments, such as corticosteroids, interferons, antiplatelet agents, vincristine, as well as local ablation with surgery. We report an infant with severe KMS and successful treatment with combination therapy using steroid, vincristine, interferon (IFN)-α and arterial embolization. A 2-month-old boy presented with rapidly enlarging mass which his parents described as having developed from a 1-2 cm birthmark on her left cheek. Despite treatment with steroids, interferon alfa-2a, vincristine, fresh frozen plasma, platelets, and blood transfusion, the mass increased in size with worsening of the coagulopathy. Systemic drug therapies were continued. At the same time selective left external carotid artery embolization with microparticles was performed. A percutaneous biopsy with 18 G needle was also performed after the embolization. The needle tract was embolized with a liquid embolizing agent for a possible oozing. The diagnosis of Kaposiform hemangioendothelioma was made according to the findings. Kaposiform hemangioendothelioma (KHE) is an aggressive vascular proliferation that has been recognized as a separate entity from other vascular tumors. After ten days of embolization therapy, the coagulopathy was corrected. 1.5 months after the embolization, the mass size was considerably decreased. In conclusion, KMS may be successfully treated with combination therapies consisting of steroid, interferon, vincristine and embolization.

0089

OFF-LABEL USE OF RFVIIA AND ITS CLINICAL EFFECTIVENESS: RESULTS FROM A SCOTTISH NATIONAL AUDIT

P. Gallipoli,[1] M. Robertson,[2] R.C. Tait[1]

[1]Glasgow Royal Infirmary, GLASGOW; [2]Royal Alexandra Hospital, PAISLEY, United Kingdom

Background. Recombinant FactorVIIa (rFVIIa) is licensed to treat bleeding in haemophiliac patients with inhibitors. Several case series and reports and few randomised studies have highlighted its potential value in controlling bleeding in intracerebral haemorrhage (ICH) and massive haemorrhage secondary to different causes. *Aims.* To assess local practice and policy on the issue of rFVIIa for off-label indications in Scotland between January and June 2006. To determine quantity, indications and apparent clinical efficacy of rFVIIa used during the 6-months audit period. To assess possible associations of rFVIIa efficacy with platelet count and coagulation screen before its use. *Methods.* All haematology departments in Scotland were asked to complete a questionnaire. The first part of the questionnaire was directed to ascertain if rFVIIa stocks were available in each acute hospital and if there were clear release procedures for its off-label use; the second part was directed to collect all the clinical and laboratory data on individual issues of rFVIIa during the audit period. Data from a previous similar audit from 2003 were used for comparison. Chi-square testing was used for statistical analysis on categorical variables. *Results.* The questionnaire was returned by 96% of the hospitals (26/27). 88% of the hospitals keep a stock of rFVIIa on site, 46% having a written protocol for its release. In 88%, Consultant Haematologist authorisation is required. Off-label use has increased since 2003 (48 v 34 episodes/year) especially in non-Haemophilia Centre Hospitals. Other than increasing use for ICH, indications have changed little over time, mainly including trauma, gastrointestinal bleedings and cardiovascular surgery. Immediate response rate [RR; defined by either major reduction or cessation of haemorrhage according to subjective clinical assessment], 24-hour survival rate [24SR] and 28-day survival rate [28SR] have not

changed - combined data showing 68% RR, 79% 24SR and 52% 28SR. A high coagulopathy score [CS; scoring 1 point for each of platelet <50 ×10×9/L, fibrinogen <1.0 g/L, and INR or APTTr > 1.5] is associated with non-significant lower RR and 24SR. Combining data from both audits, comparing CS 2-3 v. CS 0-1 by Chi-squared test gives RR of 58% v 78% and 24SR of 62% v 84% (p<0.1 for both). Platelet count <50, alone, is associated with significantly worse RR and 24SR of 45% v 83% (p<0.01) and 60% v 85% (p<0.05) respectively. There were no adverse events related to rFVIIa use reported. *Conclusions.* The current audit shows that most acute hospitals in Scotland keep stocks of rFVIIa on site for emergency use. Off-label use of rFVIIa has increased compared to previous audit because of an increased use in District General Hospitals. This might reflect wider availability of rFVIIa. It has also started to be used for ICH. rFVIIa appears to be safe when used to treat massive blood loss or ICH. It is less effective in patients who are more coagulopathic, particularly if platelets are <50 at time of administration. Overall, despite a high subjective clinical RR of 68%, 28-day survival is poor at about 50%.

0090

DISAPPEARANCE OF HIGH TITRE INHIBITOR IN CONGENITAL HEMOPHILIA A USING RITUXIMAB INDUCTION AND MAINTENANCE

M.J.P. Paloma, A.M. Redondo, J.M. Arguiñano, M.A. Ardaiz, M.C. Mateos, Y. Burguete, M.C. Montoya, F.J. Oyarzabal

Hospital Virgen del Camino, PAMPLONA, Spain

The development of Factor VIII (FVIII) inhibitors is currently the most serious complication in the management of Hemophilia A. Rituximab is a chimeric monoclonal antibody targeting CD20 antigen on neoplastic and normal B cells, approved for use in B cell malignancies as well as rheumatoid arthritis. Its use in other autoimmune diseases remains investigational. Rituximab appears to be an alternative therapy to reduce or eliminate the F VIII inhibitor in selected cases. However, the doses and appropiate schedule, as well as long-term side effects need further investigations. We report the case of a boy with severe Hemophilia A who developed a FVIII inhibitor successfully treated with rituximab, after failure of 2 courses of immune tolerance therapy with recombinant and plasma-derived FVIII. The boy had been diagnosed with severe Hemophilia A (FVIII <1%) at the age of 9 months after he suffered spontaneous hematomas. Prophylactic therapy with recombinant FVIII (Recombinate®, Baxter) was started, but soon after he developed a FVIII inhibitor. The titer of inhibitor was 45 BU at diagnosis. Immune tolerance therapy was started with a daily administration of 150 IU/Kg of the same recombinant FVIII. Thirteen months after, the treatment was stopped due infection of intravenous device and lack of response, since inhibitor level fluctuated ranging from 45 to 350 BU. At the age of 6, a second course of immune tolerance was started with human plasma-derived FVIII (Fanhdi®, Grifols) containing Von Willebrand Factor (200 IU/Kg/day) and intravenous immunoglobulins 1g/Kg/day for 2 days, every 3 weeks. Inhibitor titre remained high, between 30-1120 BU and again, immune tolerance therapy was discontinued after 12 months because of the lack of response. From then until the age of 8 years, he suffered numerous bleeding episodes into target joints. In that moment, Rituximab was commenced in off-label use after parent's informed consent. Immediately prior to starting rituximab, inhibitor titre was 100 BU. Rituximab at 375 mg/m^2 was administered weekly for 4 doses, then monthly for 4 doses and finally every 8 weeks. Therapy with human plasma-derived FVIII containing Von Willebrand Factor (200 IU/Kg/day) was associated from the second dose of rituximab. Inhibitor titre dropped to 2 BU in the first 4 weeks and turned undetectable after the 7th dose; FVIII recovery was 41%. No bleeding episodes have occurred since the start of rituximab therapy, and tolerance has been good, with only one episode of urinary tract infection. In our experience, rituximab has a significant place as rescue therapy of patients with Hemophilia A complicated with inhibitors. Extended or maintenance therapy could be used in cases of failure of induction therapy.

0091

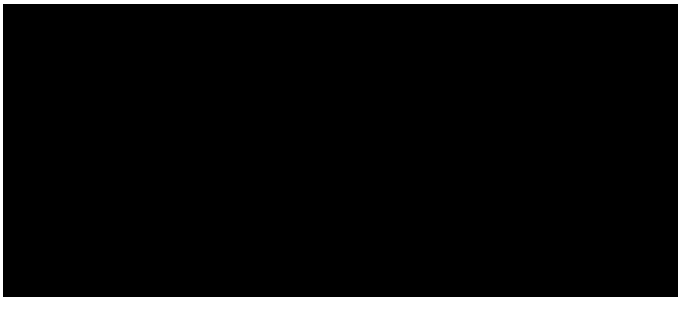
TYPE 2B 'MALMO OR NEW YORK' IS NOT SO RARE AMONG ITALIAN PATIENTS WITH VON WILLEBRAND DISEASE: THE ROLE OF P1266L/Q MUTATIONS OF THE VON WILLEBRAND FACTOR GENE IN SEVEN CASES

L. Baronciani,[1] S. La Marca,[1] G. Castaman,[2] M. Punzo,[1] B. Moroni,[1] B. Scimeca,[1] V. Rubini,[1] G. Cozzi,[1] M.T. Canciani,[1] A.B. Federici[1]

[1]Hemophilia and Thrombosis Center, MILAN; [2]Div. of Hematology, San Bortolo, VICENZA, Italy

Background. Type 2B von Willebrand disease (VWD) is due to a unique gain-of-function variant of von Willebrand factor (VWF) that spontaneously interacts with circulating platelets resulting in loss of VWF high molecular weight multimers (HMWM) in plasma and, in some cases, reduced platelet counts. Diagnosis of 2B is based on increased ristocetin-induced platelet aggregation (RIPA) in patient's platelet rich plasma (PRP). Type 2B 'Malmo or New York' is caused by the mutation P1266L that is associated with increased RIPA, but with normal multimeric distribution in plasma and no thrombocytopenia. *Aims.* To determine the incidence and the molecular defects of this rare VWF variant among a large population of VWD patients regularly followed at two Northern Italian Hemophilia Centers. *Methods.* Criteria for VWD type 2B were those recommended by the ISTH-SSC-SC on VWF. RIPA and multimeric analysis were performed according to standardized methods. Bleeding severity score (BSS) was calculated in all patients enrolled in this study. Sequence analysis of the portion of exon 28 encoding for the A1 domain was performed to identify nucleotide substitutions in all cases where RIPA was <0.8 mg/ml. *Results.* 64 patients from 16 different families satisfied the criteria for VWD type 2B. Seven patients from 3 unrelated families clearly showed normal multimeric distribution in plasma and no thrombocytopenia also after stimuli. Clinical and laboratory parameters are summarized in Table 1. Patients from family A showed five distinct substitutions (3686T>G, 3692A>C, 3735G>A, 3789G>A, 3797C>T), patient B1 two (3789G>A, 3797C>T) and patient from family C three (3692A>C, 3789G>A, 3797C>A) distinct substitutions. Two of these were silent, whereas the other caused the following amino acid changes: three in family A (V1229G, N1231T, P1266L), one in B1 (P1266L) and two in family C (N1231T, P1266Q). Mutations V1229G and N1231T have already been reported, whereas mutation P1266Q is novel. The substitutions found in families A and B correspond to the pseudogene sequence, sustaining the possibility of a gene conversion between the VWF gene and pseudogene. In family C, the nucleotide substitution causing P1266Q mutation does not match the pseudogene sequence and the patients do not show the substitution 3735G>A that is present in the pseudogene. *Conclusions.* We confirm that the substitution of proline 1266 with leucine appears to be the main cause of type 2B *Malmo New York* phenotype while its replacements with a glutamine apparently results in lower VWF activities in family C. Based on these data, gene conversion appears to be more frequent than expected and capable to generate different set of mutations.

Table 1.



0092

EFFICACY AND SAFETY OF HIGHLY PURIFIED VWF/FVIII CONCENTRATES IN THE TREATMENT OF INHERITED VON WILLEBRAND DISEASE: RESULTS FROM THE RETROSPECTIVE ITALIAN STUDY ON 103 CASES

A.B. Federici,[1] M.G. Mazzucconi,[2] G. Barillari,[3] R. Musso,[4] E. Zanon,[5] G. Castaman,[6] R. Targhetta,[7] G. Mancuso,[8] G. Muleo,[9] A. Coppola,[10] M. D'Incà,[11] G. Gamba,[12] C. Latella,[13] A. Borchiellini,[14] L . Valdrè,[15] P. Mannucci[1]

[1]University of Milan, MILAN; [2]University of Rome, ROME; [3]University of Udine, UDINE; [4]University of Catania, CATANIA; [5]University of Padoa, PADOA; [6]S.Bortolo Hospital, VICENZA; [7]University of Cagliari, CAGLIARI; [8]University of Palermo, PALERMO; [9]University of Catanzaro, CATANZARO; [10]University of Naples, NAPLES; [11]Reggio Emilia Hospital, REGGIO EMILIA; [12]University of Pavia, PAVIA; [13]Reggio Calabria Hospital, REGGIO CALABRIA; [14]University of Turin, TURIN; [15]Bologna Hospital, BOLOGNA, Italy

Background. Efficacy of highly purified VWF/FVIII concentrates with standardized VWF:RCo content has been proven in prospective clinical

trials. The aim of this retrospective study is to verify the efficacy and safety of highly purified VWF/FVIII concentrates in treatment and prevention of bleeding in inherited Von Willebrand disease (VWD). *Methods.* 103 patients were treated with study concentrates (Fanhdi and Alphanate) from 2001 to 2006 at 15 Hemophilia Centers according to Italian guidelines for VWD management. 47 males and 56 females, median age 50 years (range 6-83 years), had types 3 (10), 2A (14), 2B (20), 2M (7) and DDAVP-unresponsive 1 VWD (52) with a median bleeding severity score (BSS) of 8 (range 0-27). *Results.* Study drugs were given to treat 113 bleeding episodes in 51 cases and to prevent excess bleeding during 111 surgical procedures in 72 cases with a good/excellent clinical response in 97% (bleedings) and 99% (surgeries). To prevent the recurrence of GI bleeding (8) CNS hemorrhage (1) hemarthroses (1), menorrhagia/urogenital bleeding (6), secondary prophylaxis was also carried out in 16 cases with types 3 (3), 2A (2), 2B (2), 1 VWD (9) all characterized by BSS >6. A regimen of 40 U VWF:RCo/kg every other day or twice a week, given over a median period of 505 days (range 24-1484) totally prevented bleeding in 13 cases, strongly reducing the incidence in the other ones. No adverse reactions occurred in 4.909 infusions for a total of 10.505.000 IU FVIII. *Conclusions.* These results confirm the efficacy and safety of study concentrates not only in the management of bleedings and surgeries but also in secondary prophylaxis in severe inherited VWD.

0093

PHARMACOKINETICS OF THE REFORMULATED B-DOMAIN DELETED RECOMBINANT FACTOR VIII CONCENTRATE USING CHROMOGENIC AND ONE-STAGE ASSAYS WITH POOLED NORMAL PLASMA AND REFACTO LABORATORY STANDARD

C. Santoro,[1] M.G. Mazzucconi,[1] P. Pignoloni,[1] A. Rago,[1] F. Biondo,[1] A. Iorio,[2] F. Ferrante,[2] F. Torelli,[1] G. Agnelli,[2] R. Foà[1]

[1]*Ematologia, ROME;* [2]*Internal and Vascular Medicine, PERUGIA, Italy*

Background. The use of RLS in one stage clotting assay has been proposed to reduce the underestimation of FVIII plasma concentration measurements after infusion of BDD-rFVIII in hemophilia A patients. Both BBD-rFVIII and RLS have been recently reformulated. *Aims.* Aim of this study was to evaluate the performance of reformulated RLS in the measurement of FVIII plasma concentration after infusion of the reformulated BDD-rFVIII. *Methods.* In 13 hemophilia A patients, FVIII <1%, inhibitor <0.6 UB/mL, age >12 years, not on anti-retroviral therapy for HIV, 25 UI/kg of BDD-rFVIII were injected intravenously. Venous blood samples were collected at 0.25, 0.5, 1, 3, 6, 9, 24, 28 and 32 h after the end of the infusion. One-stage clotting assay was performed using a FVI-II immune depleted plasma. The Electrachrome Factor VIII Chromogenic Assay was performed according to the manufacturer's instructions. The reference calibration curves were built using PNP or RLS from Wyeth Pharma gmbh. Pharmacokinetic analysis was performed using a model-independent method fitted with WinNonlin (Pharsight, Inc). Comparisons among assays and standards were performed using an ANOVA model for repeated measures. *Results.* Table 1.

Table 1.

	Chromogenic Assay				One stage assay				
	Refacto ST		Plasma ST		Refacto ST		Plasma ST		
	Mean	SD	Mean	SD	Mean	SD	Mean	SD	P
r2	0.98		0.99		0.97		0.99		
Cmax (U/mL)	0.63	0.14	0.63	0.09	0.60	0.13	0.58	0.13	ns
Tmax minutes)	17	5	18	6	15	0	17	5	ns
Half_life (hours)	9.4	3.8	7.7	4.3	10.4	2.8	13.0	4.7	<.05
AUCinf	431.0	148.0	469.0	166.0	468.0	161.0	575.0	147.0	<.05

Conclusions. We confirm previous results of a better sensitivity of the one stage method for the lowest concentrations of FVIII, with a more accurate evaluation of the terminal half life. Measured Cmax is slightly superior to the expected values and independent from the assay used. The clinical utility of RLS in the evaluation of FVIII concentration after infusion of BDD-rFVIII seems to be lower after reformulation of the product.

Chronic lymphocytic leukemia and related disorders - Biology I

0094

GENE EXPRESSION PROFILING OF PERIPHERAL BLOOD T CELLS IN PATIENTS WITH INDOLENT B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)

K. Kiaii,[1] A. Österborg,[1] K. Mashayekhi,[2] A. Moshfegh,[1] A. Choudhury,[1] H. Mellstedt[1]

[1]*Karolinska Institutet, STOCKHOLM, Sweden;* [2]*Environmantal Change Institute, GALWAY, Ireland*

Background. The impact of nonmalignant cells on the growth and sustenance of the malignant cells in many different cancers is evident. There is substantial evidence that T cell functions were dysregulated in B-cell chronic lymphocytic leukemia (B-CLL) and T cells may contribute to the survival and growth of the leukemic clone. In addition, the absolute number of T cells, largely devoid of antileukemic activity, is elevated in CLL patients. *Aim.* The aim of this study was to delineate genes in T cells of indolent B-CLL patients that may support the growth of the leukemic clone. We have also attempted to identify genes whose dysregulation may be the underlying cause of the observed T cell expansion and aberrant functions. *Methods.* We performed Affymetrix gene array analysis on highly purified peripheral blood $CD3^+$ T cells of treatment-naïve, indolent B-CLL patients (n=5) and compared with multiple myeloma (MM) patients (n=5) and healthy donors (n=5). Microarray results were confirmed with T cells of 14 CLL patients, 6 MM patients, and 10 healthy donors using quantitative real time PCR (QRT-PCR). T-cells were purified using selection with immunomagnetic beads. For the QRT-PCR assay, $CD3^+CD4^+$ and $CD3^+CD8^+$ T cells were analyzed separately. The contamination of monocytes, B cells, and NK cells was <1%. *Results.* The results demonstrate that a large number of genes (356) involved in different cellular pathways and activities including signaling, proliferation control, apoptosis, metabolism, immune response, and cytoskeleton formation are dysregulated in CLL in comparison to MM patients and healthy donors. Three genes that showed the highest upregulation were the chemokines XCL1, XCL2, and the cytokine IFN-γ. CCL4 and CCL5 are two other important chemokines that also were found to be specifically upregulated in T cells of B-CLL patients as well as KLF6 and TRAF1. *Conclusions.* The four highly upregulated chemokines, as well as the other molecules that we have identified, may have an effect on the survival of the neoplastic cells in B-CLL. The results of the present study may be of significance for a better understanding of B-CLL pathobiology and development of therapeutic strategies.

0095

SECONDARY GENETIC EVENTS IN CLONAL CD8+/TCRAB+ LARGE GRANULAR LYMPHOCYTE PROLIFERATIONS

Y. Sandberg,[1] K. Szuhai,[2] D. Tielemans,[1] I. Wolvers-Tettero,[1] E.J. van Gastel-Mol,[1] J.J.M. van Dongen,[1] A.W. Langerak[1]

[1]*Erasmus MC, ROTTERDAM;* [2]*LUMC, LEIDEN, Netherlands*

Background. Expansion of large granular lymphocytes (LGL) is a type of lymphoproliferative disorder that ranges from reactive expanded activator T-cells to T-cell leukemia and shows variable presentation and clinical course. The vast majority concern $CD8^+$/$TCRab^+$ T-LGL lymphoproliferations. The development of T-LGL leukemia is likely to be a multistep process. In T-LGL leukemia the lymphocytes are clonal in nature as evidenced by clonally rearranged TCR genes. Due to various immunogenetic factors an initial polyclonal response results in clonal outgrowth, representing a pre-leukemic state. Secondary genetic events are likely to be essential for transformation of this exaggerated immune response into clinically malignant leukemia. However, well-defined clonal chromosomal aberrations have rarely been reported, whereas little is known about the secondary genetic events leading to clinically malignant $CD8^+$/$TCRab^+$ T-LGL leukemia. *Aims.* To determine genetic aberrations involved in the transformation of persistent clonal $CD8^+$/$TCRab^+$ T-LGL populations into clinically malignant T-LGL leukemia and to obtain more insight into the molecular pathogenesis of $CD8^+$/$TCRab^+$ T-LGL leukemia. *Methods.* In the present study we included 13 symptomatic

patients with CD8+/TCRab+ T-LGL proliferations. The diagnosis of T-LGL leukemia was established by clinical and laboratory parameters and all patients had a tumorload of at least 80%. Extensive immunophenotyping and BIOMED-2 PCR-based GeneScan analysis of TCRB gene rearrangements were performed in all peripheral blood (PB) samples. Genomewide analysis of DNA copy number changes in PB samples from all patients was performed using high-resolution array-based comparative genomic hybridization (array-CGH) containing about 3500 bacterial artificial chromosomes (BACs). *Results.* All patients presented with anemia and/or (severe) neutropenia with an increased T-LGL proliferation. The aberrant T-LGL population showed membrane expression of CD3, CD8, CD57 and TCRab and carried monoclonal TCR gene rearrangements. In three cases clear genetic aberrations could be detected. One case had a complete loss of the X chromosome and chromosomal gain at 10q11. In the second case loss at 4p16 and gain at 8q24 were found. This kind of gain loss pattern could be derived from an imbalanced translocation between chromosome 4 and 8. The final case had chromosomal gain at 6p22 and 14q13 with single copy loss at 6q16. We are currently looking further into candidate genes located in these regions which might be involved in the etiopathogenesis of T-LGL leukemia. *Conclusions.* Genetic instability in LGL leukemias seems to be less common and more subtle than in other mature T-/NK-cell malignancies. Although no recurrent genetic aberrations were found, we did identify some chromosomal regions that might harbour genes that are possibly relevant for the pathogenesis of T-LGL leukemia.

0096

THE MUTATION STATUS OF THE RESIDUAL ATM ALLELE IS AN IMPORTANT DETERMINANT OF TUMOUR PROGRESSION AND PATIENT SURVIVAL IN CLL CASES CONTAINING AN 11Q DELETION

B. Austen,[1] A. Skowronska,[1] J.E. Powell,[1] A. Gardiner,[2] D. Oscier,[2] M. Dyer,[3] A.M. Taylor,[1] P. Moss,[1] T. Stankovic[1]

[1]University of Birmingham, BIRMINGHAM; [2]Royal Bournemouth Hospital, BOURNEMOUTH; [3]Leicester University, LEICESTER, United Kingdom

Background. Chromosome 11q deletions occur in up to 20% of CLL tumours and are associated with an adverse outcome. The minimal region of deletion includes the Ataxia Telangiectasia Mutated (ATM) gene, and mutations in ATM also occur in CLL patients and exert a detrimental effect on patient survival. ATM is a DNA damage response protein and defects in its function lead to impairment in p53-dependent apoptosis. Interestingly, the relationship between chromosome 11q deletions, ATM mutations and the integrity of the DNA damage response has not been specifically addressed in CLL. *Aims.* Our aim was to determine if CLL patients with a chromosome 11q deletion could be divided into two subgroups based on the functional status of the remaining ATM allele and whether these patient subgroups have differential progression or survival.

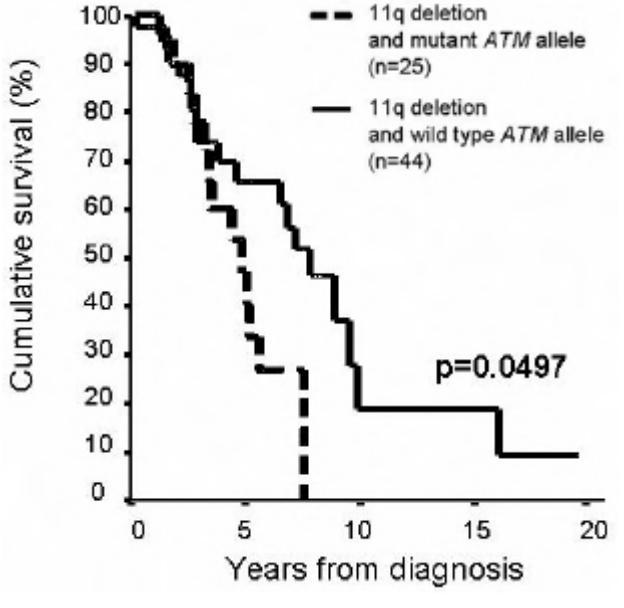


Figure 1. ATM mutations affect survival in 11q deleted CLLs

Methods. We established a cohort of 72 CLL cases that all had a chromosome 11q deletion and determined the sequence of the 62 coding exons of the residual ATM allele. We subsequently related ATM mutation status to clinical outcome, the size of the 11q-deleted tumour subclone, and the cellular responses to irradiation and cytotoxic drug exposure *in vitro*. Informed patient consent and ethical approval was obtained. *Results.* We found that the residual ATM allele is mutated in 35% of CLL tumours with an 11q deletion, thus distinguishing two genetic subgroups of these tumours; those with a second wild type and those with a second mutant ATM allele. Interestingly, the presence of a mutation in the residual ATM allele was associated with a further reduction in patient survival beyond that which is already dictated by the chromosome 11q deletion (p=0.0497). This subgroup of tumours also demonstrated impairment in the cellular response to irradiation and cytotoxic drug exposure *in vitro*, which contrasted from the preserved responses in the 11q-deleted tumour subgroup with a residual wild type ATM allele. Finally, we also found evidence for acquirement of ATM mutations during clonal evolution and observed that there was a highly significant association between the presence of ATM mutations and the expansion of the 11q-deleted subclone (p=0.002). *Conclusions.* CLL tumours with 11q deletion can be divided into two subgroups based on the integrity of the residual ATM allele. Complete loss of ATM function is associated with an impaired response to cytotoxic chemotherapeutics *in vitro*. This provides a mechanism to explain the poorer clinical outcome of patients with bi-allelic ATM abnormalities by comparison to patients with an isolated 11q deletion. Sub-clones that have acquired bi-allelic ATM defects can develop and expand during CLL clonal evolution, and we believe the use of DNA-damaging cytotoxic agents may have the potential to select these sub-clones, which in turn leads to the acceleration of disease progression.

HIGH RESOLUTION SNP ARRAYS AND DIFFERENTIAL MIRNA EXPRESSION IDENTIFY NOVEL GENOMIC ABERRATIONS IN CLL

M. Gómez-Benito,[1] C. Vicente,[1] M. Valgañón,[1] E. Bandrés,[1] N. Marcotegui,[1] A. Conchillo,[1] D. Rubio-Felix,[2] M.J. Calasanz,[3] P. Giraldo,[2] M.D. Odero[1]

[1]Center for Applied Medical Research, PAMPLONA; [2]Miguel Servet Hospital, ZARAGOZA; [3]Dpt of Genetics. University of Navarra, PAMPLONA, Spain

Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with an extremely variable clinical course. Recurrent genetic aberrations and VH mutation status are important independent predictors of disease progression and survival, allowing a risk assessment of individual patients in the course of the disease. FISH detects genomic aberrations (13q-, +12, 11q-, 17p-) in over 80% of cases, the most frequent being 13q14 deletions, associated with a favorable prognosis. In order to characterize this subgroup we defined the minimal region deleted using 11 FISH probes, and we used the high-resolution 50k Affymetrix SNP arrays (SNP-A) to study the entire genome of 8 B-CLL cases from a previously well genetically characterized series of 54 patients, all harboring 13q14 deletion. This tool allows for precise detection of simultaneous analysis of LOH and gene copy number. There was a good correlation between the FISH and SNP-A *Results.* SNP-A allowed the identification of 8 novel aberrations, 2 of them recurrent. Two cases with unmutated IgVH genes presented gains on 2p14-2pter recently described by Pfeifer *et al.* (Blood 2006), spanning the REL and BCL11A oncogenes; and 2 cases with mutated IgVH genes presented gains on 19q13.33-19qter. Besides, we detected 9 non-recurrent LOH regions with normal copy number. LOH by UPD usually occurs in fragile sites in the genome, a common location for miRNA. Recently, there has been major progress in the identification of microRNA expression profiles that could distinguish normal from malignant B cells, and identify a unique microRNA signature associated with prognostic factors. To study the relationship between LOH regions and miRNAs expression we analyzed the expression of 157 miRNAs in these patients and in PB from normal donors by real-time PCR. Consistent microRNA down-regulation was seen in miR154, the miR181a and miR181b cluster, miR199a, miR199-s, miR224, miR-299, miR-326, miR-370 and miR-let7e; whereas miRNA upregulation was seen in the miR-96 and miR-183 cluster, miR-155 and miR-210. The miR181 has been reported to be differentially expressed in CLL, and overexpression of miR-155 has been related to aggressive forms of CLL. Interestingly, 3 of the downregulated miRNAs (30%) were localized in the 14q32 region, where the IgVH genes are located. The MDR in 13q in our samples contained the miR-15a and miR-16-1 genes, located at 13q14.3. These microRNAs are frequently deleted and/or downregulated in patients with B-cell CLL and have an impor-

tant function in this disease, negatively regulating Bcl2 at a post-transcriptional level. We found both downregulated in our samples with 13q-, although if comparing with normal PB the difference was not statistically significant, probably due to normal cell contamination. We did not find a correlation between genomic deletions and miRNAs located in these regions downexpressed, suggesting that regulation of miRNA expression must be due to a more complex mechanism. In conclusion, the transforming events that lead to B-CLL are unknown, and although genetic abnormalities appear to promote disease progression, none of these is seen in every patient. Therefore, combining SNP-A technology and miRNA expression profile could be an interesting approach to understand the genetic changes that can occur in B-CLL, and to provide new biological insights into different CLL subgroups.

RITUXIMAB SENSITIZES SOME B-CLL SAMPLES TO FLUDARABINE AND CHLORAMBUCIL *IN VITRO*, REGARDLESS OF P53/ATM STATUS

M. Trbusek,[1] S. Cejkova,[1] L. Rocnova,[2] D. Potesil,[2] J. Chumchalova,[1] J. Smardova,[1] J. Malcikova,[1] P. Kuglik,[1] M. Doubek,[1] Y. Brychtova,[1] S. Pospisilova,[1] J. Mayer[1]

[1]University Hospital Brno, BRNO, Czech Republic; [2]Masaryk University, Faculty of Science, BRNO, Czech Republic

Background. Aberrations of two co-operating genes, the p53 and ATM, significantly deteriorate prognosis and treatment options for B-CLL patients. Monoclonal antibody rituximab (anti-CD20) is preferably used in combination regimens in B-CLL, often in those containing fludarabine. Very few *in vitro* data exist, however, showing an effect of such common treatment on B-CLL cells with aberrant p53 and/or ATM. In this respect, the data are also missing for a potential application of rituximab with chlorambucil. *Aims.* The aims were to assess the *in vitro* effect of the above mentioned combinations of drugs on B-CLL cells with various p53/ATM status. *Methods.* An interphase FISH was used for a determination of p53 and ATM deletions. Functional FASAY analysis coupled to sequencing was employed to supplement the screening also for p53 mutations. A metabolic WST-1 assay monitored the drugs effect on cell viability. An *in vitro* system lacking active human plasma was used, thus omitting the CDC pathway. After rituximab pre-treatment (10 μg/mL, 72h) the chemotherapeutics were applied in four concentrations for additional 48h (F: 25-0.4 μg/mL; CLB: 50-6.25 μM). Two-way analysis of variance (ANOVA) was used for determination of rituximab pre-treatment significance. *Results.* For the rituximab/fludarabine combination we tested forty samples having a median 85% of B-CLL lymphocytes, with the following characteristics: 13 were wild-type, 10 harbored ATM deletion (median 83% of deleted cells) and 17 exhibited p53 defects of various complexity - both alleles inactivation (del/mut and mut/mut) as well as the separate (one allele) aberrations (del or mut). The sensitivity to fludarabine was determined for the concentration 1.6 μg/mL, which provided significant differences among the samples. The sensitivity was assessed as follows: resistant - viability ≥60%; medium - viability <60% and ≥40%; sensitive - viability < 40%. The p53-affected samples were mostly resistant (71%) and none were sensitive. Among ATM deleted samples, on the contrary, 40% were sensitive, what was more than in wild-type subgroup (23%). Rituximab alone slightly increased a metabolic activity in most of samples, usually to 110-130% compared to untreated controls, while rarely a decrease was also noted (up to 80%). When the viability of fludarabine-treated and rituximab/fludarabine-treated samples was assessed in relation to fully untreated control, the positive sensitization effect of rituximab pre-treatment (p<0,05) was noted as follows: within the p53-affected as well as ATM-deleted subgroups in 30% of samples and within the wild-type subgroup in 62% of samples. For the rituximab/chlorambucil testing, which was performed as a pilot study in the same manner in eight samples, the positive effect of antibody pre-treatment was also noted in some samples of all the three subgroups. *Summary and Conclusions.* Our results indicate that the p53/ATM status is critical for the sensitivity of B-CLL cells to fludarabine. Regardless of the p53 and ATM aberrations, some samples are available for the rituximab-mediated sensitization to this agent. Our pilot data also support a warranty of testing a combined regimen containing rituximab and chlorambucil.

TP53 MUTATION AND 17P DELETION ARE ASSOCIATED WITH POOR SURVIVAL IN PATIENTS WITH CLL IRRESPECTIVE OF THE INACTIVATION OF THE OTHER ALLELE BY DELETION OR TP53 MUTATION: RESULTS FROM A SINGLE CENTER ANALYSIS

T. Zenz,[1] S. Häbe,[1] A. Kröber,[1] A Benner,[2] D. Kienle,[1] A. Bühler,[1] T. Denzel,[1] D. Winkler,[1] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM; [2]German Cancer Research Center, HEIDELBERG, Germany

Background. CLL patients with 17p deletion have a dismal prognosis. The exact prognostic role of TP53 mutations in the absence of 17p deletion and any differential impact of the mutation in cases with 17p deletion (vs. sole deletion) is currently unclear. *Aim.* To assess the incidence and prognostic impact of TP53 mutations as assessed by direct sequencing and DHPLC in a well characterized patient population. *Methods.* We studied 126 CLL patients from a single institution. The population is well characterized clinically and detailed genetic characteristics are available (FISH, VH-Status, CD38 expression). We used direct sequencing (n=126) and DHPLC (n=80) to detect TP53 mutations in the coding exons (2-11). The mutation analysis was performed on samples taken a median of 0.6 months after diagnosis. *Results.* We found an overall incidence of TP53 mutations of 13.5% (17/126 patients). The mutations were mainly located in the DNA binding domain (Exons 4-9). All mutations detected by direct sequencing were also detected by DHPLC. DHPLC was also informative in determining the allele status in the presence of heterozygous polymorphisms. Twelve of 15 patients with 17p deletions also had a TP53 mutation (80%). We also found TP53 mutations in the absence of 17p deletions in 4.5% (5/111). In the subgroup of patients with trisomy 12q we did not find TP53 mutations as opposed to 17/ 103 (16.5%) in all other subgroups combined (p=0.04). To study the impact on overall survival we confined the analysis to patients who were studied within 24 months of diagnosis to avoid bias. In this subgroup (n=108) we found a significant impact of the presence of the TP53 mutation (median survival 65 months vs. 15 months, p<0.0001). When separating the groups according to presence or absence of TP53 mutation and/or 17p deletion we found a highly significant influence of the presence of the TP53 mutation and/or 17p deletion on survival from the date of study (Figure 1) (p<0.0001).

Figure 1. Survival stratified by 17p and p53 Status.

Overall survival (from the time of study) was similar in the groups with deletion 17p and mutation (7.9 months), sole TP53 mutation (5.1 months) and 17p deletion without TP53 mutation (4.4 months) (vs. 66.7 months) (Figure 1). In 8/17 patients the mutation was found within 1 year of diagnosis. 4 of 6 patients with TP53 mutations and availability of serial samples, showed acquisition of mutations over time. *Conclusions.* TP53 mutations are associated with poor survival in CLL. TP53 mutations occur at a low incidence without 17p deletion and appear to be associated with poor survival once they occur. While the majority of cases with 17p deletion also have TP53 mutations, the prognosis appears to be equally poor for patients 17p deletion in the absence of TP53 mutations. These findings need to be confirmed in prospective trials. The mechanisms underlying the poor prognosis of patients with 17p deletion without TP53 mutation are under investigation.

ASSESSMENT OF ZAP-70 EXPRESSION BY FLOW CYTOMETRY USING TWO DIFFERENT ANTIBODIES AND ITS CORRELATION WITH IGVH MUTATION STATUS AND CYTOGENETICS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

W. Kern, F. Dicker, S. Schnittger, C. Haferlach, T. Haferlach

MLL Munich Leukemia Laboratory, MUNICH, Germany

Background. Prognosis of patients with chronic lymphocytic leukemia (CLL) is largely heterogeneous and may be estimated based on clinical and laboratory findings the most important ones of which include chromosomal aberrations, the IgVH mutation status, and the expression of ZAP-70. Various efforts have been made to define the optimum procedure of ZAP-70 assessment including selection of antibody clone and the method of analysis. The validation of ZAP-70 has been performed using the course of the disease as well as using the IgVH mutation status. *Aims.* To further clarify the role of ZAP-70 expression in CLL we prospectively analyzed ZAP-70 expression, IgVH mutation status, and chromosome aberrations in peripheral blood and bone marrow samples of patients with CLL. *Methods.* For the flow cytometric assessment of ZAP-70 expression the antibody clones 1E7.2 (Caltag, n=523) and SBZAP (Immunotech, n=166) have been used. IgVH mutation status has been analyzed in 407 cases and chromosome aberrations in 416 cases applying FISH with probes for del(6q), del(11q), +12, del(13q), del(17p), and t(11;14). ZAP-70 expression has been calculated as percentage of positive cells using normal T-lymphocytes as positive controls as well as using the ratio of mean fluorescence intensity (MFI) for ZAP-70 between T-lymphocytes and leukemic B-lymphocytes. *Results.* Significant correlations were found between the percentages of ZAP-70 positive cells and IgVH homology (1E7.2, $p<0.001$, r=0.239; SBZAP, $p<0.001$, r=0.437). Accordingly, patients with mutated and unmutated IgVH status (98% homology used as cut-off) significantly differed in the percentages of ZAP-70 positive cells (1E7.2, mean 32% vs. 46%, $p<0.001$; SBZAP, mean 11% vs. 35%, $p<0.001$). Even stronger correlations have been found, however, comparing the MFI ratios for ZAP-70 (normal T-lymphocytes to CLL cells) with the IgVH mutation status: 1E7.2, $p<0.001$, r=-0.283; SBZAP, $p<0.001$, r=-0.569. The respective differences between cases with mutated and unmutated IgVH status were: 1E7.2, mean MFI ratio 3.45 vs. 2.67, $p=0.001$; SBZAP, mean MFI ratio 6.33 vs. 3.14, $p<0.001$. The ratio of MFI between leukemic and normal B-lymphocytes correlated less strong with the IgVH mutation status. No significant associations of ZAP-70 expression with chromosomal aberrations have been found. *Conclusions.* The results of the present study 1) confirm the strong correlation between ZAP-70 expression and IgVH mutation status, 2) confirm the independence of ZAP-70 expression from chromosome aberrations, 3) argue in favor of analyzing ZAP-70 expression as MFI ratio between T-lymphocytes and leukemic B-lymphocytes, and 4) suggest that the SBZAP clone has a significant potential in the diagnostic work-up of CLL. Further studies are warranted to validate the role of the MFI ratio approach and of the SBZAP antibody in the clinical setting.

IGVH1-69 GENE USAGE IN B-CLL - THE SIGNIFICANCE OF SOMATIC HYPERMUTATION AND CRD3 STRUCTURAL FEATURES

L. Galligan, M.A. Catherwood, T.C.M. Morris, H.D. Alexander

Belfast City Hospital Trust, BELFAST, Northern Ireland

Background. B-CLL is a heterogenous disorder with a highly variable clinical course. Although certain acquired cytogenetic aberrations, unmutated IgVH gene status, ZAP-70 positivity and an atypical phenotype have been linked with more aggressive disease and a poorer outcome, the search for further prognostic markers is ongoing. IgVH 3-48, 3-53 and 3-21 gene usage have previously been associated with more aggressive disease and shorter survival times. In addition, IgVH 1-69 is expressed at a high frequency in B-CLL supporting the concept of antigenic selection in disease pathogenesis. It has been suggested that comparison to germline immunoglobulin sequence using the NCBI/IgBLAST database only may result in overestimation of mutated IgVH frequency associated with IgVH 1-69 rearrangements in B-CLL. Thus the clinical significance of IgVH 1-69 gene usage remains to be clarified. *Aims.* The aims of this study were to determine the frequency of VH1-69 gene usage in B-CLL, to assess the structural features of the CDR3 region, mutational status of the VH1-69 gene using the up-dated IgBLAST and V-QUEST databases and to determine if patients with VH1-69 rearrangements differ in clinical course to those patients with alternative IgVH gene usage. *Methods.* Two hundred and seventy patients were recruited for this study. IgVH gene usage was determined using multiplex BIOMED-2 primers (InVivoScribe Technologies) and protocol. IgVH mutational status was determined by sequence analysis using BigDye chemistry and homology comparison with the up-dated NCBI/IgBLAST and IMGT/V-QUEST databases. Interphase FISH analysis was performed to screen for common cytogenetic aberrations and serum thymidine kinase (TK) levels were measured using a radioenzyme assay. *Results.* We identified IgVH1-69 gene usage in 31/270 CLL patients (11.5%), 30 of which were characterised further. Our results demonstrate that it is associated with un-mutated IgVH status (80% of cases) and a preponderance of males (73% of cases). Poor/intermediate prognosis cytogenetic abnormalities were detected in 10 of 15 (75%) cases analysed. Although 21 patients (70%) were found to have Binet stage A disease upon presentation, the majority have since progressed to stage B or C. The median TK level was 16.1 U/L (>8.5 U/L is associated with progressive disease). IgVH somatic hypermutation was found in 6 cases (20%) and was associated with shorter CDR3 regions, IGJH 4 gene usage and lower TK levels (median of 6.8 U/L). *Summary and conclusions.* We have found that IgVH1-69 gene usage is over-expressed in B-CLL, is associated with advanced disease and may have potential as a supplemental predictive marker of disease progression. However, it remains to be determined if IgVH1-69 gene usage is an independent poor prognosis marker, as its association with un-mutated IgVH status in most patients may be the overriding factor. We present evidence that IgVH1-69 B-CLL cases can be divided into mutated (n=6) and un-mutated (n=24) sub-groups and that mutated cases are defined by short CRD3 regions and biased IGJH 4 gene usage. We are currently investigating the possible common antigenic stimuli which may be involved in leukaemogenesis in this subgroup.

0102

NOTCH2 MIGHT BE INVOLVED IN THE PKC-DEPENDENT SURVIVAL OF B-CLL CELLS

R. Hubmann,[1] M. Hilgarth,[2] S. Schnabl,[1] D. Demirtas,[1]
J.D. Schwarzmeier,[1] U. Jaeger,[1] M. Shehata[1]

[1]Medical University of Vienna, VIENNA; [2]Medival University of Vienna, VIENNA, Austria

Notch2 plays a determining role in the development/homeostasis of murine Cd5+ B1 B-cells, suggesting a potential function for human NOTCH2 in B-CLL leukemogenesis. Here we show that freshly isolated B-CLL lymphocytes (n=30) express an activated form of NOTCH2 (N2IC) irrespective of their prognostic marker profile (ie. IgVH mutational status, CD38 expression, cytogenetics). Although the majority of cultured B-CLL samples downregulate their NOTCH2 activity within one day (24 out of 30), DNA-bound N2IC complexes could be maintained by the phorbol esther TPA (1 ng/mL) accompained by an upregulation of the NOTCH2 target gene CD23 and increased cell viability. These effects are sensitive to the Protein kinase C-delta (PKC-‰) inhibitor Rottlerin. The TPA induced NOTCH2 activity was found to be resistant to the g-secretase inhibitors (GSI) DAPT and compound E in 24 out of 30 B-CLL cases suggesting that the vast majority of B-CLL cases express an activated form of N2IC which is not tethered to the plasma membrane and, thus, does not require g-secretase for signaling. NOTCH2 inhibition either by DAPT in a GSI sensitive B-CLL case or by RNAi mediated NOTCH2 gene silencing suggests a functional relation between NOTCH2 dependent CD23 expression and B-CLL cell viability. Thus, deregulated NOTCH2 signaling seems to be a common phenomenon in B-CLL and might be critically involved in the PKC-dependent survival of B-CLL cells.

0103

BIALLELIC DELETION 13Q14.3: A NEW PROGNOSTIC MARKER IN CHRONIC LYMPHOCYTIC LEUKEMIA?

C. Chena,[1] J. Sanchez Avalos,[2] G. Arrossagaray,[1] R. Bezares,[3]
K. Turdo,[4] A. Bistmans,[5] I. Slavutsky[1]

[1]Instituto de Invest. Hematologicas, BUENOS AIRES; [2]Instituto Fleming, BUENOS AIRE; [3]Hospital Alvarez, BUENOS AIRES, Argentina; [4]Hospital Aeronautico, BUENOS AIRES; [5]Hospital Ramos Mejia, BUENOS AIRES, Argentina

Background. Chronic lymphocytic leukemia (CLL), the most frequent type of adult leukemia in the Western world, is characterized by a highly variable clinical course with survival times ranging from months to decades. Genomic alterations in CLL are considered independent predictors of disease progression and survival. Monoallelic deletion of 13q14.3 (13q14x1) is the most common anomaly (55-60% of patients), associat-

ed to a favorable outcome. Biallelic deletion of 13q14.3 (13q14x2) alone or concomitant 13q14x1/13q14x2 has been observed in about 10-20% of patients with CLL. It has been scarcely evaluated in the literature. *Aim.* We analyzed the clinical, cytogenetic and FISH (fluorescence *in situ* hybridization) characteristics of 9 patients with 13q14x2 in order to evaluate its prognostic significance. *Patients and Methods.* From 1997 to 2006, a total of 100 patients with diagnosis of CLL were cytogenetically and FISH studied in our Institution. Among them, 9 cases (5 males; mean age 63 years; range 47-77 years) showed 13q14x2. Immunophenotypic analysis showed expression of pan-B antigen (CD19, CD20, CD22) with co-expression of CD5 and CD23. Rai clinical stages were: I-II: 5; III-IV: 4. Eight patients were under treatment, the remaining one did not accept to be treated. Five patients have already died at the moment of this analysis. Chromosome studies were performed on stimulated peripheral blood lymphocytes. G-banded technique was used. FISH analysis for trisomy 12, and deletions of D13S319 at 13q14 band, ATM at 11q22.3 and TP53 at 17p13 (VYSIS) was carried out according to standard protocols. *Results.* Six out of 9 patients with CLL showed normal karyotypes and 13q14x2 alone or concomitant 13q14x1/13q14x2. Mean time from diagnosis to treatment for this group was 26 months (range 3-61 months). The remaining three had other genomic alterations: trisomy 12 (5.5% of cells), i(17)(q10) and complex karyotype. The last two patients were studied at the progression of the disease after more than ten years of stable disease. The patient with +12 was studied at diagnosis and had a poor outcome with a very short survival (4 months).Two cases showed only biallelic deletion 13q14 (58% y 88% of cells). The other seven cases (78%) had concomitant 13q14x1/13q14x2, being biallelic clones larger than monoallelic ones in 5 cases (5/7:71.4%). Simultaneously, we used the defined set of hierarchical FISH risk categories to compare FISH results by stable versus progressive disease. FISH was abnormal for 27/46 (58.7%) patients with stable disease and 47/54 (87%) cases with progressive disease (p<0.003). Interestingly, all six patients with normal karyotypes and 13q14x2 showed progressive disease respecting to 38.7% of the cases with 13q14x1 alone (p<0.01). A high proportion of patients with progressive disease was also observed for anomalies +12, 17p- and 11q-. *Conclusions.* The high frequency of patients with concomitant 13q14x1/13q14x2 suggests that the biallelic deletion would result from clonal evolution. Our data indicate that 13q14x2 would represent a more aggressive anomaly than 13q14x1 and could be considered as a marker of possible prognostic value in CLL. More studies must be performed to confirm these results.

0104

GELDANAMYCIN HAS OPPOSING EFFECTS ON WILD-TYPE AND MUTANT P53 AND INDUCES P21CIP1 EXPRESSION AND CYTOTOXICITY IRRESPECTIVE OF P53/ATM STATUS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

A.R. Pettitt, G.G. Johnson, P.D. Sherrington, K. Lin

University of Liverpool, LIVERPOOL, United Kingdom

Background. Wild-type (wt) p53 has a beneficial effect in cancer, whereas mutant p53 has a deleterious effect by virtue of its tumorigenic and anti-apoptotic properties and high level of expression. In keeping with this, p53 mutation/deletion in chronic lymphocytic leukaemia (CLL) is strongly associated with rapid clonal expansion, propensity to transform, and resistance to chemotherapy, and developing new and better ways of treating such patients has become a major priority. Cancer cells seem to depend more than normal cells on the Hsp90 chaperone protein, which can be inhibited by the ansamycin geldanamycin (GA) and its derivative 17-AAG. Previous studies have shown that GA or 17-AAG can kill CLL cells in a selective fashion via depletion of the Hsp90 client proteins Akt and Zap-70. However, there is also evidence to suggest that Hsp90 inhibition can induce changes in the p53 pathway that might be of potential therapeutic benefit in CLL patients with or without p53 defects. The present study was conducted to explore this possibility. *Aims.* To examine the effect of Hsp90 inhibition on the p53 pathway in CLL cells of defined ATM/p53 status, and to determine whether ATM/p53 defects are associated with resistance to *in vitro* cytotoxicity. *Methods.* CLL patients were characterized for their ATM/p53 status using a combination of p53 functional analysis, p53 gene sequencing, and FISH analysis for ATM/p53 deletion. Three groups were identified: no ATM/p53 defect; p53 defect (p53 mutation with deletion of the second allele); and ATM inactivation (no p53 mutation or deletion but p53 functional defect of the type associated with ATM mutation). CLL cells from these cases were treated *in vitro* with GA (10 nM-10 μM) for up to 5 days. Changes in the expression of specific proteins were detected with Western blotting. Cell viability was measured by FACS analysis of cells after staining with dihexolyloxacarbocyanine iodide (DiOC6) and propidium iodide (PI). *Results.* GA down-regulated mutant p53 protein and up-regulated wt p53 protein. The up-regulation of wt p53 by GA was accompanied by down-regulation of Akt and the active form of MDM2, indicating a possible mechanism. In addition to its effects on wt and mutant p53, GA also induced a biphasic increase in p21CIP1, a cyclin-dependent kinase inhibitor that is transcriptionally activated by wt p53. The late increase in p21CIP1 protein levels was seen in cases with no ATM/p53 defects or ATM inactivation but not in those with mutant p53, indicating that the effect was dependent on wt p53 but not ATM. In contrast, the early increase in p21CIP1 was not influenced by p53/ATM status. GA killed CLL cells in a dose-dependent manner irrespective of p53/ATM status. *Conclusions.* Our findings indicate that GA has opposing effects on wild-type and mutant p53 and induces p21CIP1 expression and cytotoxicity independently of ATM/p53 status, all of which should favour clonal regression *in vivo*. These findings reveal an important new dimension to the action of ansamycins in CLL and strongly support the further evaluation of these agents, especially in cases with p53 mutation or ATM inactivation.

0105

MONITORING OF THE STATUS OF BOTH P53 ALLELES IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA - RELEVANCE TO PROGNOSIS AND TREATMENT

J. Malcikova, M. Trbusek, J. Smardova, S. Cejkova, P. Kuglik, Y. Brychtova, M. Doubek, D. Dvorakova, J. Mayer, S. Pospisilova

University Hospital Brno, BRNO, Czech Republic

Background. Deletions and/or mutations of p53 gene, a key cell-cycle and apoptosis regulator, represent the most important prognostic factor related to treatment in B-cell chronic lymphocytic leukemia. The presence of aberrations (occurring in 10-15% of patients) almost inevitably leads to treatment requirement and poor outcome and the gene thus constitutes the strongest independent marker for disease-related death. A proportion of p53 mutations originates through spontaneous mutagenesis, however the suspicion exists that some mutations might be induced by DNA-damaging chemotherapy. *Aims.* In this study we determine the proportion of individual p53 aberrations (deletions, mutations, combination of both) in our set of unselected B-CLL patients and correlate the data to p53 protein level, indicating non-functionality of the gene. Further, we evaluate the influence of these alterations on prognosis, therapy requirement and the presence of previous treatment. *Methods.* The deletions of p53 locus (17p13.1) were detected using an interphase FISH and mutations in the gene were searched out using yeast functional analysis (FASAY), coupled to sequencing of templates from yeast colonies bearing the mutated p53 genes. Western blotting was used for determination of p53 protein level. *Results.* We screened 340 B-CLL patients for the deletions and mutations of the p53 gene and 12% of patients manifested a p53 alteration. Most of affected patients (61%) exhibited a complete gene inactivation (deletion/mutation), in a case of missense mutations mostly leading to high p53 protein level. However, single allele missense mutations or deletions also occurred (in 21% or 18% of p53-affected patients, respectively) and were only rarely accompanied by p53 protein over-expression. The requirement for therapy was prominent in p53-affected patients (85%) in comparison to the p53 wild-type group (54%). In this respect, we report a clear difference within the p53-affected patients relating to the treatment necessity and complexity of p53 aberration: all the patients in deletion/mutation subgroup underwent chemotherapy and a quarter of them has died within two years after diagnosis. In the single allele aberration subgroup only 64% of patients required a therapy and none of them died within the stated interval. In approx. a half of affected patients the p53 abnormality occurred before any treatment. We observed five patients changing from wild-type to mutant p53 status, always in connection to undergoing polychemotherapy. Moreover, in two intensively treated patients we detected a p53 mutation mosaic - i.e. each cell tested (n=10-15; cloned through FASAY analysis) beared different (mostly missense) mutation. *Summary and conclusions.* We suggest that monitoring of both p53 alleles might be useful in B-CLL patients, because the correlation among deletion, mutation and protein over-expression is not absolute and the course of the disease may be possibly grouped according to complexity of the p53 inactivation. Although a significant proportion of the p53 mutations is being confirmed as a result of spontaneous biological process, the possibility that DNA-damaging chemotherapy may induce or select some p53 mutations should not be rejected and needs further investigation.

THE ROLE OF IL-6 IN THE IMMUNE DYSFUNCTION OF B-CLL

G.S. Buggins, P.E.M. Patten, J. Richards, N.S.B. Thomas, G.J. Mufti, S. Devereux

King's College London, LONDON, United Kingdom

Immune dysfunction, manifest as susceptibility to infection and autoimmune disease, is a major clinical feature of B-cell chronic lymphocytic leukaemia (B-CLL). Although this is in part directly caused by the tumor load, defective T-cell function is also observed including patients with early stage disease. In this study we investigated the role of tumor derived soluble factors in the pathogenesis of immune dysfunction in B-CLL. Supernatants from B-CLL tumor cells (TSN) inhibited a third party allogeneic mixed lymphocyte reaction between T cells from two normal unrelated donors in 9/9 cases (p=0.002) and reduced both cell cycle entry and division of normal T cells in response to CD3/CD28 ligation (p=0.0096 and 0.02). TSN also inhibited CD40L upregulation and IL-2 secretion by activated T cells in 17/17 cases (p=0.0001). This is contrary to previous work that suggests loss of CD40L is exclusively due to tumor cell contact and we show that TSN inhibits by a different mechanism. We also demonstrate that the CD40L defect in B-CLL is reversed by separation of T cells from leukemic cells. Following the inhibitory effect of TSN on the Th1 cytokine IL-2 we investigated whether this was due to Th2 polarization of the T cells. Activation of normal T cells in TSN induced a 7-10 fold increase in IL-4 secretion. To identify the component of TSN causing this we did a cytokine bead array assay for IL-2, γ-Interferon (γ-IFN), Tumor Necrosis Factor-α, IL-10, IL-4, and IL-6. The levels of IL-6 were >85 ng/mL in all cases studied (n=5). The remaining cytokines were consistently present at <0.5 ng/mL except γ-IFN which was found in 2/5 cases at 1.5 and 3.0 ng/mL respectively. Neutralization of IL-6 reversed the inhibitory effect of TSN on T cell activation and IL-2 production whilst addition of the recombinant cytokine reproduced the findings. Blockade Of the IL-6 receptor on T cells restored CD40L expression by normal T cells, activated in the presence of TSN, from a mean of 41±4.3% to 63±4.3% of that observed in CM (p=0.0067). Our results demonstrate that IL-6 secretion is one of the mechanisms by which B-CLL cells modify the immune system. These findings have a number of implications for the treatment of B-CLL. Immunotherapy of B-CLL whether by allogeneic hematopoietic stem cell transplantation or more experimental strategies is most likely to be successful in the context of minimal residual disease. When this is not possible, inhibition of the IL-6 effect may be a strategy to improve the graft versus leukaemia effect in this disorder. In addition and perhaps more importantly, blockade of IL-6 signaling might both reduce the systemic symptoms and immune dysfunction that are such a central feature of B-CLL and slow disease progression by removing one of the factors in the cytokine network that supports the survival and proliferation of the tumor. Tocilizumab, a humanized antibody which blocks the IL-6 receptor, is well tolerated and effective in a number of IL-6 mediated disorders and our data suggest it as a potential adjuvant to the treatment of B-CLL.

B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL) WITH 14Q32 TRANSLOCATIONS: HAEMATOLOGICAL FEATURES AND CLINICAL OUTCOME

F. Cavazzini,[1] J.A. Hernandez,[2] A. Gozzetti,[3] A. Russo Rossi,[1] R. Tiseo,[1] R. Maffei,[4] A. Bardi,[1] E. Tammiso,[1] R. Crupi,[3] M.P. Lenoci,[3] R. Marasca,[4] F. Lauria,[3] G. Torelli,[4] J.M. Hernandez,[5] G.M. Rigolin,[1] A. Cuneo[1]

[1]Section of Hematology, FERRARA, Italy; [2]Hospital de Fuenlabrada, MADRID, Spain; [3]Division of Haematology and Transplants, SIENA, Italy; [4]Department of Oncology and Haematology, MODENA, Italy; [5]Universidad de salamanca-CSIC, SALAMANCA, Spain

Background. Translocations of 14q32 involving the IgH locus occur at a low incidence (approximately 2-5%) in B-CLL. The prognostic significance of 14q32/IgH translocation is still uncertain. *Methods and Aims*. 600 cases of B-CLL seen at 3 institutions over a 20-year period were assessed by conventional cytogenetic analysis and by FISH with the following panel of probes (17p13/TP53, 11q22.3/ATM, 6q21, chromosome 12 centromere, 13q14) and with a probe spanning the IGH locus. Patients with no detectable aberration or with isolated 13q- were included into a favourable cytogenetic group (group 1), those with +12, 6q- into an intermediate risk group (group 2) and those bearing 17p-, 11q-, or complex karyotype into an unfavourable group (group 3). Patients with 14q32/IgH translocation as primary chromosome change (i.e. absence of additional aberrations, presence of other aberrations in a minority of cells) were included into a specific category (group 4). Cases with 14q32/IgH translocation by conventional cytogenetics and/or by FISH were studied with probes spanning BCL1, BCL2, BCL3, BCL6, c-MYC, BCL11A, PAX5, CCND3 and CDK6 for the detection of translocation partners. Cases with t(11;14)(q13;q32)/BCL1 rearrangement were excluded. The aim of the study was to isolate cases with 14q32/IgH aberration as a possible primary abnormality in order to identify translocation partners and to study define the clinicobiological features associated with this abnormality. *Results.* We found 29/600 cases (4.8%) with 14q32/IGH break in interphase FISH (46-83%). Two cases carrying 11q- and 2 with 17p- were allocated into group 3. Twenty-five cases were included in group 4: an additional abnormality was present in a minority of nuclei (13-40%) in 11/25 cases: 7 cases with 13q-, 3 cases +12, 1 case 17p-. The latter 4 cases were included into the 14q32/IgH group (group 4) because additional aberrations were confined to a sideline. Translocation partners of 14q32/IGH translocations were so far identified in 8/25 cases (2p13/BCL11A: 1 case; 6p21/CCND3: 1 case; 18q21/BCL2: 6 cases). The study of the remaining cases is ongoing. We then evaluated the clinical impact of 14q32/IGH rearrangement in a series of 411 patients with complete clinicobiological data. Cases with 14q32/IGH translocations were characterized mainly by typical morphology and classical immunophenotype (immunophenotypic score 5 in 92% of the cases). Mutational analysis of IgVH gene showed an intermediate incidence of unmutated cases (60%). Patients with 14q32/IgH translocation did not differ significantly in terms of interval between diagnosis and treatment as compared with other CLL. However, in univariate analysis patients carrying the 14q32/IGH had a shorter interval between diagnosis and treatment when compared with group 1 (p=0.0084), while no significant difference was observed with respect to patients in groups 2 and 3. In multivariate analysis the presence of 14q32/IGH translocation maintained a significant independent impact (p 0.012) on the interval between diagnosis and treatment, along with stage (p<0.001) and CD38 positivity (p< 0.001). *Conclusions.* Clinical and biological features support the concept that the presence of 14q32/IGH rearrangement as primary abnormality could identify a subset of CLL patients which should be allocated into an intermediate risk category.

COMPREHENSIVE PROTEIN AND RNA EXPRESSION ANALYSIS OF GENETIC SUBGROUPS OF CHRONIC LYMPHOCYTIC LEUKAEMIA

D. Winkler, C. Schneider, D. Kienle, H. Döhner, S. Stilgenbauer

University of Ulm, ULM, Germany

Chronic lymphocytic leukemia is a disorder with a highly variable clinical course. The VH mutation status and genomic aberrations such as deletion 11q, trisomy 12, deletion 13q, and deletion 17p identify subgroups with different survival times. Protein expression levels of candidate genes involved in cell cycle and apoptosis (AKT1, Apaf-1, ATM, BAX, BCL-2, CDK2, CDK4, cIAP2, Cyclin-D1/D2/D3, MCL-1, MDM-2, p21, p27, p53, PI3K, RB, SMAC, Survivin, XIAP) were studied by immunoblotting. 97 CLL cases divided into subgroups with 11q- (n=23), +12q (n=24), 13q- (n=19), 17p-/p53 mutation (n=15) or a normal karyotype (n=16) were examined and compared to the cell lines EHEB, JVM-2 and Granta-519. In 25 cases, mRNA expression data (studied by RQ-PCR) was compared for AKT1, ATM, BAX, BCL-2, CDK4, Cyclin-D1/D2/D3, MCL-1, p21, p27, p53, PI3-K to assess if protein expression and mRNA levels are correlated. Expression levels were related to EHEB for standardization. VH-mutation status was available for 91 cases. 28 cases had mutated VH genes. In the normal karyotype subgroup a highly homogenous expression pattern for all proteins studied was observed independently of the VH-status. CLL samples with +12q, 13q- or normal karyotype had equal levels of ATM protein, whereas the 11q-subgroup showed reduced levels in 5 cases and absent ATM protein in 1 case (among 15 evaluable cases). The 17p-subgroup included 13 cases without deletion 11q showing ATM protein levels comparable to the normal karyotype group. 17p-cases showed stronger expression of p53 compared to all other cases, except for 4 cases with normal karyotype or deletion 11q. In all of these a p53 mutation could be detected in exons 2-11 by sequencing. Survivin protein and mRNA was absent or low in all cases. CDK4 protein expression was high in cases with 17p-, 11q- and 13q- but low in the subgroup with +12q and normal karyotype. MCL-1 expression was highest in the 17p-subgroup. Regarding PI3K, MDM-2, p21, p27, CDK2, Cyclin-D1, -D2, -D3, BAX, BCL-2, Apaf-1, SMAC, XIAP, cIAP2, RB, E2F, AKT1, ARF and STAT6 no variation in protein expression levels were observed across the subgroups. P27-expression was higher in all CLL cases compared to the cell lines contrary to

stronger levels of p21 in the cell lines. Clear concordance between RNA and protein expression was seen for BCL-2, Cyclin-D2, p21 and p27 regardless of the subgroup affiliation. However, the exact levels of RNA expression could not be retrieved by immunoblotting. In conclusion, the 17p-subgroup was the only group with a high level of p53 and MCL-1 protein expression suggesting that p53 is the affected gene in this subgroup. In contrast, the ATM protein levels are reduced only in a part of 11q- cases indicating a possible role of additional candidate genes. Cases with trisomy 12 and normal karyotype showed weak expression of CDK4 pointing to a functional relevance in these subgroups. Protein levels and mRNA levels correlated only for a subset of the genes investigated. This may be due to posttranscriptional mechanisms regulating gene expression or a lower sensitivity of immunoblotting to detect subtle expression differences.

DOUBLING TIME OF SOLUBLE CD23 (SCD23DT) ALLOWS TO IDENTIFY A GOOD PROGNOSTIC SUBGROUP IN ZAP+ STAGE A UNTREATED CLL PATIENTS

N. Meuleman,[1] V. Delrieu,[1] B. Stomatopulos,[1] J. Bennani,[1] A. Kentos,[2] P. Heimann,[2] A. Delforge,[1] L. Lagneaux,[1] D. Bron[1]

[1]Institut Jules Bordet, BRUSSELS; [2]Erasme, BRUSSELS, Belgium

Background. Chronic lymphocytic leukemia (CLL) is a disease with unpredictable natural history in stage A patients (pts). Recently, it has been suggested that ZAP-70 expression could be a surrogate marker for IgVH mutational status as a biological prognostic factor. Indeed, analysis of mutational status is a heavy procedure but ZAP 70 expression is not always reproducible and the optimal technique has still to be validated. We previously reported that the doubling time of soluble CD23 (sCD23DT) is a major prognostic factor for progression of disease in untreated stage A CLL. Therefore we prospectively evaluated ZAP-70 protein expression and IgVH mutational status in untreated stage A B-CLL pts and correlated these markers with sCD23DT. *Methods.* sCD23 level was evaluated by a commercially available enzyme-linked immunosorbent assay (ELISA). ZAP-70 expression is determined in leukemic cells by flow cytometry, and positive expression was defined as >20% positive cells. When tests became available, ZAP-70 gene expression and IgVH mutational status were also evaluated in all pts included in the sCD23 study. *Results.* 60 pts with untreated stage A B-CLL were included in the study. Median age was 62 (42-82) years. The median follow-up was 58 (16-129) months. The sCD23DT was clearly associated with a progression of the disease: median Treatment-Free Survival (TFS) was 20 Mos in pts with sCD23DT inferior to one year comparing to 141 months in pts with sCD23 DT superior to one year (p<0.0001) with a median overall survival (OS) of 80 mos when the sCD23DT was inferior to one year compared to 176 months for the other group (p<0.0001). Median TFS and OS were respectively 20.7 months and 84 months in ZAP+ pts versus 104.2 mos (p=0.0003) and 176 months (p=0.0003) in the group of pts with negative ZAP-70. According to the mutational status the median TFS and OS were 20.7 mos and 84.8 months for pts with unmutated IgVH and 104 mos (p<0.0001) with a median OS not reached (p=0.0002) for pts with mutated status. Among pts with ZAP+ expression, the analysis of sCD23DT allows to detect a population with a better prognosis with a median TFS of 14 mos in the group of ZAP+ with sCD23DT inferior to one year comparing to a median TFS not reached in ZAP+ pts with sCD23DT superior to one year (p=0.0003). The median OS was 82 mos for pts ZAP+ with a sC23DT inferior to 1 year compared to a median OS not reached for ZAP+ pts with sCD23DT (p=0.0194). Among pts with ZAP– expression, sC23DT allowed also to isolate pts with worse evolution: median TFS of 60 months vs 141 mos (p=0.0017) but without difference in median OS. In pts with ZAP+ expression, the mutational status allowed also to detect a difference in terms of TFS: 14 months for ZAP+ unmutated pts versus median not reached for ZAP+ mutated pts, but we there was no difference in term of OS. In the group of ZAP– pts, there were no differences according to the mutational status. Even among pts with unmutated status and ZAP+ expression, we identified with sCD23DT two subgroup with different evolution in terms of median TFS: 16 mos with a sCD23DT inferior to one year and 54 months for the other pts (p=0.019), but in this small population there is no statistical difference in terms of OS according to sCD23DT (84 versus 112 mos, p=0.087). *Conclusions.* A) We confirmed that sCD23DT is a biological prognostic marker for EFS and OS in untreated stage A CLL. B) Mutational status is correlated with ZAP-70 expression and is an additional prognostic factor in ZAP+ pts. C) SCD23DT is even more reliable to identify a good prognostic group in ZAP+ stage A untreated CLL.

HLA-DR ASSOCIATIONS AND CELL CONTACT IMPLICATE SPECIFIC T-CELL RESPONSES IN THE PATHOGENESIS OF SPLENIC MARGINAL ZONE LYMPHOMA

S. Devereux,[1] Z. Davis,[2] A.M. Little,[3] P.E.M. Patten,[1] F. Fowles,[3] J. Richards,[1] D.G. Oscier[2]

[1]Kings College London, LONDON; [2]Royal Bournemouth Hospital, BOURNEMOUTH; [3]Anthony Nolan Trust, LONDON, United Kingdom

Background. There is now strong evidence that interactions between the B-cell receptor (BCR) and antigen are central to the pathogenesis of a number of chronic lymphoproliferative disorders including B-cell chronic lymphocytic leukaemia (B-CLL) and splenic marginal zone lymphoma (SMZL). Compared to normal B-cells, B-CLL cells use a restricted range of immunoglobulin variable heavy chain (Vh) genes which, along with other structural similarities, suggests that these tumours arise from cells that have responded to a limited number of antigens. A particularly marked homology has been noted in the Vh3-21 subset with a short conserved complementarity determining region 3 and expression of the same Vlamba2-14 light chain strongly suggesting recognition of a common antigen. Restricted Vh gene usage has also been observed in SMZL; for example in one series, Vh1-02 expression was reported in 18/40 cases. In addition to signals through the BCR, there is also evidence that T-cell costimulation plays a role in the pathogenesis of many low grade lymphomas. In gastric marginal zone lymphoma for example, T-cell responses to Helicobacter pylori derived peptides provide signals that sustain the developing B-cell tumour and responses to autoantigens and other infectious organisms have been implicated in extranodal lymphomas at other sites. In B-CLL, activated CD40L+ T-cells neighbour proliferating leukaemic cells in so called pseudofollicles within the bone marrow and lymph nodes and, although the reason for their presence is unclear, it is suggested that they play a key role in the tumour microenvoronment. *Aims.* To investigate whether antigen specific T-cell responses promote the progression of B-CLL and SMZL. *Methods.* HLA typing was performed on subsets of B-CLL and SMZL and a group of 1667 normal controls. Sections of SMZL spleen were analysed by multiparameter confocal immunofluorescence microcopy. *Results.* Of 36 patients with SMZL, 30 (83%) expressed either HLA-DR15, HLA-DR4 or both compared to only 931 (56%) of the normal controls (p=0.001). The significance of this association was maintained when corrected for the analysis of multiple HLA-DR alleles (corrected p=0.013). Surprisingly, the nature of the HLA-DR association was dependent on the Vh gene utilised by the tumour. Of the 18 cases of Vh1-02 SMZL, 11 (61%) expressed HLA-DR15 compared to 26% of normal controls (p=0.0022, corrected p=0.029) whilst 13 (72%) of the 18 non Vh1-02 cases expressed HLA-DR4 compared to 36% of the controls (p=0.0023, corrected p=0.03). An excess of HLA-DR4 expression was also observed in patients with Vh1-02 SMZL that did not express HLA-DR15 (71% vs 19% of controls, p=0.015). No clear association between any of the subgroups of B-CLL and HLA type was observed. Analysis of SMZL spleen showed that proliferating tumour cells frequently contact T lymphocytes whereas non-proliferating cells do not (Figure 1. T-cells red, B-cells green, Ki67 white). *Conclusions.* Taken together these results suggest that a specific T-cell response to antigen plays a role in the pathogenesis of this B-cell disorder. The observation that the Vh gene used by the tumour specifies the type of HLA restriction implies that the BCR and costimulatory T-cells respond to the same antigen.

ZAP-70 MRNA EXPRESSION QUANTIFIED IN B CELLS BY REAL TIME PCR IS A POWERFUL PROGNOSTIC FACTOR IN CHRONIC LYMPHOCYTIC LEUKEMIA

B. Stamatopoulos, N. Meuleman, B. Haibe-Kains, H. Duvillier, M. Massy, P. Martiat, D. Bron, L. Lagneaux

Bordet Institute, BRUSSELS, Belgium

Background. Chronic Lymphocytic Leukemia (CLL) is a heterogeneous disease with respect to prognosis and clinical outcomes. Two different groups in terms of overall survival and clinical characteristics are now classified on the IgVH mutational status. However, this costly analysis is very laborious and surrogate markers have been investigated. *Methods.* We developed a standardised and quantitative PCR (qPCR) method to measure Zap-70 mRNA (ζ-associated protein 70) expression in sorted CD19+ cells. The comparison of this method with others (Zap-70 and CD38 by flow cytometry, and lipoprotein lipase (LPL) mRNA by qPCR) was performed in a cohort of 108 patients with a median follow up of 82 months to evaluate their association with IgVH mutational status, overall survival (OS) and treatment-free survival (TFS). *Results.* The association between Zap-70 by qPCR and IgVH mutational status was clearly significant [$\tilde{}X^2$=50.95; p<0.0001] and characterised by a Cramer's V statistic of 0.72 indicating a very strong relation. This method also presents 87.8% sensitivity, 85.7% sensibility, 87.5% positive predictive value and 86% negative predictive value. Zap-70 expression was significantly associated with OS [p=0.0021] and TFS [p<0.0001]. Zap-70-positive patients had a significantly shorter median TFS (24 months) than Zap-70-negative patients (157 months). Moreover, Zap-70 by qPCR seems to have a better prognostic power than IgVH mutational status and the other prognostic marker tested. *Conclusions.* Zap-70 mRNA expression quantified by real time PCR is a strong surrogate marker of IgVH mutational status and a powerful prognostic factor.

0112

RITUXIMAB COMBINED WITH CLADRIBINE OR CLADRIBINE AND CYCLOPHOSPHAMIDE IN HEAVILY PRETREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

T. Robak, P. Smolewski, B. Cebula, J.Z. Blonski, O. Grzybowska-Izydorczyk

Medical University of Lodz, LODZ, Poland

Background. The results of preclinical and clinical studies suggest that rituximab can increase an antineoplastic activity of purine nucleoside analogs in CD20-positive B-cell lymphoid malignancies. *Aims.* The aim of current study was to determine the feasibility, effectiveness and toxicity of combined regimens consisting of rituximab and cladribine (2-CdA) (RC) and RC plus cyclophosphamide (RCC) in the treatment of patients with recurrent or refractory chronic lymphocytic leukemia (CLL). *Methods.* The RC regimen consisted of RIT at a dose of 375 mg/m^2 on day 1 and 2-CdA at a dose of 0.12 mg/kg in 2-hour infusion on days 2 to 6. The RCC protocol consisted of RIT at a dose of 375 mg/m^2 on day 1, 2-CdA at a dose of 0.12 mg/kg/day in 2-hour infusion on days 2 to 4, and cyclophosphamide at a daily dose of 250 mg/m^2 on days 2 to 4. The courses were re-administrated at time intervals 4 weeks or longer if severe myelosuppression occurred. If a response was documented, patients were treated until maximal response or prohibitive toxicity. Guidelines for response developed by the NCI-WG were used. *Results.* Fourty six patients with CLL entered the study. 33 (72%) patients had recurrent disease and 13 (28%) patients were refractory to prior therapy. Eighteen patients were treated with RC regimen and 28 with RCC regimen. The median number of courses administrated were 3 cycles (range 1-6 cycles). Three (6.5%) patients (95% CI 1-14%) achieved a complete response (CR) and 30 (65%) patients (95% CI 51-79%) a partial response (PR). According to the particular regimen, the overall response rate (OR) was obtained in 12 (67%) patients treated with RC (95% CI 45-89%) and in 21(75%) patients treated with RCC (95% CI 59-91%). Noteworthy, out of 2 patients who were previously treated with alemtuzumab and then relapsed, both responded to RCC. The median failure free survival (FFS) of responders was 9 (3-46) months. Hypersensitivity to rituximab (fever, chills, rush, hypotonia) was the major toxicity of RC/RCC regimens and occurred in 16 (33%) patients mostly during the first infusion of the drug. Grade 3/4 neutropenia was seen in 6 (13%) patients, grade 3/4 thrombocytopenia in 3 (9%) patients, and grade 3/4 infections were observed in 10 (28%) patients. *Conclusions.* The data indicate that both RC and RCC regimen have high therapeutic activity and relatively low toxicity in heavily pretreated patients with CLL.

0113

ALEMTUZUMAB AS CONSOLIDATION THERAPY AFTER FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB REGIMEN (FC-R) FOR THE TREATMENT OF YOUNG PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

F. Gonnella, A. Carola, M. Esposito, S. Improta, A. Lucania, M.R. Villa, L. Mastrullo

U.O.C. Ematologia, NAPLES, Italy

Background. B-cell chronic lymphocytic leukemia (CLL) is a clonal hematopoietic disorder characterized by proliferation and accumulation of small lymphocytes. CLL has traditionally been considered indolent, with a prolonged clinical course. However, a large proportion of patients with CLL have severe symptoms, a poor prognosis, and often require more immediate treatment of their leukaemia. Several randomized studies indicate that cytotoxic therapy based on alkylating agents or new purine nucleoside analogs, such as fludarabine, in the indolent phase of disease, does not prolong the survival time of CLL patients. The monoclonal antibodies directed against CD52 antigen (alemtuzumab, Campath-1H) and CD20 antigen (rituximab) demonstrate also considerable activity in CLL patients. These agents have significant single-agent activity, distinct mechanism of action and generally, favorable toxicity profiles. The use of rituximab with the cytotoxic agents cyclophosphamide and fludarabine (FC-R) has achieved complete remission (CR) with no detectable CLL, as assessed by minimal residual disease (MRD) techniques, in a significant proportion of previously untreated and previously treated CLL patients. Moreover, monotherapy with alemtuzumab has also been shown to achieve a complete response with undetectable MRD in several patients with relapsed/refractory disease. *Aims.* We have investigated, in a small cohort of young untreated CLL patients, the feasibility and effectiveness of a combination therapy using alemtuzumab consolidation to improve the quality of response to FC-R induction. *Methods.* In our institution we treated 12 patients (4 F and 8 M; median age: 45 years, r.: 35-52 years; Rai stage III-IV) with 6 cycles of FC-R (fludarabine at a dose of 25 mg/m^2 i.v. on days 1-3, cyclophosphamide at a dose of 250 mg/m^2 i.v. on days 1-3, and rituximab at a dose of 375 mg/m^2 on day 0). One month after the last cycle all patients were subjected to a disease re-staging that showed a clinical CR, but 9 out of 12 patients showed the presence of MRD in the bone marrow. Thereafter all patients received, after an initial dose escalation over 3 days, alemtuzumab 10 mg subcutaneously three times per week for 12 weeks. Cytomegalovirus reactivation occurred in 10 patients, all of whom were successfully treated with oral valganciclovir. *Results*. At a clinical re-staging performed after one, three and six months from the end of therapy all patients showed a CR with undetectable MRD (molecular CR). At the present, (month +14) all patients are alive and in molecular CR. *Summary and conclusions.* FC-R is highly active as initial therapy also in young CLL patients. However, a consolidation therapy with alemtuzumab seems to be required for achieving a stable molecular CR. Moreover our preliminary results show acceptable toxicity profile of this therapeutic approach.

0114

WHAT CAN WE CURRENTLY LEARN FROM NEW PROGNOSTIC MARKERS OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN THE EVERYDAY HAEMATOLOGICAL PRACTICE?

M. Doubek,[1] E. Cmunt,[2] J. Schwarz,[3] M. Brejcha,[4] M. Heidekerova,[1] M. Trbusek,[1] Y. Brychtova,[1] M. Klabusay,[1] S. Pospisilova,[1] J. Mayer[1]

[1]University Hospital, BRNO; [2]General Faculty Hospital, PRAGUE; [3]Institute of Hematology, PRAGUE; [4]Mendel Oncologic Centre, NOVY JICIN, Czech Republic

Introduction. The opinions about the pathogenesis and prognostic factors of CLL have undergone significant changes over the past decade and a variety of new prognostic factors have been discovered. On the other hand, however, indication for the start of therapy continues to be based on the conventional hematological and clinical findings, while a range of new and effective therapeutic procedures is now used in the CLL therapy. The exact current role of the new prognostic markers of CLL therefore remains undefined. *Aims and Methods.* The aim of our work was to analyze the impact of following new prognostic markers on the fate of CLL patients who were diagnosed and treated at 4 independent

hematological centers in one country: a flowcytometric analysis cZAP70; a cytogenetic analysis of ATM; a cytogenetic, molecular genetic and functional analysis of p53; and a mutational status of IgVH. *Results.* The total of 501 patients (median age 61 years, 35-86) suffering from CLL who have been treated and monitored at the haematological centres referred to above underwent the analysis The median follow-up time was 53 months (1'325). del/mut p53 and mutational status of IgVH were the only prognostic markers of those listed above with a significant impact on the overall survival (OS). The median OS in patients with del/mut p53 (33 patients) was 90 months, while in patients without this aberration was 280 months (p<0.001). The median OS in patients with unmutated IgVH (173 patients) was 155 months, while in patients with mutated IgVH was not reached (p<0.001). The remaining prognostic markers did not significantly influence the OS. The patients with unmutated IgVH (173 patients) and patients with del ATM (56 patients) were treated significantly more frequently than patients without these changes: 66.5% vs. 19.5% of patients with unmutated vs. mutated IgVH received therapy, and 68.3% vs. 25.9% of patients with vs. without del ATM required therapy. In patients with unmutated IgVH, the presence of del ATM or del/mut p53 had no impact on the requirement of therapy. ZAP70 expression had not statistically significant influence on OS. When considering also a mutational status, the cZAP70 expression had not influence on the need of therapy. *Conclusions.* According to our analysis, the condition of p53 and mutational status of IgVH are the only prognostic factors influencing the OS. Condition of ATM has no impact on the OS in the current times of modern therapeutic procedures. The importance of the cZAP70 expression has been evaluated as the least significant of all studied markers. This analysis showed which markers have the strongest predictive value also in an unselected large group of patients from a r*eal hematological practice* and moreover, stresses the need for (inter)national standardization of new prognostic markers analysis.

AUTOLOGOUS TRANSPLANTATION PROLONGS EVENT FREE SURVIVAL AND OVERALL SURVIVAL IN B-CLL PATIENTS WITH B AND C BINET STAGES: RESULTS OF THE PROSPECTIVE GOELAMS LLC 98 TRIAL

P. Feugier,[1] B. Mahé,[2] B. Kolb,[3] B. Audhuy,[4] P. Colombat,[5] H. Maisonneuve,[6] C. Foussard,[7] A. Bureau,[8] A. Brion[9]

[1]CHU Nancy, VANDOEUVRE LES NANCY; [2]CHU Nantes, NANTES; [3]CHU Reims, REIMS; [4]CH Colmar, COLMAR; [5]CHU Tours, TOURS; [6]Ch la Roche sur Yon, LA ROCHE SUR YON; [7]CH Angers, ANGERS; [8]CH Besancon, BESANÇON; [9]CH Beancon, BESANÇON, France

Background. The role of high dose chemotherapy with autologous progenitor cell support in first line therapy in patients with B-CLL remains to be defined. *Aims.* The aim of the prospective randomized GOELAMS LLC 98 trial was to compare two therapeutic strategies in previously untreated advanced B-CLL patients younger than 60 years. *Methods.* Conventional chemotherapy (Arm A) consisted of six monthly courses of ChOP, (i.e. vincristin IV 1 mg/m^2 on day 1, doxorubicin IV 25 mg/m^2 on day 1, cyclophosphamide (Cy) 300 mg/m^2 and prednisone 40 mg/m^2 both given orally from day 1 to day 5, followed by 6 ChOP courses every other 3 month in case of response. Fludarabine (25 mg/m^2 /d IV for 5 consecutive days) was used in case of non response (stable disease or progression) after 3 ChOP. Conventional therapy was compared to high dose therapy with autologous CD34$^+$ progenitor cell support (Arm B), using as consolidation of Complete Remission (CR) (NCI criteria) or Very Good Partial Response (VGPR, defined by >50% tumoral response and <30% bone marrow lymphocyte count) obtained after 3 monthly courses of CHOP. In case of absence of CR or VGPR, 3 to 6 monthly-courses of fludarabine were realized before mobilization with Cy 4 g/m^2 + G-CSF administration. Conditioning regimen included TBI 12 Gy and Cy 60 mg /kg /d for 2 days. *Results.* Between March 1999 and December 2004, 86 patients were randomized of which 82 were evaluable (39 in arm A and 43 in arm B). Sex-ratio, Binet stages and median age were similar in the two groups, as well as the number of unmutated patients (data available in 61 patients). In Arm B, 14 out of 43 patients were not transplanted because of disease progression (n=9), death during the first CHOP course (n=1), hepatitis C (n=1), mobilization failure (n=2) and graft contamination (n=1). One graft was not used because of contamination. Finally, 29 grafts were performed and CD34$^+$ cells purification was realized in 14 patients. Post transplant grade 3-4 non-hematological toxicity was infectious (2 CMV and 1 aspergillus infections). Second cancers occurred in 6 patients in Arm A (2 skin cancers,1 prostatic cancer, 1 multiple myeloma, 1 breast cancer and 1 acute myeloid leukaemia) and 5 patients in arm B (2 skin cancers, 1 bladder cancer, 1 breast cancer and 1 myelodysplasia). Cumulative number of death was 13 in arm A and 4 in arm B (p=0.013), due to 16 cases of progression (13 in arm A, 3 in arm B) and one case of toxicity in arm B. As an intent-to-treat analysis and with a median follow-up time of 49.7 months (range 1-94), median EFS was 22 months in Arm A and 53.1 months in Arm B (p<0,001) ; moreover, overall survival was significantly better (p=0.017) in intensive arm. *Conclusions.* We have shown that front-line high dose therapy with autologous progenitor cell support is feasible and prolongs EFS and overall survival in advanced B-CLL patients.

Martino, GENOVA; [5]IRCCS Policlinico, Genetica Molecolare, MILANO; [6]UOC di Ematologia, Ospedale Maggiore, TRIESTE; [7]SS Diagnostica Mal. Linfo Prol, IST, GENOVA; [8]UOC di Oncologia AO Pugliese-Ciaccio, CATANZARO, Italy

Background. (B-CLL) is a clinically heterogeneous disease with some patients exhibiting an indolent and others an aggressive course. Markers such as cellular expression of ZAP-70 or CD38 and IGVH gene mutational status have been used to assess prognosis. *Aims*. We investigated the CD38, ZAP-70 and IGVH status in a representative cohort of 179 Binet stage A B-CLL patients in order to define subgroups in terms of disease progression based on the time to first treatment (TTT). Gene expression profiling analysis was also performed to identify specific transcription profiles in B-CLL groups with a specific TTT. *Methods*. The proportion of CD38+ leukemic cells was determined by triple staining for CD19 FITC, CD38 PE, and CD5 Cy-Chrome. CLL Ig VH gene usage and mutation was determined on cDNA according to reported methods. Determination of ZAP-70 was carried out by Western blot. Gene expression profiling was performed in 60 patients on U133A chips using the 7G scanner (Affymetrix). Supervised analyses were made using the SAM (Significance Analysis of Microarrays) algorithm. *Results*. Statistically significant difference in terms of TTT at 4 years were observed in patients showing ZAP-70 strong versus cases ZAP-70 neg/weak (clustered together) (log rank 10.5, p=0.001), CD38 expression >30% (log rank 27, p<0.0001) or non-mutated IGVH (log rank 29.8, p<0.0001). In multivariate analysis the factors that turned out to correlate significantly with TTT were CD38 and VH mutational status, while Zap-70 showed a borderline significance. Since the RR associated with each of the 3 factors was comparable, we constructed a new potential prognostic model by a combination of these biological variables assigning a score of 1 for each prognostic marker with a final score ranging from 0 to 3 with intermediate values of 1 and 2. Approximately 54%, 22%, 13% and 11% of cases scored 0, 1, 2, and 3, respectively. At 4 years, 94%, 92%, 47%, and 37% of cases scoring respectively 0, 1, 2, and 3, remained therapy-free. Pooling together score 0 with 1 cases (low risk), and score 2 with 3, (high risk) the final curves showed, at 4 years 2% and 58% of cases who necessitated treatment (chi-square 34.2, p<0.0001). Gene expression profiling analyses on a representative panel of 60 patients (15 score 0, 16 score 1, 15 score 2, and 14 score 3) revealed 37 genes differentially modulated between the four classes. Differences in expression were more significant when group 0 and 1 were evaluated against 2 and 3 (46 genes) whereas the major changes were found between patients with score 0 and 3 (119 genes). Functional analyses of differentially expressed genes revealed their involvement in several biological processes such as transcription regulation, electron transport, protein transport and metabolism, cell cycle regulation and apoptosis. *Discussion.* The combination of biological and molecular features of B-CLL prompted us to propose a scoring system that can contribute to assist in designing clinical trials. In particular, it could be helpful to test to what extent early treatment of high risk patients (e.g. score 2 and 3) confers clinical advantages.

LONG TERM FOLLOW UP OF HAIRY CELL LEUKEMIA PATIENTS TREATED WITH INTERFERON-α. THE IMPORTANCE OF MAINTENANCE

M. Angelopoulou, K. Anargyrou, S. Sachanas, S. Kokoris, T.P. Vassilakopoulos, Z. Galani, M.N. Dimopoulou, F.N. Kontopidou, E. Plata, P. Tsaftaridis, E. Dimitriadou, M.P. Siakantaris, G.A. Pangalis

University of Athens, ATHENS, Greece

Background. HCL is a chronic B-cell lymphoproliferative disorder with specific clinical, morphologic and immunophenotypic features. Although purine analoges are the most recommended first-line treatment, they are associated with significant immune suppression and secondary malignancies. IFN-α is an alternative treatment with fewer long-term side effects and considerable efficacy. *Aims.* The analysis of the outcome of HCL patients (pts) treated with IFN-α as first-line therapy and as maintenance in a single Hematology Unit. *Methods.* 75 consecutive HCL pts diagnosed and followed in our Department between 1980 and 2005, treated with IFN-α were retrospectively analyzed. *Results.* 77.3% were males and their median age was 51 years (30-81). 57% had splenomegaly and 12% hepatomegaly at diagnosis. Their median complete blood counts were as follows: hemoglobin 11.3g/dL (4.5-14.3), leukocyte and absolute neutrophil counts 3.1×10^9/L (0.9-26) and 0.77×10^9/L (0.03-3.9), respectively, platelets 79×10^9/L (20-295). 33% had hypergammaglobulinemia and the median percentage of bone marrow infiltration at diagnosis was 75%. 10% of the pts were splenectomized before IFN-α treatment. The median time from diagnosis to IFN-α initiation was 0.7 months. The majority of pts (68%) received IFN-α induction at a dose of 3MU/day, while 15% 3MU every other day. Median duration of IFN-α induction was 23.5 months. 8% of pts achieved a complete response with a negative bone marrow, while 73% had a partial remission with a >50% reduction of bone marrow infiltration and a complete restoration of all blood counts. The median time to complete hematologic restoration was 10.7 months. 79% of pts received IFN-α maintenance, the majority of whom (58%) at a dose of 3MU/week. 69% of pts never needed a 2d line treatment, while among those who did, 65% were retreated with IFN-α. The median follow-up was 95 months (9-287) and the 10-year overall survival was 80%. There were 2 cases of secondary neoplasia. At last follow-up 9% of pts were dead due to unrelated causes, 3% due to 2ary neoplasia, while none died due to disease. Two factors were of prognostic significance for freedom from 2d treatment (FF2T). FF2T was significantly longer for pts older than 51 years old ($p<0.0004$) and for those receiving IFN-α maintenance compared to those who did not ($p<0.03$). *Conclusions.* IFN-α has significant efficacy in HCL with a slow but sustained response and a low incidence of secondary neoplasia. Continuous maintenance seems to be important in maintaining response. Younger patients might benefit less from IFN-α.

0118

THE ACTIVITY OF ALEMTUZUMAB IS INDEPENDENT OF P53 MUTATIONAL STATUS IN FLUDARABINE REFRACTORY CLL: INTERIM ANALYSIS FROM THE CLL2H STUDY OF THE GCLLSG

T. Zenz,[1] S. Häbe,[1] T. Denzel,[1] D. Winkler,[1] A. Kröber,[1] D. Kienle,[1] M. Hallek,[2] M. Hensel,[3] E. Lengfelder,[4] L. Trümper,[5] P. Dreger,[3] U. Jäger,[6] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM, Germany; [2]University of Cologne, COLOGNE, Germany; [3]University of Heidelberg, HEIDELBERG, Germany; [4]University of Mannheim, MANNHEIM, Germany; [5]University of Göttingen, GÖTTINGEN, Germany; [6]University of Vienna, VIENNA, Austria

Background. The prognosis of fludarabine-refractory CLL is poor with a median survival time of 10 months. Campath-1H (Alemtuzumab) is approved for fludarabine refractory CLL and there is growing evidence that Alemtuzumab is active irrespective of high-risk genetic subgroups. *Methods.* In order to assess the incidence of TP53 mutations in fludarabine refractory CLL we studied TP53 mutations in the CLL2H trial of the GCLLSG. We used DHPLC to screen for TP53 mutations (Exons 2-11). Aberrant DHPLC profiles lead to sequencing of the respective exons. In addition, detailed clinical history and genetic studies (VH-mutation status, FISH) were available for all patients. *Results.* At an interim analysis we found 19 TP53 mutations in 58 patients with completed mutational analysis. DHPLC results on all 109 patients suggest the presence of further mutations which will be updated at the meeting. There was a high concordance rate between 17p deletions and mutations (15 of 19 analysed patients with 17p- also had a TP53 mutation (79%)). A preliminary analysis of the impact of the presence of a TP53 mutation showed no difference in overall survival for the subgroup with currently confirmed TP53 mutation, suggesting that alemtuzumab is active irrespective of p53 status. The overall response (CR and PR) rate for patients with TP53 mutation was 31% compared to 34% percent at this interim analysis. *Conclusions.* Campath-1H appears to be effective in genetic high risk subgroups including those patients with TP53 mutations. The functional consequences of 17p deletions with and without TP53 mutation are under investigation.

Figure 1. Overall survival for fludarabine refractory CLL.

DOES REDUCED-INTENSITY ALLOGENEIC TRANSPLANTATION CONFER A SURVIVAL ADVANTAGE TO PATIENTS WITH POOR PROGNOSIS CHRONIC LYMPHOCYTIC LEUKAEMIA? A CASE-CONTROL RETROSPECTIVE ANALYSIS

J. Delgado,[1] S. Brunet,[1] G. Pratt,[2] J. Briones,[1] R. Lovell,[2] R. Martino,[1] J. Ewing,[2] D. Valcarcel,[1] A. Sureda,[1] D.W. Milligan,[2] J. Sierra[1]

[1]Hospital Sant Pau, BARCELONA, Spain; [2]Heart of England NHS Trust, BIRMINGHAM, United Kingdom

Background. Reduced-intensity allogeneic haematopoietic cell transplantation (HCT) is increasingly considered as a therapeutic option for several haematologic malignancies. However, relatively few patients with chronic lymphocytic leukaemia (CLL) have been treated with this approach. The disease has a long natural history, so there is reluctance to offer a procedure with a significant morbidity and mortality. However, up to 40% of CLL patients are younger than 60 years old at diagnosis, and these patients almost invariably die of their disease. Unfortunately, no prospective randomised trial comparing allogeneic HCT with conventional chemo- or immunotherapy has ever been performed. *Aims.* To assess retrospectively the outcome of CLL patients undergoing reduced-intensity allogeneic HCT compared with a group of matched controls that were candidates for transplantation but did not have a suitable donor or refused the procedure. *Methods.* Our databases were screened for cases having information available on the following variables: CLL diagnosis according to the WHO classification; age; time and type of CLL-specific treatment; and survival. Information on VH mutational status, cytogenetic abnormalities (i.e. 13q deletion, trisomy 12, 11q23 deletion, p53 deletion), CD38 and ZAP-70 expression was also available in 50% of patients. Cases comprised 30 patients diagnosed from 1992 to 2003, who underwent reduced-intensity allogeneic HCT at Barcelona and Birmingham. Unmanipulated haematopoietic cell grafts were harvested from HLA-matched siblings (23) and HLA-matched (3) or mismatched (4) unrelated donors. Controls consisted of 64 patients diagnosed from 1986 to 2005 at both institutions who received conventional therapy only. Matching variables were age at diagnosis and time to first CLL-specific therapy. *Results.* Both patient groups were well balanced in terms of CD38 and ZAP-70 expression, cytogenetic abnormalities and VH mutational status. Median age at diagnosis was 51 years (range 32-61) for the HCT group and 54 years (range 28-64) for the control group ($p= 0.138$). All patients required CLL-specific therapy within 4 years of diagnosis, with no significant differences between groups ($p=0.988$). The median number of therapy lines was not significantly different between groups ($p=0.163$) and 23% of cases and 27% of controls received an autograft as part of their therapy ($p=0.805$). Finally, median overall survival was 115 months for HCT patients and 93 months for controls, a difference that was not statistically significant ($p=0.59$, Fig-

ure 1). *Conclusions.* Results for reduced-intensity allogeneic transplantation are promising for selected patients with poor prognosis CLL. There is, however, insufficient data at this point in time to recommend the procedure outside clinical trials. International multicentre studies with greater numbers of patients could help clarify this issue.

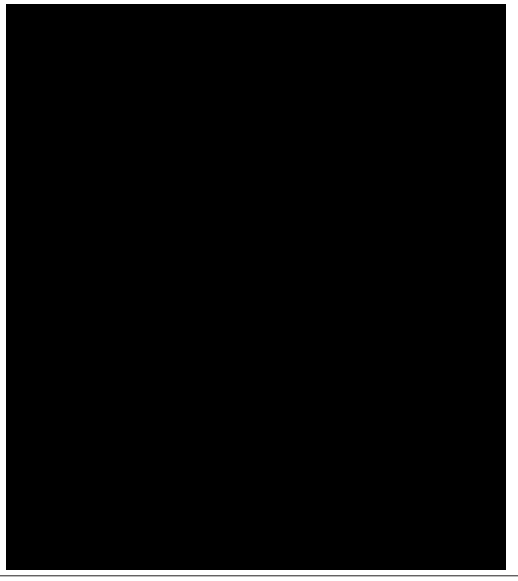

Figure 1. Overall survival according to therapy.

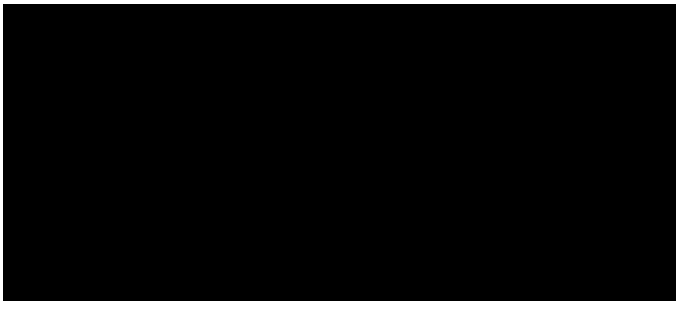
PHASE III STUDY OF CLADRIBINE PLUS CYCLOPHOSPHAMIDE COMPARED WITH FLUDARABINE PLUS CYCLOPHOSPHAMIDE FOR PATIENTS WITH PROGRESSIVE CHRONIC LYMPHOCYTIC LEUKEMIA: REPORT OF PALGCLL3 TRIAL

T. Robak,[1] J.Z. Blonski,[1] J. Gora-Tybor,[1] K. Jamroziak,[1] B. Ceglarek,[2] L. Konopka,[2] M. Calbecka,[2] A. Kostyra,[2] B. Stella-Holowiecka,[2] J. Kloczko,[2] K. Warzocha,[2] I. Seferynska,[2] A. Dmoszynska,[2] M. Kowal,[2] K. Lewandowski,[2] J. Dwilewicz-Trojaczek,[2] G. Charlinski,[2] K. Kuliczkowski,[2] S. Potoczek,[2] A. Hellmann,[2] A. Mital,[2] A. Skotnicki,[2] W.S. Nowak,[2] A. Zdunczyk,[2] J. Dybowicz,[2] K. Sulek,[2] K. Zawilska[2]

[1]Medical University of Lodz LODZ; [2]Polish Adult Leukemia Group, (PALGCLL3), Poland

Background. Purine analogues, Cladribine (2-CdA) and Fludarabine (FA), are highly effective in treatment of chronic lymphocytic leukemia (CLL). *Patients and Methods.* This prospective randomized phase 3 trial was designed to compare the efficacy and toxicity of 2-CdA and cyclophsophamide (CC regimen) with FA and cyclophsophamide (FC regimen) in previously untreated progressive CLL. The primary end points of the study were complete response (CR) and overall response (OR) after completion of the therapy.

Table 1.



The secondary end points were progression free survival (PFS), overall survival (OS) and treatment related toxicity. Eligible patients were assigned to receive 6 courses of either 2-CdA 0.12 mg/kg/d i.v. with cyclophosphamide 250 mg/m^2/d i.v. for 3 consecutive days or FA 25 mg/m^2/d i.v. with cyclophosphamide 250 mg/m^2/d i.v. for 3 consecutive days administered at 28 day intervals. The treatment response and toxicity were evaluated according to NCI-SWOG guidelines. Minimall residual disease (MRD) was evaluated in patients with CR using three-color cytometry. *Results.* The study was started in January 2001 and here we present updated results from the 296 evaluated patients performed in December 2006. There were no significant differences in the rates of overall response (OR), complete response (CR), grade 3/4 neutropenia, thrombocytopenia and infections, MRD negativity and number of died patients. PFS was also similar in both groups (p=0.77). *Conclusions.* CC and FC regimens produced similar CR, OR and PFS, as well as have similar toxicity in previously untreated, progressive CLL.

0121

IMMUNE THROMBOCYTOPENIA IMPAIRS SURVIVAL OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

C.V. Visco,[1] R. Stasi,[2] M. Ruggeri,[1] F. Frattini,[3] R Zanotti,[3] A. Ambrosetti,[3] S. Fortuna,[1] I. Giaretta,[1] D. Madeo,[1] G. Pizzolo,[3] F. Rodeghiero[1]

[1]Ospedale S Bortolo, VICENZA; [2]Ospedale Regina Apostolorum, ALBANO LAZIALE; [3]Policlinico GB Rossi, VERONA, Italy

Background. Immune thrombocytopenia (IT) is the most frequent autoimmune disorder during CLL, second only to hemolytic anemia. However, the real prevalence and the natural history of this complication are largely unknown. *Aims.* To determine main clinical features and overall survival (OS) of patients developing IT in the course of CLL. *Methods.* We retrospectively analyzed clinical records of 1233 consecutive patients with CLL admitted for the first time to three tertiary hematological center between 1 January 1995 and 31 December 2004. All patients met the diagnostic criteria for CLL of the National Cancer Institute. To be considered as affected by IT, patients had to fulfill the following criteria: rapid (<2 weeks) and severe fall (at least half of the initial level and below 100×10^3/μL) of the platelet count; normal or augmented number of megakaryocytes in the absence of extensive (>90%) lymphoid infiltration; no or limited splenomegaly; no recent (less than one month) cytotoxic treatment. Complete response (CR) to treatment for IT was defined by a platelet count ≥150×10^9/L, while partial response (PR) by a platelet count > 50×10^9/L or at least doubling the initial level. Remaining patients were considered as no responders (NR). *Results.* Sixty-four patients (5,1%) had IT at presentation or developed it during the course of the disease. IT could be established concomitantly to CLL diagnosis in 14 cases, while median time to IT for the remaining 50 patients was 30 months (range 2-117). The median platelet count at IT diagnosis was 14×10^9/L (range, 1-71). Twenty-six patients (41%) presented with moderate bleeding signs at IT diagnosis, with 5 patients (8%) experiencing severe hemorrhagic episodes. Fifty-six of the 64 patients (87%) received at least one treatment for IT.

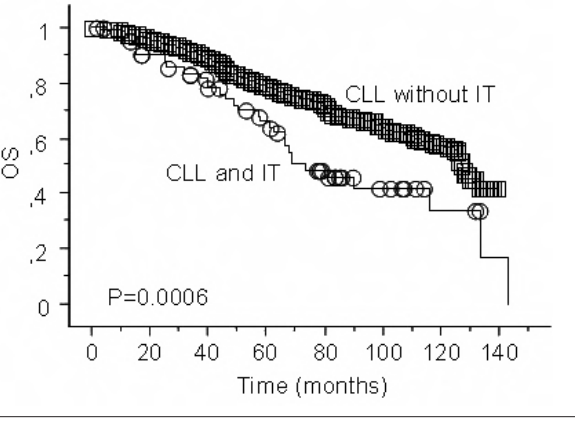

Figure 1.

Of the 33 patients who received i.v. Ig alone or in combination with steroids, 39% had at least a PR; 10 patients underwent splenectomy and 7 (70%) experienced a durable CR; 73% of patients who were treated with chemotherapy (Chlorambucil, COP, CVP) ± steroids obtained at least a PR. Two spontaneous remissions were observed. With a median follow-up of 63 months from IT onset 16 of the 56 treated patients are still NR (29%) and 13 of them still require treatment. No significant clinical differences were observed at CLL presentation between patients

with IT and patients without IT (RAI stage 0-2 in 91% vs 84% respectively, p=0.16). First line treatment for CLL was similar in the two groups consisting of Chlorambucil alone in 70% of patients. Five- and 10-year overall survival (OS) for all patients was 73% and 50%. Patients with CLL and IT experienced a significantly worst OS than other patients with CLL (p=0.0006), as shown in the Figure 1. Refractoriness to treatment for IT had an additional negative impact on survival. *Conclusions.* Our study, for the first time, demonstrates that occurrence of IT in CLL has a significant negative impact on survival, at variance with common belief.

0122

CT SCAN GIVES ADDITIONAL INFORMATION OF CLINICAL VALUE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

N.E. Norin,[1] E. Kimby,[1] J. Lundin[2]

[1]Karolinska University Hospital Huddinge, STOCKHOLM; [2]Karolinska University Hospital Solna, STOCKHOLM, Sweden

Background. CLL is the most common chronic leukemia in adults and shows an extremely variable prognosis. Traditional staging systems (Rai and Binet) are based on clinical examination and presence of anemia and/or thrombocytopenia. However, lymph node stations that are not readily available for clinical examination such as abdominal and thoracic lymph nodes are not incorporated in these staging systems, nor is spleen enlargement not noted by palpation. These systems were developed before CT scan became a routine method for obtaining information about lymph node status in hematologic malignancies. We therefore decided to analyse if CT scan would provide additional prognostic information in CLL patients. *Aims.* To find out whether CT scan of thorax and abdomen could provide additional prognostic information in patients with CLL requiring first-line therapy. *Methods.* We identified 77 patients who had been included in four phase II studies at Karolinska University Hospital between 1990 and 2000. In these studies a CT scan was mandatory before start of therapy and also for assessment of response at the end of therapy. Data was retrospectively collected and analysed. Assessment of response was based on information from the charts of the patients using the NCI criteria. To obtain more detailed information of lymph node status we also used the GELF criteria originally developed for follicular lymphoma. *Results.* Time from CLL diagnosis to institution of first-line therapy was 12 (0-269) months. The median age at this time point was 66 (40-85) years and Rai stage was I (n=24), II (n=6), III (n=33) or IV (n=14). With the addition of a CT scan lymphadenopathy and/or splenomegaly was detected in totally 74 patients, leading to a modified Rai stage in 9 patients, in all cases from I to II. CT scan also revealed bulky (>7cm) abdominal lymphadenopathy in 11 patients. In total 54 patients had CT verified splenomegaly, in 22 cases this was not detected during clinical examination. The time from first-line treatment to start of next therapy was 29 months (1-156). Patients with a high lymphadenopathy tumor burden according to the GELF criteria had a significantly shorter time to therapy requirement than those with less advanced lymphadenopathy (p=0.038). *Summary and conclusions.* Clinical examination alone is not sufficient to rule out splenic enlargement and abdominal lymphadenopathy in CLL. The degree of lymphadenopathy appears to be of importance to predict duration of response to therapy. CT might also be of value for evaluation of progression and the need of further therapy. A larger study, preferably made at the time of CLL diagnosis is warranted.

Background. Lumiliximab, an IgG1 chimeric monoclonal antibody targeting CD23, has been shown to enhance fludarabine- and rituximab-mediated apoptosis in chronic lymphocytic leukemia (CLL) cells in a caspase-dependent manner. *Aims.* A phase I/II open-label dose-escalation multicenter study was initiated to evaluate the safety and efficacy of lumiliximab in combination with fludarabine, cyclophosphamide, and rituximab (FCR) in the treatment of relapsed $CD23^+$ B-cell CLL. *Methods.* Thirty-one patients with relapsed $CD23^+$ B-cell CLL whose disease was not refractory to FCR were enrolled after informed consent was obtained. They were treated with 375 mg/m^2 (n=3) or 500 mg/m^2 (n=28) of lumiliximab in combination with FCR for a maximum of 6 cycles. Response was assessed using National Cancer Institute Working Group criteria at weeks 13 and 25, and patients were to be followed for 48 months. *Results.* The median age of patients was 58 years. The median absolute lymphocyte count was $41\times10^3/\infty$L and the median number of previous regimens was 2 (range 1-9). Twenty-two patients (71%) responded to treatment with FCR plus lumiliximab (FCRL); the complete response rate was 52%. There were responses in 6 of 8 patients with del(11q22.3), 5 of whom achieved a complete response. One of 4 patients with del(17p13.1) had a partial response to treatment. Grade 3 or 4 adverse events were reported in 65% of patients, but these events were manageable and were expected with FCR therapy. The most common adverse events (all grades) were nausea (77%), pyrexia (61%), neutropenia (58%), chills (55%), and fatigue (48%). Data from the phase I/II trial were compared with published data from a study in 177 patients with relapsed or refractory CLL who were treated with FCR alone (Wierda W, *et al.* J Clin Oncol. 2005;23:4070-4078). The characteristics of patients treated with FCRL or FCR alone were comparable, with the exception of Rai stage I/II disease (74% vs 47%) and previous exposure to rituximab (60% vs 12%). The overall response rates were similar with the 2 regimens (71% vs 73%), but FCRL produced a complete response rate that was double the rate observed with FCR alone (52% vs 25%). The regimens had similar incidence rates and levels of severity of myelosuppression and other toxicities; approximately 45% of patients in both studies completed 6 cycles of treatment. *Conclusions.* These data suggest that lumiliximab administered in combination with FCR has a high level of activity in the treatment of relapsed CLL. The FCRL regimen has an acceptable safety profile and does not appear to add to the toxicity of FCR. The complete response rate achieved with FCRL appears encouraging, even in patients with del(11q22.3). A randomized trial comparing FCRL with FCR alone has been initiated and is currently enrolling patients.

0124

POST-REMISSIONAL RITUXIMAB ADMINISTRATION FOR THE TREATMENT OF OLDER CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS RESPONSIVE TO FIRST-LINE THERAPY WITH CHLORAMBUCIL AND PREDNISONE

F.R. Mauro,[1] I. Del Giudice,[2] M. Gentile,[2] G. De Angelis,[2] M.S. De Propris,[2] M.E. Ghia,[2] M. Marinelli,[2] L. Quattrocchi,[2] P. Fisinger[2] A. Guarini,[2] R. Foà[2]

[1]Division of Hematology, Università La Sapienza, Rome; [2]Division of Hematology Università La Sapienza, Rome, Italy

Background. Chlorambucil treatment is manageable and well tolerated in CLL patients, but is associated with partial responses and short response duration. *Aims.* With the aim of improving the quality of response, the anti-CD20 monoclonal antibody Rituximab was given as post-remissional therapy to older CLL patients (≥60 years) responsive to first-line treatment with 6 monthly courses of chlorambucil (C: 10 mg/sqm/day, d1-d5) and prednisone (P: 25 mg/sqm/day, d1-d5). *Methods.* This study included 19 CLL patients in PR after 6 courses of CP treatment who received 4 weekly doses of Rituximab (R: 375 mg/m^2). Median age was 65 years (range, 61-81 years). Five patients showed unmutated IgVH, while 14 were mutated. Prior to starting Rituximab treatment, the median number and the rate of residual PB $CD5/CD20^+$ lymphocytes were respectively 638×10^9/L (range: 129-8134$\times10^9$/L) and 54% (range: 13-87%) of lymphocytes, while the median rate of residual BM $CD5/CD20^+$ lymphocytes was 26% (range: 7-55%). Moderately (≥2cm) enlarged nodes and/or spleen were present in 8 patients (42%). Clinical and cytometric responses were assessed 4 weeks after the last Rituximab administration and, thereafter, every 3 months up to disease progression. *Results.* After Rituximab, the median number and the rate of PB $CD5/CD19^+$ lymphocytes decreased to 110×10^9/L (range: 6-1700 $\times10^9$/L) and 9% (range: 1-61%) of lymphocytes, respectively, and the median rate of BM $CD5/CD19^+$ lymphocytes to 5% (range: 0-50%). In all cases but 2, no enlarged nodes or splenomegaly were observed. Overall, the reduction of residual disease produced an upgrade of the previous response from PR to CR in 13 cases (68%), while no significant changes were documented in 6. Two of the 13 (15%) patients who achieved a CR after Rituximab showed less than 1% $CD5/CD19^+$ lymphocytes both in the PB and the BM. No evidence of a clinical benefit of Rituximab administration was observed in 3/5 IgVH unmutated

patients. After a median follow-up of 65 months (range 32-76), all patients have relapsed. The median time free from disease was 16 months (range: 3-46). A second-line therapy has been required by 12 patients (63%), with a median time to the next treatment of 29.5 months (range: 15-68). Rituximab infusion was well tolerated; mild infusion-related side effects were observed in 3 cases. No patient showed hematologic toxicity or infection. *Conclusions.* The results of this study indicate that Rituximab, given as post-remissional therapy in older CLL patients treated with CP, produced a clinical benefit with a good safety profile in the majority of cases. Additional studies need to be designed to explore new Rituximab schedules, the association of Rituximab with C and post-remissional treatment strategies in CLL patients not eligible for aggressive treatment modalities.

0125

COMBINATION OF IGVH MUTATIONAL STATUS AND GENETIC ABNORMALITIES MAY FURTHER REFINE PROGNOSTIC STRATIFICATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

L. Smolej,[1] M. Hrudkova,[1] P. Zak,[1] D. Belada,[1] S. Pekova,[2] L. Kucerova,[1] J. Schwarz,[3] J. Sobotka,[4] V. Holubova[4]

[1]University Hospital and Medical School, HRADEC KRALOVE; [2]Na Homolce Hospital, PRAGUE; [3]Institute of Hematology and Transfusion, PRAGUE; [4]J.G. Mendel Memorial Oncology Institute, NOVY JICIN, Czech Republic

Introduction. Chronic lymphocytic leukemia (CLL) is a disease with an extremely variable clinical course. New prognostic factors such as mutation status of immunoglobulin heavy chain variable region (IgVH) or genetic aberrations detected by fluorescent *in situ* hybridization (FISH) can identify patients with high risk disease. However, a single prognostic factor is not sufficient to assess the prognosis of an individual patient accurately enough. *Aims.* To assess the prognostic impact of combination of IgVH mutational status and genetic aberrations in a single-center CLL cohort. *Methods.* 91 patients with CLL diagnosed according to NCI-WG criteria were included in the study. IgVH mutation status was analyzed using cDNA transcribed from B-CLL RNA for touch-down reverse transcriptase polymerase chain reaction (RT-PCR) with degenerate primers for VH1-7 families; IgVH sequences were aligned to the nearest germline using the Ig BLAST database. Forty-two patients carried mutated IgVH and 49 unmutated IgVH genes. Genetic aberrations were detected using commercially available FISH kits for del 13q, del 11q, del 17, and trisomy 12 by Abbott. There were 33 cases with del 13q as a sole abormality, 25 patients with del11q, 18 with trisomy 12 and 14 patients with del17p. More than 2 abnormalities were detected in 14 cases.

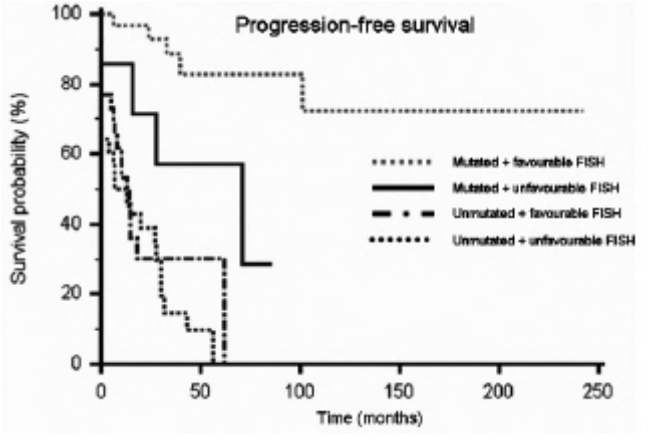

Figure 1. Combination of IgVH and FISH and PFS.

Results. As expected, patients with unmutated IgVH had significantly shorter PFS in comparison to mutated IgVH genes (median PFS 15 vs. 101 months, $p<0.0001$). According to FISH results, patients were divided into a subgroup with favourable (i.e., no abnormality or del 13q as a sole aberration) and unfavourable (del 11 q and/or del 17p and/or trisomy 12). The group with unfavourable abnormalities had significantly shorter PFS in comparison to favourable FISH (median PFS 16 vs. 101 months, $p=0.0002$). When we combined these two factors together, FISH results had significant impact on PFS in patients with mutated but not unmutated IgVH genes: unfavourable FISH significantly worsened PFS in the subgroup of patients with mutated IgVH (mutated + favorable vs. unfavourable FISH, median PFS not reached vs. 71 months, $p=0.011$). However, FISH did not have additional prognostic impact in IgVH-unmutated cohort (unmutated + favourable vs. unfavourable FISH, median PFS 13 vs. 13 months, $p=0.476$). *Conclusions.* This study confirms that IgVH mutation status and genetic aberrations play a major role as prognostic factors in CLL. Data obtained in our single center retrospective analysis show that results of FISH may refine prognosis in terms of progression-free survival in IgVH-mutated patients but fail to add prognostic information in patients with unmutated IgVH genes. Larger, prospective study with longer follow-up is needed to perform a more detailed statistical assessment including multivariate analysis and impact of these prognostic factors on overall survival. THE VALUE OF SERUM BETA 2-MICROGLOBULIN (β-2M) IN COMPARISON WITH CD38 AND ZAP-70 EXPRESSION, AND IG VH GENE STATUS IN PREDICTING THERAPY FREE INTERVAL IN EARLY B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL) PATIENTS

F. Morabito,[1] G. Cutrona,[2] M. Gentile,[1] V. Callea,[1] C. Mazzone,[1] M. Spriano,[3] S. Matis,[2] E. Rossi,[3] G. Festini,[4] A. Neri,[5] S. Molica,[6] M. Ferrarini[2]

[1]UOC di Ematologia, COSENZA; [2]Division of Medical Oncology C, IST, GENOVA; [3]Dpt di Ematologia , AO S. Martino, GENOVA; [4]UOC di Ematologia, Ospedale Maggiore, TRIESTE; [5]IRCCS Policlinico, Genetica Molecolare, MILANO; [6]UOC di Oncologia AO Pugliese-Ciaccio, CATANZARO; Italy

Background and Aims. Cellular expression of ZAP-70 or CD38, IgVH gene mutational status and chromosome abnormalities are well-established prognostic features in B-cell chronic lymphocytic leukemia (CLL). However, studies addressing the value of newer prognostic factors in comparison to older ones (i.e., β-2M]) are lacking. With this in mind we wondered whether serum levels of β-2M, when compared with cellular expression of ZAP-70 or CD38 and IgVH gene mutational status, might retain its role in predicting clinical outcome of B-CLL patients. The patient cohort included 194 previously untreated B-cell CLL cases with available information on either CD38, ZAP-70, IgVH status or β-2M. For the purpose of the present study 166 Binet stage A patients assigned to a wait and see policy were analyzed. Time to first treatment (TFT) was the end point taken into account. *Results.* Serum levels of β-2M did not correlate with CD38- or ZAP-70-expression while the same did not apply for mutational status of IgVH. As a matter of fact, higher levels of β-2M were more frequently found among patients with unmutated IgVH in comparison to patients with mutated IgVH ($p=0.05$). In univariate analysis patients with increased serum levels of β-2M ($p=0.001$), higher CD38- ($p<0.0001$) or ZAP-70-expression ($p<0.0001$) and unmutated IgVH ($p<0.0001$) showed a significantly shorter 4-year TFT. In multivariate analysis, β-2M together with CD38-expression and mutational status of IgVH ($p=$) retained their prognostic value in predicting TFT. Interestingly,a subset analysis carried out among patients with unmutated and mutated IgVH status, respectively, revealed significant different TFT curves as a function of β2-m only in patients with unmutated CLL. *Conclusions.* In conclusion, our results confirm the role of newer prognostic variables (i.e., ZAP-70 or CD38, IgVH gene mutational status) in forecasting the clinical outcome of patients with early CLL. Interestingly, β2-m may allow an improved prediction of TFT in patients with unmutated IgVH.

PROGRESSION FREE SURVIVAL IS SUPERIOR WITH ALEMTUZUMAB VS CHLORAMBUCIL AS FRONT-LINE THERAPY FOR PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

P. Hillmen,[1] A. Skotnicki,[2] T. Robak,[3] B. Jaksic,[4] C. Sirard,[5] J. Mayer[6]

[1]Leeds General Infirmary, LEEDS, United Kingdom; [2]Jagiellionian Univ Collegium Medicum, KRAKOW, Poland; [3]Kopernik Memorial Hospital, LODZ, Poland; [4]Clinical Hospital Merkur, ZAGREB, Croatia; [5]GENZYME, CAMBRIDGE, MASSACHUSETTS, USA; [6]University Hospital Brno, BRNO, Czech Republic

Background. CAM307 is a phase III, open-label, multinational, randomized controlled trial comparing alemtuzumab (CAM) to chlorambucil (CHLO) for previously untreated BCLL. *Aims.* To compare efficacy and safety of alemtuzumab (CAM) to chlorambucil (CHLO) as front-line therapy. *Methods.* Eligible patients had Rai Stage I-IV and were randomized 1:1 to either CAM 30 mg IV tiw up to 12 weeks or CHLO 40 mg/m^2 po q 28 days up to 12 cycles. CAM patients received prophylactic

trimethoprim/sulfamethoxazole DS and famciclovir treatment during therapy and until CD4+ counts were ≥200 cells/μL. The primary endpoint was PFS; secondary endpoints included response rate, time to alternative therapy, survival, and safety. A total of 297 patients were randomized (CAM n=149 and CHLO n=148; median age: 60 years); performance status 0-1: 96%; maximum lymph node size ≥5 cm: 22%; and Rai stage I-II: 63%. An independent response review panel (IRRP) confirmed diagnosis, Rai stage, response and disease progression that were used in the efficacy analysis. *Results.* PFS was superior for CAM (p=0.0001, stratified log-rank test) with a hazard ratio of 0.58 (95%CI: 0.43, 0.77). Response rate was higher for CAM than CHLO, previously reported (ASH, 2006;301). CAM was superior to CHLO in patients <65 years of age, <70 years of age, with maximum lymph node size <5 cm, and performance status <2 as measured by PFS and response rates. Kaplan-Meier median time to alternative treatment was significantly longer for CAM (23.3 months) compared to CHLO (14.7 months); p=0.0001 (stratified log-rank test), hazard ratio 0.54 (95%CI: 0.39, 0.74). With a median duration on treatment of 11.7 weeks for CAM and 28.3 weeks for CHLO, the difference in time off active treatment is even greater for the CAM patients. There was no overall difference in overall survival with 24 deaths in each arm and a median follow-up time of 2 yrs for the study. A trend towards improved PFS with CAM was observed in patients with 17p deletion, not statistically significant due to small sample size. Common drug related adverse events (AEs) (≥15%) in the CAM arm (n=147) were pyrexia (64%), CMV PCR positivity (53%), chills (50%) and urticaria (15%) and in the CHLO arm (n=147) were nausea (35%) and vomiting (18%). Symptomatic CMV infection occurred in 16% in CAM arm only, none grade 4. Excluding CMV, infections occurred in 46% of CAM and 50% of CHLO patients. Relevant grade 3/4 treatment-emergent AEs (CAM vs CHLO): pyrexia (8% vs 0%), CMV events (8% vs 0%) and chills (3% vs 0%). Treatment-emergent grade 3/4 thrombocytopenia (12% vs 12%) and anemia (11% vs 18%) were similar for CAM vs CHLO. Although grade 3/4 treatment-emergent neutropenia was more common with CAM vs CHLO (41% vs 25%), bacteremia/sepsis (3% vs 2%) and febrile neutropenia (5% vs 3%) were comparable. *Conclusions.* CAM307 demonstrates that CAM is superior when compared to CHLO in therapy-naïve BCLL patients with significantly longer PFS, time to alternative treatment, higher overall ORR, CR and MRD negative rate, with manageable toxicities.

CYTOGENETIC ABNORMALITIES AND ASSOCIATED EFFICACY FROM A PHASE III STUDY COMPARING ALEMTUZUMAB VS. CHLORAMBUCIL AS FIRST LINE THERAPY FOR B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

T. Robak,[1] A. Skotnicki,[2] A. Dmoszynska,[3] J. Hébert,[4] Y. Wang,[4] M. Belkaci,[4] C. Sirard,[5] J. Mayer,[6] P. Hillmen[7]

[1]Kopernik Memorial Hospital, LODZ, Poland; [2]Jagiellionian Univ Collegium Medicum, KRAKOW, Poland; [3]Clinical Hospital No. 1, LUBLIN, Poland; [4]Cirion BioPharma Research Inc., LAVAL, QUEBEC, Canada; [5]Genzyme, CAMBRIDGE, MASSACHUSETTS, USA; [6]University Hospital Brno, BRNO, Poland; [7]Leeds General Infirmary, LEEDS, United Kingdom

Background. CAM307 is a randomized Phase III trial comparing the efficacy and safety of alemtuzumab (CAM) with chlorambucil (CHLO) in 297 previously untreated B-cell chronic lymphocytic leukemia (BCLL) patients requiring therapy according to NCIWG criteria. *Aims.* To evaluate outcome relative to cytogenetics at baseline using molecular cytogenetic analysis by fluorescent *in situ* hybridization (FISH) of peripheral blood cells. *Methods.* Patients were randomized 1:1 to CAM (n=149) vs. CHLO (n=148) using standard dosing regimens. Fluorescence *in situ* hybridization (FISH) on interphase nuclei of lymphocytes isolated from blood was analyzed for cytogenetic abnormalities prior to the start of therapy. FISH analysis was performed using 13 DNA probes to detect chromosomal aberrations in 17p13.1 (P53), 13q14 (RB1, D13S319 and D13S25), 11q22.3-11q23 (ATM and MLL), 6q27 (subtelomere), 6q21 (chromosome 6q21/alphasatellite 6 cocktail probe), trisomy 8q24 (MYC locus), trisomy 12 (CEP12) and translocations involving the locus of immunoglobulin heavy chain gene (IGH, 14q32.33). Samples were analyzed in 282 patients (95%); chromosomal aberrations were detected in 231 patients (82%) while 51 patients (18%) exhibited a normal interphase FISH pattern. *Results.* The most frequent abnormalities were deletions (del) at loci 13q (49%), sole 13q (24%), 11q (19%), 17p (7%), 6q (4%), and trisomies 12 (14%) and 8q (5%). Translocations involving the IGH gene were detected in 10 patients (4%). An exploratory analysis was performed to correlate time to event variables (assessed by an independent response review panel) with cytogenetics. Chromosomal aberrations are presented according to Döhner's hierarchical model (Döhner, 2000, N Engl J Med) that included del 17p, del 11q, trisomy 12, normal, and sole del 13q. Coexistence of del 17p and del 11q was not observed. Although del 13q was observed with all chromosome abnormalities, nearly half of the cases with del 13q14.3 (D13S25 and D13S319 loci) coincided with an ATM deletion (11q22.3). *Conclusions.* Overall, 82% of treatment naïve BCLL patients revealed cytogenetic aberrations by FISH and 59% of cases showed combination of abnormalities. In patients with del 17p, ORR, CR rate and PFS were over 3 times higher for CAM vs CHLO. Despite the significant improvement in ORR for patients with del 11q, when comparing CAM vs CHLO, no difference in PFS was seen. Further investigation of CAM therapy in high risk cytogenetic subgroups is warranted.

Table 1. Response and Kaplan-Meier Estimate of Median PFS (months) by Cytogenic Abnormality.

	CAM				CHLO				PFS	
Mutations	n	ORR %	CR %	Kaplan-Meier Median PFS (months)	n	ORR %	CR %	Kaplan-Meier Median PFS (months)	p-value[1]	Hazard Ratio (95% CI)[2]

PARENTAL ORIGIN DETERMINATION I FISH A NEW METHOD TO CHARACTERIZE THE PARENTAL ORIGIN OF HUMAN CHROMOSOMES ON A SINGLE CELL LEVEL

M. Gross,[1] H. Mkrtchyan,[2] H. Thieme,[1] F. Von Eggeling,[1]
B. Horsthemke,[1] Chr. Jonsrud,[3] U. Claussen,[1] TH Liehr,[1] A. Weise[1]

[1]Institute of Human Genetics, JENA, Germany; [2]Yerevan State University, YEREVAN, Armenia; [3]Dept. of Medical Genetics, TROMSO, Norway

The discrimination of homologues (chromosomal) regions could up to now be done exclusively by molecular genetic *Aims.*using microsatellite or SNP-analysis. Only in exceptional cases a distinction on a single cell level by chromosomes was possible. Therefore, we developed a method called parental origin determination fluorescence *in situ* hybridization (pod-FISH) that is suited for a single cell analysis and can distinguish every homologues chromosome pair on the basis of copy number polymorphisms (CNP). Presently we selected 225 of over 2191 reported polymorphic regions in the human genome and used them as pod-FISH probes. pod-FISH results were verified by microsatellite analysis. We established pod-FISH probe sets for all 24 human chromosomes. To enable working with more than one polymorphic BAC probe at the same time, chromosome specific pod-FISH sets using 5 different fluorochromes were developed. For larger chromosomes like chromosomes 1, 2, 3, 4, 6, 9 and X it was more convenient to create chromosome arm specific pod-FISH sets for an easier analysis and to prevent double labeling. Up to now two cases with a known UPD, 2 cases with maternal contamination and three leukemia cases (AML with trisomy 8) were analyzed successfully. Also the method was applied on a unique case which is a chimera of two cell lines: one female cell line with a complete paternal isodisomy (97%) and one normal male cell line (3%). The results obtained by pod-FISH were in complete concordance with data obtained by microsatellite-analysis. The usefulness and feasibility of the new pod-FISH approach was compared to conventional microsatellite analysis and proved to be as reliable. Thus, the pod-FISH method will open new horizons for diagnostic and scientific fields that could not be questioned by now. E.g. the analysis of single cells will allow in leukaemia to get new diagnostic markers for therapy control after transplantations or to detect maternal contamination in prenatal diagnosis.

ALTERATIONS OF THE TP53 IN AML AND CLL ARE STRONGLY ASSOCIATED WITH A COMPLEX ABERRANT KARYOTYPE

C. Haferlach, F. Dicker, H. Herholz, S. Schnittger, W. Kern,
T. Haferlach

MLL - Munich Leukemia Laboratory, MUNICH, Germany

The TP53 gene is the most frequently mutated gene in human tumors identified so far. However, in leukemia TP53 alterations seem to be rare. It was the aim of this study to determine the incidence of TP53 mutations in AML and CLL and analyze their relation to cytogenetic and other molecular genetic aberrations. Overall 235 AML cases were analyzed for TP53-mutations, FLT3-length mutations (FLT3-LM), MLL partial tandem duplication (MLL-PTD) and NPM1 mutations. TP53 mutation screening of exons 3-9 was performed by denaturing high performance liquid chromatography (DHPLC). All mutations detected were verified by direct sequencing. The first 149 patients were unselected, the remaining were selected to increase the numbers in rare cytogenetic subgroups. In the unselected cohort a TP53 mutation was detected in 13.4% (20/149 cases). In the total cohort a TP53 mutation was observed in 33 of 235 cases (14%). 29 of these 33 cases (87.9%) showed a complex aberrant karyotype. In the four remaining cases with TP53 mutation a normal karyotype, a trisomy 8, a trisomy 13, and a t(8;21)(q22;q22) each as the sole abnormality were observed, respectively. This data confirms results from our previous independent series demonstrating a high incidence of TP53 mutations in AML with complex aberrant karyotype (1. series 78%, current series 69%). In all other cytogenetic subgroups TP53 mutations are very rare (4/193, 2.1%). Two cases withTP53 mutation showed also a FLT3-LM and one a MLL-PTD. TP53-mutations were not found together with NPM1 mutations. In addition 194 consecutive CLL patients were screened for TP53-deletion by fluorescence *in situ* hybridization (FISH) and for TP53-mutations. A TP53 deletion was detected by FISH in 18 cases (9.3%). 16 of these 18 cases also showed a TP53 mutation. In four further cases without a TP53 deletion a TP53 mutation was observed. Therefore, the total incidence of TP53 alterations in CLL was 11.3% (22/194) with a significant association between TP53 deletions and TP53 mutations ($p<0.0001$). In 160 of 194 CLL cases including 15 cases with a TP53 mutation a chromosome banding analyses had been performed. 11 of 15 cases (73.3%) with TP53 mutation showed a complex aberrant karyotype (≥ 3 aberrations). The remaining 4 cases with TP53 mutation showed a 13q deletion, 3 of these with one other abnormality in addition. Therefore, the frequency of TP53 mutations in CLL with complex aberrant karyotype was 50% (11/22) as compared to only 2.9% in the remaining cytogenetic subgroups (4/138). In conclusion, 13.4% of AML cases and 10.3% of CLL cases show a TP53 mutation. In both leukemia subtypes a high frequency of TP53 mutations was found in cases with a complex aberrant karyotype (69% and 50%, respectively), while TP53 mutations were rare in all other cytogenetic subgroups (2.1% and 2.9%, respectively).

[1]Institute of Hematology and Blood Transf, PRAGUE 2; [2]General Faculty Hospital and 1st Med. Fa, PRAGUE 2, Czech Republic

Background. Structural rearrangements of the long arm of chromosome 3 (3q) have been described in approximately 2,5% of patients with acute myeloid leukemia (AML), myelodysplastic syndrome (MDS) as well as in lower percentage of patients in the blastic crisis of chronic myeloid leukemia (CML BC). They are connected with unfavorable outcome and poor prognosis. Deletions of the short arm (3p) were described in solid tumors, however, they are rather rare in myeloid neoplasias. *Aims.* Precise identification and description of chromosome 3 rearrangements in bone marrow cells of patients with myeloid malignancies by means of various molecular cytogenetic techniques. Evaluation of the relationship between chromosome 3 aberrations and hematological parameters including outcome and survival of the patients. *Methods.* Using conventional cytogenetic techniques we examined 37 patients (18 males, 19 females; average age 58,3 years) with myeloid malignancies (21 MDS, 13 AML, 3 CML BC), with chromosome 3 rearrangement in bone marrow cells. They represented 4,2% out of all the patients with myeloid malignancies, examined in our Department during the years 2000-2006. Multicolor banding technique for chromosome 3 (mBAND, MetaSystems™) was carried out in 30 patients, deletions of the telomeric regions were proved using TelVysion 3p and 3q Probes (Abbott-Vysis™). Chromosomes involved in complex translocations were identified by multicolor FISH (mFISH, MetaSystems™). *Results.* The clinical outcome was very poor in this cohort with short survival time (median 5 months). No significant difference in survival of patients with MDS and AML was found, no difference in male/female ratio. Abnormal chromosome 3 was found at the time of diagnosis in 34 patients, in three others (two with MDS and one with CML BC) clonal evolution with 3q rearrangements was seen during the course of the disease and treatment. In all cases it occurred together with other chromosomal abnormalities. Complex karyotypes were confirmed in 35 patients, in 21 patients monosomy 7 or rearrangement of chromosome 7 were ascertained. On the contrary, in our cohort inversion inv(3)(q21q26) was proved in one patient only. Non-reciprocal translocation accompanied by deletion 3p or 3q was the most frequent aberration. Deletion of the short arm was detected in 14 patients and in12 of them deletion of the 3p subtelomeric region was ascertained. As the most of published studies were done by conventional cytogenetic techniques on G-banded chromosomes, cryptic deletions could be easily overlooked. Thus high sensitivity of mBAND and FISH techniques increased radically identification of 3p deletions. *Summary.* Using molecular cytogenetic methods we detected cryptic aberrations of chromosome 3. High percentage of 3p deletions (37,8%) in our cohort of patients is the most important finding not described previously. Studies of these rearrangements could provide new information about genes possibly involved in genomic instability during progression of leukemias.

ANALYSIS OF AML/MDS CELL LINES HIGHLIGHTS GENES TARGETED BY CONCOMITANT 5Q DELETION AND 11Q23 AMPLIFICATION

B. Schneider, S. Nagel, M. Kaufmann, H.G. Drexler, R.A.F. MacLeod

DSMZ, BRUNSWICK, Germany

Background. In addition to chromosome rearrangements causing a variety of gene fusions, MLL1 may be targeted by regional chromosomal copy-numberr gains amplifying the 11q23 region (amp-11q23) in acute myeloid leukaemia (AML) and myelodysplastic syndromes (MDS). However, conflicting reports suggest that other genes at 11q23 may be targeted. Amp-11q23 is invariably partnered by deletions affecting the long-arm region of chromosome 5 (5q-) implying collaboration of genes at these loci. *Aims.*To identify genes targeted by 5q-/amp-11q23 and characterize AML/MDS cell line models for this disease entity. *Methods.* Fluorescence *in situ* hybridization with tilepath clones covering 11q2 and 5q; genomic (G) and reverse transcription (RT) q(uantitative)-PCR. *Results.* Key candidate target genes, notably, DDX6, FLI1 and MLL1, displayed mean 4.5x genomic amplification by G-qPCR. Of these, only MLL1 displayed consistently elevated gene expression by RT-qPCR, averaging 5.6x upregulation overall. We then analyzed the expression of known downstream targets of MLL1-gene fusion rearrangements in an AML context, including, MEIS1, HOXA7, HOXA9, CDKN1B, CDKN2C - where only the last named displayed consistent upregulation. All amp-11q23 cell lines displayed 5q- with a common deleted region at 5q31 extending from 133-140 Mbp. Of 5q genes recently identified as possible deletion targets, only BRD8 and KCT2 were consistently downregulated, with expression levels at ~0.25x, and ~0.4x, control levels, respectively. In addition, although genomic copy number increases at 8q24 were present, MYC was not consistently upregulated. *Summary and Conclusions.*Taken together, these results highlight MLL1 as a salient target of 11q23 amplification and implicate CDKN2C as a possible downstream target. Furthermore, our data imply that leukemogenic overexpression requires downregulation of BRD8 (a nuclear receptor coactivator) and KCT2 (a membrane receptor protein) in AML/MDS cells. These findings highlight candidate loci to serve as potential therapeutic targets in AML/MDS, together with cell lines which may be useful in further investigations.

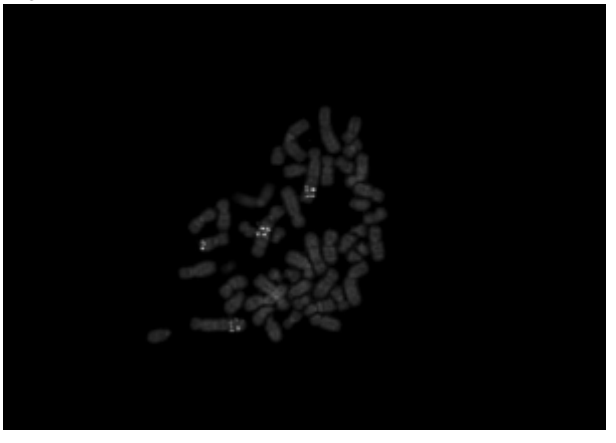

Figure 1. MLL1 amplification.

ANALYSIS OF 1Q21 COPY NUMBER CHANGES IN PATIENTS IN PROGRESSION AND RELAPSE OF MULTIPLE MYELOMA

J. Balcarkova, V. Scudla, M. Holzerová, H. Pospisilova, M. Zemanova, J. Bacovsky, K. Indrak, M. Jarosova, M. Jarosova

University Hospital Olomouc, OLOMOUC, Czech Republic

Chromosomal abnormalities have biologic and prognostic significance in multiple myeloma (MM), especially among patients with relapsed and refractory disease. The primary translocations occur as early and perhaps as initiating events during the pathogenesis of MM. However, these translocations are not sufficient for the malignant progression of this disease and the accumulation of additional genetic alterations are necessary for a fully malignant phenotype. Previous comparative genomic hybridization (CGH) studies have revealed, that the gain or amplification of 1q, consistently involving 1q21, is associated with a poor prognosis of MM. The aim of this study was to determine the 1q21 copy number changes in patients with a relapse and progression of the disease using molecular cytogenetic methods and to correlate these findings with other cytogenetic changes and clinical parameters. We analyzed bone marrow cells from 23 MM patients, 13 with a relapse of MM and 10 with a progression of MM. All patients (median of the age 60 years) were examined by conventional cytogenetics and by FICTION method with locus specific probes 1q21/1p36 (QBiogene, MP Biomedicals, CA), RB1, IgH, IgH/CCND1, IgH/FGFR3 and centromeric probes for chromosomes 7, 9, 11, 15, 17 (Abbott-Vysis, Downers Grove, IL, USA). Comparative genomic hybridization (CGH) (Abbott-Vysis, Downers Grove, IL, USA) and multicolor fluorescence *in situ* hybridization (M-FISH) (MetaSystem, Altussheim, Germany) were used to detect chromosomal changes in 2 patients with a complex karyotype. Using FICTION method we detected copy number changes of 1q21 in 12 (52%) out of 23 analyzed cases. All patients with copy number changes of 1q21 had other cytogenetic abnormalities: deletion of RB1 gene and t(4;14) were found in 4 (17%) patients, deletion of RB1 gene and deletion of IgH gene in 4(17%), trisomy of examined chromosomes in 2 (9%), a single t(11;14) in 1(4%) and a single t(4;14) in 1(4%) patient. The detected cytogenetic changes and clinical data were analyzed and will be presented.

FREQUENCY AND CLINICAL IMPLICATIONS OF ADDITIONAL CHROMOSOMAL ABERRATIONS IN ETV6/RUNX1 POSITIVE CHILDHOOD ALL

Z. Zemanova,[1] K. Michalova,[1] L Babicka,[1] M. Jarosova,[2] M Holzerova,[2] A. Oltova,[2] M. Hruba,[2] K. Muzikova,[3] J Zuna,[3] J Trka,[3] V. Mihal,[2] J. Sterba,[2] R. Formankova,[4] P. Sedlacek,[5] A. Vrzalova,[4] J. Stary[5]

[1]General Faculty Hospital, PRAGUE 2, [2]Faculty Hospital, OLOMOUC, ; [3]CLIP - Childhood Leukaemia Investigation, PRAGUE; [4]Faculty Hospital Motol, PRAGUE; [5]2nd Medical Faculty of Charles Univ., PRAGUE, Czech Republic

Background. Cryptic translocation t(12;21)(p13;q22) which give origin to the hybrid gene ETV6/RUNX1 is one of the most reliable predictors of a favourable clinical outcome in childhood ALL. Despite of generally favourable prognosis of ETV6/RUNX1 positive ALL, late relapses may occur within this group of patients with current therapy. One of the reasons could be the high instability of the genome of leukemic cells, which is manifested at the chromosomal level by formation of secondary abnormalities. Additional chromosomal abberations were proved in about 50-70% of patients with ETV6/RUNX1 positive ALL. Genetic changes that are most frequently associated with t(12;21) are the deletion of the wild type ETV6 allele, trisomy of chromosome 21 and/or duplication of the ETV6/RUNX1 fusion gene. Also non-specific structural and/or complex chromosomal rearrangements could be found. *Aims.* The aim of the present study was to evaluate the frequency and clinical implications of additioanal and/or complex chromosomal aberrations for prognosis of chidren with ETV6/RUNX1 positive ALL. *Methods.* For the assessment of ETV6/RUNX1 fusion gene RT-PCR and/or double target interphase FISH (I-FISH) with locus-specific probe (Abbott-Vysisä) were used. Karyotypes were analyzed by conventional G-banding and by molecular cytogenetic methods. Structural and/or complex chromosomal aberration were proved by FISH with whole chromosome painting probes (Cambioä) and/or by mFISH with the *24XCyte* probe kit (MetaSystemsä). *Results.* We examined 126 children with ALL and ETV6/RUNX1 fusion gene detected by RT-PCR and/or I-FISH. Patients were diagnosed between 1995 and 2006, age ranged between 15 months and 16.6 years (median 4.2 years). Relapse appeared in 20 children (15.9%), five patients died. In 75 children (59.5%) we found besides t(12;21)(p13;q22) additional chromosomal aberrations, the most frequently trisomy or tetrasomy of chromosome 21 (23 cases), deletion of non-translocated ETV6 allele (29 cases), deletion of 6q (8 cases) and/or rearrangements of the long arm of chromosome X (6 cases). Complex karyotypes were identified in 40 children (31.7%). In twelve of them variant translocations of chromosomes 12 and 21 with other partners were observed. Univariate analysis indicated that patients with complex aberrations in ETV6/RUNX1 positive cells had significantly shorter event-free survival (p=0.01). *Conclusions.* In this cohort of children with ETV6/RUNX1 positive ALL complex karyotypes were connected with worse prognosis. Our findings suggest the importance of comprehensive molecular cytogenetic analysis in identifying additional and/or complex chromosomal aberrations in ETV6/RUNX1 positive cells.

ROUTINE DETECTION OF CYTOGENETIC ABNORMALITIES IN B-CELL LYMPHOPROLIFERATIVE DISORDERS USING INTERPHASE FISH TECHNIQUES

J.M. O'Connor, S.L. Barrans, K.R. Turner, B.S. Dickinson, A.S. Jack, R.G. Owen

Leeds Teaching Hospitals NHS Trust, LEEDS, United Kingdom

Background. Specific cytogenetic abnormalities are increasingly used to segregate patients with B-cell lymphoproliferative disorders (B-LPD) into good and poor risk sub-groups which may influence clinical decision making. The critical indications are in the differential diagnosis of diffuse large B-cell lymphoma (DLBCL)/Burkitt lymphoma (BL); B-CLL/mantle cell lymphoma (MCL); the differential diagnosis of CD5- B-LPDs and the identification of prognostic variables such as a p53 deletion. Conventional karyotyping significantly underestimates the incidence of cytogenetic abnormalities in B-LPD and fails in a significant proportion of cases. The purpose of this study was to evaluate the applicability of interphase fluorescent *in situ* hybridisation (iFISH) in the routine diagnostic laboratory. *Methods.* iFISH analysis was carried out on 3,126 (2,643 B-LPD and 483 myeloma) cases (excluding Myeloma IX samples) from the Yorkshire and Humberside region presenting to HMDS between 2003 and 2006. B-LPD samples were initially categorised on the basis of CD5 expression, with $CD5^+$ cases (B-CLL and MCL) assessed for deletions of p53, ATM, 13q14, trisomy 12 and BCL-1/IgH translocation ($CD5^+CD23^-$) and CD5- cases (Burkitt/DLBCL, FL and MZL) assessed for rearrangements of cMYC, BCL-2, IgH, MALT-1(extranodal MZL), BCL-6 and p53 deletions. Myeloma cases were assessed for deletion/monosomy 13 and IgH rearrangements. Cases with an IgH rearrangement were further investigated to determine the translocation partner. The only selection criteria used in myeloma cases was that smears contained >10% plasma cells that had a neoplastic phenotype by flow cytometry. iFISH was carried out on blood or marrow smears, dab/imprint of fresh tissue, or cytospins of CSF/effusions. Probes were used according to the manufacturer's protocol (BCL1/IgH, cMYC/IgH, BCL2/IgH dual colour translocation probe sets; BCL6, cMYC, MALT-1 and IgH BreakApart's: Abbott Molecular Diagnostics and IgH, PAX-5, BCL-3; CCND1 Split-Signal: Dako: p53/α 17, ATM/α 11, 6q21/α6, QBioGene). *Results.* Successful results were obtained in 2,558/2,683 (96.9%) B-LPD cases, and in 459/483 (95.0%) myeloma cases. Abnormal results were detected in 86.1% of B-LPD cases and in 83.7% of myeloma cases. 271/1010 (26.8%) B-CLL cases were re-designated as adverse risk because of a p53 and/or an ATM deletion; 110/391 (28.1%) DLBCL cases were re-designated as adverse risk, based on rearrangements of either BCL-6, cMYC or BCL-2; 253/483 (52.3%) myeloma cases have deletion/monosomy 13 and 152/483 (31.5%) an IgH rearrangement, of these 33/483 (6.8%), had BCL-1/IgH; 22/483 (4.6%) had FGFR3/IgH; 6/483 (1.2%) had cMAF/IgH and 1/483 (0.2%) had a cMYC/IgH translocation. The number of patients with unidentified translocation partners (90/152, 59.2%) appears higher than that reported in the literature and is worthy of further study. *Conclusions.* This large series of cases provides evidence for the applicability and robustness of iFISH in a routine diagnostic setting. We conclude that iFISH is applicable to the routine assessment of patients with B-LPD or myeloma. The majority of patients have abnormal patterns and the failure rate is very low compared to conventional karyotyping. Interphase FISH performed directly on smears/dabs/cytospins is rapid, reliable and relatively inexpensive and can be integrated into diagnostic laboratories and should ultimately allow for risk stratification in real time.

COMPARISON OF PROGNOSTIC IMPACT OF CHROMOSOME 1Q21 GAIN IN PATIENTS WITH MULTIPLE MYELOMA TREATED BY BORTEZOMIB, THALIDOMIDE AND ANY CONVENTIONAL THERAPY

P. Nemec,[1] H. Greslikova,[1] R. Zaoralova,[1] H. Filkova,[2] V. Vranova,[2] R. Kupska,[2] J. Smejkalova,[1] A. Oltova,[2] P. Kuglik,[3] R. Hajek[4]

[1]Myeloma Basic Research Centre, BRNO; [2]Dep. of Medical Genetics, Faculty Hosp., BRNO; [3]Genetics & Mol. Biology, F. of Science, BRNO; [4]Dep. of Int. Hem.-oncol., Faculty Hosp., BRNO, Czech Republic

Background. Amplification of chromosome band 1q21 as well as increased expression of CKS1B gene in this area is a frequently mentioned prognostic factor for patients with multiple myeloma (MM). *Aims.* This study was aimed at comparison of prognostic impact of 1q21 gain in three selected groups of patients with diagnosed MM based on treatment regiment. *Methods.* Plasma cells were identified by cytoplasmic light-chain fluorescence *in situ* hybridisation (cIg-FISH), 1q21 amplification (Amp1q21) utilizing the 1q21/1p36 DNA probe. Amp1q21 was taken such as detection of one or more additional signals of 1q21 DNA probe. Cut-off level for presence of Amp1q21 was established to 20%. Patients with Amp1q21 and patients lacking Amp1q21 of each group were statistically correlated with clinical parameters. Up to date we have carried out analysis of 66 (n=66) patients. This group of patients with median of follow'up 8,6 months (range: 0,3-30,4) was divided according to the undergone therapy into 3 groups: *C-group* comprises 17 patients treated by any conventional therapy; *T-group* comprises 27 patients treated by thalidomide; *V-group* comprises 22 patients treated by Bortezomib. The response and other parameters such as time to progression (TTP) and overall survival (OS) were assigned by IMWG criteria. *Results.* Amp1q21 was found in 62.1% of all 66 patients. Percentage of patients with Amp1q21 in C/T/V-groups were as follows: 64.7%/40.7%/86.4%, respectively. Clinical parameters valid for patients with Amp1q21 (listed in C/T/V order) were as follows: overall response rate (ORR) 42.8% /83.3%/50%; TTP 8.8/12.1/8.0 months; OS 16.1/6.6 / not yet reached for V-group. The same parameters valid for patients lacking Amp1q21: ORR 33.3%/80%/66.7%; TTP not yet reached for C-group / 8.2/not yet reached for V-group; OS not yet reached for all groups. TTP median of patients with Amp1q21 vs. patients lacking 1q21 was: 8.2 vs. 12.1 months (p=0.269), OS 6.6 vs. not yet reached (p=0,072) in thalidomide group. We didn't find any other significant differences between patients with/without Amp1q21 and their parameters in V- and C-group. *Summary and conclusions.* Our results suggest that patients with Amp1q21 treated by thalidomide show a trend towards the worst prognosis based on overall survival. We are currently investigating whether or not our findings will be confirmed on a larger cohort of patients with longer follow-up.

ROUTINE DETECTION OF CYTOGENETIC ABNORMALITIES IN B-CELL LYMPHOPROLIFERATIVE DISORDERS USING INTERPHASE FISH IN PARAFFIN EMBEDDED TISSUE

S. Barrans, K. Turner, S. O'Connor, B. Dickinson, R. Owen, A. Jack

Leeds Teaching Hospitals NHS Trust, LEEDS, United Kingdom

Specific cytogenetic abnormalities are increasingly being used in the differential diagnosis of B-cell lymphoproliferative disorders (B-LPD) and to segregate patients into risk sub-groups which may influence clinical decision making. Paraffin embedded tissue (PET) is often the only diagnostic material available for analysis and it is therefore essential that molecular techniques are applicable in this setting. The critical indications for performing FISH on PET are in the differential diagnosis of diffuse large B-cell lymphoma (DLBCL)/Burkitt lymphoma (BL); B-CLL/mantle cell lymphoma (MCL); confirming the diagnosis of follicular lymphoma (FL), especially where BCL2 is negative; and in extranodal marginal zone lymphoma (ExMZL). The purpose of this study was to evaluate the applicability of interphase fluorescent *in situ* hybridization (iFISH) on PET in the routine diagnostic laboratory. Paraffin iFISH analysis was carried out on 329 B-LPD cases diagnosed in HMDS between 2003 and 2006, where only a paraffin block was available for analysis. Cases were investigated based on the provisional diagnosis following histology and immunohistochemistry. 221 cases with a differential diagnosis of BL/DLBCL were investigated for rearrangements of cMYC, BCL2, and BCL6; 22 FL and 81 ExMZL were assessed for t(14;18) and BCL6 rearrangements and IgH and MALT1 rearrangements respectively. 6 cases with a differential diagnosis of B-CLL/MCL were investigated for BCL1 rearrangements. Cases with an IgH rearrangement were further investigated to determine the translocation partner. An adaptation of our 'fresh' iFISH protocol was used, with an additional enzymatic digestion with Sigma Protease XXIV and a 90C pre-denaturation step. We have validated this method by comparison with iFISH on fresh tissue and PCR on the same sample. Probes were used according to the manufacturer's protocol (BCL1/IgH, cMYC/IgH, BCL2/IgH dual colour translocation probe sets; BCL6, cMYC, MALT-1 and IgH BreakApart's: Abbott Molecular Diagnostics and IgH, PAX-5, BCL-3; CCND1 Split-Signal: Dako). Successful results were obtained in 318/329 (96.6%) of cases, which is comparable to fresh material. 89/221 BL/DLBCL cases had a cMYC rearrangement as the sole abnormality and a final diagnosis of BL was made based on this basis. The remaining 132 cases were classed as DLBCL and had either a t(14;18), a BCL6 rearrangement, additional cMYC rearrangements, or extra copies of any combination of the probes assessed. The t(14;18) was seen in 8/12 FL-common type and 1/8 FL-BCL2neg cases had an unbalanced BCL2 rearrangement. 4/6 B-CLL/MCL cases had rearrangement of BCL1 and were therefore re-classified as MCL. 10 cases of ExMZL had rearrangement of MALT1, and 10 had IgH

rearrangements. This large series of cases provides evidence for the applicability and robustness of iFISH on paraffin embedded tissue in a routine diagnostic setting, where the presence of a specific abnormality is essential in confirming the diagnosis. A high proportion of patients have abnormal patterns and the failure rate is very low. iFISH performed on thin paraffin sections is rapid, very reliable and relatively inexpensive and can be integrated into diagnostic laboratories and allows for definitive diagnostic testing and risk stratification in real time.

NPM1 HAPLOINSUFFICIENCY IN MDS/AML WITH DEL(5Q)/MONOSOMY 5

R. La Starza,[1] G. Roti,[1] L. Brandimarte,[1] E. Varasano,[1] F. Arcioni,[1] A. Pierini,[1] B. Crescenzi,[1] D. Diverio,[2] G. Guglielmini,[3] M.F. Martelli,[1] A. Aventin,[4] C. Mecucci[1]

[1]Hematology, University of Perugia, PERUGIA, Italy; [2]Hematology, University La Sapienza, ROME, Italy; [3]Internal and Vascular Medicine, PERUGIA, Italy; [4]Hematologia, H De La Santa Creu, BARCELONA, Spain

Background. NPM1, a gene mapping at band 5q35, is implicated in different forms of leukaemia and NPM1 haploinsufficiency induces preleukemic MDS-like features in mice. It is not known whether NPM1 is involved in the pathogenesis of MDS/AML with del(5)(q)/-5 which occurs as an isolated change or as part of complex karyotypes in MDS and in AML. *Aims.* To study NPM1 genomic status in MDS/AML with del(5)(q)/-5 by fluorescence *in situ* hybridization (FISH) and denaturing high-performance liquid chromatography (DHPLC). *Methods*. We studied 58 patients with MDS and 47 with AML (total 105 patients), all bearing del(5q)/-5 which was isolated or associated with 1 other aberration in 51 cases and included in complex karyotypes in 54. FISH was done with the following DNA clones for the long arm of chromosome 5: centromere- LSI EGR1/D5S721/D5S23 5q31-LSI CSF1R/ D5S721/D5S23 5q34 (Vysis, Abbott, Italy) - RP11-117L6 (NPM1/5q35.1) - CTC-286C20 (FGFR4/5q35.2) - CTC-549A4 (NSD1/5q35.3) - RP1-240G13 (5qter) - telomere. Cut-off limits for monosomy/deletion in interphase analyses were the highest values in normal samples (4% for RP11-117L6, 7% for CTC-286C20, 6.5% for CTC-549A4, 8% for RP1-240G13). Exon 12 NPM1 mutations were studied by DHPLC in 57/105 patients (20 with isolated del(5q)/-5; 37 with complex karyotypes). *Results.* FISH detected NPM1 deletion in 10/58 (17%)patients with MDS and in 22/47 (47%) with AML (Fisher's exact test, $p<0.0014$). NPM1 deletion was found in 4/51 (7.84%) cases with isolated del(5q)/-5 and in 28/54 (51.85%) cases with complex karyotypes ($p<0.0001$). Recurrent cytogenetic abnormalities in complex karyotypes i.e. aneuploidy, -7/del(7q), +8, del(12p), translocation/del(17p), markers, rings, were analysed in relation to the NPM1 deletion. Only aneuploidy was more frequent in complex karyotypes with NPM1 deletion (85.7% cases) than in complex karyotypes with normal NPM1 (56% cases) ($p<0.0308$). NPM1 exon 12 mutations were detected only in 2 cases of MDS with isolated del(5q) and normal NPM1 at FISH analysis. *Conclusions*. For the first time, we establish NPM1 haploinsufficiency 1) is a rare event in MDS/AML with isolated del(5q)/-5 and does not play a major role in the origin of these malignancies and 2) is a frequent event in MDS/AML with del(5q)/-5 in complex karyotypes (>50% of cases) where it is significantly related to aneuploidy and is probably an early event generating a cascade of mitotic mistakes which underlie chromosomal instability and numerical changes.

GENETIC PATHWAYS IN LOW- AND HIGH-GRADE HCV-RELATED LYMPHOMAS ARE DIFFERENT

C. Matteucci,[1] M. Bracci,[2] G. Barba,[1] M. Carbonari,[2] M. Casato,[2] A. Pulsoni,[3] G. Roti,[1] R. La Starza,[1] B. Crescenzi,[1] M.F. Martelli,[1] M. Fiorilli,[2] C. Mecucci[1]

[1]Haematology, University of Perugia, PERUGIA; [2]Clin Immunol, University La Sapienza, ROME; [3]Haematology, University La Sapienza, ROME, Italy

Background. Chronic infection with hepatitis C virus (HCV) causes monoclonal B-cell lymphoproliferative disorders including type II mixed cryoglobulinemia, a benign monoclonal lymphoproliferation, and B-cell non-Hodgkin's lymphomas (NHL) with marginal zone lymphoma (MZL) and large B-cell lymphoma (LBCL) as the most common subtypes. Genetic information on HCV-associated lymphoproliferations is limited to detection of the IgH/BCL2 rearrangement in mixed cryoglobulinemia and less frequently in NHL. *Aims.* We studied 16 HCV-positive patients with NHL, with or without cryoglobulinemia, classified as follows: 8 case of MZL, 6 of which were splenic lymphomas; 4 cases of LBCL, 3 cases of small lymphocytic lymphoma (SLL) and 1 case of lymphoplasmacytic lymphoma (LPL). We also analysed 19 patient with type II mixed cryoglobulinemia without lymphoma to identify genetic pathways that are common to mixed cryoglobulinemia and B-cell NHL. *Methods.* DNA extracted from lymph nodes and/or spleen and/or bone marrow aspirate and/or peripheral blood lymphocytes of the patients with NHL was analysed by metaphase and/or array- Comparative Genomic Hybridization (CGH). Subsequently, Fluorescence *in situ* Hybridization (FISH) with a selected panel of probes for chromosomes 2 and 3 was applied to samples from patients with NHL and type II mixed cryoglobulinemia. *Results.* Genomic imbalances were detected in 11/14 cases (78%) with lymphoma. The most frequent changes were gains of 1q (19%) and 3q (25%) and loss of 2q (31%). Gain of 3q was observed only in low-grade splenic marginal zone lymphomas (SMZL) (4/6 cases). In three of these cases antiviral therapy led to lymphoma regression. In 1/19 patients with type II mixed cryoglobulinemia without lymphoma we found 80% of circulating B-cells carrying trisomy 3. Loss of 2q was observed in 4/5 patients with aggressive large B-cell type lymphomas, with or without a MZL component; was often associated with 1q gain and was mutually exclusive of 3q gain. These patients did not respond to antiviral treatment. Deletion mapping by FISH narrowed the minimal 2q lost region to 850 kb at 2q22.3. Cryptic duplication or deletion events in the other cases were excluded by FISH analysis. *Conclusions.* This first molecular cytogenetic investigation into B-cell lymphomas associated with HCV infection used an integrated CGH and FISH approach and identified two distinct, mutually exclusive events: 3q gain is a hallmark of B-cell clonal expansion rather than malignancy, as it occurs in low-grade SMZL as well as in the non-malignant lymphoproliferative phase of type II mixed cryoglobulinemia. Conversely, deletion of 850 kb at 2q22.3 emerges, for the first time, as a genomic aberration in HCV-related aggressive B cell lymphomas.

Aims. We planned a prospective analysis involving 3 multicentric national studies of the GIMEMA (Gruppo Italiano Malattie Ematologiche dell'Adulto) CML Working Party (WP) to evaluate the correlation between conventional cytogenetics (CC) and FISH response in chronic myeloid leukemia (CML) patients in chronic phase (CP) treated with imatinib. METHODS. Karyotype and FISH analyses were performed on bone marrow cells in 26 local laboratories and in 12 WP reference labs. Cytogenetic examinations were performed at enrollment, after 3 (in 1 study), 6 and 12 months of treatment. Peripheral blood samples for quantitative RT-PCR were centralized in Bologna at enrollment, after 3, 6 and 12 months on imatinib. *Results.* A strong correlation between CC and FISH was observed ($r=0.91$, $p=0.008$). Table 1 shows the demonstration of FISH data according to CC data and the number of metaphases available for CC. Of 263 patients (pts) in CCgR by CC and > 20 metaphases observed, 79.5% were FISH negative, 16.7% showed a low rate of FISH positive cells (1-5%) and 3.8% an higher rate. Of 102 pts in CCgR by CC but with < 20 metaphases observed, 72.5% were FISH negative, 20.7% showed a low rate of FISH positive cells (1-5%) and 6.8% an higher rate. Of 50 pts in PCgR by CC, 52% were FISH positive with a range between 1 and 5% and 48% were FISH positive with a superior amount of positive cells. Moreover, 358 samples were performed simultaneously by CC, FISH and quantitative RT-PCR: 179 (50%) samples in CCR showed major molecular response

(MMolR, defined as a BCR-ABL x 100 ratio <0.1%): 164 (91.6%) were FISH negative and 15 (8.4%) were FISH positive (1.3-10% positive cells). *Summary and conclusions* We suggest that interphase FISH is a very releable method of monitoring the CCgR once it has been achieved. The relationship of FISH with molecular response is at least as good as the relationship of CC with molecular response. It remains to be confirmed if the same results can be obtained on peripheral blood cells, that are already widely used for molecular monitoring. ACKNOWLEDGEMENTS. NUP98 RECOMBINATIONS TARGET CD34+ HEMATOPOIETIC CELLS IN AML AND T-ALL

B. Crescenzi,[1] R. La Starza,[1] P. Gorello,[1] S. Romoli,[1] V. Pierini,[1] L. Van Zutven,[2] B. Beverloo,[2] M. Negrini,[3] M.F. Martelli,[1] C. Mecucci[1]

[1]Haematology, University of Perugia, PERUGIA, Italy, [2]Dept Clinical Genetics, Erasmus MC, ROTTERDAM, Netherlands; [3]Dept Exp and Diagnostic Medicine, FERRARA, Italy

Introduction. NUP98, a versatile gene, recombines with various partners in myeloid disorders, such as acute myeloid leukemia (AML), myelodysplastic syndromes (MDS), chronic myeloid leukaemia (CML), and in T-cell acute lymphoblastic leukaemia (T-ALL), where to date, four different fusions have been reported. As the cell of origin of NUP98+ leukaemia is unknown we hypothesized involvement of a totipotent hematopoietic stem cell. To study hematopoietic lineages affected by NUP98 changes in MDS/AML and in T-ALL we used a FICTION approach, combining simultaneous immunophenotyping and interphase FISH. *Materials and Methods.* Patients: We analyzed one case of MDS (refractory anemia with excess of blasts) bearing add(11)(p15)/NUP98-NSD1, one case of AML with inv(11)(p15q22)/NUP98-DDX10, one case of AML carrying t(4;11)(q1?;p15)/NUP98-RAP1GDS1 and one case of T-ALL with t(4;11)(q21;p15)/NUP98-RAP1GDS1. In all cases metaphase FISH identified NUP98 disruption; RT-PCR showed fusion products from NUP98/NSD1, NUP98/DDX10, and NUP98/RAP1GDS1. FICTION: The following monoclonal antibodies were used: Anti-CD34, anti-CD133, anti-CD33, anti-CD13, anti-CD14, anti-glycophorin A , anti-CD19, anti-CD20, anti-CD3, anti-CD7. Clone RP11-348A20, encompassing the entire NUP98 gene, was used to detect NUP98 rearrangements. Immunophenotype (in red) and hybridization signals (in green) were simultaneously identified and counted under an Olympus fluorescence microscope with filter sets for Cy-3 (red) and FITC (green). At least 15 cells (range 15-100) were analysed for each antibody. Cytospins with bone marrow cells from two healthy donors were used as normal controls for each antibody. The cut-off for NUP98 split was established at the upper limit from normal controls. *Results.* The percentage of cells bearing split NUP98 overlapped in patients with MDS and AML: CD34+ from 36% to 93%; CD133+ from 58% to 85%; CD33+ from 60% to 76%; CD13+ from 31% to 76%; CD14+ from 60% to 90%; Glycophorin A+ from 33% to 78%; CD 19+ from 35% to 69%; CD20+ from 39% to 69%; CD3+ from 41% to 70%; CD7+ from 50 to 76%. In the patient with T-ALL split NUP98 was found in 90% CD34+ cells, in 67% CD133+ cells, in 100% CD3+ T cells and in 83% CD7+ T cells. Compared with normal controls no significant differences emerged in erytroid precursors, B lymphoid cells, CD33+, CD14+ and CD13+ cells. *Conclusions.* In both AML and T-ALL NUP98 rearrangements target a CD34+ totipotent hematopoietic stem cell. In the hematopoietic differentiation cascade both myelomonocytes and lymphocytes are involved in NUP98+ AML while only T-lymphocytes are involved in T-ALL. Consequently, we hypothesize that microenviromental and/or genetic factors other than NUP98 fusions determine phenotypic features in NUP98+ leukemias.

Vall d'Hebron, BARCELONA; [11]Hosp. del Mar, BARCELONA; [12]Hosp. Morales Meseguer, MURCIA, Spain

Background and Aims. Different from AML, the prognostic significance of complex karyotype is not known in adults with ALL. The aim of study was to analyze the possible prognostic influence of complex karyotype in Ph- adult ALL patients treated with risk-adapted protocols from the Spanish PETHEMA Group. *Patients and Therapy.* The cytogenetic studies were reviewed following the ISCN criteria (2005). Complex karyotype (CK) was defined as the finding of 3 or more structural chromosomal aberrations. Patients were included in two different trials: ALL-96 for standard-risk (SR) ALL, and ALL-93 or ALL-AR03 for high-risk (HR) ALL. *Results.* 266 evaluable patients. SR: n=49, 26 males, WBC count 12×10^9/L (SD: 14), 24 patients with normal karyotype (NK)(54,5%), 15 non-complex karyotype (non- CK)(34,1%) and 5 complex karytotype (CK)(11,4%). HR: n= 217, 119 males, WBC count 58×10^9/L (SD: 77), 104 with NK (53,9%), 64 non-CK (33,2%) and 25 CK (12,9%). CR, DFS and OS according to karyotype group and trial (Table 1). *Conclusions.* Complex karyotype did not have any prognostic relevance in adults with Ph- high-risk ALL, whereas a significant short survival observed in standard-risk patients with complex karyotype.

Supported in part by grant P-EF-06 from Jose Carreras Leukemia Foundation.

Table 1.

CR	ALL - 96 trial (n= 49)			ALL - 93/03 trials (n=217)		
NK	13/24 (79%)		p=0.05	88/104 (85%)		p=0.05
Non- CK	13/15 (86%)			57/64 (89%)

CYTOGENETIC ABNORMALITIES OF BONE MARROW-DERIVED MESENCHYMAL STEM CELL IN LEUKEMIC PATIENTS WHO HAD RECEIVED TOTAL BODY IRRADIATION BEFORE ALLOGENEIC TRANSPLANTATION

S.P. Yeh, C.F. Chiu, C.L. Lin, W.J. Lo, Y.M. Liao, C.C. Lee

China Medical University Hospital, TAICHUNG, Taiwan

Background. High dose chemotherapy or chemoradiotherapy including total body irradiation (TBI) is routinely used before hematopoietic stem cell transplantation and may result in many adverse effects on normal tissue, including secondary malignancies. Nevertheless, the effect of TBI on bone marrow stromal cells, the mesenchymal stem cells (MSCs), has never been investigated. *Aims.* To evaluate the cytogenetic status of MSCs isolated from leukemic patients who had received myeloablative chemotherapy or chemoradiotherapy as conditioning treatment before allogeneic peripheral blood stem cell transplantation (PBSCT). *Methods.* Bone marrow-derived MSCs were isolated and *ex vivo* expanded from 8 patients of leukemia who had received Busulfan / Cyclophosphamide or Cyclophosphamide / TBI before sex-mismatched, allogeneic PBSCT. Immunophenotyping using flow cytometry and induction of adipocytic and osteocytic differentiation were conducted in all specimens to confirm the characteristics of MSCs. Cytogenetic studies were conducted using traditional G-banding. For further investigation the effect of irradiation on MSCs, MSCs isolated from 2 normal adults and had normal karyotypes were subjected to irradiation with blood irradiator (Cs137) using the same regimen as TBI before allogeneic transplantation (200cGy twice daily for consecutive 3 days; 1200cGy total radiation dose). *Results.* MSCs can be successfully isolated and *ex vivo* expanded from bone marrow of all the 8 patients who had received myeloablative treatment before allogeneic PBSCT. Despite the intensive chemotherapy or chemoradiotherapy, they were all recipient-origin after allogeneic transplantation, in contrast to complete donor chimerism of bone marrow blood cells. Interestingly, some of the MSCs had cytogenetic abnormalities after transplantation using TBI as conditioning treatment (Table 1). One of these patients (Case No. 7) had a normal Robertsonian variant der (13;14)(q10;q10) before allogeneic transplantation, and get a new, clonal t(1;17)(q21;p13) after transplantation. For 2 MSCs isolated from normal adults and had normal karyotype, complex chromosomal abnormalities developed after direct irradiation using blood irradiator Cs137. *Conclusions.* This is the first report showing that irradiation, either using TBI before transplants or using blood irradiator in experiments, may result in chromosomal abnormalities of bone marrow-derived MSCs. Since the clinical application of bone marrow-derived MSCs increased rapidly, we strongly suggest that MSCs isolated from patients who had received TBI should be avoided from further clinical usage. Besides, further study is needed to observe the tumorogenesis of these cells.

Table 1.

Cytogenetic Status of BM-MSCs Before / After Allogeneic PBSCT					
Case No	Disease	Conditioning Treatment	Chromosome of BM-MSCs		Chromosome of BM-blood cells after PBSCT
			Before PBSCT	After PBSCT

TRANSCRIPTIONAL REGULATION OF SONIC HEDGEHOG EXPRESSION BY NF-κB

S. Fulda,[1] H. Kasperczyk,[2] K.M. Debatin,[1] S. Fulda[1]

[1]University Children's Hospital, ULM; [2]UNiversity Children's Hospital, ULM, Germany

Ligand-dependent hedgehog pathway activation has recently been implicated in carcinogenesis and progression of human cancers. However, the mechanisms controlling Shh expression are poorly understood. Here, we report for the first time that Shh is regulated by the transcription factor NF-κB through direct and indirect mechanisms. Electro mobility shift assays revealed that NF-κB complexes comprising NF-κB subunits p50 and p65 specifically bind to putative NF-κB binding sites identified in the human Shh promotor region by computer-assisted analysis. Furthermore, NF-κB activation by TNFa or p65 overexpression causes increased Shh promoter activity. NF-κB-mediated transcriptional activation of Shh was mapped to a minimal NF-κB consensus site at position +139 of the Shh promotor by deletion and mutation analysis. TNFa also activates the Shh promotor via NF-κB but independent of the minimal NF-κB binding site. Moreover, NF-κB activation by TNFa results in increased Shh mRNA and protein expression in pancreatic carcinoma cells. Importantly, specific NF-κB inhibition by IκBa superrepressor also blocks TNFa-induced Shh promotor activation and Shh expression. By demonstrating that NF-κB regulates Shh expression, our findings have important implications. Thus, NF-κB inhibition may provide a novel strategy to target aberrant Shh activation in human cancers, which warrants further investigation.

0145

POST TRANSLATIONAL TAX MODIFICATIONS CONTROL CRITICAL CYTOPLASMIC AND NUCLEAR STEPS OF NF-κB ACTIVATION: UBIQUITYLATED TAX ACTIVATES IKK ON A CENTROSOME-ASSOCIATED IKK SIGNALOSOME AND SUMOYLATED TAX MEDIATES THE FORMATION OF RELA-ENRICHED TAX NUCLEAR BODIES AND TRANSCRIPTIONAL ACTIVATION

A. Bazarbachi,[1] Y . Kfoury,[1] R. Nasr,[1] A. Favre-Bonvin,[2] M. El-Sabban,[1] N. Renault,[3] M. Giron,[3] H. El Hajj,[1] E. Chiari,[2] A.G. Mikati,[1] O. Hermine,[4] A. Saib,[3] H. De Thé,[3] C. Pique,[2]

[1]American University of Beirut, BEIRUT, Lebanon; [2]Université Paris 5, PARIS, France; [3]UMR 7151 CNRS, PARIS, France; [4]Necker Hospital, PARIS, France

Background. The Tax oncoprotein plays a crucial role in the proliferation and transformation of HTLV-I infected T lymphocytes through various mechanisms, including activation of the NF-κB pathway. *Results.* We found that cytoplasmic ubiquitylation of Tax C-terminal lysines is critical for Tax binding to the IκB kinase complex and subsequent nuclear translocation of RelA. Conversely, we demonstrate that the same lysines are sumoylated in the nucleus, an event required for the formation of RelA/p300-enriched Tax nuclear bodies and full NF-κB transcriptional activation. In contrast, Tax ubiquitylation and sumoylation are dispensable for its activation of CREB-dependent genes. We further show that ubiquitylated Tax is not associated with active cytosolic IKK subunits, but binds endogenous IKK-α,β,γ and targets them to the centrosome. K63-ubiquitylated Tax colocalizes at the centrosome with IKKγ while K48-ubiquitylated Tax is massively stabilized upon proteasome inhibition. *Summary and Conclusions.* Altogether, these results support a model in which K63-ubiquitylated Tax activates IKK in a centrosome-associated signalosome, leading to the production of Tax-free active cytoplasmic IKK. Thus, ubiquitylation and sumoylation of the same residues of Tax regulate two essential steps controlling NF-κB activation, demonstrating how these post-translational modifications can cooperate to promote Tax-induced transformation. These observations highlight an unsuspected cellular and biochemical complexity in Tax-induced NF-κB activation.

0146

ARSENIC TRIOXIDE INDUCES ACCUMULATION OF CYTOTOXIC LEVELS OF CERAMIDE IN ACUTE PROMYELOCYTIC LEUKEMIA AND ADULT T-CELL LEUKEMIA/LYMPHOMA CELLS THROUGH *DE NOVO* CERAMIDE SYNTHESIS AND INHIBITION OF GLUCOSYLCERAMIDE SYNTHASE ACTIVITY

A. Bazarbachi,[1] G. Dbaibo,[1] Y . Kfoury,[1] N. Darwiche,[1] S. Panjarian,[1] L. Kozhaya,[1] R. Nasr,[1] M. Abdallah,[1] O. Hermine,[2] M. El-Sabban,[1] H. De Thé[3]

[1]American University of Beirut, BEIRUT, Lebanon; [2]Necker Hospital, PARIS, France; [3]UMR 7151 CNRS, PARIS, France

Background. Arsenic trioxide (As) is an effective treatment for acute promyelocytic leukemia (APL) and potentially for HTLV-I associated adult T cell leukemia/lymphoma (ATL). Many cytotoxic drugs induce apoptosis through the generation and accumulation of the sphingolipid breakdown product, ceramide, a coordinator of the cellular response to stress. *Aims.* We investigated the contribution of ceramide to the mechanism of action of As in APL and ATL. *Results.* Treatment of APL and ATL derived cells with clinically achievable concentration of As induced accumulation of cytotoxic levels of ceramide. Arsenic effects on ceramide levels in APL cells were more potent compared to all trans retinoic acid (ATRA) effects. We also show that As downregulated neutral sphingomyelinase activity and that, in contrast to ATRA, As-induced ceramide accumulation was not due to induction of acidic sphingomyelinase, but rather resulted from both de novo ceramide synthesis and inhibition of glucosylceramide synthase activity. Interestingly, As effects on de novo ceramide synthesis were similar in APL and ATL derived cells despite the defective pathway in ATL cells. Summary and *Conclusions.* These results indicate that As-induced ceramide accumulation may represent a general mediator of As effects, which paves the way for new therapeutic interventions that target the metabolic pathway of this important sphingolipid secondary messenger.

INSULIN-LIKE GROWTH FACTOR II: A NOVEL AUTOCRINE GROWTH FACTOR IN THE A POPTOSIS, PROLIFERATION, AND MATURATION OF ERYTHROID PROGENITORS IN UMBILICAL CORD BLOOD

T. Nagatomo,[1] K. Muta[2]

[1]Ehime prefectural Central Hospital, MATSUYAMA, [2]Kyushu University, FUKUOKA, Japan

Human umbilical cord blood (CB) contains a higher proportion of erythroblasts compared with adult peripheral blood (PB). The increased number of erythroid progenitor cells (EPCs) in CB could compensate for intrauterine hypoxia. On the other hand, it remains unclear how the abundant EPCs contribute to the fetal hematopoiesis by themselves. To search the novel function of EPCs, CB-derived $CD36^+$ EPCs were subjected to cDNA microarray. It revealed 124-fold higher levels of insulin-like growth factor II (IGF-II) gene expression in CB-EPCs than those in stimulated lymphocytes of adult PB. Then, the following experiments were conducted to determine whether IGF-II exerts as an autocrine erythropoietic factor, which suggests a novel function of EPCs. *Methods/ Results.* The real-time PCR verified that IGF-II mRNA levels were highest in CB-EPCs of all other CB- or adult PB-fractionated cells studied. When CB-EPCs were cultured with erythropoietin (EPO) in serum-free medium, the addition of anti-IGF-II-antibody (Ab) reduced the number of erythroid colonies. To reveal the role of IGF-II in erythropoiesis via an autocrine mechanism erythroid colony-forming cells (ECFCs) were purified from CB and adult PB for further analysis. In brief, CB samples were obtained from normal full-term deliveries. Mononuclear cells (MNCs) were separated by density gradient centrifugation. After depletion of adherent cells, nonadherent cells were collected and negative selection was performed using anti-CD3, CD11b, CD15, and CD45RA antibodies and immunomagnetic beads. The remaining cells were cultured with FCS, human AB serum, stem cell factor (SCF), interleukin-3 (IL-3), and EPO (day0). Day3 ECFCs were collected and incubated under serum-free condition without IL-3. Day7 ECFCs were collected and used in the following experiments. When CB- and adult PB-ECFCs were cultured with IL-3, SCF and EPO, the mRNA levels of IGF-II and type 1 or type 2 IGF receptor increased with the maturation of both ECFCs. The increasing rate of ECFC maturation by IGF-II was higher in CB-ECFCs than in adult PB-ECFCs. Immunocytochemistry demonstrated IGF-II protein in the majority of CB-ECFCs. The addition of anti-IGF-II Ab, but not anti-IGF-I Ab, reduced the number of ECFCs in the liquid culture with EPO. Anti-IGF-II Ab effectively inhibited the proliferation, and accelerated the apoptosis of ECFCs, assessed by MTT and BrdU assays, and flow cytometry. The addition of anti-IGF-II Ab reduced the proportion of glycophorin-A+ cells in ECFCs, which showed a larger in size with a less nuclear condensation, indicating immature erythroid cells. *Summary.* The microarray analysis and quantitative PCR demonstrated the high expressions of IGF-II mRNA in EPCs. The expression levels of IGF-II, type 1 or 2 IGF receptor in the mature erythroid cells were higher than those in the immature erythroid cells. We confirmed that IGF-II is produced by EPCs by themselves, and has a crucial role in fetal erythropoiesis by modulating the apoptosis, proliferation and maturation in an autocrine fashion.

BCL11B KNOCKDOWN LEADS TO APOPTOSIS OF MALIGNANT T-CELLS

K. Dittmann,[1] P. Grabarczyk,[2] K. Dittmann,[2], G.K. Przybylski,[3] M. Depke,[2] U. Völker,[2] J. Bahr,[2] K. Assmus,[2] B. Bröcker,[2] R. Walther,[2] C.A. Schmidt[2]

[1]Universität Greifswald, GREIFSWALD, Germany; [2]University of Greifswald, GREIFSWALD, Germany; [3]Insitute of Human Genetics, POZNAN, Poland

Background. The B-cell CLL/lymphoma 11B gene (BCL11B) encodes a Krüppel-like zinc finger protein which plays a crucial role in thymopoiesis and has been associated with hematopoietic malignancies. A tumor suppressor function of BCL11B has been hypothesized, but the precise protein function has not yet been elucidated. *Aims.* To get more insights in the biological function of BCL11B we analyzed the effects of BCL11B knock down in Jurkat and HUT-78 T-cell lines, Raji B-cell line and in normal T-lymphocytes. *Methods.* Upon BCL11B downregulation using siRNA the DNA content was analyzed by propidium iodide incorporation assay, apoptosis was determined by Annexin V binding assay and Caspase 3 activation was measured by FACS. The genes regulated by Bcl11b were screened by comparing the expression profile of the siRNA and mock transfected T-cell lines using the Affymetrix microarray Genome U133 Plus 2.0. and subsequently confirmed by quantitative real-time PCR. *Results.* We demonstrated that the survival of human T-cell leukemia and lymphoma cell lines depends critically on Bcl11b. Suppression of Bcl11b by RNA interference selectively induced apoptosis in transformed T-cells while normal mature T-cells remained unaffected. The apoptosis was executed by simultaneous activation of death receptor-mediated and intrinsic apoptotic pathways, most likely as a result of TRAIL up-regulation and suppression of the Bcl-xL antiapoptotic protein. Our data indicate an antiapoptotic function of Bcl11b. The resistance of normal mature T-lymphocytes to Bcl11b suppression-induced apoptosis and restricted expression pattern make it an attractive therapeutic target in T-cell malignancies. *Summary and Conclusions.* Our study provides for the first time clear evidence for Bcl11b being an anti-apoptotic protein in T-cell malignancies. The resistance of normal mature T-lymphocytes to Bcl11b suppression-induced apoptosis and restricted expression pattern make it an attractive therapeutic target in T-cell malignancies.

0149

P19 (CDKN2D) PLAYS AN IMPORTANT ROLE IN THE ENDOMITOTIC ARREST LINKED TO THE ACCELERATION OF THE MEGAKARYOCYTE MATURATION

D. Bluteau, R. Guièze, L. Gendre, V. Cordette-Lagarde, D. Baudry-Bluteau, R. Favier, N. Debili, W. Vainchenker, H. Raslova

Inserm U790, VILLEJUIF, France

Ploidization, which appears during normal megakaryocyte differentiation, is linked to a modification in gene expression profile. One of the genes which transcription is positively regulated during ploidization, is a cell cycle inhibitor, p19(CDKN2D). p19, p18, p16 and p15 are members of INK4 family of cyclin dependent kinase (CDK) inhibitors that function in G1 to block the activity of CDKs 4 and 6. Except the role of p19 in cell cycle, this protein can regulate neuronal and macrophage differentiation and has been found to be expressed in erythroid cells. p19 acts also as a protector against apoptotic cell death. In this work, for the first time we have evidenced the role of p19 in megakaryopoiesis. Here we demonstrated that the expression level of p19 in megakaryocyte lineage is 10-fold higher than in the erythroid lineage. Moreover, the expression of p19 increases not only during ploidization after sorting the MKs according to their DNA content but also during MK differentiation (in diploid $CD34^+CD41^+CD42^-$, $CD34^+CD41^+CD42^+$ and $CD34^-CD41^+CD42^+$ populations) both at the mRNA and protein level. Transduction of $CD34^+$ cells at day 1 and 2 of culture by two different shRNAs p19 leads to a moderate increase (31.7±5%) in mean ploidy level suggesting a role of p19 in the arrest of endomitosis as well as mito-

sis during differentiation. Surprisingly, the repression of p19 induced a decrease in MK differentiation. Indeed, the about 70% diminution in p19 expression leads to a 38.6%±17% decrease in $CD41^{high}CD42^{high}$ MKs. This decrease was not linked to a differentiation blockage but to a delay in differentiation. The number of proplatelet forming MKs was diminished when cells were transduced with shRNA p19. However, when mature $CD41^{++}CD42^{++}$cells were analyzed, no difference in the number of proplatelet forming MK cells was detected suggesting that p19 did not play a direct role in platelet formation. Knowing that polyploidization is linked to MK differentiation, we tried to dissect the role of p19 in the arrest of endomitosis and in the regulation of MK maturation. To perform such experiments, polyploid MKs were transduced with shRNA p19 and 72 hours later, 22.3±6.6% increase in mean ploidy level was observed. However, when each ploidy class was analyzed separately, a slight decrease in CD42 expression in polyploid MKs was observed suggesting that these cells will accelerate their maturation once the cell cycle is achieved. To confirm our results, $CD34^+$ cells were transduced by a lentivirus encoding for p19 cDNA, a 59.7±6.8% decrease in mean ploidy level was detected. Furthermore, in each ploidy class, an important increase in CD41 and slight increase in CD42 expression is observed. All together our results demonstrated that p19 has an important role in the arrest of endomitosis allowing the acceleration of MK maturation.

THE LEUKEMOGENIC CALM/AF10 FUSION PROTEIN ALTERS THE LOCALIZATION OF THE EPIGENETIC REPRESSOR IKAROS

A. Greif,[1] B. Tizazu,[1] A. Krause,[1] E. Kremmer,[2] S.K. Bohlander[1]

[1]GSF / LMU, MUNICH; [2]GSF, MUNICH, Germany

The t(10;11)(p13;q14) translocation leads to the fusion of the CALM and AF10 genes. This translocation can be found as the sole cytogenetic abnormality in acute lymphoblastic leukemia, acute myeloid leukemia and also in malignant lymphomas. The expression of CALM/AF10 in primary murine bone marrow cells triggers the development of an aggressive leukemia in a murine bone marrow transplantation model. Here we show that AF10 interacts with the epigenetic repressor Ikaros in yeast-two-hybrid assays. Interestingly, Ikaros is required for normal development of lymphocytes and aberrant expression of Ikaros has been found in leukemia. In a murine model, the expression of a dominant negative isoform of Ikaros causes leukemias and lymphomas. The Ikaros interaction domain of AF10 was mapped to the leucine zipper domain of AF10, which is required for malignant transformation by both the CALM/AF10 and the MLL/AF10 fusion protein. The interaction between AF10 and Ikaros was confirmed by GST-pulldown and co-immunoprecipitation. In contrast to AF10, CALM/AF10 alters the nuclear localization of Ikaros. The transcriptional repressor activity of Ikaros is reduced by AF10. These results suggest that CALM/AF10 might have a dominant negative effect on Ikaros, and thereby block differentiation of the leukaemia propagating cell in CALM/AF10 positive leukemias.

Figure 1. *In vivo* localization in co-transfected NIH 3T3 fibroblasts (Confocal Laser Scan).

BRAIN-EXPRESSED X-LINKED-2 (BEX2): EPIGENETIC REGULATION OF A POTENTIAL MARKER FOR ACUTE MYELOID LEUKEMIA WITH MIXED LINEAGE LEUKEMIA REARRANGEMENTS

H. Quentmeier, C. Fischer, J. Reinhardt, M. Zaborski, H.G. Drexler

DSMZ, BRAUNSCHWEIG, Germany

In epigenetically regulated genes, methyl-CpG recognizing proteins like MeCP2 may bind to methylated CpG-rich areas and contribute to silencing of these genes by recruitment of histone deacetylases (HDAC) and histone methyltransferases. Previously, we identified BEX2 as candidate gene for the diagnosis of acute myeloid leukemia (AML) with mixed lineage leukemia translocations (MLLmu), similarly as extensively described for HOX gene expression in MLLmu acute lymphoblastic leukemia. Human brain expressed X-linked (BEX) is a novel gene family consisting of at least six family members. Human BEX1 and BEX2 are highly expressed in various brain-derived tissues, show diverse expression patterns in peripheral tissues like the liver or pancreas, but are not expressed in hematopoietic tissues like spleen, thymus, lymph node or peripheral blood lymphocytes. We show here that a strict correlation exists between the methylation status of the BEX2 5´ CpG-rich area and expression of BEX2 mRNA: BEX2-negative MLL wild-type (MLLwt) cell lines showed hypermethylation, BEX2-positive MLL mutant (MLLmu) cell lines showed hypomethylation of this specific CpG-rich area. Supporting the view that the expression of BEX2 is epigenetically regulated, we found that treatment of MLLwt cell lines with the demethylating agent Aza-2´deoxycytidine (Aza) induced BEX2 expression in MLLwt cell lines. Furthermore, treatment of MLLwt cell lines with the HDAC inhibitor trichostatin provoked upregulation of BEX2 mRNA in these cells, alone and in combination with the demethylating agent Aza. Chromatin immunoprecipitation assays confirmed the specific binding of acetylated histone H3 to the BEX2 5´region in BEX2-positive, but not in BEX2-negative cells. Methylated CpG-rich areas may not only silence genes by recruitment of HDAC and histone methyltransferases, but also by preventing binding of specific transcription factors to their DNA target regions. The CpG-rich area in the 5´region of BEX2 contains an ARNT-1 binding site. Stimulation of cells with 3-methylcholantrene (3-MC) leads to binding of the receptor AhR to ARNT-1, translocation of the AhR/ARNT-1 complex from the cytoplasm into the nucleus, and induction of ARNT-1 target genes like CYP1A1. A clearly positive effect of 3-MC on BEX2 expression was detectable only, if MLLwt cells were preincubated with Aza. These data suggest that BEX2 negativity in MLLwt cell lines is the consequence of CpG hypermethylation, recruitment of HDAC and prevention of ARNT-1 binding to its cognate binding site.

DOWN REGULATION OF DLX3 EXPRESSION IN MLL/AF4 CHILDHOOD LYMPHOBLASTIC LEUKEMIAS IS MEDIATED BY PROMOTER REGION HYPERMETHYLATION

M. Campo Dell'Orto,[1] B. Banelli,[2] E. Giarin,[1] B. Accordi,[1] L. Trentin,[1] M. Romani,[2] G. Te Kronnie,[1] G. Basso[1]

[1]University of Padua, PADUA; [2]Laboratory of Experimental Oncology C, GENOA, Italy

Background. Chromosomal translocations that inactivate or create new fusion genes are a common hallmark of acute lymphoblastic leukemia (ALL) and may serve as diagnostic and prognostic markers in subtypes of ALL. Aberrant methylation of clustered cytosine-guanosine motifs (CpG), especially in CpG islands located in gene promoter regions, is an early and essential step in tumour development and methylation has been proved to be a mechanism of gene silencing as common as the disruption of tumour-suppressor genes by mutation or deletion. Moreover, DNA hypermethylation and transcriptional silencing of genes involved in tumor invasiveness, cell growth and apoptosis, may also influence recurrence after treatment and overall survival. Inactivation of cancer-related genes by DNA methylation is a frequent event also in paediatric and adult ALL and, by looking at differences in the methylation pattern of multiple genes, specific risk groups among patients have been identified. The DLX genes implicated in haematopoiesis and in a number of other processes with highly dynamic spatio-temporal expression patterns and well-defined CpG islands in their promoter regions, are attractive targets for methylation studies in leukemia subtypes. In particular, the down-regulation of DLX2, 3 and 4 had been described in a group of paediatric B-ALL characterized by the t(4;11)(MLL-AF4) chromosomal rearrangement and, in several cancer cell lines, is directly connected to an increased resistance to apoptosis. The presence of extended CpG islands at the 5' end of DLX2, 3 and 4 genes, their possible role in resistance to apoptosis, and the recent finding of DLX5 promoter methylation as one of the epigenetic markers of chronic lymphoblastic leukemia, prompted us to study the methylation and gene expression pattern of DLX2, 3 and 4 in specific paediatric ALL subtypes. *Aims.* Our main purpose was to understand if, in pediatric leukemias, the methylation of DLX2, 3 and 4 genes could have a functional role in their gene and protein expression and if differential methylation patterns were able to dis-

tinguish between genotypic B-cell leukemia subgroups with different responses to chemotherapy. *Methods.* Methylation Specific PCR, RQ-PCR, 5'-Aza-2'dC treatment, Western Blot. *Results.* Analysis of methylation and gene expression patterns of DLX3 in 64 specimens of B-lineage ALL revealed that DLX3 presents aberrant methylation in paediatric B-ALL patients. *in vitro* experiments with 5'-Aza-2'dC on leukemia cell lines, confirmed by western blot analysis, indicated that the methylation of DLX3 CpG islands has a functional role and interferes with DLX3 gene and DLX3 protein expression in B-ALL cells. To validate this data we studied two groups of patients with the two better known paediatric chromosomal rearrangements: MLL-AF4 and TEL-AML1 respectively. Hypermethilation of DLX3 significantly reduces its expression in MLL/AF4 rearranged leukemias while methylation is almost absent in TEL-AML1 positive ALL specimens. *Conclusions.* Our results show for the first time the aberrant methylation of DLX3 gene and its functional inactivation role in the specific cohort of paediatric B-ALL with the MLL-AF4 chromosomal aberration. This finding proposes DLX3 as a new epigenetic candidate marker involved in leukemiogenesis of this high-risk acute lymphoblastic leukemia.

LBH589, A NOVEL DEACETYLASE INHIBITOR (DACI), IN THE TREATMENT OF CUTANEOUS T-CELL LYMPHOMA (CTCL): CHANGES IN TUMOR GENE EXPRESSION PROFILES RELATED TO CLINICAL RESPONSE AFTER THERAPY

Y. Pan,[1] H.M. Prince,[1] J. George,[2] R.W. Johnstone,[1] L. Ellis,[1]
C. McCormack,[1] G.K. Smyth,[3] R. Williams-Truax,[2] P. Atadja,[4]
D. Butterfoss,[5] M. Dugan,[5] K. Culver5

[1]Peter MacCallum Cancer Centre, EAST MELBOURNE, Australia; 2Duke University, DURHAM, USA; [3]Walter and Eliza Hall Institute, MELBOURNE, Australia; [4]Novartis Institutes for Biomedical Res, CAMBRIDGE, United States of America, [5]Novartis Pharmaceuticals, EAST HANOVER, USA

Background. In preclinical and Phase I studies, deacetylase inhibitors (DACIs) have shown promise in the treatment of hematological malignancies, in particular cutaneous T-cell lymphoma (CTCL); however, the target genes affected by DACIs remain unknown. LBH589, a novel DACI, is currently undergoing clinical trials for the treatment of CTCL. *Aims.* To determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of oral LBH589 in patients with CTCL, and to characterize the biologic activity of oral LBH589 when administered to this patient population. *Methods.* This is an ongoing Phase I study of LBH589 in patients with advanced-stage CTCL. Patients were entered into either an oral DLT regimen of 30 mg three-times weekly (M, W, F; n=1), or an MTD regimen of 20 mg three-times weekly (M, W, F; n=9). Treatment was discontinued in the event of disease progression or unacceptable toxicity. Gene expression profiling using Affymetrix U133A plus 2.0 GeneChip? with 54,675 probe sets was carried out in 3-mm punch biopsies of CTCL skin lesions taken from patients 0, 4, 8, and 24 hours after LBH589 administration. F-statistics were used to adjust for differences between the subjects, allowing for the prioritization of genes that responded consistently over time to LBH589. Assessment of hyperacetylation of histone H3 as a biological marker of LBH589 activity in patient samples was conducted by immunohistochemistry and assessment of blood mononuclear cells. *Results.* All 10 patients were evaluable for response: 2 achieved a complete response (CR), 4 achieved a partial response (PR), and 2 had stable disease (SD) (RR = 6/10; 60%). Median duration of treatment was 4 weeks in the DLT arm and 23 weeks in the MTD arm. Duration of response was 178.5 days for both arms. One patient in the DLT arm experienced grade 4 diarrhea (n=1). Patients in the MTD arm experienced grade 3 diarrhea (n=1), grade 3 neutropenia (n=3), and grade 3 thrombocytopenia (n=1). Microarray data from 6 patients demonstrated that within individual patient tumors, alterations in gene expression were observed at all time points in the first 24 hours post-treatment. Global changes in gene expression patterns were also observed when all patients and all time points were investigated. The following were major findings following LBH589 treatment: there were rapid changes in gene expression; more genes were repressed than were activated; gene expression changes were observed in both responders and non-responders. qRT-PCR confirmed array analysis. Hyperacetylation levels were observed up to 72 hours following LBH589 administration. *Conclusions.* LBH589 induces CR in patients with CTCL. Ongoing disease regression is apparent weeks after discontinuation of therapy. CTCL provides a unique scenario in which the effect of a drug on genes can be observed over time using microarray analysis. Treatment with LBH589 results in the differential expression of numerous genes, which may help elucidate the biologic activity of LBH589 in the CTCL patient population.

WNT PATHWAY MUTATIONS IN ACUTE LEUKEMIA PATIENTS

M. Sayitoglu, O. Hatirnaz, F. Atalar, Y. Erbilgin, U. Ozbek

Istanbul University, ISTANBUL, Turkey

Aims. WNT signaling pathway proteins function as haematopoietic growth factors and regulate proliferation in normal T-cell and B-cell development. Not much is known about activation of this pathway, its ligands and receptors in leukaemia pathogenesis. Genetic alterations in WNT pathway associate with different types of cancers as well as acute leukemias. Here we determined β-catenin expression levels and mutational alterations in the β-catenin, AXIN1 and APC genes in acute leukemia patients. Patients and Method; Peripheral blood and/or bone marrow samples were taken at diagnosis. β-catenin mRNA levels were determined by quantitative real time PCR (QRT-PCR). Acute lymphoblastic (n=126) and myeloblastic leukemia patients (n=30) showed ~4 fold increased β-catenin mRNA levels. Using denaturing high-performance liquid chromatography (DHPLC) analysis and DNA sequencing, acute lymphoblastic leukemia and acute myeloblastic leukemia patients were screened for inactivating WNT pathway mutations. Sequence variations of AXIN1 (exons 1-5, APC, MKK, GSK3 β and β-catenin binding domains) and APC (exon 15, AXIN and β-catenin binding domains) were determined. Results and Conclusion; These variations were found to be 35% for AXIN1 (exons 1-5) and 50% for APC (exon 15) in ALL patients and 19% for AXIN1 and 54% for APC genes. There was no β-catenin (exon 3) mutation in AML patients, and one ALL patient have this mutation. Cytoplasmic B-catenin accumulation frequently occurs in leukemia. According to our findings β-catenin mutations are rare in leukemia samples. Our preliminary results also support that, abnormal β-catenin accumulation via ligand-independent manner in acute leukemias seem to closely associated with AXIN1 and APC mutations.

WNT5A GENE EXPRESSION AND PROMOTER METHYLATION IN ACUTE LEUKEMIA PATIENTS

O. Hatirnaz, M. Sayitoglu, F. Atalar, Y. Erbilgin, U. Ozbek

Istanbul University, ISTANBUL, Turkey

WNT5A which is a member of WNT family, functions as a tumor suppressor gene in haematopoietic tissue. It promotes intracellular Ca^{++} release and activation of protein kinase C. WNT5A was found to be over-expressed in various cancer types, where as acute lymphoblastic (ALL) and acute myeloblastic (AML) leukemia patients showed loss of WNT5A gene expression. Previous results indicated that WNT5A/Ca^{++} dependent pathway suppresses cyclin D1 expression and WNT5A null mice develop B-cell lymphoma and chronic myeloid leukemia. We determined WNT5A and its downstream targets c-MYC and cyclin D1 expression levels in acute leukemia patient. Bone marrow and/or peripheral blood samples were obtained from ALL (n=126) and AML (n=34), at the time of diagnosis. Also normal bone marrow (n=6), normal peripheral blood (n=10) and $CD19^{+}$ cells samples were used as controls. The relative expression levels of WNT5A, c-MYC and cyclin D1 genes were detected by quantitative-real time PCR (QRT-PCR). Methylation status of WNT5A promoter is determined by methylation specific PCR (MSP). Our results indicated that the mRNA levels of WNT5A and cyclin-D1 were decreased, but level of c-MYC was increased. This confirms the finding that c-MYC expression is independent of WNT5A presence, but cyclin-D1 is WNT5A dependent. To investigate the decrease in WNT5A mRNA expression levels, we performed MS-PCR and found hypermethylation of WNT5A promoter in 86% of ALL's and 85,7% of AML's. Loss of WNT5A gene dosage was observed in several primary tumors depending on the homozygous deletions of WNT5A, RNA or promoter silencing. Here we determined decreased WNT5A expression depending on the WNT5A promoter hypermethylation in ALL and AML patients.

ONCOGENETIC FUNCTION OF KTS+ ISOFORM OF WT1 IN ACUTE AND CHRONIC LEUKEMIAS

D. Cilloni, I. Defilippi, S. Carturan, F. Messa, V. Rosso, F. Arruga,R. Catalano, C. Bittoto, C. Boveri, E. Messa, P. Nicoli, E. Bracco, G. Saglio

University of Turin, TURIN, Italy

Background. The Wilms' tumour gene (WT1) is overexpressed in a variety of hematological malignancies including acute and chronic leukemias, myeloproliferative disorders and myelodysplastic syndromes and nowadays it is considered a sort of universal marker of leukaemia. WT1 was originally identified as responsible for the kidney tumour of Wilms and described as a tumour suppressor gene but, in the setting of leukaemia, it seems to function as an oncogene. WT1 has different isoforms. In particular, KTS$^+$ and KTS$^-$ are 2 isoforms derived from alternative spicing of exon 9. In normal cells the two isoforms are approximately equally represented. *Aims.* the aim of the study was to analyze the different function and distribution of the two isoforms. *Methods.* After informed consent, 132 BM samples were collected from 86 AML and 46 CML patients at diagnosis and 20 samples from healthy subjects. 62 patients were also evaluated during follow-up. WTS$^+$ and KTS$^-$ isoforms were quantified by capillary electrophoresis The relative amount of two isoforms was calculated by measuring the picks area of electropherogram . NIH3T3 and 293T cell lines were transfected with WT1 KTS$^+$ or WT1 KTS$^-$ plasmids. WT1 protein was studied by Western blot and immunofluorescence in BM cells and transfected cell lines. Downstream genes transcriptionally activated by WT1 such as Spred-2 and E-Cadherin were evaluated by Real Time PCR. *Results.* We demonstrated that AML and CML patients have an unbalanced KTS$^+$/KTS$^-$ ratio with a significant increase of KTS$^+$ isoform as compared to KTS$^-$. The ratio observed ranges from 1.6 to 6.1 in AML from 1.6 to 9.5 in CML. In 10% of the patients we observed a complete disappearance of the KTS- isoform . Western blot and immunofluorescence carried out in BM cells and transfected cell lines allow to establish that the KTS+ isoform is mainly localized in the cytoplasm and KTS$^-$ isoform is mainly nuclear localized. In BM cells carrying the isoform KTS$^+$ or in cells transfected with KTS$^+$ isoform we observed the lack of transcription of downstream genes such as Spred1 or E-cadherin. In addition, in patients who achieved a complete remission after chemotherapy, WT1 KTS$^+$/KTS$^-$ ratio returned within the normal range and Spred1 and E-cadherin transcript and protein were significantly upregulated. Finally, cells transfected with KTS$^+$ isoform presented morphology changes, altered adhesion properties and increased proliferation as compared to KTS- transfected cells. *Conclusions.* This study demonstrates that in leukemic cells there is a disruption of the normal transcription activity of WT1 and this is mainly due to the unbalanced ratio between the two isoforms KTS$^+$ and KTS$^-$ with different localization and function. This alteration results in a defective transcriptional activity of WT1 which can probably play an oncogenic role in leukemic cells.

0157

ANKHD1 PROTECTS LEUKEMIA CELLS FROM APOPTOSIS AND BINDS TO SIVA, A PROAPOPTOTIC PROTEIN

FT Traina, P.R.M. Lima, F.F. Costa, S.T.O. Saad

State University of Campinas, CAMPINAS, Brazil

Background. Ankyrin-repeat-containing proteins regulate multiple cellular functions including transcription, cell-cycle, cell survival and participate in protein'protein interactions via their repeat motifs. Ankyrin Repeat and KH Domain Containing 1, ANKHD1, has been recently described, in humans, as a cytoplasmic protein overexpressed in prostate cancer cell line and in leukemia cells compared to normal hematopoietic cells. Its homologous protein, MASK, was described in Drosophila melanogaster as an essential protein for differentiation, proliferation and cell survival. However, the role of ANKHD1 in leukemia cells has not been fully elucidated. *Aims.* The aim of this study was to identify new proteins associated with ANKHD1 and the role of ANKHD1 in the apoptotic process of leukemia cells. *Methods.* In order to identify possible targets of the ANKHD1 protein, we performed a yeast two-hybrid screen using ANKHD1 protein (amino acids 1130-1243) in pGBKT7 vector, as the bait, and a Matchmaker pACT2-cDNA library from normal human bone marrow (Clontech), as the prey. The protein interaction detected was confirmed using the yeast two-hybrid assay, through co-transfections of AH109 yeast with the ANKHD1-pGBKT7 bait and the new candidate for protein interaction identified in pGADT7 vector. Post-transcriptional ANKHD1 gene silencing was done using small interfering RNA, SMARTpool siRNA duplexes (Dharmacon), at a concentration of 400 nM. Transient transfections of Jurkat cells were performed by electroporation in a Bio-Rad Gene Pulser II (300V, 975 microfarads). Cells were cultured for 48 h after transfections and then submitted to Western blotting and apoptosis analysis. Apoptotic cell death was evaluated using Annexin V-FITC/PI staining and FACS analysis. *Results.* The yeast two-hybrid screening identified the new protein interaction between ANKHD1 and SIVA. Co-transfections of AH109 with pGBKT7-ANKHD1 and different SIVA-pGADT7 constructs (SIVA1, SIVA2, SIVA C-terminal, SIVA N-terminal, SIVA Dead Domain) confirmed the association between ANKHD1/SIVA1 and ANKHD1/SIVA2, and the need for both the N-terminal and C-terminal regions of SIVA for the interaction with ANKHD1. Western blotting confirmed that ANKHD1 expression was reduced by 80% in the Jurkat cells transfected with ANKHD1 siRNA compared with controls cells (electroporated cells). Treatment of Jurkat cells with the ANKHD1 siRNA resulted in increased apoptosis (27% of apoptotic cells) compared with control cells (14% of apoptotic cells). *Conclusions.* The association between ANKHD1 and SIVA isoforms suggests that ANKHD1 participates in the apoptotic signaling in leukemia cells, since we know that SIVA1 and SIVA2 are overexpressed in acute lymphoblast leukemia cell lines and induce apoptosis in Jurkat cells. The increased apoptotic rate after posttranscriptional ANKHD1 gene silencing indicates an anti-apoptotic function of ANKHD1 in Jurkat cells. In conclusion, ANKHD1 protects leukemia cells from apoptosis and binds to SIVA, possibly inhibiting the proapoptotic function of SIVA. These results indicate that ANKHD1 is associated with the abnormal phenotype of leukemia cells; the identification of new disease-specific targets for acute leukemia immunotherapy expands treatment options and increases our chances of successfully treating this heterogeneous disease and lowering the unacceptably high mortality rate.

PLASMA PROTEOMIC PROFILES MAY PREDICT EARLY ACUTE GRAFT-VS.-HOST DISEASE FOLLOWING REDUCED INTENSITY CONDITIONING ALLOGENEIC HLA-IDENTICAL SIBLING TRANSPLANTATION

M. Mohty,[1] M. Mohty,[2] A. Goncalves,[2] E. Esterni,[2] Y. Toiron,[2] B. Gaugler,[2] C. Faucher,[2] J. El-Cheikh,[2] S. Furst,[2] J.A. Gastaut,[2] P. Viens,[2] D. Olive,[2] C. Chabannon,[2] J.P. Borg,[2] D. Blaise[2]

[1]Imperial College, LONDON, United Kingdom, [2]Institut Paoli-Calmettes, MARSEILLES, France

Background. Modern approaches to predict the occurrence/severity of aGVHD are needed. *Aims.* This study aimed to identify a plasma protein signature correlating with occurrence of early aGVHD. *Methods.* We performed Surface-Enhanced Laser Desorption/Ionization time (SELDI) of flight mass spectrometry profiling of plasma from 88 pts who received RIC allo-SCT from HLA-identical siblings. *Results.* Median age of pts was 51 (range, 18-70) y. 41 pts (47%) had a myeloid malignancy, whereas 30 (34%) had a lymphoid malignancy. 17 pts (19%) were treated for metastatic non-hematological malignancies. The RIC regimen included fludarabine, busulfan and ATG in 53 pts (60%) and low dose irradiation in 35 pts (40%). With a median FU of 400 (range, 127-829) d, 20 pts (23%) had early (prior to day 35 after allo-SCT) grade 2-4 acute GVHD (12 grade 2 and 8 grade 3-4). Denatured plasma samples (collected at a median of 28 d.) were incubated with H50 and CM10 ProteinChip arrays and subjected to SELDI analysis. Pts population was divided into a training (n=59) and a validation set (n=29). In the training set, 36 protein peaks were differentially expressed according to early aGVHD occurrence. By combining partial least squares and logistic regression methods, we built a multiprotein model that correctly predicted outcome in 96% of pts (14/14 patients with early aGVHD; specificity, 96%). The observed correct prediction rate in the validation set was 69% with a sensitivity of 67%, and a specificity of 70%. While negative predictive value of the model was only 36%, predictive positive value was estimated to 89% in the validation set. The performances of the model remained very similar after iterative (500 times) random resampling (correct prediction rate: 74%, median sensitivity: 48%, median specificity: validation set: 83%). Univariate and multivariate analyses of known risk factors (demographic features, diagnoses and transplant procedures) for early grade 2-4 aGVHD did not show any statistically significant difference between the group of 20 patients who had early grade 2-4 aGVHD as compared to the remaining patients, and suggested that the multiprotein index is likely to be the only independent prognostic parameter. Major components of this multiprotein index are currently being characterized and will be presented. *Conclusions.* Obviously, larger prospective studies are still needed, but our results already suggest that proteomic analysis of plasma will prove increasingly important in the early and clinical diagnosis of aGVHD.

PROTEOME PROFILING IDENTIFIES APOLIPOPROTEIN A1 AS A SERUM MARKER CORRELATED TO JAK2 V617F BURDEN IN POLYCYTHEMIA VERA AT DIAGNOSIS

P. Mossuz,[1] A. Bouamrani,[2] S. Brugière,[3] M. Arlotto,[2] S. Hermouet,[4] E. Lippert,[5] F. Laporte,[1] F. Girodon,[6] I. Dobo,[7] V. Praloran,5 J. Garin,[3] J.Y. Cahn,[1] F. Berger[1]

[1]CHU Grenoble, GRENOBLE; [2]INSERM U318, GRENOBLE; [3]CEA, UNIT-M 201, GRENOBLE; [4]CHU Nantes, NANTES; [5]CHU Bordeaux, BORDEAUX; [6]CHU Dijon, DIJON; [7]CHU Angers, ANGERS, France

Background. Polycythemia Vera (PV) is a myeloproliferative disorder (MPD) originating from a multipotent haematopoietic progenitor cell. The great majority of PV are characterized by a recurrent acquired gain-of-function mutation of the JAK2 protein (JAK2-V617F). Modifications of JAK2-V617F burden are associated with changes of PV phenotype and probably impact on the risk of complications. However, we don't know whether if the proportion of JAK2-V617F allele modifies certain serum proteins. *Aims.* The purpose of our study was to generate serum proteome profiles of PV patients to discover and identify novel serum protein correlated with the levels of granulocyte JAK2-V617F. *Methods.* PV serums were collected in a multicenter study and were randomly affected in two independent learning and validation sets. Proteome profiles were generated by SELDI-TOF mass spectrometry. JAK2 V617F status was determined by quantitative-PCR analysis of purified granulocytes. *Results.* Unsupervised clustering analysis of the learning set showed that PV patients could be separated in two major subgroups tending to be different with respect to the mean percentage of mutated JAK2 (p=0.09), the number of PRV-1 transcripts (p=0.08) and Ht (p=0.09). Comparative analysis of proteome profiles found significant difference (p<0.05) for 27 protein or peptide masses (characterized by their m/z ratio) between these two subgroups. To validate the association of these proteins with JAK2-V617F levels, we applied the 27 markers to the validation set. Two subgroups with significantly different mean percentage of JAK2 V617F (p=0.04) were thus isolated. The two groups also differed by their number of PRV-1 transcripts (p=0.02), their hematocrit level (p=0.01) and their platelet number (p=0.05). Among the 27 protein markers, we selected a 28kDa m/z marker (p28) that retained the highest discriminative value between PV subgroups in each of the two independent sets; p28 expression being the highest for PV patients with more than 75% of mutated alleles. Separate fragmentation analysis in tandem mass spectrometer (nano-LC-MS/MS) of amino-acid sequence of 10 proteolytic peptides unambiguously identified Apolipoprotein A1 (Apo-A1) as the 28kDa m/z marker. Immuno-assay on an automated random immuno-analyser confirmed the correlation between serum Apo-A1 concentrations and JAK2-V617F percentages, and showed that serum Apo-A1 assay allowed the specific discrimination of PV patients with more than 75% of mutated alleles. *Conclusions.* Our results showed that serum proteome profiles of PV patients are influenced by JAK2 V617F burden. In particular we showed that Apolipoprotein A1 is a serum biomarker correlated to the percentage of JAK2-V617F in granulocytes. These results suggest that serum Apolipoprotein A1assay should provided useful information for identification of PV with high levels of mutated JAK2.

0160

GRAFT VERSUS HOST DISEASE AND OTHER COMPLICATIONS CAN BE DEPICTED BY SPECIFIC PROTEOMIC PATTERNS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

E. Mischak-Weissinger,[1] E. Schiffer,[2] B. Hertenstein,[3] M. Stadler,[1] E. Holler,[4] J.L. Ferrara,[5] H.J. Kolb,[6] A. Zander,[7] A. Ganser[1]

[1]Hannover Medical school, HANNOVER, Germany; [2]Mosaiques-diagnostics GmbH, HANNOVER, Germany; [3]Klinikum Bremen Mitte, BREMEN, Germany; 4University of Regensburg, REGENSBURG, Germany; [5]University of Michigan, ANNABOR, USA; [6]Klinikum Großhadern, MÜNCHEN, Germany; [7]UKE Hamburg, HAMBURG, Germany

Background. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a curative treatment for many hematologic malignancies or hematopoietic dysfunction syndromes, but the application is still limited due to major complications, such as severe graft versus host disease (GvHD) and infectious complications. Diagnosis GvHD is based on clinical features and biopsies, a non invasive, unbiased laboratory test does not exist. *Results.* Here we describe the blinded evaluation of a proteomic pattern useful for early diagnosis of acute GvHD, evaluated on 902 samples collected from 168 patients undergoing allo-HSCT at 5 different transplant centers. The majority of the patients included were transplanted for hematological malignancies (n=158), 10 for hematopoietic failure syndromes (sAA, n=6; PNH n=1; OMF, n=3). Forty-five patients were treated with dose-reduced conditioning regimens; GvHD-prophylaxis consisted of antibodies plus Cyclosporin (CsA) plus Metotrexat (MTX) or mycophenolic acid (MMF), respectively. Most patients were transplanted from matched unrelated donors (MUD, n=100), while 63 received stem cells from matched related (MRD, SIB, 1 syngeneic), 3 from haplo-identical, and 2 from mismatched donors. Using capillary electrophoresis coupled online with mass spectrometry (CE-MS), 170 potentially aGvHD-specific polypeptides were identified in a training set of 13 urine samples from 10 allo-HSCT patients with aGvHD (> grade II) and samples (n=50) of 23 patients without aGvHD. The application of the aGvHD specific pattern and calculated model allowed correct classification of blinded and prospectively collected urine samples with high accuracy: The model enabled the diagnosis of aGvHD > grade II with a sensitivity of more than 83% [95% CI 73.1 to 87.9]). High resolution proteome analysis with diagnostic peptide patterns may help to identify patients at risk of severe aGvHD development prior to clinical features (mean: 7 days, range: 1 to 13 days prior to clinical symptoms) in an unbiased laboratory based screening assay. Other patterns (bacterial infection/septicaemia, CMV and EBV reactivation and infection) will be shown. Application of proteomic based patterns may lead to the establishment of a diagnostic tool suitable for pre-emptive therapy of aGvHD based on proteomic patterns.

MOLECULAR STUDY OF PORTUGUESE PATIENTS WITH CLINICAL DIAGNOSIS OF SHWACHMAN-DIAMOND SYNDROME

E. Costa,[1] J. Oliveira,[2] E. Vieira,[2] F. Duque,[3] P. Garcia,[3] I. Gonçalves,[3] L. Diogo,[3] J. Barbot,[4] R. Santos[2]

[1]Instituto Politécnico de Braganaç, BRAGANÇA; [2]Unidade de Genética Molecular, IGM, PORTO; [3]Hospital Pediátrico de Coimbra, COIMBRA; [4]Hospital de Crianças Maria Pia, PORTO, Portugal

Shwachman-Diamond syndrome (SDS; MIM# 260400) is a rare autosomal recessive disorder characterized by the association of exocrine pancreatic and bone marrow dysfunction. Other systemic findings (skeletal, liver and psychomotor) or problems secondary to bone marrow dysfunction may also be detected. Intermittent or persistent neutropenia is the most common haematological finding, but anaemia and thrombocytopenia are present in approximately 40% of the patients. The SDS locus was mapped to chromosome 7q11 where disease-associated mutations were later reported in the Shwachman-Bodian-Diamond syndrome gene (SBDS; MIM# 607444). The present report summarises the molecular analysis of 14 Portuguese patients with suspected diagnosis of SDS. Direct sequencing of all coding regions of the SBDS gene, including exon-intron boundaries, was conducted in all cases. Additional molecular studies including long-range PCR and cDNA analysis were performed to clarify the involvement of a refractory mutation in a case where only a heterozygous mutation had been detected by direct sequencing. Four patients were found to be compound heterozygous for the common c.181_184TA>CT and c.258+2T>C mutations. One of the patients was a compound heterozygote for the c.258+2T>C mutation and a previously unreported genomic deletion (c.258+374_459+250del). This novel mutation, predictably giving rise to an internally deleted polypeptide (p.Ile87_Gln153del), appears to have arisen from an excision event mediated by AluSx elements present in introns 2 and 3 of SBDS gene. In the remaining nine patients no pathogenic mutations were found. Eight previously reported polymorphisms were also detected in the course of this study (c.129-162TTGGGGGTAAGAAAdelinsGGGGGCGGGGG, c.129-71G>A, c.141C>T, c.201A>G, c.258+54T>G, c.459+92A>G, c.635T>G and c.651C>T). The previously reported mutations c.181_184TA>CT and c.258+2T>C, arising from gene conversion events, are the most frequent mutations associated with SDS in this group of patients. The detection of a large genomic deletion encompassing exon 3 illustrates the importance of screening for gross rearrangements, especially in patients where a single mutation is detected by routine methods. The considerable number of patients in which no mutations were found, may be explained by variations in intronic or regulatory regions that were not screened, the involvement of other genes acting in a common pathway, or broad selection criteria permitting inclusion of misdiagnosed patients.

METHYLATION PROFILE IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA

D. Marinitch,[1] N.D. Volcovets,[1] D.G. Tsvirko,[1] Y.L. Buryanov,[2] T.V. Shevtchuk,[2] O.V. Dyachenko[2]

[1]Byelorussian Hematology Center, MINSK, Rebublic of Belarus; [2]Institute of Bioorganic Chemistry, PUSHTCHINO, Russian Federation

Epigenetic (nonmutational) changes in the promoter region of multiple genes are very important in leukemia triggering and development including chronic myeloid leukemia (CML). To further characterize this event, the methylation status of the 5'-promoter region of multidrug-resistance (MDR-1) gene and calcitonin (CT) gene in CML patients was investigated. Totally 26 DNA samples obtained from mononuclear cells of peripheral blood and bone marrow of 18 CML patients were investigated. Ten patients were in chronic phase of the disease, 5 - in accelerated stage and 3 - in blast crisis. As a control we used genomic DNA obtained from 10 healthy donors. We applied methyl-dependent polymerase chain reaction (PCR) method, investigating the intensity of CpG-sites methylation of both genes in the 5'-promoter area. The methylsensitive (HpaII) and methyl insensitive (MspI) restriction endonucleases were used for the digestion of DNA-samples. The products of the PCR were scanned directly in agarose gel. According to the data of the experiments, the intensity of the MDR-1 gene methylation progressively decreased from stage to stage of CML. Conversely, the methylation level of 5'-CT-gene became higher. The CT/MDR-1 optical density ratio was used for the semiquantitative analysis. We revealed a sustained increase of this index during the disease progression. The mean donor (normal volunteers) index was 0.44±0.14, whereas the similar figures in CML were 0.82±0.21 in chronic phase; 1.35±0.17 in accelerated phase and 2.19±0.4 in blast crisis. It is interesting to notice, that this index was higher in patients (in chronic phase), who received imatinib, compare to those, who was under conventional (hydrea) therapy. It is well known, that DNA-methylation often reversely correlates with gene expression. Thus, the revealed hypomethylation state of 5'-region of the MDR-1 gene suggests that the progression of CML is likely accompanied by acquisition of multidrug-resistance phenotype. CT-gene hypermethylation, as it was stated earlier, strongly correlates with the loss of expression of tumor suppressor genes. Both components are crucial in the illness progression. These findings might be useful in the disease monitoring and also serve as a marker of treatment efficacy in CML.

IDENTIFICATION OF NEW PROTEINS INVOLVED IN THE PATHOGENESIS OF THE ANTIPHOSPHOLIPID SYNDROME BY PROTEOMIC ANALYSIS: EFFECTS OF *IN VIVO* STATINS TREATMENT

C. Lopez-Pedrera,[1] M.J. Cuadrado,[2] V.H. Hernandez,[1] M.A. Khamashta,[2] P. Buendia,[1] M.A. Aguirre,[1] N. Barbarroja,[1] L.A. Torres,[1] F. Velasco[1]

[1]Reina Sofia Hospital, CORDOBA, Spain; [2]St Thomas Hospital, LONDON, United Kingdom

Background. Antiphospholipid syndrome (APS) is an autoimmune disease manifested by thrombotic or obstetrical events in the presence of antiphospholipid antibodies (aPL). In spite of the recent progresses, many aspects of this disease remain unclear, such as the molecular mechanisms leading to thrombosis. In addition to its anti-inflammatory and immunomodulatory properties, statins have been shown antithrombotic effects, although the molecular mechanisms leading to this effect are not yet fully understood. This study analyzed, by using proteomic techniques: a) changes in proteins expression of monocytes from APS patients related to the pathophysiology of the syndrome; and b) the *in vivo* effects of Fluvastatin on the pattern of protein expression in this cellular setting. *Patients and Methods.* Proteomic analyses were performed in 25 APS patients. Control groups included: 10 patients with aPL antibodies but without previous thrombosis, 10 patients with previous thrombosis but without aPL antibodies, and 10 healthy donors. Ten patients with APS and previous history of thrombosis further received Fluvastatin (20 mg/day) for one month. Blood samples were obtained before treatment and after one and three months of treatment. All patients were tested for the presence of anti-cardiolipin autoantibodies and lupus anticoagulant. Monocytes were isolated from peripheral blood mononuclear cells by magnetic depletion of non-monocytes. Proteomic analyses were performed using two-dimensional electrophoresis and MALDI-TOF mass fingerprinting analysis. *Results.* Approximately 500 protein spots were detected on the comassie-stained gels from the donors' material. Proteins identified as more significantly altered between monocytes from APS patients and controls' donors belonged to the group of signal transduction mediators (i.e. lipocortin I, Annexin II, Rho A proteins, Ubiquitin conjugating enzyme, zinc finger proteins), metabolic enzymes (i.e. α-enolase, ATP-synthase) and immunomudulators (i.e. Hsp60, disulfide isomerase). Some of these differentially expressed proteins (such as annexin II, Rho A proteins and Hsp60) have previously been shown to play a relevant role in the pathogenesis of the APS. *in vivo* statins treatment for one month reversed the changes observed in the expression levels of those proteins. These levels then suffered a slowly return, although remained significantly changed in relation to control values after three months of the end of the treatment. To confirm the results, more specific analytical techniques, such as real time RT-PCR and Western blot were used. Moreover, to assess the effect of aPL on monocyte proteomics, monocytes from normal individuals were treated with affinity purified patients' IgG, in the presence or in the absence of fluvastatin. All those studies further supported the data presented. *Conclusions.*Our study has identified, by proteomic analysis, for the first time: 1) some proteins that may be involved in the pathogenic mechanisms of the APS syndrome; and 2) the changes that protein patterns of monocytes from APS patients suffered when statins treatment was used for 1 month. These findings might provide new targets for rational pathogenesis-based therapies of APS.

EVALUATION OF MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA) TO DETECT GENOMIC DELETIONS IN CHRONIC LYMPHATIC LEUKEMIA A COMPARISON WITH CYTOGENETICS, FISH AND PCR

P. Irnstorfer,[1] R. Marschon,[1] S. Heuritsch,[1], K. Enzenhofer,[2]
S. Hochreiter,[2] G. Webersinke[1]

[1]Krankenhaus der Barmh. Schwestern, LINZ, Austria, [2]Institut für Bioinformatik JKU Linz, LINZ, Austria

Background. MLPA is a new method to detect losses or gains of genes or gene fragments. CLL ist the most common leukemia in the western world. Genetic variances, like deletions, are important prognostic factors in this form of leukemia. *Aims.*Was to test the clinical applicability of MLPA in CLL-cases in comparison with established standards for risk evaluation like cytogenetics and FISH. *Methods.* Peripheral blood and bone marrow samples were collected from 70 CLL patients at various stages of disease, 22 healthy persons and a human B cell lymphoma cell line (DOHH-2) showing characteristic chromosomal aberrations as a control. If possible, karyotyping by GTG banding was performed. The samples were checked for CLL typical chromosomal aberrations with a FISH panel containing probes for 11q, 13q, 17p and CEP12. For MLPA, 20-500 ng of genomic DNA were used. After hybridisation of the probes to their target sequences, a ligation reaction was carried out. The ligation products were amplified by PCR. The CLL optimised MLPA-Kit contains probes for the detection of del(11q) (ATM), del(17p) (TP53), Trisomy 12, Trisomy 19, del(13q), amplification of 2p24 (MYCN), and 6q rearrangements. 1 μL of the PCR product was analysed on an ABI3130 Genetic Analyzer and evaluated with the SeqPilot v1.3.1 program. In cooperation with the Institute for Bioinformatik of the Johannes Kepler University of Linz a Feature Selection Analyse with the P-SVM (Potential Support Vector Machine) program was performed to detect markers predicting CLL. For this, the raw data from the ABI 3130 was converted into Excel files and analysed with this program. *Results*. The relative peak area (RPA) represents difference of the peak area of the patient file and the median of the peak area of 19 control data. All RPA data below 75% were scored as deleted, whereas all data over 125% were scored as amplified. The present MLPA data generated by the SeqPilot Program show significant correlation to FISH results and karyotyping. Furthermore we have tested the sensitivity for detecting aberrations in cell mosaics because this is a common observation in CLL. At least 30 percent mosaicism is well detectable in cell dilution experiments with the DOHH-2 cellline; the limited sensitivity has to be considered in the clinical setting. The (P-SVM) feature selection analyses showed that MYC (localised on chromosome 8) was the best marker to predict CLL in samples of unknown origin, 49 of the 70 analysed CLL patient samples are predicted right (70%). 20 of the 22 control samples were predicted as negative (91%). *Summary and Conclusions.* This study shows that MLPA may be a helpful tool for the assessment of losses or gains of gene fragments in CLL, although a solitary application of this method in routine diagnostic is not practical at the moment. The result of the P-SVM shows that MYC may be an interesting marker in the diagnosis of CLL.

HEMOCHROMATOSIS GENOTYPES AND RISK OF 31 DISEASE ENDPOINTS - META-ANALYSES INCLUDING 66,000 CASES AND 226,000 CONTROLS

C. Ellervik,[1] H. Birgens,[1] A. Tybjærg-Hansen,[2] B.G. Nordestgaard[1]

[1]Herlev Hospital,University of Copenhagen, HERLEV; [2]Rigshospitalet, University of Copenhagen, COPENHAGEN, Denmark

Background. Hemochromatosis genotypes have been associated with liver disease, diabetes mellitus, heart disease, arthritis, porphyria cutanea tarda, stroke, neurodegenerative disorders, cancer, and venous disease, but studies have reported conflicting results. *Aims.* We examined associations between hemochromatosis genotypes C282Y/C282Y, C282Y/H63D, C282Y/wild type, H63D/H63D, H63D/wild type vs. wild type/wild type and 31 disease endpoints. *Methods.* Meta-analyses including 202 studies with 66,263 cases and 226,515 controls were conducted. Potential sources of heterogeneity were explored. *Results.* For liver disease, the odds ratio for C282Y/C282Y vs. wild type/wild type was 3.9(99% CI: 1.9-8.1) overall, 11(3.7-34) for hepatocellular carcinoma, 4.1(1.2-14) for hepatitis C, and 10(2.1-53) for nonalcoholic steatohepatitis. For porphyria cutanea tarda, the odd ratios were 48(24-95) for C282Y/C282Y, 8.1(3.9-17) for C282Y/H63D, 3.6(1.8-7.3) for C282Y/wild type, 3.0(1.6-5.6) for H63D/H63D, and 1.7(1.0-3.1) for H63D/wild type vs. wild type/wild type. Finally, for amyotrophic lateral sclerosis the odds ratio was 3.9(1.2-13) for H63D/H63D vs. wild type/wild type. These findings were consistent across individual studies. *Conclusions.* In aggregate, C282Y/C282Y associated with liver disease, all 5 hemochromatosis genotypes associated with porphyria cutanea tarda, while H63D/H63D associated with amyotrophic lateral sclerosis.

IDENTIFICATION OF HISTONES H2B AND H4 OVEREXPRESSION IN MANTLE CELL LYMPHOMA BY MASS SPECTROMETRY-BASED PROTEOMIC STUDY

D. Rolland,[1] A. Bouamrani,[1] A. Barbarat,[2] M. Arlotto,[1] F. Berger,[3]
P. Felman,[2] S. Brugière,[4] J. Garin,[4] R. Houlgatte,[5] F. Berger,[1]
C. Thieblemont[6]

[1]INSERM U836 (équipe 7), GRENOBLE, France; [2]Laboratoire d'hématologie, CHLS, LYON; [3]Laboratoire anatomo-pathologie, CHLS, LYON; [4]EMR-0201 INSERM/CEA, GRENOBLE; [5]INSERM U533, NANTES; [6]Hématologie, hôpital Saint Louis, PARIS, France

Background. Mantle cell lymphoma (MCL) is a non germinal centre small B-cell lymphoma that represents about 6-10% of all non-Hodgkin lymphomas (LNH). The MCL genetic hallmark is the chromosomal translocation t(11;14)(q13;q32) leading to the overexpression of cyclin D1 an important regulator of the G1 phase of the cell cycle. However, the cyclin D1 overexpression is not sufficient to induce MCL. Additional genetic alterations may occur in subsets of MCL. Most of these alterations appear to disturb the cell cycle machinery / interfere with the cellular response to DNA damage, thus making MCL a paradigm for cell cycle and DNA damage response deregulation in cancer in general. *Aims.* Our goal was to expand the current understanding of the molecular pathogenesis of MCL using proteomic strategy and to provide the basis for identification of biomarkers specific to MCL compared to other small B-cell lymphomas. *Methods.* Using Surface Enhanced Laser Desorption/Ionization - Time of Flight (SELDI-TOF) technology the MCL proteome was compared to the proteome of 2 other non germinal centre small B-cell lymphomas, the small lymphocytic lymphoma (SLL) and the marginal zone lymphoma (MZL). Whole cell lysates obtained from 18 MCL (17 nodes and 1 spleen), 20 SLL (20 nodes), 20 MZL (1 node and 19 spleens) fresh frozen biopsies and 7 traumatic normal spleens were applied on two different ProteinChip array surfaces (CM10 and Q10) that were bombarded by 4 different laser intensities. All spectra were aligned and peak intensities were normalized to the total ion current (M/Z<50,000 Da) after baseline subtraction. All protein peaks detected were analyzed at the same time with Eisen's hierarchical clus-

tering software to identify specific proteomic signatures. SELDI-TOF-assisted purification followed by in gel trypsin digestion and LC-MS/MS peptides identification was used to identify proteins overexpressed in MCL tumors. *Results.* The combination of all data obtained with the two different ProteinChip generated 1300 analyzable protein peaks. The protein patterns were first analyzed using hierarchical clustering in an unsupervised fashion revealing a very homogenous protein pattern among all lymphoma samples. The second analysis using hierarchical clustering in a supervised method (discriminating score) pointed out tissue specific protein signatures (node and spleen). Those tissue signatures were subtracted from the data and specific protein signatures for SLL, MZL and MCL were found based on the expression level of 34 protein peaks. SELDI-TOF-assisted purification was used to optimize protein purification before in gel digestion and LC-MS/MS identification. We identified two core histones as overexpressed proteins in MCL tumor biopsies: histone H2B and histone H4. *Conclusions.* The proteomic profiling of MCL tumor biopsies using SELDI-TOF technology leads to the characterization of a specific MCL protein signature. Among proteins overexpressed in MCL, we identified histones H2B and H4. The overexpression of these two core histones in MCL was concordant with the cell cycle deregulation previously reported in this lymphoma entity.

0167

HIGH FREQUENCY OF MICROSATELLITE INSTABILITY IN LYMPHOID TUMOUR CELL LINES

A. Siebert,[1] C. Mielke,[2] S. Fähnrich,[1] Y. Merkhoffer,[1] H.G. Drexler,[1] W.G. Dirks1

[1]DSMZ, BRAUNSCHWEIG; [2]Heinrich-Heine-University, DÜSSELDORF, Germany

Background. The mismatch repair (MMR) system is specialized in removing replication errors which are thought to be recognized by the heterodimers MutSα (MSH2 and MSH6) and MutSβ (MSH2 and MSH3). Defective MMR can be detected via microsatellite instability (MSI) and causes diseases like HNPCC. *Aims.* With our studies we wanted to gain insights in the frequency of MSI in tumour cell lines from different tissues and in the contribution of defective expression of MSH2, MSH3 and MSH6 to the MSI phenomenon. *Methods.* Fluorescence PCR in combination with capillary electrophoresis was used to analyse 500 human tumour cell lines for length shortening of BAT26, a marker for MSI detection. MSI cell lines were further investigated for presence of transcripts and proteins of MSH2, MSH3 and MSH6 by RT-PCR and western blot analysis, respectively. cDNAs of MSH2, MSH3 and MSH6 were inserted into a bicistronic vector allowing expression of each protein fused to EGFP for localization studies by fluorescence microscopy. *Results.* MSI was proven in 8% (41/500) of tumour cell lines. The relative amount of MSI cell lines among cell lines of special tumour groups was significantly highest in T-cell leukaemia (59%) and ovarian adenocarcinoma (50%), followed by colon adenocarcinoma (25%) and B-cell leukaemia cell lines (24%). Further investigation revealed presence of full-length transcripts for MMR genes in 81% of MSI cell lines, while only 51% expressed the corresponding proteins. In addition to MSH2, MSH3 and MSH6 full-length transcripts seven alternatively spliced variants were obtained from MMR proficient cell lines. Cloning and stable expression of EGFP fusion proteins with the wildtype transcripts of MSH2, MSH3 and MSH6 and their variants showed that only MSH2 WT, MSH3-WT, MSH3-V3, MSH3-V5, MSH6-WT and MSH6 V1 fusion proteins are restricted to the nucleus, whereas expressed MSH2 V1, MSH6-V2 and MSH6-V3 are mainly localized in the cytoplasm and MSH3-V4 fusion protein is distributed all over the cell. For functional characterization we set a UV-A beam to a defined area of the nucleus and live imaging revealed an accumulation of MSH2-WT and MSH6-V1 fusion proteins but not MSH3-WT fusion protein at the site of the UV-A damage. *Summary and Conclusions.* The MSI phenomenon could be shown in an unexpected high number of T- and B-cell leukaemia cell lines. Genomic deletions or epigenetic silencing of MSH2, MSH3 and MSH6 genes are not the predominant mechanisms responsible for absence of MMR activity, indicating that loss of function mutations may play a bigger role. 10 wildtype and variant transcripts for MSH2, MSH3 and MSH6 demonstrated diverse localization properties upon heterologous expression, suggesting additional functions or regulatory mechanisms. MutSα but not MutSβ seems to be involved in DNA repair after UV-A damage.

0168

METALLOPROTEINASE POLYMORPHISMS IN PH-NEGATIVE CHRONIC MIELOPROLIFERATIVE DISORDERS: NEW GENETIC FACTORS?

M.L. Biondi,[1] G.V. Melzi d'Eril,[2] F. Pateri,[1] L. Ferri,[1] M. Erario,[1] G. Fontana,[2] N.N. Fantini,[2] G.C. Gerli[2]

[1]Laboratorio Chimica-Clinica e Microbiolo, MILAN; [2]Università degli Studi, MILANO, Italy

Background. Philadelphia-negative chronic myeloproliferative disorders (MPDs) are characterized by clonal proliferation of haematopoietic progenitor cells in the bone marrow and by different degrees of extramedullary haematopoiesis, which is associated with increased $CD34^+$ circulating cells. The transient mobilization of haematopoietic stem cells and progenitor cells has been attributed to the induction of a highly proteolytic environment within the bone marrow. Matrix metalloproteinases (MMPs) are central factors in the control of extracellular matrix turnover and have been implicated in connective tissue destruction and remodelling associated with cancer invasion and metastasis. A common insertion polymorphism (an additional guanidine) in the nucleotide sequence of the MMP-1 gene promoter has been reported. The 2G homozygotes show an increased transcription activity compared to 1G homozygotes ad controls. On the promoter of the MMP-3 gene has been described a polymorphism that *in vitro* assays demonstrate that the promoter activity of the 5A allele had 2-fold higher promoter activity than the 6A allele. *Aims.* We investigated whether the MMP-1 and/or the MMP-3 promoters polymorphisms are associated with susceptibility and/or progression of MPDs. *Methods*. 46 patients: 21 with Polycythemia Vera (PV); 18 with Essential Thrombocythemia (ET) and 7 with Idiopathic Myelofibrosis (cIMF) and 133 healthy controls were genotyped for the two polymorphisms. Genotypes were determined with PCR-RFLP methods. Results MMP-1 genotype was statistically different between patients and controls (patients vs controls ;1G/1G vs 1G/2G+2G/2G 6% vs 26%; OR 4.78; CI% 1.35-25.22; p=0.007); for MMP3 the 5A/5A genotype was less represented (13% vs 27%; OR 2.59: CI% 0.97-8.07; p=0.04)).No correlation was observed with spleen size, $CD34^+$ percentage, and JAK2-V617F mutation. *Conclusions.* Our data suggest a role of MMP1 and MMP3 in the matrix remodeling associated with CMD. However, no firm conclusion regarding the clinical significance of these Metalloproteinase promoter polymorphisms can be drawn until much larger cohorts have been analysed.

0169

NEW DATA ON ROBUSTNESS OF GENE EXPRESSION SIGNATURES IN LEUKEMIA: COMPARISON OF THREE DISTINCT TOTAL RNA PREPARATION PROCEDURES

M. Campo Dell'Orto,[1] A. Zangrando,[1] L. Trentin,[1] R. Li,[2] W. Liu,[2] G. Te Kronnie,[1] G. Basso,[1] A. Kohlmann[2]

[1]University of Padua, PADUA, Italy, [2]Roche Molecular Systems, Inc., PLEASANTON, USA

Background. Gene expression microarrays had been used to classify known tumor types and various hematological malignancies enforcing the objective that microarray analysis could be introduced soon in the routine classification of cancer. However, there are still doubts about gene expression experiments performance in clinical laboratory diagnosis. For instance, the quality of starting material is a major concern in microarray technology and there are no data on the variation in gene expression profiles ensuing from different RNA extraction procedures. *Aims.* Here, as part of the internal multicenter MILE Study program, we want to assess the impact of different RNA preparation procedures on gene expression data, analyzing 27 patients representative of nine different subtypes of pediatric acute leukemias. We compared the three currently most used protocols to isolate RNA for routine diagnosis and microarray experiments. *Methods.* The methods are named as method A: lysis of mononuclear leukemia cells, followed by lysate homogeniziation, followed by total RNA isolation; method B: TRIzol RNA isolation, and method C: TRIzol RNA isolation followed by total RNA purification step. The methods were analyzed in triplicates for each sample (24) and additional three samples were performed in technical replicates of three data sets for each preparation (HG-U133 Plus 2.0). *Results.* Method A results in better total RNA quality as demonstrated by 3'/5' GAPD ratios and by RNA degradation plots. High comparability of gene expression data is found between samples in the same leukemia subclasses and collected with different RNA preparation methods thus demonstrating that sample preparation procedures do not impair the overall signal distribution. Unsupervised analyses showed clustering of samples first by

each patient's replicate conditions, then by leukemia type, and finally by leukemia lineage. In fact, B-ALL samples are clustered together, separately from T-ALL and AML, demonstrating that clustering reflects biological differences between leukemias and that the RNA isolation method is a secondary effect. Also, supervised cluster analyses highlight that samples are grouped depending on intra-lineage features (i.e. chromosomal aberrations) thus confirming the clustering organizations as reported in recent gene expression profiling studies of acute leukemias. Our study shows that biological features of pediatric acute leukemia classes largely exceed the variations between different total RNA sample preparation protocols. However, technical replicates analyses reveal that gene expression data from method A have the lowest degree of variation, are more reproducible and more precise as compared to the other two methods. Furthermore, compared to methods B and C, method A produces more differentially expressed probe sets between distinct leukemia classes and is therefore considered the more robust RNA isolation procedure for gene expression experiments using high-density microarray technology. *Conclusions.* We therefore conclude that method A (initial homogenization of the leukemia cell lysate followed by total RNA isolation) combined with a standardized microarray analysis protocol is highly reproducible and contributes to robustness of gene expression data and that this procedure is most practical for a routine laboratory use.

0170

GENOMIC IMBALANCE PROFILES IN MAJOR SUBSETS OF B-NHL: A DESCRIPTIVE META-ANALYSIS OF 1831 PUBLISHED CASES ANALYZED BY CGH

M. Baudis

RWTH Aachen University, AACHEN, Germany

Background. In the search for disease specific genomic imbalance patterns and genomic aberration hot spots, Comparative Genomic Hybridization (CGH) has been applied to virtually all types of malignant neoplasias. Since single publications of genomic screening data can only describe a limited set of cases, for statistically meaningful comparisons of several entities data has to be derived from large-scale data collections. *Aims.* This study compares overall aberration profiles in different subsets of B-cell non-Hodgkin's lymphomas (NHL), with the aim to identify disease-specific aberration hot spots and imbalance patterns. This data will be useful when evaluating presumptive oncogenetic targets, as well as for diagnostic marker identification. *Methods.* For the Progenetix molecular-cytogenetic database, genomic aberration data from currently 15810 cases has been collected, including approximately 50% of all published chromosomal CGH data. For the application of data mining methods, the ISCN related karyotype annotations of all cases were converted to a band specific data matrix. From this collection, 1831 B-NHL analyzed by CGH were selcted for subset specific analysis. *Results.* B-NHL cases were assigned to clinico-pathological subsets: DLBCL (695 cases), CLL (549), MCL (217), FCL (175), marginal zone lymphoma (MZL and SMZL, 93 cases), Burkitt lymphoma (66) and PMBCL (26).

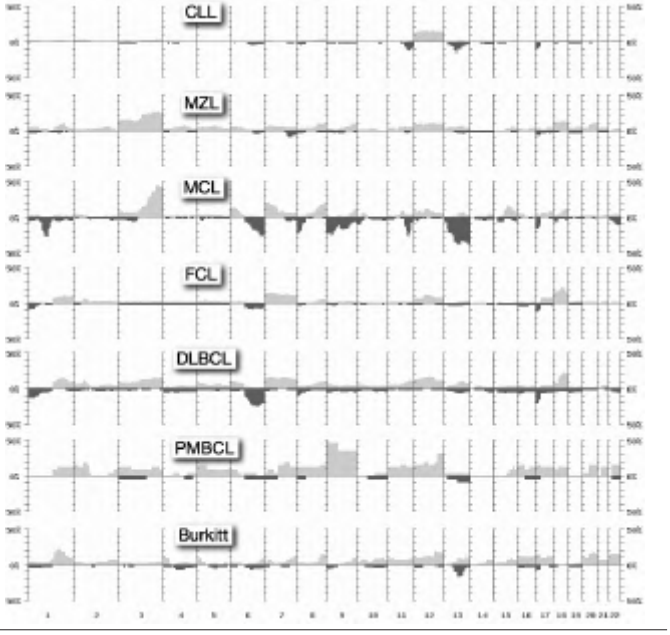

Figure 1. CGH in B-NHL: genomic gains (up) and losses (down).

For all subsets, imbalance profiles were generated, capturing the band-specific frequencies of genomic gains and losses. As an approximation for chromosomal instability, the median number of aberrant chromosomes was derived, ranging from 1 (CLL, FCL, MZL) to 5 (MCL). Average imbalance profiles showed remarkable differences between different diagnostic groups in frequency and distribution. Frequent gain hot spots were found on 3q26q27 (MCL and MZL), 9p (only in PMBCL), 1q (BL, DLBCL, PMBCL, FCL), 12q (several), 7 (MCL, FCL, DLBCL, PMBCL) and 18q21 (most in FCL, DLBCL). Frequent losses were found on 6q25q27 (MCL) and 6q16q21 (DLBCL), 13q (most in MCL, BL, CLL) as well as on 1p, 8p, 9, and 11q in MCL (Figure 1). *Summary*. Genomic imbalance patterns in B-NHL entities are disease-specific and may reflect varying pathogenetic mechanisms. With the possible exception of 9p gains in PMBCL, regional hot spots occur in several entities, but with varying frequencies and in different combinations. This meta-analysis supports the existence of separate regions *targeted* by lossen on 6q in FCL/DLBCL (6q16q21) and MCL (6q25q27). Of all entities, DLBCL case show the largest variation in individual imbalance patterns.

0171

EVI1 OVEREXPRESSION IN A SERIE OF 212 HEMATOLOGICAL MALIGNANCIES

H. Luzardo,[1] M.T. Gomez-Casares,[1] J.D. Gonzalez-San Miguel,[2] J. Lopez-Brito,[1] J.M. Calvo-Villas,[3] A. Molines,[4] S. De La Iglesia,[1] A. Caballero,[1] C.E. Lopez-Jorge,[1] G. Santana,[1] A. Suarez,[1] T. Molero[1]

[1]Hospital u. de Gran Canaria Dr. Negrin, LAS PALMAS DE G.C.; [2]Hospital u. Insular de Gran Canaria, LAS PALMAS DE G.C.; [3]Hospital General De Lanzarote, ARRECIFE; [4]Hospital Materno Infantil De G.C., LAS PALMAS DE G.C., Spain

Background. The ecotropic viral integration site 1 (EVI1), located in chromosome 3q26, has been recognized in the last years as one of the most aggressive oncogenes associated to human leukemias. The inappropiate expression of EVI1 in hematopoietic cells has been implicated in the development or progress of myeloid disorders. Previous studies, applying microarray technology, indicate that high levels of EVI1 expression are detected in 10% of patients with AML .The correlation between overexpression of EVI1 in bone marrow and poor outcome in AML and MDS is a frecuent issue of discussion in the literature. *Aims.* To analyze the incidence of EVI1 expression in haematological malignancies and its value as prognostic factor. *Methods.* The study was performed restrospectively on a total of 212 patients (118 male/94 female, age range 1-92) 122AML, 23 MDS, 38 CML and 29 ALL. Also 7 healthy volunteers were studied. Expression of EVI1 gene (EVI1+) was examined in bone marrow samples and/or peripheral blood at diagnosis and during follow-up by RT-PCR .Survival curves in the cases of AML, LLA and MDS patients were plotted following the Kaplan Meier method and differences between the curves were analysed with the Log Rank test and Breslow test. *Results.* Of the 212 patients 53 overexpressed EVI1.The relation of EVI1+ in the different pathology groups was: 27/113 (23, 8%) AML (FAB subtypes: 2M0, 1 M1,3 M2, 6 M4, 7 M5, 1 M6, 4 AML 2ªMDS,3 unclassificated); 14/55 (25,4%) CML; 8/25(32%) MDS (1 RA; 1CRDM; 1 CRDM-SA; 3AREBI; 2 AREBII) and 4/29(13, 8%)LLA(2 ALL-B, 1 ALL-T and 1 ALL-Phi +). Survival curves in the different pathology groups didn´t show any significant differences in overall survival and disease free survival when comparing EVI1+ to EVI1- population. When survival curves were analyzed in the AML group with age range >14 to <60 all treated with similar chemotherapy schemes, no significant difference was observed. However, in ALL patients with the same age range , and a small samples size, a shorter survival was observed in the EVI-1+ group. *Conclusions.* 1) Although the higher expression of EVI1 gene was clearly associated with myeloid malignancies, is not restricted to this group. It is note worthy that 13, 8% of EVI1 overexpression in the LLA patients group was observed.2) In AML samples a greater than expected incidence of overexpression of EVI1 was observed (22,8% vs 11% previosly described), without a statistically significant prognosis.3) EVI1 overexpression could have a marked relevance in the development and progression of hematological malignancies but probably without a clear implication in the outcome (prognostic) of the illness.

0172

SNP ARRAY PROFILING OF FOLLICULAR LYMPHOMA REVEALS NOVEL REGIONS OF ACQUIRED UPD

D. O'Shea,[1] S. Iqbal,[2] E. Carlotti,[2] A. Davies,[2] T. Chaplin,[2] J. Matthews,[2] M. Manoj,[2] A. Norton,[3] J. Fitzgibbon,[2] T.A. Lister,[2] B.D. Young[2]

[1]CRUK, LONDON; [2]CRUK Medical Oncology, LONDON; [3]Barts and the London School of Medicine, LONDON, United Kingdom

Background. The use of Single Nucleotide Polymorphism (SNP) array profiling has uncovered extensive regions of acquired uniparental disomy (aUPD) in the cancer genome undetected using cytogenetics or array-CGH platforms. These usually arise by mitotic recombination and can render a cell homozygous for a pre-existing abnormality. *Methods.* SNP array analysis was performed using the Affymetrix 10K Gene-chip mapping array on DNA extracted from a series of Follicular Lymphoma (FL) lymph nodes biopsies from 52 patients, taken at time of diagnosis (n=20), progression (n=26) and transformation (n=34), and the t(14;18) positive lymphoma cell lines SCI-1, DoHH2 and RL 2261. Analysis was performed using the genome oriented laboratory file system (GOLF), a software package designed to interpret SNP data. In the absence of available germline DNA from the majority of these patients; an algorithm was devised to define significant regions of homozygosity. The criteria of > 96% homozygosity in at least 50 contiguous SNPs was found to detect no abnormalities in 23 normal remission bone marrows and was therefore adopted. *Results.* Abnormalities were detected in 63/80 patient specimens; these were non-random with recurring sites of aUPD on several chromosomes. In the patient samples aUPD was observed most frequently at 6p (n=12; 23%) and 12q (n=10; 19%); all 3 cell lines had aUPD 12q and aUPD 6p was seen in SCI-1. Additionally, loss of heterozygosity at 1p was seen in 7 patients (13%); this was copy neutral in 4/7 cases with reduced copy number in the other 3 cases. Rearrangements of the distal end of chromosome 1p have been described in >10% of cases of Non-Hodgkin's Lymphoma and in all 7 cases the overlapping region included 1p36 the location of the known tumour suppressor genes CHD5, ID3 and p73. Twelve out of 52 patients studied (23%) have either loss of the whole of chromosome 6 (n=2) or aUPD of chromosome 6p (n=10). This appears an early event in lymphomagenesis given that it was identified at disease presentation, progression and transformation. The sites of mitotic recombination cluster in a region immediately proximal to the MHC complex at 6p21-12 in 9/12 cases. Mutations in CCND3, CDKN1A, HLA-DQB1 and two translocation partners of BCL6; SRP20 and HIST1H4I, which are all located within or just distal of this cluster, were excluded by direct sequencing. Ten patients had aUPD of 12q, which ran from varying points on the long arm to the telomere in 9/10 cases; 1 case had an interstitial UPD of 17 Mb (95-112 Mb). *Conclusions.* This study highlights a high frequency of novel areas of aUPD in FL and the selective basis of aUPD at these locations in the pathogenesis of lymphoma continues to be investigated.

0173

INCREASED LEVEL OF B-CATENIN MRNA AND MUTATIONAL ALTERATIONS IN APC GENE ARE PRESENT IN ACUTE LEUKEMIA

F. Atalar,[1] M. Sayitoglu,[1] O. Hatirnaz,[2] Y. Erbilgin,[1] U. Ozbek[2]

[1]Istanbul University, DETAE Genetics Dept, ISTANBUL; [2]Istanbul University,DETAE Genetics Dept, ISTANBUL, Turkey

*Background.*WNT proteins initiate B-catenin-regulated canonical signaling cascade by binding to seven-transmembrane spanning receptors of the Frizzled (FZ) family,leading to phosphorylation of the disheveled protein forming a complex with the axin and APC (adenomatous polyposis coli) proteins that blocks the kinase activity of GSK3B. A functional APC protein is necessary for the proper regulation of the Wnt signaling pathway. Loss of APC expression interferes with the phosphorylation and degradation of B-catenin, allowing a B-catenin/TCF/LEF transcription factor complex to act in the nucleus, where it stimulates cell growth by targeting genes such as cyclin D1 and c-myc. *Aims.*Our aim was to determine the role of the WNT pathways in the development of acute leukemias. *Method*. We studied the gene expression levels of several components of WNT signaling pathway; WNT5A, WNT10B, FZ5, B-catenin, APC, TCF1 (T-cell factor), LEF1 (lymphoid enhancer factor) and their important targets c-MYC and CCND1 (cyclin D1), in 34 AML patient and 118 ALL patient (T-ALL, n=42, B-ALL, n=46 and preB-ALL, n=30) bone marrow and/or blood samples and normal hematopoietic cells by quantitative real time polymerase chain reaction. APC and B-catenin mutations were studied with dHPLC and sequencing methods. *Results.*Results were compared by peripheral blood samples from healthy donors by using Ct values. WNT5A, WNT10B, FZ5, B-catenin and LEF-1 showed high level of mRNA in B-ALL patients. APC expression levels in pre B-ALL samples were higher than B-ALL (p>0.001) and T-ALL (p>0.001). LEF-1 expression was found to be increased in B-cell and in preB-ALL samples and significantly different in T-ALL patients (p=0.01). Highest level of TCF-1 mRNA was observed in the T-ALL patients. c-MYC expression levels were found to be increased both in preB-ALL(p=0.02) and T-ALL (p=0.02) patients. B-ALL patients did not significantly express c-MYC gene compared to normal hematopoietic controls (p=0.3). CCND1 mRNA level was observed to be slightly increased in preB-ALL (p=0.04) but not in T-ALL and B-ALL groups . In AML FZ5 gene expression (10 fold) and LEF1gene expression (3 fold) showed a significant increase when compared to controls (p>0.01 and p=0.02 respectively). B -catenin was 5 fold higher in AML patients than normal peripheral blood samples. The WNT10b expression was slightly lower comparing to other genes. TCF1 expression level also seemed to be higher in AML patients (p=0.06). c-MYC gene expression in AML patients showed five fold increase compare to CCND1 gene expression (p>0.001). The decreased APC mRNA levels led us to investigate APC and B-catenin mutations with dHPLC and sequencing methods. Sequential alterations in APC gene were determined in 65% of AML patients and 47% of ALL patients. B-catenin mutation was detected in one ALL patients and no mutation was observed in AML patients. *Summary.*These results provide the evidence of WNT signal activation existing in acute leukemia patients and the different functions of WNT signaling through TCF/LEF between acute lymphoid and myeloid leukemias. We also believe that APC function could be the key to the pathogenesis of acute leukemias therefore we are currently studying its methylation status in our patient group .

0174

RELATION BETWEEN LOW PML-RARα LEVELS, FLT3-ITD, OVEREXPRESSION OF CXCR4 GENE AND UNFAVORABLE PROGNOSIS IN ACUTE PROMYELOCYTIC LEUKEMIA

M.C. Chillón,[1] C. Fernández,[1] C. Santamaría,[1] R. García-Sanz,[1] A. Balanzategui,[1] P. Martín-Jiménez,[1] A. Armellini,[1] M. Alcoceba,[1] M.E. Sarasquete,[1] M. Vargas,[1] F. Ramos,[1] L. Guerras,[2] M. González,[1] J.F. Jesús Fernando[1]

[1]Hospital Universitario de Salamanca, SALAMANCA; [2]Hospital Clínico de Valladolid, VALLADOLID, Spain

Background. The quantification of PML-RARα fusion transcripts have become an important part of the routine clinical practice. Moreover, there is an increasing interest in gene expression analyses for identifying different subclasses of AML. However, few clinical studies have been carried out in this way, and there are discrepancies concerning their prognostic significance. *Aims.* 1) To determine the correlation of PML-RARα levels, FLT3 mutations and gene expression patterns with pre-treatment characteristics of 141 newly diagnosed APL patients. 2) To evaluate the prognostic significance of these alterations to identify subsets of patients at increased risk of relapse. Methods. Real-time quantitative RQ-PCR (TaqMan technology) was used. The normalized copy number (NCN) of fusion gene was reported as: number of PML-RARα copies per 1×10^4 ABL copies. Genes encoding multi drug resistance proteins (MDR1 and MRP1), the chemokine receptor CXCR4, the tyrosine kinase receptor FLT3 and growth factors upregulated in APL (HGF and FGF13) were studied. *Results.* 84 (59.6%), 5 (3.5%) and 52 (36.9%) patients showed the bcr1, bcr2 and bcr3 PML-RARα isoforms, respectively. The median NCN was 4100 with a wide range of expression (1100-35000). The low levels of transcripts (NCN<3500) were significantly associated with adverse features at diagnosis: higher WBC counts (26 vs 6×10^9/L, $p<0.0001$), higher blast cells percentage in bone marrow (86 vs 79, $p=0.006$) and in peripheral blood (55 vs 35, $p=0.002$) and elevated LDH levels (971 vs 614, $p<0.0001$). Moreover, patients with NCN<3500 showed worse overall (OS, $p=0.05$) and disease free survival (SLE, $p=0.031$), with higher relapse risk (23% vs 8%, $p=0.025$). When the cut off was established in 2500 copies, OS and DFS of patients with NCN<2500 were even worse ($p=0.01$ and $p=0.006$, respectively). Moreover, the study of FLT3 status showed an increased incidence of ITDs in the group with NCN<3500 (42% vs 5.4%, $p=0.001$), being the size of the ITD longer in them ($p=0.004$). However, no differences in expression of the FLT3 gene were observed. Interestingly, FGF13 gene was underexpressed when NCN<3500 (0.76 vs 1.17, $p=0.027$), this finding was associated with worse OS in the global series ($p=0.034$). The high expression of the CXCR4 gene was also related with shorter DFS in the overall group ($p=0.031$), but it did not explain the bad prognosis of patients with NCN<3500. The rest of genes did not show significant differences. Moreover, immunophenotypical analyses were performed: expression of CD34 and CD117 was more frequent in patients with NCN<3500 although not significant (29.6% vs 15.1%, $p=0.124$, and 100% vs 87.5%, $p=0.083$, respectively). In adition, 70% of these patients did not express CD15 ($p=0.033$). Multivariate analysis indicated that poor DFS in the overall group was related to lower expression of PML-RARα ($p=0.005$) and higher expression of CXCR4 ($p=0.033$). *Conclusions.* Our data demonstrate the bad outcome of APL patients with low levels of fusion transcript, which could be explained by the presence of adverse clinical characteristics, FLT3 mutations and different gene expression patterns. Moreover, a relationship with a more immature phenotype was found, suggesting that these leukemias have a lower ability to produce transcripts.

Hodgkin Lymphoma

THE VALUE OF IMMUNOHISTOCHIMICAL EXPRESSION OF P53 AND K167 AND AGNOR IN HODGKIN'S LYMPHOMA

A. Al-khazraji,[1] F. Helmi[2]

[1]AJLOUN, Jordan; [2]Al Doha University, DOHA, Qatar

Introduction. P53 tumor suppressor gene functional inactivation is a key step in carcinogenesis or progression of many human malignancies. This is due to either gene mutations, binding and inactivation, or degradation by viral or cellular proteins. Ki67 is a monoclonal antibody that detects a nuclear antigen that is strictly associated with cell proliferation. Nucleolar Organizer Regions represents loops of DNA which have the genes for ribosomal RNA, together with a number of acidic protein that have a high affinity for silver. AgNOR is used for rapid identification of NORs in light microscope sections using a simple one-step silver technique. The AgNOR proteins are considered to be a marker both for rRNA transcriptional activity and/or the DNA transcription potential. *Aim of the study.* Evaluate the P53 & Ki67 and AgNOR in Hodgkin's lymphoma cells in relation to histological subtypes to determine their role in disease prognosis. *Material and Methods.* Sixty-five cases of Hodgkin's lymphoma were diagnosed, at the Dept. of Histopathology in Medical City Teaching Hospital-Baghdad, during the period between January 1990 to December 2001. Informations regarding the clinical features, including age and sex, also the site of lymph node biopsies and histological subtype were recovered from the routine histopathological files. Lymph node biopsies stained with H & E, P53, Ki67, and Ag NOR. *Results.* Cervical lymph nodes were the most common sites of involvement in this study (67.70%) followed by axillary lymph node and generalized lymphadenopathy (9.23% each). Gender distribution according to subtypes of Hodgkin's lymphoma studied. It showed a statistically significant difference ($p<0.01$). The mean ages showed significant statistical differences among the subtypes of Hodgkin's lymphoma. Positive P53 score show statistically significant difference from negative P53 score in relation with Hodgkin's lymphoma subtypes, while intensity of P53 staining reveals no statistically significant relationship with the histological subtypes of Hodgkin's lymphoma. The study of Ki67 stain positivity in relation to gender, age, and site of lymph node involvement show no statistical significance. Ki67 stain percentage differs according to Hodgkin's lymphoma subtype. LDHL subtype have the higher mean±SD followed by NSHL (we excluded one case of stage II), and MCHL for classical HL, while NLPHL have the lowest mean±SD for all subtypes. Mean number of dots of AgNOR staining according to Hodgkin's lymphoma subtypes, showing significant differences within Hodgkin's lymphoma subtypes. We found that there is a strong direct correlation between P53 scoring & Ki67 stain percentage and a strong direct correlation between AgNOR dot numbers & Ki67 stain percentage both at $p<0.05$. *Conclusions.* P53 and Ki67 immunohistochemistry are valuable parameters in the evaluation of clinical outcome of HL subtypes in that they can be used as prognostic markers in this particular tumor for Iraqi patients. P53 and Ki67 results are going side by side almost in all cases studied and thus can be regarded as analogous as well as mutual indicators of the final clinical outcome. Accordingly, each one of them can be used alone or alternatively they can be used together as prognostic factors in the context of HL. AgNOR as a prolifrative index gives figures similar to that of Ki67. Thus, AgNOR may substitute Ki67 as a prognostic factor, especially when one takes in consideration the new methods used for AgNOR counting. The latter has helped bringing the figures of both prolifrative indices (Ki67 and AgNOR) closer together.

0176

TREATMENT APPROACH OVERPOWERS IPI PROGNOSTIC SIGNIFICANCE IN HODGKIN'S DISEASE

S. Trpkovska Terzieva, A. Stojanovic, Z. Stojanovski, S. Trajkova, T. Sotirova, S. Genadieva-Stavric, A. Latifi, S. Stankovic, O. Karanfilski

University Clinical Center, SKOPJE, Macedonia

Our Department has been engaged in managing more than 500 HD patients over a 25-year period. We have studied the prognostic impact that disease onset manifestations, mostly included in the IPI scoring system, but also different treatment approaches, a parameter not evaluated by the IPI concept, have on the disease course and its outcome. Of a total of 473 HD evaluable patients, 119 were with clinical stages 1-2A,

and were analyzed regardless of the disease mass (bulk). Evaluable advanced stage patients, with clinical stages 2B-4, also irrespective of tumor mass size, were 348 of them. Multivariate statistical analyses show that of the seven IPI parameters, the scoring system backbone still retains its prognostic significance: Hb and Alb levels. Patient's gender, and a slightly modified range for age (<40 vs >50) and clinical stage (eqally 3B and 4) of the disease, also remain important factors. Selective statistics reveal that this importance is valid mostly due to factor's impact on advanced stages of HD, whereas the evidently better prognosis of early stage HD patients does not seem to be affected by these parameters. The values for the chi-square tests are 45.9023 and 24.5866 for 3 degrees of freedom (gender, Hb, Alb) for the whole population and the advanced disease subset respectively, and the p-values are highly significant (0.00000 and 0.00002), when the analysis is performed on standard IPI values. Modified values achieve even higher significance and incorporate more parameters. Historical and timely stratified analysis, reveals that the IPI concept is dominantly applicable to the patients treated in the MOPP-like era. Early stage patients are also incomparable, since by default their IPI consist of a maximum of only 6 prognostic factors. Patients treated in the ABVD-like period are not influenced by all of the IPI parameters. Realizing that onset manifestations did not have statistical influence on the outcome of early stage disease patients, we extended the analysis to the post-diagnostic period. Analyzing different types of treatment engaged through the historical observation period, as well as similar approaches, it is clearly evident that these patients benefit from treatment modalities containing the gold standard and the increasingly competitive newer chemotherapy regimen: ABVD and BEACOPP. Interestingly enough, and possibly due to the low number of entries, combined modality treatment did not show significant advantage over chemotherapy alone in these early stage patients. On the other hand, advanced stage disease course with a poor IPI could not be significantly altered by employing even more aggressive treatment approaches. Rough grouping of the standardly and contemporarily treated subsets, show an evident difference of 25-40% in overall survival ($p<0.001$). Both observations clearly imply that rapid diagnosis, diminishing the possibility of disease advancement, and utilization of aggressive treatment options in the first instance, speculating that the appreciated effect is mostly attributable to the potential of doxorubicin and very possibly etoposide, are the milestones on which the successful story of HD management has been created and installed.

0177

ADDING RADIOTHERAPY TO CHEMOTHERAPY DOES NOT IMPROVE OUTCOME OF PATIENTS WITH STAGE I-II HODGKINS LYMPHOMA: RESULTS OF A RETROSPECTIVE ANALYSIS OF A REGIONAL ITALIAN EXPERIENCE

F. Olcese,[1] M. Clavio,[1] E. Rossi,[2] M. Spriano,[2] M. Balocco,[1] F. Ballerini,[1] L. Canepa,[1] I. Pierri,1 S. Aquino,[1] R. Varaldo,[1] A. Manna,[3] V. Secondo,[4] P. Carrara,[4] O. Racchi,[5] E. Balleari,[6] S. Napoli,[7] A.M. Carella,[2] R. Ghio,[6] M. Gobbi[1]

[1]Clinica Ematologica Univ. Genova, GENOVA; [2]Division of Hematology, S. Martino H., GENOVA; [3]Oncology Dept., LA SPEZIA; [4]Dept. Int. medicine Galliera H., GENOVA; [5]Dept. Oncology Villa Scassi H, GENOVA; [6]Dept. Hematology S. Martino H., GENOVA; [7]Internal Medicine Sanremo H., SANREMO (IM), Italy

Background. Six-eight courses of ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine) represent the standard treatment for patients with advanced stage Hodgkin's Lymphoma (HL). Radiotherapy, on the other hand, forms the basis of conventional therapy for early stage HL patients. The observation of late risks of developing second tumours and coronary heart disease after radiotherapy has led to a reduced utilization of involved or extended field radiotherapy in the front line treatment. There is increasing evidence that early stage HL patients are likely to be cured by 3-6 courses of ABVD, with radiotherapy being utilized only on limited residual disease. *Methods and patients.* With the aim of comparing outcome of early stage HL patients treated with the association of chemotherapy and radiotherapy or with chemotherapy only, we retrospectively reviewed clinical features, therapy and long term outcome of 120 stage I-II HL patients diagnosed and followed in oncohaematologic divisions of Liguria (Italy) from 1995 to 2005. Fifty patients (41,7%) were treated with 3-6 courses of ABVD (CT group) and 70 patients (58,3%) were treated with chemotherapy (a median of 3 courses of ABVD or Stanford V regimen) plus involved field or extendend field-radiotherapy (CT+RT group). The two therapeutic groups were statistically comparable for median age (32 years and 31 years, for CT and CT+RT, respectively), male/female ratio, histology (nodular sclerosis in 80% and 84%; lymphocyte predominance in 12% and 9%, mixed cellularity in 8% and 7%, respectively), stage distribution (86% and 87% had stage II disease, respectively), B symptoms (42% and 38%) , bulky disease (18% and 16%). The two therapeutic groups had a different median follow up (38 and 77 months for CT and CT+RT groups, respectively). *Results.* In the CT group 44 patients achieved CR (88%) and 5 obtained PR (10%) after first line therapy. Two out of the 5 partial responders achieved CR after high dose therapy (HDT), so that 46 patients overall (96%) achieved CR. In the CT+RT group 69 patients achieved CR (98,6%) and 1 obtained CR after high dose therapy (HDT), so that the final CR rate was 100%. All relapses occurred in the first 48 months after the completion of therapy, 6 in the CT group (12%) and 8 in the CT+RT group (11,4%). At 48 months relapse free survivals are 88% and 89% in patients receiving chemotherapy only and in those treated with chemotherapy and radiotherapy, respectively. All patients of both groups are alive at 48 months. A second neoplasia has been diagnosed in 5/70 patients treated with chemotherapy and radiotherapy. *Conclusions.* The retrospective analysis of our series shows that in the vast majority of stage I-II HL patients long term control of disease may be achieved with a limited utilization of radiotherapy. The addition of radiotherapy might furthermore increase the risk of developing a second neoplasia.

0178

REFRACTORY AND RELAPSED HODGKINS LYMPHOMA: PRELIMINARY RESULTS OF THE BEACOPP REGIMEN

E. Cavalieri, A. Matturro, N. Frattarelli, S. Tempera, C. Petroni, R. Foà, A. Pulsoni

Hematology, La Sapienza University, ROME, Italy

Background. 25-30% of Hodgkin's lymphoma (HL) patients relapse or do not respond to first line chemotherapy. Durable responses after a second line treatment followed by peripheral blood stem cells transplantation (PBSCT) can be achieved in about 50%. Patients relapsing after PBSCT have a poor prognosis and a low probability of obtaining a subsequent durable complete remission (CR). A large and well-known experience demonstrates the efficacy of the BEACOPP regimen (doxorubicin, cyclophosphamide, etoposide, vincristine, bleomycin, procarbazine and prednisone) as first-line treatment for advaced stage HL, while no data are available for relapsed or refractory HL patients. *Aims.* To retrospectively evaluate the efficacy of the BEACOPP regimen in refractory or relapsed HL patients after first-line therapy or after PBSCT. Response rate, overall survival (OS), disease-free survival (DFS) and toxicity were analyzed. *Methods.* Eighteen HL patients, admitted between December 2005 and May 2006, were studied. Nine patients (group A) were refractory or relapsed after first-line therapies and 9 patients (group B) were refractory or relapsed after PBSCT. All patients received salvage chemotherapy with BEACOPP (4-8 cycles) at standard or escalated dose on the basis of previous treatment, medical history, disease status and the general conditions of patients. *Results.* Of the 9 group A patients, 7 were treated in first relapse and 2 were refractory to first-line treatment. Of these, 8 (89%) achieved CR, 1 patient was refractory and underwent salvage chemotherapy and PBSCT. After a median follow-up of 11 months, 7 patients (67%) are in continuous CR and 2 patients (22%) have relapsed after 18 and 11 months, respectively. One patient died in CR 12 months later due to acute leukaemia. Of the 9 patients treated after PBSCT (group B), 7 were treated after relapse and 2 were refractory. Eight patients (89%) achieved CR and 1 proved refractory: in this patient, a transformation into non-Hodgkin lymphoma (NHL) was demonstrated. After a median follow-up of 12 months (range 3-41 months), 5 patients (55%) are in CR, 3 patients have relapsed 1, 9 and 12 months off-therapy, respectively, and the patient with NHL died due to disease progression. OS and DFS are 88% and 60% for group A and 70% and 58% for group B, respectively. Summarizing, 16 of the 18 patients (89%) achieved a CR, while 2 resulted refractory. Considering the 16 responding patients, after a median follow-up of 11 months, 11 patients (68%) are in CCR, 3 patients (18%) have relapsed after 9, 12 and 18 months, respectively; 2 patients have died. OS and DFS are 80% and 60%, respectively. All patients had hematologic toxicity (WHO 3-4); one patient presented an aspergillary pneumonia during severe neutropenia and 1 patient suffered from an acute pericarditis. One patient had a congestive heart failure 10 months off-therapy. Two patients had an aseptic osteonecrosis caput femoris. *Conclusions.* Our retrospective study indicates that the BEACOPP regimen is efficacy also for relapsed and refractory HL patients, allowing to achieve a high CR rate (89%), although a longer follow-up is necessary. The BEACOPP regimen should be considered in these poor prognosis patients, especially after a PBSCT.

0179

ESHAP VS GIN AS SALVAGE AND MOBILIZING REGIMENS IN RELAPSED OR REFRACTORY HL

P. Tsirkinidis, T.P. Vassilakopoulos, M. Moschogiannis, Z. Galani, K. Anargyrou, S. Masouridis, F. Kontopidou, S. Sachanas, E. Dimitriadou, V. Kalotychou, C. Kalpadakis, A. Antoniadis, E. Prassas, D. Chasiotis, E. Variami, N.-A. Viniou, S. Kokoris, M. Siakantaris, Y. Rombos, G.A. Pangalis, M. Angelopoulou

University of Athens, ATHENS, Greece

Background. Patients with relapsed or refractory HL are treated with salvage chemotherapy and subsequent high dose therapy and autologous stem cell transplantation (HDT/ASCT). Salvage chemotherapy aims to disease debulking, testing of chemosensitivity , as well as mobilization of peripheral blood stem cells. Platinum-based regimens (DHAP, ESHAP, ICE) are frequently used for this purpose. However, the optimal salvage chemotherapy regimen is still not known. Recently the combination of gemcitabine, ifosphamide, vinorelbine and methylprednisolone (GIN) has been shown to be an effective salvage and mobilizing regimen in HL. *Aims.* To compare the efficacy of ESHAP (etoposide, methylprednisolone, high dose cytarabine and cis-platinum) vs GIN chemotherapy as 2nd line treatment for relapsed or refractory HL patients eligible for HDT/ASCT. *Methods.* Between 2001 and 2006 most patients scheduled for ASCT received ESHAP as first salvage (n=37), while GIN was introduced as first salvage during the last year (n=10). We retrospectively compared these two regimens regarding mobilization parameters, disease control (overall response rate) and a combined endpoint, including both successful mobilization and disease control prior to ASCT. *Results.* Patients' characteristics did not differ between ESHAP and GIN groups, except of bulky disease at relapse/progression, which was more frequent in the latter (3 vs 1 patient, p=0.047). GIN was more effective as a mobilizing regimen: peak circulating $CD34^+$ cell count was higher (median 206.2 vs 75.2, p=0.003), the number of total $CD34^+$ collected cells was higher (median 14.71×10^6/kg vs 4.32×10^6/kg, p=0.002), while all patients were successfully mobilized with GIN vs 90% in the ESHAP group. In addition, time to neutrophil engraftment following ASCT was faster with GIN (median 9 vs 10 days, p=0.02). The median time to apheresis was also shorter with GIN (12 vs 16 days, p<0.001). Response rates were similar with both regimens (60% vs 53% with GIN vs ESHAP, p=0.69). The combined endpoint of successful mobilization and disease control prior to ASCT was achieved in a similar percentage of patients with both regimens (60% vs 51%, p=0.63). *Conclusions.* GIN appears to be a more effective mobilizing regimen compared to ESHAP in relapsed/refractory HL. More patients are needed for a meaningful comparison of efficacy.

PROGNOSTIC ROLE OF MUM1/IRF4 IN CLASSICAL HODGKIN LYMPHOMA

S. Valsami,[1] V. Pappa,[1] D. Rontogianni,[2] F Kontsioti,[1] E. Papageorgiou,[1] J Dervenoulas,[1] T. Karmiris,[3] N. Harhalakis,[3] S. Papageorgiou,[1] P. Tsirigotis,[1] I Kaitsa,[1] N. Xiros,[1] E. Nikiforakis,[3] T. Economopoulos[1]

[1]2nd Dep. Internal Medicine,Attikon Hosp, ATHENS; [2]2Pathology Department, Evangelismos Hosp, ATHENS; [3]Department of Hematology, Evangelismos, ATHENS, Greece

Background. Although most cases of Classical Hodgkin lymphoma (CHL) are cured, a significant minority experiences refractoriness to treatment. The investigation of biological markers could ameliorate the predictive capacity of clinical staging systems. The aim of our study was the detection of MUM1/IRF4 expression in CHL and the correlation of its expression with different clinical characteristics and prognosis. *Methods.* Clinical data and biopsy samples from 107 patients with CHL diagnosed from 1992-2003 were enrolled in the study. 55 were males and 52 females. The median age at diagnosis was 37 years (range 13 to 79 years). Immunohistochemical staining was performed using the monoclonal antibody MUM1/IRF4 (clone MUM1p, DAKO, dilution 1:20) in paraffin embedded tissue. Fisher's-exact test, the Kaplan-Meier method, the Mann-Whitney test and the log-rank test were used for statistical analysis. Univariate and multivariate analyses were also performed. *Results.* A positive MUM1/IRF4 nuclear staining was observed in 96 cases (92.3%). H/RS cells showed moderate or strong nuclear positivity in the majority of positive cases (92.7%). MUM1/IRF4 expressing patients were less prompt to progressive disease (p<0.001), they had better time to disease progression (TTP) (p<0.001), and overall survival (OS) (p=0.03). No significant association was found between MUM1/IRF4 expression and the rest of clinical and laboratory characteristics of the patients. Univariate analysis for TTP revealed that lack of MUM1/IRF4 expression, age>45 and advanced stage (III/IV) disease were associated with significantly worse TTP (p<0.001, p=0.009, p=0.017 respectively). Univariate analysis for OS revealed that lack of MUM1/IRF4 expression, age >45, advanced stage (III/IV) disease, B symptoms and extralymphatic sites of involvement were associated with significantly worse OS (p=0.043, p=0.009, p=0.017, p=0.049, p=0.01 respectively). MUM1/IRF4 expression was an independent predictor factor for reduced TTP (p<0.001) on multivariate regression analyses. *Conclusions.* In conclusion our study has shown that MUM1/IRF4 is expressed in the majority of CHL cases and the lack of its expression in a minority of cases is associated with significantly shorter TTP and OS suggesting an association with a more aggressive clinical course. The above findings need to be confirmed in larger number of cases to demonstrate the prognostic role of this marker in CHL.

0181

CHOP21 FOR HODGKIN'S LYMPHOMA. AN EXPLORATORY EVALUATION IN COMPARISON TO ABVD AT A SINGLE INSTITUTION

J. Walewski,[1] J. Tajer,[1] E. Lampka,[1] E. Kraszewska,[2] W. Osiadacz,[1] J. Meder

[1]MSCM Institute and Cancer Centre, WARSZAWA; [2]Postgraduate Medical Education Centre, WARSZAWA, Poland

Background. ABVD remains a standard chemotherapy for Hodgkin's Lymphoma (HL) despite many efforts to prove a superiority of other regimens. Bleomycin was proven marginally active in this combination (J Clin Oncol 2004; 22:1532) but adding significant toxicity. Response to ABVD is often slow and relapse rate of 20-30% is a concern. ABVD has never been directly compared to CHOP, the other global standard for other lymphomas that is composed of agents certainly active in HL. *Aims.* Current study is an update on initial report of 2004 (Blood 2004; 104: Abstract 1311). *Methods.* In addition to extending the follow up, we compared outcome after CHOP in a pilot series of previously untreated patients with a retrospective results of ABVD therapy at our institution. *Results.* CR/CRu rates were 88% and 62% for CHOP and ABVD, respectively. In CHOP CS III-IV group, more patients had at least 3 risk factors (80%) than in ABVD CS III-IV group (40%). In contrast to ABVD, there were no deaths in CHOP group but EFS was inferior. This might result from a higher risk level in CHOP patients. A median follow up for CHOP and ABVD patients was 47 and 63 months. In a multivariate analysis of EFS the hazard ratio [95% C.I.] for CHOP vs. ABVD in CS I-II and CS III-IV patients was 2.4 [0.99, 5.8] (p=0.054) and 3.63 [1.14, 11.5] (p=0.029). Toxicity: grade 3/4 leukopenia in 9%, grade 1/2/3 peripheral neuropathy in 6% of ABVD pts., no grade 3/4 toxicity in CHOP pts. *Conclusions.* CHOP-21 is an active and low toxic regimen in HL with risk factors. A prospective comparison of CHOP with a standard chemotherapy in a randomized study will be justified.

0182

EXPRESSION OF ANGIOGENESIS RELATED FACTORS IN HODGKIN'S LYMPHOMA

F.H. Passam,[1] M. Kafousi,[2] M. Foteinou,[1] G. Tsirakis,[3] P. Roussou,[1] D.S. Kyriakou,[4] M.G Alexandrakis,[3] E. Stathopoulos[2]

[1]Sotiria Hospital, ATHENS; [2]Dept of Pathology, Medical School Crete, HERAKLION, [3]Dept of Hematology, Medical School Crete, HERAKLION; [4]University Hospital of Larisa, LARISA, Greece

Background. Angiogenesis is a prerequisite for solid tumour growth and dissemination but there is relatively few data related to its significance in Hodgkin lymphoma. *Aims*. The purpose of the study was to examine the immunohistochemical expression and distribution of angiogenic and proliferation markers in Hodgkin biopsies and their relationship to clinical parameters. *Materials and Methods.* Slides from paraffin embedded lymph nodes from 62 patients with Hodgkin lymphoma were obtained from the Pathology Departments of two tertiary hospitals. Immunohistochemical staining was performed on tissues after dewaxing and rehydration with Vascular Endothelial Growth Factor (VEGF) (Santa Cruz), Hypoxia Inducible Factor 1 α (HIF1a) (Santa Cruz), Platelet Derived Growth Factor Receptor alpha (PDGFRa) and MIB-1 (Neomarker). Alkaline phosphatase polymer was used for detection of all antibodies. CD31 staining was performed and the microvessel density (MVD) was defined by identifying three hot spots at 100X magnification and counting at 400X with a graded graticule corresponding to a 0,0625 mm^2 surface area. Appropriate negative and positive controls were used. In all cases neoplastic cells, reactive background cells and endothelial cells were evaluated. A case had a score of 0 when less than 10% of neoplastic cells reacted with the antibody, 1 for staining of 10-30% of cells, 2 for 30-50% and 3 when more than >50% of cells were stained. *Results*. Immunohistochemistry showed that VEGF was negative in the neoplastic population in 53% of cases whereas 30% of cases showed strong staining (score 3). The reactive population in the lymph node biopsy was positive in over 50% of cases. HIF1a was positive in the neoplastic compartment in 31% of cases whereas PDGFRa in 95% of cases. MIB-1 was positive in 70% of cases and in the range of 20-50% of Reed Stenberg and alike cells. The MVD had a median of 2.6 which was not different from reactive lymph nodes. VEGF in the non-neoplastic compartment correlated significantly with Ann Arbor stage with increased staining in I-II versus stages III and IV (spearman rho: -0.329, *p*:0.017). Also higher VEGF score in reactive cells correlated with increased incidence of complete response (*p*:0.03). Increased MVD was associated with the presence of necrotic lesions in the material (*p*:0.05). *Conclusion.* Microvessel formation is not increased in Hodgkin in comparison to reactive lymph nodes although there is expression of angiogenic molecules by neoplastic and surrounding cells. VEGF shows a higher level of expression in earlier stages of disease.

0183

EARLY INTERIM FDG-PET SCAN IN LOCALISED HODGKIN LYMPHOMA: EVALUATION IN 5 FRENCH CENTERS

M.S. Dilhuydy,[1] P. Brice,[2] T. Traulé,[3] P. Solal-Celigny,[4] S. Hirt,[5] A. Pariente,[6] O. Fitoussi[5]

[1]CHU de Bordeaux, PESSAC CEDEX; [2]Hopital Saint Louis, PARIS; [3]Hospices Civils de Lyon, LYON; [4]Centre Jean-Bernard, LE MANS; [5]Polyclinique Bordeaux Nord, BORDEAUX; [6]Département de Pharmacologie, BORDEAUX, FranceBackground.

Long-term survival from Hodgkin lymphoma (HL) in early-stage (I-II) patients is more than 85%. However, certain patients have a primary refractory disease with a worse evolution. Early interim FDG-PET scan performed after 2 courses of chemotherapy (PET-2) provides an early and accurate assessment of response and a correlation has been demonstrated between normalization of PET-2 and patient outcome. *Aims.* To evaluate the percentage of negative PET-2 in early-stage patients, and to seek clinical or biological factors predictive of positive PET-2. *Methods.* Forty-seven patients from five French centers with early-stage Hodgkin lymphoma received ABVD as first-line chemotherapy. PET-2 was performed 3 weeks after the second course of ABVD. Radiotherapy and changes in management according to FDG-PET scan result could be decided by the clinician. Evaluation was retrospective. *Results.* The median age was 33 years (range17-72). Thirty patients were male. Seventy percent of patients were in unfavorable group according to EORTC criteria (one or more of the following criteria: age > 50, systemic symptoms, elevated ESR >50 mm, bulk disease and more than three lymph node areas involved). Thirty-nine patients had a pre-treatment FDG-PET scan with a modification of staging in 6 cases. Initial staging according to CT scan or FDG-PET scan was as follows: IA: 5 patients, IB: no patient, IIA: 26 patients and IIB: 16 patients. Thirty nine patients (83%) had a negative PET-2 and 2 had minimal residual uptake whereas 6 patients (13%) had a clearly positive PET-2. Among the 39 patients with negative PET-2, 31 patients undergo radiation therapy after completion of four courses of ABVD. Among the 6 patients with positive PET-2, treatment intensification (BEACOPP) occurred for 3 patients with a negative FDG-PET scan after two courses. For patients having ABVD, FDG-PET scan results after four cycles were as follows: one remained with minimal disease, one had a negative FDG-PET scan and one had a positive FDG-PET scan. At a median follow-up of nine months, one patient with negative PET-2 relapsed early after the end of chemotherapy. The 46 other patients are in failure-free survival. Unfortunately, no clinical or biological factor (from EORTC criteria) was significantly predictive for PET-2 result. *Conclusions.* We showed in this series that negative PET-2 is obtained in 83% of patients with early stage disease. These results are similar to those expected in the EORTC H10 trial which evaluates PET-2 guided treatment adaptation and expect about 85-90% of negative PET-2. No clinical or biological factor was significantly predictive for PET-2 result. Prospective studies, like H10 EORTC trial are warranted to confirm these results and find predictive factors for a positive PET-2.

Immunology and gene therapy

0184

EARLY RECOVERY OF THYMUS-DERIVED NAÏVE T CELLS AND OF NK CELLS IN PEDIATRICS PATIENS AFTER T-CELL DEPLETED HLA-HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOR THALASSEMIA

A. Isgrò,[1] P. Sodani,[1] M. Marziali,[1] P. Polchi,[1] B. Erer,[1] J. Gaziev,[1] K. Paciaroni,[1] A. Roveda,[1] L. Spitaleri,[1] W. Leti,[2] M. Campagna,[2] F. Aiuti,[2] G. Lucarelli[1]

[1]Mediterranean Institute of Hematology, ROMA; [2]Dept. of Allergy & Clinical Immunology, ROMA, Italy

Background. Delayed immune recovery post transplant remains a significant obstacle and results in increased risk of infections. T cells are regenerated via 2 pathway, thymus-derived and peripheral expansion, processes for which IL-7 is critical. *Methods.* To analyse the mechanisms involved in immunological reconstitution, we studied six thalassemia patients after 20 and 60 days post T-cell-depleted HLA-haploidentical stem cell transplantation. The mean age ranged from 14 to 5 years. As controls, 6 healthy donors matched by sex and age with the patients were included. We analysed T cell subsets by flow cytometry. Stromal cells, obtained from long term culture of bone marrow mononuclear cells were analysed by immunohystochemistry and the stromal IL-7 production was analysed by ELISA. *Results.* Day + 20 post transplant, the patients had significantly lower $CD4^+$ T cells in comparison to the controls (1.9±1.4% vs. 47.5±6% respectively), and this reduced number was mainly observed in $CD45RA^+CD62L^+$ (naïve phenotype) subset (1.3±2% in patients vs. 52±12% in controls). A significant decrease of peripheral $CD45RA^+CD31^+$ Th cells (thymic naïve Th cells) (on average 0.5±0.3% in patients vs. 37±10% in controls) was observed, whereas $CD8^+$ T cells numbers did not statistically differ between patients and controls (24.2±33.7% vs. 20±7%). NK cells were among the first lymphocytes to repopulate the peripheral blood, and up to 70% of these cells were CD56 bright whereas CD56dim $CD16^+$ NK cells were reduced. Day + 60 post transplant an increase in the percentages of $CD4^+$ T cells, naïve $CD4^+$ cells and in thymic naïve Th cells were observed (3±1.2%, 2.9±2.1%, 2.7±1%, respectively). $CD8^+$ T cells were also increased (in mean 35±27.5%). Compared with normal subjects, thalassemia patients showed a significant increase of $CD4^+$ cell activation markers (CD95, HLA-DR and CCR5) and this was observed after 60 days post transplant, in parallel with the increase of the $CD56^{dim}$ $CD16^+$ NK cells especially in the patients with full engraftment. Stromal cells secreted lower IL-7 levels (0.3+0.1 pg/mL vs. 0.8+0.1 pg/mL, in controls) and displayed by immunohistochemistry an altered phenotype (macrophage-like morphology). *Discussions*. A significant decrease in total lymphocyte counts and depletion of $CD4^+$ T cells expressing predominantly the $CD45RA^+CD62L^+$ phenotype were observed after 60 days post transplant. Also the $CD4^+CD45RA^+CD31^+$ T cell subset was initially reduced but an increase has been observed at day + 60 post transplant, suggesting a thymus involvement in these patients. An IL7/IL7R pathway dysregulation has been also observed, possibly involving bone marrow stromal cells. NK cells were among the earliest lymphocytes to repopulate the peripheral blood, but. $CD56^{dim}$ $CD16^+$ NK cells were increased after 60 days post transplant, especially in the patients with full engraftment, suggesting a role of donor NK cells on bone marrow engraftment. We hypothesize that the recovery of T cell compartment may be due to an altered production of new T cells starting from the haematopoietic stem cells under the influence of stromal cytokines production.

0185

VACCINATION WITH DENDRITIC CELLS: CELLULAR IMMUNE MODULATION BY LEUKOCYTAPHERESIS IN PATIENTS WITH METASTATIC MALIGNANT MELANOMA

M. Hendelmeier,[1] A. Oehring,[1] M. Erdmann,[2] J. Doerrie,[2] N. Schaft,[2] E. Kohler,[3] R. Zimmermann,[1] E. Strasser,[1] R. Eckstein1

[1]Transfusion Medicine, ERLANGEN; [2]Department of Dermatology, ERLANGEN; [3]Center for Molecular Medicine, ERLANGEN, Germany

Background. Monocyte-derived Dendritic Cells (DC) are promising tools for the cellular immunotherapy of cancer (Banchereau et al, Nature Rev Immunol 2005; 5:296-306). Monocytes are, however, immune competent cells and consist of different subpopulations (Gordon et al, Nature Rev Immunol 2005; 5:953-964) with different physiological roles (Clancy *et al.,* J Leukoc Biol 2006; 79:757-766). However, no data is available yet considering the impact of leukocytapheresis on monocyte subpopulations in patients with metastatic malignant melanoma. *Aims.* Leukocytapheresis is a stimulus for recruitment of distinct monocyte subpopulations in patients and the enrichment of monocytes in apheresis products. The focus is on the main population of $CD14^{++}$ monocytes and the subpopulations of $CD14^+CD16^+$ monocytes, CD33dim$CD16^+$ monocytes, and CD33bright monocytes. The impact of the apheresis procedure on these important monocyte subpopulations was demonstrated. *Methods.* 18 patients with metastatic malignant melanoma and 22 healthy blood donors were investigated before and after leukocytapheresis procedures. Additionally, monocyte apheresis products (MAP) of patients were compared with the results of healthy blood donors. The percentage of monocyte subpopulations were investigated by flow cytometry (FACS Calibur, BD). The impact of the apheresis procedure was demonstrated by calculation of the recruitment factor (RF). Calculation formula: RF = (postdonation cell count + cell yield) / predonation cell count. *Results.* Monocyte subpopulations showed different enrichment in patients, in healthy blood donors and in MAP. In patients (n=18) with metastatic malignant melanoma the $CD14^+CD16^+$ monocytes increased by 57% (p=0.002) in the postdonation count. Additionally, the CD33dimCD16+ monocytes increased by 40.3% (p=0.002) whereas the same cell population in healthy blood donors decreased by 12% (p=0.079) in blood counts after apheresis procedure. $CD14^+CD16^+$ monocytes were enriched in MAP by factor 2 (4.99±2.53% vs. 10.14±6.71%, p<0.0001). The pre- and postdonation counts of CD14+CD16+ monocytes in donors (n=22) differed significantly (4.8% vs. 5.3%, p=0.001). Significant differences between the RF of $CD14^{++}$ monocytes and $CD14^+CD16^+$ monocytes could be demonstrated (p=0.003). The calculated RF of CD33bright monocytes differed significantly from the RF of $CD14^+CD16^+$ monocytes (p=0.003) and CD33dim$CD16^+$ monocytes (p=0.016). Between the RF of $CD14^+CD16^+$ monocytes and the RF of CD33dim$CD16^+$ monocytes no significant difference was detectable. *Summary and Conclusions.* These results suggest a different cell recruitment of monocyte subpopulations in patients with metastatic malignant melanoma compared to healthy blood donors. $CD14^+CD16^+$ monocytes and $CD33^{dim}CD16^+$ monocytes were increased in patients with metastatic malignant melanoma after leukocytapheresis. The leukocytapheresis procedure itself is a cellular immune modulation because of both, the removal and the different mobilization of distinct monocyte subpopulations. This immune modulation may have implications for the development of cellular therapies with DC and may impact on the results of vaccination with DC.

Figure 1.

0186

PROGNOSIS AFTER UNMANIPULATED HLA HAPLOIDENTICAL BLOOD AND MARROW TRANSPLANTATION IS CORRELATED TO THE NUMBERS OF KIR LIGANDS IN RECIPIENTS

X.-J. Huang, X.-Y. Zhao, K.-Y. Liu, L.-P. Xu, D.-H. Liu

Peking University Institute of Hematology, BEIJING, China

Background and Aims. The goal of this study was to explore the role of NK cell alloreaction in predicting prognosis under unmanipulated HLA-haploidentical blood and marrow transplantation and examine whether the presence of any individual donor-activating KIR gene had an influence on the clinical outcome. *Methods.* We studied the HLA and KIR genotype of 64 donor-recipient pairs, who underwent transplantation. *Results.* In contrast to Perugia's KIR ligand-ligand mismatch model or Handgretinger's KIR receptor-ligand mismatch model or Bignon's KIR gene-gene mismatch model between donor-recipient pairs, we found that the cumulative incidence of 3-year disease-free survival (DFS), overall survival (OS), and transplantation-related mortality (TRM) were best predicted by the number of KIR ligands carried by patients (HR 0.355, 95%CI, 0.186-0.678, p=0.002 for DFS; HR 0.445, 95%CI, 0.233-0.848, p=0.014 for OS; HR 0.450, 95%CI, 0.219-0.926, p=0.030 for TRM). Moreover, an analysis of KIR ligand numbers was found to be correlative in patients with lymphoid malignancy. The KIR ligand-ligand mismatch model is a good predictor of acute graft versus host disease (aGVHD, HR 3.812, 95%CI, 1.667-8.720, p=0.002). Meanwhile, the presence of donor-activating KIR2DS3 also contributed significantly to acute (HR 2.967, 95%CI, 1.265-6.958, p=0.012) and chronic GVHD (HR 2.541, 95%CI, 1.127-5.730, p=0.025). *Conclusions.* These data indicate that prognosis after transplantation is associated with the numbers of KIR ligands in recipients and T cell alloreaction may play a predominant role in this model.

0187

DENDRITIC-LEUKEMIA CELL HYBRIDS GENERATE SPECIFIC ANTI LEUKEMIA CTLS *IN VITRO*

R. Eshel, M. Shpringer, R. Ben-Yosef, A. Vexler, E. Naparstek

Tel-Aviv Sourasky Medical Center, TEL-AVIV, Israel

Background. Allogeneic stem cell transplantation (alloSCT) contributes significantly to better disease control in patients diagnosed with high risk AML. . Nevertheless, a significant proportion of patients suffer from recurrence of the disease. For those high risk patients, novel therapeutic strategies based on cellular immunotherapy have been explored to improve the clinical outcome of alloSCT. However, in most cases the leukemia specific antigens are unknown, and hence the cellular or non-antigen specific immunotherapy is based preliminary on the administration of allogeneic, donor derived T lymphocytes (DLI), aiming to induce a clinically significant graft-versus-leukemia responses. *Aims.* The aim of our study was to induce a potent and specific anti-leukemia cytotoxic T lymphocyte (CTL) response, utilizing dendritic-leukemia cell hybrids, to treat leukemic relapse in patients after alloSCT. Such fusion cell vaccine has the advantage of presenting both known and unidentified leukemic antigens, in the context of co-stimulatory signals. *Methods and Results.* Purified human monocyte-derived dendritic cells (DCs) were isolated from peripheral blood mononuclear cells of 5 healthy HLA-identical stem cell donors. Immature DC were successfully fused with recipients irradiated leukemic cells utilizing polyethylene glycol (PEG), and underwent further maturation in the presence of TNF-α , IL-6 , IL-1β , and PGE2. Fused population of DC-leukemia was estimated by flow-cytometry using two membrane incorporated fluorescent dyes, and DAPI stain was utilized to confirm the true presence of DC - leukemia cell hybrids. Generation of leukemia specific donor CTLs was performed by co-culture of donor mononuclear cells with irradiated DCs-leukemia hybrids under IL-2 deprivation. T cells were then further expanded in culture, and tested for their specific in-vitro cytotoxic activity against the leukemia cells that was utilized as fusion partner by LDH cytotoxicity colorimetric assay. In 4 out of 5 cases we were able to demonstrate a significant and specific cytotoxic activity of the hybrids-primed CTLs against the patients leukemic cells. *Conclusions.* Our results clearly demonstrate that the hybrid vaccination approach in AML is technically feasible. Such specific anti-leukemic donor CTLs may be utilized to maximize the anti-tumor effects of DLI in patients relapsing after allogeneic transplantation.

0188

TOLL-LIKE RECEPTOR EXPRESSION ON TRANSPLANTED T-CELL SUBSETS INFLUENCES OUTCOME AFTER ALLOGENEIC UNRELATED STEM CELL TRANSPLANTATION

U. Platzbecker, J. Stoehlmacher, C. Pabst, Ch. Thiede, G. Ehninger, M. Bornhauser

Universitätsklinikum Carl Gustav Carus, DRESDEN, Germany

Introduction. Recently, Toll-like receptor (TLR) 2 and 4 have been identified as the most important receptors for LPS, which is contained in the cell wall of gam-negative bacteria and is known to be a main inducer of graft versus host disease (GVHD). The role of TLR expressing T-cells within the graft for the induction of GVHD in patients after unrelated peripheral blood stem cell transplantation (PBSCT) is unknown. *Methods and patients.* We therefore determined by flow cytometry TLR expression on T-cells within the graft of 63 patients receiving unrelated PBSCT after intensive conditioning followed by cyclosporine A and methotrexate as GVHD prophylaxis. Additionally, donor specific single nucleotide polymorphisms (SNP) for TLR2-R753Q, TLR4-D299G and TLR4-Y135A were determined. The data were finally correlated with clinical endpoints. *Results.* As expected, TLRs were not significantly expressed on T-cells in peripheral blood of healthy donors (TLR 2: <1.0%, TLR4 <0.5% of T-cells, n=6). In contrast we detected a distinct up-regulation of these receptors on T-cells within the grafts. TLR2 and TLR4 expression on $CD4^+$ T-cells ranged from 1.2%-12.3% (median 3.1%) for TLR2 and from 1.2%-12.0% (median 3.7%) for TLR4. Among the $CD8^+$ T-cells 0.9%-16.1% (median 3.3%) expressed TLR2 and 0.7%-13.3% (median 3.5%) expressed TLR4. The SNP for TLR2-R753Q and TLR4-D299G was found in 8.6% and 10.3% of the allogeneic donors, respectively but did neither correlate with the expression levels of TLR on T-cells nor with clinical endpoints. Treatment-related mortality from infections was observed in 10 patients (16%). Interestingly, higher expression of TLR2 and 4 on $CD4^+$ but not $CD8^+$ T-cells was significantly associated with an increased cumulative incidence of fatal infections (38% vs. 8% p=0.03 for TLR2 and 37% vs. 9% p=0.007 for TLR4). Neither the overall $CD3^+$, $CD4^+$ and $CD8^+$ cell dose nor the expression of TLR2 and 4 on $CD4^+$ and $CD8^+$ T-cells showed a significant association with the incidence of acute or chronic GVHD or relapse. *Conclusions.* These data suggest a previously unrecognised up-regulation of TLR on $CD4^+$ and $CD8^+$ T-cells contained in G-CSF mobilized apheresis products. Whether these phenotypic changes impact on T cell function or patient outcome warrants further investigation.

0189

GENETIC LABELING OF HUMAN CD34-POSITIVE HEMATOPOIETIC PROGENITOR CELLS AND MESENCHYMAL STEM CELLS BY HIGHLY EFFICIENT MRNA-BASED GENE TRANSFER

J. Greiner,[1] J. Torzewski,[1] P. Ponsearts,[2] M. Rojewski,[3] D. Kronawitter,[1] H. Schrezenmeier,[3] V. Hombach,[1] H. Döhner,[1] M. Schmitt,[1] M. Wiesneth,[3] O. Zimmermann,[1] J. M. Wiehe[1]

[1]University of Ulm, ULM, Germany; [2]University of Antwerp, ANTWERPEN, Netherlands, [3]Institute of Clinical Transfusion Med., ULM, Germany

Transfection is an essential tool for numerous *in vitro* applications including studies of gene expression, promoter analysis, intracellular signaling pathways and therapeutic strategies such as tissue engineering and gene therapy. Furthermore, genetic labeling of HPC and their consecutive fate-mapping *in vivo* is an approach to answer intriguing questions in stem cell biology. We recently reported an efficient transient genetic labeling of human $CD34^+$ HPC by nucleofection with the truncated low affinity nerve growth factor receptor (deltaLNGFR) that is nowadays accepted for human *in vivo* application. In this study we optimized this method regarding transfection efficiency and viability loss by transfering *in vitro* transcribed mRNA in human $CD34^+$ HPC and MSC and compared the data with samples transfected with plasmid DNA. The marker gene deltaLNGFR was *in vitro* transcribed to mRNA or was cloned in the pVAX1 plasmid. Cells were transfected with LNGFR-encoded mRNA or plasmid DNA using nucleofector technology (amaxa system). Marker gene expression was assessed using antiLNGFR antibody by flow cytometry over a time periode of 10 days. Nucleofection of $CD34^+$ HPC and MSC with mRNA of the marker genes deltaLNGFR and EGFP resulted in transfection efficiencies up to 85% or 91% one day after nucleofection, respectively, without a significant viability loss (72% or 68% viable cells, respectively). In contrast, introduction of plasmid DNA caused a decrease in viability with a gene expression of only 50%. Transgene expression declined background levels 6 days after transfection, showing no differences between mRNA and plasmid transfection.

Cell viability was not affected by mRNA-transfection. Moreover, differentiation assays of deltaLNGFR-selected MSC after transfection, showed that differentiation of MSC into mesenchymal cells like chondrocytes, adipocytes and osteoblasts was not affected by mRNA nucleofection. Taken together, nucleofection is a powerful, highly efficient and non-toxic approach for transient labelling of human progenitor cells. This transfection method is significantly more efficient using mRNA instead of plasmid DNA. Nucleofection with mRNA might be a useful tool to transiently manipulate stem and progenitor cells without inducing cell toxicity.

SELECTIVE DEPLETION OF ALLOANTIGEN-REACTIVE T CELLS BY TRYTOPHAN CATABOLITE 3-HYDROXYANTHRANILIC ACID

S.K. Seo, Y.D. Joo, S.-M. Lee, I.-H. Choi

Inje University College of Medicine, BUSAN, South-Korea

Background. Indoleamine 2,3-dioxygenase (IDO) is a potent immunoregulatory enzyme that converts the essential amino acid tryptophan to catabolic products collectively known as kynurenines. Generation of tryptophan-derived catabolites by IDO is an important mechanism in IDO-induced T cell tolerance. *Aims.* We show the downstream molecular mechanism of the selective depletion of alloantigen-reactive T cells by tryptophan catabolite 3-hydroxyanthranilic acid (3-HAA). *Methods.* Peripheral blood mononuclear cells (PBMCs) were labeled with CFSE to distinguish between alloantigen-reactive T cells and resting T cells. CFSE-labeled PBMCs were cocultured with allogeneic cells in the presence or absence of 3-HAA. FACS analysis was performed to measure the cell cytotoxicity, intracellular ROS generation, and GSH levels. Lethally irradiated BDF1 mice were transplanted with T cell-depleted bone marrow plus splenocytes form B6 donors. Recipients were intraperitoneally treated with 3-HAA or with control solvent. *Results.* 3-HAA selectively depleted alloantigen-reactive T cells by inducing apoptosis *in vitro*. Treatment with 3-HAA markedly increased intracellular reactive oxygen species (ROS) generation by depleting intracellular glutathione (GSH) in alloantigen-reactive T cells. Replenishment of GSH with 2-mercaptoethanol (2-ME) and N-acetylcysteine (NAC) completely protected against selective T cell depletion by 3-HAA. Administration of 3-HAA in mouse prevented GVHD by selectively depleting alloantigen-reactive donor T cells through apoptosis. *Conclusions.* 3-HAA enhances intracellular ROS generation of depleting GSH in activated T cells, thus resulting in selective depletion of alloantigen-reactive T cells *in vitro* and *in vivo*. Our data suggest that tryptophan catabolites, especially 3-HAA, could represent a novel target for the development of new drugs for the treatment of transplantation rejection.

IMPROVING THE CLINICAL APPLICABILITY OF CHIMERIC-RECEPTOR TRANSDUCED T CELLS: CD20 AS A MARKER FOR SELECTION, TRACKING AND ANTIBODY-MEDIATED KILLING OF TRANSDUCED CELLS

V. Marin,[1] H. Kakuda,[2] A. Tintori,[1] A. Biondi,[1] G. D'Amico,[1] D. Campana[2]

[1]M.Tettamanti Research Center, MONZA, Italy; [2]St.Jude Children's Research Hospital, MEMPHIS, USA

Background. an emerging new tool for cancer immunotherapy is the infusion of T lymphocytes transduced with chimeric-receptors that redirect them against molecules expressed on the surface of cancer cells. The clinical applicability of this approach could be further augmented by effective methods to enrich, track and eliminate genetically modified cells. *Aims.* we tested whether a chimeric-receptor directed against CD19, a molecule widely expressed in B-lineage acute lymphoblastic leukemia (ALL) and B-cell non-Hodgkin lymphoma, could be co-expressed with CD20. This would offer a means to select transduced cells *ex vivo* and eliminate them *in vivo* using anti-CD20 antibodies. *Methods.* a MSCV retroviral vector containing the anti-CD19-CD28-zeta-IRES-CD20 insert (M-CD19-CD28-zeta-I-CD20) was generated by substituting the GFP gene with the human CD20 gene in the anti-CD19-CD28-ζ-IRES GFP vector. The CEM-C7 and Jurkat cells were then transduced by incubation with retroviral supernatant on retronectin-coated tube. Three days after transduction the expression of chimeric receptor and CD20 has been evaluated by flow cytometry and $CD20^+$ cells were then immunomagnetically purified. *Results.* CEM-C7 and Jurkat cells were efficiently transduced with the M-CD19-CD28-zeta-I-CD20 vector. After transduction, the anti-CD19 receptor was expressed by 11% of CEM-C7 and by 32% of Jurkat cells. Although levels of expression were weaker than that achieved with constructs lacking CD20, the receptor was functional, as shown by the induction of IL-2 transcripts after exposure of transduced Jurkat cells to the CD19+ALL cell line OP-1. Expression of CD20 was detected on 35% of CEM-C7 and on 63% of Jurkat cells; after immunomagnetic cell-sorting with an anti-CD20 antibody over 95% of sorted cells expressed the anti-CD19 receptor. Experiments to determine whether exposure to the clinical anti-CD20 antibody Rituximab can eliminate the transduced cells, and the relative potency of radioisotope-conjugated anti-CD20 antibodies are planned.

0192

DNA VACCINE AND ALL-TRANS RETINOIC ACID COMBINED TREATMENT ELICITS SPECIFIC AND PROTECTIVE CELLULAR IMMUNE RESPONSES IN A MOUSE MODEL OF PRE-ESTABLISHED ACUTE PROMYELOCYTIC LEUKAEMIA

R.A. Padua,[1] K. Furugaki,[1] H. Moins-Teisserenc,[1] K. Pokorna,[1] M. Reboul,[1] M.-H. Schlageter,[2] D. Charron,[1] C. Chomienne,[1] M. Pla[1]

[1]Institut Universitaire D'Hematologie, PARIS; [2]AP-HP, Hôpital Saint-Louis, PARIS, France

Background. DNA vaccines can be effective in the acquisition of humoral and cell-mediated immune responses. Our studies on an acute promyelocytic leukemia (APL) mouse model show that DNA vaccination combined with all-trans retinoic acid (ATRA) results in a survival advantage with a significant increase in the Th1 cytokine IFNg (Padua *et al.,* Nat. Med. 9:1413, 2003). ATRA alone can act as an adjuvant to induce immune responses as measured by an increase in anti-RARa antibody production, which correlated with improved survival in mice. Similar increases in antibody production have been observed in our patients after maintenance therapy (Robin *et al.,* Blood 108:1972,2006). *Aim.* 1) To use immunomonitoring and functional assays to evaluate the presence of activated T-cells and to demonstrate APL-specific killing. 2) To determine if the protective effect of DNA vaccination is $CD4^+$ mediated. *Methods.* Cytokine release was measured using a cytokine bead array kit. Using an APL transplant model in FVB/N mice, CD107a, expressed on the surface of lytic granules of activated T-cells, was measured by flow cytometry. A flow based CFSE assay was used to measure APL specific cell killing by cytotoxic T-cells (CTLs). As FVB/N mice have H2q haplotyes, blocking anti-H2q antibodies were used to determine if the cytotoxic activity was MHC restricted. Immunophenotyping by measuring $CD4^+$ and $CD8^+$ absolute counts were conducted. Mice injected with APL cells were depleted of $CD4^+$ cells with anti-CD4 antibody treatment and assayed for efficacy of the DNA+ATRA combined therapy. *Results*. In long-term survivors, Th1 cytokines TNFa and IFNg were increased and specific activated CD3/CD8 T cells were detected and observed to release cytotoxic granules in the presence of APL cells. A dose dependent decrease in CFSE positive cells was observed assaying effectors from spleens of ATRA alone, ATRA+DNA treated mice and CD107a+ sorted cells from the latter using APL cells as targets. This effect was MHC restricted as anti-H2q antibodies reduced the specific cytotoxic activity. $CD4^+$ absolute numbers of non-responders (NR) (died before 80 days) and responders (R) (survived more than 80 days) showed a significantly higher number of $CD4^+$ cells in the latter compared with the former on day38 (p=0.007). The DNA +ATRA treated mice died earlier in the CD4+ depleted mice compared with the undepleted animals. *Summary and conclusions.* In the long-term survivors, the presence of activated T-cells and MHC restricted APL specific cell killing was detected. An increase of Th1 cytokines is indicative of DNA effects. DNA vaccination requires CD4+ cells for efficacy as there was no extension of lifespan in DNA treated mice in the $CD4^+$ depleted FVB/N. This correlates with the observation that on days 38 of the protocol following transplant of APL there is an increase in $CD4^+$ absolute numbers in the Rs compared to NRs. These data are consistent with an increase in anti-RARa antibody production previously measured in other protocols. Therefore we have been able to detect protective cellular and humoral responses in mice with the combined treatment of DNA+ATRA, which correlates with outcome.

0193

IMMUNE RECONSTITUTION OF THE T CELL COMPARTMENT IN HEMATOLOGICAL MALIGNANCIES FOLLOWING ALLOGENEIC NON MYELOABLATIVE HEMATOPOIETIC CELL TRANSPLANTATION

P. Omedé,[1] B. Bruno,[2] M. Gilestro,[1] M. Spagnolo,[2] F. Ferro,[2] M. Ruggeri,[2] M. Brunetti,[2] S. Caltagirone,[2] C. Di Bello,[2] A. Fantauzzo,[2] L. Cimolin,[2] C. Sfiligoi,[2] S. Cena,[2] L. Giaccone,[2] F. Fiore,[2] M. Rotta,[2] R. Sorasio,[2] M. Boccadoro[2]

[1]ASO San Giovanni Battista, TORINO; [2]Divisione di Ematologia, TORINO, Italy

Background and Aims. Allografting is a potentially curative therapy for a variety of hematological malignancies. However, relapse and treatment-related toxicity are major obstacles to cure. Reduced-intensity/non-myeloablative conditionings were designed to initially establish hematopoietic mixed-chimerism and then to serve as a platform for additional cell immunotherapy aimed at eradicating tumor cells in medically unfit or elderly patients (up to 70 years). However, the risk of post-transplant infections and the efficacy of graft-versus-tumor effects also rely on the thymic function, potentially reduced with age. For this reason it is mandatory to evaluate the residual thymic function. *Material and methods.* The immune recovery of the T cell compartment was evaluated by flow cytometry in 66 patients with hematological malignancies, median age 54 years (range 34-64), conditioned with low dose TBI (200 cGy), with/without fludarabine (90 mg/m^2 total), followed by G-CSF mobilised peripheral blood stem cell infusion from HLA identical siblings. The analyses were performed at different timepoints: baseline, at day +28, at 3, 6 months, and at 1, 2, 3, 4, 5, 6 years post-transplant. Briefly, fresh peripheral whole blood samples were red cell depleted and stained with four-colour combinations with the following MoAbs: CD3, CD4, CD8, CD16, CD45RA, CD45R0, CD62L. At least 80000 events for each combination were acquired on a FacsCalibur (Becton Dickinson), and analysed with CellQuest Pro software. T cell Receptor Excision Circles (TRECs) were evaluated by real-time quantitative PCR with an ABI PRISM 7900HT Sequence Detection System at the same timepoints. *Results*. Peripheral CD4+ T cells to >200/ul promptly recovered by day +28 with median values of 274/uL, gradually increasing to 474/ul, 682/uL, and 964/uL, at 1, 3 and 6 years, respectively. Naïve CD4+CD45RA+bright T cells increased to 49/uL, 66/uL, 122/uL, at day +28, and at 2, 6 years, respectively. Memory CD4+CD45R0+bright remained stable with median values of 153/ul and 128/uL from day +28 through month +3, respectively; then increased to 234/uL, 332/uL, 529/uL, at 1, 2, 6 years. The evaluation of the coexpression of the CD45 isoforms showed that the number of CD4+CD45RA+CD45R0+ T cells reached median values of 63/ ul by day +28 and 73/ul at 6 months; then increased to 128/ul, 191/ul, 237/ul at 2, 5, 6 years, respectively. CD8+ T cells reached median values of 156/ ul by day +28, increasing to 445/uL, 880/ulL, at 6 months, and at 4 years, respectively. CD4/CD8 ratio was 1.8 by day +28, decreased to 0.57 at 1 years, and then increasing at 0.9 at 4 years. In a subset of 35 patients the presence of naïve CD4+CD62L+CD45RA+bright T cells and of memory CD4+CD62L-CD45R0+bright T cells was evaluated. Preliminary data showed an increase of these cell populations at 4 years with a median value of 836/ul, and 433/ul, respectively, while they remained stable at 5 and 6 years. TREC copies/100 ng DNA from peripheral mononuclear cells and sorted CD4 cells were measured in 52 and 46 patients, respectively, at the same timepoints: median baseline value from PBMC was 0.5, then it gradually increased to 2.6 at 1 years, reached 53.7 at 5 years, and remained stable at 6 years. A significant correlation was demonstrated between TREC values from PBMC and CD4+CD62L+CD45RA+bright T cells (p<0.00003). *Conclusions.* Our findings suggest a slow T immune reconstitution during the first two years post-transplant that differs from normal T lymphocyte ontogenesis. Preliminary results show a significant correlation between the quantitative analysis of TRECs and the analysis of very naïve T cells by CD62L expression and allow to quantify the residual thymic function in this group of elderly patients.

0194

USING HSV-TK SUICIDE GENE TRANSFER TO IMPROVE THE SAFETY OF DLI

S. Borchers, E.M. Weissinger, A. Ganser

MHH, HANNOVER, Germany

Background. The possibility to manipulate the graft, e. g. to select CD34 positive cells or to deplete CD3 positive cells, has lowered the incidence of acute graft versus host disease (aGvHD) occurring after hematopoetic stem cell transplantation (HSCT). But this beneficial effect has its drawback in high relapse rates, increased infection rates, and a higher risk of graft failure due to the lack of T-cells. To circumvent these problems, donor lymphocyte transfusions (DLI) are given to the patients. *Aims.* Transfusion of unmanipulated donor T-cells can lead to aGvHD even after 100% donor chimerism is achieved. In order to have the benefit of DLI and lower the risk of aGvHD, the DLI can be transduced with a suicide gene (e.g. the herpes simplex virus thymidine kinase HSV-TK) in order investigate the possibility of eliminating severe aGvHD by induction of the suicide mechanism using ganciclovir (5 μg/kg BW). Safety and feasibility of this technique were investigated in a set of 9 patients in our institute. *Methods.* 9 patients, 7 with AML and 2 with CML, were enrolled in the study. They were transplanted from HLA-identical sibling donors with CD34-enriched stem cells without further immunosuppression. Donor-T-cells were transduced with the replication-deficient retrovirus SFCMM-3, which expresses HSV-TK as a suicide gene and the truncated version of the low affinity nerve growth factor receptor ('LNGFR) for selection purposes. In the follow up blood samples of the patients were collected at certain intervals and the transduced cells were tracked by flow cytometry and PCR. In addition, reconstitution of the TCR repertoire was checked by spectratyping. *Results.* After transfusion, SFCMM-3 transduced T-cells were detectable in all patients by PCR and FACS-analyses immediately after transfusion and during the follow up period (range: 1.1-3.8 years). One of 9 patients developed aGvHD of the skin, grade 1, at 56 days after the transfusion of the transduced cells. In a patient positive for bcr-abl, bcr-abl gene expression was not detectable any more after an expansion of transduced cells. Donor chimerism was stabilized after transfusion of the transduced cells in all patients treated. Spectratyping showed a normalisation of the TCR repertoire over time, additionally the transduction apparently did not cause severe skewing in transduced donor cells. To date, 8 of 9 patients are alive and well. *Conclusions.* The administration of DLIs transduced with a suicide gene showed no negative side effects so far. Therefore, a phase II clinical trial in an haplo-identical setting using this technique has been started at our institution.

0195

MINOR HISTOCOMPATIBILITY ANTIGEN ALLOREACTIVITY: CLINICAL RELEVANCE OF FUNCTIONAL TESTS

F. Garban,[1] D. Laurin,[2] D. Hannani,[2] M. Pernollet,[2] A. Moine,[2] J. Plumas,[2] J.C. Bensa,[2] J.Y. Cahn[3]

[1]CHU Grenoble, GRENOBLE; [2]EFS Rhone Alpes & INSERM U823, LA TRONCHE; [3]CHU Grenole, GRENOBLE, France

Background. Minor Histocompatibility (mH) antigens alloreactivity play a determinant role in Graft versus Host Disease (GvHD) and Graft versus Leukemia effect (GvL) after HLA-identical hemapoietic stem cell transplantation. *Aims.* We investigated the impact of alloreactivity against minor antigens on GVHD and relapse from donor versus recipient or versus current identified mH epitopes measured in blood samples until 3 months or later after allogeneic transplantation. *Methods.* 27 patients transplanted with an HLA compatible donor were studied for mismatch in un mismatch en mHA parmi HA-1 HA-2 HA-3 HA-8 HB-1 ACC-1 UGT2B17 H-Y HwA-9 HwA-10. Function against recipient of T lymphocytes after transplant was studied by ELISPOT (IFN γ) and the detection of T lymphocyte performed by flow cytometry using multimere HLA-minor antigen derived peptides. Biological findings were correlated with clinical data : GVHD or risk of relapse (Graft versus leukemia). *Results.* Alloreactivity, during the 3 first months is associated with acute GvHD and GvL (p″0.015). Functional response measured by ELISpot IFN-γ against mH epitopes is also relevant to acute GvHD and GvL (p″0.046) but the presence of specific T-cells measured by multimers HLA/peptides is not. Correlation of early alloreactivity and risk of relapse appears strong since the median post transplant follow-up for patients reach 24 month. Donor versus recipient reactivity observed next to the third month is associated with chronic GvHD and has a positive predictive value of 91% on GvL (p″0.01). Nevertheless the response observed individually against mH epitopes by ELISpot assay beyond 3

month is not relevant to chronic GvHD or GvL. The presence of mH epitope specific T-cells is also not linked to the GvHD but very interestingly is associated to the GvL effect (GvL $p''0.01$). *Conclusions.* Our results suggest that monitoring of mH responses on a restricted panel of antigens could have interest very early following hemapoietic stem cell transplantation. This a could give arguments for early therapeutic intervention for patients with a high risk of relapse and when no detectable alloreactivity could be observed during the first 3 months post transplant.

0196

HIGH ALLOREACTIVE POTENTIAL OF SUICIDE GENE EXPRESSING CENTRAL MEMORY T LYMPHOCYTES CULTURED WITH HOMEOSTATIC Γ-CHAIN CYTOKINES FOR THE CURE OF HEMATOLOGICAL MALIGNANCIES

S. Kaneko,[1] S. Mastaglio,[1] A. Bondanza,[1] M. Ponzoni,[1] L. Aldrighetti,[1] S. Toma,[2] M. Radrizzani,[2] S. La Seta-Catamancio,[2] F. Ciceri,[1] T. Nagasawa,[3] C. Bordignon,[1] C. Bonini[1]

[1]Scientific Institute San Raffaele, MILAN, Italy; [2]MolMed, MILAN, Italy; [3]University of Tsukuba, TSUKUBA, Japan

Background. Alloantigen targeting adoptive immunotherapy is a powerful therapeutic approach to increase the graft-versus-leukemia (GvL) effect mediated by allogeneic hematopoietic stem cell transplantation, for the cure of hematological malignancies. Although alloreactivity mediated by donor lymphocytes plays a crucial role in treating and preventing disease relapse, its extensive exploitation is limited by the risk of a life-threatening complication: Graft-versus-host disease (GvHD). To solve this double bind, we've investigated the therapeutic potential of donor lymphocytes retrovirally transduced to express the suicide gene thymidine kinase of Herpes Simplex virus (TK cells) in patients affected by leukemia, and showed that the infusion of TK cells induces GvL and allows to control severe GvHD by ganciclovir (GCV). Initial clinical experience showed that infused TK cells have a reduced alloreactivity and are mainly $CD45RA^-/CD62L^-$ effector memory (EM) T cells, known to have limited survival potential. This functional phenotype is possibly due to the *ex vivo* manipulation based on the enforced expansion of lymphocytes by polyclonal stimulation (soluble anti-CD3 antibodies) and high concentration of IL-2. *Aims.* The aim of the study is to maximize the alloreactive potential of TK cells for the cure of leukemia, while controlling severe GvHD. *Methods.* We hypothesized that culture with anti-CD3/CD28Ab coated magnetic beads (3/28b) and homeostatic γ-chain cytokines may allow to fully maintain alloreactivity on TK cells, while permitting retroviral transduction. We tested IL-7, a central regulator of the survival and maintenance of naïve and memory T lymphocytes, and IL-15, a regulator of the initiation, clonal expansion, contraction, and maintenance of memory cells. We used the SFCMM3 vector for T cells transduction. Phenotypes, antigen reactivity, and survival of TK cells were analysed *in vitro* and *in vivo*; using a murine model based on TK cells infusions in NOD/Scid mice, previously transplanted with allogeneic human skin. *Results.* The combination of 3/28b, IL-7 and IL-15 generated high numbers of $CD45RA^-/CD62L^+$ central memory (CM) TK cells with preserved CD4/CD8 ratio, a g-IFN/IL-2 secretion profile, and persistent expression of high levels of IL-7R-α, a molecule associated to memory lymphocytes survival. In mixed lymphocytes cultures, CM TK cells showed higher alloreactivity than EM TK cells, and maintained a CM phenotype after multiple allogeneic stimulations. Moreover, CM TK cells were eliminated by GCV as efficiently as EM TK cells. *in vivo,* infused CM TK cells were engrafted and expanded more than EM TK cells, showing preserved CD4/CD8 ratio and persistent expression of high levels of IL-7R-α. Most importantly, CM TK cells were more potent than EM TK cells in inducing both xenogeneic and allogeneic GvHD, as documented by higher engraftment and a more extensive infiltration of TK lymphocytes in the allogeneic human skin (grade 3 vs grade 1 allo-GvHD). *Summary.* This study shows that CM TK cells, generated by CD3/CD28 activation and culture in the presence of homeostatic cytokines combine a high alloreactive potential with the selective sensitivity to GCV-mediated cell death, providing a tool for maximal anti-leukemia activity and controlled GvHD.

0197

SELECTIVE DEPLETION OF ALLOREACTIVITY AND PRESERVING OF ANTI-TUMOR ACTIVITY OF SPECIFIC T CELL CLONES IN PATIENS WITH LEUKEMIA AND RENAL CARCINOMA

E. Matejkova, Z. Hrotekova, A. Stejskalova, D. Kyjovska, P. Vidlakova, J. Michalek

Masaryk University, BRNO, Czech Republic

Background. A major challenge in the field of hematopoietic stem cell transplantation (HSCT) is to prevent the alloreactivity of donor T-cells which leads to acute graft-versus-host disease (GVHD) while preserving graft-versus-tumor (GVT) effect. GVHD is leading cause of morbidity and mortality after HSCT. *Aims.* Selective depletion using anti-CD25 immunotoxin (IT) can eliminate harmful alloreactive T-cells while preserving other donor T-cells with antileukemic/antitumor reactivity. *Methods.* We have used irradiated peripheral blood mononuclear cells (PBMC) from cancer patients and healthy donor PBMC as responder cells in primary mixed leukocyte reaction (MLR).To prepare GVL/GVT-specific T-cells, alloreactive T-cells in primary MLR were depleted with anti-CD25 IT. The remaining T-cells had insignificant alloreactivity in secondary MLR. Allodepleted donor cells were then repeatedly stimulated using purified leukemia/tumor cells from the same cancer patient. Leukemia/tumor-reactive donor T-cells were purified immunomagnetically on the basis of INF-γ production. *Results.* 17 MLRs (10 with leukemic and 7 with renal carcinoma cells) were performed. Selective depletion of alloreactive donor T-cells with anti-CD25 IT led to more than 2log depletion. Graft-versus-leukemia (GVL) effect of donor T-cells was well preserved while the graft-versus-host (GVH) reactivation of donor cells was negligible ever after repeated stimulation with patient's PBMC. In the case of renal carcinoma GVT-effect was less dominant and GVH-reactivation of donor cells led to significant amount. *Summary.* In conclusion, it is possible to selectively deplete donor alloreactive T-cells with anti-CD25 IT. In the case of patients with leukemia, the GVL-effect can be separated from GVHD, but in case of renal carcinoma severe GVHD-effect re-appeared.

WT1 FULL LENGTH PROTEIN VACCINATION SHOWS HIGH IMMUNOGENICITY AND SIGNIFICANT ANTI-TUMOUR ACTIVITY IN THE MOUSE MODEL

D. Cilloni, I. Defilippi, P. Nicoli, A. Roetto, A. Bondi, E. Girola, F. Arruga, F. Messa, S. Carturan, V. Rosso, R. Catalano, R. Taulli, E. Bracco, G. Saglio

University of Turin, TURIN, Italy

Background. The Wilms' tumor gene (WT1) is overexpressed in many types of haematological malignancies including Acute Myeloid Leukaemia (AML), Acute Lymphoblastic Leukaemia (ALL), Chronic Myeloid Leukaemia (CML) and Ph negative myeloproliferative disorders. WT1 holds great promise for immunotherapy of leukaemia since it is expressed at high levels in blast cells but not in normal tissues, it is involved in the maintenance of malignant phenotype and it is spontaneously immunogenic. Many clinical trials using MHC class I-restricted WT1 peptide, have been recently performed in patients affected by AML, MDS, lung and breast cancer with satisfactory clinical results and without relevant toxicity. *Aims.* the aim of the study was to set up a vaccination approach in the mouse model using the WT1 full length protein and to test the safety and efficacy of the vaccine. *Methods.* We purified the WT1 full length protein. Complete coding sequence was cloned in a pGEX bacterial expression vector for the production of the fusion protein GST-WT1 that was subsequently purified by glutathione conjugated beads. The murine leukemic cell line C1498 was transduced with lentiviral vector PKG WT1 (kindly provided by Dr. L. Naldini) in order to obtain a syngeneic cell line expressing WT1. 40 C57BL7/6 mice were immunized with 50 μg of purified WT1 protein and 50 μL of Freund adjuvant every 15 days, for a total of 3 immunizations; 40 mice were injected with GST and adjuvant and 40 with PBS alone as control. 2 weeks after the last administration, 10 vaccinated mice and 10 controls have been injected with 200.000 TRAMP-C2 cells and 10 of each group with C1498. 10 mice from for each group were sacrificed and lymphocytes, cultured in presence of interleukin-2 to perform a cytotoxicity assay. Antibodies against WT1 have been evaluated. Long term toxicity has been evaluated. Blood values have been constantly tested. *Results.* Toxicity on normal tissues has been ruled out using the histochemical analysis of different tissues. After mice vaccination, no organ toxicity has been observed. White blood cell, Hb and platelets counts did not change

significantly in the different groups. Iimmunized mice showed high levels of both, IgM and IgG antibodies with a mean value of luminescence of 690000 in WT1 injected mice vs 7500 in control mice and high levels of CTLs against WT1 as compared to mice injected with PBS or GST alone. Importantly, in control mice injected with TRAMP-C the mean size of the tumor was 1,6±0,4 cm and 2±0,5 cm in control mice injected with C1498. By contrast in vaccinated mice the tumour mass was significantly smaller (0,3±0,1 cm) after 8 weeks of follow-up. *Conclusions.* The full length protein vaccination approach is able to elicit both, umoral and cytotoxic response and it results in a significant antitumor effect *in vivo*. Although further studies are required to compare the efficacy of this approach to the peptide based vaccine, WT1 full length protein could represent a valid vaccination strategy allowing to overcome the HLA restriction limit of the peptide approach

0199

DETECTION OF HUMORAL IMMUNE RESPONSES AGAINST WILMS TUMOR GENE (WT1) PRODUCT IN PATIENTS AFFECTED BY HAEMATOLOGICAL MALIGNANCIES

D. Cilloni, P. Nicoli, I. Defilippi, E. Girola, A. Bondi, E. Messa, A. Roetto, S. Carturan, F. Messa, F. Arruga, R. Catalano, V. Rosso, E. Bracco, G. Saglio

University of Turin, TURIN, Italy

Introduction. The Wilms tumor gene (WT1) is expressed at high levels in many types of haematological malignancies including Acute Myeloid Leukaemia (AML), Acute Lymphoid Leukaemia (ALL), Chronic Myeloid Leukaemia (CML), Ph negative Myeloproliferative disorders (CMPD) and Myelodysplastic Syndromes (MDS). Moreover WT1 gene is overexpressed in many types of solid tumours. Humoral immune responses against WT1 product has been described in Acute Leukemias and in Chronic Myeloid Leukemia (CML). At present, many clinical trials using WT1 peptides are ongoing. *Aims.* The aim of the study was to investigate the presence of a humoral response against WT1 protein in patients affected by haematological malignancies in order to explore the possibility to elicit an immune response against WT1 with vaccination using WT1 peptides or protein. *Methods.* After informed consent sera and Peripheral Blood samples were collected from 98 patients: 30 Myelodysplastic syndromes (MDS), 11 Acute Myeloid Leukaemia (AML), 4 Acute Lymphoblastic leukaemia (ALL), 23 Multiple Myeloma (MM), 20 Chronic Myeloid Leukemia (CML), 6 Idiopatic Myelofibrosis (IM), 4 Chronic Myelomonocytic Leukaemia (CMML). In addition 20 healthy subjects were evaluated as control. Using dot blot technique we analyzed the presence of WT1 IgG and IgM antibodies. WT1 transcript amount was evaluated by quantitative Real Time PCR in PB samples. *Results.* We detected a significant levels of IgG in 64% of MDS, 54% of AML, 66% of ALL, 70% of CML, 70% of MM, 100% of CMML and 66% of IM. The levels of IgG antibodies were significantly higher in chronic myeloproliferative disorders as compared as acute leukemias. A significant level of IgM antibodies were present in 60% of MDS. Among them they were present in 75% of RA, 30% of RAEB and 25% of s-AML. 10% of de novo AML, 10% of ALL, 20% of CML, 220% of MM, 100% of CMML and 50% of IM. By contrast IgG and IgM were undetectable in healthy subjects. Regression analysis showed that the levels of antibodies were not correlated with WT1 expression levels (r=0,41). *Conclusions.* These data demonstrate that humoral immune responses against the WT1 protein could be elicited in patients with haematological malignancies. Moreover, the data suggest that strong and persistent stimulation by WT1 antigen, which usually occurs in patients with a large amount of leukemic cells is needed to generate immunoglobulin isotype class switching from IgM to IgG. Finally, although Multiple Myeloma patients present low levels of WT1 transcript in BM, they have significant amount of antibodies in the serum. These data suggest that patients affected by haematological malignancies, including Multiple Myeloma patients could be candidate for WT1 based immunotherapy.

γ-GLOBIN GENE TRANS-ACTIVATION IN K562 CELLS BY A SYNTHETIC ZINC-FINGER ACTIVATOR GENE TRANSFER

E. Stavrou,[1] E. Lagadinou,[2] E. Papapetrou,[3] C. Barbas III,[4] N. Zoumbos,[2] A. Athanassiadou[3]

[1]University of Patras, PATRAS, Greece; [2]Dep of Hematology, University of Patras, PATRAS, Greece; [3]Dep of Biology, University of Patras, PATRAS, Greece; [4]The Scripps Research Institute, LA JOLLA, USA

The activation of the γ-globin gene pharmacologically or by γ-globin gene transfer has been considered a valid alternative strategy for treatment of diseases arising from mutations in this locus, such as of sickle-cell anemia and thalassaemia versus the transfer of the normal β-globin gene. Lately (Graslund et al 2005) the development of a selective, synthetic activator of γ-globin gene, Zif-VP64, based on zinc-finger DNA binding proteins was presented, producing potentially therapeutic levels of Haemoglobin F. K562 cells express the γ-globin gene and are trisomic for chromosome 11, the aim, therefore, is to establish an increase in the γ-globin in the transfected cell lines, as compared to the untransfected ones, using a non-viral episomal vector. We constructed an episomal vector containing: the activator Zif-VP64; the reporter gene eGFP, driven by the CMV promoter; the S/MAR element, which enables the plasmid to establish itself in the nucleus of the host cell. We transferred this new, episomal vector of γ-globin activator, Zif-VP64-Ep1, into human hematopoietic K562 cells, by electroporation. Routinely 1x107 K562 cells were used for every experiment and transfection efficiencies were around 55%. Our results show that Zif-VP64-Ep1 is maintained as a stable episome in K562 cells without integrations in the genome as shown with Southern Blot and plasmid rescue experiments, running into the tenth month of continuous culture with and without selection pressure and without loss in cell viability or in expression of eGFP, as observed under Fluorescent Microscope and documented by Flow Cytometry. RT-PCR, Western blotting and Intracellular Flow Cytometry were employed to investigate γ-globin mRNA and Haemoglobin F protein levels in transfected K562 cells. Our data indicate a significant increase in Haemoglobin F protein of up to 350% of its level in the untransfected K562 cells, at list 200 generations post-transfection. This is the first time that an episomal vector for gene transfer is applied for the trans-activation of specific gene expression.

COMBINATION ANTIFUNGAL THERAPY WITH ECHINOCANDIN AND POLYENE IN IMMUNOSUPPRESSED PATIENTS WITH INVASIVE FUNGAL INFECTIONS FAILING FIRST LINE TREATMENT

L. Pagani,[1] E. Morello,[2] C. Vedovelli,[1] P. Mian,[1] B. Amato,[2] P. Viale[3]

[1]Infectious Diseases Unit, BOLZANO; [2]Bone Marrow Transplantation Unit, BOLZANO; [3]Udine University, UDINE, Italy

Background. Invasive fungal infections (IFI) are strongly associated to illness and death in immunosuppressed or high risk patients (pts), especially in those experiencing failure to primary therapy. *Aims.* At evaluating second line combination antifungal therapy (CAT) with echinocandin and polyene in critically ill pts with IFI. *Methods.* From November 2003 to April 2005, 18 pts affected by IFI (8 with candidemia due to C. albicans, 3 due to C. glabrata, 2 due to C. krusei, and 5 with pulmonary aspergillosis), who had failed primary antifungal therapy, were treated with Caspofungin (CSP) 70 mg on 1st day, and 50 mg thereafter, plus low dose (LD) AmphotericinB deoxycholate (dAmB) 0.5 mg/kg/d. All pts had high risk underlying conditions (5 acute myelogenous leukemias, 6 solid tumors, 5 prolonged intensive care unit (ICU) stays, and 2 major abdominal surgical interventions). Failure to prior therapy was determined by: 1) fever and worsening of clinical conditions, and 2) persistent candidemia, or 3) worsening of lung CT scan together with increase of Aspergillus galactomannan antigenemia (AGA), after 96 hours (hrs) from the start of antifungal therapy. *Results.* All 18 pts were clinically unstable and critically ill, and 13 out of 18 had been admitted to ICU at the time of switching therapy; 5 patients never required admission to ICU. Within 72-96 hrs from the beginning of CAT, clinical stability and fever clearance, together with negative blood culture, or negative AGA were observed, and confirmed thereafter. LD dAmB did not require any premedication, but none of the pts suffered from side effects, nor treatment discontinuation was needed. All patients survived. Mean CAT duration was 26 days, and mean ICU stay was 9 days, before pts transfer to either medical or surgical wards. None of the pts relapsed within a follow up period of at least 60 days from the end of treatment. *Conclusions.* In heavily immunosuppressed pts, antifungal therapy remain a major challenge. CAT with echinocandin, such as CSP, and polyene, is an appealing option supported by promising data. In our experience, this treatment schedule with CSP and LD dAmB appeared effective in critically ill pts with IFI failing primary treatment. The synergistic activity of dAmB, even at LD, plus CSP seems to be clinically relevant; LD dAmB allows not only a lower incidence of side effects, but also a remarkable cost sparing in comparison with lipid formulations. Moreover, compared to the available clinical data in similar situations, both time to clinical stability, and to discharge from ICU appear shortened in patients under CAT. Wider clinical studies in these selected settings are needed to clarify the impact on survival of this salvage treatment schedule.

0202

HIGH INCIDENCE OF INVASIVE FUNGAL SINUSITIS IN PATIENTS UNDERGOING UNDERGOING INDUCTION THERAPY FOR ACUTE MYELOID LEUKAEMIA OR MYELODYSPLASIA WITH FLUDARABINE AND CYTARABINE BASED REGIMENS: A RETROSPECTIVE ANALYSIS

T. Todd,[1] M.W. Besser,[2] E.J. Gudgin,[2] D.A. Enoch,[3] C. Crawley,[4] J.I.O. Craig,[4] M.S. Young Min,[5] J. Cargill,[5] P. Sartori,[1] H.A. Ludlam,[6] G.A. Follows,[1] R.E. Marcus[1]

[1]Addenbrooke's Hospital, CAMBRIDGE; [2]Dept.Haematology, Addenbrooke's Hospital, CAMBRIDGE; [3]Dept.Microbiology, Addenbrookes Hospital, CAMBRIDGE; [4]Dept Haematology, Addenbrooke's Hospital, CAMBRIDGE; [5]Dept.Haematology, West Suffolk Hospital, BURY ST.EDMUNDS, SUFFOLK; [6]Addenbrookes Hospital, CAMBRIDGE, United Kingdom

Background. Invasive fungal infections have been relatively well documented in stem cell transplantation4 (SCT) but not in the setting of intensive chemotherapy (ICT) alone. Aspergillus species are the commonest causative organism. Optimal treatment involves systemic antifungal therapy, combined with surgical debridement 1,6. Reported mortality is 40-70%5,7 and long term morbidity approaches 70%. *Aims*. We evaluated the impact, and differential incidence, of IFS in patients with de novo, relapsed or refractory acute myeloid leukemia (AML) or myelodysplasia (MDS) who received either fludarabine plus cytarabine (FLA) based induction chemotherapy or alternative ICT. *Methods.* All 121 patients from 2 centres with a primary diagnosis of AML or MDS who received ICT between 1 January 2003 and 1st October 2006 were retrospectively included in the study. Over that time 39/121 patients received FLA based regimens. Records of hospital maintenance/ construction activity, climatic data and microbiological surveillance were also reviewed. IFS was classified according to current EORTC/ BAMSG criteria. *Results.* 5 proven, 1 probable and 1 possible cases of IFS were identified. The latter was excluded due to subsequent identification of a possible dental abscess. By univariate analysis there was no significant difference between the FLA and other ICT group in median age, sex, duration of neutropenia and incidence of positive blood cultures (table 1). The FLA group contained significantly more patients with relapsed/ refractory AML. All patients received prophylactic fluconazole except during a brief period of minor construction work on one unit when itraconazole was used. IFS occurred only in the FLA group (Chi2 analysis $p<0.001$) and in all but 1 patient developed within 21 days of receiving FLA. No other possible contributory factors were identified. During the study period 260 patients underwent haemopoietic SCT (179 autologous, 81 allogeneic). None developed IFS. 129 patients received ICT for acute lymphoblastic leukaemia with one episode of IFS and one patient with aplastic anaemia developed Mucor spp IFS whilst on iron chelation. Treatment included surgical debridement (4 cases) and liposomal amphotericin B (L-AmB). Treatment commenced at 1-3 mg/kg/day but all cases clinically progressed and ultimately required at least 5mg/kg/day, however the total cumulative per kilogram dose varied considerably. Two patients also received caspofungin and clinically improved within 48 hours but this coincided with L-AmB dose escalation and neutrophil recovery. 2 patients received intravenous voriconazole in addition to L-AmB for 72 hours. Two patients had significant long term morbidity. No patient died due to IFS. Of 5 patients scheduled for further ICT, 4 had subsequent treatment delayed (35 to >50 days) and 1 had treatment abandoned. Two of this group died of relapsed haematological disease. *Summary and conclusions.* A major change in AML/ MDS remission induction therapy over the last decade has been the introduction of FLA based regimen. Recent studies have questioned both their superiority compared to other regimens especially in view of profound immunosuppression due to fludarabine. Our study highlights a high incidence of IFS as a previously unrecognised consequence of FLA chemotherapy in patients with previously treated or de novo myeloid malignancy.

Table 1. Characteristics of the patient cohorts.

0203

ERYTHROCYTE POPULATIONS WITH CD55 AND/OR CD59 DEFICIENCY IN PATIENTS WITH HIV INFECTION AND HEMOPHILIA

A. Sarantopoulos,[1] E. Terpos,[2] A. Kouramba,[1] O. Katsarou,[1] J. Stavropoulos,[2] S. Masouridi,[1] J. Meletis,[1] A. Karafoulidou[1]

[1]Laikon General Hospital, ATHENS; [2]251 General Airforce Hospital, ATHENS, Greece

Background. Anemia is present in almost 35% of patients with HIV infection. Its pathogenesis is multifactorial and includes chronic inflammation, anti-viral agents, hemolysis, etc. Myelodysplastic syndrome (MDS)-like features have also been described in HIV. CD55 and CD59 are complement regulatory proteins that are linked to the cell membrane via a glycosyl-phosphatidylinositol anchor. They are reduced mainly in paroxysmal nocturnal hemoglobinuria (PNH) and other hematological

disorders, such as MDS. An increased sensitivity of lymphocytes from HIV-infected patients to lysis by complement has been directly correlated with a decreased expression of CD55 and CD59. The aim of this study was to evaluate the presence of CD55 and/or CD59 deficient erythrocytes in HIV patients and explore possible correlations with clinical parameters. *Patients and Methods.* CD55 and CD59 expression was evaluated in erythrocytes surface of 37 patients (30M/7F; median age 39 years) with HIV infection. Twenty five of them were hemophilia patients. At the time of evaluation, all patients were under antiretroviral therapy. The detection of CD55- and CD59-deficient red cells was performed using the sephacryl gel microtyping system (DiaMed-ID MicroTyping System PNH test, Cressier-sur-Morat, Switzerland). The presence of the deficient red cell populations was blindly scored by two independent observers and expressed semiquantitatively as 100%, 75%, 50%, 25% and 10%. In all samples with CD55- or CD59-negative populations Ham and sucrose lysis tests were also performed. Eight patients with PNH and 121 healthy subjects were also studied as control populations. *Results.* Anemia was present in 14/37 (37.8%) HIV patients. Interestingly, we found that all HIV patients had erythrocyte populations with CD55 and/or CD59 deficiency. More specifically, deficient red cell populations for both CD55 and CD59 antigens were detected in 8 patients (21.6%): in seven of them erythrocytes were deficient for both antigens at a proportion of 10%, while one patient had erythrocytes with 25% of CD55 deficiency and 10% of CD59 deficiency. Isolated CD55 negativity was observed in 29/37 patients (78.3%): 26 had red cells with 10% CD55 deficiency and only 3 had erythrocytes with 25% CD55 deficiency. Isolated CD59 deficiency was not detected. Among 121 normal subjects, two of them (1.6%) had red cells with double negativity for CD55 and CD59, while 3 others (2.4%) had erythrocytes with an isolated CD55 or CD59 deficiency; these red cells were counted for not more than 10% of the total. All patients with PNH had a simultaneous CD55 and CD59 deficiency. Positive Ham and sucrose tests were found only in patients with PNH. There was no correlation between the percentage of red cell population with CD55 and/or CD59 deficiency and the type or length of antiretroviral therapy, the $CD4^+$ counts, the plasma viral load or the concomitant hepatitis C infection. *Summary and conclusions.* Our study provides evidence supporting the presence of erythrocytes with CD55 and/or CD59 deficiency in patients with HIV. Further studies using molecular techniques will be required for clarifying the exact role of this deficiency to the increased susceptibility of these populations in complement lysis and the subsequent development of anemia in these patients.

0204

PREVENTION OF OVARIAN DAMAGE DURING CHEMOTHERAPY BY GONADOLIBERINE ANALOGUES ADMINISTRATION

L. Smardova

University Hospital, BRNO, Czech Republic

Background. Frequent negative consequence of chemotherapy is ovarian damage and premature ovarian failure (POF). The risk of POF onset depends mainly on women's age and foliculogenesis status in ovary, chemotherapy regimen used and cumulative dose of single cytotoxic agents. *Aims.* Aim of this prospective case-control study is evaluation of gonadoliberine analogues (GnRH-a) administration to patients with Hodgkin´s lymphoma (HL) during chemotherapy and prevention of ovarian damage depending upon chemotherapy dose and regimen.*Methods.* Study group consists of 72 patients in fertile age (28.4±4.1 years) with HL diagnosis treated in 2004-2005 by curative chemotherapy together with GnRH-a administration according standardized protocol. Patients were divided to 3 groups according clinical stage of disease and risk factors and treated by three types of chemotherapy regimens with increased cytotoxicity (German Hodgkin Study Group protocols): group A - ABVD regimen, group B - baseline BEACOPP and ABVD regimen in combination, group C - dose-escalated BEACOPP regimen. Ovarian function of all patients was assessed by gonadotrophins levels (FSH, LH) analysis from peripheral blood before treatment and also 6 and 12 month after it. Number of women with POF after chemotherapy in study groups was compared with control group (n=45, age 26.8±4.6) of patients treated in 2002-2003 according the same protocol, but without protective GnRH-a application. In statistical evaluation two sample binomial test with α/α=0.05 was adopted together with adjustment of level of statistical significance by Bonferroni correction for multiple tests. *Results.* In study group with GnRH-a administration during chemotherapy there was statistical significantly (p<0.001) less cases with POF (38.2%) in 6 month after end of chemotherapy than in control group (73.4%). After 12 month POF was detected in 48.8% of cases versus 69.3% in control group (p<0.001). Comparative analysis depending on cytotoxicity of chemotherapy regimen used showed statistically significant differences in percentage of patient with acquired POF between study and control group only in less aggressive chemotherapy protocols (group A and B). Difference in number of cases with POF in patients treated with chemotherapy regimen C was not statistically significant (74.1% vs. 63.5%) in both observation periods. *Summary and Conclusions.* Study proved significant reduction of ovarian failure risk in women with HL treated with less aggressive chemotherapy regimens. Reproductive functions protection in fertile women requires early and close cooperation between oncology department and assisted reproduction center.

PEGYLATED G-CSF AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

C. Annaloro,[1] P. Usardi,[1] A. Della Volpe,[1] F. Onida,[2] C. Basilico,[1] G. Lambertenghi Deliliers[2]

[1]Fondazione Ospedale Maggiore Policlinico, MILANO, Italy; [2]Università degli Studi di Milano, MILANO, Italy

Background. It has been claimed that, in patients receiving aggressive chemotherapy, pegylated G-CSF has advantages over conventional G-CSF in terms of PMN recovery, infectious complications and the duration of hospitalisation. *Aims*. The aim of this study was to compare the efficacy of pegylated and conventional G-CSF in autografted patients receiving the same supportive therapy. Methods Over the last 12 months, 38 consecutive autografted patients received pegylated G-CSF on day +1 to shorten the duration of neutropenia. The baseline diagnoses were AML (1), HD (3), multiple myeloma (18) and NHL (16); the conditioning regimens were Mel-200 in 22, BCNU-containing in seven, TBI-containing in three, and melphalan/mitoxantrone in six. The patients were comparable in age, gender and the number of infused CD34 cells with a historic group of 86 patients autografted in the previous three years, who had received daily G-CSF 5 mcg/kg from day +5. Their baseline diagnoses were AML (5), HD (7), multiple myeloma (36) and NHL (38), and the conditioning regimens were Mel-200 in 46, BCNU-containing in 23, TBI-containing in six, and melphalan/mitoxantrone in eleven. All of the patients received oral levofloxacin 500 mg and fluconazole 400 mg as prophylaxis for febrile neutropenia. Febrile episodes were treated with an empiric antibiotic combination including piperacillin/tazobactam and amikacin; empirical antifungal therapy was started after five days of ineffective antibiotic therapy. The selected study endpoints were time to PMN (>500/mcL) and platelet recovery (>50.000/mcL), the number of febrile episodes, the rate of empiric antifungal therapy, the duration of hospitalisation, and the number of G-CSF administrations in the control group. *Results*. There was no significant difference between the patients receving or not receiving pegylated G-CSF in terms of PMN recovery (median 10 vs 11 days), platelet recovery (14 vs 14 days), hospitalisation (17 vs 17 days) or empiric antifungal therapy; the median duration of treatment in the G-CSF group was eight days (range 6-30). There was a significant between-group difference in the number of febrile episodes (p<0.05); considering the patients receiving Mel-200, 11/22 remained afebrile in the pegylated group and 10/45 in the control group (p=0.02). Conclusions In our two groups of autografted patients receiving the same supportive therapies but different types of G-CSF, the use of pegylated G-CSF led to no advantage in terms of most of the considered endpoints, and the number of G-CSF administrations in the control group does not suggest any significant cost reduction with the pegylated form; PMN recovered earlier after pegylated G-CSF, but larger series are required to show a possible significant difference. Nevertheless, the patients receiving Mel 200 (accounting for about half of both groups) form a subset that may benefit from pegylated G-CSF, which proved to be effective in reducing the number of febrile episodes, thus improving their quality of life and avoiding the possible toxicity of antimicrobial agents.

0206

POTENTIAL ROLE OF CMV IN THE ONTOGENY OF MONOCLONAL TCRαβ+/CD4+ T-LARGE GRANULAR LYMPHOCYTE [LGL] LYMPHOCYTOSIS

R.C. Arancha,[1] A.C. Garcia-Montero,[1] J. Almeida Parra,[1]
P. Barcena Carrasco,[1] S. Muñoz-Criado,[1] F. Ruiz-Cabello,[2] A. Orfao[1]

[1]Salamanca University SALAMANCA; [2]Virgen de las Nieves Hospital, GRANADA, Spain

Background. Patients with TCR-Vβ13.1+/CD4+ T-LGL lymphocytosis display a common HLA-DRB1*0701 genotype and express identical motifs in the CDR3-TCR-Vβ sequence, suggesting an antigen-driven chronic T-cell stimulation origin for this particular disease.[1] Interestingly, peripheral blood [PB] CMV-specific CD4+ T-cells from healthy adults are mostly antigen-experienced cytotoxic T-cells, which show a marked bias of the TCRVβ repertoire associated with certain HLA genotypes.[2] Of note, the expansion of CMV-specific TCR-Vβ13.1+ CD4+ T-cells was associated with the HLA-DRB1*0701 allele. Thus, CMV would be a good candidate to play a role in the ontogeny of monoclonal TCRαβ+/CD4+ T-LGL lymphocytosis. *Aims.* To identify and characterize the CMV-specific clonal CD4+ T-cells from patients with different T-cell chronic lymphoproliferative disorders [CLPD]. *Methods.* PB samples from patients with monoclonal TCRαβ+/CD4+ T-LGL lymphocytosis [n=12], TCRαβ+/CD8+ LGL leukemias [n=2], TCRγδ+ LGL leukemias [n=4] and other CD4+ T-CLPD than LGL [n=9], were stimulated for 6h with both CMV and EBV whole lysates. Identification of virus-specific CD4+ T-cells was assessed by flow cytometry, through the detection of surface TNFα on secreting cells. Soluble levels of IFNγ, TNFα, LTα, GM-CSF, IL-2, IL-3, IL-4, IL-5, IL-6, IL-9, IL-10, IL-12 and IL-13 in culture supernatants were quantified using the Cytometric Bead Array(TM) system [BDB]. Surface detection of CD69 and CD25 as well as intracytoplasmic detection of IFNγ in CD4+ T-cells were both performed in TCRαβ+/CD4+ T-LGL patients, to evaluate CMV and EBV-specific responses after longer periods of stimulation [24-48h]. *Results.* Most patients [92%] were found to be CMV- and EBV-seropositive. However, the percentage of patients with CMV-specific CD4+/TNFα+ T-cells was significantly higher in TCRαβ+/CD4+ T-LGL lymphocytosis [83%] than in either non-CD4+/T-LGL leukemias [17%] or non-LGL/CD4+ T-CLPD [22%]. Furthermore, the former cases produced larger amounts of both IFNγ [$p<0.001$] and TNFα [$p=0.002$] Th1 cytokines in response to CMV. Interestingly, TCRαβ+/CD4+ T-LGL patients showed a percentage of clonal CMV-specific TNFα+/CD4+ T-cells significantly higher than that of normal residual CMV-specific TNFα+/CD4+ T-cells [median 4% vs 0.9%; $p=0.02$]. In contrast, the percentages of EBV-specific TNFα+/CD4+ T-cells were similar within clonal and normal CD4+ T-cells [median 0.1%]. The response of clonal CD4+ T-cells to CMV maintained stable after long periods of stimulation, as shown by the high percentage of CD69+ and CD25+ CMV-specific T-cells [~40%] observed after 48h stimulation. Likewise, the percentage of IFNγ+/CD4+ T-cells was significantly higher [$p=0.04$] in response to CMV [median 10%] than to EBV [median 1.2%]. *Summary and conclusions.* The specific response of clonal TCRαβ+/CD4+ T-LGL cells to CMV suggests that the T-cell expansion could originate in a CMV-driven chronic T-cell stimulation.

THE IMPACT OF ORAL CANDIDIASIS AND HERPES SIMPLEX VIRUS INFECTION ON CHEMOTHERAPY-INDUCED ORAL MUCOSITIS

Y.K. Chen, P.R. Hsueh, C.L. Kao, Y.C. Chen, M. Yao, S.Y. Huang, W.C. Chou, B.S. Ko, C.Y. Chen, J.L. Tang, W. Tsay, Y.C. Chen, H.F. Tien

National Taiwan University Hospital, TAIPEI, Taiwan

Background and Aims. Oral mucositis is an important problem in patients receiving chemotherapy. Multiple factors influence the severity of mucositis. We evaluated the role of oral candidiasis and herpes simplex virus (HSV) infection in chemotherapy induced oral mucositis. *Methods.* We retrospectively reviewed charts of patients receiving chemotherapy for hematological malignancies at National Taiwan University Hospital from January 2005 to November 2006. 136 episodes (in 81 patients) of chemotherapy-induced oral mucositis that had been evaluated by cultures for both fungus and HSV were analyzed. The results were correlated with associated clinical features. *Results.* Among the 81 patients, 38 were males and 43 were females and the median age was 47 years. The hematological malignancies these patients had included AML (n=26), NHL (n=24), ALL (n=15), MM (n=11), HD (n=1), acute biphenotypic leukemia (n=1), CML (n=1), CLL (n=1) and myelofibrosis (n=1). 76% (n=103) of the mucositis were detected at the time when absolute neutrophil counts were below 1000/μL. Overall, 104 episodes (76%) of the oral mucositis were related to either fungal or HSV-1 infections, including 63 episodes (46%) of fungal infection alone, 23 episodes (17%) of HSV-1 infection alone and 20 episodes (15%) of both fungal and HSV-1 infections. Among the 83 episodes of fungal mucositis, C. albicans was the most common pathogen isolated (69 episodes), followed by C. tropicalis (8 episodes). Thirty-three of the 84 patients (39%) who had received anti-fungal agents before the occurrence of mucositis had HSV-1 infection, compared with 10 of the 52 (19%) who had not ($p=0.0221$). Those patients with HSV-1 infection suffered from grade 3~4 mucositis more frequently (13/43 versus 12/93, $p=0.0302$) and tended to depend on longer TPN ($p=0.0447$) for nutritional support and topical lidocaine for symptomatic relief (17/43 versus 17/93, $p=0.0107$). *Conclusions.* These results suggest that Candida albicans and HSV-1 play an important role in oral mucositis. It is essential to perform fungal culture and HSV isolation promptly once mucositis occurs after chemotherapy and to start empirical treatments immediately. HSV infection should be considered in the differential diagnosis of oral mucositis particularly in those patients who have prior antifungal therapy.

0208

CONTRIBUTION OF GALACTOMANNAN DETECTION FOR EARLY DIAGNOSIS OF INVASIVE ASPERGILLOSIS IN DIFFERENT GROUPS OF HEMATOONCOLOGICAL PATIENTS

Z. Racil, I. Kocmanova, B. Wagnerova, M. Lengerova, J. Mayer

University Hospital Brno, BRNO, Czech Republic

Background. Invasive aspergillosis (IA) has been a significant cause of life-threatening opportunistic infections in hematooncological patients (pts.). Serum galactomannan (GM) detection is considered to be a useful test for early diagnosis and follow 'up of invasive aspergillosis. *Aims.* To assess the role of galactomannan detection for diagnosis of IA in various groups of pts. with hematological malignancy. *Methods.* From 5/2003 to 10/2006 patients at risk for IA, with hematological disorders and/or bone marrow transplant, were monitored for GM using a double sandwich ELISA assay (Platelia Aspergillus, BioRad, France). Test positivity was defined in accordance with the manufacturer's recommendations (index of positivity - IP>0.5). Patients were considered to have confirmed or probable invasive aspergillosis, based on clinical and radiological data.

Table 1. PPV of GM ELISA in different treatment groups.

Results. 11 360 of blood samples from 911 pts. have been tested for GM (mean no. of samples/pt. - 12.5). 42 pts. in this period had proven or probable IA. 891 samples (8%) had IP > 0.5 and 128 pts (14%) fulfilled criteria to be considered as GM positive (2 x IP >0.5). Sensitivity, specificity, PPV and NPV of the test in the entire group of pts. were 97.6%, 90.1%, 32% and 99.9%. False positivities were significantly more frequent in groups of pts where prevalence of IA is low - 48.8% of false positive results in high risk group (allogeneic HSCT, treatment for AML) vs. 77.6% in low risk group (autologous HSCT and treatment for other hematological malignancies). PPV of the test (very low in the entire group of pts. - 32%) markedly differ in various pts groups: allogeneic HSCT -

75%, induction for acute leukemia - 50%, consolidation for acute leukemia - 33%, autologous HSCT - 10%, other treatment for miscellaneous hematological malignancies - 33%. *Summary and conclusions.* GM detection by Platelia Aspergillus kit is very useful for diagnosis of IA in hematooncological pts. The test has very high sensitivity and especially very high NPV and so negative test result can exclude IA. The main problem of the test is false positivities, especially common in group of hematological pts. with low prevalence of IA. Therefore the regular screening for GM should be performed only in pts. groups were prevalence of IA is high - pts undergoing allogeneic HSCT or treatment for acute leukemia. In low risk group the test should be performed only when there is clinical suspicion of invasive fungal infection and positive result should be interpreted very carefully to avoid overtreatment with expensive new antifungals.

This work was supported by grant of Ministry of Health of the Czech Republic (IGA NR8452-3/2005).

INCIDENCE OF INVASIVE ASPERGILLOSIS IN ALLOGENEIC STEM CELL TRANSPLANTATION RECIPIENTS: AN ITALIAN PROSPECTIVE MULTICENTER STUDY

N. Mordini,[1] D. Mattei,[1] B. Bruno,[2] A. Busca,[3] B. Allione,[4] F. Carnevale Schianca,[5] R. Sorasio,[2] A. Davit,[1] M. Rotta,[2] D. Rapezzi,[1] M. Boccadoro,[2] A. Levis,[4] M. Aglietta,[5] E. Gallo,[3] A. Gallamini[1]

[1]ASO S.Croce e Carle, CUNEO; [2]University of Turin, TURIN; [3]S.Giovanni Battista Hospital, TURIN; [4]SS. Antonio e Biagio Hospital, ALESSANDRIA; [5]IRCC, CANDIOLO, Italy

Background. So far only retrospective studies have been published focusing on the incidence of Invasive Aspergillosis (IA) in allogeneic hematopoietic stem cell transplantation (alloSCT). *Patients and Methods.* Between December 2003 and October 2005, 206 patients admitted to four Piedmont Hematological institutions, on behalf of *vita vitae* project. Patients, accounting for 217 alloSCT, were consecutive enrolled in the trial on the role of combined intensive screening for circulating galactomannan (GM) and early high resolution chest CT (HRCT) for IA diagnosis. GM sampling were collected twice in a week from admittance until day +365; HRCT and/or bronchoscopy with bronco-alveolar lavage (BAL) were performed when IA was suspected. AlloSCT were performed for: Multiple Myeloma (61), Lymphoma (39), Acute Leukemia (64), Myeloprolipherative Disorders (15), Severe Aplastic anemia (2), solid tumor (14) and Chronic Lymphocytic Leukemia (8). Donors were HLA-Identical siblings (179) or alternative (38). Stem cell source was peripheral (190), cord blood (2) and bone marrow(15). Conditioning was myeloablative (104) or Reduced-intensity (113). Previous autologous SCT was done in 82 patients. One-hundred-fifty-five patients underwent alloSCT in PR and 72 in CR. Acute and chronic Graft versus Host Disease (GvHD) affected 157 alloSCTs. Only proven and probable IA, diagnosed according to the EORTC/MSG criteria were considered for the analysis of IA incidence. *Results.* With a follow-up range of 12 to 34 months, 115 patient were alive and 91 had died. Relapse accounted for 57 deaths, transplant related mortality (TRM) for 58, including 10 due to IA Twenty-five cases of IA were diagnosed: 2 proven and 23 probable. Six cases were classified as early IA (within day +40 from SCT) and 19 as late IA (beyond day +40 to one year), with an overall incidence of 11,5%. Neutropenia <500/mm^3) was observed in 7/25, persistent fever in 10 and GvHD in 17. Diagnosis of IA was made thanks to high GM serum values in most patients (23/25), in one for Aspergillus spp. detection on BAL and in one for high GM values on CSF fluid. Chest CT scan contributed to IA diagnosis in 23/25 patient; in more than half of them(14/23), major clinical criteria were present. The remaining 2 cases were CNS aspergillosis. In 15/23 CT positive patients GM elevation occurred before CT scan, and in 13 of them GM was the trigger for further evaluation, in absence of clinical suspect of IA. No deaths due to aspergillosis were observed among the early IA. Among 19 late IA, only 10 patients had died for overt IA. *Conclusions.* The IA incidence is 11.5% in our experience, with a lethality rate for IA of 40%. This figure compares favourably with previous published mortality rates up to 60-90%. Such combined GM/ HRCT diagnostic approach allows an early IA diagnosis, a prompt preemptive antifungal treatment, with a significant lowering of IA attributable death.

0210

CMV SPECIFIC TETRAMERS MONITORING PATIENTS AFTER STEM CELL TRANSPLANTATION

S. Borchers, G. Grabow, S. Luther, A. Ganser, E.M. Weissinger

MHH, HANNOVER, Germany

Background. The reactivation of latent viruses like Cytomegalovirus (CMV) contributes significantly to morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). Risk factors for the reactivation of CMV are the conditioning regimen, prophylaxis of graft versus host disease (GvHD), like T-cell depletion of the graft, the development and treatment of acute or chronic GvHD. Moreover, transplantation of a CMV-seropositive recipient with cells from a CMV-seronegative donor is a risk factor for recurrent reactivation of CMV. To control viral reactivation, the existence of virus-reactive T-cells is crucial. *Aims.* In order to improve the understanding of restoration of CMV-immunity, we monitored absolute numbers of CMV-reactive cytotoxic T-cells using MHC-I-peptide-tetramers available for the major HLA class I groups. In addition we checked the percentage of patients that can be monitored with one or more currently commercially available tetramers to answer the question, whether this technique is suitable as a standard test. In some patients reactivity of tetramer-positive T-cells has been compared with the number of CD8$^+$ IFN-γ secreting cells after stimulation with pp65. *Methods.* Screening for CMV-epitope specific CD8+ T-cells was started prior to HSCT and continued on days +50, +80, +100, + 180 and +365 or weekly in case of CMV reactivation or increased immunosuppressive treatment due to development of GvHD. *Results.* To date we included 53 patients, 26 are currently monitored prior and after Tx, 17 were included past day +100, another 10 are either pre Tx or deceased. The cut off for protection against recurrent CMV-reactivations seems to be 10 CMV-specific T-cells/µL blood. Interestingly, in 2 patients transplanted from seronegative donors CMV-reactive Tcells (total of 13 to 59 cells/µL) were detected around day +50 and seem to provide protection against CMV-reactivation. Taking all patients undergoing HSCT in a certain time period from July 2006 until February 2007 in consideration, 67% of our patients could be monitored after stem cell transplantation with the commercially available set of tetramers. The setting seropositive recipient and seronegative donor contributes 18% of this cohort. Of 36 patients monitored before and after Tx, including those still prior to Tx or deceased, 17 can be monitored with 1 tetramer, 16 patients match 2 and 3 patients match 3 of the tetramers. *Conclusions.* Our results indicate that under certain conditions screening of patients with CMV-specific tetramers is suitable to predict the risk of CMV-reactivation and/or protection against reactivation due to recipient/donor CMV-specific T-cells. Thus, for patients at risk of reactivation suitable therapies, like the infusion of CMV-specific T-cells, can be considered early on. Yet the question how many T-cells binding the tetramers are functionally active has still to be answered. Lack of a compatible HLA-I-tetramer complexes and epitopes, respectively, can be an additional problem. Therefore an intracellular staining test will be used in parallel to answer this questions, while tetramer screening is ongoing.

0211

HUMORAL AND CELL MEDIATED RESPONSE TO THE PNEUMOCOCCAL CONJUGATE VACCINE (PREVENAR) IN PATIENTS WITH MYELOMA AND CHRONIC LYMPHOCYTIC LEUKAEMIA

H. Greenfield,[1] R. Borrow,[2] J. Adams,[1] R. Warrington,[2] P. Balmer,[2] J. Cavet,[3] K. Mutton,[2] J.A. Liu Yin[1]

[1]Manchester Royal Infirmary, MANCHESTER; [2]NW Regional Health Protection Agency, MANCHESTER; [3]Christie Hospital, MANCHESTER, United Kingdom

Background. Infection with Streptococcus pneumoniae is responsible for significant mortality in patients with a defective humoral response. Immunisation with pneumococcal polysaccharide vaccine (PsV) is not always effective in these individuals. Conjugation of polysaccharides renders vaccines more immunogenic through a T-cell dependent mechanism. Impressive results in children lend themselves to evaluation in other high risk groups. *Aims.* To assess the humoral and cell mediated responses to Prevenar in patients with myeloma and CLL. *Methods.* The schedule followed UK Department of Health guidance for vaccination of high risk children; two doses of Prevenar followed by a dose of PsV (Group 1). Patients who had previously received PsV were only offered Prevenar (Group 2). For assessment of humoral immunity we utilised a serotype-specific IgG Bioplex assay for all 7 serotypes in Prevenar, levels of ≥0.35 ∝g/mL are protective. Cellular responses were evaluated using

3H-thymidine uptake in cell cultures. *Results.* Data are available on 30 individuals. Twenty four patients had a diagnosis of myeloma and 6 CLL. The median age was 64 years (range 51-75). Six patients had never required treatment. The median number of prior chemotherapeutic treatments was 2 (range 0-5). Seventeen patients had undergone a transplant procedure. The median time from last treatment was 14.5 months (range 6-69). Eight patients with myeloma were receiving maintenance thalidomide. Two patients had low baseline total IgG levels, 11 low IgM and 8 low IgA. Prior to vaccination, the median number of serotypes per patient with protective antibody levels was 1 in Group 1 [n=20], (range 0-6) and 4 in Group 2 [n=10], (range 0-7). Following vaccination the median number of serotypes with protective antibody levels increased to 5 in Group 1 (range 1-7). 45% of patients achieved an adequate response. In Group 2 the median number of serotypes with protective levels remained at 4 (range 0-7). The proportion of patients with an adequate response did not increase. In preliminary experiments, 5 individuals had cellular responses evaluated. Proliferative responses to the protein conjugate were observed only in those who subsequently developed a protective antibody response (3 individuals). *Conclusions.* The pneumococcal conjugate vaccine Prevenar appears to be immunogenic in patients naïve to PsV; however it does not benefit those previously immunised with PsV.

0212

DIAGNOSING LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH HAEMATHOLOGICAL MALIGNANCIES: USE OF THE NEW T-CELL INTERFERON- RELEASE ASSAYS

A. Ferrari,[1] A. Ferrari,[2] M. Losi,[2] F. Luppi,[2] M. Meacci,[2] B. Meccugni,[2] F. Rumpianesi,[2] R. Marasca,[2] M. Luppi,[2] L. Richeldi,[2] L.M. Fabbri,[2] G. Torelli,[2]

[1]Division of Hematology, MODENA; [2]University of Modena and Reggio Emilia, MODENA, Italy

Background. patients with haematological malignancies have an increased risk of progression to active tuberculosis (TB), and TB mortality. The standard diagnostic test for latent tubercolosis infection (LTBI), the tuberculin skin test (TST), may be unreliable in immunosuppressed patients. T-cell interferon-γ (IFN-γ) release assays (TIGRAs) QuantiFERON-TB Gold In tube (QFT-IT) and T-SPOT.TB (TS.TB) hold promise to provide a more accurate diagnosis of LTBI. Blood tests are based on detection of IFN-γ produced by T cells in response to antigen specific M. tuberculosis antigens encoded by the RD1 region. *Methods.* between February 1st 2006 and February 1st 2007 96 patients (mean age 61.3±14.5 years) have been blindly tested with TST, QFT-IT and TS.TB at the time of first diagnosis, about at half of the chemotherapy course and 1 month at least after treatment completion. *Results.* patients were affected by non Hodgkin's lymphoma (n=46), chronic lymphocytic leukemia (n=31), Hodgkin's disease (n=8), multiple myeloma (n=7), idiopathic myelofibrosis (n=1), myelodysplastic syndrome (n=1), hairy cell leukaemia (n=1) and systemic amyloidosis (n=1). Patients were treated according to current institutional protocol. Two patients were excluded due to high background levels with QFT-IT and 1 with TS.TB. At enrolment, 10/96 (10.4%), 21/94 (22.3%, $p<0.001$ vs TST), 24/95 (25.3%, $p<0.001$ vs TST) patients tested positive with TST, QFT-IT and TS.TB, respectively. TIGRAs had moderate agreement with the TST (QFT-IT vs TST k=0.50, TS.TB vs TST k=0.45). QFT-IT had more indeterminate tests (n=4, 4.3%) compared to TS.TB (0%). All TST-positive patients were also positive with both blood tests. Evaluation during treatment of 49 patients showed high concordance between TIGRAs (QFT-G IT vs TS.TB k=0.68) and a lower concordance with the skin test (TST vs TS.TB k=0.52, TST vs QFT-IT k=0.53). In patients after treatment completion (n=20) concordance between TIGRAs was still good (QFT-IT vs TS.TB k=0.64), while concordance with the skin test further dropped (QFT-IT vs TST k=-0.05, TS.TB vs TST k=-0.07). *Conclusions.* TIGRAs provided more positive results compared to the skin test in patients with haematological malignancies, thus suggesting that the prevalence of LTBI in these group of patients may be higher than previously estimated. Results of blood tests seem not to be affected by chemotherapy, while TST efficacy may be more susceptible to immunosuppressive treatment.

0213

POLYMORPHISMS WITHIN CHEMOKINE (CCL5, CXCL12) AND CHEMOKINE RECEPTOR (CCR5) GENES AND THEIR ASSOCIATION WITH THE RISK OF EBV REACTIVATION IN PATIENTS AFTER ALLOGENEIC HSCT

A. Lange,[1] D. Duda,[2] A. Gieryng,[1] A. Kuzyk,[1] S. Madej,[2] A. Lange[2]

[1]L.Hirszfeld Inst. of Immunol. Exp. Ther., WROCLAW; [2]Lower Silesian Center for Cellular Trans, WROCLAW, Poland

Backround. Our former studies showed that the risk of EBV reactivation after allogeneic HSCT is associated with the presence of the low producer IFNG3/3 genotype in the recipient (Bogunia-Kubik et al. Br J Haematol 2006). *Aims.* In the present study the CXCL12 (3'UTR 801 G/A), CCL5 (-28 C/G; -403 G/A) single nucleotide polymorphisms and CCR5D32 deletion were analyzed in 76 HSCT donor-recipient pairs and related with EBV load. The control group for the polymorphism study constituted 99 healthy individuals. *Methods.* DNA was extracted from peripheral blood taken onto EDTA using silica membranes. Viral load were assessed 2-3 months after HSCT in blood cells by qPCR. The detection threshold for viral reactivation equaled 10 EBV-DNA copies/105 peripheral blood cells that were apparent in 27 patients. The CCR5d32 mutation was detected by PCR while SDF-1 and CCL5 alleles by PCR-RFLP. *Results.* Distribution of CCR5, CCL5 -28 and CXCL12 genotypes was similar in patients, donors and controls while CCL5 -403 AA homozygosity was more frequent in donors than controls (0.61 vs 0.47, $p=0.036$). The higher number of EBV copies were detected in patients lacking CCR5>32 deletion (0.42 vs 0.13, $p=0.026$). No significant correlation was found between EBV reactivation and CCL5 -28 C/G or CXCL12 801 G/A polymorphisms. Patients transplanted with donors homozygous for the CCL5 A allele (genotype associated with an increased expression of the CCL5 gene) more frequently presented with EBV reactivation (0.85 vs 0.49, $p=0.002$). In conclusion, the lack/lower expression of functional CCR5 or the presence of CCL5 low producer genotype decreases the susceptibility for EBV reactivation. Lack of the relationship with CXCL12 might be explain by the results of the recent study on the SDF-1 gene expression in EBV-transformed lymphoblastoid cells that did not show any evidence for the contribution of the SDF-1 3'UTR 801 A/G polymorphism to the amount of the SDF-1 mRNA.

Supported by the MNiSW grant No. 2 P05B 085 28.

PULMONARY DISPOSITION OF AMPHOTERICIN B LIPID FORMULATIONS

S. Weiler, H. Vogelsinger, R. Bellmann-Weiler, M. Joannidis, R. Bellmann

Medical University of Innsbruck, INNSBRUCK, Austria

Background. Invasive fungal infections of the lung are a major cause of morbidity and mortality in patients suffering from haematological malignancies. Lipid formulations of amphotericin B (AmB) are a cornerstone in their treatment. The three licensed preparations liposomal AmB (LAMB), AmB colloidal dispersion (ABCD) and AmB lipid complex (ABLC) display considerable differences in their pharmacokinetic behaviour. *Aims.* AmB concentrations in epithelial lining fluid (ELF) and whole lung tissue were determined after administration of AmB lipid formulations in order to investigate their target-site penetration. *Methods.* AmB levels in ELF were measured in bronchoalveolar lavage specimens of 30 critically ill patients, who were on treatment with lipid formulated AmB (LAMB: n=6, ABCD: n=18, ABLC: n=6). The penetration ratio was calculated by comparing the concentrations in ELF with simultaneous levels of lipid formulated AmB in plasma. Whole lunge tissue concentrations of AmB were determined in autopsy material of 29 patients (LAMB: n=7, ABCD: n=13, ABLC: n=9). All samples were concentrated and purified by solid phase extraction. Subsequently AmB was quantified by high-performance liquid chromatography. *Results.* Remarkable differences in the lung penetration of the three AmB lipid formulations were found. After treatment with ABCD and ABLC, mean concentrations in lung tissue were higher than after LAMB (ABCD: 32.62 μg/ml, ABLC: 31.96 μg/mlL, LAMB: 11.63 μg/mL). Mean concentrations in ELF were much lower compared to whole lung tissue. The highest concentrations in ELF, were observed after treatment with LAMB (1.86 μg/ml) and ABLC (1.86 μg/mL) in contrast to ABCD (0.33 μg/mL). The penetration ratio in ABLC- and ABCD treatment was higher than in LAMB therapy. *Conclusions.* The levels of AmB at target-site may depend on the administered formulation. Further studies are required for clarifying the impact of these differences on clinical outcome.

TUBERCULOSIS (TBC) FOLLOWING SINGLE-UNIT MYELOABLATIVE UMBILICAL CORD-BLOOD TRANSPLANTATION (UCBT) FOR ADULTS WITH HEMATOLOGICAL MALIGNANCIES

S. Cantero, I. Jarque, G. Sanz, M. Salavert, I. Lorenzo, G. Martin, A. Sempere, P. Montesinos, J. Sanz, L. Algarra, J. Moscardo, R. Renart, F. Gomis, G. Orti, M.A. Sanz

Hospital La Fe, VALENCIA, Spain

Introduction. Allogeneic hematopoietic stem cell transplantation (allo-SCT) recipients, especially those receiving UCBT, are prone to serious infections, including TBC. Incidence rates of TBC after allo-SCT in several case series vary from less than 0.1 to 5.5%. However, only one study has been published on TBC after UCBT. *Patients and Methods.* Medical records of 106 adult patients with hematological malignancies who underwent single-unit UCBT with a myeloablative conditioning at our institution from May 1997 to December 2006 were retrospectively reviewed for the diagnosis of TBC. Conditioning regimen included thiotepa, busulfan (oral, 43; iv, 63' iv single daily dose, 34), cyclophosphamide (72) or fludarabine (34), and antithymocyte globulin (Lymphoglobulin, 32; Thymoglobulin, 74). All received cyclosporine plus prednisone for graft-versus-host disease (GVHD) prophylaxis and filgrastim to fasten engraftment. Diagnoses were acute lymphoblastic leukemia (ALL) in 37, acute myeloblastic leukemia (AML) in 30, chronic myelogenous leukemia (CML) in 22, myelodysplastic syndrome (MDS) in 9 and other lymphoid malignancies in 8. No patient had personal or family history of TBC prior to UCBT. The pretransplant evaluation of the respiratory system included chest radiographs and pulmonary function tests that were normal in all patients. Sputum smears and cultures for acid-fast bacilli were not routinely obtained. A diagnosis of TBC was based on the identification of M. tuberculosis in at least one fluid or tissue specimen (sputum, bronchoalveolar lavage, pleural fluid, lymph node). *Results.* Median age and weight were 31 yr (range, 15-49) and 71 kg (range, 41-112). HLA match (HLA-A and -B at antigen and -DRB1 at allelic level) was 6/6 in 6 (6%), 5/6 in 39 (37%), and 4/6 in 61 cases (57%). The median number of nucleated cells and $CD34^+$ cells infused was 2.1×10^7/kg and 1×10^5/kg respectively. Median time to neutrophils > 0.5×10^9/L was 22 days (range, 11-57). Mycobacterium tuberculosis infections were diagnosed in six of the 106 patients (5%). They had no different risk factors for TBC compared with the other 100 patients. Their detailed clinical characteristics are shown in Table 1. Patient #1 had a Mycobacterium kansasii infection 6 months before TBC. Patients were scheduled to receive antituberculous treatment according to drug susceptibility patterns for at least 6 months. Patients #2, #5, and #6 died of disseminated TBC. *Conclusions.* TBC is an infrequent but severe infection after allo-SCT, and is associated with high mortality, especially when occurring within 3 months of transplantation. It can also complicate post-transplant management as antituberculosis drugs frequently interfere with immunosuppressive therapy and they may narrow therapeutic ranges. T-cell recovery is one of the most important factors for curing TBC infection. Shortening the diagnostic delay could also have a pivotal impact on survival. Transplantation centers should maintain a high level of suspicion for TBC in patients receiving UCBT. Screening before UCBT with PPD skin test or other tests should be performed in these patients.

PALIVIZUMAB TREATMENT OF RESPIRATORY SYNCYTIAL VIRUS INFECTION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

F. Sicre, M. Robin, R. Peffault de Latour, R. Porcher, C. Scieux, C. Ferry, V. Rocha, K. Boudjedir, A. Devergie, A. Bergeron, A. Gluckman, E. Azoulay, J. Lapalu, G. Socie, P. Ribaud

Saint Louis Hospital, PARIS, France

Respiratory syncytial virus (RSV) infections after HSCT can lead to severe respiratory failure and is associated with a fatal issue in a substantial number of patients (pts). Since palivizumab (P) has been shown to be efficient to lower RSV infection related hospitalization in high risk infant, P has been used in an uncontrolled manner to treat RSV infections in HSCT recipients, including in our transplant unit, with no clear knowledge of its impact on outcome. This study was conducted to determine outcome in HSCT recipients diagnosed with RSV infection and to estimate P impact, if any, on mortality. From January 1999 to March 2006, all pts with RSV infections after HSCT at Saint- Louis Hospital were retrospectively reviewed in order to determine cumulative incidence of RSV-related death, risk factors for 4-month transplant-related-mortality post RSV diagnosis (early TRM), and eventual impact of P. Forty pts with RSV infections were identified (median age : 16 years - range 3 to 65), at a median interval from transplant to RSV diagnosis of 90 days (d) (range: -15 d to 987 d). 24 pts had received an unrelated stem cell graft. Characteristics at diagnosis were: pneumonia in 16, bronchitis or bronchiolitis in 8 and upper respiratory disease in 16 pts; 16 pts had hypoxemia. Among them, 18 received P at diagnosis (15 mg/kg - intravenous course - 1 to 3 monthly injections. Pts treated with P were significantly younger, have received more cord blood transplant, had lower neutrophil and lymphocyte counts, and a shorter interval between transplantation and infection. One-year overall survival was 75% (95% CI: 63-91), corresponding to 77% (95% CI: 60-99) and 75% (95% CI: 59-97) for palivizumab-treated and -untreated patients, respectively. P did not shorten RSV excretion or significantly prevent progression from upper to lower respiratory tract infection Only one patient (treated with P) died from RSV pneumonia alone, giving a 2.6% cumulative incidence of RSV-related death (95% confidence interval (CI): 0-7.7). Seven other pts died during the 4 months following RSV diagnosis. All of them died from respiratory failure of multiple causes (RSV +: n = 4; RSV-: n = 3). Four-month non-relapse mortality was 16% (95% CI: 17-27): 23% (95% CI: 0-50) and 9% (95% CI: 0-22) of patients treated with or without P, respectively. In a multivariate Cox model, the only risk factors for 4-month non-relapse mortality were stem cell source (unrelated cord blood, hazards ratio (HR): 4.9, 95% CI: 1.1-22, p=0.039; and oxygen required at RSV diagnosis (HR: 7.31, 95% CI: 1.8-49, p=0.012). In conclusion this study doesn't support the use of P as an RSV curative therapy after HSCT. Because P was predominantly used in pts with classical poorer prognosis, we cannot robustly test its impact; nevertheless classical poorer prognosis factor were not found to be significant in this study. Given the high cost of palivizumab therapy and the arrival of several new compounds, our findings do not support further use of this drug in an uncontrolled manner.

0217

TUBERCULOSIS AMONG A COHORT OF 35 PATIENTS WITH BLOOD DISEASES

C. Ulibarrena,[1] E. Lavilla,[2] J.L. Sastre[1]

[1]Complexo Hospitalario de Ourense, OURENSE; [2]Complexo Hospitalario Xeral-Calde, LUGO, Spain

Tuberculosis (TBC) is still a common infection in Spain, especially in the North-Western region of Galicia, with Incidence/prevalence rates over 40 cases /100,000 inhabitants. Tuberculous infection in hematological patients has been scarcely studied. *Methods.*We describe the pattern of infection in 35 patients from 3 Hospitals in Galicia. Data were obtained from a questionnaire sent to Hematology Services, which gathered cases form their databases, necropsic reports and reports from Microbiology Services. The diagnostic criteria for TBC were those defined by WHO (010 to 018 in CIE-9 classification); infections needed to be documented with microbiological and/or pathological data. 'Blood diseases' included acute leukemias, myeloproliferative disorders (MPD), myelodysplastic syndromes (MDS), myeloma (MM), lymphoma and aplastic anemia. The diagnosis or TBC should have been made concomitant or subsequent to the hemopathy, not priorly. *Results.* 35 HIV (-) patients were included (median age, 73.7; range 53-86): 15 non-Hodgkin lymphoma; 6 MDS; 5 MPD (3 essential thrombocythemia; 2 CML); 3 MM; 3 acute leukaemia; 3 chronic lymphocytic leukaemia. The involved organs were: lymph nodes, 15 (41%); lung, 14 (35%); kidney, 1; skin, 1; peritoneum, 1; bone, 1; pericardium, 1; 3 cases presented with the miliary form. Diagnosis was obtained by: detection of acid-fast bacilli, 12 cases; culture, 24; examination of tissue, 18 (2 fine-needle aspiration, 16 biopsies). The majority of biopsies came from adenopathies (neck, 10; axilar, 2; mediastinum, 1; 2 unknown). 26 patients have died when data were collected. Post-mortem diagnosis was made in 5 cases (4 lung; 1 peritoneal); the infection could have contributed to the death of other 13. In 12 cases, the diagnosis of TBC and the hematologic disease was concomitant (lung, lymph nodes); in the other 23, TBC was found after the other disease (median interval, 31.7 months; range: 1-90 mo.). In 3 patients there was a history of probable TBC more than 30 yr. before. Only 12 patients had recorded data of PPD test: it was negative in 4; due to several reasons, positivity was followed by prophylaxis with isoniazid only in 1of the remaining 8 (who developed TBC anyway 9 yr. after). According to IDSA criteria, former risk procedures were: glucocorticoids, 19 cases; chemotherapy (including low dose araC), 15; in 11, no adscription to risk groups could be established; 4 received only hydroxyurea. 29 patients diagnosed while being alive received anti-TBC therapy. *Conclusions.* TBC may be extremely proteiform in hematologic patients (especially in the elderly), with a majority of extrapulmonary cases, affecting unusual areas (lymph nodes predominantly). The infection may occur concomitantly or after the start the hemopathy, in both cases posing a difficult diagnostic problem due to the coincidence of symptoms with blood diseases. In highly prevalent areas like ours, TBC must be always taken into account, even in patients not belonging to risk groups, since the delay of therapy may be lethal. PPD test should also routinely performed in hematologic patients, even though its negativity does not preclude latent infection and prophylaxis is not completely protective nor safe.

Myelodysplastic syndromes I

0218

PRION-LIKE DOPPEL GENE (PRND): A NEW MOLECULAR MARKER POTENTIALLY INVOLVED IN LEUKEMOGENESIS

R. Invernizzi,[1] E. Travaglino,[1] C. Benatti,[1] A. Azzalin,[2] B. Rovati,[1] S. Comincini[2]

[1]Fondazione IRCCS Policlinico S. Matteo, PAVIA; [2]University of Pavia, PAVIA, Italy

The PRND gene encodes Doppel (Dpl), a protein that is strongly expressed in testis and at much lower levels in other tissues. Despite the recent discovery of Dpl involvement in spermiogenesis and in apoptotic death of cerebellar neurons, the physiological role of this prion-like protein remains unknown. Recently, we observed a weak Dpl expression in normal CD34$^+$ bone marrow cells, whereas high levels of PRND transcripts were detected in leukemic cell lines as well as in bone marrow cells from patients with acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS). In order to clarify the clinical and biological relevance of Dpl overexpression in these disorders, we searched for possible correlations among Dpl expression, some biological parameters and clinical-pathological features. In some MDS patients we sequentially studied Dpl levels, to evaluate their changes in the time as well as the influence of the disease progression and of therapy, whereas in AML patients treated with aggressive polychemotherapy Dpl levels were sequentially quantified to assess minimal residual disease. Moreover, we characterized PRND transcriptional and translational patterns. Immunocytochemistry, flow cytometry, biochemical and molecular (real-time quantitative PCR) studies were carried out on bone marrow cells from 64 AML patients at diagnosis, after induction therapy and at relapse, and from 98 MDS patients at diagnosis and during disease progression. Controls were 16 non-hemopathic subjects. Dpl, barely detectable in normal controls, was detected in almost all AML and MDS cases, with median percentages of positive cells of 11.5% (IQR 7-24%), and 17.5% (IQR 11-29%) respectively. In AML no significant relationship was observed between Dpl levels and clinical and laboratory features nor did Dpl levels predict response to therapy. In patients achieving complete remission (22/34) a significant reduction of both transcript and protein levels (p=0.02) was observed. In 5 relapsing patients Dpl was again overexpressed at levels similar to those observed at onset. Also in MDS, Dpl levels were unrelated to clinical and laboratory aspects nor did they predict disease progression. Their behaviour was variable during evolution towards acute leukemia. In pathological samples Dpl was abnormally localized in the cell cytoplasm, while normal CD34+ cells exhibited the expected membrane localization. The ectopic localization was probably dependent on abnormal cellular trafficking because of glycosylation pattern modifications of the protein. Moreover, in pathological samples an abnormal nuclear retention of the transcript was observed. In conclusion, our findings confirm the clinical usefulness of Dpl evaluation for AML or MDS diagnosis and for the assessment of minimal residual disease. Moreover, they suggest its possible physiopathological role at least in the early phases of cell transformation. Studies are in progress to better understand which factors may contribute to the modulation of PRND activity: identifying the promoter region and critical elements for the activation of the gene may provide new insights into the involvement of Dpl in leukemic transformation.

0219

BIOLOGICAL AND CLINICAL RELEVANCE OF MATRIX METALLOPROTEINASES 2 AND 9 IN ACUTE MYELOID LEUKEMIAS AND MYELODYSPLASTIC SYNDROMES

R. Invernizzi, E. Travaglino, C. Benatti, L. Malcovati, M.G. Della Porta, M. Cazzola

Fondazione IRCCS Policlinico S. Matteo, PAVIA, Italy

Matrix metalloproteinases (MMP) are a family of zinc-dependent endopeptidases which are able to degrade all the protein components of the extracellular matrix. MMP-2 (type IV collagenase, gelatinase A) and MMP-9 (type V collagenase, gelatinase B) have been implicated in tumor progression and metastasis and, recently, it was suggested that these enzymes may also contribute to leukemic dissemination. We analyzed the expression of MMP-2 and MMP-9 in bone marrow cells from 54 patients with acute myeloid leukemia (AML), 153 patients with myelodysplastic syndrome (MDS) (68 RA, 32 RARS, 31 RAEB, 5 RAEB-t, 17 CMML), not previously treated, and 52 non hemopathic subjects,

in order to evaluate whether abnormalities in their expression were associated with relevant laboratory and clinical findings. Moreover, a possible correlation was investigated between MMP positivity and altered apoptosis level, as measured by TUNEL technique, or altered proliferative activity, as evaluated by MIB-1 immunostaining. MMP-2 and MMP-9 were detected on bone marrow smears by an immunoalkaline phosphatase method (streptavidin-biotin complex) using primary murine monoclonal antibodies raised against human MMP-2 (clone A-Gel VC2, NeoMarkers) and human MMP-9 (clone IIA5, NeoMarkers). In normal samples MMP-2 was detected only in occasional myeloid cells, whereas MMP-9 was expressed in some 20-30% of maturing myeloid cells. Normal $CD34^+$ bone marrow cells did not express MMPs. MMPs were detected in almost all MDS and AML cases. In MDS the percentages of MMP-2 positive myeloid cells (median 34%, IQR 18-49%) were significantly higher than in normal controls ($p<0.0001$); in early forms also MMP-9 positive myeloid cells (median 41%, IQR 29-53%) tended to be more numerous than in normal controls ($p=0.06$). MMP-2 and MMP-9 were often coexpressed in MDS myeloid cells; moreover, many erythroblasts expressed MMP-2. There was a significant positive correlation between MMP-2 erythroblast expression and erythroid dysplasia ($p=0.009$) and a significant inverse correlation between either MMP-2 or MMP-9 myeloid expression and blast cell percentage ($p=0.05$ and $p=0.03$ respectively), whereas MMP expression was independent of the apoptosis levels or proliferative rate. In the whole MDS group a high MMP-2 or MMP-9 expression was associated with significantly longer overall survival ($p=0.008$ and 0.02 respectively) and evolution-free survival ($p=0.03$ and 0.05). In AML percentages of MMP-2 positive cells (median 15.5%, IQR 3-28%) lower than in MDS ($p<0.0001$) but higher than in controls and percentages of MMP-9 positive cells (median 8%, IQR 4-21%) lower than in both MDS and control cases ($p<0.0001$) were observed. MMP levels were unrelated to clinical and laboratory aspects nor did they predict response to therapy. In conclusion, we have demonstrated an abnormal MMP expression profile not only in AML but also in MDS. Our findings suggest that the production and release of these enzymes may influence hematopoietic cell behaviour, possibly by the processing of regulatory proteins in marrow. The detection of their deregulated expression in MDS may be important also from the clinical point of view: it may provide a useful tool for diagnosis, prognosis and a possible target for experimental treatments.

0220

PROPOSED MINIMAL DIAGNOSTIC CRITERIA FOR MYELODYSPLASTIC SYNDROMES

P. Valent,[1] H.-P. Horny,[2] C. Fonatsch,[1] U. Germing,[3] P. Greenberg,[4] T. Haferlach,[5] D. Haase,[6] H.-J. Kolb,[7] O. Krieger,[8] M. Loken,[9] A. Van de Loosdrecht,[10] K. Ogata,[11] A. Background. In most patients with MDS, the diagnosis based on the typical clinical presentation with macrocytic transfusion-dependent anemia and frank dysplasia in bone marrow smears is straightforward. However, not all patients with MDS have these clinical features at diagnosis, particularly at an early phase of disease. Aims and Methods. To assist in evaluation of these *early phase* patients, we propose minimal diagnostic criteria for MDS, sufficient to separate MDS from other diseases and from idiopathic cytopenia of uncertain significance (ICUS). Results. Our Consensus Working Group recommends that these minimal criteria include two required diagnostic prerequisites: constant cytopenia (for at least 6 months unless accompanied by a specific karyotype or bilineage dysplasia, in which case only 2 months of stable cytopenias are needed) and the exclusion of other potential disorders as a primary reason for dysplasia or/and cytopenia. In addition to these two diagnostic prerequisites, the diagnosis MDS requires at least one of three MDS-related (decisive) criteria: i) dysplasia (at least 10% in one or more of the three major bone marrow lineages), a blast cell count of 5-19%, and iii) a specific MDS-associated karyotype, e.g. del(5q), del(20q), +8, or -7/del(7q). Further, several co-criteria have been defined and can help reach the conclusion that the patient has a bone marrow disease resembling (highly suspicious for) MDS. These co-criteria include flow cytometry, bone marrow histology and immunohistochemistry (to detect or exclude fibrosis, dysplastic megakaryocytes, or an increase and atypical localization of immature progenitors, ALIP), and colony forming progenitor assays. These investigations help to distinguish MDS from patients with ICUS, a condition defined by unexplained constant cytopenia without the minimal diagnostic criteria of MDS. Summary. our newly proposed diagnostic criteria for MDS and for ICUS should assist in early and improved diagnosis and management of these patients.

0221

STEM CELL CULTURES AS A DIAGNOSTIC TOOL IN MYELODYSPLASTIC SYNDROMES

S. Vercauteren,[1] A. Eaves,[2] C. Eaves,[2] A. Karsan[1]

[1]BC Cancer Research Centre, VANCOUVER; [2]Terry Fox Laboratory, VANCOUVER, Canada

The diagnosis of myelodysplastic syndrome (MDS) can be difficult as some of the hallmarks of the disease, cytopenias and dysplasia, can occur in other malignant and non-malignant conditions. Cytogenetic abnormalities are helpful in establishing the diagnosis, but are only seen in 40-70% of patients. The quantity and quality of specific hematopoietic progenitors can be assessed using stem cell cultures. Small studies have shown abnormal stem cell cultures in MDS patients, but no large study has evaluated stem cell cultures as a diagnostic tool in MDS. We investigated whether the different MDS subgroups can be distinguished from normal controls using stem cell cultures. We also evaluated whether stem cell cultures can be used in identifying MDS patients with normal cytogenetics and blast count <5% to discriminate this group from normal controls or patients with non-malignant cytopenias and dysplasia. Results of stem cell cultures performed on bone marrow (BM) and peripheral blood (PB) cells of MDS patients (BM and PB n=186, BM only n=43 and PB only n=20) and normal controls (BM n=50 and PB n=30) were examined. Cells were cultured in methylcellulose medium containing 50 ng/mL stemcell factor, 10 ng/mL GM-CSF, 10 ng/mL IL-3, 10 ng/mL IL-6 and 3 units/ml erythropoietin. Colonies were counted at day 16. Patients were subclassified based on the FAB classification. In the BM, an increase was seen in the total number of progenitors in patients with RAEBIT ($p=0.01$) and a decrease in patients with RARS ($p<0.01$), del5q syndrome ($p=0.05$) and MDS-NOS ($p=0.01$). A significant decrease in number of CFU-E (colony-forming unit-erythroid) and BFU-E (burst-forming unit-erythroid) was seen in all subgroups of MDS (p"0.01). CFU-GEMM (colony-forming unit-granulocyte, erythrocyte, monocyte, megakaryocyte) were lower in RARS ($p<0.01$), RAEB ($p<0.01$), del5q syndrome ($p<0.01$) and MDS-NOS ($p<0.01$). CFU-GM (colony-forming unit'granulocyte-macrophage) was significantly higher in RAEBIT ($p<0.01$), del5q syndrome ($p=0.03$) and MDS/MPD ($p<0.01$). In the PB we observed an increase in total progenitors in RAEBIT ($p=0.01$) and MDS/MPD ($p<0.01$); a decrease in BFU-E in RARS ($p<0.01$), RAEB ($p<0.01$), RAEBIT ($p<0.01$) and del5q syndrome ($p=0.02$); a decrease in CFU-GEMM in RARS ($p<0.01$), RAEB ($p<0.01$), RAEBIT ($p<0.01$) and del5q syndrome ($p=0.02$); and an increase in CFU-GM in patients with RA ($p=0.04$), RAEBIT ($p<0.01$), del5q syndrome ($p<0.01$) and MDS/MPD ($p<0.01$). MDS patients with normal karyotype and blast count <5% (BM and PB n=54, BM only n=14 and PB only n=7) could be distinguished from normal controls and patients with non-malignant cytopenias and dysplasia by a decrease in total progenitors ($p<0.01$ and $p<0.01$ respectively) in the BM. Erythroid progenitors and CFU-GEMM were also significantly decreased compared to normal and the non-malignant group (CFU-E $p<0.01$ and $p=0.01$, BFU-E $p<0.01$ and $p<0.01$, CFU-GEMM $p<0.01$ and $p<0.01$). No significant differences were seen in the PB. In conclusion, stem cell cultures not only distinguish between normal controls and the subgroups of MDS, they are also helpful in discriminating between patients with MDS and patients with non-malignant cytopenias and dysplasia. More importantly, these findings can give insight into the pathogenesis of this set of diseases.

0222

COMPARISON OF IWG 2006 AND IWG 2000 RESPONSE CRITERIA FOR ANEMIA OF MDS IN 419 PATIENTS: THE GFM EXPERIENCE

C. Kelaidi,[1] S. Park,[2] S. Grabar,[2] O. Beyne-Rauzy,[2] F. Picard,[2] D. Vassilieff,[2] V. Coiteux,[2] G. Leroux,[2] P. Lepelley,[2] H. Dombret,[2] M.T. Daniel,[2] S. Cheze,[2] B. Mahé,[2] L. Adès,[2] A. Ferrant,[2] C. Ravoet,[2] N. Vey,[2] M. Escoffre-Barbe,[2] L. Aljassem,[2] F. Dreyfus,[2] P. Fenaux[2]

[1]Hôpital Avicenne, BOBIGNY, France; [2]GFM, PARIS, France

Backgground. Correction of anemia is an important goal in low risk MDS. Erythroid response criteria were recently modified (IW 2006) with elimination in particular of minor responses. *Aims*. In order to evaluate IW 2006, we compared responses according to IWG 2000 and 2006 criteria in a cohort of lower risk MDS. *Methods.* 419 MDS pts including 61 RA, 68 RCMD, 81 RARS, 57 RCMD-RS, 93 RAEB-1, 26 RAEB-2, 17 5q-syndromes and 16 CMML, median age 73.5 years, with Hb <10 g/dL and RBC transfusions in 55% patients, received 30,000 to 60,000 U/week of EPO or 300 mg DAR±G-CSF during at least 12 weeks in GFM centers(Park S et al, ASH 2006 #522). IPSS score was low, int-1, int-2 and high in 38%, 49%, 11% and 2%. *Results.* According to IWG 2000 criteria, the overall response rate was 63% (41% major and 22% minor) and median response duration 20 months, (24 and 14 months for major and minor responses). Predictive factors of response were endogenous EPO <200 UI/L, transfusion <2 RBC/month, IPSS low and int-1 but not WHO classification. With IWG 2006 criteria, 49% of the patients became responders and median response duration was 24 months. Prognostic factors of response were similar to those using IWG 2000 criteria except that IWG 2006 lowered response rates mainly in RARS, RCMD-RS and RAEB-1 (p=0.02 for responses in RARS+RCMD-RS vs. RA+RCMD, p=0.04 for RAEB-1 vs. MDS with <5% BM blasts) (Table 1).

Table 1.

Significantly shorter response was seen with IPSS>1 and presence of multilineage dysplasia, using both IWG 2000 and 2006. Of 88 minor responders (IWG 2000), 32/88 (36%) and 56/88 (63%) were reclassified as *responders* (R) and *non responders* (nR) with IWG 2006. R did not differ from nR for EPO level, transfusion requirements and WHO, but tended to differ for% of IPSS low and int-1 (100% in R, 88% in nR, p=0.06). Response duration was 16 months vs. 12.5 months in R vs. nR (p=NS). *Summary and Conclusions.* With switching from IWG 2000 to 2006 multilineage dysplasia and/or sideroblastic anemia tended to be poorer prognostic factors of response. On the other hand, among IWG 2000 minor responders, outcome of those who remained IWG 2006 *responders* could not be distinguished from those who became *non responders*, questioning the elimination of this category which, for instance, could benefit from combination therapy with EPO and other drugs.

0223

FUNCTIONAL CHARACTERIZATION OF ADULT MESENCHYMAL STROMAL CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROME

U. Platzbecker, S. Boxberger, B. Mohr, M. Bonin, G. Ehninger, M. Bornhauser

Universitätsklinikum Carl Gustav Carus, DRESDEN, Germany

Introduction. There is still some debate whether the *microenvironment* or *stroma* is part of the clone or rather has bystander functions in patients with MDS. Interestingly, some studies indicate that mesenchymal cells are cytogenetically and functionally normal, whereas others suggest that important quantitative and functional alterations are present in patients with MDS. Given the complex network of different cell types summarized within the term *stroma* including macrophages, known to be clonally involved, the aim of this study was to characterize mesenchymal stroma cells (MSC) of MDS patients in comparison to normal donors. *Methods.* Bone marrow samples were collected from healthy donors (n=12) and patients with MDS (n=19; 5q-syndrome n=5, RA(RS) n=5, RAEB n=9). After density centrifugation MSC were isolated according to the standard adhesion protocol and further characterized by flowcytometry, cytogenetic analysis, clonogenic (CFU-F) and osteogenic differentiation assays. Additionally, secreted SDF-1 levels and the ability of MSC to support long-term growth of hematopoietic cells (LTC-IC) were determined. *Results.* The efficiency of MSC generation and expansion was highly reduced in some patients. In fact, MSC from one third of the MDS patients seemed to grow slower than controls with a prolonged time to reach confluence. Additionally, preliminary data also suggest decreased levels of secreted SDF-1. Nevertheless, fibroblastic colony formation (CFU-F) was comparable to controls (control: 29.7±13.2; n=8, MDS: 25.±31.83; n=5). Long-term cultures (LTC-IC) showed a profound support and colony formation of healthy $CD34^+$ cells. Like controls, MSC from MDS patients also expressed the typical antigens for MSC being positive for CD 105, CD73, CD166, CD90 and negative for typical hematopoietic markers like CD45 and CD34. Patient specific chromosomal aberrations, being present in hematopoietic cells, could not be detected within the MSC pool by FISH analysis. Additionally, osteogenic differentiation assays resulted in the typical presence of Ca3(PO4)2 crystal deposits detected by von Kossa staining, and an increase in alkaline phosphatase activity. Interestingly, the latter could be inhibited by the incubation with thalidomide (100 ∝M). *Conclusions.* These data do not suggest that MSC are generally involved in the pathogenesis of patients with MDS. Nevertheless, there might be an altered response of MSC to the endogenous environment or exogenous signals e.g. drugs.

0224

CLINICAL RELEVANCE OF CYTOGENETIC EVOLUTION IN MYELODYSPLASTIC SYNDROMES: A STUDY ON 151 PATIENTS

P. Bernasconi,[1] M. Boni,[1] P.M. Cavigliano,[2] I. Giardini,[1] R. Zappatore,[3] S. Calatroni,[1] B. Rocca,[3] I. Dambruoso,[1] M. Caresana,[3] M. Lazzarino[1]

[1]Fondazione IRCCS Policlinico San Matteo, PAVIA; [2]Fondazione IRCSS Policlinico San Matteo, PAVIA; [3]Fondazione IRCCS Policlinico san Matteo, PAVIA, Italy

Our study wants to evaluate whether the cytogenetic pattern may change during MDS outcome, establishes how the newly developed chromosomal abnormalities effect overall survival (OS) and progression-free interval (PFI) and distinguishes chromosomal defects simply indicating karyotipic instability from those truly heralding MDS/AML progression. The 151 patients entered in the study were examined between January 1990 and December 2005 and were included in a larger series of 491 consecutive MDS patients. Seventy-four were females and 77 males; their median age was 60 years (range 18-89). According to FAB classification 30 patients were classified as RARS, 51 as RA, 59 as RAEB and 11 as RAEB-t. WHO classification was applied to 140 patients, 17 classified as RARS, 19 as RA, 12 as 5q- syndrome, 32 as RCMD-RCMDS, one as U-MDS, 28 as RAEB-1 and 31 as RAEB-2. Considering IPSS score, 34 patients were low-risk, 55 intermediate-1 risk, 38 intermediate-2 risk and 24 high-risk. At the time of the analysis 60 patients have experienced MDS/AML progression and 39 have died. Median cytogenetic follow-up was 22 months (range 2-168) and each patient was examined at least three times. On clinical diagnosis a normal karyotype was revealed in 56 patients, a 5q- syndrome in 12, -7 in eight, del(7)(q31q35) in six, +8 in nine, 12p- in seven, 20q- in seven, various defects in thirty-six, and a complex karyotype (with>3 defects) in five. Interestingly, five additional patients presented normal metaphases along with 1-3 metaphases showing defects not confirmed by FISH (non clonal defects). All reverted to a completely normal karyotype on subsequent analyses. Overall, a cytogenetic evolution occurred in a total of 48 patients (31.7%). It significantly predicted MDS/AML progression (p<0.001) and occurred in 35/60 (58.3%) patients who had progressed and in only 13/91 (14.2%) patients who did not. In the former patients the most common defects were +8 (22.4%), 5q- (14.2%), 7q- (8.1%), 17p-(8.1%), 3q-(6.1%), whereas in those with stable MDS various defects were observed in a limited number of cells (1-3%). Considering progressed patients only, cytogenetic evolution occurred in 11/16 normal karyotypes, in 2/3 5q- syndromes, in 3/4 del(7)(q31q35), in 3/8 +8, in 3/5 20q-, in 7/14 various defects and in 2/2 complex karyotypes; in contrast, it occurred at a lower frequency in -7 (2/8 patients). Intriguingly, a patient with the 5q- syndrome developed an additional clone with a single +8 which became predominant upon progression into RAEB-2 and a RA patient showed the disappear-

ance of the original clone marked by t(7;16)(p15;p13) and developed a new clone marked by 5q- along with +8 just before AML progression. In conclusion, i) in our series karyotipic evolution occurred in ablout 31% of patients; ii) some non clonal defects, which presence was not confirmed by FISH, simply signaled the instability of the dysplastic clone; iii) some clonal defects, especially +8, del(7)(q31q35) and 17p-, represented true steps in disease progression; iv) cytogenetic evolution significantly predicted MDS/AML progression and when occurred in patients of the IPSS good risk cytogenetic category completely changed their outcome.

T-CELL RECEPTOR VB CDR3 OLIGOCLONALITY FREQUENTLY OCCURS IN CHILDHOOD REFRACTORY CYTOPENIA

A. de Vries,[1] M.M. van den Heuvel-Eibrink,[1] A.C.H. de Vries,[1] B. Verhaaf,[2] C.M. Niemeyer,[3] J. Stary,[4] K. Schmiegelow,[5] E.R. van Wering,[6] A. Beishuizen,[1] A.W. Langerak,[2]

[1]Erasmus MC Sophia Children's Hospital, ROTTERDAM, Netherlands; [2]Erasmus MC, Department of Immunology, ROTTERDAM, Netherlands; [3]University of Freiburg, FREIBURG, Germany; Charles University, PRAGUE, Czech Republic; [5]National University Hospital, COPENHA; [6]Dutch Childhood Oncology Group, THE HAGUE, Netherlands

Background. Severe acquired aplastic anemia (SAA) and myelodysplastic syndrome (MDS) are rare diseases in childhood. SAA is a bone marrow failure syndrome charecterized by immune mediated destruction of hematopoietic progenitors. MDS is a malignant clonal stem cell disorder, in which the hypoplastic variant is, in case of absence of a cytogenetic clone, difficult to separate from SAA. Recently, studies provided a *molecular signature* of autoimmunity in adult SAA, by showing oligoclonality of TCR Vβ CDR3 region, which is refered to as TCR Vβ skewing. We investigated the value of TCR Vβ repertoire analysis in pediatric MDS-RC and (v)SAA patients. *Methods.* Peripheral blood and/or bone marrow mononuclear samples of patients with (v)SAA (n=38), MDS-RC (n=28) and 18 controls were analysed with Vβ heteroduplex analysis of extracted RNA. *Results.*Skewing was found in 21/38 (55%) of the SAA patients and in 17/28 (61%) of the RC patients. Seventeen patients with clinical SAA showed no oligoclonality. A significant difference in TCR skewing was found between the (v)SAA + MDS-RC patients as compared to the controls (χ^2 analysis, p=0.001), but not between MDS-RC and (v)SAA (χ^2 analysis, p=0.8). In this study paired samples (PB and BM) of 25 cases showed a high correlation between the skewing results in both compartments (Pearson correlation, rr 0.98). *Conclusions.* In this study TCR Vβ repertoire analysis did not discriminate between MDS-RC and (v)SAA. Prospective studies will be necessary to investigate whether there is a role for this molecular tool in pediatric MDS-RC for the identification of a subset of patients that is associated with autoimmunity and therfore could be treated with IST up-front, and whether it can be used for molecular response monitoring.

0226

INVOLVEMENT OF A T-CELL RECEPTOR REPERTOIRE IN THE PATHOGENESIS OF MYELODYSPLASTIC SYNDROMES

T. Momot, J. Koenig, A. Ganser, E.-M. Mischak-Weissinger

Medical School Hannover, HANNOVER, Germany

Background and aims. The involvement of a T cell-mediated autoimmune process in the pathogenesis of the cytopenia in myelodysplastic syndromes is still under evaluation. To further investigate a T-cell involvement in the pathogenesis of MDS we have studied the complementarity-determining region 3 (CDR3) size distribution of the CD3, CD4 and CD8 T-cell receptor (TCR) V-β-chain subfamilies in the bone marrow and peripheral blood samples of MDS patients (n=63). *Methods.* We used the multiplex PCR based technique TCR spectratyping based on the size heterogeneity of the CDR3 region and compared the results with age-matched controls (n=16). *Results.* TCR V-β skewing of T-cell repertoire is more frequent in the bone marrow samples of MDS patients than in the whole blood samples. The most frequently skewing of TCR V-β fragments occurs in V-β short 1 (28%), V-β short 3 (20%) and V-β short 5.3 (25%). CD8 T-cells harbour the most pronounced deviations from a Gaussian distribution of TCR fragment length compared to CD4 T-cells. MDS subtype RA shows a different spectratyping pattern compared with MDS subtype RAEB. Five of the patients are now far enough after different types of therapy to evaluate the changes of the spectratyping pattern. *Summary.* We conclude that TCR V-β skewing is frequent in MDS especially an CD8 T-cells. Normalization of at least 1 initially skewed V-β profile after therapy occurred in 5 MDS patients. The analysis of a potential correlation between response to therapy and normalization of the TCR repertoire still requires a larger population.

0227

PRACTICAL RECOMMENDATIONS ON THE MANAGEMENT OF HAEMATOLOGICAL ADVERSE EVENTS IN MDS PATIENTS TREATED WITH LENALIDOMIDE

A. Giagounidis,[1] M. Cazzola,[2] P. Fenaux,[3] G. Mufti,[4] P. Muus,[5] U. Platzbecker,[6] G. Sanz,[7] L. Cripe,[8] M. Von Lilienfeld-Toal,[9] R. Wells[10]

[1]St. Johannes Hospital, DUISBURG, Germany; [2]University of Pavia & IRCCS Policlinico, PAVIA, Italy; [3]Hopital Avicenne, PARIS, France

[4]GKT School of Medicine, LONDON, United Kingdom; [5]University Medical Center Nijmegen, NIJMEGEN, Netherlands; [6]University Hospital Dresden, DRESDEN, Germany; [7]Hospital Universitario La Fe, VALENCIA, Spain; [8]Indiana University School of Medicine, INDIANAPOLIS, USA; [9]St. Jamess University Hospital, LEEDS, United Kingdom; [10]University of Toronto, TORONTO, Canada

Background. In January 2007, an international group of myelodysplastic syndromes (MDS) specialists reached a consensus on practical recommendations regarding the management of Lenalidomide (Len) treatment in transfusion-dependent intermediate-1/low-risk (IPSS) MDS patients with del5q. *Aims.* The presentation of practical recommendations on the management of haematological adverse events (AE) in MDS patients treated with Len. *Methods.* A moderated round table discussion. *Results.* In published studies, haematological AE have been the most common AE and the most frequent reason for dose adjustment. Transient neutropenia of CTC grade 3 or more occurred in 55%, mostly early in the treatment phase. Weekly monitoring of full blood count (FBC) is mandatory for the first 2 months of treatment, and may be continued biweekly up to 5 months. Biweekly monitoring may be considered thereafter, depending on haematological status. To prevent severe neutropenia, coadministration of G-CSF is recommended if the absolute neutrophil count (ANC) reaches <1000/∝L, or Len can be temporarily discontinued. As neutropenic sepsis is the only reported drug-related cause of death, patients should receive clear guidance how to react in the event of febrile neutropenia. This includes patient education, access to specialised haematological care at all times and application of antibiotics within 3 hours of fever onset. Transient thrombocytopenia of CTC grade 3 or more occurred in 44%. Len should be interrupted if platelets fall <25000/∝L without platelet support. Thrombocytopenia at baseline is not a contra-indication for Len; prophylactic thrombocyte transfusions may be considered until counts rise. Venous thromboembolism (VTE) occurred in 3% of MDS patients receiving Len monotherapy. Concurrent use of erythropoietin may increase the risk of VTE. Although VTE prophylaxis is not generally recommended in MDS patients because of the low incidence and an increased risk of bleeding, patients should be informed about and monitored for symptoms. In patients with VTE it is prudent to interrupt Len treatment and carefully re-introduce once stable anticoagulation has been established. In some patients, polycythaemia may occur. In those cases, Len should be continued and phlebotomy may be considered, depending on ferritin levels. Although usually transient, sometimes treatment interruption may be necessary. *Discussion.* A stringent strategy for the management of haematological AE due to treatment with Len is recommended.

0228

COMPARISON OF HYPOPLASTIC MYELODYSPLASTIC SYNDROME WITH NORMO-/HYPERCELLULAR MDS BY INTERNATIONAL PROGNOSTIC SCORING SYSTEM, CYTOGENETIC AND GENETIC STUDIES

T.-C. Huang, Tien, B.S. Ko, C. Hsu, C.-Y. Chen, W. Tsay, J.-L. Tang, S.-Y. Huang, M. Yao, Y.C. Chen, M.C. Shen, C.H. Wang

National Taiwan University Hospital, TAIPEI, Taiwan

Background. Hypoplastic myelodysplastic syndrome (MDS) differs from aplastic anemia in several ways including bone marrow morphology, cytogenetic changes, and prognosis. The distinction between hypoplastic MDS (h-MDS) and normo-/hypercellular MDS (NH-MDS) remains unsettled. *Aims.* In this study, we aimed to compare h-MDS and NH-MDS patients in terms of clinical and laboratory features, chromosomal abnormalities, genetic and epigenetic markers, and prognosis. Meanwhile, the applicability of International Prognostic Scoring Sys-

tem (IPSS) to h-MDS was also investigated. *Methods*. We retrospectively reviewed medical records of 227 primary MDS patients diagnosed according to the criteria of French-American-British (FAB) classification at National Taiwan University Hospital. Secondary MDS due to antecedent hematological diseases or drugs was excluded. Every patient received bone marrow (BM) aspiration and trephine biopsy simultaneously. All patients were categorized by FAB classification and IPSS. MDS patients with BM cellularity less than 30% were considered as having h-MDS. Metaphase G-banding technique was utilized for chromosome study. Mutations of RAS, AML1, JAK2, PTPN11, KIT and FLT3 internal tandem duplication were analyzed by PCR with pertinent primers followed by direct sequencing. Hypermethylation of SOCS1 and SHP1 was detected by methylation-specific PCR. Demographics, complete blood counts, cytogenetics, genetic and epigenetic markers were all compared by Mann-Whitney U test or Pearson chi-sqaure test. Acute leukemic transformation rate and survival analysis were performed with Kaplan-Meier analysis. *Results*. Among the 37 patients (16.3%) diagnosed as having h-MDS, male-to-female ratio was 3.6 to 1. Mean white blood cell count, absolute neutrophil count and platelet count were significantly lower in h-MDS than in NH-MDS ($p<0.001$, $p=0.002$, and $p=0.014$ respectively). Based on FAB classification, refractory anemia (RA) was the predominant subtype (56.8%) in h-MDS whereas refractory anemia with excess of blast (RAEB) was the most common diagnosis (36.3%) in NH-MDS. Clonal cytogenetic abnormality was detected in 14 (42.4%) of 33 h-MDS patients and 76 (42.2%) of 180 NH-MDS patients who had the study. Monosomy 7 or 7q deletion was not found in h-MDS patients, compared with 16.1% in NH-MDS patients ($p=0.023$). In an array of genetic markers including mutations of RAS, AML1, JAK2, PTPN11, the internal tandem duplication of FLT3, and hypermethylation of SOCS1 and SHP1, there was a trend of lower incidence of RAS and AML1 mutations in h-MDS patients. But the distribution of other genetic alterations in these two groups of patients was not significantly different. Acute leukemic transformation occurred less frequently in h-MDS patients than in NH-MDS patients (8.1% vs. 27.1%, $p=0.005$)(Figure 1). Using Kaplan-Meier survival analysis, International Prognostic Scoring System (IPSS) was proved to be an ideal parameter to predict prognosis in h-MDS patients (median survival: 112 months in patients with low and Int-1 risk subgroups vs. 16 months in those with Int-2 and high risk subgroups, $p=0.002$)(Figure 2), similar to NH-MDS patients (Figure 3). Among patients of low and Int-1 risk subgroups, h-MDS patients had a significantly longer survival than NH-MDS patients (median survival: 112 months vs. 32 months, $p=0.002$) (Figure 4). *Conclusions*. Distinct from NH-MDS, h-MDS has different patterns of hemogram, FAB classification distribution, cytogenetic change and prognosis. IPSS is applicable to prognostic evaluation in h-MDS as in NH-MDS. In MDS patients with Low and Int-1 risk subgroups, h-MDS patients have better prognosis than NH-MDS patients.

PRACTICAL RECOMMENDATIONS ON THE MANAGEMENT OF NON-HAEMATOLOGICAL ADVERSE EVENTS IN MDS PATIENTS TREATED WITH LENALIDOMIDE

A. Giagounidis,[1] M. Cazzola,[2] P. Fenaux,[3] G. Mufti,[4] P. Muus,[5] U. Platzbecker,[6] G. Sanz,[7] L. Cripe,[8] M. Von Lilienfeld-Toal,[9] R. Wells[10]

[1]St. Johannes Hospital, DUISBURG, Germany; [2]University of Pavia & IRCCS Policlinico, PAVIA, Italy; [3]Hopital Avicenne, PARIS, France; [4]GKT School of Medicine, LONDON, United Kingdom; [5]University Medical Center Nijmegen, NIJMEGEN, Netherlands; [6]University Hospital Dresden, DRESDEN, Germany; [7]Hospital Universitario La Fe, VALENCIA, Spain; [8]Indiana University School of Medicine, INDIANAPOLIS, USA; [9]St. Jamess University Hospital, LEEDS, United Kingdom; [10]University of Toronto, TORONTO, Canada

Background. In January 2007, an international group of myelodysplastic syndromes (MDS) specialists reached a consensus on practical recommendations regarding the management of lenalidomide treatment in patients with transfusion-dependent MDS with del5q. *Aims.* To present practical recommendations on the management of non-haematological adverse events (NHAE) in intermediate-1 and low-risk (IPSS) MDS patients with del5q treated with lenalidomide. *Methods.* A moderated round table discussion. *Results.* The most common NHAE of any CTC grade were rash (36%), pruritus (42%) or dry skin (14%). Severe skin reactions were observed in 6%. Most resolve with time and do not necessitate discontinuation of lenalidomide treatment. A course with unselective antihistamines (e.g. clemastin) has proven effective in most patients. If unsuccessful, a short course (14 days) of 10 mg prednisone orally may be attempted. In case of persistent or severe rash, lenalidomide should be interrupted until it resolves. In the experience of the panel, lenalidomide can then be restarted without recurrence. Other NHAE include fatigue (grade 3/4: 3%), pruritus (3%), diarrhoea (3%), nausea (3%), and muscle cramps (2%). As these are mostly non-specific symptoms, other causes such as anaemia or auto-immune disorders should be ruled out. Generally, patients should be screened for thyroid-stimulating hormone (TSH) and baseline TSH levels should be compared to levels during the course of treatment. Diarrhoea is a common NHAE that should be treated symptomatically after other underlying causes have been ruled out. In some cases, diarrhoea has been attributed to the lactose in lenalidomide tablets and additional lactase supplementation has been helpful. Unlike thalidomide, lenalidomide does not lead to dose-dependent peripheral neuropathy, somnolence or constipation. In general, lenalidomide is well tolerated in patients with intermediate and low-risk MDS with del5q. *Discussions*. A concise strategy for the management of NHAE of lenalidomide is presented, which will aid safe administration and avoid unnecessary dose reduction and discontinuation, thus assuring best efficacy.

CORRELATION BETWEEN OCCURRENCE OF CYTOPENIAS AND RESPONSE TO LENALIDOMIDE THERAPY IN DEL 5Q MDS PATIENTS

A. Sekeres,[1] J.P. Maciejewski,[1] A. Giagounidis,[2] K. Wride,[3] R. Knight,[3] A. List[4]

[1]Cleveland Clinic Taussig Cancer Center, CLEVELAND, USA; [2]St. Johannes Hospital, DUISBURG, Germany; [3]Celgene Corporation, SUMMIT, NJ, USA; [4]H. Lee Moffitt Cancer Center, TAMPA, FL, USA

Background. Lenalidomide is effective in myelodysplastic syndromes (MDS) patients with or without deletion (del) 5q cytogenetic abnormalities. The most common toxicities reported with lenalidomide therapy are neutropenia and thrombocytopenia. Both occurrence of cytopenias and response to lenalidomide therapy is more common in patients with the del 5q cytogenetic abnormality. *Aims.* This analysis was conducted to determine if the occurrence of cytopenias predicts response to lenalidomide treatment in del 5q MDS patients. *Methods.* This is a retrospective data analysis of patients enrolled in the MDS-003 study. Transfusion-dependent MDS patients with an associated del 5q abnormality were treated with 10 mg lenalidomide (daily or 21/28 days). Thrombocytopenia was defined as a platelet count <150,000/mm^3; neutropenia as an absolute neutrophil count (ANC) <2000/mm^3 (grade 1-4 using the CTC v2.0 or 3.0). Medication side effects of platelet and neutrophil compromise were assessed within the first 8 weeks of therapy. Response to lenalidomide therapy was assessed using the International Working Group criteria. *Results.* The 148 patients enrolled had a median age of 71 yrs, median duration of MDS of 2.5 yrs and median RBC transfusion rate of 6 units/8 weeks; 66% were female and 81% had a low/int-1 risk IPSS score. Of 147 evaluable patients, 59 (40%) had throm-

bocytopenia at baseline, 59 (40%) had neutropenia and 84 (57%) had either neutropenia or thrombocytopenia. As reported previously (List et al. NEJM 2006), 99 patients (67%) achieved RBC transfusion independence. Regardless of whether or not a patient was thrombocytopenic at baseline, a drop in platelet count by ≥50% within the first 8 weeks of therapy correlated with a higher chance of RBC transfusion independence (p=0.005). Comparing patients who had a ≥50% drop vs those who did not, transfusion independence was achieved in 76% vs 47% of patients without baseline thrombocytopenia and in 67% vs 38% of patients with baseline thrombocytopenia. Similar results held for patients without baseline neutropenia: 82% whose ANC fell ≥75% achieved RBC transfusion independence, compared to 56% whose ANC fell <75% (p=0.018). In patients with baseline neutropenia, however, ANC drop did not correlate with RBC response (p=0.75). In patients with at least one cytopenia at baseline, those whose ANCs fell by ≥75% and platelets fell by ≥50% were more likely to achieve RBC transfusion independence than those whose counts did not drop substantially, even controlling for baseline cytopenias (71% vs. 60%, p=0.024). *Summary and conclusions.* In MDS patients with del 5q, a drop in platelet count and, in those with normal baseline ANCs, a drop in ANC, correlates with response to lenalidomide, thus indicating an association between the induction of cytopenias and therapeutic response.

ENDOPLASMIC RETICULUM GENE EXPRESSION PROFILE OF ERYTHROID PROGENITORS IN LOW RISK MYELODYSPLASTIC SYNDROMES

E.G. Gyan,[1] A. Sternberg,[2] S. Leclercq-Cardus,[3] L. Willems,[3] N. Cagnard,[1] E. Frisan,[1] F. Dreyfus,[1] C. Lacombe,[3] P. Vyas,[2] M. Fontenay[1]

[1]Institut Cochin, PARIS, France; [2]Wheatherall Institute of Molecular Medic, OXFORD, United Kingdom; [3]Laboratoire d'hématologie hôpital Cochin, PARIS, France

Background. Ineffective erythropoiesis in low risk myelodysplastic syndromes (LR-MDS) is supported by morphological evidence and an impaired *ex vivo* differentiation of erythroid precursors with excessive apoptosis. We have previously shown that excessive apoptosis of eythroid precursors obtained by *ex vivo* culture of MDS bone marrow CD34+ cells involved a Fas-dependent amplification of caspase activation. We have observed also an accumulation of calcium in the endoplasmic reticulum (ER) of LR-MDS erythroid precursors and demonstrated a role for the ER in the spontaneous apoptosis of these cells. Whether these abnormalities, i.e. activation of a Fas-mediated pathway to death and abnormal accumulation of Ca^{2+} in the ER, are driven by intrinsic defects (such as genetic and epigenetic changes) or by extrinsic signals (from an altered bone marrow microenvironment or an auto-immune response), remains controversial. *Aim and Methods.* In the pilot phase of a study to provide some answers to these questions, we analyzed the gene expression signature of LR-MDS and normal control erythroid progenitors derived by *in vitro* liquid culture from $CD34^+$ bone marrow cells. Five LR-MDS (RA = 4, RAEB<10% blasts = 1) and 4 normal control samples were cultured for 7 days in the presence of Epo, IGF-1, SCF and dexamethasone. At this time point, the culture generated a majority of proerythroblasts and basophilic erythroblasts. In LR-MDS samples, apoptosis of erythroid precursors was observed 2 to 3 days later. For each sample, cRNA was processed for hybridization to GeneChip HG U133A gene chips (Affymetrix). *Results.* After normalization of signals using the GC-RMA method and significance analysis (ANOVA, p<0.01), we identified the differential expression of 134 genes between patients and controls. Based on this signature, hierarchical clustering using the GeneSpring software clearly separated LR-MDS from normal samples. Ten of these transcripts were confirmed to be differentially expressed in 8 LR-MDS and 6 control samples by RT-qPCR. Neighborhood analysis identified a pattern of 107 genes predictive of MDS (underexpressed: 66; overexpressed: 41). Ingenuity software classified these genes according to their biological theme (cell death & stress: 48, cell growth & signaling: 24, cell cycle: 18, DNA replication and repair: 17). In the group of cell death & stress genes, 27 (59%) play a role in ER stress response. Twenty-four of them (protein synthesis: 13; protein folding and maturation: 6; protein transport: 1; calcium homeostasis: 3; transcription: 1) were downregulated whereas three others (CALR, HSPA5, PDIA4) were overexpressed. In accordance with these changes, immunoblot analysis of LR-MDS erythroid cells identified an increased expression of calreticulin and Grp78/HspA5 proteins in MDS erythroid progenitors. *Conclusions.* Altogether, this preliminary study performed on a small number of samples suggests that a gene signature of LR-MDS erythroid precursors could be identified. The importance of changes in the expression of genes that regulate the ER metabolism enforces the previous demonstration of a role of this organelle in the disease pathophysiology.

ALLOGENEIC STEM CELL TRANSPLANTATION FOR MDS AND SAML FOLLOWING FLAMSA-CHEMOTHERAPY, REDUCED INTENSITY CONDITIONING AND PREEMPTIVE DONOR LYMPHOCYTE TRANSFUSION

H.J. Kolb,[1] C. Schmid,[2] M. Schleuning,[3] A. Rank,[1] R. Buhmann,[4] J. Tischer,[1] P. Valent,[5] G. Ledderose[1]

[1]University of Munich, MUNICH, Germany; [2]Med.Klinik II, Klinikum Augsburg, AUGSBURG, Germany; [3]Deutsche Kloinik für Diagnostik, WIESBADEN, Germany; [4]GSF-National Research Centre for Environ, MUNICH, Germany; [5]Dept. of Internal Medicine I, VIENNA, Austria

Myelodysplastic syndrome (MDS) and secondary acute myeloid leukemia (sAML) are diseases of the hematopoietic stem cell that are potentially curable by allogeneic stem cells transplantation (ASCT). MDS and sAML are most frequent in elderly patients with significant co-morbidity. Here we report our results with reduced intensity conditioning regimen and preemptive donor lymphocyte transfusions that have been successful in patients with advanced and refractory AML. Sixty seven patients were treated for MDS and 90 patients for sAML. The FLAMSA regimen consisted of a 4 day course of chemotherapy (Ara-C 2 g/m^2, Fludarabin 30 mg/m^2, and amsacrin 100 mg/m^2) followed by 3 days rest and reduced intensity conditioning with 4 Gy total body irradiation (TBI), cyclophosphamide (CY)±antithymocyte globulin (ATG). Overall survival at 10 years was 50% for MDS and 26% for sAML (p=0.014, log rank). In the MDS group most patients had preleukemic forms (IPSS 3 and 4). Survival at 5 years was 58% with FLAMSA, 44% with myeloablative conditioning with TBI and 67% with Busulfan (BUS). Non-relapse mortality at 5 years was 41% with FLAMSA, 20% for BUS and 50% for TBI. The relapse or progression rate was 0% for FLAMSA, 24% for BUS and TBI respectively. In sAML the 5 year survival was 17% for FLAMSA, 57% for BUS and 30% for TBI. Non-relapse mortality was 60% for FLAMSA, 36% for BUS and 66% for TBI, whereas the relapse rate was 62% for FLAMSA, 12.5% for BUS and 37% for TBI (p=0.04). In multivariate analysis adjusted for disease, conditioning treatment and source of stem cells ' marrow vs. mobilized blood - differences were not significant and the only significant prognostic factor was age less than 30 years (p=0.003). Therefore patients of the age of 60 years and older with AML were treated with FLAMSA containing BUS (8 mg/kg in two days) instead of 4 Gy TBI. The overall survival at 2 years was 64%, 61% with FLAMSA-TBI and 70% with FLAMSA-BUS. The non-relapse mortality was 9% for FLAMSA-BUS and 37% for FLAMSA-TBI; the relapse rate was 25% at 2 years. At day 120 patients received donor lymphocytes (DLT) in3 escalating doses from 1×10^6/ kg, 5×10^6/ kg on day 150 and 1×10^7/kg on day 180, if they had no GVHD, infection or relapse. Preemptive DLT appear to prevent relapse when compared to a historical control and contemporary patients not given DLT. We conclude from these data that MDS/sAML may have a different biology in young patients, and that in the elderly we can optimize the treatment with FLAMSA-BUS as a dose reduced regimen and preemptive immunotherapy for maintenance of remission.

PREFERENTIAL CYTOGENETIC RESPONSE TO LOW-DOSE DECITABINE IN MDS WITH CHROMOSOME 7 ABNORMALITIES

R. Claus,[1] P. Wijermans,[2] B. Rüter,[1] R. Kunzmann,[1] M. Lübbert[1]

[1]University of Freiburg Medical Center, FREIBURG, Germany; [2]Leyenburg Hospital, THE HAGUE, Netherlands

Background. Decitabine (5-aza-2'-deoxycytidine, Dacogen®, DAC) is a powerful demethylating agent that induces hematologic and cytogenetic remissions even in elderly and frail patients (pts) with MDS and AML. Cytogenetic remissions in pts with chromosomal aberrations are associated with improved overall survival (Lübbert et al., Br. J. Haematol. 114:349-57, 2001). The other zanucleoside very active in MDS, Vidaza® (5-azacytidine) has been suggested as effective in MDS patients with monosomy 7 (Raj *et al.,* ASH 2005, Blood 106 (Suppl. 1): 2530a). We now performed a retrospective evaluation of cytogenetic responses in MDS patients with aberrations of chromosome 7 upon treatment with low-dose DAC. *Methods.* 115 successfully karyotyped MDS pts (median age 70 years, range 38-89) treated with low-dose DAC (120-150 mg/mÇ) within three European phase II trials (PCH91-1, PCH95-11,

PCH97-19) were studied. Conventional cytogenetic analyses were done on bone marrow samples prior to therapy and during treatment (response evaluation prior course three and later). In selected cases, monosomy 7 was monitored by fluorescence *in situ* hybridization (FISH) during treatment. *Results.* Of 115 karyotyped pts, 51 (44%) had a normal karyotype and 64 (56%) had chromosomal aberrations. 34 (30%) pts showed single aberrations, including 6 pts with loss of chromosome 7 or del(7)(q22q34). In 20 (17%) pts, complex karyotypes were detected, 11 of these contained chromosome 7 abnormality. 4/6 (67%) pts with isolated chromosome 7 abnormality achieved complete (n=3) or major (n=1) cytogenetic responses. Median number of courses until best cytogenetic response was 2 (range 2-3), median time to (cytogenetic) relapse was 13.5 months (range 9-15). Median cytogenetic response duration in the 15 pts with other cytogenetic abnormalities was 8 months (range 3-12), this difference was statistically significant by t-test. 4/11 pts with complex karyotype including aberrations of chromosome 7 showed cytogenetic responses (median response duration 8 months, range 7-9) compared to 2 responders out of 9 pts with complex karyotype not containing chromosome 7 abnormality. *Conclusions.* A high cytogenetic response rate to low-dose DAC was seen in pts with sole chromosome 7 abnormalities, with a significantly longer response duration than for responding pts with aberrations of chromosome 7 in the context of a complex karyotype, or cytogenetic responders without initial chromosome 7 abnomalities. The reason for this preferential response is presently unclear, but might be associated with the more frequent methylated phenotype of these patients

DISEASE PROGRESSION IN DEL(5Q) MDS PATIENTS TREATED WITH LENALIDOMIDE: ANALYSIS OF RISK FACTORS AND LONG TERM OUTCOME IN 45 PATIENTS

A. Giagounidis,[1] S. Haase,[2] V. Lohrbacher,[2] B. Schuran,[2] M. Heinsch,[2] C. Aul[1]

[1]St. Johannes Hospital, DUISBURG; [2]Medizinische Klinik II, DUISBURG, Germany

Lenalidomide is a novel immunomodulatory drug (IMiD?) that has successfully been used in patients with transfusion-dependent MDS with del(5q.31) chromosomal abnormality. The recently published Lenalidomide-MDS-003 study reported a 76% erythroid response rate with 67% transfusion independency in an intent-to-treat analysis of 148 patients. This result was unaffected by cytogenetic complexity or bone marrow blast percentage in the study population. During the first year of study, a number of disease progressions to higher FAB subtypes or to AML occurred that raised the question whether lenalidomide might promote disease progression in some patients. *Patients and Methods.* We retrospectively analysed data on 45 patients that were treated with lenalidomide at our institution to identify risk profiles that might account for progression. 28 female patients and 17 male patients (median age 71 years) were treated with initial lenalidomide doses of 10 mg po daily. Additional therapy used was G-CSF in case of neutropenia grade >2 and antibiotics. *Results.* 13 out of 45 patients (29%) experienced progression of disease to either higher FAB subtype or AML. Analysis of contributing factors showed that 7 of the 13 patients had RAEB at the point of first drug intake. 3 of those 7 patients had additional chromosomal aberrations (2, trisomy 21; 1, complex karyotype). Of the remaining 6 patients, 2 had a complex karyotype at time of lenalidomide therapy commencement, and 1 an additional inv(9)(p11q12). Of the remaining 3 patients, 1 patient had a hypocellular bone marrow at the start of lenalidomide therapy so that no FAB subtype could be assigned. *Conclusions.* Within the subgroup of del(5q) MDS, the best survival has been identified in patients with an isolated del(5q) chromosomal aberration and a bone marrow blast count of <5%. Patients with additional chromosomal abnormalities or a higher blast percentage have a much shorter overall survival and a higher risk for AML development. Our retrospective analysis confirms these data showing that progression to higher MDS subtypes or AML has nearly exclusively happened in patients with additional risk factors like >5% bone marrow blasts or additional chromosomal anomalies. Only 2 out of 45 patients (4.4%) with 5q-syndrome progressed to AML. Interestingly, both those patients developed acute erythroid leukaemia (FAB M6). Lenalidomide does not seem to increase the risk of transition of del(5q) MDS to higher stages of disease.

FUSION OF FIP1L1 AND RARA AS A RESULT OF A NOVEL T(4;17)(Q12;Q21) IN A CASE OF JUVENILE MYELOMONOCYTIC LEUKEMIA

A. Buijs, M. Bruin

University Medical Center Utrecht, UTRECHT, Netherlands

Juvenile myelomonocytic leukemia (JMML) is a pediatric myeloproliferative disease (MPD), characterized by proliferation of granulocytic and monocytic lineages. 17q12 RARA rearrangements are the hallmark of acute promyelocytic leukemia (APL), characterized by a differentiation arrest of abnormal promyelocytes. Beside the frequent t(15;17) resulting in PML/RARA fusion, variant rearrangements involving 17q21 RARA in APL are PLZF/RARA t(11;17)(q23;q21), NPM1/RARA?t(5;17)(q35;q21), NUMA/RARA ?t(11;17)(q13;q21), STAT5b/RARA?der(17) and t(3;17)(p25;q21). In chronic eosinophilic leukemia (CEL) a FIP1L1/PDGFRA fusion gene has been identified due to a chromosome 4q12 interstitial deletion. FIP1L1 is an integral subunit of cleavage and polyadenylation specificity factor (CPSF). By FISH and RT-PCR analyses we identified FIP1L1/RARA fusions as a result of a t(4;17)(q12;q21) in a case of JMML. Sequencing analysis demonstrated an in-frame FIP1L1/RARA?fusion of exon 15 of FIP1L1, which is downstream of FIP1L1/PDGFRA breakpoints that are distributed in introns 7-13. The breakpoint fuses exon 3 of RARA, identical to all other RARA fusions. All known chimeric RARA fusion proteins provide additional homodimerization motifs, promoting formation of chimeric homodimers critical for leukemic transformation. Recently, it was shown that FIP1L1/PDGFRA mediated transformation, is FIP1L1 independent and results from disruption of the autoinhibitory JM domain of PDGFRA. Fusion of a strong homodimerization domain of ETV6 to PDGFRA could overcome the inhibitory function of the PDGFRA JM domain. These studies suggest that FIP1L1 does not seem to render direct homodimerization ability to FIP1L1/PDGFRA. Observations using retroviral transduced FIP1L1/PDGFRA?and FIP1L1/PDGFRA with an N-terminal deletion of the FIP1L1 moiety showed differences with respect to cytokine-independent colony formation and activation of multiple signaling pathways in human primary hematopoietic precursor cells (personal communication, Dr. Buitenhuis and Prof. Coffer, Dept. Immunology, University Medical Center Utrecht). These observations indicate that FIP1L1 does contribute to FIP1L1/PDGFRA resulting in a myeloproliferative phenotype. Therefore, our results, together with the data van Buitenhuis and Coffer, suggest a functional role of FIP1L1 in both chimeric proteins other than overt self-association. In conclusion, we report a t(4;17)(q12;q21) resulting in reciprocal FIP1L1/RARA fusion transcripts in a case of JMML. This is the second chromosomal aberration involving 4q12 FIP1L1 in MPD. Functional studies using FIP1L1/RARA and FIP1L1/PDGFRA might give new insights in the mechanistic contributions of chimeric FIP1L1 and RARA fusion proteins in MPD and APL. We will discuss this remarkable observation in relation to disease phenotype and molecular mechanism.

BONE MARROW RENIN-ANGIOTENSIN SYSTEM EXPRESSION IN POLYCYTHAEMIA VERA AND ESSENTIAL THROMBOCYTHAEMIA DEPENDS ON JAK2 MUTATIONAL STATUS

M. Marusic Vrsalovic,[1] V. Pejsa,[1] T. Stoos Vejic,[1] S. Ostojic Kolonic,[2] R. Ajdukovic,[1] V. Haris,[1] O. Jaksic,[1] R. Kusec[1]

[1]Dubrava University Hospital, ZAGREB; [2]Merkur University Hospital, ZAGREB, Croatia

Background. Discovery of V617F mutation in JAK2 tyrosine kinase gene in myeloid progenitors provided new insight into the pathogenesis and clinical understanding of CMPD. There are several lines of evidence suggesting the existence of local hematopoietic bone marrow renin-angiotensin system (RAS) which contributes to the regulation of normal and disturbed hematopoiesis. Recently, it was shown that Jak2 kinase is important upstream component in the regulation of the AGT mRNA transcription: activated Jak2 kinase stimulates AGT gene transcription. These observations suggest possibility for constitutively active, mutated Jak2 to modulate transcriptional activation of AGT gene as well as the expression of other RAS genes in CMPD. *Aims.* We analyzed the expression of RAS genes (ACE, AGT, AT1R and REN) in normal BM and that of PV and ET patients with the respect to the presence of activating V617F JAK2 mutation. *Methods.* Fourteen PV-JAK2V617Fpos

patients (7 male, 7 female, median age 68), thirteen ET-JAKV617Fpos patients (6 male, 7 female, median age 72) and seven ET-JAK2V617Fneg patients (3 male, 4 female, median age 66) were included in the study. Samples of normal bone marrow were obtained from five healthy donors and one sample was from a non-Hodkgin's lymphoma patient with no lymphoma involvement of the marrow. Real-time PCR analysis for ACE, AGT, AT1R1, REN genes and internal housekeeping gene GAPDH was performed using Real Time PCR System. To compensate for inter-PCR variations, normalisation of target genes (ACE, AGT, AT1R1, REN) with an endogenous control (GAPDH) was performed. JAK2 V617F mutational status was determined by the allele-specific PCR. *Results.* ACE expression in BM of PV and ET patients was down-regulated to 2-20% of the donor BM values with no statistically significant difference in expression between patients. AGT expression was significantly higher in PV and in ET JAK2V617F pos comparing to ET JAK2V617F neg patients. Renin has shown similar pattern of expression as AGT: it was significantly higher in PV and in ET JAK2V617F pos patients comparing to ET JAK2V617F neg patients. AT1R gene was significantly higher expressed in PV patients in comparison to both ET subgroups, JAK2V617F positive or negative patients. ET patients did not differ for AT1R expression by their JAK2 mutational status. *Conclusions.* Our findings indicate up-regulation of AGT, AT1R and REN genes and down-regulation of ACE gene expression in clonal hematopoiesis of PV and ET. Different expression pattern of major RAS components in BM of PV and ET compared to normal BM is clearly related to the existence of JAK2V617F mutation and less to the PV or ET disease phenotype. However, interesting exception is excessive expression of AT1R in PV that was not observed in ET irrespective of JAK2 mutation. This latest observation provides ground for the future experimental and clinical studies for the use of AT1R blockers in improving clinical management of JAK2V617Fpos PV.

0237

THE MYELOPROLIFERATIVE DISEASE JAK2 V617F MUTANT CANNOT BE REGULATED BY SOCS PROTEINS

M. Hookham,[1] J. Elliott,[1] Y. Suessmuth,[1] A. Ward,[2] J. Staerk,[3] W. Vainchenker,[4] M. Percy,[5] M.F. McMullin,[5] S. Constantinescu,[3] J. Johnston1

[1]Queens University Belfast, BELFAST, United Kingdom; [2]Deakin University, BURWOOD, Australia; [3]Ludwig Institute for Cancer Research, BRUSSELS, Belgium; [4]INSERUM Institut Gustave Roussy, PARIS, France; [5]Haematology, Belfast City Hospital, BELFAST, United Kingdom

Background. Many myeloproliferative disorders including Polycythaemia Vera (PV) are associated with a valine to phenylalanine (V617F) somatic mutation in the pseudokinase domain of JAK2, which leads to constitutive kinase activity. This JAK2 mutant requires a cognate receptor such as the Epo receptor (EpoR) for transformation to occur. Suppressor of cytokine signalling (SOCS) proteins are known to strongly negative regulate erythropoietin (Epo) signalling through interaction with both the EpoR and JAK2. *Aims*. The aim of this study was to determine to role of SOCS3 in the regulation of JAK2 V617F. *Methods*. Expressing the EpoR and JAK2 WT or JAK2 V617F in Ba/F3 cells that also express SOCS under the control of the Tet-off system as well as transient expression of the above proteins in 293T we also investigated the expression of SOCS-3 in leukocytes derived from PV patients and healthy donors. *Results.* We found that SOCS3 could not negatively regulate the mutant JAK2. Furthermore we found that the activation of JAK2 V617F can be enhanced in the presence of SOCS3 and that normal SOCS turnover is inhibited, causing an accumulation of both proteins. *Conclusions.* The presence of SOCS3 strongly inhibits cell proliferation in the presence of wild-type JAK2, but SOCS could not inhibit proliferation when co-expressed with JAK2 V617F. Moreover, leukocytes derived from PV patients express SOCS3 at higher levels than those derived from healthy donors. These findings suggest that the JAK2 V617F mutant can counteract normal SOCS3 regulation and may exploit this to enhance the myeloproliferative disease.

DETECTION OF ACTIVATED STAT5 IN THE CYTOPLASM OF NEOPLASTIC CELLS IN VARIOUS MYELOID NEOPLASMS

K. Sonneck,[1] R. Fritz,[1] L. Müllauer,[1] K.V. Gleixner,[1] M. Mayerhofer,[1] S. Florian,[1] M. Kerenyi,[2] W.R. Sperr,[1] C. Sillaber,[1] R. Moriggl,[3] P. Valent[1]

[1]Medical University of Vienna, VIENNA; [2]University of Vienna, IMP, VIENNA; [3]Ludwig Boltzmann Institute of Cancer Res, VIENNA, Austria

Background. The signal transducer and activator of transcription 5 (STAT5) has recently been implicated as essential pro-oncogenic factor in the pathogenesis of myeloid leukemias in mice (Cancer Cell 2005;7:87-99). More recently, STAT5 activation has also been described to occur in human leukemias. However, so far, little is known about the expression of activated/tyrosine phosphorylated STAT5 (pSTAT5) in various myeloid neoplasms and about the distribution of pSTAT5 in the cellular compartments of the normal and leukemic bone marrow (bm). *Methods.* We have examined the expression of pSTAT5 in the bm in patients with acute myeloid leukemia (AML, FAB M0, n=3, M1, n=6, M2, n=4, M3, n=5, M4, n=5, M5, n=4, M6, n=5, M7, n=4), chronic myeloid leukemia (CML, chronic phase, n=4, accelerated phase, n=5, blast phase, n=5), and systemic mastocytosis (SM, n=30), as well as in the normal bm (n=5). Expression of pSTAT5 was determined on paraffin-embedded bm sections by immunohistochemistry using the pSTAT5-specific antibody AX1. *Results.* In the normal bm, the antibody AX1 was found to react with megakaryocytes and immature myeloid progenitor cells, whereas erythroid cells and mature granulocytic cells did not stain positive for AX1. In patients with AML and CML, the distribution of pSTAT5 showed a similar pattern. In fact, pSTAT5 was found to be expressed in leukemic blast cells without differences among FAB types as well as megakaryocytic cells, but not in erythroid cells. In patients with SM, neoplastic mast cells were found to be immunoreactive for pSTAT5. Interestingly, in all patients and all cells examined, pSTAT5 was found to be localized in the cytoplasm rather than in the nucleus. The cytoplasmic distribution of pSTAT5 in neoplastic cells was confirmed by immunocytochemical staining experiments performed on primary isolated neoplastic cells (AML, CML, mastocytosis) and respective cell lines (U937, KG1, K562, KU812, HMC-1). In each case, the reactivity of neoplastic cells with the AX1 antibody was abrogated by preincubation of the antibody with a pSTAT5-specific blocking peptide. Moreover, the expression of cytoplasmic pSTAT5 in the leukemic cell lines was demonstrable by flow cytometry. To study the molecular mechanisms underlying STAT5-activation in neoplastic cells, Ba/F3 cells with doxycycline-inducible expression of disease-specific oncoproteins, namely BCR/ABL (CML) and KIT-D816V (SM) were employed. Induction of these oncoproteins in Ba/F3 cells resulted in massive activation of pSTAT5 and DNA binding activity as shown by EMSA and supershift assays. *Summary.* Our data show that neoplastic cells in AML, CML, and SM express cytoplasmic pSTAT5, and that disease-related oncoproteins contribute to STAT5-activation. The particular cytoplasmic localization of pSTAT5 in neoplastic cells suggests that apart from its function as a transcription factor, pSTAT5 may have an additional role as a cytoplasmic regulator in these malignancies.

NF-E2 OVEREXPRESSION DELAYS ERYTHROID DIFFERENTIATION AND INCREASES ERYTHROCYTE PRODUCTION

A.S. Magin, H. Pahl, M. Mutschler, M. Buerge, B. Will, H. L. Pahl

University Hospital Freiburg, FREIBURG, Germany

Background. A point mutation in the Jak2 kinase, Jak2V617F, is found in up to 95% of patients with Polycythemia vera (PV). Jak2V617F leads to constitutive kinase activation and in a mouse model recapitulates many disease features including erythrocytosis. However, the molecular mechanism by which the mutation exerts its effect has not been delineated. The transcription factor Nuclear Factor-Erythroid 2 (NF-E2) is overexpressed in the vast majority of PV patients. In murine cells, NF-E2 overexpression leads to EPO-independent growth, a hallmark of PV. Moreover, ectopic NF-E2 expression can reprogram myeloid cells towards erythroid maturation. *Aims*. We therefore hypothesized that Jak2V617F-induced erythrocytosis is mediated by NF-E2 overexpression. Consequently, we investigated the effect of NF-E2 overexpression in healthy peripheral blood $CD34^+$ cells. *Methods*. Peripheral blood $CD34^+$ progenitor cells were purified from healthy donors using antibody-based magnetic bead separation. Cells were retrovirally transduced with a NF-E2 cDNA in conjunction with a GFP marker. GFP-expressing cells were sorted and assayed for colony formation in methyl cellulose, or maintained in liquid culture medium promoting erythroid differentiation. Erythroid maturation was assessed by CD36 and CD235a (Glycophorin A) staining and FACS analysis as well as Wright-Giemsa staining of cytospins. *Results.* NF-E2 overexpression drastically altered erythroid colony formation. While empty vector transduced cells mainly formed CFU-E (70%±20%) and to a small degree BFU-E (30% ±20%), NF-E2 overexpressing cells formed almost exclusively BFU-E (80%±5%). In addition, NF-E2 overexpressing BFU-E were larger and more dispersed than control BFU-E. Concurrently, the absolute number

of erythroid colonies was reduced in NF-E2 overexpressing cells. Xu et al. have previously reported a similar reduction in cloning efficiency of Idiopathic Myelofibrosis CD34+ cells, which have been shown to overexpress NF-E2. NF-E2 overexpression lead to a delay in erythroid differentiation, manifested by a belated appearance of CD235a (Glycophorin A) positive mature erythroid cells. Morphological evaluation similarly revealed more immature cells in NF-E2 overexpressing cultures. Protracted differentiation lead to a significant increase in the accumulated number of mature erythroid cells per progenitor cell. *Summary and conclusions.* NF-E2 overexpression delays the early phase of erythroid differentiation. This results in an expansion of early erythroid progenitors, thereby increasing the total number of mature erythrocytes derived from one CD34+ cell. These data propose a role for NF-E2 in mediating the erythrocytosis of PV.

STEPWISE TRANSFORMATION OF PRIMARY BONE MARROW PROGENITOR CELLS *EX VIVO*

M. Scherr,[1] Y. Dogan,[1] G. Beutel,[1] K. Battmer,[1] L. Venturini,[1] D. Schaefer,[1] L. Wilkens,[2] A. Ganser,[1] M. Eder[1]

[1]Hannover Medical School, HANNOVER, Germany; [2]University of Bern, BERN, Switzerland

Background. Leukemogenesis is considered a multistep process of accumulating genetic alterations in hematopoietic stem or progenitor cells. Current experimental models using established cell lines or murine stem cell transplantation assays do not sufficiently allow investigation of the cooperative effects of defined genetic alterations. *Aims.* We established immortalized cell lines from murine bone marrow to study their stepwise progression into more transformed phenotypes. *Methods and Results.*Primary murine lineage negative bone marrow cells were retrovirally transduced to express either AML1-ETO or HoxB4 along with EGFP as a quantitative reporter under serum free conditions in the presence of SCF+IL-3+IL-6. Immortalized EGFP+ cell lines could be established in both conditions. The resulting cell lines are dependent on expression of the respective transgene but show strikingly different phenotypes. First, long-term cultures for AML1-ETO remain strictly SCF-dependent, whereas HoxB4 cultures only require IL-3 for cell survival and proliferation. Secondly, AML1-ETO but not HoxB4 cells express c-Kit and Sca-1 on more than 90% of the cells with a high proportion of side population (SP) cells. In addition, AML1-ETO cells form only blast like colonies with very low plating efficiency ($<10^{-4}$), whereas HoxB4 cultures give rise to large colonies of mature granulocytes and monocytes with a plating efficiency of more than 10%. Subsequent retrovirus-mediated expression of the V559D c-Kit mutant resulted in generation of cytokine-independent subclones for HoxB4 but not AML-1/ETO lines. These HoxB4/Kit cells maintain full differentiation and colony formation potential but do not induce hematopoeitic malignancies in murine stem cell transplantation assays. Interestingly, additional lentivirus-mediated RNA interference to silence p53 expression results in fully transformed cell lines, which induce lethal myeloproliferation in transplanted mice with very short latency. In contrast, AML1-ETO cells could only be transformed to factor independent growth *ex vivo* by silencing of p53 expression and simultaneous overexpression of V559D c-Kit. *Conclusions.* Primary murine bone marrow cells can be transformed to malignant phenotypes by specific genetic alterations in a defined order *ex vivo*. The cooperation of genetic alterations, their impact on gene expression, and the efficacy of therapeutic intervention can be studied in such models.

A NOVEL ARG371HIS MUTATION IN THE HIF PROLYL HYDROXYLASE PHD2 IS ASSOCIATED WITH ERYTHROCYTOSIS

M.J. Percy,[1] P.W. Furlow,[2] P.A. Beer,[3] T.R.J. Lappin,[4] M.F. McMullin,[4] F.S. Lee[2]

[1]Belfast City Hospital, BELFAST, United Kingdom; [2]University of Pennsylvania School of Med, PHILADELPHIA, USA; [3]Addenbrooks Hospital, CAMBRIDGE, United Kingdom; [4]Queens University, BELFAST, United Kingdom

Background. Disorders of erythrocytosis are characterised by an elevated red cell mass and variable erythropoietin (Epo) levels. Inappropriately normal or elevated Epo values suggest that the underlying defect lies in the oxygen-sensing pathway. This process controls Epo synthesis and is regulated by the hypoxia-inducible factor (HIF) transcription complex, which consists of an α and a β subunit. In normoxia the α subunit of HIF is proteasomally regulated by the prolyl hydroxylase domain (PHD) family of enzymes, whose activity is abolished in the absence of oxygen. The PHD2 family member specifically hydroxylates two prolines in the oxygen dependent degradation (ODD) domain of HIFα and promotes the association of the von Hippel Lindau (VHL) protein. Ubiquitinylation of HIF-α follows and degradation of the subunit by the proteasome occurs. Mutations in the VHL gene account for a high proportion of the inherited erythrocytoses identified thus far. Recently a novel mutation of PHD2, Pro317Arg, has been described in 3 members of the same family with erythrocytosis identifying this prolyl hydroxylase as a critical modifier of HIF in the oxygen sensing pathway. *Aims.* To identify molecular defects in the PHD2 gene in erythrocytosis individuals who are negative for mutations in the VHL gene and to investigate the effect of any mutations on the oxygen sensing pathway. *Methods.* DNA was isolated from peripheral blood and PCR-direct sequencing of the PHD2 gene was performed. Mutant and wild type PHD2 protein was prepared by *in vitro* translation and *in vitro* binding and enzymatic functional assays were performed. *Results.* Sequencing the PHD2 gene detected a heterozygous change of G to A at base 1112 in PHD2 in an individual with erythrocytosis, who presented in his early thirties with a raised haematocrit and an Epo level at the upper end of the normal reference range. The absence of the G1112A base change in 200 normal control DNA samples was confirmed. This mutation causes exchange of arginine with histidine at amino acid 371, which is located three residues away from an active site iron-chelating residue in PHD2, His-374. *In vitro* binding studies detected substantially less association of the Arg371His variant with the HIF substrate. Enzyme assays indicated the G1112A mutation significantly reduced the ability of PHD2 to hydroxylate HIF, and the mutant was also less active than wild type PHD2 in downregulating HIF-induced Hypoxia Response Element reporter gene activity.

Pini Hospital, MILAN; [4]University of Milan, MILAN; [5]University of Milan-San Paolo Hospital, MILAN; [6]Cardiology Unit-IRCCS Policlinico, MILAN; [7]University of Milan-Bicocca, MILAN;

Background. Emerging evidence underlines the primary role of angiogenesis in Pulmonary Arterial Hypertension (PAH) development. Chronic Idiopathic Myelofibrosis (CIMF) is associated with an increased angiogenic status and PAH is a common complication of this disease. *Aims.* To investigate the prevalence of PAH in a cohort of CIMF patients and its association with angiogenic status. *Patients and Methods.* Systolic pulmonary arterial pressure (sPAP) was assessed by Doppler echocardiography in 36 CIMF patients (M/F: 20/16; median age 64.5 years [36-83]). Patients with PAH (sPAP ≥35 mmHg) were evaluated by high-resolution lung CT, lung perfusion scintigraphy, arterial blood gas analyses and pulmonary function tests with Dlco. Circulating Endothelial Cells (CECs: $CD45^-$, $CD146^+$, $CD31^+$) and Endothelial Progenitor Cells (EPCs: $CD45^-$, $CD133^+$, $CD34^+$) were evaluated by flow cytometry. Age-matched controls: 10 healthy (named Controls) and 10 affected by pulmonary hypertension due to cardio-pulmonary diseases (named S-PH). Serum VEGF, ET-1, TGFβ, PDGF-AB and sE-selectin were determined by ELISA. Bone marrow biopsy MicroVessel Density (MVD) were evaluated on 33 CIMF and 16 normal specimens using the *hot spots* method. *Results.* PAH, never due to cardio-pulmonary or thromboembolic diseases, was documented in 14 patients (36%), being mild (45≤sPAp<55 mmHg) in six of them. Three of these patients were symptomatic. EPCs were higher in CIMF (0.77×10^6/l [0-4.31], p″0.02) than both Controls and S-PH (0.29×10^6/L [0.13-1.71] and 0.41×10^6/L [0-0.56]). However EPCs were significantly lower in CIMF with PAH than in CIMF without (0.43×10^6/L [0-2.46] and 0.94×10^6/L [0.13-4.31], p=0.009). Additionally, EPCs negatively correlated with sPAP (p=.01). CECs number was significantly higher in CIMF in comparison to Controls (16.1×10^6/L [0.3-165.7] and 7.12×10^6/L[1.4-18.1], p=0.01). S-PH group's CECs were also higher than Controls (44.3×10^6/L[5-59.8], p=0.009), but not significantly different in comparison to CIMF, both with and without PAH. VEGF levels were significantly higher in CIMF in comparison to both Controls and S-PH (1484 pg/mL [267-2369], 260 pg/mL [69-303] p=.006 and 399 pg/mL [117-840] p<0.001). VEGF was also higher in CIMF with coexistent PAH than in PAH negative (1850 pg/mL [1151-2306] and 1037 pg/mL [267-2369],

p=0.03). There were no significant differences in the other assessed cytokine levels between CIMF and Controls, or among the subsets of CIMF. ET-1 was significantly higher only in S-PH. An increased MVD was present in CIMF group in comparison to normal (56.6 [23.2-90] and 15.2 [2.4-34.4], p<0.0001). Additionally, CIMF with PAH had higher MVD than PAH negative (66.6 [39.6-90] and 51.8 [23.2-88], p=0.006). *Conclusions.* PAH is frequent in CIMF without any known pulmonary or heart complications, being moderate in a subset, in whom close follow-up is advisable. CIMF complicated by PAH have markedly high VEGF levels and increased MVD together with relatively low EPCs levels. Our findings suggest that development of PAH in this setting is associated with an abnormally increased angiogenic status associated to EPCs insufficiency. Our results support the hypothesis that common mechanism(s) may be involved in CIMF-associated PAH pathogenesis, thus warranting studies regarding the role of bone marrow derived stem cells in angiogenesis.

Figure 1.

JAK2V617F AND MPLW515L: PRESENCE OF MYELOPROLIFERATIVE DISEASE ASSOCIATED MUTATIONS DOES NOT NECESSARILY LEAD TO ACTIVATION OF DOWNSTREAM SIGNALLING PATHWAYS

H. Quentmeier, J. Reinhardt, M. Zaborski, H.G. Drexler

DSMZ, BRAUNSCHWEIG, Germany

The JAK2V617F mutation occurs frequently in polycythemia vera (PV) (95% of reported cases), essential thrombocythemia (ET) (65%) and idiopathic myelofibrosis (IM) (50%). As reported extensively, JAK2V617F encodes for a constitutively active tyrosine kinase which stimulates downstream signalling pathways and confers cytokine-independent growth to hematopoietic cells. In accordance, we found that the JAK2 mutant cell lines SET-2 (DSM ACC 608) and UKE-1 were 100-fold more sensitive to JAK-inhibition than JAK2 wild-type cell lines. However, contradictory to the view of JAK2V617F acting as oncogene was that two of the four MPD-derived JAK2V617F cell lines described hitherto are cytokine-dependent. Removal of growth factors led to dephosphorylation of JAK2, of downstream STAT molecules and finally to cell death of cell lines MB-02 and MUTZ-8, both homozygous for the JAK2V617F mutation. Therefore we conclude that expression of JAK2V617F alone will not automatically lead to cytokine-independent cell growth. Recently, MPLW515L and MPLW515K mutations have been presented as further gain of function mutations in IM (5%) or ET (1%). We tested 6 acute myeloid leukemia derived cell lines established from patients with history of IM or ET for presence of MPL mutations: cell lines MARIMO and MONO-MAC-6 (DSM ACC 124) carried the MPLW515L mutation. Immunoprecipitation studies showed that, as for JAK2V617F, the MPLW515L mutated cell lines did not show constitutive phosphorylation of the affected proteins and of downstream signalling pathways. Both cell lines, MARIMO and MONO-MAC-6, express MPL mutated and MPL wild-type messenger RNA. Assuming that both variants of the MPL protein are expressed, the mutated version is not dominant and constitutively active. Our results do not contradict the view that the JAK2 or MPL mutations contribute to the etiology of the disease or to the advent of the described cell lines. On the contrary, the importance of these mutations is underscored by the observation that 5/6 cell lines with history of IM or ET either carry the JAK2V617F mutation (MB-02, SET-2, UKE-1) or the MPLW515L mutation (MARIMO, MONO-MAC-6). However, our data show clearly that the presence of JAK2V617F or MPLW515L mutations alone does not mean that the downstream signalling pathways are constitutively active. This is the first description of MPD-derived cell lines carrying the MPLW515L mutation. Our results indicate that they will be very useful tools to elucidate the role of this mutation for basic cellular processes, possibly contributing to onset of MPD.

0244

JAK2 MUTATIONS (V617F AND EXON 12) IN CHILDREN WITH ERYTHROCYTOSIS

M.L. Randi, M. Scapin, E. Pacquola, E. Duner, R. Scandellari, S. Bonato, M.C. Putti

University of Padua, PADUA, Italy

Background. Polycythemia vera (PV) is a myeloproliferative disorder of the median-advanced age, characterised by an high hematocrit often associated with increased WBC and platelets count. Recently, V617FJak2 mutation has been found in almost all PV patients. In children PV is extremely rare; most children with primary erythrocytosis are difficult to distinguish from real PV cases and at present no information are available regarding the Jak2 mutation in these patients. *Aims.* We report 6 children (2 females and 4 males, age at diagnosis 4 moths-15 years) with primary erythrocytosis (hematocrit range 53-71%). Two were siblings. On the basis of PVSG criteria all patients could be affected by PV. *Mathods.* Mutations of Jak2 was searched in peripheral blood granulocytes DNA with sequencing analysis and allele- specific PCR to confirm and determine homozygosis of V617FJak2 mutation. In the females the state of activation of the X-chromosome was determined the polymorphism the HUMARA, PGK and MPP1 gene (p55). Spontaneous erythroid colony formation (EEC) from peripheral blood mononuclear cells isolated on Ficoll-Hypaque density gradient was searched by placing a cell suspension into a semi-solid medium, such as methylcellulase, supplemented with nutrients and cytokines, followed by incubation at 37°C in 5% CO2 for 14 to 16 days. Colony evaluation can be done *in situ* by light microscopy. *Results.* Our results are summarized in the Table 1. Two of our cases are familial erythrocytosis. No molecular alteration have been observed at present in these patients. In 2 cases, oxygen sensing pathway genes alteration (heterozygous VHL mutation) has been found. Only one patient (VE) who had also increased WBC and platelets, exhibits V617FJak2 mutation, EEC formation, low serum erythropoietin (EPO) levels and monoclonal pattern associated with the clinical positive diagnostic criteria for PV. This is a pediatric case of PV and does not seem to differ from adult cases. In one male with sporadic erythrocytosis we failed to recognize the cause of the disease. *Conclusions.* Since the diagnosis of pediatric erythrocytosis requests a large panel of tests, we propose a new algorithm for the diagnosis of pediatric erythrocytosis. In this scheme, dosage of serum EPO, discriminates which mutational analysis (Jak2, oxygen sensing pathways and EPO-R genes).

POTENT AND SELECTIVE INHIBITION OF EEC COLONY FORMATION IN JAK2V617F POLYCYTHEMIA VERA AND THROMBOCYTHEMIA BY LOW DOSES OF ITF2357, A NEW HISTONE DEACETYLASE INHIBITOR

V. Guerini, O. Spinelli, A. Salvi, G. Finazzi, T. Barbui, M. Introna, J. Golay, A. Rambaldi

Ospedali Riuniti of Bergamo, BERGAMO, Italy

Background. A somatic point mutation in the JAK2 gene (JAK2V617F) has been recently recognized as the key pathogenetic lesion in Polycythemia Vera (PV) and Essential Thrombocythemia (ET). Histone-Deacetylase inhibitors (HDACi) are known inducers of cell differentiation, apoptosis and cell cycle arrest of neoplastic cells. ITF2357 is a new HDACi (Italfarmaco, Milano, Italy) which, at low micro molar concentration *in vitro*, inhibits the secretion of several cytokines such as IL-1, IL-6, VEGF and IFN-γ and exerts a potent anti tumor activity against multiple myeloma (MM) and acute myeloid leukemia cells (AML). For these latter properties, this drug is currently tested in Phase I/II trials in AML and MM patients. *Aims.* We investigated the ability of ITF2357 and the prototypic HDAC inhibitor Suberoyl Anilide Hydroxamic Acid (SAHA), to inhibit the spontaneous endogenous erythroid colony (EEC) growth of hematopoietic stem cells obtained from patients with PV (all positive for JAK2V617F), ET (JAK2V617F positive in 53%) and Idiopathic Erythrocytosis (all negative for JAK2V617F). *Methods.* The *in vitro* EEC assays was performed using mononuclear cells (MNC) from peripheral blood samples obtained from PV, ET and IE patients at the time of regular follow-up visits in our clinic. The inhibitory activity played by ITF2357 on the EEC colony growth was performed with or without the addition of exogenous cytokines including GM-CSF, IL-6, G-CSF, IL-3, EPO and Stem Cell Factor, in the presence of a log scale concentration of ITF2357 (from 0.001 to 0.75 mM). We also investigated the JAK2V617F at the single colony level on colonies picked-up at the end of a 14 days EEC assay. The molecular analysis of JAK2V617F was performed using allele specific Polymerase Chain Reaction (PCR) on DNA extracted by a single colony. *Results.* MNC obtained from IE or ET patients negative for JAK2V617F neither exhibited spontaneous EEC formation nor EPO hypersensitivity (from 0.1 UI/mL up to 10UI/mL). On the contrary, MNC from JAK2V617F PV and ET patients invariably sustained the spontaneous EEC outgrowth with a marked hypersensitivity to exogenous cytokines. ITF2357 induced a 90% EEC inhibition in all JAK2V617F PV and ET patients at 0.01mM concentration while SAHA displayed a similar inhibitory activity only when used at 0.25 mM. When the JAK2V617F mutation analysis was performed on single colonies obtained from PV and ET cells plated with exogenous cytokines, the addition of ITF2357 allowed the reproducible outgrowth of normal hematopoietic colonies ranging from 30 to 60% in different experiments. *Conclusions.* ITF2357, at concentration easily attained after oral administration, shows a potent inhibitory activity on the autonomous proliferation of hematopoietic stem cells of PV and TE carrying JAK2V617F mutation. The inhibitory effect of ITF2357 is remarkably selective and more evident on JAK2V617F mutated hematopoietic progenitors. This warrants evaluating the clinical activity of this molecule in Phase II trials designed for patients with chronic myeloproliferative disorders carrying the JAK2V617F mutation.

0246

A SMALL DELETION AT 20Q13.13 INDICATES NFATC2 AS A CANDIDATE GENE IN ESSENTIAL THROMBOCYTHEMIA

L. Vieira,[1] A. Vaz,[1] P. Matos,[1] M. Nogueira,[1] B. Marques,[1] A.P. Ambrósio,[1] A.M. Pereira,[2] M.G. Da Silva,[3] P. Jordan[1]

[1]Instituto Nacional de Saúde, LISBOA; [2]Hospital Garcia de Orta, ALMADA; [3]Instituto Português de Oncologia, LISBOA, Portugal

Essential thrombocythemia (ET) is a chronic myeloproliferative disorder (MPD) characterized by megakaryocytic proliferation and an excessive production of platelets. Approximately half of ET and most other MPD patients show a somatic activating point mutation in JAK2 (JAK2V617F) which is believed to represent a secondary pathogenetic event. Recent data from the literature showed that JAK2V617F is significantly associated with deletion of the long arm of chromosome 20, suggesting that a yet undefined molecular lesion on 20q precedes JAK2V617F and is responsible for initiation of clonal hematopoiesis. We describe a cytogenetic and molecular study of an acquired three-way translocation t(X;20;16)(p11;q13;q23~24) identified in a JAK2V617F-positive ET patient. Using fluorescence *in situ* hybridization with 27 different probes mapping along the 20q12-20q13.2 region, we identified a 500-kilobase deletion associated with a breakpoint at 20q13.13. Subsequent deletion mapping using polymerase chain reaction (PCR) analysis confirmed deletion of 3 genes: nuclear factor of activated T-cells cytoplasmic 2 (NFATC2), SAL-like 4 (SALL4) and ATPase class II type 9A (ATP9A). The SALL4 gene has recently been implicated in the pathogenesis of acute myeloid leukemia, however, we have sequenced the SALL4 coding sequence and flanking intronic regions and demonstrate that it is not mutated in 28 patients with ET. We further found that neither SALL4 nor ATP9A are expressed in 2 JAK2V617F-positive cell lines (SET-2 and HEL) although their expression was detected in 16 different normal tissue samples. In contrast, NFATC2 was strongly expressed in SET-2, HEL and in 7 other leukemic cell lines and normal leukocytes, making it the most likely candidate gene from the deleted region. To further address the role of NFATC2 in megakaryocyte proliferation, we simulated the effects of a deletion by suppressing NFATC2 gene expression in SET-2 megakaryocytic cells using small interfering RNAs. After 24 hours of transfection, NFATC2 mRNA and protein levels were 48% reduced compared to SET-2 cells transfected with a control siRNA. The specific suppression of NFATC2 resulted in a 34% increase in cell number which was accompanied by an increase in megakaryocyte cell size. Furthermore, the suppression of NFATC2 correlated with an up-regulation of cyclin B1 and cyclin E protein levels, indicating that the higher cell number was a consequence of cell cycle progression. Since NFATC2 regulates the expression of several hematopoietic cytokines and is expressed at high levels in megakaryocytes, mutations that affect NFATC2 expression may have important consequences in the control of megakaryopoiesis and consequently, contribute to ET pathogenesis.

0247

EVIDENCE THAT OVERPRODUCTION OF CYTOKINES AND OTHER MOLECULES LINKED TO JAK2 ACTIVATION CONTRIBUTES TO ABNORMAL HEMATOPOIESIS IN POLYCYTHEMIA VERA

M. Boissinot, I. Corre, D. Pineau, S. Hermouet, Y. Jacques

Institut de Biologie, NANTES CEDEX, France

Background. Polycythemia vera (PV) is a clonal myeloproliferative disorder arising from a multipotent progenitor and resulting in excessive erythropoiesis. Activating mutations of JAK2, a key signalling molecule for hematopoietic cytokines, are found in almost all PV patients. The V617F mutation (JAK2-V617F) is found in >90% of PV; other JAK2 mutations have been described in JAK2-V617F negative PV. However, there is evidence that onset of clonality and/or disease phenotype may be due to other molecular abnormalities. We previously described the partial dependence of PV erythroid progenitors on interleukin-11 (IL-11), a cytokine that activates JAK2, stimulates erythropoiesis and is overproduced in PV, notably by bone marrow (BM) stromal cells (BMSC). *Aims.* To identify other JAK2-activating molecules with altered production in PV. *Methods.* We used cytokine antibody arrays (Raybiotech Inc.) to establish the cytokine profile of serum from 20 PV patients and 27 patients with second erythrocytosis (SE) and of BM plasma (21 PV, 21 SE). Molecules of interest were then measured by ELISA in serum (32 PV, 33 SE) and in BM plasma (27 PV, 26 SE). Correlations between cytokine levels, blood cell counts and%JAK2-V617F, measured by quantitative allele-specific PCR in blood granulocytes, were analysed using Pearson's or Spearman's rank correlation tests. *Results.* In addition to IL-11, cytokine arrays revealed two new molecules linked to JAK2 activation and present at high levels in PV: tissue inhibitor of metalloproteases-1 (TIMP-1) and hepatocyte growth factor (HGF). Overexpression of TIMP-1 in PV was confirmed by ELISA in BM plasma (102 ng/ml vs 58 ng/ml in SE, p=0.013). Overexpression of HGF was confirmed by ELISA in BM plasma (PV: 7929 pg/ml vs 4438 pg/mL in SE, p=0.01) and in serum (PV: 5176 pg/mL vs 1765 pg/ml in SE, p<0.0001). As previously described in PV, the%JAK2-V617F correlated with counts of white blood cells (WBC) (n=26, r=0.41, p<0.05) and neutrophils (n=19, r=0.46, p<0.05) but not with hematocrit. Serum HGF levels correlated with the%JAK2-V617F (n=44, r=0.37, p<0.01) and, logically, with WBC (n=27, r=0.47, p<0.01) and neutrophils (n=21, r=0.71, p<0.001) but not with hematocrit. In contrast, serum IL-11 level correlated with hematocrit (n=45, r=0.43, p<0.01) but not with WBC or neutrophils. For TIMP-1, the only correlation found was between BM plasma level and the%JAK2-V617F (n=15, r=0.49, p<0.05). Finally, exposure of PV BMSC to HGF induced a dose- and time-dependent increase in IL-11 production, and IL-11 is known to induce TIMP-1 secretion. *Conclusions.* HGF, IL-11 and TIMP-1, three molecules acting sequentially and known to promote erythroid cell proliferation via JAK2, were found elevated in PV and correlated with the%JAK2-V617F (HGF, TIMP-1), WBC and neutrophils (HGF) and hematocrit (IL-11). These results, combined with reports from other groups that HGF acts in synergy with IL-11, suggest that the three molecules contribute to hematopoiesis deregulation in PV.

0248

COMPARISON OF WHOLE BLOOD VS PURIFIED BLOOD GRANULOCYTES FOR THE DETECTION AND QUANTITATION OF JAK2-V617F

E. Hermouet,[1] S. Hermouet,[2] I. Dobo,[3] E. Lippert,[4] M.-C. Boursier,[2] L. Ergand,[2] F. Perrault-Hu,[2] D. Pineau[2]

[1]Laboratoire d'Hematologie, NANTES; [2]Laboratoire d'Hematologie, CHU Nantes, NANTES; [3]Laboratoire d'Hematologie, CHU Angers, ANGERS; [4]Laboratoire d'Hematologie, CHU Bordeaux, BORDEAUX, France

Background. Detection of the V617F mutation of JAK2 (JAK2-V617F) is now one of the first tests performed in the diagnostic work-up of polycythemia and thrombocytoses. When studied in purified blood granulocytes, the JAK2-V617F allelic ratio is typically >20% in Polycythemia vera (PV) but <15% in half of mutated essential thrombocythemia (ET). Such low levels of mutant, often missed by sequencing, are detected in purified granulocytes by allele-specific PCR (AS-PCR) techniques. However, many diagnostic laboratories opt to work on whole blood. Since lymphocytes do not express JAK2-V617F, the JAK2-V617F burden is likely underestimated in whole blood assays and patients with low levels of mutant might be found negative. *Aims.* To determine whether whole blood allows reliable detection of JAK2-V617F in patients with <15% JAK2-V617F in purified granulocytes. *Methods.* We used a quantitative AS-PCR that detects 0.1% JAK2-V617F in granulocytes (Lippert et al. Blood 2006;108:1865) to compare results obtained with genomic DNA extracted from whole blood or purified blood granulocytes of 48 patients: 12 PV, 26 ET, 3 idiopathic myelofibrosis (IMF), 7 with secondary erythrocytosis. Twelve patients had been receiving cytoreductive treatment; all others were examined at the time of diagnosis. *Results.* The JAK2 status (JAK2-V617F positive or negative) of patients, including 2 with 1% mutant, was identical in whole blood and in purified granulocytes. For the 24 patients studied at diagnosis, the%JAK2-V617F in whole blood correlated with the%JAK2-V617F in purified granulocytes (n=24, r=0.99, p<0.001) and with the white blood cell (WBC) counts (n=24, r=0.83, p<0.001) and% neutrophils in blood (n=24, r=0.51, p=0.01). The JAK2-V617F allelic ratio in whole blood (on average 15% lower than in granulocytes) could be corrected using the% neutrophils. The 12 patients with cytoreductive treatment were characterized by lower WBC counts, a lower% neutrophils and a higher% lymphocytes. In contrast to patients at diagnosis, the%JAK2-V617F in whole blood and the% neutrophils were no longer correlated and the variations between the%JAK2-V617F measured in whole blood and in purified granulocytes were not significantly reduced when adjusted for the% neutrophils in blood. *Conclusions.* Provided that the AS-PCR used detects <1% JAK2-V617F, whole blood is suitable for the diagnosis of MPD; the JAK2-V617F burden thus measured may be adjusted using the% neutrophils. For the follow-up of the mutated clone in treated patients, it is advisable to assess JAK2-V617F before and during treatment in the same population of purified cells as blood cell ratios are altered. For the purpose of assessing the JAK2-V617F burden during treatment, blood granulocytes remain the easiest cells to obtain and purify.

0249

TWO JAK2 V617F MUTATED ALLELES ARE NECESSARY FOR EPO INDEPENDENCE IN POLYCYTHEMIA VERA

S. Dupont,[1] D. Pisani,[1] A. Massé,[1] N. Casadevall,[2] J.L. Villeval,[1] W. Vainchenker,[1] F. Delhommeau[3]

[1]Inserm, VILLEJUIF; [2]APHP, Hôtel-Dieu, Saint-Antoine, PARIS; [3]Université Pierre et Marie Curie, PARIS, France

Background. JAK2 V617F is frequently found in Polycythemia vera (PV) and Essential Thrombocythemia (ET). Most PV patients have a mix of wild-type, V617F heterozygous, and V617F homozygous erythroid progenitors. In contrast, most ET patients have only wild-type and heterozygous progenitors. The duplication of the mutant allele that occurs in homozygous erythroid progenitors may modify their response to EPO, and therefore influence the disease phenotype. *Aims.* To test this hypothesis, we studied the effects of different JAK2 V617F levels on EPO hypersensitivity or independence in two models: ET and PV primary erythroid progenitors, and the Ba/F3-R-EPO cell line expressing various amounts of mutant JAK2. *Methods.* We analysed bone marrow $CD34^+$ progenitors from 5 PV, 5 ET and 3 healthy controls. We picked $CD34^+$ derived erythroid colonies grown in methylcellulose in the presence of 0, 0.001, 0.01, 0.05 and 0.5 IU/ml EPO, and genotyped them using real time PCR. We infected Ba/F3-R-EPO cells with a retrovirus encoding JAK2 V617F and the GFP. After single cell fluorescence activated cell sorting, seven clones, which expressed 0, <10%, 25%, 40%, 60%, 75%, 90%, and 100% of JAK2 V617F, were selected and expanded. EPO sensitivity, proliferation, cell cycle, apoptosis, and cell signalling were further studied. *Results.* Wild-type erythroid progenitors from healthy controls and patients were not EPO hypersensitive. In contrast, mutated cells were found EPO hypersensitive or independent. The effect was greater in V617F homozygous progenitors from PV patients: 69±3% of homozygous progenitors were EPO independent compared to only 22±3% of heterozygous ones. We then analyzed the response to EPO of Ba/F3-R-EPO clones. Two clones with 90% and 100% of JAK2 V617F expression were EPO independent. Clones expressing 0 to 75% of mutant were not EPO hypersensitive. In the presence of low EPO concentration we found a correlation between the JAK2 V617F level and the proportion of cells in the S phase of the cell cycle. In cells expressing less than 50% and 75% of V617F, 0.1 and 0.05 IU/mL of EPO were respectively necessary to promote G1/S phase transition. In contrast, G1/S phase transition was EPO independent for clones expressing more than 90% of mutant JAK2. Moreover, at low concentrations or in the absence of EPO, an increase in apoptosis was observed in clones that expressed less than 90% of JAK2 V617F, but not in clones with 90% and 100% of JAK2 V617F. In the later clone, EPO depletion resulted in a four-fold increase in Bcl-xl, that was not seen in clones with low JAK2 V617F levels. *Conclusions.* Only Ba/F3-R-EPO clones engineered to mimic homozygous cells (clones with 90 to 100% of mutant JAK2) were EPO independent, able to promote G1/S phase transition, and to increase Bcl-xl level in low EPO concentration conditions. In addition, most homozygous erythroid progenitors from PV patients seemed to be EPO independent. These observations are consistent with the hypothesis that EPO independence is induced by the biological consequences of the presence of the V617F mutation on two JAK2 alleles.

0250

INACTIVATION OF SUPPRESSOR OF CYTOKINE SIGNALING-1 AND -3 (SOCS-1 AND -3) AND SH2-CONTAINING PHOSPHATASE-1 (SHP-1) IN PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISORDERS (CMPD)

M. Lunghi, D. Rossi, C. Deambrogi, M. Cerri, S. Rasi, S. Franceschetti, A. Conconi, P. Riccomagno, D. Capello, G. Gaidano

Division of Hematology, NOVARA, Italy

Background. Ph-negative chronic myeloproliferative disorders (CMPD) are a clinically overlapping group of disorders characterized by somatic point mutations of the JAK2 gene, leading to constitutive JAK-STAT activation. The negative regulators of cytokine signaling SOCS-1, SOCS-3 and SHP-1 have a crucial function in the down-regulation of JAK-STAT activation in response to cytokines. SHP-1, SOCS-1 and SOCS-3 may be silenced by aberrant DNA methylation and/or mutation in human malignancies. *Aims.* To test epigenetic and genetic inactivation of SOCS-1, SOCS-3 and SHP-1 in CMPD and acute myeloid leukaemia (AML). *Methods.* The study was based on: i) 112 CMPD, including 43 essential thrombocythemia (ET), 28 polycythemia vera (PV), 24 idiopathic myelofibrosis in pre-fibrotic phase (MF), 11 atypical chronic myeloid leukemia (ACML), and 6 chronic myelomonocytic leukemia (CMML); ii) 20 AML post-CMPD, including 10 AML from ET, 5 AML from PV and 5 AML from MF. For comparison, 20 normal bone marrow samples were also investigated. All cases were analysed for SOCS-1, SOCS-3 and SHP-1 aberrant methylation by methylation-specific PCR and for JAK2V617F mutation status by allele specific PCR. SOCS-1 and SOCS-3 mRNA levels were detected by real-time RT-PCR. Mutation of SOCS-1 and SOCS-3 were tested by DNA direct sequencing. *Results.* SOCS-3 aberrant methylation occurred with high frequency both in CMPD (46/112, 41%) and in AML post-CMPD (10/17; 59%), and was distributed throughout the different WHO categories: 20/43 (46%) ET, 13/28 (46%) PV, 5/24 (21%) MF, 5/11 (45%) ACML and 3/6 (50%) CMML. Methylation of SOCS-1 and SHP-1 occurred with lower frequency both in CMPD (14/112, 12.5% for SOCS-1; 8/112, 7% for SHP-1) and in AML post-CMPD (3/20, 15% for SOCS-1; 1/20, 5% for SHP-1). In particular, SOCS-1 methylation was detected in 5/43 (12%) ET, 5/28 (18%) PV, 3/24 (12.5%) MF, 1/11 (9%) ACML, 0/6 CMML. SHP-1 methylation was observed in 4/43 (9%) ET and 4/28 (14%) PV, while it was absent in MF, ACML and CMML. All normal bone marrow samples (n=20) scored negative for SOCS-1, SOCS-3 and SHP-1 methylation. JAK2V617F mutation was detected in 66/112 (59%) Ph-CMPD, including 24/43 (56%) ET, 23/28 (82%) PV, 19/24 (79%) MF, and in 5/20 (25%) AML post-CMPD. SOCS-3, SOCS-1 and SHP-1 methylation occurred in both JAK2V617F-positive (26/66, 39% for SOCS-3; 11/66, 17% for SOCS-1, 6/66, 9% for SHP-1) and JAK2V617F-negative CMPD (12/46, 26% for SOCS-3; 2/46, 4% for SOCS-1, 2/46, 4% for SHP-1). This pattern of SOCS-3, SOCS-1 and SHP-1 methylation was conserved also when the analysis was restricted to PV, ET and MF each as a single group and after stratification for JAK2V617F mutation. By combining the results of SHP-1, SOCS-1 and SOCS-3 methylation status, 29/66 (44%) JAK2V617F mutated cases carried SHP-1 and/or SOCS-1 and/or SOCS-3 methylation as opposed to 29/46 (43%) germline cases. Similar results were obtained in JAK2V617F-positive and JAK2V617F-negative AML post-CMPD. To verify the correlation between aberrant methylation and gene expression, we analyzed SOCS-3 and SOCS-1 mRNA levels by real-time RT-PCR. SOCS-3 mRNA levels were significantly higher in unmethylated samples (n=10) compared to methylated samples (n=6; p=0.005) and to normal bone marrow (n=10; p=0.03). Similar results were obtained for SOCS-1. SOCS-1 and SOCS-3 missence mutations were detected in 2/104 (2%) and 1/93 (1%) CMPD, respectively. *Conclusions.* i) Inactivation by aberrant methylation of SOCS-3, SOCS-1 and SHP-1 is involved in the pathogenesis of CMPD, is selectively associated with neoplastic hemopoiesis and correlates with reduced gene expression; ii) methylation of SOCS-3, SOCS-1 and SHP-1 occurs in both JAK2V617F positive and negative cases; iii) the methylation rate of SOCS-3, SOCS-1, and SHP-1 is similar in CMPD and in AML post-CMPD, suggesting that SOCS-3, SOCS-1 and SHP-1 silencing is not involved in leukemic transformation; iv) SOCS-1 and SOCS-3 mutations are rarely involved in CMPD.

0251

CHARACTERIZATION OF DIFFERENTIALLY EXPRESSED MICRORNAS IN GRANULOCYTES FROM PRIMARY MYELOFIBROSIS

P. Guglielmelli,[1] A. Pancrazzi,[1] C. Bogani,[1] L. Tozzi,[1] R. Zini,[2] A. Bosi,[1] R. Manfredini,[2] A.M. Vannucchi[1]

[1]Florence University, FLORENCE; [2]University of Modena and Reggio Emilia, MODENA, Italy

Background. Despite advances in defining diagnostic and prognostic criteria in patients with Primary Myelofibrosis (PMF), and the recent description of Val617Phe mutation in JAK2 exon12 and of MPL W515K/L mutation, the molecular defect(s) associated with the development of PMF remain still largely to be defined. Comparative transcriptome microarray analysis has allowed us to evidentiate a complex pattern of aberrantly regulated genes in PMF. The underlying mechanism is still poorly understood, but microRNAs might be supposed to play a role in abnormal gene regulation. AIMS. As an approach to identify possibly aberrantly regulated microRNAs in PMF, we used a Human Panel including 150 individual miRNA assays. We performed a comprehensive transcriptome comparative microRNA analysis of normal and PMF granulocytes. METHODS. To this purpose, we prepared four pools, each comprising three subjects, of granulocytes from PMF subjects, two from JAK2V617F wild-type (WT) and two from homozygote patients; two pools from blood donors were used as controls. The method uses stem-looped primers for reverse transcription (RT) of the miRNA, followed by quantitative real-time PCR. The cDNA was analysed with the aid of a TaqMan MicroRNA Assay Human Panel Kit (Applied Biosystem). *Results.* Ninety six differentially expressed microRNAs were identified; 87 were decreased and 9 were increased. In order to validate these data, we have selected 7 miRNAs which were extremely aberrantly regulated in PMF and we performed a Real-time PCR (RT-PCR) using single TaqMan MicroRNA Assay (Applied Biosystem); these were carried out in an indipendent cohort of normal controls and patients with PMF, polycythemia vera (PV), essential thrombocythemia (ET) and idiopathic erytrocytosis (IE). Three of these gene (miR-150, miR-95 and miR-183) allowed to discriminate patients with PMF from both healthy subjects, IE and others chronic myeloproliferative disorders. We found no difference in expression profile between WT and JAK2V617F homozygote patients. With the aim to confirm the biological effects of these microRNAs, we have combined miRNA expression data with previously described transcriptosome of CD34+ PMF using microarray analysis (Guglielmelli et al, Stem Cells, 2007:165-73). After identified a number of predicted miRNA 'Targets, we have measured gene expression levels in granulocytes by RT-PCR. We found that MYB, MYCN, LEPR and PRAME were significantly increased in PMF compared with healthy controls as expected for the low levels of miR-150 and miR-183; on the other hand, both DTR and FOSB, and their putative regulatory miR-95 and miR-31, were found concurrently decreased. *Conclusions.* Recent studies have implicated miRNAs in a number of fundamental cell processes and in hematopoiesis. These data show an unique expression profiling of PMF patients as compared to normal controls, with an observed overall miRNA downregulation, as reported in other cancer cells. Moreover, 3 miRNAs were identified as a predictive signature of PMF as opposed to other myeloproliferative disorders. Finally, we showed correlation between some microRNAs and abnormally regulated putative target genes, suggesting their possible role in disease pathogenesis.

Myeloma and other monoclonal gammopathies - Clinical I

THALIDOMIDE INDUCED IMPOTENCE IS A COMMON BUT FREQUENTLY UNRECOGNIZED COMPLICATION IN MALE HEMATOLOGY PATIENTS

Ph. Murphy, J.R. O'Donnell

Beaumont Hospital, DUBLIN, Ireland

Background. Thalidomide has recently become an important therapy in myeloma. Well recognized complications of this drug include somnolence, venous thromboembolic disease, constipation and peripheral neuropathy. Male sexual dysfunction is described as a 'rare complication' of thalidomide, despite absence of any scientific data on its true incidence. *Aims.* We wished to ascertain the frequency and severity of erectile dysfunction induced by thalidomide therapy in male patients attending our hematology department who had been exposed to this drug. *Methods.* All male patients attending the hematology department at Beaumont Hospital who were taking or had taken thalidomide were asked specifically about erectile dysfunction associated with the use of this agent. Severity of erectile dysfunction was graded according to the National Cancer Institute Common Toxicity Criteria (version 2). *Results.* 16 male patients were receiving or had received thalidomide: 14 had myeloma, one had angioimmunoblastic lymphadenopathy and one had massive inoperable abdominal haemangioma. 5 cases (median age 74, range 59-79) were impotent (grade 3 erectile dysfunction) prior to diagnosis of myeloma and commencement of any therapy. 5 further cases of myeloma denied problems of erectile dysfunction during thalidomide therapy: 3 relapsed myeloma cases received up to thalidomide 100mgs daily in combination with intermittent high dose corticosteroids for periods of between 2 months and 21 months, and the other 2 patients received single agent thalidomide 50 mgs daily as maintenance therapy post autologous peripheral stem cell transplant (PSCT) for 1 month and 18 months respectively. 4 of these 5 cases developed grade 1 peripheral neuropathy during thalidomide therapy. All 6 remaining patients developed erectile dysfunction (grade 3 in 5 cases) within 4 weeks of starting thalidomide. Only 2 of these cases had mentioned this side effect prior to direct questioning about this complication. All 6 cases also developed thalidomide induced grade 1 peripheral neuropathy. Of the 2 patients developing erectile dysfunction whilst taking single agent thalidomide 50 mgs daily as maintenance post PSCT, one patient (aged 44) developed grade 1 erectile dysfunction which has resolved following drug discontinuation after 14 months of therapy, whilst the second individual (aged 51), who discontinued thalidomide after 15 months, remains impotent. 2 further patients (aged 58 and 64), who had received a combination of thalidomide (maximum dose of 200 mgs in both cases) and intermittent high dose corticosteroids for 3 months and 24 months respectively, remain impotent despite discontinuation of thalidomide for 12 months and 23 months respectively. The final 2 patients with thalidomide induced impotency remain on this medication: one patient (aged 55) with massive intraabdominal hemangioma has had a marginal clinical improvement since starting thalidomide 100mgs daily 6 months ago, whilst a patient (aged 63) with relapsed myeloma is responding to a combination of thalidomide (maximum dose 150 mgs daily) and intermittent high dose corticosteroids, started 2 months ago. *Conclusions.* The results from this study of a small number of patients suggest that erectile dysfunction in male hematology patients may be a much more common problem than previously suspected. The probable reason for this *blind spot* is that embarrassing questions about erectile dysfunction are not asked at hematology review of these patients, who are equally unlikely to volunteer such information. However, as this complication could be regarded as important by some such patients and their sexual partners, the issue needs to be taken seriously by the hematology community. As many male myeloma patients are likely to receive thalidomide in the foreseeable future, studies on larger numbers of patients are required to establish the true incidence of thalidomide induced sexual dysfunction, its relationship to thalidomide dose, patient age, other therapies and its liklihood of recovery on drug discontinuation.

0253

BORTEZOMIB, DOXORUBICIN AND DEXAMETHASONE COMBINATION THERAPY FOLLOWED BY THALIDOMIDE AND DEXAMETHASONE AS A SALVAGE TREATMENT FOR RELAPSED MULTIPLE MYELOMA: PRELIMINARY ANALYSIS OF EFFICACY AND SAFETY

S.S Lee,[1] J.H. Lee,[2] B.S. Kim,[3] J.S. Chung,[4] Y.D. Joo,[5] H.M. Ryoo,[6] Y.R. Do,[7] J.Y. Jin,[8] H.J Kang,[9] K.W. Lee,[10] M.H. Lee,[11] H. Shim,[12] K. Kim,[13] S.S. Yoon,[14] C. Suh[1]

Introduction. PAD was reported to be highly effective regimen as an induction therapy before high dose therapy. TD is an another effective regimen with no cross resistance. We conducted a phase II study with PAD followed by TD in relapsed MM to test effectiveness of this combination. *Method.* Patients were planned to receive 6 cycles of PAD, (bortezomib 1.3 mg/m^2 days 1, 4, 8 and 11, doxorubicin 4.5 mg/m^2 days 1-4, dexamethasone 40 mg days 1-4, every 21 days). Responders following 6 cylces of PAD received 12 cycles of TD (thalidomide 100 mg days 1-28 and dexamethasone 40 mg days 1-4, every 28 days). In patients with progression during PAD therapy, regimen was changed to 12 cycles of thalidomide 200 mg days 1-28 and dexamethasone 40 mg days 1-4, every 28 days. Response was assessed by EBMT criteria, with additional categories of nCR and VGPR. Adverse events were graded by the NCI-CTC, Version 3.0. *Results*. This study aimed to enroll 35 patients till Oct 2007 and we are reporting preliminary result with 25 patients. Efficacy could be assessed in 20 patients. After two cycles of PAD, 14 patients showed response with 4 CR. Overall response rate to 6 cylces of PAD was 84% with 32% CR. Five of total 11 patients with TD showed further improvement of response status with 2 additional CR. Overall response to PAD followed by TD was 90%: CR 42%, nCR 11%, VGPR 5%, PR 32%, MR 5%, PD 5%. There was no prognostic factor for CR+nCR achieving in the univariate analysis. The median follow-up was 7.7 months with 1 year PFS 64% and 1 year OS 85%. Ninty-five PAD cycles in 24 patients were assessable for safety. The most common hematologic toxicity was thrombocytopenia, with grade 3/4 in 21%. Grade 3/4 neutropenia was observed in 20%. Sensory neuropathy occurred with grade 2 in 38% and grade 3 in 4%. The median dose intensity was 1.52 mg/m^2/week for bortezomib and 5.37 mg/m^2/week for doxorubicin, which correspond 88% and 90% of the planned dose intensities, respectively. A total of 42 TD treatment cycles (median 3, range 1-6 cycles) was administered. One patient developed grade 3 neutropenia and thrombocytopenia. Non-hematology toxicities occurred infrequently and mild. *Conclusions.* PAD followed by TD in patients with relapsed multiple myeloma is very active and tolerable.

0254

COMBINATION OF BORTEZOMIB, DOXORUBICIN AND DEXAMETHASONE FOR PATIENTS WITH ADVANCED MULTIPLE MYELOMA

A. Palumbo,[1] F. Gay,[1] A. Falcone,[2] N. Pescosta,[3] V. Callea,[4] T. Caravita,[5] F. Morabito,[6] P. Falco,[1] A. Larocca,[1] F. D'Agostino,[1] P. Musto,[7] N. Cascavilla,[2] M. Boccadoro[1]

[1]Az. Osp. S. Giovanni Battista, TORINO; [2]IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO (FG); [3]Ospedale Centrale, BOLZANO; [4]Ospedale Riuniti, REGGIO CALABRIA; [5]Università Tor Vergata, ROMA; [6]Az. Osp. di Cosenza, COSENZA; [7]Centro Riferimento Oncologico Basilicata, RIONERO IN VULTURE (PZ), Italy

Background. Bortezomib has significant activity in patient with multiple myeloma (MM); its efficacy is increased by the addiction of Dexamethasone and it demonstrates synergy with Doxorubicin. Two different studies evaluated the efficacy of the combination of Anthracyclines, Dexamethasone and Bortezomib showing encouraging response rate of 72% in relapsed-refractory patients and 95% in newly diagnosed patients. *Aims.* We assessed the safety and efficacy of the association of Bortezomib, Doxorubicin and Dexamethasone (PAD) in patients with advanced MM. *Methods.* Sixty-four patients with relapsed/refractory MM (median age 65 years; range 41-85 years) were treated with PAD:

Bortezomib 1.3 mg/m^2 days 1,4,8,11; Doxorubicin 20 mg/m^2 i.v. days 1,4 or Pegilated Lyposomal Doxorubicin 30 mg/m^2 i.v. day 1; and Dexamethasone 40 mg p.o, days 1,2,3,4. Each cycle was repeated every month. *Results.* Patients received a median number of 4 cycles (range 1-8). Median number of prior therapies was 2 (range 1-7) and median time from diagnosis was 31 months (range 2-181 months): 27% patients received prior Bortezomib based-regimens, 75% prior Thalidomide based-regimens and 58% prior transplantation. Forty-three patients (67%) achieved at least partial response (PR) including 16 patients (25%) who showed at least very good partial response (VGPR) and 6 patients (9%) who achieved a complete response (CR). In patients who received PAD as 2nd line treatment, the PR and VGPR rates were 80% and 27%, respectively; CR was reported in 13%. Responses were equal or superior to that induced by previous treatment schedules in 69% of patients. The PR (59% vs 66%) and VGPR (18% vs 28%) rates were similar between patients who received or not prior Bortezomib regimens. Similarly, the PR (67% vs 69%) and VGPR (27% vs 19%) rates were analogous between patients who received prior Thalidomide regimens or those who did not. From the start of PAD therapy, the 1-year progression free survival (PFS) and the 1-year overall survival (OS) were 34% and 67%, respectively. Patients treated with PAD as 2nd line, showed a 1-year PFS of 57%. The 1-year PFS was not different between patients who received prior Bortezomib based-regimens and those who did not (16% vs 39%, p<0.1). Grade 3 or more hematological toxicities included trombocitopenia (48%), neutropenia (36%), anemia (13%); non-hematological toxicities ≥ grade 3 included infections (17%), neuropathy (13%), gastrointestinal (11%), fatigue (6%) and cardiac (3%). Sixteen patients died: 2 for infections, 1 for heart failure and 13 for progressive disease. *Conclusions.* The PAD regimen showed a high proportion of responses. Both responses and PFS were not influenced by previous Bortezomib treatments. Toxicities were predictable and manageable.

DAILY LOW DOSE THALIDOMIDE PLUS MONTHLY HIGH-DOSE DEXAMETHASONE AS CONSOLIDATION/MAINTENANCE TREATMENT IN ELDERLY MULTIPLE MYELOMA PATIENTS

M. Gentile,[1] C. Mazzone,[1] C. Iorio,[1] E. Lucia,[1] E. Vigna,[1] F. Mazzei,[2] P. Carnevale,[2] M.G. Bisconte,[1] C. Gentile,[1] F. Morabito[1]

[1]*Haematology Unit, COSENZA;* [2]*Pharmacy Unit, COSENZA, Italy*

Background. Thalidomide (Thal) is currently considered as one of the most active anti-myeloma agents. Thal has shown significant activity as frontline, salvage and maintenance therapy as well as in patients with relapsed disease. The association of Thal with Dexamethasone (Dex) has shown a superior efficacy in de novo and relapsed MM patients. *Aims.* The purpose of this study was to assess feasibility, tolerability and efficacy of the Thal/Dex schedule administered as consolidation/maintenance therapy in elderly MM patients not eligible for aggressive therapy. *Methods.* A combination of Thal at dose of 100 mg/d with Dex at dose of 40 mg/d for 4 days every 28 days was administered to 30 MM patients. Median age was 71 years (range 47-83 years). *Results.* Before starting Thal and Dex schedule, 2 patients (7%) were in complete response (CR), 15 (50%) in partial response (PR) while the remaining 13 patients (43%) in stable disease (SD). After a median Thal/dex administration of 12 months (range 1-42 months), 2 patients (7%) discontinued treatment because of WHO grade III-IV peripheral neuropathy (1 pt) and severe fatigue (1 pt). Dose-limiting toxicities were also defined as WHO grade I/II constipation (11/30 pts), peripheral neuropathy (9/30), fatigue (8/30), dizziness and/or somnolence (8/30). Although no patient received anti-thrombotic prophylaxis, no case of DVT occurred during Thal/Dex therapy. Six out of 15 patients (40%) in PR and 10/13 (76%) in SD showed an improvement of the previous response. In particular, considering the best response after Thal/Dex therapy, 15 pts achieved CR, 12 PR, 2 PD and 1 SD. The overall response rate (CR and PR) has improved from 56% to 90% (overall CR from 7% to 50%). The median progression free-survival (PFS) and overall survival (OS) of the 30 patients treated with Thal/Dex were 12 months and 23 months, respectively. *Conclusions.* The results of this study indicate that Thal/Dex treatment, given as consolidation/maintenance treatment in elderly MM patients, is feasible and tolerable, with a cumulative incidence of grades III and IV toxic events of only 7%. Moreover, this treatment produced a noticeable clinical benefit. Additional randomized studies need to be designed to explore if low dose Thal associated with monthly Dex, given as consolidation/maintenance treatment, may affect life expectancy of MM patients not eligible for aggressive treatment modalities.

COMBINATION OF TCD (THALIDOMIDE, CYCLOPHOSPHAMIDE AND DEXAMETHASONE); AN EFFECTIVE AND SAFE ALTERNATIVE TO CONVENTIONAL VAD (VINCRISTINE, ADRIAMYCIN AND DEXAMETHASONE) AS A FIRST-LINE THERAPY IN MULTIPLE MYELOMA

Y.-K. Kim,[1] J.J. Lee,[1] S.K. Sohn,[2] H.J. Shin,[3] S.R. Lee,[1] H.J. Shim,[1] J. S. Ahn,[1] D.H. Yang,[1] S.H. Cho,[1] I.J. Chung,[1] H.J. Kim[1]

[1]*Chonnam National University Hwasun Hosp, JEOLLANAM-DO;* [2]*Kyungpook National University Hospital, DAEGU;* [3]*Pusan National University Hospital, PUSAN, South-Korea*

Background. Conventional VAD (vincristine/adriamycin/dexamethasone) has been shown to induce rapid remissions in patients with newly diagnosed multiple myeloma. However, the high toxicity and short duration of the response after VAD warrants the search for alternatives. *Aims.* To examine the efficacy and safety of TCD (thalidomidecyclophosphamide/dexamethasone), compared with conventional VAD, in patients with newly diagnosed multiple myeloma. *Methods.* A total of 71 patients with multiple myeloma were initially treated with TCD or VAD between July 1997 and October 2006. TCD regimen: thalidomide (50 mg/day, daily), cyclophosphamide (150 mg/m^2 P.O. on D1-4), and dexamethasone (20 mg/m^2 I.V. on D1-5, D15-19) and VAD regimen: vincistine (0.4 mg C.I.V. on D1-4), adriamycin (9 mg/m^2 C.I.V. on D1-4), and Dexamethasone (40 mg P.O. on D1-4, D9-12, D17-20). Autologous peripheral blood stem cells (PBSC) were collected after mobilizing with G-CSF with or without cyclophosphamide. *Results.* 71 patients (TCD regimen: 35 patients, VAD regimen: 36 patients) who received at least 4 cycles or more were evaluated for response and toxicity. No significant difference showed in age and sex between two treatment groups. There were 11 (31.4%) complete responses and 18 (51.4%) partial responses for TCD regimen and 10 (27.8%) complete responses and 18 (50%) partial responses for VAD regimen, respectively. There was no significant difference in overall response rate between two treatment groups (TCD: 82.8% vs. VAD: 77.8%, p=0.77). A trend for longer progression-free survival (PFS) was observed in patients treated with TCD compared with VAD, but there was no statistical significance (19.4±4.8 ms vs. 10.4±4.1 ms, p=0.12). In addition, there was no significant difference in overall survival (OS) between two groups (NA. vs. 45.5±10.3 ms, p=0.24). However, there was a significantly lower incidence of NCI-CTC (grade 3/4) neutropenia (14.3% vs. 36.1%, p<0.05) and treatment-related mortality (5.7% vs. 22.2%, p<0.05) in patients treated with TCD compared with those treated with VAD. 2 patients (5.7%) with thrombosis in TCD group and 1 patient (2.8%) with dilated cardiomyopathy (DCMP) in VAD group were observed. 11 (TCD group) and 10 (VAD group) patients who achieved more than partial response to induction proceeded to PBSC collection and the median number of CD34+ cells collected failed to show significant difference between two groups (p=0.78). *Conclusions.* Low dose thalidomide containing regimen (TCD) was as effective as conventional VAD regimen for patients with newly diagnosed multiple myeloma. Further, TCD may emerge as the superior regimen in terms of tolerability and safety.

0257

FREE LIGHT CHAIN ASSAYS FOR EARLY DETECTION OF RESISTANCE TO BORTEZOMIB-BASED REGIMENS

R. Hajek,[1] R. Hajek,[2] Z. Cermakova,[3] L. Pour,[2] H. Novotna,[3] V. Maisnar,[4] M. Tichy,[5] Z. Adam,[2] M. Krejci,[2] A. Krivanova,[2] K.H. Havlikova[2]

[1]*Czech Myeloma Group, BRNO;* [2]*IHOK University Hospital and IHOK LF MU, BRNO;* 3*Dep. of Clinical Biochemistry Hospital, BRNO;* [4]*Def. of Hematology University Hospital, HRADEC KRALOVE;* [5]*Faculty of Military Health Sciences, HRADEC KRALOVE, Czech Republic*

Background. Several studies have shown that immunoassays measuring free light chains (FLC) in the serum are useful for diagnosis and monitoring of multiple myeloma (MM). Because of short half-life of light chains, FLC assay is also a promising tool for the early detection of responses to treatment. The early detection of responses would be helpful in making the clinical decision whether to continue the treatment, especially with expensive agents. The role of FLC assay in the detection of responders and non-responders to bortezomib-based regimens was evaluated by us in 2006 and now an update of this analysis is presented. *Aims.* To evaluate the FLC assay as an early indicator of sensitivity or resistance to bortezomib-based regimens. *Methods.* Patients with at least one relapse of MM were prospectively evaluated on days 1 and 11 of every cycle of bortezomib-based regimens. The results of serum FLC

assays (for lambda or κ chains) and M-Ig analysis using immunofixation electrophoresis were analysed for three categories (time to reduction of parameters to 25% (minimal response - MR), 50% (partial response - PR) and 75% (very good partial response - VGPR) of the pre-treatment values) to establish their value for the detection of early response. The cohort of 24 patients from our pilot analysis (2006) was enlarged to a total of 39 patients who had had at least 5 cycles of therapy. *Results.* A total of 21 patients (54%) responded to the therapy (3% complete response, 15% VGPR, and 36% PR). Further 20% patients achieved minimal response (MR). Overall treatment responses (i.e. at least PR) were detected on days 22/33/44/55/66 of the treatment in 41%/49% /56%/59%/59% of patients using FLC assay versus 13%/18%/41%/ 46%/51% of patients using electrophoresis. The differences were statistically significant for all reported days up to day 55 (p=0.004-0.019). The results of the two methods became similar on day 66 (59% vs. 51%; p=0.060). Response after day 66 was only seen in one patient, who achieved PR after 88 days (FLC), or 99 days (M-Ig) of the treatment. Moreover, the patients who did not respond with at least 25% reduction of serum single chain as detected by FLC during the first 33 days never achieved PR. *Conclusions.* We confirmed our pilot data in that we did not observe PR in patients who did not have at least 25% reduction in serum free chain as measured by FLC by day 33. Thus, FLC assay can be used to detect resistance early during bortezomib treatment. By day 66 (day 1 of cycle 4 in the routine schedule of bortezomib treatment) 20 out of 21 responding patients achieved response (at least PR). With some limitation, day 66 can be suggested as a cut-off time for the chance of achieving long-term response to bortezomib-based therapy.

EFFICACY AND SAFETY OF MELPHALAN, PREDNISONE, THALIDOMIDE AND DEFIBROTIDE IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA PATIENTS: RESULTS OF A MULTICENTER PHASE I/II TRIAL

A. Palumbo,[1] A. Larocca,[1] C. Rus,[1] F. Gay,[1] D. Rossi,[2] P. Pregno,[1] P. Falco,[1] I. Avonto,[1] V. Magarotto,[1] F. D'Agostino,[1] M. Iacobelli,[3] G. Gaidano,[2] C. Mitsiades,[4] P.G. Richardson,[4] K. Anderson,[4] M. Boccadoro[1]

[1]Az. Osp. S. Giovanni Battista, TORINO, Italy; [2]Univ. Studi Piemonte Orientale, Avogadro, NOVARA, Italy; [3]Gentium S.p.A., COMO, Italy; [4]Dana-Farber Cancer Institute, BOSTON, USA

Background. Defibrotide (DF) is a novel orally bioavailable oligonucleotide with protective effects on endothelial cells but without significant systemic anticoagulant effects and bleeding risk. *in vitro*, DF showed minimal inhibitory effect on multiple myeloma (MM) cells growth but *in vivo* (human MM xenografts in SCID/NOD mice) markedly increased the responsiveness of MM cells to cytotoxic agents (melphalan or cyclophosphamide) and dexamethasone. DF may therefore abrogate tumor cell interaction with marrow stromal cells and enhance sensitivity to chemotherapy, thus improving the activity of Melphalan, Prednisone and Thalidomide, while protecting against thrombosis. *Aims.* We designed a study to determine the efficacy and safety of Melphalan, Prednisone, Thalidomide and Defibrotide (MPTD) as salvage treatment in patients with relapsed/refractory MM. Safety was assessed by defining dose-limiting toxicity (DLT) and maximum tolerated dose (MTD) of DF when administered in combination with MPT. DLT was defined by the occurrence of febrile neutropenia, or Grade 4 neutropenia ≥ a week, or any other Grade 4 hematologic toxicity, or any ≥ Grade 3 non-hematologic toxicity, in >30% of patients at first cycle. MTD was the dose level prior to that resulting in DLT. *Methods.* Between March and November 2006, 24 patients in first or second relapse (excluding primary refractory patients and/or patients receiving therapeutic anticoagulation) were enrolled. MPTD consisted of 6 X 35 days cycles of oral melphalan (0,25 mg/Kg day 1-4), prednisone (1,5 mg/kg day 1-4), thalidomide (50-100 mg/day continuously) and DF at 3 different dose levels (17 mg/Kg i.v. or 2.4 g p.o. D 1-4, 1.6 g p.o. D 5-35; 34 mg/Kg i.v. or 4.8 g p.o. D 1-4, 3.2 g p.o. D 5-35; 51 mg/Kg i.v. or 7.2 g p.o. D 1-4, 4.8 g p.o. D 5-35), without prophylaxis against deep vein thrombosis (DVT). *Results.* Nineteen pts (median age 69 years ;range: 47 - 88) completed at least one cycle and were evaluable for response. According to EBMT/IBMTR criteria, after a median of 3 cycles, 42% of patients achieved at least partial response (including 16% very good partial response). To date no significant difference in response rate was noted among the 3 DF dose levels, but follow up remains short. DLT consisted of grade 3 ileus in the 1st dose level, 1 acute myocardial infarction (AMI) in the 2nd (both considered unrelated to DF) and none in the 3rd. MTD was therefore not reached in any cohort. Greater than or equal to grade 3 hematological toxicities included neutropenia (47%), thrombocytopenia (10%), and anemia (21%). Non-hematological toxicities ≥grade 3 were observed in <5% and no DVTs were reported. Three patients stopped treatment because of adverse events : AMI (requiring additional anticoagulation as treatment), ileus (because of the finding of amyloidosis AL and disease progression), and persistent G4 neutropenia in one heavily pre-treated patient. In none of these cases was DF thought contributory and no significant bleeding was reported. Pharmacokinetic studies and analysis of surrogates are ongoing. *Conclusions.* MPTD provided promising evidence of anti-tumor activity in relapsed/refractory MM, with manageable toxicities. A protective role of DF in reducing thrombosis is suggested, although the thrombotic risk from thalidomide-based therapy is more variable in advanced MM than that seen in the up-front setting. The absence of other significant non-hematologic toxicity, including neuropathy, is encouraging. An update of these data will be presented at the meeting.

0259

LIPOSOMAL DOXORUBICIN INCREASES THE ANTI-TUMOR EFFICACY OF LOW DOSE BORTEZOMIB, THALIDOMIDE AND DEXAMETHASONE THERAPY IN ADVANCED MULTIPLE MYELOMA

S. Ciolli,[1] F. Leoni,[1] C. Casini,[1] C. Breschi,[2] A. Bosi[1]

[1]Azienda Universitaria Ospedaliera Caregg, FLORENCE; [2]Department of Oncology Del Ceppo hosp, PISTOIA, Italy

Background. standard chemotherapeutics plus bortezomib may have higher anti-tumor activity than bortezomib alone. The combination with anthracyclines is attractive but it may have a significant toxicity in advanced myeloma. Liposomal doxorubicin has a longer half-life than standard doxorubicin, lower cardiac toxicity and comparable efficacy. To improve outcome while minimizing therapy-related toxicity, we added non-pegylate liposomal doxorubicin (Myocet®) to the low dose Bortezomib, Dexametasone and Thalidomide regimen (LD-VTD) that we previously applied. *Aims*. Safety, ORR, TTP and OS in respect to LD-VTD. *Methods.* since February 2004, all refractory myeloma patients were enrolled in the study once they had a measurable disease, irrespective of PS. Planned therapy was: Bortezomib (Velcade®) 1.0 mg/m^2 i.v. bolus days 1, 4, 8 and 11 of a 28-d cycle, oral Dexamethasone 24 mg on the day of and the day following each bortezomib dose and Thalidomide 100 mg/d if non contraindicated (LD-VTD). In patients enrolled from January 2005, liposomal doxorubicin (Myocet®) 50 mg/m^2 i.v. was added on day 4 (LD-VTD/My).

Table 1. Patients characteristics (#65).

	LD-VTD Group 1 (# 28)	LD-VTD+Myocet Group 2 (#36)	*p*
Age, median	67(53-78)	66(42-81)	n.s.
Peripheral neuropathy>2	4(14%)	8(22%)	n.s.
Hb<10 gr/dL (#pts)	7(25%)	15(41%)	n.s.
Plt<100x10^9/L (#pts)	7(25%)	8(22%)	n.s.
β2 microglobulin 4 mg/L	11(39%)	11(39%)	n.s.
Stage III	19(68%)	29(80%)	n.s.
Yrs from diagnosis, median	5	6	n.s.
Number of prior treatments	4(2-8)	3(2-6)	n.s.
MP	22	9	
VAD	17	11	
VED	4	3	
Thal/Dex	28	36	
Autologous transplant	5	6	
Allogeneic transplant	2	2	
Primary refractory	10(36%)	17(47%)	n.s.
Relapsed/refractory	18(64%)	19(53%)	n.s.
#pts valuable for response	28	33	
CR+nCR	6(21%)	14(42%)	n.s.
PR	4	10	
MR	4	0	
ORR	50%	73%	0.04
PD/SD	3/11	0/9	
Median time to response, months	2(1-4)	1,2(1-3)	n.s.
Time to progression (TTP), months	7	16	0.02
Overall survival, months	23	Not reached	n.s.

Response was defined according to EBMT criteria. Patients with PD were removed from the study, the others continued until best response for a maximum of 6 cycles. LVEF was evaluated before and at the end of treatment. Time to response was from the date of study entry to the first evidence of response, time to progression (TTP) from the date of first response to progression. *Results.* as of February 28th 2007, 65 patients were enrolled, 28 received LD-VTD (group1) and 36 LD-VTD+My (group2). 13(20%) pts did not receive thalidomide due to previous neurotoxicity. Patients characteristics and results are reported in Table 1. As expected, haematologic toxicity was more frequently recorded in group2 and resulted in a major incidence of infections. Extra-haematologic toxicity was negligible in both groups and no patient experienced progression of PN. No case of DVT or cardiac failure was recorded and most patients were treated on an outpatient basis. Median time to response was 2 and 1,2 months, ORR 50% and 73% (p=0,04), median TTP 7 and 16 months (p=0,02) in group1 and 2, respectively. OS of the two groups was comparable. At the day of last follow-up, 11 group1 and 27 group2 patients were alive. *Conclusions.* liposomal doxorubicin increases the antimyeloma efficacy of bortezomib, thalidomide and dexametasone combination regimen with acceptable toxicity in elderly and heavily pre-treated patients. This might translate in a prolonged OS but an extended follow-up is needed.

0260

FEASIBILITY AND EFFICACY OF BORTEZOMIB RE-TREATMENT IN MULTIPLE MYELOMA

S. Ciolli, F. Leoni, C. Casini, A. Bosi

Azienda Universitaria Ospedaliera Caregg, FLORENCE, Italy

Background. despite improved response and survival, multiple myeloma (MM) still relapse and remain an incurable disease. Safety and efficacy of bortezomib in previously treated MM, either as single agent or with thalidomide or standard chemotherapeutics, have been well established. However, no therapy is curative and upon relapse myeloma cells develop resistance to therapies that had been previously effective. Until recently, few data are available on the feasibility and benefits of re-treatment with bortezomib which is a weak substrate for multi-drug resistance efflux pumps and has the potential to avoid resistance. To assess the safety and efficacy of bortezomib re-treatment in advanced MM, we reviewed the outcome of patients who were re-challenged with bortezomib after a previous response in our institution. *Methods.* since January 2005, all myeloma patients previously treated with a bortezomib based therapy and achieving at least a stable disease were considered suitable for re-treatment. They were required a measurable disease and a life expectancy >1 months. Planned therapy was: bortezomib (Velcade®) 1.0 mg/m^2 i.v. bolus days 1, 4, 8 and 11 of a 28-d cycle, oral dexamethasone 24 mg on the day of and the day following each Velcade dose. Patients receiving thalidomide (50/100 mg) as maintenance continued the drug, if not contraindicated. Adverse events were assessed at each visit and graded according to NCI criteria. Efficacy was assessed after each cycle and response defined according to EBMT criteria. Patients with PD were removed from the study, the others continued until best response for a maximum of 8 cycles. Overall survival (OS) was from the date of bortezomib re-treatment to the date of death or last follow-up. Time to progression (TTP) from the date of first response to progression. *Results.* as of February 28th 2007, 11 were the patients re-treated. They all had a progressive disease, were heavily pre-treated and in most of them neuropathy of any grade was present. Patients characteristics: median age 64 yrs (42-80), 8 stage III (2 stage IIIB), 5 β2microglobulin >4 mg/L, WBC 3.7×10^9/L ((2.0-9.7), haemoglobin 10 gr/dL(7,8-14,5), platelets 135×10^9/L(10-258). Median time from diagnosis to first bortezomib was 4 yrs (1-15,8) and a median of 4 (1-8) were the previously delivered therapy lines. 4 were the patients relapsed after a bone marrow transplant prior to first bortezomib. Toxicity was negligible, not increased in comparison with first bortezomib therapy. Grade 1 neutropenia was recorded in two patients, grade 2 thrombocytopenia in 2. A negative impact on haemoglobin level was never registered. Overall, the most commonly reported adverse events of grade >1 were fatigue (50%) and nausea (22%). There was not a clinical progression of pre-existing neuropathy. At the date of last follow-up, 10 patients were valuable for response. 6 patients, who had achieved a response with first bortezomib, again responded (4 nCR , 2 PR) while 4 SD with the previous bortezomib, again achieved a SD. After a medium follow-up of 13 months, 5 patients were alive. Median TTP was 9 (2-12) months. *Conclusions.* bortezomib re-treatment is safe, effective and not associated with new or cumulative toxicity. Responsive patients may benefit from re-challenging the drug.

0261

SALVAGE THERAPY WITH INTRAVENOUS BORTEZOMIB, MELPHALAN AND DEXAMETHASONE IN PREVIOUSLY TREATED MYELOMA PATIENTS

F. Di Raimondo,[1] A. Chiarenza,[1] V. Del Fabro,[1] L. Schinocca,[1] P. Fiumara,[1] G.A. Palumbo,[1] C. Conticello,[2] G. Amato,[2] R. Giustolisi[1]

[1]Hematology Dept, Univ.of Catania, CATANIA; [2]Mediterranean Institute of Oncology, VIAGRANDE, CATANIA, Italy

Background. Bortezomib, Melphalan, and Steroids are among the most effective drugs for treatment of multiple myeloma and their combination has already tested in elderly myeloma patients. However, so far the contemporary administration of these drugs has not been explored. *Aims.* We therefore designed a protocol with monthly courses of contemporary intravenous administration of these drugs in patients with advanced multiple myeloma. *Methods.* Bortezomib was given at dosage of 1.3 mg/m^2 i.v. days 1,4,8,11, Melphalan 5 mg/m^2 i.v. days 1,4,8,11, Dexamethasone 40 mg days 1-2, 4-5, 8-9, 11-12. So far, 21 patients have been enrolled. Median age was 64.5 (range 53-82). All patients had been already treated with a median of 2 previous lines of treatment (range 1-6) including autologous bone marrow transplant in 7 patients and and Bortezomib alone or in combination in 5 patients. All patients included in this study were no longer eligible for a bone marrow transplant procedure. Fourteen patients were resistant to previous therapies while 7 were considered as relapsed. *Results.* Hematological toxicity grade 3 and 4 occurred in 38%, 36%, 33%, and 50% after I, II, III, and IV cycle respectively of patients after the first cycle. Three patients developed also grade 3 non-hematological toxicity (Herpes zoster, vomit). So far, 4 patients have stopped treatment for toxicity after 1, 3, 3, and 4 courses. All of these patients were in stable disease. Five patients achieved a very good partial remission (M-protein not detectable at electrophoresis), 5 patients a partial remission (reduction of M-protein > 50%) while in two other patients reduction of the M-protein was associated with increase of bone marrow plasmacells. Two patients were in stable disease, one was in progression and 2 are not yet evaluated. *Conclusions.* The contemporary intravenous administration of Bortezomib, Melphalan, and Dexametasone, appears to be an highly effective treatment even for heavily pretreated patients. However, in these patients, haematological toxicity was the limiting factor. Therefore, the dosage of the drugs or their schedule has to be modified.

0262

SALVAGE TREATMENT WITH MELPHALAN 100 MG/M² IN FULMINANT PROGRESSION OF MULTIPLE MYELOMA

R. Hajek,[1] M. Krejci,[2] A. Krivanova,[2] L. Pour,[2] Z. Adam,[2] L. Zahradova,[2] E. Vetesnikova,[2] J. Mayer,[2] J. Vorlicek[2]

[1]Czech Myeloma Group, BRNO; [2]IHOK University Hospital and IHOK LF MU, BRNO, Czech Republic

Background. Patients with a rapid fulminant progression of multiple myeloma (PGMM) have poor prognosis. The treatment options are very limited due to a pancytopenia and/or a general poor status of patients. The treatment with melphalan (MEL) 100 mg/m^2 as a salvage therapy up front followed by infusion of stored autologous peripheral blood stem cells (PBSCs) can stop PGMM almost immediately. This strategy provides a window of opportunity for the application of new immunomodulatory or targeted drugs, such as thalidomide and bortezomib as consolidation treatment. *Aims.* The aim of our analysis was to evaluate the efficacy and toxicity of MEL 100 mg/m^2 (MEL 100) with PBSC support in the PGMM after the first autologous transplantation. *Methods.* We have retrospectively evaluated 18 patients with fulminant PGMM treated with MEL 100 in our centre from 2004 to 2006. Median follow-up from MEL 100 was 5 months (range: 3-14 months). The baseline characteristics of the patients are as follows: median age 58 years (range: 40-68); median number of relapse 1 (range: 1-4); clinical stages according to Durie and Salmon 17%-II/83%-III; clinical stages according to ISS 1-28%/2-44%/3-28%; extramedullary disease in 40% (7/18), renal impairment in 22% (4/18), high degree of bone marrow infiltration with peripheral pancytopenia in 61% (11/18). Following the MEL 100 salvage regimen, the patients were treated mostly with bortezomib (5/18) or with thalidomid based regimen (10/18). *Results.* There was no treatment-related mortality. The median time to the neutrophils engraftment (above 0.5×10^9/L) was 11 days (range: 7-12 days); the median duration of hospitalization after MEL 100 was 21 days (range: 13-90). Mucositis grade 3-4 developed in 27% (5/18) of patients, and febrile neutropenia occurred in 44% (8/18) of patients. Overall response rate (ORR) was 61% (11/18) and only 1 patient had continuous progression. Very rapid

progression within 3 months after MEL 100 occurred in 39% (7/18) of patients. Time to progression (TTP) and overall survival (OS) were evaluated in 78% (14/18) of patients who had median follow-up above 4 months or who died due to event. Median of TTP after MEL 100 was +3.3 months (range 1-11 months) but TTP was +11, 5, 5, +4,+4 months in patients at least in PR after MEL 100. Median OS was +5 months (range 1-12 months) but will be further improved as 44% (8/18) of patients still alive. *Conclusions.* Fulminant PGMM is usually fatal event when conventional chemotherapy as well as new agens are used due to very aggressive features of this event. MEL 100 is safe salvage regimen for PGMM with good response rate (61% ORR) and acceptable toxicity. However outcome is poor for substantial part of patients it is opportunity for 1/3 of patients to achieve at least PR and stop rapid continuation of progression. Such a strategy followed by optimal combination with new drugs (Velcade, IMIDs) can further prolong survival of patients with this fatal form of PGMM.

0263

THALIDOMIDE-DEXAMETHASONE AS EFFECTIVE TREATMENT OF THE FIRST RELAPSE AFTER TANDEM AUTOLOGOUS PERIPHERAL BLOOD STEM CELLS TRANSPLATATION OF MULTIPLE MYELOMA

G. Charlinski, E. Wiater, W. Wiktor-Jedrzejczak, J. Dwilewicz-Trojaczek

Medical University of Warsaw, WARSAW, Poland

Background. Thalidomide-Dexamethasone (TD) is an efficient drug combination, which is used in primary treatment of patients with multiple myeloma (MM). We have attempted to evaluate the use of this protocol in pts with MM relapsing after tandem autologous peripheral blood stem cells transplantation (auto-PBSCT). *Aims.* The end points of the study were: response, EFS, OS and toxicity. *Metods.* An analysis was conducted after the relapse MM in 30 patients (15F/15M) with a median age of 50 years (range 44-60), who entered the study between February 2003 and October 2006. Nineteen patients had IgG producing MM, 4-IgA, 1-nonsecretory, 6-light chain. Clinical stage according ISS: 21 pts in stage 1, 3-stage 2, 6-stage 3. Prior treatment included primary VAD protocol (vincristin, adriamycin, dexamethasone) followed by cyclophosphamide mobilization and tandem autoPBSCT after conditioning with high dose melphalan. Patients were then observed until first signs of disease progression and then treated with TD. Thalidomide was used in doses 200 mg/day po. continuously until any sign of progressive disease or relapse, and dexamethasone 40 mg po. for 4 days every 3 weeks. Fifteen (50%) patients received enoxaparin prophilaxis. The response rate was assessed using EBMT/IBMTR criteria. *Results.* Four out of 30 patients (13.3%) achieved complete remission (CR), 10 patients (33.3%) partial remission (PR) (M-protein reduction 50-99%), 16 patients (53,4%) stable disease (SD) (M-protein reduction 0-49%). Time to response was 6 weeks. Six pts, who had initially stable disease a progression was observed after 6 months. These pts underwent another mobilization treatment with cyclophosfamide 4 g/m^2 and the 3rd autoPBSCT. For remaining patients on TD the median EFS was 14 months (4-31.3). Duration of treatment TD was 14.6 months (median), (3-48.6). The median OS has not been reached. The major adverse events of TD were: constipation-2 patients, somnolence-3 patients, deep-vein thrombosis-1 patient. We did not observed neuropathy after TD in this particular group of patients. *Conclusions.* The chemotherapy according TD protocol is effective in pts with relapsing MM after tandem auto-PBSCT. Time to response was short-median 6 weeks. TD was well tolerated.

PRACTICAL RECOMMENDATIONS ON THE MANAGEMENT OF VTE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WHO ARE TREATED WITH LENALIDOMIDE AND DEXAMETHASONE

A. Palumbo,[1] M. Dimopoulos,[2] J. San Miguel,[3] J.L. Harousseau,[4] M. Attal,[5] M. Hussein,[6] S. Knop,[7] H. Ludwig,[8] M. von Lilienfeld-Toal,[9] P. Sonneveld[10]

[1]Az. Osp. S. Giovanni Battista, TORINO, Italy; [2]University of Athens School of Medicine, ATHENS, Greece; [3]University Hospital of Salamanca, SALAMANCA, Spain; [4]Hôtel-Dieu Hospital, NANTES, France; [5]Centre Hospitalier Université de Purpan, TOULOUSE, France; [6]H.Lee Moffitt Cancer, Research Institute, TAMPA, FL, USA; [7]University Hospital, WUERZBERG, Germany; 8Wilhelminenspital, VIENNA, Austria; [9]St. Jamess University Hospital, LEEDS, United Kingdom; [10]Erasmus Medical Center, ROTTERDAM, Netherlands

Background. In January 2007, an international group of multiple myeloma (MM) specialists reached a consensus on practical recommendations regarding the management of lenalidomide treatment (in combination with dexamethasone) in patients with relapsed/refractory MM, who have received at least one prior therapy. *Aims.* To present practical commendations for prevention and management of venous thromboembolism (VTE) in these patients. *Methods.* A moderated round table discussion. *Results.* Treatment with lenalidomide/dexamethasone (Len/Dex) in patients with relapsed/refractory MM has been reported to be associated with a rate of VTE of 12%. Therefore, it is important to assess the VTE risk and consider the use of prophylaxis. There was consensus that the following factors increase the risk for VTE in this setting: high-tumour mass, concomitant chemotherapy, doxorubicin, high-dose dexamethasone, erythropoietin use, ongoing infection/inflammation, older age, thrombophilia, previous VTE, or pre-existing coagulation disorders. Neither baseline coagulation studies nor screening for VTE in asymptomatic patients are recommended. Sonography for diagnosis of VTE is recommended in symptomatic patients. We recommend prophylactic anticoagulation if any of the above risk factors is present at treatment with Len/Dex and no prophylaxis in patients without risk factors. The risk of VTE is particularly high in the first 4'6 months of therapy. At present there is no evidence of the best prophylaxis: daily aspirin, low-molecular-weight heparin (LMWH), or therapeutic doses of warfarin, are the options. The panel suggests the use of low-dose aspirin (ASA) (81-100 mg) or prophylactic dose of LMWH. Low-dose warfarin is not recommended, therapeutic-dose warfarin seems to be associated with an increased risk of severe haemorrhage. All patients need to receive clear instructions on how to proceed in case clinical symptoms of VTE occur. When VTE has occurred, the patient can be continued on treatment with Len/Dex or retreated after stabilization depending on the severity of the VTE. For therapeutic anticoagulation, patients previously on ASA should be switched to LMWH; and patients already on prophylactic doses of LMWH should receive therapeutic doses. *Conclusions.* In relapsed/refractory MM patients who receive lenalidomide, VTE prophylaxis with ASA or LMWH is suggested if at least one of the above listed risk factors is present.

PRACTICAL RECOMMENDATIONS ON THE MANAGEMENT OF CYTOPENIAS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WHO ARE TREATED WITH LENALIDOMIDE AND DEXAMETHASONE

A. Palumbo,[1] P. Sonneveld,[2] M. Dimopoulos,[3] J. San Miguel,[4] J.L. Harousseau,[5] M. Attal,[6] M. Hussein,[7] S. Knop,[8] H. Ludwig,[9] M. von Lilienfeld-Toal[10]

[1]Az. Osp. S. Giovanni Battista, TORINO, Italy; [2]Erasmus Medical Center, ROTTERDAM, Netherlands; [3]University of Athens School of Medicine, ATHENS, Greece; [4]University Hospital of Salamanca, SALAMANCA, Spain; [5]Hôtel-Dieu Hospital, NANTES, France; [6]Centre Hospitalier Université de Purpan, TOULOUSE, France; [7]H.Lee Moffitt Cancer, Research Institute, TAMPA, FL, USA; [8]University Hospital, WUERZBERG, Germany; [9]Wilhelminenspital, VIENNA, Austria; [10]St. Jamess University Hospital, LEEDS, United Kingdom;

Background. In January 2007, an international group of multiple myeloma (MM) specialists reached a consensus on practical recommendations regarding management of lenalidomide treatment (in combination with dexamethasone) in patients with relapsed/refractory MM, who received ?1 prior therapy. *Aims.* This communication focuses on recommendations regarding the management of cytopenias in these patients. *Methods.* Moderated round table discussion. *Results.* In published studies, 11.6% of patients treated with lenalidomide/dexamethasone (Len/Dex) had NCI grade 3 neutropenia and 3.3% grade 4 neutropenia (Chen et al., Blood 2006; 108:3556). This was the most frequent reason for discontinuation of therapy and dose reduction. The rate of grade 4 febrile neutropenia was <1%. Thrombocytopenia occurred in 11.1%. Risk factors for cytopenia during Len/Dex include low counts at baseline, previous chemotherapy and response to treatment. Patients with renal insufficiency were reported to suffer from more severe thrombocytopenia, but age has not been reported to be a risk factor. Recommendations regarding monitoring and management of cytopenia during treatment with Len/Dex for relapsed/refractory MM have been developed. In case of a normal baseline full blood count (FBC), biweekly monitoring is recommended. If baseline FBC is abnormal because of MM infiltration, treatment should still be pursued with full dose and at least weekly monitoring. Standard dose-reduction strategies should be followed for all other causes of abnormal baseline and follow-up FBC. As a general rule,

G-CSF can be used in neutropenic patients. In case of neutrophils <1000/∝L, G-CSF is recommended to prevent dose reduction and febrile neutropenia aiming at >500/µL neutrophils. If neutrophils fall <500/∝L, Len should be interrupted and restarted (same dose for first fall and no other toxicity; lower dose for subsequent falls) once neutrophils >500/∝L. Similarly, if platelets fall <50,000/∝L, anticoagulation should be stopped and in case of thrombocytopenia <30,000/∝L, Len should be interrupted and restarted at a lower dose once platelets >30,000/∝L. Also, antibiotic prophylaxis with cotrimoxazole should be applied if patients receive Len with high dose Dex. Patients should receive clear instructions to seek medical care within 3 hours if febrile while neutropenic. *Conclusions.* A stringent strategy for the management of cytopenia due to treatment with Len/Dex is recommended.

PRACTICAL RECOMMENDATIONS ON THE MANAGEMENT OF NON-HAEMATOLOGICAL ADVERSE EVENTS IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS TREATED WITH LENALIDOMIDE/DEXAMETHASONE

A. Palumbo,[1,11] M. Attal,[2] M. Dimopoulos,[3] J. San Miguel,[4] J.L. Harousseau,[5] M. Hussein,[6] S. Knop,[7] H. Ludwig,[8] P. Sonneveld,[9] M. von Lilienfeld-Toal[10]

[1]Az. Osp. S. Giovanni Battista, TURIN, Italy; [2]Centre Hospitalier Université de Purpan, TOULOUSE, France; [3]University of Athens School of Medicine, ATHENS, Greece; [4]Hospital Universitario de Salamanca, SALAMANCA, Spain; [5]Hôtel-Dieu Hospital, NANTES, France; [6]H.Lee Moffitt Cancer, Research Institute, TAMPA, FL, USA; [7]University Hospital, WUERZBERG, Germany; [8]Wilhelminenspital, VIENNA, Austria; [9]Erasmus Medical Center, ROTTERDAM, Netherlands; [10]St. Jamess University Hospital, LEEDS, United Kingdom; [11]University of Torino, TURIN, Italy

Background. In January 2007, an international group of multiple myeloma (MM) specialists reached a consensus on practical recommendations regarding the management of lenalidomide treatment (in combination with dexamethasone) in patients with relapsed/refractory MM, who have received at least one prior therapy. *Aims.* This communication focuses on recommendations for management of non-hematological adverse events (NHAE) in these patients. VTE management recommendations are presented separately. *Methods.* A moderated round table discussion. *Results.* Treatment with lenalidomide/dexamethasone (Len/Dex) is well tolerated in patients with relapsed/refractory MM. Nevertheless, some NHAE may occur. The most common NHAE of all grades in two randomised studies were fatigue (38%; versus 37% with dexamethasone alone), constipation (39% vs. 19%), diarrhoea (29% vs. 25%), nausea (22% vs. 19%), muscle cramps (30% vs. 21%), rash (16% vs. 8%); and paraesthesia (12% vs. 13%). The most common NHAE leading to dose reduction/interruption were fatigue (4%) and pneumonia (2%). A randomised study comparing lenalidomide combined with high-dose or low-dose dexamethasone demonstrated considerably less toxicity with low-dose dexamethasone; however, efficacy data from this study are not yet available. Atrial fibrillation (AF) appears to be more common in patients treated with Len/Dex (grade 3/4 NCI: 3% vs. 1%), especially if high-dose dexamethasone is used or if patients had previous AF, and regular monitoring is recommended. In contrast to monotherapy with lenalidomide alone, rash is less frequent with Len/Dex. In case of grade ¿2 rash, we recommend treating the patient with antihistamines. If persistent, continuous low-dose prednisone (10-20 mg/d) should be added. Rash is mostly self-limiting with a duration of several weeks but in some cases dose reduction or discontinuation of lenalidomide is necessary. In case of fatigue, other causes such as anaemia, infection, depression or hypothyroidism should be ruled out. Also, patients benefit from counselling. Dose reduction may be considered for severe fatigue. Dexamethasone therapy may predispose patients to infection; therefore we recommend the use of routine antibiotic prophylaxis for all patients upon initiation of Len/Dex treatment. In addition, vaccinations (influenza, pneumococci, meningococci and haemophilus) should be considered. *Conclusions.* A concise strategy for NHAE management of Len/Dex is presented, which will aid safe and efficient administration.

0267

PATIENT ELIGIBILITY FOR LENALIDOMIDE/DEXAMETHASONE TREATMENT IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

A. Palumbo,[1] M. Dimopoulos,[2] J. San Miguel,[3] J.L. Harousseau,[4] M. Attal,[5] M. Hussein,[6] S. Knop,[7] H. Ludwig,[8] P. Sonneveld,[9] M. von Lilienfeld-Toal[10]

[1]Az. Osp. S. Giovanni Battista, TORINO, Italy; [2]University of Athens School of Medicine, ATHENS, Greece; [3]University Hospital of Salamanca, SALAMANCA, Spain; [4]Hôtel-Dieu Hospital, NANTES, France; [5]Centre Hospitalier Université de Purpan, TOULOUSE, France; [6]H.Lee Moffitt Cancer, Research Institute, TAMPA, FL, USA; [7]University Hospital, WUERZBERG, Germany; [8]Wilhelminenspital, VIENNA, Austria; [9]Erasmus Medical Center, ROTTERDAM, Netherlands; [10]St. Jamess University Hospital, LEEDS, United Kingdom

Background. In January 2007, an international group of multiple myeloma (MM) specialists reached a consensus on practical recommendations regarding the management of lenalidomide treatment (in combination with dexamethasone) in patients with relapsed/refractory MM, who have received at least one prior therapy. *Aims.* This communication deals with patient-eligibility for treatment with lenalidomide and dexamethasone. *Methods.* A moderated round table discussion. *Results.* Response rates of combination therapy with lenalidomide/dexamethasone (Len/Dex) in the setting of relapsed/refractory MM are approximately 60% and lead to a survival advantage over treatment with dexamethasone alone. This effect was seen in all groups of patients, including patients of all age groups, independent of disease stage, duration of disease prior to Len/Dex treatment, ECOG performance status, cytogenetics including t(4;14) and del(13q), level of β2-microglobulin and renal or hepatic impairment. Of note, patients with a creatinine >2.5 ng/dL had not been included in clinical trials. Response to Len/Dex was superior to Dex alone, independently of the type of prior therapy (bortezomib, thalidomide, or prior transplant). It is important to note that patients refractory to thalidomide still respond to Len/Dex, although the overall response might be less than in patients not refractory to thalidomide (not significant). Patients with only 1 previous line of therapy had a greater survival advantage than patients with more than 1 previous line of therapy. There is some evidence that a lower dose of Dex may result in less toxicity (Rajkumar *et al.,* Blood 2006; 108:799), but efficacy data are not yet available. However, the dexamethasone dose may be adjusted in elderly, fragile patients >75 years. Also, as lenalidomide is mainly renally excreted, dose reduction of lenalidomide depending on the severity of renal impairment will be provided. Adjustments for mild to moderate hepatic dysfunction or potential drug-interactions are not required. *Conclusions.* Len/Dex is recommended for patients with relapsed/refractory MM regardless of baseline factors.

0268

EARLY BORTEZOMIB TREATMENT IMPROVES RESULTS IN RELAPSED MYELOMA PATIENTS. BETTER SECOND THAN FURTHER LINES

L.F. Casado Montero,[1] I. Cano,[2] C. Calle,[2] M.I. Gómez-Roncero,[2] F. Solano,[2] M.A. Foncillas,[2] D. De Miguel,[2] M.J. Bustos-Medina,[2] A.R. López-Quiñones,[2] J.R. Romero[2]

[1]Hospital Virgen de la salud, TOLEDO, Spain; [2]Grupo Clínico de la SCMHH, CASTILLA LA MANCHA, Spain

Background. Proteasome inhibition with bortezomib (VELCADE) is the standard of care in patients with relapsed/refractory multiple myeloma (MM) who have received at least one prior therapy. The phase II SUMMIT trial of patients with relapsed and refractory MM showed that bortezomib is active, with a response rate of 27% (CR/PR) as a single agent, median TTP of 7 months, and median OS of 17 months. The phase 3 APEX trial in pts with relapsed MM following 1 3 prior therapies showed btz to be superior to high-dose dexamethasone (dex) in terms of response rate, TTP, and OS. Updated APEX data show a CR/PR rate of 43%, median TTP of 6.2 months, and median OS of 29.8 months. Preliminary data from the APEX trial showed that earlier treatment (second vs further lines of therapy) resulted in better RR,TtPD and OS. *Aims.* To compare patients receiving bortezomib as second line therapy vs those receiving it as third or subsequent lines of treatment. *Methods.* 63 patients with relapsed or refractory MM were treated with bortezomib at a dose of 1.3 mg/m^2 on days 1, 4, 8, and 11 in a 21-day cycle. 80% of patients received dexamethasone at a dose of 20 mg on days 1, 2, 4, 5, 8, 9, 11 and 12. Median age was 68.9 years old (range 43-87). Twenty-four patients received only one line of therapy with melphalan-prednisone, and 39 of them received previously 2 or more lines of therapy;

median of 3 lines, range 2-6 (37% BMT and 40% Thalidomide).Treatment was administered till disease progression, unacceptable toxicity or complete response (CR), up to a maximum of 8 cycles. *Results.* 321 cycles were administered; median 4 cycles (range 2-10). Dose reductions were done in 18% of cycles, mainly due to neuropathic pain or peripheral neuropathy. The most frequent grade 3-4 toxicity was thrombocytopenia in 28% of patients. The most frequent grade 1-2 non-hematological toxicity was neuropathic pain and peripheral neuropathy (in 25% of patients) and asthenia in 17% of them. Response rate by treatment branch are shown in Table 1. Median TtPD was 200 days in the group of patients treated in third or subsequent lines of therapy, and was not reached in the second line group. *Conclusions.* Treatment with bortezomib and dexamethasone is hignly efficacious in patients with refractory MM. Earlier treatment produced better results.

IN VITRO AND *IN VIVO* ACTIVITY OF THE VEGF INHIBITOR PAZOPANIB IN MULTIPLE MYELOMA

K. Podar,[1] G. Tonon,[1] M. Sattler,[1] Y.-T. Tai,[1] S. Le Gouill,[2] H. Yasui,[1] K. Ishitsuka,[1] S. Kumar,[3] R. Kumar,[4] L.N. Pandite,[4] T. Hideshima,[1] D. Chauhan,[1] K.C. Anderson[1]

[1]Dana-Farber Cancer Institute, BOSTON, USA; [2]Hotel-Dieu Centre Hospitalier University, NANTES, France; [3]Mayo Clinic, ROCHESTER, USA; [4]GlaxoSmithKline, RESEARCH TRIANGLE PARK, USA

Background. Vascular endothelial growth factor (VEGF) and its receptors play an important role in the pathogenesis of multiple myeloma (MM). VEGF present in the MM bone marrow microenvironment induces neovascularization; triggers tumor cell growth, survival and migration; inhibits dendritic cell maturation; and promotes osteoclastogenesis. VEGF therefore provides a potential therapeutic target in MM. *Aims.* To evaluate the therapeutic potential of the novel, potent VEGF receptor inhibitor pazopanib in MM. *Methods.* Effects of pazopanib on MM and endothelial cell growth, survival, and migration were evaluated using western blot analysis, 3H-thymidine uptake, Boyden- modified chamber, tubule formation assays, FACS analysis as well as microarray analysis, RT- PCR, and specific cMyc knockdown by siRNA. *in vivo* effects of pazopanib were evaluated using a MM xenograft mouse model. *Results. In vitro*, pazopanib inhibits VEGF- triggered VEGF receptor phosphorylation and activation of downstream signaling molecules including Src kinase in MM cells and blocks MM cell migration, growth, and survival. Moreover, gene expression and signaling network analysis in pazopanib- treated cells demonstrate transcriptional changes of several signaling pathways, including marked downregulation of cMyc. siRNA targeting cMyc blocked VEGF production and secretion in MM cell lines. In addition, pazopanib reduced VEGF in the microenvironment and directly inhibited endothelial cell growth, migration, and vessel formation. Furthermore, pazopanib inhibited VEGF- induced upregulation of adhesion proteins on both endothelial and MM cells, thereby abrogating endothelial cell -MM cell adhesion and associated tumor cell proliferation. Pazopanib also strongly sensitized tumor cells bound to endothelial cells to DNA- damaging chemotherapeutic agents (i.e. melphalan), immunomodulatory drugs, and bortezomib. Similar activity of pazopanib was demonstrated *in vivo* using a MM xenograft mouse model. Ongoing studies evaluate effects of pazopanib on MM bone disease and immune deficiency. *Summary and Conclusions.* In summary, this is the first report showing anti- MM activity of an anti-VEGF compound in both *in vitro* and *in vivo*, strongly supporting its clinical evaluation either as a single agent or in combination with other therapies.

0270

IDENTIFICATION AND CHARACTERIZATION OF HLA CLASS I RESTRICTED T-CELL EPITOPES IN THE PUTATIVE TUMOR ASSOCIATED ANTIGENS P21 ACTIVATED SERIN KINASE 2 (PAK2) AND CYCLIN DEPENDENT KINASE INHIBITOR 1A (CDKN1A)

M. Witzens-Harig, G. Li, M. Hundemer, S. Wolfrum, A.D. Ho, H. Goldschmidt

University of Heidelberg Hospital, HEIDELBERG, Germany

Multiple myeloma (MM) is one of the most common hematological malignancies. Despite a variety of therapeutical approaches including high dose cytostatic treatment with subsequent autologous or allogeneic stem cell transplantation, as well as vaccination, cures remain rare exceptions. An important issue for future immunological treatments is the identification and characterization of appropriate tumor associated antigens. However, the number of tumor associated antigens in MM is limited. PBK/TOPK and activated serin kinase 2 (PAK2) are novel serin kinases that have recently been identified. PBK/TOPK is overexpressed in Burkitt Lymphoma, acute lymphoblastic leukemia and MM, PAK2 is expressed on malignant lymphatic cells. The cyclin kinase inhibitor 1A (CDKN1A) is overexpressed in MM compared to normal plasma cells. We here identified and characterized for the first time HLA class I restricted immunogenic peptides in the amino acid sequences of PAK2 and CDKN1A. Using two independent prediction algorithms we identified 2 peptides in PAK2 and 3 peptides in CDK1NA with high binding to HLA-A2. Using an IFN-γ Elispot assay we could demonstrate the pres-

ence and functional activity of CD8 peptide specific T cells with all tested peptides. To show HLA-A2 restricted antigen recognition, specific inhibition of T cell recognition was demonstrated with an anti HLA-A2 blocking antibody. By analysis of peripheral blood of 34 healthy donors for presence and functional activity of CD8 T cells specific for these peptides, we could demonstrate that 50-60% of the tested donors contain peptide T-cell precursors specifically recognizing at least one of the tested peptides and that these T-cell precursors can be expanded *in vitro*. We conclude that PAK2 and CDKN1A derived peptides can elicit a strong and consistent CD8 T cell response in an *in vitro* model. Further investigations will examine the presence and functionality of such T-cells in the tumor bearing host.

0271

CELLULAR IMMUNE RESPONSES AGAINST THE CANCER TESTIS ANTIGEN SPAN-XB IN HEALTHY DONORS AND PATIENTS WITH MULTIPLE MYELOMA

M. Witzens-Harig, C. Frank, M. Hundemer, A.D. Ho, H. Goldschmidt

University of Heidelberg Hospital, HEIDELBERG, Germany

The cancer-testis antigen SPAN-XB has been recently identified in multiple myeloma. In the present study we identified and characterized for the first time a cytotoxic cellular immune response against SPAN-XB in healthy donors and patients with multiple myeloma. Using two independent computer algorithms two SPAN-XB derived peptides (peptides 624 and 626) with predicted binding to HLA-A2 were identified. To further improve the immunogenicity of peptide 626 we designed a heteroclitic peptide (peptide 627) by modifying one amino acid on the HLA binding position 2 of peptide 626. Using an IFN-γ Elispot assay we could demonstrate the presence and functional activity of CD8 peptide specific T cells with all tested peptides. By analysis of peripheral blood of 13 healthy donors and 5 patients with multiple myeloma peptide specific T-cell precursors specifically recognizing at least one of the tested peptides could be detected and expanded in 9 of 13 of tested donors and 3 of 5 tested patients. Importantly, in two donors specific peptides could be generated against the heteroclitic peptide 627 but not against the native peptide 626. We conclude that SPAN-XB derived peptides can elicit a consistent CD8 T cell response in healthy donors and patients with multiple myeloma.

CLINICAL RELEVANCE OF SOLUBLE HLA CLASS I IN WALDENSTROMS MACROGLOBULINEMIA AND IGM MGUS

Th. Gastinne,[1] Y. Sebti,[2] A.-S. Moreau,[3] A. Duhamel,[4] G. Le Friec,[2] V. Coiteux,[5] L. Amiot,[2] S. Poulain,[6] B. Hennache,[7] P. Morel,[8] I.M. Ghobrial,[3] S.P. Treon,[3] T. Facon,[5] E. Zorn,[9] X. Leleu[3]

[1]CHU, NANTES, France; [2]Laboratoire d'Hématologie et UPRES 38-89, RENNES, France; [3]Dana-Farber Cancer Institute, BOSTON, USA; [4]Laboratoire de Biostatistique, CHRU, LILLE, France; [5]Service des Maladies du Sang, CHU, LILLE, France; [6]Laboratoire de Biologie Moleculaire, VALENCIENNES, France; [7]Laboratoire de Biochimie, CHRU, LILLE, France; [8]Service d'Hématologie, LENS, Franc; [9]Service d'hématologie clinique, CHU, NANTES, France

Background. Waldenstrom's Macroglobulinemia (WM) is a B-cell neoplasm characterised by excess secretion of IgM by lymphoplasmacytic bone marrow cells and characterized by a broad heterogeneous clinicobiological presentation throughout the disease history. Serum β-2-microglobulin level is one of the best survival prognostic factors in WM, but other HLA class I molecules might be of interest. Soluble HLA class I molecules (HLA-Is) as well as the main soluble HLA-G isoform (HLA-Gs) are known to have immunosuppressive properties and have been implicated in the pathogeny of several malignancies, including recently in Multiple Myeloma. We hypothesized therefore that expression of soluble HLA class I molecules may help to better characterise IgM-related disorders. *Methods.* We assessed the serum soluble HLA molecules levels in 111 patients with IgM-related disorders [WM (n=42) and IgM-MGUS (n=63), and compared the results to 30 healthy subjects. *Results.* We found higher levels of HLA-Is in WM compared to IgM-MGUS and healthy donors. HLA-Gs levels were similar in WM and in IgM-MGUS, but higher than in healthy donors. HLA-Is, but not HLA-Gs, correlated with markers of tumour burden and with markers of adverse prognosis in WM. HLA-Is also separated patients with symptomatic to asymptomatic diseases within the WM subgroup. High levels of HLA-Is were observed in patients with presence of autoimmune complications, especially cryoglobulinemia, although independently of IgM-MGUS or WM diagnostic. In contrast, low levels of HLA-Is related to IgM-related neuropathy, another complication linked to the presence of the IgM monoclonal protein. Finally, HLA-Is (high) and HLA-Gs (low) levels were inversely associated to neutropenia and lymphopenia. *Conclusions.* HLA-Gs is a marker linked to the presence of a clonal B lymphocyte, with no survival prognostic impact in IgM-disorders and especially in WM, in our study. In contrast, HLA-Is level isolated subsets of patients within the very heterogeneous group of patients with IgM disorders. HLA-Is was related to the occurrence of autoimmune complications and disorders linked to the presence of the monoclonal IgM protein, such as cryoglobulinemia syndrome and neuropathies, in addition to its previously published survival prognostic impact in plasma cell disorders. Together our results suggest a role for soluble MHC class I molecules in IgM-related disorders. Further studies are necessary to confirm those results in a larger population of patients.

0273

PLASMA CELLS FROM MULTIPLE MYELOMA PATIENTS EXPRESS B7-H1 (PD-L1) AND INCREASE EXPRESSION FOLLOWING STIMULATION WITH IFN- AND TLR LIGANDS VIA A MYD88-, TRAF6-, AND MEK-DEPENDENT PATHWAY

B. Quesnel,[1] J. Liu,[2] A. Hamrouni,[2] D. Wolowiec,[3] V. Coiteux,[1] K. Kuliczkowski,[3] D. Hetuin,[2] A. Saudemont[2]

[1]CHU Lille, LILLE, France; [2]INSERM, U837, LILLE, France; [3]Department of Hematology, WROCLAW, Poland

Background. Multiple Myeloma (MM) cells inhibit certain T-cell functions. A possible candidate responsible for such T-cell inhibitory mechanisms in MM plasma cells is B7-H1. B7-H1 (also known as PD-L1 or CD274) is a B7 family member and is the ligand for PD-1 (programmed death-1), a member of the CD28 family. *Aims.* We wanted to determine the role of B7-H1 in CTL inhibition and the mechanisms that control its expression in malignant plasma cells. *Methods.* We examined the expression of B7-H1, in CD138-purified plasma cells isolated from 82 MM patients, 42 monoclonal gammopathy of undetermined significance (MGUS) patients, and 20 healthy donors. *Results.* We observed that B7-H1 was expressed in most MM plasma cells, but not cells isolated from MGUS or healthy donors (Figure 1).

Figure 1. B7-H1 in MM, MGUS, and Healthy controls (HD).

This expression was increased or induced by IFN-γ and Toll-Like Receptor (TLR) ligands in isolated MM plasma cells. Blocking of the MEK/ERK pathway inhibited IFN-γ- and TLR-mediated expression of B7-H1. Inhibition of the MyD88 and TRAF6 adaptor proteins of the TLR pathway not only blocked B7-H1 expression induced by TLR ligands, but also that mediated by IFN-γ. IFN-γ induced STAT1 activation, via MEK/ERK and MyD88/TRAF6, and inhibition of STAT1 reduced B7-H1 expression. MM plasma cells stimulated with IFN-γ or TLR ligands inhibited CTLs generation and this immunosuppressive effect was inhibited by pre-incubation with an anti-B7-H1 antibody, the UO126 MEK inhibitor, or by transfection of a dominant-negative mutant of MyD88. *Conclusions.* We have shown that B7-H1 is expressed on malignant plasma cells, that it is involved in inhibition of T-cell responses by these malignant cells, and is upregulated by IFN-γ and TLR ligands through a common pathway involving MEK/ERK and MyD88. B7-H1 represents a new immune escape mechanism in MM.

0274

NEOPLASTIC PLASMA CELLS ARE DEMONSTRABLE AT BONE MARROW SITES DISTANT TO SOLITARY PLASMACYTOMA OF BONE AND PREDICT FOR PROGRESSION TO MULTIPLE MYELOMA

Q. Hill,[1] A.C. Rawstron,[2] J.A. Child,[2] R.M. De Tute,[2] R.G. Owen,[2]

[1]Leeds General Infirmary, LEEDS, United Kingdom, [2]HMDS, LEEDS, United Kingdom

Background. Solitary plasmacytoma of bone (SPB) typically present as single destructive lesions within the spinal column or long bones. Local radiotherapy is the treatment of choice but approximately 50% of patient's progress to myeloma. Many patients have a monoclonal protein detectable in their serum and/or urine at diagnosis and persistence of this for >1 year after radiotherapy predicts for progression to myeloma. Identification of high risk patients at the time of diagnosis is clearly desirable as it would enable risk stratification and more careful monitoring of patients. Although prophylactic adjunctive chemotherapy has not definitively been shown to benefit unselected patients with SPB, future therapeutic advances might be targeted on patients with a high risk of progression. Interestingly it has recently been shown that patients positive for serum free light chains are at greater risk of progression to myeloma. We and others have previously demonstrated that neoplastic bone marrow plasma cells are distinguishable from their normal counterparts by virtue of their lack of CD19 expression and/or their aberrant expression of CD56. We have developed a multiparameter flow cytometry assay which predicts outcome following autologous transplantation in myeloma patients and risk of progression in patients with MGUS. *Aims.* In this study we have applied this assay to assess the staging bone marrow specimens from patients with biopsy proven SPB for the presence of occult disease at sites distant to the primary lesion. *Methods.* 52 patients were included in this analysis (31 male, 21 female, median age 65) and in each case the staging bone marrow aspirate and trephine biopsy (obtained from a site distant from the SPB, typically the right iliac crest) was not indicative of myeloma (<10% plasma cells). *Results.* Plasma cells comprised a median of 0.6% (0.05-6.2%) of bone marrow leucocytes while distinct populations with a neoplastic immunophenotype (>30% CD19- and/or $CD56^+$ as per convention) were demonstrable 35/52 (67%). Neoplastic plasma cells when present comprised a median of 70% (35-100%) of bone marrow plasma cells. 21 patients (40%) developed myeloma with a median time to progression of 476 days (range 18-1632). Progression occurred in 18 of the 35 (51%) patients with neoplastic plasma cells in their staging marrows and in 3/17 (18%) patients with a normal phenotypic profile. The difference was significant using Chi-square analysis with Yates' correction for continuity (p=0.04). The overall risk of progression was similar in patients with a 'myeloma pattern- in which >90% of bone marrow plasma cells had a neoplastic phenotype (5/12, 42%) and those with an MGUS or mixed pattern in which distinct populations of both normal and neoplastic cells are demonstrable (13/23, 57%). *Conclusions.* Neoplastic plasma cells are frequently found at bone marrow sites distant to SPB and their presence predicts for progression to multiple myeloma. Trials of adjuvant systemic therapy are warranted in this group.

INHIBITION OF CELL PROLIFERATION BY LENALIDOMIDE IS ASSOCIATED WITH STIMULATION OF EGR1 TRANSCRIPTIONAL ACTIVITY IN A CHROMOSOME 5 DELETED BURKITTS LYMPHOMA AND MULTIPLE MYELOMA CELL LINE

A. Gandhi, J. Kang, D. Stirling, P. Schafer

Celgene Corporation, SUMMIT, USA

Background. The mechanism by which lenalidomide exerts its antiproliferative effects in deletion 5q MDS clones or MM cells is not yet fully elucidated. Early growth response (Egr1) gene is a tumor suppressor gene located on chromosome 5q31.1 that encodes a transcription factor involved in the regulation of cell proliferation and apoptosis. *Aims.* The present study examines the hypothesis that lenalidomide may act by enhancing the expression or activity of Egr1 in sensitive hematopoietic tumor cells, especially those with only a single copy of the Egr1 gene. *Methods.* Luciferase assay. Cells were transfected with Egr1-luciferase (Stratagene) using Lipofectamine 2000 (Invitrogen) reagent according to manufacturer's instructions. Six hours post-transfection, cells were treated with 1 ÌM lenalidomide or DMSO for 16 hours. Luciferase activity was assayed using luciferase substrate (Promega) and measured using a luminometer (Turner Designs). qRT-PCR and siRNA silencing. Cells were transfected with Egr1 or non-targeting siRNA (Dharmacon) using Dharmafect2 (Dharmacon) reagent according to manufacturer's instructions. Gene expression analysis used gene expression assays (Applied Biosystems) and expression was measured on a real-time PCR System 7500 (Applied Biosystems). Relative quantifications were calculated with SDS v.1.3.1 software. Cell proliferation assay. Cells were incubated in 96-well cell culture plates with compounds for 72 hours and assayed by 3H-thymidine incorporation. IC_{50}s were calculated by nonlinear regression analyses with GraphPad Prism. *Results.* Lenalidomide stimulated the transcriptional activity of Egr1 in the lenalidomide-sensitive chromosome 5 deleted Burkitt's lymphoma Namalwa CSN.70 and in the MM cell line LP-1. Egr1 siRNA Namalwa cells proliferated more than mock controls, indicating that Egr1 functions as a tumor suppressor in Namalwa cells. Lenalidomide had no effect on expression of Egr1, but augmented Egr1 nuclear transport in a dose-dependent manner. Lenalidomide did not affect expression of the Egr1 downstream effector genes ATF3, fibronectin, p53, PTEN, and TGF-β1, while p21 levels increased. However, lenalidomide-induced p21 expression was not affected in Egr1 siRNA Namalwa cells. Interestingly, lenalidomide's anti-proliferative potency was greater in Egr1 siRNA Namalwa but not in Egr1 siRNA LP-1 cells. *Conclusions.* Lenalidomide induces nuclear transport and transcriptional activation of the tumor suppressor Egr1, which may contribute to lenalidomide's anti-proliferative activity. This activity may be related to the levels of Egr1 expression, explaining why del 5q31 myelodysplastic clones are especially sensitive to the cytotoxic effects of lenalidomide.

0276

DEPLETION OF BLOOD DENDRITIC CELLS (BDC) AND ITS PROGNOSTIC SIGNIFICANCE IN PATIENTS WITH MULTIPLE MYELOMA

S.P. Smolewski, B. Cebula, A. Branicka, O. Grzybowska-Izydorczyk, H. Urbanska-Rys, T. Robak

Medical University of Lodz, LODZ, Poland

Background. The number and function of dendritic cells (DC), which are an important part of anti-tumor response, may be crucial for development and natural course of malignancy. There are several types of DC, including those circulating in the peripheral blood (blood DC; BDC), as was recently distinguished by the panel of monoclonal antibodies against BDC antigens (named BDCA-1, -2 and -3). *Aims.* Since these BDC subtypes have not been assessed in multiple myeloma (MM) we aimed to investigate their frequency and absolute numbers in this disease. *Material and Methods.* The study was performed in 41 untreated MM patients. Circulating BDC were detected in blood (MM, control) and bone marrow (MM) samples by the flow cytometry. Three BDC subsets were determined: plasmacytoid (PDC), BDCA-2+/CD123+/HLA-DR+, myeloid 1 (MDC1), BDCA-1+/CD11c+/CD14-/HLA-DR+, and myeloid 2 (MDC2), characterized by BDCA-3+/CD32-/CD19-/HLA-DR+ immunophenotype. The rates and absolute numbers of all DC (total DC; tDC) as well as their particular subsets were calculated. Results obtained in MM patients were compared with age- and sex-matched healthy controls. Moreover, they were correlated with the outcome. The study endpoints were response to first line treatment, progression free survival (PFS) and overall survival (OS) time. *Results.* Objective response to first line treatment was achieved in 27 (66%) patients, including 9 (22%) complete and 18 (44%) partial responses. The remaining 14 (34%) patients were either resistant or even progressive upon chemotherapy. The median follow up was 18 months (5-28). The median PFS of responders was 13.5 months (8-21). In MM patients total frequency and absolute numbers of BDC were significantly lower than in healthy subjects (0.69±0.37% vs. 1.24±0.40%; p=0.002, and 16.2±13.5 cells/μL vs. 31.7±13.3 cells/μL; p=0.005, respectively). Significantly lower rates and counts in MM patients concerned all BDC subtypes, including MDC1 (p=0.035 and 0.029, respectively), MDC2 (p=0.033 and p=0.009, respectively) and PDC (p=0.007 and p=0.0005, respectively). Moreover, all those BDC subtypes were also found in the bone marrow of MM patients. Importantly, a frequency of blood DC in the bone marrow was even higher than in the peripheral blood (for tDC - p=0.017, for MDC2 - p=0.015, and for PDC - p=0.021, respectively). Total DC rates and counts were significantly higher in responders than in resistant patients (0.90±0.40% vs. 0.41±0.29; p=0.009, and 25.3±14.7 cells/μL vs. 9.3±6.0 cells/μL; p=0.032, respectively). The difference was due to prevalence of blood MDC1 in responders (responders vs. non-responders - p=0.011 for rates and p=0.008 for numbers, respectively). Lower (less than median) MDC1 number at the diagnosis correlated with shorter PFS of patients (log rank test: p=0.027) and showed a trend toward longer OS (log rank test: p=0.073). *Conclusions.* This is the first study demonstrating a profound deficiency of all subtypes of BDC in patients with MM. It may reflect either an impairment of immune system, facil-

itating tumor development, or engagement of DC in anti-tumor response. Low pretreatment numbers of BDC may be considered as an biological, negative prognostic marker for further studies.

0277

HIGH HEPATOCYTE GROWTH FACTOR LEVELS AND LOW THROMBOSPONDIN LEVELS IN MYELOMA PATIENTS CORRELATE CLOSELY WITH POOR POSTRANSPLANT RESPONSE

L. Pour,[1] M. Penka,[2] Z. Adam,[3] L. Kovarova,[2] J. Smejkalova,[2] V. Krizalkovicova,[4] D. Kyjovska,[2] P. Vidlakova,[2] J. Michalek,[2] J. Vorlicek,[3] R. Hajek,[5]

[1]Laboratory of Experimental Hematology, BRNO; [2]Laboratory of Experimental Hematology, BRNO; [3]IHOK FN BRNO, BRNO; [4]Masaryk University Brno, BRNO; [5]LEHABI and IHOK FN and Masaryk universit, BRNO, Czech Republic

Backround. Angiogenesis is involved in the development and progression of multiple myeloma (MM). It has already been shown that angiogenesis as assessed by micro-vascular density in the bone marrow of MM patients plays a significant role in the prognosis of MM. Vascular endothelial growth factor (VEGF), hepatocyte growth factor (HGF) and basic fibroblast growth factor (bFGF) plays a key roles as angiogenesis activators in MM. Role of angiogenesis inhibitors in MM remains very unclear. The most important inhibitors seem to be thrombospondin, endostatin and angiostatin. *Aims.* Aim of this study was to evaluate the role of VEGF, HGF, bFGF, thrombospondin, endostatin, and angiostatin peripheral plasma (PP) and bone marrow plasma (BM) levels in a group of patients with MM who underwent autologous stem cell transplant (ASCT) and their influence on treatment response. *Methods.* We studied PP and BM levels of factors in 92 MM patients (43M/39F, median age: 51 years) who underwent an ASCT after high dose melphalan conditioning. PP and BM levels of VEGF, HGF, bFGF, thrombospondin, endostatin, and angiostatin were measured in time of diagnosis MM. Patients were divided into three groups according to treatment response: group A) 43 patients who achieved at least very good partial response (VGPR); group B) 35 patients who achieved partial response (PR); group C) 14 patients who did not achieved even PR. The levels of factors in the time of diagnosis in different groups were compared using nonparametric Kruskal-Wallis ANOVA *Results.* HGF concentration at the time of diagnosis in both PP and BM is significantly lower at group A (PP-median=472 pg/L; 95%IS 417-823pg/L. BM-median= 886 pg/L; 95% IS 928-2111pg/L) than at group B (PP-median=623 pg/L; 95%IS 493-990pg/L;/p=0,025/. BM-median= 1165 pg/L; 95% IS 1140-2656 pg/L/; p=0,001/) and group C (PP-median=1870 pg/L; 95% IS 522-4971pg/L;/p=0,001/. BM-median= 2605 pg/L; 95%IS 1328-5355pg/L/;p=0,001/). Thrombospondin concentration at the time of diagnosis only in BM not in PP is significantly lower at group C (BM-median= 188 pg/L; 95%IS 38-678pg/L) than at group B (BM-median= 303 pg/L; 95%IS 249-705p/L/;p=0,036) and group A (BM-median= 351pg/L; 95%IS 437-916pg/L/; p=0,001/. VEGF, bFGF, endostatin and angiostatin concentrations at diagnosis time did not differ significantly in PP and BM in patiensts with VGPR, PR and no response. *Conlusions.* Our results confirmed that key angiogenesis activators in MM is HGF. If the treatment is successful low levels of HGF occurs only. There is important finding that thrombospondin in BM is higher in patients with successful treatment. It means, that angiogenesis is more inhibited in patients with VGPR than in other. Hovewer thrombospondin concentrations in PP are influenced with activated endothelium and platelets, so only BM level of thrombospondin is good candidate for angiogenesis monitoring. Postransplant response is strong prognostic factor and PP HGF levels and BM thrombospondin levels at diagnosis time corelates closely with it. Such as they could became a new prognostic and predictive factor in MM .

MULTIPLE MYELOMA PLASMA CELLS SHOW DIFFERENT CHEMOKINE RECEPTOR PROFILES AT SITES OF DISEASE ACTIVITY

L. Trentin,[1,2] M. Miorin,[3] M. Facco,[2] I. Baesso,[3] S. Carraro,[2] N. Maschio,[4] M. Bortoli,1 C. Gattazzo,[2] L. Bonanni,[2] F. Piazza,[2] G. Binotto,[4] R. Zambello,[2] C. Agostini,[2] G. Semenzato,[4]

[1]Università di Padova, PADOVA; [2]Dept. Clin. Exp. Med., Hematol. Sect., VIMM, PADOVA; [3]Dept. Clin. Exp. Med., Hematology Section, PADOVA; [4]Dept. Clin. Exp. Med. Hematology Sect., IOV, PADOVA, Italy

Background. Chemokines and their receptors play a pivotal role in the regulation of B-lymphocyte trafficking. *Aims.* This study was aimed at investigating the pattern of chemokine receptor expression, and the migration ability of malignant plasma cells (PC) obtained from Multiple Myeloma (MM) patients. *Methods.* PC were recovered from the bone marrow of 29 MM patients, from extramedullary sites of 10 MM patients and from the bone marrow of 5 controls. 3 myeloma cell lines were also analyzed. By flow cytometry analysis the chemokine receptor expression, including CCR1 to CCR3, CCR5 to CCR7, CXCR1 to CXCR5, was investigated. Moreover, the functionality of the most expressed receptor (CXCR4) was tested by a cell migration assay. *Results.* Flow cytometry analysis showed that the receptors mainly expressed on malignant bone marrow PC were represented by CXCR4 (70% of patients), CCR1 (25%), CCR2 (25%), CCR5 (17%) and CXCR3 (20%), while other receptors were commonly lacking. The analysis performed on extramedullary (peripheral blood and pleural effusion) malignant PC demonstrated that the most represented receptors were CXCR4 (100%), CCR2 (66%) and CXCR1 (60%). The migratory capability evaluation of malignant PC at resting conditions identified 3 groups of patients with different migration (low, intermediate and high). Since CXCR4 was the relevant chemokine receptor expressed by MM PC, its ligand CXCL12 induced their migration. *Conclusions.* These data suggest that malignant PC from MM display different chemokine receptor profiles and that CXCR4 is fully functional and might play a role in the spreading of the disease.

EVALUATION OF CYTOKINE NETWORK PROBABLY INVOLVED IN EVOLUTION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE INTO MULTIPLE MYELOMA

S. Misso,[1] L. Paesano,[2] M. D'Onofrio,[2] B. Feola,[1] L. Bene,[3] V. Mettivier,[3] G. Fratellanza,[4] E. D'Agostino,[4] S. Marotta,[1] A. Minerva[1]

[1]Hospital S. Sebastiano and S. Anna, CASERTA; [2]Hospital S. Giovanni Bosco, NAPLES; [3]Hospital A. Cardarelli, NAPLES; [4]University Federico II, NAPLES, Italy

*Backround.*Monoclonal gammopathies are lymphoproliferative diseases characterised by the production of immunoglobulins or only light or heavy chains, known as *M component*, by a neoplastic B-cell clone. Gammopathies are classified on the basis of their degree of malignancy and their M component. Monoclonal gammopathy of undetermined significance (MGUS) is characterised by being asymptomatic and having a modest M component (<3 g/dL), with bone marrow infiltration <10% and a low proliferative activity, without other alterations typical of multiple myeloma (MM). The risk of progression of MGUS to multiple myeloma or related disorders is about 1 percent per year. MM is typically characterised by osteolytic lesions, the presence of Bence-Jones protein and kidney failure, while plasma cell infiltration of bone marrow is variable. The mechanisms of neoplastic transformation and evolution of monoclonal gammopathies have been studied by many authors, who have predominantly focused their attention on an involvement of programmed cell death, on anomalies of cell adhesion mechanisms and on the role of cytokines. *Aims.* The aim of this study was to evaluate the cytokine network in patients with MGUS and MM and to identify any changes in cytokine concentrations in patients developing a MM from MGUS in order to establish whether the cytokines are involved in this evolution. *Methods.* Fifty-one patients with multiple myeloma (MM) divided into 3 groups according to disease stage (MM1, MM2, MM3), 60 with monoclonal gammopathy of undetermined significance (MGUS) and 50 healthy controls (C) were studied in Caserta's Hospital and in University. The levels of sCD138 (Syndecan-1), TGF-β1, sVCAM-1, IL-13, Fas/APO-1, IL-6, β2-microglobulin (β2-M) and C-reactive protein (CRP) were assayed. Seven of the 60 cases of MGUS (11.6%) evolved into MM3 during the 5-year follow-up; these cases were studied in order to identify any changes in the cytokine network. *Results.* β2-M and CRP concentrations increased significantly through C, MGUS and the three stages of MM. TGF-β1, sVCAM-1, Fas/APO-1 and IL-6 levels were significantly higher, while IL-13 concentration was significantly lower, in MGUS and in MM than in C (p<0.001). The level of sCD138 was significantly lower in MGUS than in C and significantly higher in MM than in C (p<0.001). On the other hand, TGF-β1 concentration was significantly higher, while IL-6 and sCD138 concentrations were significantly lower, in MGUS than in MM (p<0.001). Only sCD138 was significantly higher in MM3 than in MM1 and in MM2 (p<0.001), while the concentrations of all the other cytokines did not differ significantly between MM1, MM2, and MM3. There were no significant differences in cytokine values between MGUS which evolved into MM3 and MGUS which did not evolve. Moreover, in the 7 cases of MGUS which did evolve into MM3, the cytokine levels were not significantly different between the start of the study and at the end of the follow-up. *Conclu-*

sions. We conclude that syndecan-1, like the better recognised β2-M, CRP and IL-6 markers, has a prognostic value for the evolution of monoclonal gammopathies.

0280

HIGHLY PRESERVED POLYCLONAL REGULATORY T CELLS (TREGS) CAN DOMINATE EFFECTOR FUNCTIONS IN MULTIPLE MYELOMA PATIENTS

M. Foglietta

Division of Hematology, TORINO, Italy

Naturally occurring $CD4^+CD25^+$ T regulatory cells (Tregs) are a subpopulation of $CD4^+$ T cells vital to homeostasis and maintenance of tolerance. Tregs play a key role in hampering anti-tumor immune surveillance by regulating T-cell immune responses against tumor cells. Depletion of Tregs brings to improved anti-tumor immune responses in both preclinical and clinical settings. Contradictory data have been reported in the frequency and function of Tregs cells in multiple myeloma (MM). The aim of this study was to characterize MM Tregs from the phenotypic, molecular and functional standpoints. We studied both peripheral blood (PB) and bone marrow (BM) samples from patients with symptomatic MM and from healthy donors. $CD4^+CD25^{high}$ Tregs were normally represented in both PB and BM of MM patients and expressed a memory and activated phenotype. No differences were observed between PB and BM Tregs of healthy donors and MM patients, based on the expression of CD45R0, HLADR, CD40L and CD69 cell surface antigens. Flow cytometry was also used to assess the intracellular expression of Foxp3, a transcription factor which has been shown to be crucial for the inhibitory function of Tregs cells. More than 90% of $CD4^+$CD25high T cells were Foxp3-positive in PB and BM of MM patients and healthy donors. Numbers and distribution of BM Treg were further confirmed by immunohistochemical analyses of Foxp3-positive cells in whole tissue paraffine embedded sections. $CD4^+CD25^+$ T cells were purified from PB of newly diagnosed MM by MACS sorting. These cells were anergic to the stimulation via TCR and they were as effective as normal donor-derived $CD4^+CD25^+$ cells in inhibiting the TCR-mediated proliferation of autologous $CD4^+CD25^-$ counterparts. Moreover MM Tregs equally inhibited autologous and allogeneic CD4+CD25- from normal donors. To investigate whether clonal restriction had occurred in MM Tregs, we studied TCR diversity of $CD4^+CD25^+$ and $CD4^+CD25^-$ cells by determining the reciprocal usage of BV gene segments (TCRBV repertoire) with a novel multiplex polymerase chain reaction assay, Our results demonstrate an highly preserved polyclonal TCRBV repertoire, providing the first evidence in cancer patients that TCR diversity of Tregs is not skewed by the long lasting exposure to tumor cells. Based on these data, we propose that inhibitory signals delivered by the highly preserved Tregs subset in MM can easily overwhelm the effector mechanisms of antitumor immunosurveillance which are deeply compromised in MM. Thus, depletion or neutralization of Tregs should be considered in future trials aimed at controlling the disease in MM patients by immune intervention.

PERSISTENCE OF LYMPH NODE T(14;18) BEARING CELLS IN FOLLICULAR LYMPHOMA PATIENTS IN CLINICAL COMPLETE REMISSION: PROOF OF PRINCIPLE FOR MAINTENANCE THERAPY?

J. Mayer, A. Janikova, L. Kren, D. Dvorakova, I. Kroupova, J. Smardova, J. Neubauer, I. Vasova

University Hospital Brno, BRNO, Czech Republic

Background. Despite many new therapeutic options, follicular lymphoma (FL) is a chronic relapsing malignant disease rarely cured by conventional treatments. Some institutions use PCR t(14;18) blood and/or bone marrow monitoring, however, its real importance remains controversial. *Aims.* We hypothesized that lymph nodes are much more better compartment for FL monitoring than peripheral blood/bone marrow. We asked whether it would be possible to monitor regularly the disease in patients by ultrasound-guided fine needle aspirations (UG-FNA) like we usually monitor acute leukemias by bone marrow aspirations. *Methods.* First we asked about the efficacy of FNA to detect FL by FISH and/or PCR. For this purpose we investigated either autopsy material or surgically removed lymph nodes both by FNA and classical histology.Then, upon informed consent, we performed UG-FNA in patients either with advanced disease or in clinical remission in order to search for lymph node t(14;18) bearing cells in involved nodes, or in previously involved node areas. Real time (RQ) PCR (Taqman) gives results as copies/10^6 cellular equivalents. *Results.* In 22 tested paired samples (histology vs. FNA) by PCR, 20/22 samples gave identical results. In one case each, histology vs. FNA or vice versa, gave discordant negative results. We performed 31 UG-FNA on out-patients basis without any complications. In 15 cases, both FISH and PCR were available, with FISH being positive in 13/15 samples and PCR in 8/15 samples. In only 4/31 cases, the FNA was not eventually carried-out for very small nodes. In 3/31 samples, the material did not contain vital nodal cells. All unsuccessful UG-FNA were performed in patients in remission (see below). Therefore, 24/31 samples could be examined by FISH and/or PCR: 10/24 in newly diagnosed patients, 9/24 in relapsed patients, and 5/24 in patients in remission. RQ PCR gave much higher copy numbers in lymph nodes (median: 2.3×10^6)> bone marrow (16×10^3)>peripheral blood (4.2×10^3). There were 12 UG-FNA in 11 remission patients (CT and usually also PET, and PCR from blood/or marrow, when available). 4/12 were technically unsuccessful and 3/12 samples did not contain material suitable for further examination. Four of these 7 patients had had PCR positivity at the time of diagnosis, and 6/7 are still in sustained remission. In 5 aspirations in 4 patients, there was detection of t(14;18). One patient is in long lasting remission despite two UG-FNA positive *Results.* Remarkably all other 3 patients relapsed 3, 6, and 12 months after an UG-FNA. *Summary*. This study is the proof of principle of the detection of residual (lymphoma progenitor, stem?) t(14;18) bearing cells in the previously involved lymph nodes despite patients being in well defined remission. Further study is needed to define the biological and clinical importance of this finding. This study is also the theoretical basis for maintenance therapy with rituximab, however, with the current strategy, some patients might be overtreated and the best schedule is not known.

NK-CELL ASSOCIATED RECEPTORS EXPRESSION IN EPSTEIN-BARR VIRUS-POSITIVE GAMMA-DELTA T-CELL LINES DERIVED FROM PATIENTS WITH NASAL T-CELL LYMPHOMA AND CHRONIC ACTIVE EBV INFECTION

Y. Zhang

Tokyo Medical University, TOKYO, Japan

Background and Aim. The contribution of chronic antigen stimulation to the occurrence of lymphoproliferative disorder (LPD) with the γ-δ T-cell lineage is unclear, despite the fact that Epstein-Barr virus (EBV) positive T-cell LPD is derived from antigen-stimulated cytotoxic T-cells. Given the possible association of antigen stimulation with the development of cytotoxic T-cell LPD, we compared gene expression patterns in Epstein-Barr virus (EBV)-positive γ-δ T-cell lines derived from patients with nasal T-cell lymphoma and chronic active EBV infection and those in γ-δ T-cells from healthy volunteers. [METHODS] Three EBV-positive γ-δ T-cells lines, SNT cells (SNT-8, SNT-13 and SNT-15), were used in this study. SNT-8 was established from patients with nasal T-cell lym-

phoma and SNT-13, -15 were established from patients with chronic active EBV infection (Zhang Y, *et al.,* Br J Cancer 94:599-608, 2006). All the SNT cells exhibits common rearrangement of Vγ9-JγP and Jδ3 genes. The γ-δ T-cells obtained from healthy volunteers were expanded *ex vivo* by 1 μM of zoledronate (ZOL) plus IL-2 for 14 days incubation. Global gene expression was analyzed using the Affymetrix Human Genome U133 2.0 Plus GeneChip Set. Analysis of variance (ANOVA) was done using GeneSifter® (VizXLabs). Values of $p<0.05$ were considered to be a statistically significant difference. *Results.* SNT cells share a common molecular signature, including transcriptional regulation of genes related to cytokine-cytokine receptor interaction and natural killer cell mediated cytotoxity: up-regulated genes in SNT cells include chemokine (C-C motif) receptor 7, CSF1 receptor, and major histocompatibility complex class II. Expression of killer cell lectin-like receptor subfamily B, member 1(KLRB1:CD161), NK-cell IRC1c (CD300A) were significantly down-regulated in SNT cells. Expression of killer cell immunoglobulin-like receptors (KIRs) , i.e. KIR3DL1, KIR3DL2, KIR2DL4, were evident in SNT-13 cells as well as γ-δ T-cell obtained from healthy volunteers. *Conslusions*. Our results suggest that γ-δ T-cell expansion in EBV-positive T-LPD is in principle due to inappropriately expressed NK-cell associated receptors (NKRs), thereby, being resistant to activation-induced cell death. Further study of NKRs may provide insights into the pathogenesis of EBV-positive LPD with γ-δ T-lineage, which may lead to the development of novel therapeutic strategies.

AMPLIFICATION AT 7Q22 IN THE ANAPLASTIC LARGE CELL LYMPHOMA CELL LINE SU-DHL-1 TARGETS CYCLIN-DEPENDENT KINASE 6

S. Nagel, H. Quentmeier, C. Meyer, M. Kaufmann, H. Drexler, R. MacLeod

DSMZ, BRAUNSCHWEIG, Germany

Background. Genomic amplification is microscopically visible extrachromosomally as double-minute chromosomes (DMIN) or intrachromosomally as homogeneously stained regions (HSR). Both DMIN and HSR comprise iterated copies of short genomic regions effecting copy number increases associated with upregulation of target genes which in cancer cells are usually well known oncogenes such as cMYC. *Results.* Cytogenetic analysis of the anaplastic large cell lymphoma (ALCL) cell line SU-DHL-1 revealed an HSR on the long arm region of chromosome 7 (7q). Chromosome analysis of this region by fluorescence *in situ* hybridization using tilepath BAC clones identified an amplicon corresponding to 86-95 Mb (NCBI Build 36.1) at 7q22. Expression analysis using reverse transcription (RT)-PCR of candidate genes mapped within the amplified genomic region comprising, DBF4, SRI, AKAP9, GATAD1, CDK6 and PPP1R9A, highlighted cyclin-dependent kinase 6 (CDK6) as a plausible amplification target. With reference to another ALCL cell line SR-786 which lacks this amplicon, SU-DHL-1 displays upregulation of CDK6 at both the RNA and protein levels as indicated by semiquantitative RT-PCR and immuno-cytochemistry. In contrast to SR-786, SU-DHL-1 cells are resistant to the effects of rapamycin on proliferation and G1 cell cycle arrest, implying that CDK6 overexpression may confer proliferative advantage. *Summary.* Taken together, we identified an amplicon at 7q22 in ALCL cells targeting CDK6 expression. CDK6 is an important cell cycle regulator probably connected to the increased proliferative capacity of ALCL cells and susceptible to small-molecule inhibition which may represent a potential therapeutic target in this disease entity.

0284

LOCALIZED FOLLICULAR LYMPHOMA: SPREAD OF BCL-2/IGH+ CELLS IN THE BLOOD AND BONE MARROW FROM THE PRIMARY SITE OF DISEASE AND POSSIBILITY OF CLEARANCE AFTER INVOLVED FIELD RADIOTHERAPY

A. Pulsoni, I. Della Starza, N. Frattarelli, E. Ghia, E. Carlotti, E. Cavalieri, A. Matturro, S. Tempera, A. Rambaldi, R. Foà

Hematology, La Sapienza University, ROME, Italy

Background. Localized forms of follicular lymphoma (FL) have a good prognosis being curable in 40-50% of cases with local radiotherapy alone. Polymerase chain reaction (PCR) of Bcl-2/IgH rearranged cells provides a sensitive measure of peripheral blood (PB) and bone marrow (BM) minimal non-Hodgkin's lymphoma (NHL) cell contamination in FL. *Aims.* To evaluate whether a more sensitive technique could document the presence of circulating NHL cells in limited stage FL and the possibility of inducing the disappearance of PCR$^+$ cells from the PB and BM after involved field radiotherapy. *Patients and Methods.* Between April 2000 and April 2006, 24 consecutive patients with FL, Ann-Arbor stage I or IIA, entered the study. Median age was 57 years (range: 27-74), with 9 males and 15 females. Involved field radiotherapy was performed in all patients. PCR was evaluated in the BM and PB of all patients at diagnosis and was re-evaluated 3 months after treatment and, thereafter, every 6 months. *Results.* PCR analysis performed at presentation demonstrated the presence of Bcl-2/IgH$^+$ cells in the PB and/or BM of 16 of the 24 patients studied (66.6%). The rearrangement fell in the major breakpoint region (MBR) in 15 cases and in the minor cluster region (mcr) in 1. Cases Bcl-2/IgH negative at baseline were all negative for JH rearrangement. Of the 16 Bcl-2 positive patients at baseline, at least one post-treatment molecular evaluation was performed in 15 (1 patient refused). Among these evaluable patients, 9 (60%) achieved a PCR negativity in the PB and BM, while 6 (40%) remained positive. RQ-PCR could be performed on the baseline material of 7 Bcl-2/IgH positive cases. The molecular clearance of BCL2/IgH$^+$ cells occurred, following therapy, only in the 3 patients who at diagnosis had a PB or BM tumor infiltration lower than 1 positive cell/100,000. Conversely, the 4 patients with a higher tumor contamination (1 positive cell in 10,000 or more) remained PCR positive after irradiation and 2 patients ultimately relapsed. After treatment, all patients achieved a clinical complete remission (CR) that still holds, except for 2 persistently Bcl-2$^+$ patients who had a clinical relapse 39 and 9 months after treatment, and 1 patient who obtained a PCR negativity but relapsed 36 months after diagnosis. The follow-up ranged from 11 to 70 months (median 43.5). Among the 6 patients persistently positive for Bcl-2/IgH rearranged cells in the BM and/or PB after treatment, 2 (33.3%) have relapsed, while among the 17 patients negative either at baseline or after treatment only 1 (5.8%) has so far relapsed. *Conclusions.* In the majority of stage I/IIA FL patients at presentation, PCR analysis demonstrates the presence of viable Bcl-2$^+$ cells in the BM and PB. A durable disappearance of Bcl-2$^+$ cells from BM and/or PB samples can be obtained in a high proportion of patients after local radiotherapy alone. The possibility of a persistent lymphoma cell clearance is proportional to the amount of cells detected at presentation by quantitative PCR.

HAEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN ADULTS: A SERIES OF 19 PATIENTS

M. Motta,[1] L. Consoli,[2] C. Cattaneo,[2] M. Micheletti,[2] E. Borlenghi,[2] M.A. Capucci,[2] G. Tabellini,[3] S. Parolini,[3] M. Ungari,[4] F. Facchetti,[4] G. Savoldi,[5] P. Mella,[5] G. Rossi[2]

[1]Spedali Civili, Brescia, BRESCIA; [2]Dpt. Ematologia Spedali Civili, BRESCIA; [3]Dpt. Scienze Biomediche e Biotecnologie, BRESCIA; [4]Dpt. Patologia, Università di Brescia, BRESCIA; [5]Laboratorio Nocivelli, BRESCIA, Italy

Background. Haemophagocytic Lymphohystiocytosis (HLH) is a rare, fatal disease, usually of early infancy, characterized by uncontrolled hyperinflammation on the basis of inherited or acquired immune deficiencies. Both acquired and genetic forms are associated with impaired natural killer (NK) and cytotoxic T- cell (CTL) function. Perforin (PRF) mutations have been demonstrated in a proportion of patients diagnosed with the familial form of HLH. Impaired PRF activity results in ineffective killing, sustaining NK and CTL activation with a hypersecretion of pro- inflammatory cytokines, leading to macrophage activation and organ infiltration. Cardinal symptoms of HLH are fever, cytopenias and hepatosplenomegaly. Characteristic laboratory findings include elevated triglyceride, ferritine, transaminases, bilirubin and low fibrinogen. *Aims.* Data on the occurrence of HLH in adult patients are limited to single cases or small series. The aim of this study is to evaluate the occurrence of HLH in adult patients, focusing on the biological and clinical features and the underlying diseases. *Patients and Methods.* From February 2003 through August 2006 19 patients (11 male and 8 female) were diagnosed with HLH, using the revised criteria of the Histyocyte Society. The median age at diagnosis was 55 years (31-71). Thirteen (68%) patients presented a hematological underlying disease (1 Castleman's disease, 2 AIHA, 5 DLBCL, 2 B-CLL, 2 PTCL and 1 ALCL). Perforin expression was performed on NK cells by flow cytometry. NK activity of PBMCs was assessed by standard 4-hour51Cr-release assay with K562 cells. Perforin mutations were detected by polymerase chain reaction and sequencing. *Results.* All patients presented fever, cytopenia and elevated ferritin. Eleven (58%) patients showed hypertriglyceridemia and hypofibrinogenemia. Fifteen (79%) patients had splenomegaly. Bone marrow biopsy showed obvious hemophagocytosis detected both morphologically and immunohistochemically (anti-CD68R and anti-CD163) in 12 (63%) patients. EBV DNA, CMV DNA and HHV8 DNA were detected in 4, 3 and 8 cases respectively. CTL activity resulted defective in 7/9 patients evaluated: 3 patients showed no PRF mutation; 1 patient

without PRF mutation showed normal PRF expression by flow cytometry; 2 patients showed A91V heterozygous polymorphism with reduced and absent PRF expression, respectively; 1 patient showed heterozygous G1070A mutation; genetic analysis could not be performed in 3 patients. *Summary and Conclusions.* In this series of patients the occurrence of HLH in adults was higher than expected and it was associated with a high incidence of lymphoma, also of B cell lineage, and of Herpes virus DNA detection. Impaired CTL appears to be, at least in some patients, independent from PRF mutations, raising the question of whether and how these genetic events can be related, in acquired HLH of adults, to the deficiency of the lytic activity of PRF.

Background. Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignancy of mature B cells with heterogeneous prognosis. Biological markers have been used in an attempt to improve the discriminative capacity of the International Prognostic Index (IPI). Abnormalities of cell cycle constitute a marker of clonal expansion and may contribute to disease progression; thus the investigation of cell cycle regulatory genes may be of prognostic relevance. *Aims.* The aim of the present study was the investigation of gene expression levels of cell cycle regulatory genes in DLBCL and their relation to prognosis. *Methods.* The analysis included 45 newly diagnosed cases of diffuse large B-cell lymphomas and 15 cases of non-neoplastic lymphadenopathies used as controls. The IPI was available for all lymphoma cases. RNA was extracted from fresh frozen tissues and analyzed by RNase Protection Assay (RPA) with Riboquant kit (BD Biosciences). Two sets of probes were used that included cyclins, cyclin dependent kinases and their inhibitors. In more detail h-CC1 set of probes detected mRNA for the genes cdk-1,cdk-2,cdk-3,cdk-4,p16,p27,p21,PISSLRE and h-CYC1 set of probes detected mRNA for the genes of cyclins A,B,C,D1,D2,D3 and A1.The intensity of each band was compared to that of the housekeeping genes GAPDH and L32 using the Image Master Software(Pharmacia). Moreover, immunohistochemistry was performed on paraffin-embedded tissue sections in order to verify the expression of germinal center proteins, bcl6 and CD10. *Results.* The expression levels of the cell cycle regulatory genes did not correlate with any of the clinical parameters nor the prognostic markers. 85% of patients that didn't have complete remission to first line therapy, expressed the cyclinA1 (p=0,03). 92% of the patients with low IPI (0,1) expressed PISSLRE, while only 56% of the patients with high IPI (2,3,4,5),expressed this gene. Moreover, cdk2 and cdk4 expression levels were significantly higher in cases expressing bcl-6 protein (p=0,013, p=0,004 respectively). The mean expression level of cyclin B was higher in cases with positive expression of protein CD10 (p=0,007). All patients with negative expression of CD10 had a lower expression level of cyclinA1 compared to normal RNA pool (p=0,037). Moreover, patients expressing cyclinA1 had significantly shorter disease free survival (p=0,03), while the expression of PISSLRE was associated with significantly better overall survival (p=0,0329). *Summary and Conclusions.* Taking into consideration the heterogeneity of clinical behaviour of DLBCL, the cell cycle regulatory genes may serve as biologic markers with prognostic significance. Our study has shown that the expression level of cyclinA1 is associated with significantly lower response to first line therapy and lower disease free survival. Moreover the expression of PISSLRE seems to be associated with low risk disease and higher overall survival, which emphasizes the potential role of this gene as a tumour suppressor.

University of Athens, ATHENS, Greece

Background. Survivin is a member of the Inhibitor of Apoptosis Proteins and has recently gained attention as a possible therapeutic target in neoplasia, due to its dual role both as an antiapoptotic protein and as a cell cycle regulator. It is overexpressed in malignant cells and confers resistance to chemotherapy and other stimuli triggering apoptosis. Survivin as well as other antiapoptotic proteins are under NF-κB control. Z-Guggulsterone (Z-GGS) is a plant sterol, which has been used in inflammatory conditions, is a potent NF-κB suppressor and might affect Survivin. *Aims.* To evaluate Survivin expression by two large B cell lymphoma cell lines and study the effect of Z-GGS on Srvivin expression and cell viability. *Methods.* DB and HT cell lines were treated with increasing concentrations (10 μM, 20 μM and 30 μM) of Z-GGS, for 24, 48 and 72 hours. Survivin expression was tested by flow Cytometry and quantitative real time PCR using the Universal Probe Library hydrolysis probes and expressed as Survivin/abl ratio. Cell viability was assessed by the MTT assay. *Results.* Both cell lines were positive for Survivin at baseline by flow cytometry (66% of total cells for DB and 95% for HT). Treatment of DB cells with 10, 20 and 30Ìª Z-GGS resulted in a 44%, 49% and 68% reduction of Survivin expression at 24 hours, respectively, whereas the effect on HT was less prominent with a 10% reduction at 24 hours with 30 μM Z-GGS. Survivin transcripts decreased as well, with the maximum effect observed at 72 hours with 3 μM Z-GGS for both cell lines: Survivin/abl was 0.009 for untreated cells vs 0.0008 with 30 μM Z-GGS for DB cells and 0.0135 vs 0.0005 for HT cells. Linearity was observed for increasing concentrations of Z-GGS at 72 hours. Cell viability was practically unaffected at any time point with 10 and 20 μM Z-GGS for both cell lines, whereas 30 μM Z-GGS resulted in a 63% and 78% cell death at 48 and 72 hours respectively for DB cells and 67% and 83% for HT cells. *Conclusions.* The steroid Z-GGS downregulates Survivin expression in B-lymphoma cells *in vitro* and induces cell death at 30 μM concentration. Further experiments will clarify its possible role in the treatment of B-cell malignanciies

0288

CD5 POSITIVE SPLENIC MARGINAL ZONE LYMPHOMA : CLINICAL, CYTOLOGICAL, IMMUNOLOGICAL, MOLECULAR AND CYTOGENETICAL FEATURES OF A SERIES OF 35 CASES

M. Baseggio, F. Petinataud, E. Callet-Bauchu, F. Berger,
A. Traverse-Glehen, C. Thieblemont, D. Morel, G. Salles, P. Felman

Centre Hospitalier Lyon-Sud, PIERR-BENITE, France

Splenic marginal zone B-cell lymphoma (SMZL) has been recently recognized owing to clinical, cyto-histological, immunological, cytogenetical characteristics. The immunological profile, usually CD5, CD10, CD23, CD43, cyclinD1 negative B-cells, is however in lack of specific markers which could be useful in doubtful cases. For instance, the report of CD5 positive cases without histological control is still a matter of debate, and in fact the differential diagnosis with B-CLL or MCL is sometimes difficult. Nevertheless CD5 postivity has been reported in some histologically typical MZL cases and proposed as a marker for a more aggressive and disseminated disease. Here we described a series of 35 CD5 positive SMZL histologically proven in 26 cases and without t(11;14) detected by FISH, that were compared to a series of 44 *typical* CD5 negative SMZL. From a clinical, cytological and immunological point of view, the CD5 positive SMZL cases presented many similarities with the group of CD5 negative SMZL. The main differences consisted in a higher lymphocytosis at diagnosis (4,95 G/L in CD5 positive group and 1,60G/L in CD5 negative group, respectively -p=0.003-) and a more frequent IgM isotype of the monoclonal component (75% vs 53%). Interestingly, all CD5 positive cases in peripheral blood were CD5 positive on splenic specimen studied by flow cytometry and no CD5 negative B-cells were detected in spleen compartment. The tumoral mass assessed by spleen weight seemed similar between both groups.These results suggest that CD5 expression gives B-cells a higher propensity to recirculate from spleen. A good correlation was observed with the CD5 expression detected by immunohistochemistry. The few CD5 negative cases on sections corresponded in fact with a faint CD5 expression by FCM. Karyotypic changes were similar in both groups and included the chromosomal abnormalities previously described in SMZL. However, some differences were observed : trisomy 18 was more frequent (29% vs 11%) and the 7q deletion was less frequent (23% vs 36%) in the CD5 positive group than in the CD5 negative group, respectively. The frequency of 17p deletion, leading to an alteration of P53 and a more aggressive clinical course was similar in both groups. Most cases were mutated in the CD5 positive group (82%) in contrast to the CD5 negative group (55%). The IgVH analysis showed a VH4 usage gene in 4 cases (23%) of the 17 available CD5 positive cases, whereas in the CD5 negative group, an underrepresentation of VH4

usage (2/20 ie 10%) were observed. No difference in outcome and overall survival was found between both groups. In conclusion, this study allowed to confirm the existence of CD5 positive SMZL, closely related to classical CD5 negative SMZL and distinct from CLL and MCL. The differences observed with CD5 negative cases, in particular cytogenetical abnormalities and usage of IgVH gene, suggest that this entity may arise from a distinct cell in the marginal compartment, Obviously further studies of more cases are required to confirm and precise these data.

0289

ABERRANT METHYLATION OF SHP-1 (SH2-CONTAINING PHOSPHATASE 1) AND SOCS-1 (SUPPRESSOR OF CYTOKINE SIGNALLING 1) GENES IN IMMUNODEFICIENCY-RELATED LYMPHOMAS

M. Cerri,[1] C. Deambrogi,[1] D. Rossi,[1] M. Lunghi,[1] P. Zigrossi,[1] V. Spina,[1] L. De Paoli,[1] P. Riccomagno,[1] A. Gloghini,[2] M. Lucioni,[3] D. Capello,[1] M. Paulli,[3] A. Carbone,[4] G. Gaidano[1]

[1]University of Eastern Piedmont, NOVARA; [2]Division of Pathology CRO, AVIANO; [3]Division of Pathology IRCSS San Matteo, PAVIA; [4]Division of Patholohy, Nat.Cancer Inst., MILAN, Italy

Background. SHP-1 and SOCS-1 are members of a family of negative regulators of signalling that act downstream of cytokine receptors, receptor tyrosine kinases and receptor complexes of the immune and hematopoietic system. SHP-1 and SOCS-1 act through the inhibition of the JAK2/STAT pathway and their inactivation is considered to be a relevant mechanism in JAK2/STAT pathway induction. Several observations point to induction of the JAK/STAT pathway as an important mechanism of lymphomagenesis. *Aims.* Since DNA methylation and DNA somatic mutation are mechanisms of gene silencing and gene inactivation involved in the pathogenesis of human cancers, including lymphoma, here we tested the involvement of SHP-1 and SOCS-1 methylation and of SOCS-1 mutation in immunodeficiency-related lymphoma. *Methods.* Tumor samples from 48 HIV-related non-Hodgkin lymphoma (HIV-NHL) and 25 post-transplant lymphoproliferative disorders (PTLD) were analyzed for SHP-1 and SOCS-1 methylation by methylation-specific polymerase chain reaction and for SOCS-1 mutation status by DNA direct sequencing. The tumor panel included 21 HIV-diffuse large B cell lymphoma (HIV-DLBCL), 17 HIV-Burkitt lymphoma (HIV-BL), 10 HIV-primary effusion lymphoma (HIV-PEL), 10 PTLD-immunoblastic (PTLD-IB), 7 PTLD-centroblastic (PTLD-CB), 4 polymorphic PTLD (P-PTLD), 3 PTLD-BL, and 1 PTLD multiple myeloma (MM). *Results.* Among HIV-NHL, SHP-1 methylation occurred in 23/48 (48%) cases, including 12/21 (57%) HIV-DLBCL, 3/17 (17.6%) HIV-BL, and 8/10 (80%) HIV-PEL. SOCS-1 methylation occurred in 7/48 (14.6%) HIV-NHL, including 5/10 (50%) HIV-PEL and 2/21 (9.5%) HIV-DLBCL. When considering EBV status, SHP-1 was methylated in 10/11 (91%) EBV-negative HIV-NHL and in 12/22 (54%) EBV-positive HIV-NHL. Among PTLD, SHP-1 methylation was detected in 19/25 (76%) cases, including 7/10 (70%) PTLD-IB, 6/7 (86%) PTLD-CB, 3/4 (75%) P-PTLD, 2/3 (66%) PTLD-BL and 1 PTLD MM. SOCS-1 methylation was detected in 3/25 (12%) PTLD, including 2/10 (20%) PTLD-IB and 1/7 (14.3%) PTLD-CB. When considering EBV status, SHP-1 was methylated in 12/13 (92%) EBV-negative PTLD and in 6/11 (54%) EBV-positive PTLD. Missense mutations of SOCS-1 were detected in 1/15 HIV-DLBCL tested and in 1/25 PTLD. *Conclusions.* The implications of our data are threefold. First, SHP-1 methylation is involved in the majority of HIV-NHL and PTLD. Second, it is remarkable that virtually all EBV-negative HIV-NHL and EBV-negative PTLD carry SHP-1 methylation. In EBV-positive B-cells, EBV infection activates the STAT pathway. It is conceivable that, in EBV-negative HIV-NHL and in EBV-negative PTLD, SHP-1 inactivation through aberrant methylation may surrogate EBV infection for STAT activation. Third, similar to observations in NHL of the immunocompetent host, SOCS-1 methylation and mutation is rarely implicated in the pathogenesis of immunodeficiency-related NHL. This notion is consistent with the phenotype of SOCS1-deficient mice, that die of a myeloproliferative disease but do not develop a lymphoproliferative disease

0290

P53 STABILIZATION BY THE MDM2 INHIBITOR NUTLIN-3A INDUCES P53-DEPENDENT CELL CYCLE ARREST AND APOPTOSIS IN ANAPLASTIC LARGE CELL LYMPHOMA

G. Rassidakis, V. Atsaves, E. Drakos, G. Georgakis, L.J. Medeiros,

M.D. Anderson Cancer Center, HOUSTON, USA

Background. Mutations of the p53 tumor suppressor gene is the most frequent genetic alteration in human cancer. However, p53 mutation rate is relatively low in most haematologic malignancies including non-Hodgkin lymphomas. Previously we have shown that p53 mutations are uncommon in anaplastic large cell lymphoma (ALCL), an aggressive T/null cell lymphoma type, despite the variable level of expression of wild-type p53 protein [Leukemia 2005;19(9):1663]. MDM2 (HDM2 in humans) is a physiologic negative regulator of p53 levels within the cell. We hypothesized that p53 stabilization using a novel Mdm2 inhibitor, nutlin-3A, would activate p53-dependent apoptotic and cell cycle regulatory pathways in ALCL cells carrying wild-type and potentially functional p53 gene. *Methods.* Two ALCL cell lines, SupM2 and DEL, carrying wild-type p53 (wt-p53) and 2 ALCL cell lines harboring a mutated p53 (mt-p53) gene, Karpas 299, and SR-786, were used. All cell lines were treated with different concentrations of nutlin-3A (0, 2.5 , 5, 10 mM). The effects of p53 stabilization by nutlin-3A on cell viability and proliferation of ALCL cells were assessed using trypan blue and MTS assays, respectively, at two time points (24 and 48 hours). Cell cycle and apoptosis (annexin V binding) analysis was also performed using flow cytometry. To further investigate the underlying mechanisms of cell cycle arrest and apoptosis following nutlin-3A treatment, Western blot analysis was performed. *Results.* Treatment with increasing concentrations of nutlin-3A resulted in a dose-dependent increase of p53 levels, which was associated with increased levels of MDM2 a known transcriptional target of p53 gene. P53 stabilization resulted in a concentration-dependent decrease in cell viability and total cell number in ALCL cells carrying wt-p53 (SupM2 and DEL) but not in cells harboring p53 mutations (Karpas 299 and SR-786). At a concentration of 10 mM nutlin-3A, cell viability was dramatically decreased at 48 after treatment in SupM2 and DEL. Changes in cell viability were largely attributed to apoptosis, since the percentage of Annexin V+ cells was increased from 8% to 87% in SUPM2 and from16% to 50% in DEL.. By contrast, no changes in cell viability or apoptosis were observed in Karpas 299 and SR-786 cell lines(mt-p53). Apoptosis was associated with cleavage of caspase 3 and 9 in immunoblots. Cell cycle analysis revealed that nutlin-3A treatment in SupM2 and DEL resulted in cell cycle arrest. The S-phase fraction of cell cycle was decreased by approximately 50% at a concentration of 5 mM, 24 hours following treatment. Cell cycle arrest was associated with a concentration-dependent increase of the cyclin-dependent kinase inhibitor p21, which is trancriptionally regulated by p53 gene. *Conclusions.* Selective inhibition of Mdm2 by nutlin-3A leads to non-genotoxic activation of p53 pathway and may represent a novel therapeutic modality in patients with ALCL.

0291

PREVALENCE OF CHLAMYDIA PSITTACI INFECTION IN NODAL AND EXTRANODAL NON-HODGKIN LYMPHOMAS

J.M. Ferreri,[1] R. Dolcetti,[2] M. Guidoboni,[2] M.G. Cangi,[1] L. Pecciarini,[1] G.P. Dognini,[1] P.P. Ghia,[1] M. Malnati,[1] E. Pasini,[2] C. Doglioni,[1] M. Ponzoni[1]

[1]San Raffaele Scientific Institute, MILAN; [2]Centro di Riferimento Oncologico, AVIANO, Italy

Background. Ocular adnexal lymphomas (OAL) are malignancies with rapidly increasing incidence rates. Recently, we demonstrated an association between Chlamydia psittaci (Cp) persistent infection and OAL. The condition of the systemic subclinical Cp infection encountered in many OAL patients provided the rationale for searching alternative sites of lymphoma development, an uncovered issue particularly for extranodal localizations. *Methods.* 172 non-consecutive cases of non-Hodgkin lymphomas were analyzed. Thirty-one patients with non-specific tonsillitis, 36 with non-specific reactive lymphadenopathies and 7 non-neoplastic spleens were used as controls (n=74). After central pathology review, DNA was extracted from formalin-fixed, paraffin-embedded tissue blocks and amplified by a multiplex touchdown PCR assay, which simultaneously detects the DNA of the three major Chlamydiae species (i.e. C. trachomatis, pneumoniae, and psittaci). DNA of C. trachomatis L2, C. pneumoniae TW-183 or C. psittaci ORNI were included as positive controls. Amplicons encompass part of the 16S rRNA gene and the 16S-23S spacer region in the ribosomal genes. PCR products were analyzed by electrophoresis and DNA fragment size was quantified by image analysis. Samples were considered positive when Chlamydia DNA was amplified in at least two of three independent experiments. Specificity of the amplified fragments was confirmed by direct sequencing. Sequence specificity was assessed by BLAST search. In each sample negative to PCR, amplification of α-globin control gene was carried out. Prevalence of Cp DNA for each lymphoma category was compared with the prevalence in the 74 controls. *Results.* Overall, Chlamydiae DNA was detected in 20 (12%) cases of NHL. Cp turned out to be the most

prevalent in NHL tissues (17 cases; 10%); *Chlamydia pneumoniae* and trachomatis DNA was detected in 3 cases (2%) (p=0.001). Cp DNA was present in 5 (7%) out of 74 controls; it was detected in 15 (11%) out of 141 extranodal lymphomas and in 2 (6%) of 31 nodal lymphomas (p=0.48) (Table 1). Among extranodal lymphomas, the prevalence of Cp DNA was 10% and 11% respectively for B- and T-cell lymphomas. According to the histotype of extranodal B-cell lymphomas, Cp DNA was present in 4 (7%) of the 56 marginal zone B-cell lymphomas (MZL) and in 9 (15%) of 73 diffuse large B-cell lymphomas (DLBCL) (p=0.33). Cp infection was not randomly distributed among extranodal B-cell lymphomas: it was detected in 6 (25)% of cutaneous lymphomas and in 18% of DLBCL arising in the Waldeyer's ring, while it was rarely detected in gastrointestinal sites. *Conclusions.* This is the largest study revealing that Cp-related lymphomas may occur outside the ocular adnexae; these lymphomas may arise in the skin and Waldeyer's ring, two extranodal sites considered as *first-barrier* to antigen exposure. This finding may have obvious clinical implications, in view of the encouraging results offered by Cp-eradicating therapy with doxycycline in the treatment of OAL. These figures should be considered in view of the possible differences in the prevalence rate of Cp infection in OAL among different geographical regions reported in the literature.

Table 1.

SPLENIC LYMPHOMA WITH VILLOUS LYMPHOCYTES (VL>20%) CONSTITUTES A VARIANT OS SPLENIC MARGINAL ZONE LYMPHOMA WITH DISTINCT CLINICO-PATHOLOGICAL AND MOLECULAR FEATURES

M. Baseggio, A. Traverse-Glehen, F. Berger, E. Callet-Bauchu, M. Ffrench, D. Morel, C. Thieblemont, G. Salles, B. Coiffier, P. Felman

Centre Hospitalier Lyon-Sud, Pierre Benite, France

Splenic marginal zone lymphoma (SMZL) presents some degree of molecular heterogeneity, which suggests the coexistence of different diseases. Especially splenic lymphoma with villous lymphocytes (SLVL) defined at the beginning by hematologists on blood films and incorporated in WHO classification as the leukaemic form of almost all SMZL, could play a role in this heterogeneity. In our experience, the aspect and proportion of villous lymphoid cells (VL) in blood may be quite variable, and typical VL are often lacking or rare indeed in SMZL. Thus, with the aim to define more homogeneous entities, we selected among our files of SMZL, 37 cases displaying more than 20% of typical VL and for which cytogenetic and molecular data were available, and were compared them to a control group of classical non-villous SMZL. Patients presented a male predominance (sex ratio: 1.76) with a median age of 76 years old, a moderate lymphocytosis (from 4.3 G/L to 25.5 G/L) with splenomegaly (97%) without lymphadenopathy (5%) or pancytopenia (32% anemia, 15% thrombocytopenia, 3% neutropenia). Immunophenotypically, the monoclonal B cells expressed IgM (20%), IgG (20%), IgM+G (22%) or IgM+D (30%), CD76 (86%), CD11c (97%), and usually lack CD25 (one positive case) or CD5 (5 faintly positive cases). Interstingly CD103 and CD123, known as markers of hairy-cell leukemia (HCL), were expressed in 13 of 34 and in 3 of 19 available cases, respectively. Besides, the fluorescence intensity (RFI) of the CD11c and CD22 appeared different in SLVL, SMZL and HCL. On VL, the CD11c and CD22 expression was moderate (RFI CD11c=40 and CD22 RFI=138), whereas in SMZL the CD11c and CD22 staining was lower (RFI CD11c=15 and CD22 RFI=62) and in HCL the CD11c and CD22 staining was very strong (RFI CD11c=211 and CD22 RFI=268) (p<0.05). Thus typical SLVL as defined here display a characteristic immunological profile. Interstingly spleen sections showed in all available cases (14 cases) a pattern distinct from classical SMZL and HCL with predominant red pulp infiltration by small cells with round hyperchromatic nuclei. Bone marrow infiltration was essentially interstitial and intrasinusoidal without fibrosis. Cytogenetic analysis showed a frequent absence of clonal aberrations (9/26 -34%-). Most cases were mutated (84%) with a surrepresentation of VH3 and VH4. Clinically true SLVL differed from classical SMZL by a longer progression free survival (p<0.05) without significant change in overall survival. Altogether theses results support the view that these cases need to be individualised as a variant of SMZL sharing some features with HCL, which would not be surprising considering the marginal origin of these 3 entities.

PATIENTS WITH AIDS-RELATED LYMPHOMA HAVE HIGHER EPSTEIN-BARR VIRUS VIRAL LOAD THAN THOSE HIV-INFECTED WITHOUT LYMPHOMA

J.T. Navarro,[1] A. Hernández,[2] J. Grau,[1] J. Rodríguez-Manzano,[2] J.L. Mate,[3] M. Morgades,[1] L. Matas,[2] C. Tural,[4] J. Juncà,[1] F. Millá,[1] E. Feliu,[1] J.M. Ribera[1]

[1]Institut Català d'Oncologia-Badalona, BADALONA; [2]Servicio de Microbiología., BADALONA; [3]Servicio de Anatomía Patológica, BADALONA; [4]Unidad VIH. Servicio de Medicina Interna, BADALONA, Spain

Background. The incidence of lymphomas is increased among patients with AIDS. Epstein-Barr virus (EBV) has been associated with non-Hodgkin's lymphomas (NHL) as well as Hodgkin's lymphoma (HL), especially in those patients with HIV infection. Owing to EBV seems to play a role in the lymphomagenesis of AIDS-related lymphoma (ARL), the viral load of this virus might be elevated in HIV-infected patients when they develop lymphoma. *Aims.* To compare the viral load of EBV in HIV-infected patients with lymphoma with that of HIV-infected individuals without lymphoma. To study the correlation between EBV viral load and the presence of EBV in the tumor. To consider the usefulness of EBV viral load for lymphoma diagnosis and follow-up in the HIV-infected population. *Methods.* 113 HIV-infected patients were studied: 39 with lymphoma (32 NHL and 7 HL) and 74 without lymphoma. Samples from patients with lymphoma were collected at diagnosis and before any treatment. EBV viral load was measured in plasma by real-time PCR using Real Art EBV kit (QIAGEN Diagnostics, Hamburg, Germany) for LightCycler Instrument. HIV RNA load was measured using the NASBA method NucliSens Easy Q HIV-1 (bio-Mérieux, Boxtel, The Netherlands). The presence of EBV-EBER mRNA in the lymphoma was investigated by FISH. The main clinical and biological parameters were recorded, including CD4 lymphocyte count. *Results.* HIV-infected patients with lymphoma (n=39) had higher EBV viral load at lymphoma diagnosis than those HIV-positive without lymphoma (n=74) [mean (SD) 24,180 (73,387) copies/mL versus 3 (27.7) copies/mL]. The difference was statistically significant evaluating either NHL and LH together (p=0.047) or separately (p=0.013). Among patients with lymphoma, no correlations were found between EBV viral load and CD4 lymphocyte count, HIV RNA load or any clinical or biological parameter. The presence of EBV-EBER mRNA in the tumor was investigated in 17 cases: 11 were negative and 6 positive. EBV viral load were 37,935 (124,333) copies/mL and 50,652 (74,671) copies/mL respectively (p=0.022), and all 7 cases with negative EBV viral load were EBER negative. *Conclusions.* HIV-infected patients with lymphoma have higher EBV viral load at lymphoma diagnosis than those HIV-infected without lymphoma. Patients with EBER positive lymphomas have higher EBV viral load than those who are EBER negative. Serial measurement of EBV viral load might be useful for lymphoma detection in HIV-infected patients.

MYCOSIS FUNGOIDES. IMMUNOHYSTOCHEMISTRY ANALYSIS OF LYMPHOID AND MICROENVIREMENT CELLS BY MACROTISSUE ARRAY

C. Del Agua,[1] A. Rubio-Martinez,[2] F Felipo,[3] M.A. Piris,[4] P. Giraldo[2]

[1]HU Miguel Servet, ZARAGOZA; [2]Haematology Department. HU Miguel Servet, ZARAGOZA; [3]Pathology Department. HU Miguel Servet, ZARAGOZA; [4]CNIO, MADRID, Spain

Background. Cutaneous lymphomas (CL) represent a unique group of lymphomas and are the second most frequent extranodal lymphomas. CL probably is the result of a multifactor and multistep process. Firstly an inflammatory reactive process is developing secondary to various chronic stimuli that may be genetic, environmental, infectious and immunologic. The consequences are the negative effects in cell regulation and deregulation of oncogenes and/or suppressor genes later promotes transition from pre-neoplastic conditions to neoplasia. Detailed molecular expression analysis of cutaneous T-cell lymphoma is not available. Some oncogenic alterations have been demonstrated, such as functional inactivation of the Fas receptor, constitutive activity of STAT 3, or the inactivation of the p16 gene via deletion or promoter hypermethylation. Objective: To study the expression of p16, c-myc, Ki67, bcl-2, CD1a, CD123, TCL1, CD68, STAT 3, STAT 4 and MAL1 in an homogeneous group of. CL diagnosed in one tertiary Hospital in order to know more about the characteristics of this neoplastic process. *Methods.* We have study 30 CL diagnosed consecutively as Mycosis Fungoides (14 early and 16 advanced stages) between January 2005-December 2006. By macrotissue array techniques and immunohistochemistry protocol with p16, c-myc, Ki67, bcl-2, CD1a, CD123, TCL1, CD68, STAT 3, STAT 4 y MAL1 was applied in all paraffin histological samples. *Results.* In 28 samples (92%) we have observed p16 positive over expression, the two negative samples corresponding to early affectation. In 14 samples from early stages (48%) c-myc was negative. In 29 samples (96%) CD1a was positive in dermal and epidermal layer. CD123 (interleukine 3 receptor) was negative in 16 samples (52%) and TCL1 was positive in 12 cases (39%) in small cells with oval and cleaved nucleus and scarce cytoplasm. Over expression of MAL1 was observed in advanced patients with aggressive CL. *Conclusions.* In our study an over expression of p16 is observed in the majority of cases and high c-myc expression in advanced stages. Probably dendritic plasmacytic cells are involved in the pathogenesis of skin lymphoproliferative disorders with cutaneous T cell infiltration. MAL1 could be a predictor of agressive CL but it is necessary more studies and more cases in order to confirm it.

EXPRESSION OF NPM-ALK LEADS TO ONCOGENIC EFFECTS OF JUNB

P. Vesely,[1] P. Staber,[1] C. Fuchs,[1] I. Bambach,[1] S. Schauer,[1] D. Sternberg,[2] L. Kenner,[3] G. Hoefler[1]

[1]Medizinische Universitaet Graz, GRAZ, Austria; [2]Mount Sinai School of Medicine, NEW YORK, USA; [3]Medizinische Universität Wien, VIENNA, Austria

Background. The oncogene NPM-ALK arises due to a chromosomal rearrangement in human T-cells, resulting in activation of MAPK, PI3K and PLCγ signaling pathways. Enhanced activity of multiple signalling cascades and subsequently ALC(L)- lymphoma formation are the result. High expression of CD30 and JunB are a hallmark of NPM-ALK positive ALCL. In contrast to the prototypic AP-1 transcription factor c-Jun, JunB exerts an antioncogenic function in most cell types. Its functional role in the context of NPM-ALK remains uncertain. *Results.* Here we show that aberrant NPM-ALK expression leads to IL-3 independent outgrowth of Ba/F3 cells. Furthermore NPM-ALK expression induces JunB and CD30 expression, which is undetectable in the corresponding wild type cells and can be reversed by MEK-inhibition. Interruption of the NPM-ALK kinase domain impedes JunB and CD30 expression. Specific down-modulation of JUNB mRNA using small hairpin (sh) RNA avoids CD30 expression and arrests the cell cycle in G1 phase of NPM-ALK expressing cells. Conversely, ectopic JunB expression in NPM-ALK transgenic Ba/F3 cells leads to enhanced proliferation in the absence of IL3, whereas ectopic JunB expression in WT Ba/F3 is not sufficient to provoke IL3 independence and even leads to reduced proliferation in the presence of IL3. *Conclusions.* Thus, both, NPM-ALK and JunB are essential to induce CD30 expression and malignant transformation. The presence of NPM-ALK determines the oncogenic role of JunB.

0296

RITUXIMAB ENHANCES CELL-MEDIATED CYTOTOXICITY IN PATIENTS WITH B-CELL LYMPHOMA: *IN VIVO* STUDY OF NK/T-LYMPHOCYTES ACTIVITY

V. Prochazka, M. Novak, Z. Pikalova, T. Papajik, K. Indrak

Teaching Hospital, OLOMOUC, Czech Republic

Background. Rituximab dramatically improves the outcome of patients with B-cell lymphomas. The major mechanism of its action is antibody-dependent cellular cytotoxicity (ADCC) mediated by degranulation of cytotoxic lymphocytes (CTL) after binding to the Fc receptor. Although rituximab has been routinely used for 10 years, the published studies of natural killer (NK) and T-lymphocyte cytotoxic activity are limited to *in vitro* and *ex vivo* studies. The novel flow cytometry method is capable of visualizing the degranulation of T/NK cells via surface expression of lysosomal-associated membrane protein 1 (CD107a). *Aims.* To investigate changes in NK/T lymphocytes subsets and *in vivo* anti-lymphoma activity of normal NK/T lymphocytes in patients with B-cell lymphoma during the administration of chemoimmunotherapy. *Methods.* We investigated peripheral blood samples from 44 patients with newly diagnosed lymphomas (diffuse large B-cell lymphoma, DLBCL=21, follicular lymphoma, FL=16, mantle cell lymphoma=3, marginal zone lymphoma=2, B-cell lymphoma, unspecified=2). The patients were treated with chemoimmunotherapy (CHOP-like regimen=42, fludara-based regimen=2) repeated every 21 days. Rituximab was given in standard dose of 375 mg/m^2. Blood samples were obtained during the 4th therapy cycle - before and within 1 hour after the administration of rituximab. Patients with active infection or inflammation were excluded from the study. Flow cytometric analysis was performed on a FACSCalibur cytometer (BD Biosciences). Anti-human fluorescein-conjugated monoclonal antibodies: CD 3 FITC/ CD16+56+ PE, CD 4 FITC/CD 8 PE, CD 16 FITC/ CD 56 PE/ CD 3 EDC, (all Beckman Coulter) and CD 107a PE-Cy5 (BD Biosciences) were used for multi-color sample analysis. Antibody concentrations were adjusted according to the manufacturer's protocol. The results were expressed as the percentage of cells in a gated lymphocyte region. The collected data were analyzed using the Cell Quest Pro software by BD Biosciences. *Results.* We did not find any difference in the numbers of T/NK cell subsets when comparing patients with FL and DLBCL. The administration of rituximab is connected with a significant increase of all NK subsets ($CD16^+$ 12.8±9.1 vs 20.8±14.4, p=0.007; $CD56^+CD16^+$ 14.9±7.4 vs 23.1±13, p=0.03), the proportion of CD8+ lymphocytes did not change, $CD4^+$ cells decreased (14.5±2.2 vs 12.1±1.8, p=0.01). The proportion of degranulated CTL increased more than twice (CD107a+ 3.07±1.9 vs 6.37±3.8, p<0.001). No differences in absolute lymphocyte count before/after rituximab administration were observed. *Summary.* Degranulation of cytotoxic T/NK lymphocytes is the last step in innate antitumor immunity. The published data demonstrate close correlation between CD107a expression and tumor cell lysis *in vitro*. Our data show that rituximab administration *in vivo* has an direct impact on ADCC - mostly by increasing the proportion of degranulated cells (CD107a) and the numbers of $CD16^+$, $CD16^+CD56^+$ cells. The ADCC activity and numbers of NK/Tc cells vary individually. Therefore, the subgroup of low rituximab responders may be threatened by lower efficacy of induction or maintenance immunotherapy.

Therapy of non-Hodgkin's lymphoma

0297

QUALITY OF LIFE IN PATIENTS WITH NON-HODGKINS-LYMPHOMA DURING MAINTENANCE THERAPY WITH THE ANTI-CD20 ANTIBODY RITUXIMAB

M. Witzens-Harig,[1] M. Reiz,1 C. Heiss,[2] A. Benner,[2] M. Hensel,[1] K. Neben,[1] P. Dreger,[1] A. Krämer,[1] A.D. Ho[1]

[1]University of Heidelberg Hospital, HEIDELBERG; [2]German Cancer Research Center, HEIDELBERG, Germany

The introduction of rituximab into the treatment of malignant lymphomas of the B-cell lineage has had a major impact on the management of these diseases. In diffuse large B-cell lymphomas (DLBCLs) and follicular lymphomas (FLs) several multicenter prospective randomized trials consistently demonstrated an improved outcome when rituximab was added to chemotherapy. In addition, prolonged exposure to rituximab as maintenance therapy has been benefical in patients with FL and mantle cell lymphoma (MCL). For patients, the effect of any prolonged antitumor therapy on the quality of life (QoL) is a very important question. However, so far the question whether rituximab maintenance therapy may impair QoL in patients with Non-Hodgkins-lymphoma remains unanswered. To investigate this subject , we have performed a prospective randomized trial of rituximab maintenance therapy (8 cycles rituximab 375 mg/m^2 every 3 months) versus observation in patients with CD20$^+$ B-cell Non-Hodgkins-Lymphoma in our institution. Between July 2002 and December 2005, 106 patients (pts) were included into the trial. QoL was assessed with the standardized questionnaires EORTC-QLQ-C30 and EuroQol-5D. After statistical analysis with the Wilcoxon signed-rank test, we found no significant differences of the QoL between the rituximab treatment group and the observation group. We conclude that rituximab maintenance therapy is safe and does not impair quality of life in this patient population.

0298

RITUXIMAB MAINTENENANCE THERAPY IN CD20+ B-CELL NON-HODGKIN-LYMPHOMA FIRST RESULTS OF A MULTICENTER PROSPECTIVE RANDOMISED PHASE II STUDY

M. Witzens-Harig,[1] M. Hensel,[1] J. Schmier,[1] K. Neben,[1] A. Benner,[2] P. Dreger,[1] C. Kuhn,[3] I. Schmidt-Wolf,[4] A. Krämer,[1] A.D. Ho[1]

[1]University of Heidelberg Hospital, HEIDELBERG; [2]German Cancer Research Center, HEIDELBERG; [3]University of Heidelberg, Mannheim, MANNHEIM; [4]University of Bonn, BONN, Germany

Clinical and pharmacokinetic data suggest that the effect of rituximab could be improved by prolonged exposure to the drug. To test for this hypothesis we performed a prospective randomized trial of rituximab maintenance therapy in patients with CD20$^+$ B-cell Non-Hodgkins-Lymphoma. After completion of standard treatment patients were randomized to either observation or maintenance therapy with rituximab (375 mg/m^2) every 3 months for 2 years. Patients after first line therapy as well as relapse patients were included in the study. Patients with aggressive lymphoma were enrolled if they had achieved a complete response (CR) after initial treatment. Patients with aggressive lymphoma with residual tumor mass were examined with positrone emission tomography (PET) and qualified for randomization if PET showed no signs of tumor activity. Patients with indolent lymphoma qualified for the study if at least a partial response (PR) was achieved. After recruitment of 172 patients a planed interim analysis was performed. Complete data sets of 162 patients (pts) with CD20$^+$ B-cell Non-Hodgkins-Lymphoma were evaluable for analysis. Histological subtypes included diffuse large cell lymphoma (69 pts), follicular lymphoma (41 pts), mantle cell lymphoma (18 pts), primary mediastinal lymphoma (15 pts), marginal zone lymphoma (9 pts), Burkitt's lymphoma (3 pts), immunocytoma (2 pts), primary intestinal lymphoma (1 pt), hairy cell leukemia (1 pt), chronic lymphocytic leukemia (1 pt) and unclassified B-cell lymphoma (2 pts). The interim analysis showed that event free survival was significantly prolonged in the rituximab maintenance group compared to the observation group (p<0.05). However, no difference in overall survival between the two groups was observed so far. Two patients in the treatment group developed WHO grade III adverse events (1 leucopenia, 1 infection). Both pts recovered shortly after appropriate treatment. We conclude that rituximab maintenance therapy is feasable, safe and well tolerated in patients with CD20+ B-cell Non-Hodgkins-Lymphoma and may prolong event free survival in this patient population.

0299

PROGRESS IN TREATMENT RESULTS OF CHILDHOOD B-CELL LYMPHOMAS IN THE 15 YEARS EXPERIENCE OF POLISH PEDIATRIC LEUKEMIA/LYMPHOMA STUDY GROUP

E. Sowinska,[1] B. Kazanowska,[1] G. Wrobel,[1] D. Pazdzior,[1] M. Jelen,[1] J. Maldyk,[2] H. Bubala,[3] A. Dluzniewska,[4] L. Kapuscinska,[5] A. Koltan,[6] S. Popadiuk,[5] K. Roslan,[7] D.B. Sopylo,[2] J. Stefaniak,[8] K. Stefanska[9]

[1]Wroclaw Medical University, WROCLAW; [2]Warsaw Medical University, WARSAW; [3]Zabrze Medical University, ZABRZE; [4]Cracow Medical University, CRACOW; [5]Gdansk Medical University, GDANSK; [6]Bydgoszcz Medical University, BYDGOSZCZ; [7]Bialystok Medical University, BIALYSTOK; [8]Lublin Medical University, LUBLIN; [9]Poznan Medical University, POZNAN, Poland

Objectives. The efficacy of the LMB-89 protocol for children with B-NHL has been investigated. The patients (pts) were treated in 10 oncohematological centers of PPLLSG between 1992 and 2007. We have registered a total number of 149 children with B-NHL: 105 (70%) of them with Burkitt and 44 (30%) with non - Burkitt histopathological types (17 - Burkitt-like, 6 - Large B-cell, 4 -immunoblastic, 6 - centroblastic, 11 - others). Primary sites were: abdomen (50%), peripheral lymph nodes (17%), Waldeyer ring (13%), head - neck (7%),bones (4%), thorax (3%), other sites (6%). *Methods.* The diagnosis was based on histomorphological investigation and supplemented with immunophenotyping. The S. Murphy staging system was used for prognostic stratification. Treatment intensity was adapted to 3 risk groups (A,B,C), according to LMB-89 protocol. *Results.* In 1992 62% of B-NHL pts presented on admission I-III and 38% IV stages. In 2007 80% of them presented I-III (more than in 1992) and 20% IV (less than in 1992) stages. In 1992 72% pts were classified to A+B and 28% to C risk groups, whereas in 2007 87% to A+B and only 13% to C risk groups. Pts number, achieved complete remission (CR), increased from 87% (1992) to 91% (2007). Number of non-responders, early deaths, relapses and deaths in RC decreased from 11% (1992) to 9% (2007), from 13% to 5%, from 21% to 8% and from 13% to 5%, respectively. Probability of EFS for all B-NHL was 0,69 (1992) and 0,86 (2007). EFS of III and IV stages were: 0,80 and 0,56 (1992); 0,87 and 0,71 (2007). EFS for Burkitt and non-Burkitt types increased from 0.82 and 0,62 (1992) to 0.83 and 0,87 (2007), respectively. EFS of B and C risk groups were: 0,79 and 0,50 (1992); 0,89 and 0,54 (2007). *Conclusions.* The treatment outcome of children with B-NHL, estimated in 2007, has improved in comparison to previously reported observations in 1992. Higher EFS and overall survival of B-NHL in 2007 compared to this in 1992, could be achieved thanks to quick diagnosis after first tumor clinical symptoms and an improvement of intensive supportive care (adequate blood product substitutions, regular infection specific prophylaxis, amelioration of MTX therapy monitoring) for therapy toxicity elimination. The worst results are still observed in children with bone marrow involvement and in those with large tumor burden at diagnosis.

RADIOIMMUNOTHERAPY IN RELAPSED OR REFRACTORY B-CELL NON-HODGKIN'S LYMPHOMA WITH I-131-LABELED CHIMERIC ANTI CD20 C2B8 (I-131 RITUXIMAB)

H.J. Kang,[1] Y.H. Park,[1] S. Kim,[1] G.J. Cheon,[1] C.W. Choi,[1] S.M. Lim,[1] S.S. Lee,[1] I.I. Na[1] B.Y. Ryoo,[1] S.H. Yang,[1] W.S. Kim,[2] K.H. Kim,[2] S.M. Bang,[3] Y.J. Yuh,[4] S.H. Nam[5]

[1]Korea Cancer Center Hospital, SEOUL; [2]Samsung Medical Center, SEOUL; [3]Gil Medical Center, SEOUL; [4]Sanggye Paik Hospital, SEOUL; [5]Seoul Veterans Hospital, SEOUL, South-Korea

Background and Aims. Recently, the native chimeric human-mouse anti CD20 antibody IDEC-C2B8 (Rituximab) has been widely applied in NHL. This phase II study was performed to evaluate of efficacy and safety of radioimmunotherapy (RIT) with I-131 rituximab in relapsed or refractory B-cell non-Hodgkin's lymphoma (NHL). *Methods.* Inclusion criteria were as follows: B-cell NHL with relapsed or refractory to primary standard therapy, measurable disease, adequate hematologic, renal, and hepatic function, informed consent. The rituximab (Mabthera, Roche) was radiolabeled with iodine-131 (I-131) using a modified chloaramine T method with high radiochemical purity (95%) and preservation of immunoreactivity. All patients received loading doses of unlabeled rituximab (median, 70 mg; range, 20-70 mg) immediately prior to administration of therapeutic dose (median 7.3 GBq; range, 3.70-8.51 GBq), and then underwent gamma camera scan. *Results.* 20 patients were enrolled (9 low-grade B-cell NHL, 11 DLBCL, median age 63 years). Patients had received a median of three prior chemotherapy regimens

(range, 1-6) and 11 treatment cycles (range, 6-22). All patients were evaluated for response and toxicities. The total objective response rate was 35.0% (1 CR, 6 PRs), and 55.6% in low-grade lymphoma, 18.2% in DLBCL. There was a trend of higher response in low-grade lymphoma than DLBCL, but this difference was statistically insignificant (two sided Fisher's exact test, p=0.16). Adverse events were primarily hematologic toxicities; the incidence of grade 4 neutropenia and thrombocytopenia was each 25.0%. The treatment-related mortality was observed in one patient, who had been previously treated with high-dose chemotherapy plus TBI with autologous stem cell transplantation. *Summary and conclusions.* RIT with I-131 rituximab seems to be effective and tolerable in refractory low-grade B-cell NHL, although modest activity in refractory DLBCL. Further studies to define the efficacy of I-131 rituximab in DLBCL are warranted, such as consolidation RIT followed by standard chemotherapy or high-dose RIT with autologous stem cell transplantation.

0301

RITUXIMAB AND CHLORAMBUCIL AS FIRST LINE TREATMENT OF LOW-GRADE OCULAR ADNEXAL LYMPHOMAS

L. Nassi,[1] L. Rigacci,[1] M. Puccioni,[1] E. Polito,[2] S. Mappa,[1] S. Dal Pozzo,[1] R. Alterini,[1] V. Carrai,[1] B. Puccini,[1] A. Bosi[1]

[1]Careggi Hospital, FL; [2]Policlinico Le Scotte, SIENA, Italy

Background. Ocular adnexal lymphomas (OALs) represents 5-15% of primary extranodal lymphomas, and are constituted largely by extranodal marginal zone lymphomas (EMZL). Radiotherapy is associated to high rates of local disease control, but also to the risk of relapse and immediate and delayed complications, such as xerophtalmy, corneal ulcerations, cataract and retinal damage. Surgery is a feasible option, but not always satisfactory in terms of disease control. Single-agent chemotherapy with alkylating agents is used for the treatment of low-grade lymphomas, including OALs. Rituximab, a chimeric anti-CD20 monoclonal antibody, is effective in EMZL and in OALs. *Aims.* We investigated the efficacy and the safety of a combination of chlorambucil and rituximab as first line treatment in patients with OALs. *Methods.* Patients with histologically proven low-grade OALs were enrolled in this study. Staging included CT-scan of the orbit, neck, chest and abdomen, MR of the orbit, and bone marrow biopsy, and was done according to Ann Arbor classification. Treatment consisted of chlorambucil (0,1 mg/Kg/die for 45 days, then on days 1 to 15 monthly for 4 months) and rituximab (375 mg/sqm weekly for 4 doses, then monthly for 4 infusions). Toxicities were reported according to WHO criteria. At the end of treatment patients were restaged clinically and with a MR of the orbit. *Results.* Since November 2003 to December 2005 nine consecutive histologically proven low-grade OALs (eight EMZL, a grade I follicular lymphoma) have been treated according to this protocol. The median interval between onset of the first symptoms and diagnosis was 13 months (range, 4 months - 3 years). Six patients were female (66%). Median age at diagnosis was 78 years (range, 56-86 years). Disease was localized in the conjunctiva in four patients, in the lacrimal glands in 3 patients and in other orbital sites in the last two patients. Eight patients had a stage I disease, one stage IV, and no patient presented B-symptoms. LDH was within normal range in all patients, ECOG-PS was 0 in all patients. All patients completed the treatment without delay; there was no grade III-IV toxicities nor hospitalizations. Five patients had grade 1-2 rituximab infusion-related reactions usually during the first infusion. We did not observe infectious complications. Haematological toxicity was mild. At the end of treatment local symptoms were not present: eight patients (89%) were in CR, and the remaining patient (11%) obtained a PR. After a median follow-up of 22 months (range, 10-38 months) all patients are alive and we did not observe disease progressions; the median EFS was 19 months (range, 8-36 months). All patients underwent periodic ophthalmologic follow-up visits: we did not report ocular toxicities, and all patients conserved a normal visual function, including acuity. *Conclusions.* The combination of rituximab and chlorambucil proved to be a safe, feasible and effective therapy for primary OALs. However, a longer follow-up would be necessary to determine the long-term efficacy of this treatment.

0302

PHASE I STUDY OF SMILE CHEMOTHERAPY FOR ADVANCED-STAGE OR RELAPSED/REFRACTORY EXTRANODAL NK/T-CELL LYMPHOMA/LEUKEMIA

Y.L. Kwong,[1] M. Yamaguchi,[2] R. Suzuki,[3] W.S. Kim,[4] Y. Hasegawa,[5] K. Izutsu,[6] J. Suzumiya,[7] T. Okamura,[8] S. Nakamura,[3] K. Kawa,[9] K. Oshimi[10]

[1]University of Hong Kong, HONG KONG, China; [2]Mie University, TSU, Japan; [3]Nagoya University, NAGOYA, Japan; [4]Samsung Medical Center, SEOUL, South-Korea; [5]Tsukuba University Hospital, TSUKUBA, Japan; [6]University of Tokyo, TOKYO, Japan; [7]Fukuoka University, FUKUOKA, Japan; [8]University of the Ryukyus, NISHIHARA, Japan; [9]Osaka Medical Center, OSAKA, Japan; [10]Juntendo University, TOKYO, Japan;

Background. Extranodal NK/T-cell lymphoma, nasal type, and aggressive NK-cell leukemia are rare, and their standard therapy has not been established. They are Epstein-Barr virus (EBV)-associated lymphoid malignancies, and lymphoma/leukemia cells express P-glycoprotein leading to multi-drug resistance (MDR) of the disease. Almost all patients with stage IV, relapsed, and refractory diseases die within 1 year. *Aims.* To establish a more effective induction therapy for these neoplasms with untreated stage IV or relapsed/refractory state, we conducted a dose escalating feasibility study of a newly designed chemotherapeutic regimen, SMILE [Steroid=dexamethasone (DMS) 40 mg/body d2-4 IV, Methotrexate (MTX) 2 g/m^2 d1 6hr IV, Ifosfamide (IFM) 1.5 g/m^2 d2-4 IV, L-asparaginase (L-asp) 6000U/m^2 d8,10,12,14,16,18,20 IV, and Etoposide (ETP) 100 mg/m^2 d2-4 IV; every 28 days]. SMILE comprised MDR-unrelated agents and ETP that shows both *in vitro* and *in vivo* efficacy for EBV-associated lymphoproliferative disorders. *Methods.* Primary endpoint is MTD (maximum tolerated dose), and secondary endpoints are the overall response rate (ORR) and the complete response (CR) rate. Pts with newly diagnosed stage IV diseases (including aggressive NK-cell leukemia), first relapsed/recurrent diseases after CR/PR, refractory (either NC or PD) diseases with first-line chemotherapy, 15-69 years of age, and PS 0-2 were eligible. A standard 3+3 design was used to evaluate dose-limiting toxicities (DLTs). The doses of DMS, IFM, and L-asp were fixed. Four dose levels of MTX/ETP were planned to be evaluated. *Results.* At Level 1, 6 pts with extranodal NK/T-cell lymphoma, nasal type were enrolled, and showed the following features; age 28-69 yrs (median 48), M:F=5:1, newly-diagnosed stage IV: 3, 1st relapse: 2, primary refractory: 1, BM involvement: 2, elevated serum LDH: 4, and PS0: 2 , PS1: 3, PS2: 1. Among the first 3 pts, 1 pt died from sepsis with grade 4 neutropenia due to disease and delayed initiation of G-CSF administration. 1 pt developed grade 3 infection and hypofibrinogenemia. The remaining 1 pt did not develop DLT other than transient grade 3 hyponatremia, and obtained a CR. We made a protocol amendment to initiate G-CSF administration from day 6, and proposed to register additional 3 pts in Level 1. It was approved by the Data and Safety Monitoring Committee. Additional 3 pts developed DLTs (grade 3 APTT 1, grade 3 gamma-GTP 1, grade 3 hyponatremia 2, and grade 3 hyperglycemia 1) that were all manageable, and pts recovered from the toxicities rapidly. The incidence of grade 4 neutropenia was comparable, but grade 3/4 leukopenia/ anemia/ thrombocytopenia were less frequent than the first 3 pts. Of all 6 enrolled pts, 3 achieved CR, 1 PR, 1 NR, and 1 NE.%ORR was 67%, and%CR was 50%. *Summary and Conclusions.* Our results suggest that dose level 1 of SMILE is feasible and promising for advanced, refractory or relapsed NK/T-cell lymphoma. To determine the efficacy and feasibility of SMILE in a large number of cases, we will start the subsequent phase II study of SMILE in spring 2007.

0303

RITUXIMAB MAINTENANCE THERAPY FOR PATIENTS WITH FOLLICULAR LYMPHOMA. A COST-EFFECTIVE STRATEGY?

C. Francisco J.,[1] E. Conde,[2] P. Giraldo,[3] J. Gomez Codina,[4] M. Provencio,[5] E. Rios,[6] A. Rueda,[7] C. Rubio-Terres,[8] C. Varela[9]

[1]Hospital Universitario Puerta del Mar, CADIZ; [2]Hospital U. Marqués de Valdecilla, SANTANDER; [3]Hospital Universitario Miguel Servet, ZARAGOZA; [4]Hospital Universitario La Fe, VALENCIA; [5]Hospital Universitario Puerta de Hierro, MADRID; [6]Hospital Virgen del Rocío, SEVILLA; [7]Hospital Virgen de la Victoria, MALAGA; [8]HEALTH VALUE, MADRID; [9]Roche Farma, MADRID, Spain;

Background. Rituximab, a chimeric anti-CD20 monoclonal antibody, has shown to significantly improve overall survival (OS) (p=0.011) and progression free survival (PFS) (p<0.001) when compared to observation alone (OA) in patients with relapsed or refractory follicular lymphoma (FL) who attain a response with either cyclophosphamide, doxorubicin, vincristine,

and prednisone (CHOP) alone, or Rituximab + CHOP (EORTC 20981 study). *Aims.* To determine, from a Spanish perspective, if the maintenance treatment with Rituximab is cost-effective alternative compared to the current clinical practice of OA for the described population. *Methods.* Incremental cost-effectiveness of Rituximab maintenance therapy (375 mg/m^2 every 3 months until progression or for 2 years) versus OA was assessed through a deterministic, three health states (progression-free, progression and death) transition model. Base case assumptions for the model included: clinical evidence based on EORTC 20981 trial (extrapolation of PFS and OS data using a Weibull distribution), Rituximab maintenance benefit to last 5 years, 10 years time horizon, 3,5% discount rate on costs and benefits, and Spanish National Health Service perspective (direct costs only). Resource use (study drug, adverse events, treatments at relapse, surveillance/monitoring) was estimated from a Spanish expert panel and EORTC 20981 trial. Unit costs were obtained from local databases (€ May 2,006). Health states utility values were derived from an ad hoc study. Sensitivity analyses were performed for all mentioned variables. *Results.* For the base case (Table 1), more quality-adjusted life years (QALY), life-years (LY) and progression-free survival years per patient on maintenance therapy were obtained versus OA (incremental values of 0.85, 0.94 and 1.46, respectively). Total cost per patient was higher with Rituximab than with OA (+8,026 €). Incremental cost per QALY gained was 9,358 €, with a cost per LY gained of 8,493 € and a cost per PFS year gained of 5,485 €. Sensitivity analyses demonstrate results remains cost-effective for all variable tested. *Conclusions.* Rituximab maintenance therapy, when compared to observation alone, improves overall survival and progression free survival, and is a cost effective strategy in patients with relapsed or refractory follicular lymphoma who attain a response with further therapy.

Table 1. Results for base case (€ May 2, 2006)

Input	Rituximab	Observation	Difference
Cost per patient(€)	22,458.20	14,432.40	8,026.06
Quality adjusted life years (QALY)	4,1133	3.2557	0.8576
Cost per QALY(€)	**9,358.49**	-	-
Lyfe Years (LY)	5.6891	4.7441	0.9450
Cost per LY gained (€)	8,493.18	-	-
Progression free survival (PFS) years	3.1952	1.7320	1.4632
Cost per PFS year gained (€)	5,485.39	-	-

ACTIVITY OF SINGLE-AGENT FLUDARABINE IN GASTRIC MALT LYMPHOMA: IMPACT OF T(11;18)(Q21;Q21) IN MOLECULAR RESPONSE RATE

A. Salar,[1] B. Bellosillo,[2] A. Seoane,[3] A. Ferrer,[2] C. Pedro,[4] A. Alvarez-Larrán,[4] S. Serrano,[2] C. Besse[s4]

[1]Hospital del Mar, BARCELONA; [2]Pathology Department, BARCELONA; [3]Endoscopy Department, BARCELONA; [4]Clinical Hematology Department, BARCELONA, Spain

Background. Fludarabine (F) is an active agent for the treatment of indolent lymphoma. However, its clinical activity in the treatment of gastric MALT lymphoma has not been studied in depth. Moreover, there is scarce information regarding molecular response (MR) in gastric MALT lymphoma treated by purine analogs and the prognostic value of t(11;18) in this setting. *Aims.* The current study was undertaken to determine the activity of single-agent fludarabine in gastric MALT lymphoma and to analyze if these patients achieve molecular remission after this treatment. *Methods.* Treatment consisted of fludarabine (25 mg/m^2 IV) given on days 1-5, every 4 weeks, for 6 cycles; after the first cycle, oral fludarabine was allowed to be given orally at 40 mg/m^2 with the same schedule. Molecular response (MR) was assessed by RT-PCR analysis of t(11;18) or by PCR assays for analysis of IgH gene rearrangements analyzing FR1, FR2 and FR3 in endoscopic biopsies. *Results.* Eight consecutive patients were entered on this trial. All but one patient were chemonaïve. Median follow-up was 26 months (range 12-46 mo); median age was 60 years (range: 45-77). Three pts were in stage I, 2 stage II-1 and 3 stage IV according to Lugano system. Four out of 5 (80%) pts achieved a CR after three cycles and all eight cases achieved a CR after six cycles, for an overall response rate of 100%. No patient has shown clinical or endoscopic relapse at last follow-up. Hematological toxicity occurred in 75% of pts, mainly mild neutropenia and generally after the third cycle. Three cases received G-CSF (after the 2nd, 3rd and 6th cycle) and three patients required dose modification or delay (3-7 days) in the delivery of the following cycle. No cases of autoimmune hemolytic anemia developed. No blood transfusions were required. Only one patient had to be admitted because of non-neutropenic fever that resolved with broad-spectrum antibiotics. Four out of 8 pts (50%) achieved MR during the study-period. Four out of 5 (80%) pts without t(11;18) achieved MR (Figure 1). However, none case carrying t(11;18) achieved MR. Sequencing of PCR products will be presented. *Conclusions.* Monotherapy with intravenous or oral fludarabine is safe in gastric MALT lymphoma and achieves a high response rate (100%). Only pts without t(11;18) achieved MR and all those pts carrying t(11;18) had evidence of clonal residual disease by PCR.

RITUXIMABS IMPACT ON LARGE B CELL LYMPHOMA TREATMENT (ANALYSIS OF 116 PATIENTS OF A LYMPHOMA UNIT)

J. Alonso,[1] A. Canovas,[1] G. Barreiro[2]

[1]Hospital Cruces. SVS. UPV Vizcaya, BILBAO; [2]Hospital de Cruces. UPV, BILBAO, Spain

Background. A possible selection bias occurring in multicentric trials could cause their outcomes not to be appliable to the real, nonselected population of patients or to different environments. *Aims.* To validate the results of chemotherapy added Rituximab in a population of non selected large B cell lymphoma patients. *Methods.* We perform a comparative analysis of response, time to first treatment failure and survival among all large B cell lymphoma patients who received CHOP or alike chemotherapy in our Lymphoma Unit since January 1997 until March 2002 (Historical Cohort:HC) and the same outcomes in patients treated with Rituximab added to similar schedules of chemotherapy since April 2002 until January 2007 (Rituximab Cohort: RC). Suspension due to intolerance, progression, relapse or death was considered *primary treatment failure*. *Complete remission* was defined by disappearance of disease or long term observation and/or PET validated inactive residual mass. Different outcomes were defined as *non response*. Demographic and prognostic variables, primary chemotherapy response, time to primary treatment failure and overall survival were analysed. Statistical *Methods.* Student's T, chi*2, Kaplan-Meier's survival tables and log-rank test. *Results.* 116 patients were included: 57 in the first period and 59 in the second one. No significant differences in the distribution of sex (male/female ratio: 1,19 in HC and 0,69 in RC) or age (58 years mean,15-84 years range in HC; 63 years mean, 17-88 years range in RC) were observed between the two cohorts. The clinical stage (1-2 versus 3-4: 23/34 in HC and 27/32 in RC) and IPI score were also similar (0-2/3-5:26/31 in HC and 27/32 in RC). A non significant higher number of patients with AIDS (5 versus 2) and mediastinal lymphoma (9 versus 1) were detected in HC. A lower, non significant number of grade three follicular lymphoma (2 versus 7), was found in HC. The extranodal lymphoma's rate was balanced (ten patients each). High dose chemotherapy and stem-cell autotransplantation was administered as consolidaton therapy in ten patients of HC and one of RC. A significantly higher proportion of patients achieved complete remission in RC (93 versus 79%; p<0,05). The probability of survival without treatment failure was significantly higher in RC (75 versus 55% at three years; p<0,01). The median overall survival wasn't achieved by neither of the groups, but the probability of survival was higher in RC (89% versus 59% at three years; p<0,005). *Conclusions.* Our results confirm the superiority of standard chemotherapy added Rituximab versus classical chemotherapy schedules, regarding proportion of response, time to treatment failure and overall survival. Further observation is required to determine whether this greater or equal to 20% difference in time to treatment failure and overall survival is sustained.

0306

RISK-ADAPTED IMMUNOCHEMOTHERAPY OVERCOMES THE NEGATIVE PROGNOSTIC IMPACT FCGRIIIA OF THE RECEPTOR GENOTYPE IN PATIENTS WITH FOLLICULAR LYMPHOMA

V. Prochazka, S. Rozmanova, M. Jarosova, T. Papajik, K. Indrak

Teaching Hospital, OLOMOUC, Czech Republic

Background. Antibody (rituximab) dependent cellular cytotoxicity (ADCC) is a key mechanism in killing CD20+ lymphoma cells. The Fc portion of the rituximab molecule is bound by Fc receptors on the surface of cytotoxic lymphocytes (NK cells). FCGR3A-158 V/F gene polymorphism leads to expression of 3 variants of the FcγIIIa receptor (FcγRIIIa) with different receptor affinity. The published studies with FL patients treated with rituximab monotherapy demonstrated better outcomes of patients with the V/V or F/V genotypes over the F/F genotype. *Aims.* To assess whether the FcγIIIa receptor genotype influences the treatment response quality (molecular remission) in newly diagnosed patients with FL treated with risk-adapted immunochemotherapy. *Methods.* We studied 34 patients with newly diagnosed FL (grades I-IIIa) who had detectable bcl-2/IgH (using standard or long-distance PCR) rearrangement in bone marrow and/or peripheral blood. The median age was 55 years (31-84), 31 out of 34 patients had advanced (III/IV) clinical stages. The FLIPI scores were as follows: low 4/34, intermediate 13/34 and high 17/34. The first-line treatment was stratified according to the generally used risk factors (FLIPI, GELF, β-2-m level, bulk disease). Patients under 60 (65) years of age with high-risk disease (FLIPI equal or more than 3, or additional risk factors) were indicated to autologous stem cell transplantation (ASCT). Whereas 16 patients underwent ASCT, 18 patients were treated conventionally (R-CHOP- or R-fludarabine-based regimens). The treatment response was classified according to the standard Cheson criteria (1999). Patients who achieved CR/CRu plus PCR bcl-2/IgH negativity were classified as CRm (molecular CR). Genotyping of the FCGR3A-158 V/F gene was performed using the PCR followed by allele-specific restriction enzyme digestion. *Results.* Complete or unconfirmed complete response with Bcl-2/IgH negativity (molecular remission) was achieved in 83.5% of patients, 1 patient achieved CR, 4 patients had partial remission and one patient stable disease. The frequencies of FcγRIIIa 158 V/V, V/F and F/F were 8.2%, 47.3% and 44.7%, respectively. Homozygous FcγRIIIa 158 F/F carriers had higher FLIPI index (chi square p=0.05), compared to V/F+V/V carriers. The treatment modalities (conventional versus ASCT) had the same distribution in V/V+V/F vs F/F patients (chi square p=0.38). The distribution of CRm rate was not significantly different in the subgroups of V/V+V/F vs F/F patients (chi-square, p=0.92). *Summary.* We found no difference in the quality of treatment response (molecular remission) after first-line immunochemotherapy among the FcγRIIIa subgroups. Risk-adapted intensive concomitant immunochemotherapy overcomes the negative prognostic impact of the FcγRIIIa genotype. The following question is whether patients with the F/F genotype will have the same benefit from rituximab maintenance treatment.

90Y-IBRITUMOMAB TREATMENT FOR RELAPSED AND/OR REFRACTORY B CELL TYPE NON-HODGKIN`S LYMPHOMA. MULTIINSTITUTIONAL ARGENTINIAN STUDY

R. Cacchione, J. Dupont, J. Milone, J. Bordone, L. Riera, M. Ardaiz, M. Castro-Rios, M. Iabstrebner, G. Pombo, A. Basso, G. Avila, S. Rodríguez, N. Tartas, J. Plana, G. Garay, D. Riveros, A. Carrasco, F. Bezares

CEMIC, BUENOS AIRES, Argentina

Abstract. The radionucleid conjugate with monoclonal antibodies (antiCD20/90Y-ibritumomab tiuxetan) have been approved for the treatment of relapsed, refractory and transformed (high grade) follicular lymphomas. Between September 2005 and February 2007, 27 patients with refractory/relapsed lymphoma were enrolled. Median age was 58 yrs old (45-76). Fourteen were women and 13 were men. Twenty-two were follicular and 5 were mantle cell lymphoma. Ten patients had bulky disease, 5 had bone marrow involvement and 16 had stage III-IV disease. Time from diagnosis was 0-3 years in 5 pts, 3-6 in 8 pts and over 6 years in 13 pts.. Eight pts had received 1-2 previous treatments, and 18 pts had received 3-5 previous treatments including 5 pts with autologous bone marrow transplantation. All had previously received anti-CD20 monoclonal antibody therapy. Two pts. received previous radiotherapy. 90Y-Ibritumomab (Zevamab TM Schering Argentina) was administered at 0,3 or 0,4 mCi, based on initial platelet count. Seven days before, and the same day of the inmunoconjugate administration, pts received rituximab 250 mg/m^2. Fifteen pts responded, (11 CR, 4 PR) and 10/11 CRs continued in remission between 3 and 15 months of follow-up. Eleven pts required filgrastim administration for neutropenia, 8 pts required platelet transfusions, 6 pts had neutropenia plus fever, 4 pts required red blood cells transfusion, and only 5 pts had to be admitted for complicated pancytopenia. One patient died 40 days after treatment with hypoplastic bone marrow complicated with septicemia. Five pts with previous bone marrow transplantation, required filgrastim, transfusions and 2/3 had febrile neutropenia. Our experience shows 41% CR. Even heavily treated pts, that had previous bone marrow transplantation were able to receive the radioimmunoconjugate, although they required extra support. Our experience favours the use of 90Y-Ibritumomab tiuxetan in relapsed and refractory lymphomas even if they had received previous autologous bone marrow transplantation.

Kliniken, IDAR-OBERSTEIN; [8]Carl-Thieme-Klinikum, COTTBUS; [9]Asklepios Klinik St. Georg, HAMBURG; [10]Krankenhaus Nordwest, FRANKFURT; [11]Uniklinkik Gießen-Marburg, GIEßEN

Background/Aims. HDT is an established treatment for relapsed aggressive B-NHL (aNHL) and its use in indolent lymphoma (iNHL) is supported by several trials. In a phase I study we could demonstrate the safety/feasibility of the combination of Rituximab with Dexa-BEAM followed by HDT with R-BEAM or R-TBI/CY for treatment of relapsed lymphoma. Here we present the results of a prospective multicentre phase II study testing the efficacy of this treatment. *Methods.* After informed consent, patients aged 18-65, ECOG 0-2 with relapsed/refractory B-NHL after at least 3 cycles of anthracycline-containing chemotherapy were eligible. Rituximab (R) pre-treatment, but no prior HDT was allowed. Treatment consisted of 2 cycles of R-Dexa-BEAM (dexamethasone 8 mg *3, day 1-10; BCNU 60 mg/m^2, day 2; etoposide 75 mg/m^2, day 4-7; cytarabinoside 200 2 mg/m^2, day 4-7; melphalan 20 mg/m^2, day 3; Rituximab 375 mg/m^2, day 1). Stem cell mobilization was performed after the second cycle. HDT-regimens were BEAM (BCNU: 300 mg/m^2, day -7, etoposide 100 mg/m^2 day -6 - -3, cytarabinoside 400 mg/m^2 in two doses, day -6 - -3; melphalan 140 mg/m^2 day -2) or TBI/CY (total body irradiation 12Gy, day -6 - -4; cyclophosphamide 60 mg/kgbw, day -3 - -2;) in combination with 2 doses of Rituximab 375 mg/m^2, day -7/-2. *Results.* After ethics approval the study started 2001 and finished 2005. Overall, 103/107 patients are evaluable for analysis. For 67 patients with aNHL (DLCL 55, MCL 7, FL °3: 5) median age was 54 years (21-65) and median number of pre-treatments was 1(1-2). A low/low intermediate IPI was present in 74% and ECOG was 0 or 1 in 90% of aNHL patients. The corresponding figures for 36 iNHL patients (FL °1-2: 29, MZL 6, IC 1) are: median age 55 (22-64), pre-treatments 1 (1-3), low/low intermediate IPI and ECOG < 2 in 86 and 94%. Premature discontinuation: 28 patients did not proceed to HDT: treatment related mortality (sepsis, cerebral hemorrhage) (3, aNHL), progression (12, aNHL), mobilization failure (10, 8 aNHL, 2 iNHL), refusal (2, iNHL) or secondary cancer (1, iNHL). Therefore, 66% of patients with aNHL and 86% with iNHL underwent HDT. HDT (R-BEAM in 84% of aggressive and 75% of indolent NHL) could be performed with manageable toxicity, 1 patient died due to MOF. Recovery occurred timely (ANC > 500 median 11 days (8-27). Restaging at day 60 revealed an ORR of 80% (59% CR, 21% PR) in patients with aNHL and 90% (81, 10%) with iNHL. With a median follow up of 2.2 years post HDT, PFS and OS for patients with aNHL are 63 and 83%. Corresponding figures for iNHL are: 63 and 100%. There were no statistical differences between patients with or without R-pretherapy. *Conclusions.* The inclusion of Rituximab in salvage therapy and HDT resulted in high response rates and sustained remissions. R-containing pre-therapy was not associated with inferior outcome, underlining the continuous importance of HDT for relapsed/refractory lymphoma, which seems to be further improved with the inclusion of R. With no comparative studies available R-DexaBEAM followed by HDT can be considered as an established relapse therapy for NHL.

Novel therapeutics and targeted therapies I

FUNCTIONAL CHARACTERISTICS AND GENE EXPRESSION PROFILES OF PRIMARY ACUTE MYELOID LEUKAEMIA CELLS IDENTIFY PATIENT SUBGROUPS THAT DIFFER IN THE SUSCEPTIBILITY TO HISTONE DEACETYLASE INHIBITORS

C. Stapnes,[1] A. Ryningen,[1] K. Hatfield,[1] A.M. Oyan,[2] G.E. Eide,[3] K.H. Kalland,[2] B.T. Gjertsen,[1] O. Bruserud[1]

[1]Institute of Medicine, BERGEN; [2]The Gade Institute, BERGEN; 3Centre for Clinical Research, BERGEN, Norway

Modulation of gene expression through histone deacetylase (HDAC) inhibition is now considered a possible therapeutic strategy in several malignancies, including acute myeloid leukaemia (AML). In the present study we investigated the *in vitro* effects of various HDAC inhibitors on primary human AML cells. The relation between the biological response to HDAC inhibitors and basal gene expression profiles were assessed. AML cells were derived from 59 consecutive patients. Effects of structurally different HDAC inhibitors on cell proliferation, apoptosis induction, colony formation and CD34 cell subsets were studied. Basal gene expression of untreated cells was examined by microarray techniques. The HDAC inhibitors valproic acid, PXD101, trichostatin A and sodium butyrate were investigated. All drugs inhibited AML cell proliferation in a dose-dependent manner when tested at high concentrations. However, at lower concentrations, proliferation increased for a subset of patients. HDAC inhibitors also decreased proliferation of clonogenic and $CD34^+$ leukaemic cells and increased apoptosis. Again the inhibition was observed at high concentrations whereas enhanced proliferation and decreased apoptosis were observed for a subset of patients at lower concentrations. Based on basal expression of 100 genes it was possible to separate patients (a group of 17 FLT3-ITD+ patients with normal cytogenetics) with growth enhancement at intermediate HDAC inhibitor concentrations and those without this response into two mutually exclusive groups. Several of the genes have previously been used for classification of AML patients. E.g. high expression of Dynein light chain 1 (DLC1) and low expression of transmembrane 4 superfamily member 2 (TM4SF2) has been associated with bad prognosis; DLC1 showed high expression in patients with drug-induced growth enhancement, whereas high TM4SF2 expression was observed for our group without growth enhancement. Low expression of members of the apolipoprotein system has been associated with adverse prognosis, and our patients with growth enhancement also showed low levels of Apolipoprotein C1 (APOC1). The two groups could not be separated on the basis of expression of HDACs and histone acetyl transferases. In conclusion, functional characterisation and gene expression analyses identify AML patient subsets that differ in their response to HDAC inhibitors *in vitro*. These observations may explain why HDAC inhibitor therapy affects only a subset of AML patients.

0310

TARGETED THERAPY OF ADULT T CELL LEUKEMIA: FROM THE BENCH TO BEDSIDE

A. Bazarbachi,[1] R. Nasr,[1] M. El-Sabban,[1] H. El Hajj,[1] Y . Kfoury,[1] L. Haddad,[1] H. Hasegawa,[2] W. Hall,[2] H. De Thé,[3] O. Hermine[4]

[1]American University of Beirut, BEIRUT, Lebanon; [2]University College Dublin, DUBLIN, Ireland; [3]UMR 7151 CNRS, PARIS, France; [4]Necker Hospital, PARIS, France

Background. Adult T-cell leukemia/lymphoma (ATL) is an aggressive malignancy of mature activated T-cell caused by human T cell lymphotropic virus type I (HTLV-I). ATL carries a very bad prognosis because of intrinsic chemoresistance and severe immunosuppression. The viral transactivator protein Tax is responsible for several aspects of the malignant transformation such as proliferation, resistance to apoptosis, genetic instability, tumor dissemination, immnune escape and chemotherapy resistance. Through all of these activities, Tax acts as a powerful oncogene, and represents the most attractive viral protein for targeted therapy. Among Tax properties, activation of the NF-κB pathway plays a crucial role in the proliferation and transformation of the infected cells. Indeed, most of the activated cellular genes in HTLV-I infected cells are through this mechanism. *Results.* We have, using an *in vitro* model of ATL derived cells, identified several potential targeted therapies for ATL: 1) Arsenic trioxide (As) synergizes with interferon-α (IFN) to induce G1 arrest and apoptosis in ATL through shut-off of the NF-κB pathway and Tax degradation by the proteasome. This combination yielded promising clinical results in relapsed/refractory ATL patients. 2) Clinically achievable concentrations of bortezomib, a selective proteasome inhibitor, targeted multiple cellular pathways that resulted in dramatic inhibition of cell proliferation and apoptosis of ATL-derived cells. 3) ATL cells secrete high concentrations of functional angiogenic factors, establish functional gap junctions with endothelial cells, and extravasate through the endothelial barrier using mechanisms involved in angiogenesis. Angiogenesis inhibitors, such as anti-VEGF monoclonal antibodies (bevasizumab) or specific kinase inhibitors of the VEGF receptors (PTK-787) inhibit ATL-induced angiogenesis and impede ATL cell invasion. We are investigating the *in vivo* therapeutic potential of these targeted therapies identified in our *in vitro* studies, using as a preclinical model SCID mice injected with lymphomatous spleen cells from transgenic mice for the Tax gene of HTLV-I. Results of these ongoing studies, with respect to tumor regression, apoptosis induction and survival will be presented.

0311

HE TYROSINE KINASE INHIBITOR DASATINIB SUPPRESSES IGE-DEPENDENT ACTIVATION AND HISTAMINE RELEASE IN BASOPHILS

M. Kneidinger,[1] K. V. Gleixner,[1] A. Böhm,[1] A. Vales,[1] K. Sonneck,[1] S. Florian,[1] M. Weghofer,[1] C. Lupinek,[1] S. Vrtala,[1] R. Valenta,[1] G. Superti-Furga,[2] F.Y. Lee,[3] P. Valent[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]CeMM, Research Center f. Mol. Med., VIENNA, Austria; [3]Oncol. Drug Disc., Bristol-Myers Squibb, PRINCETON, NJ, USA

Background. Dasatinib (BMS354825) is a small molecule-type inhibitory drug that blocks several tyrosine kinases including src kinases, PDGFR, KIT, and BCR/ABL. Recently, dasatinib has been introduced as a new effective antileukemic agent in patients with imatinib-resistant chronic myeloid leukemia (CML) and acute lymphocytic leukemia. Moreover, dasatinib may act on normal lymphocytes and other physiologic cells through diverse target structures. In particular, dasatinib has recently been examined for its immunosuppressive and anti-inflammatory effects. Methods and *Results.* We here report that dasatinib at 1 μM completely blocks the anti-IgE-induced release of histamine in human blood basophils in healthy subjects. The effects of dasatinib on histamine secretion in basophils were dose-dependent (IC_{50}: 50-100 nM) and were found to be specific for IgE-dependent activation of basophils in that no inhibition was seen in C5a-activated or Ca-ionophore-exposed basophils. Moreover, dasatinib was found to block recombinant allergen-induced release of histamine from human basophils in sensitized individuals. In addition, as assessed by flow cytometry, dasatinib (1 μM) was found to inhibit the IgE-dependent upregulation of several activation-linked antigens, including aminopeptidase N (CD13), LAMP-3 (CD63), endolyn (CD164), and the basophil-related ecto-enzyme E-NPP3 (CD203c) on human basophils. The effects of dasatinib on upregulation of basophil differentiation antigens were found to be dose-dependent and were seen in normal subjects as well as in allergic individuals. *Conclusions.* Dasatinib blocks IgE-mediated activation and histamine release in human blood basophils. These anti-allergic effects of dasatinib may have clinical implications and may point to additional indications for this multifunctional drug.

0312

MLN3897, A NOVEL CCR1 INHIBITOR, IMPAIRS OSTEOCLAST FORMATION AND FUNCTION ASSOCIATED WITH DOWNREGULATION OF C-FOS

S. Vallet,[1] N. Raje,1 K. Ishitsuka,[1] T. Hideshima,[1] I. Breitktreutz,[1] T. Kiziltepe,[1] H. Yasui,[1] S. Pozzi,[1] D. Cirstea,[1] E. Ocio,[1] N. Shiraishi,[1] M. Ladetto,[2] M. Boccadoro,[2] K. Anderson[1]

[1]Dana Farber Cancer Institute, BOSTON, USA; [2]Università degli studi di Torino, TORINO, Italy

Background. Osteolytic lesions due to enhanced osteoclast (OC) activity are a hallmark of myeloma bone disease and other metastatic cancers. Chemokines play a critical role in enhancing OC formation and activity. *Aims.* Since CCR1 is one of the main chemokine receptors expressed on monocytes and OC, we here characterized the effects of MLN3897 (Millennium Pharmaceuticals), a novel specific antagonist of CCR1, on OC formation and function. *Methods.* In order to analyze the effects of MLN3897 on osteoclastogenesis, we generated OC from peripheral blood mononuclear cells of healthy donors stimulated with RANKL and M-CSF (50 ng/mL) for 3 weeks, in the absence or presence of MLN3897. Mature OC were multinucleated TRAP+ cells, and their

functional activity was confirmed by pit formation and collagen release ELISA assays. *Results.* CCR1 expression was induced early during OC formation, at one week 60% of the monocyte population expressed CCR1 by flow cytometric analysis. Macrophage inflammatory protein-1 α secretion was also stimulated, from 57 pg/mL at 24 hours to 156 pg/mL at one week. Treatment with MLN 3897 (10 nM) resulted in inhibition of both OC formation (by 40%) and function (by 70%) in a dose-dependent way ($p<0.05$). Our data demonstrate that MLN3897 induced a 60% reduction in the multinucleated cell number at one week (control 61±14 vs treated 35±9), without affecting cell viability. MLN3897 also inhibited the OC-specific protease cathepsin k activity and protein expression, suggesting an independent effect of CCR1 inhibition on OC formation and activity. We further characterized the mechanism of action of MLN3897, analyzing the expression levels of c-fos and ERK, important mediators of OC differentiation. MLN3897 (10 nM) resulted in reduced c-fos transcription levels and concomitant abrogation of ERK activation. *Conclusions.* Taken together, these data suggest that CCR1 inhibition by MLN3897 blocks ERK pathway activation and c-fos expression and results in impaired monocyte multinucleation process as well as cathepsin K expression. These studies delineate a novel mechanism of action of MLN3897 on osteoclastogenesis, and provide the therapeutic rationale for its clinical evaluation for treatment of osteolytic bone disease.

0313

LS104 IS A NOVEL SUBSTRATE INHIBITOR OF MUTANT JAK2 KINASE AND ACTS SYNERGISTICALLY WITH ATP-BINDING-SITE KINASE INHIBITORS IN JAK2 V617F POSITIVE CELLS

D.B. Lipka,[1] L. Hoffmann,[1] S. Kasper,[1] B. Markova,[1] F. Heidel,[1] F. Breitenbuecher,[1] Th. Kindler,[2] R. Levine,[2] G. Gilliland,[2] J. Elliot,[3] CH Huber,[1] Th. Fischer[1]

[1]University Hospital Mainz, MAINZ, Germany; [2]Howard Hughes Medical Institute, BOSTON, USA; [3]LymphoSign Inc., EAST TOWER MARKHAM, Canada

Background. The JAK2 V617F mutation (V617F) is a novel molecular marker in Ph-negative myeloproliferative disease (MPD). The incidence of the V617F mutation in essential thrombocythemia and in idiopathic myelofibrosis is about 50%, whereas it is more than 90% in polycythemia vera (PV). *In vitro*, the V617F mutation confers cytokine independent growth of Ba/F3 cells expressing erythropoietin receptor (EpoR) and constitutive activation of the JAK2 kinase and of the JAK-STAT pathway. In a murine bone-marrow transplant model the V617F mutation alone is sufficient to induce a PV-like phenotype. Therefore, development of JAK2 kinase inhibitors is considered as an important step towards targeted therapy of MPDs. *Aims.* In this report, we characterize the small molecule kinase inhibitor LS104 as a novel non-ATP-competitive JAK2 kinase inhibitor. *Methods.* Ba/F3 cells transfected with EpoR and the V617F mutant (Ba/F3-EpoR-VF) were treated with LS104. Proliferation and apoptosis assays as well as immunoblotting of JAK2 and of downstream signalling pathways were performed. Results obtained were compared with those observed in cells transfected with EpoR and expressing endogenous wildtype JAK2. Target validation was performed by transfection of JAK2 siRNA. In addition, we performed a JAK2 kinase assay to evaluate the effect of LS104 on JAK2 kinase activity. ATP-doses in the kinase assay were escalated and the effects on kinase activity using various kinase inhibitors were measured. Apoptosis assays were performed employing a combination of LS104 with JAK-inhibitor I, which acts via the ATP-binding site. For this purpose we chose dose levels, where each inhibitor alone induced only low to moderate levels of apoptosis. Finally, the ability of LS104 to inhibit growth of endogenous erythroid colonies (EECs) obtained from patients with V617F positive MPD was investigated. *Results.* LS104 exhibited dose-dependent and selective growth inhibition and induction of apoptosis in Ba/F3-EpoR-VF cells in comparison to control cells. By immunoblotting we found inhibition of JAK2 autophosphorylation and of downstream targets as STAT5, AKT and ERK upon treatment with LS104. Activation of these targets by JAK2 was confirmed in experiments using JAK2 siRNA. In an *in vitro* kinase assay, LS104 inhibited JAK2 kinase activity in a dose dependent manner with an IC_{50} of <5 μM, and this effect was not reversible using escalated ATP-doses. Combination treatment of Ba/F3-EpoR-VF cells using LS104 plus JAK-inhibitor I lead to significantly increased apoptosis as compared to each substance alone. Furthermore, LS104 significantly inhibited *in vitro* formation of EECs: We observed 89% inhibition at 10 μM LS104 whereas growth of CFU-GM obtained from normal controls was virtually unaffected. *Conclusions.* Taken together, our data show that LS104 specifically inhibits JAK2 kinase activity and JAK2 downstream signals in V617F positive cells. LS104 also inhibits growth and induces apoptosis in Ba/F3-EpoR-VF cells. Our data demonstrate that LS104 is a substrate kinase inhibitor and may be combined with ATP-competitive JAK2 inhibitors to enhance treatment efficacy. Growth of EECs from patients with MPD is shown to be significantly suppressed by LS104. Based on these data, a phase I/II clinical trial of LS104 for patients with JAK2 V617F positive MPDs is currently in preparation.

LENALIDOMIDE STRONGLY ENHANCES NATURAL KILLER CELL AND MONOCYTE MEDIATED ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY OF RITUXIMAB TREATED CD20+VE CANCER CELLS *IN VITRO*

L. Wu, M. Adams, P. Schafer, G. Muller, D. Stirling, J.B. Bartlett

Celgene Corporation, SUMMIT, USA

Lenalidomide is an anti-angiogenic, anti-proliferative and immunomodulatory drug that is approved for the treatment of transfusion-dependent patients with anemia due to low- or intermediate-1-risk MDS associated with a del 5q cytogenetic abnormality with or without additional cytogenetic abnormalities, and in combination with dexamethasone is for the treatment of multiple myeloma patients who have received at least one prior therapy. Encouraging early results suggest a potential for clinical efficacy in B cell non-Hodgkin's lymphoma (NHL) and chronic lymphocytic leukemia (CLL). Lenalidomide has been shown to enhance Th1-type cytokines and T cell and NK cell activation markers in patients with advanced cancers. Furthermore, lenalidomide has been shown to enhance rituximab-mediated protection in a SCID mouse lymphoma model *in vivo*. We have utilized an *in vitro* ADCC system to assess the ability of lenalidomide to directly enhance human NK cell and monocyte function in response to rituximab (chimeric anti-CD20 mAb). Pre-treatment of NK cells with lenalidomide greatly enhanced IFN-g production by NK cells in a dose-dependent manner. In a functional ADCC assay, NHL cell lines (Namalwa, Farage, Raji and Jeko-1) were pre-coated with rituximab and exposed to either NK cells or monocytes pre-treated with lenalidomide. After 4 (NK cells) or 15 (monocytes) hours in culture the viability of the tumor cells was assessed. Lenalidomide consistently and synergistically increased the killing of tumor cells in a dose-dependent manner and up to 6-fold compared to rituximab alone. Rituximab alone had only a small effect and there was no killing of cells in the absence of rituximab. The presence of either exogenous IL-2 or IL-12 was required to see enhanced killing by lenalidomide-treated NK cells but was not required for killing by lenalidomide-treated monocytes. Enhanced ADCC is most likely due to increased signaling through NK and monocyte FCg receptors. Preliminary results suggest an inhibitory effect of lenalidomide on NK cell SHIP-1 activity, although other pathways are also being investigated. In conclusion, we have shown that lenalidomide strongly enhances the ability of rituximab to induce ADCC mediated killing of CD20+ve NHL cell lines and primary CLL cells *in vitro*. This provides a measure of the potential synergy of combining lenalidomide with current and investigational monoclonal antibodies in these and other diseases, and supports further study.

0315

DASATINIB IS AN EFFECTIVE TREATMENT OF CENTRAL NERVOUS SYSTEM PH-POSITIVE LEUKEMIA

P. Koskenvesa,[1] J. Rimpiläinen,[2] T. Lundan,[1] S. Mustjoki,[1] B. Brethon,[3] H. Hjorth-Hansen,[4] M. Höglund,[5] H. Knutsen,[6] S. Parikh,[7] E. Raffoux,[3] J. Stromsheim,[6] L. Ågren,[2] F. Gruber,[8] L. Strauss,[9] K. Talvensaari,9 H. Dombret,[3] E. Elonen,[1] R. Paquette,[10] B. Simonsson,[5] C.M. Zwaan,[11] K. Porkka[1]

[1]Helsinki University Central Hospital, HELSINKI, Finland; [2]North-Karelia Central Hospital, JOENSUU, Finland; [3]Hôpital Saint-Louis, PARIS, France; [4]NTNU University Hospital, TRONDHEIM, Norway; [5]Academic Hospital, UPPSALA, Sweden; [6]Åkershus University Hospital, LORENSKOG, Norway; [7]Duke University Medical Center, DURHAM, NC, USA; [8]University of Tromso, TROMSO, Norway; [9]Bristol-Myers Squibb, PRINCETON, NJ, USA; [10]UCLA, LOS ANGELES, USA; [11]Erasmus MC/Sophia Children's Hospital, ROTTERDAM, Netherlands

Central nervous system (CNS) involvement is a relatively common complication in Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) and chronic myeloid leukemia (CML) in blast crisis (BC). The current treatment options (intrathecal or systemic chemotherapy, radiotherapy) for CNS leukemia are limited. The BCR-ABL kinase

inhibitor imatinib, which is widely used in the treatment of Ph-positive leukemia, has a poor penetrance into cerebrospinal fluid (CSF) with inadequate concentrations for kinase inhibition. Animal model data indicate that dasatinib, a potent SRC/BCR-ABL inhibitor, may cross the blood-brain barrier (BBB) in clinically significant amounts. We assessed the clinical efficacy of dasatinib therapy in the treatment of CNS leukemia in patients with Ph+ALL and BC CML. A total of 11 patients were included in the study, most treated within clinical studies (Bristol-Myers Squibb, n=9) in Europe and the US. Nine patients received dasatinib as a front-line therapy for CNS disease, and 2 patients had a CNS relapse while on dasatinib. Some patients received intrathecal chemotherapy in combination with dasatinib. All patients showed significant clinical activity of dasatinib (Table 1). One of the two patients who had a CNS relapse while on dasatinib therapy had the T315I BCR-ABL mutation in blasts isolated from CSF. This mutation confers absolute resistance to dasatinib. The finding of a mutated clone in CSF is indicative of selection pressure exerted by dasatinib and thus access of the drug into CSF. Pharmacokinetic data are being collected. In conclusion, dasatinib penetrates the BBB and induces significant clinical responses even as monotherapy in patients with Ph-positive leukemia.

Table 1.

0316

EFFICACY OF APO010, A FAS-ACTIVATING MOLECULE, IN MULTIPLE MYELOMA

E.M. Ocio,[1] P. Maiso,[1] M. Garayoa,[1] M. Dupuis,[2] A. Pandiella,[1] J.F. San Miguel[1]

[1]*Cancer Research Center, SALAMANCA, Spain;* [2]*Apoxis SA, LAUSANNE, Switzerland*

Background and Aims. The Fas receptor is expressed on the surface of many malignant cells. Fas activation triggers strong apoptotic signals, and therefore represents an interesting anticancer target. APO010 is a recombinant form of Fas Ligand with a hexameric structure that is currently being evaluated as an anticancer agent in Phase 1 clinical trials. In order to identify possible target indications, we tested the *in vitro* efficacy of APO010 on multiple myeloma (MM) cells. *Material and methods.* Eight MM cell lines were used: MM1S, MM1R, U266, RPMI-LR5, RPMI-Dox40, MM144, RPMI-8226 and OPM-1. PBMCs from 3 healthy donors were isolated by Ficoll-Hypaque. Cytotoxicity induced by APO010 was analyzed by MTT and Annexin V staining. Cell cycle changes were studied by propidium iodide uptake by flow cytometry and changes in protein expression by Western-blotting. ELISA for BrdU was used to evaluate the proliferation induced by the presence of microenvironment. *Results.* The sensitivity of eight MM cell lines to cell killing by APO010 was determined in a cytotoxicity assay (MTT). Six cell lines were highly sensitive to APO010 with IC-50 at 24h of 0.5-20 ng/mL (2.5-100 pM), whereas two were resistant (RPMI-8226 and OPM-1). We found a clear correlation between the APO010 sensitivity and the expression of Fas by flow cytometry. Activation of apoptosis was rapid (within two hours of incubation) with maximum effect at 10 hours, as determined by Annexin V staining. In comparison, APO010 cytotoxicity against PBMCs (both resting and activated) from 3 healthy donors was not significant at doses effective against MM cell lines. APO010 was also able to overcome the proliferative advantage conferred to multiple myeloma cells by the presence of IL-6, IGF-1 and the coculture with BMSCs. The mechanism of action of APO010 was studied in the sensitive cell line MM1S. Apoptosis was, as expected, the main mechanism of cell death as assessed by Annexin-V staining by flow cytometry. Cell killing was independent of variations on the cell cycle profile. Treatment with APO-010 induced PARP, caspase-3, caspase-7, caspase-8 and caspase-9 cleavage, suggesting activation of both the intrinsic and extrinsic apoptotic pathways. The presence of the pan-caspase or caspase-8 inhibitors (Z-VAD-FMK and Z-IETD-FMK respectively) and not the caspase-9 inhibitor (Z-LEHD-FMK) were able to completely abrogate the APO010-induced cell death. APO010 also provoked cleavage of MCL-1 and BIM and a decrease of BID. An important downregulation of pAKT was also induced by APO010. Regarding activation of the MAPK pathway, although an initial upregulation of pERK was induced with the treatment (after 2h), this upregulation was transient and decreased even below baseline levels after 6h of exposure to APO010. Finally, the addition of Doxorrubicin and Bortezomib, and in a less extent of Melphalan and Lenalidomide, to APO010 potentiated the efficacy of the drugs alone. *Conclusions.* These data show that APO010 triggers efficient killing of multiple myeloma cells by apoptosis, and provide an initial rationale for the use of this compound for treatment of multiple myeloma patients. Future work will aim at determining the activity of APO010 in animal studies.

SIGNIFICANT PRECLINICAL ANTILEUKEMIC ACTIVITY OF THE TYROSINE KINASE INHIBITOR BVT I IN ACUTE MYELOID LEUKEMIA

S. Eriksson,[1] S. Hassan,[2] M. Höglund,[1] R. Larsson,[2] E. Lindhagen,[2] A. Åleskog,[1] A. Löthgren,[3] K. Föhlenhag,[3] A. Jenmalm Jensen,[3] V. Parrow[3]

[1]*Uppsala University Hospital, UPPSALA;* [2]*Uppsala University, UPPSALA;* [3]*Biovitrum AB, STOCKHOLM, Sweden*

Background. BVT I is a novel kinase inhibitor which has shown activity against several receptor tyrosine kinases in enzymatic assays. *Aims.* The major aim of this study was to further explore the antileukemic activity of BVT I in hematological malignancies *in vitro* as well as *in vivo*. *Methods.* The semiautomated fluorometric microculture cytotoxicity assay (FMCA) was used for *in vitro* evaluation of BVT I activity in a cell line panel as well as in primary tumor cells from 42 patients with hematological malignancies (acute myeloid leukemia (AML; n=16), acute lymphocytic leukemia (n = 12) and chronic lymphocytic leukemia (n=14)). For comparison, normal peripheral blood mononuclear cells (PBMC; n=7) were used. Assessing the *in vivo* activity, cells from 2 patients with AML and the flt-3-positive AML cell line MV-4-11 were cultured in semipermeable hollow fibers. The fibers were implanted subcutaneously into NMRI male mice, which were treated twice daily with either 20 mg/kg or 40 mg/kg of BVT I subcutaneously, or vehicle only. After 6 days the fibers were retrieved and cell density evaluated using the MTT-assay. *Results.* The most sensitive cell line in terms of IC_{50} was the flt-3-positive AML cell line MV-4-11. Furthermore, results from the cell line panel showed that BVT I was not influenced by any resistance mechanism studied. BVT I showed activity *in vitro* against all hematological malignancies tested, as well as against PBMC. AML tended to be the most sensitive cell type with IC_{50} below 10 μM. In the subsequent *in vivo* study, significant antileukemic effect was observed in primary AML cells as well as in MV-4-11 (Figure 1).

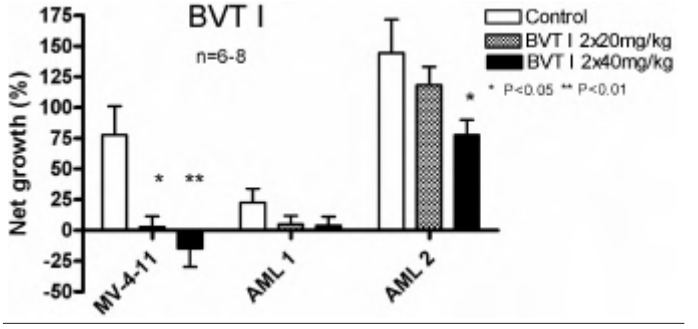

Figure 1. ***In vivo*** **activity of BVT I against AML cells (cell line MV-4-11 and primari AML cells from two individual patients) in the mouse hollow fiber assay. Results are presented as net growth, defined as the percent change in cell density in the fibers during the 6 days of** ***in vivo*** **experiment.**

No major toxicity, neither hematological nor non-hematological, was observed in the animals. *Conclusions.* The tyrosine kinase inhibitor BVT I has significant *in vitro* and *in vivo* effect in AML. Lack of toxicity in the hollow fiber study, suggests that BVT I is well tolerated in mice. Further preclinical studies in AML are ongoing.

0318

FACTORS DETERMINING CLINICAL ACTIVITY OF THE HISTONE DEACETYLASE INHIBITOR SODIUM VALPROATE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKAEMIA

C. Craddock,[1] F. Khanim,[2] J. Arrazi,[2] M. Griffiths,[3] B. Turner,[2] C. Bunce[2]

[1]Queen Elizabeth Hospital, BIRMINGHAM; [2]University of Birmingham, BIRMINGHAM; [3]Birmingham Women's Hospital, BIRMINGHAM, United Kingdom

Background. Histone deacetylases inhibitors (HDIs) represent an important new class of drugs in the treatment of acute myeloid leukaemia (AML). However the mechanism by which they induce tumour specific apoptosis *in vivo* and the factors regulating tumour cell sensitivity are not known. Aims; In order to define factors determining clinical sensitivity to the HDI valproic acid (VPA) we have correlated the impact of VPA exposure on gene expression *in vitro* and *in vivo* with clinical responses in patients with high risk AML. Methods; A panel of 14 haemato-lymphoid cell lines were tested for their sensitivity (IC_{50}) to apoptotic cell killing by VPA. Gene expression array analyses using HGMP chip 6500 gene arrays were performed on the same cell lines prior to HDI exposure. A bioinformatics approach combined the array and IC_{50} data to generate a score for each gene identifying those whose elevated expression correlated with resistance, or sensitivity to VPA *in vitro*. In a concurrent Phase I/II clinical trial 24 patients with high risk AML (relapsed n=11, newly diagnosed n=6, primary refractory n=3) with a median age of 64 yrs (41 -83 yrs) received combination treatment with VPA, all trans-retinoic acid (ATRA) and theophylline. *in vivo* histone acetylation and expression of HDI responsive genes was measured in leukaemic blasts before and after commencement of VPA therapy. Expression of genes associated with VPA sensitivity *in vitro* were re-analysed with respect to their expression in pre-treatment blasts from non-responding and responding trial patients. *Results.* By combining LC50 values to VPA and microarray data generated from pre-treatment RNA in 14 haematolymphoid cell lines we were able to identify candidate genes mediating sensitivity to VPA killing *in vitro*. These studies identified potential VPA-signalling networks containing sensitivity genes including IL-1β and genes associated with VPA resistance including PLOD2, cyclin B1 (CCNB1) and ACVR2A. In the clinical trial 5 patients, all with relapsed AML, achieved clinical responses (complete remission n=1, partial remission n=4). Treatment with VPA and ATRA for 28 days resulted in increased histone acetylation in peripheral blood mononuclear cells and increased expression of the pro-apoptotic genes p15, p16, p21 and TRAIL in patient myeloblasts. Combined upregulation of p21 and TRAIL was only observed in myeloblasts from the patient whom achieved a CR. We then specifically compared the pattern of gene expression, as defined by microarray studies, in responding and non-responding patients with the previously identified *in vitro* VPA signalling networks. The pattern of expression of VPA sensitivity and resistance genes in pre-treatment myeloblasts from 4 patients identified similar networks to those defined *in vitro* and appeared to be correlated with clinical response. *Conclusions.* This study demonstrates induction of pro-apoptotic gene expression by VPA in a clinical context and identifies potential mechanisms through which its anti-leukaemic effect may be mediated *in vivo*. Furthermore we have identified potential VPA-signalling networks containing novel sensitivity and resistance genes whose expression correlates with VPA-mediated tumour cell killing *in vitro* and may predict clinical activity.

0319

GOLD COMPOUND AURANOFIN INDUCES APOPTOSIS IN MYELOMA CELLS VIA TARGETING IL-6 SIGNALING PATHWAY

A. Nakaya, M. Sagawa, A. Muto, H. Uchida, Y. Ikeda, M. Kizaki

Keio University School of Medicine, TOKYO, Japan

[Background] Multiple myeloma is an incurable B-cell malignancy, requiring new therapeutic strategies. Recent understanding of the biology in multiple myeloma has led to the development of various novel agents, which target the myeloma cells and its microenvironment. These new agents have shown remarkable activity against refractory myeloma in early clinical trials, but prolonged drug exposure may result in the development of de novo drug resistance. In addition, unexpected pulmonary complications by bortezomib, a promising agent for multiple myeloma, have been reported. Therefore, identification and validation of novel agents with less toxicity to overcome drug resistance and to improve clinical outcome of multiple myeloma are necessary. *Aims.* Auranofin (AF) is a coordinated gold compound, which has been widely used for the treatment of rheumatoid arthritis. Recent studies have shown that AF induces apoptosis in leukemia cells. Therefore, assuming that AF has a potency to induce apoptosis in myeloma cells as well, it may become a candidate of a novel targeted therapeutic agent. *Methods.* To address our hypothesis, the effects of AF on inducing apoptosis of various myeloma cells were examined. Further, the molecular mechanism of AF-induced apoptosis in myeloma cells was investigated. *Results.* AF inhibited the growth of U266 myeloma cells in a time (0-24 h)-dependent manner with IC_{50} of 50 nM. AF significantly induced cell cycle arrest at G1 phase and subsequent apoptosis of U266 cells. AF upregulated the expression of cdk inhibitor p21 and caused dephosphorylation of Rb protein. Furthermore, AF-induced apoptosis in myeloma cells involved the activation of caspase-8 and the cleavage of Bid, a mediator that is known to connect the death receptor to the mitochondrial apoptosis pathway. We also found that AF induced the cleavage of Mcl-1 protein, but had no effect on the expression of Bax or Bcl-2 proteins. To clarify the importance of Mcl-1 in AF-induced apoptosis, the Mcl-1 expression vector was introduced into U266 cells. Induction of apoptosis by AF was almost abrogated in Mcl-1-overexpressed U266 cells. AF also inhibited IL-6-induced activation of JAK2 and phosphorylation of STAT3 in U266 cells, suggesting that AF could inhibit the IL-6-mediated signaling pathway in myeloma cells. Previous reports have demonstrated that STAT3 binds to the Mcl-1 gene promoter and activates its transcription, resulting in the upregulation of Mcl-1 expression. Therefore, we then examined the effect of AF on the DNA binding activity of STAT3. Electrophoretic mobility shift assays using U266 nuclear extracts demonstrated that IL-6-induced STAT3 binding activity was inhibited by the presence of AF. *Conclusion.* We report here for the first time that AF induced apoptosis in human multiple myeloma cells. Down-regulation of Mcl-1 with modulation of IL-6-mediated signaling pathway plays an important role in AF-induced apoptosis in myeloma cells. Low pharmacological concentration (50 nM) of AF is widely employed for the management of rheumatoid arthritis without any side effects, and may be used for treating myeloma without the risk of severe toxicity. We conclude that AF is one of the promising candidates for the new therapeutic agent as a signal transduction therapy of myeloma.

0320

DASATINIB INHIBITS T CELL ACTIVATION AND PROLIFERATION IN A DOSE-DEPENDENT MANNER

R. Weichsel,[1] C. Dix,[1] J. Zezula,[2] E. Greiner,[2] D.A. Price,[3] H. Einsele,[1] R. Seggewiss[1]

[1]University of Wuerzburg, WUERZBURG, Germany; [2]Laboratory of Medicinal Chemistry, NIDDK, BETHESDA, USA; [3]Human Immunology Section, VRC, NIH, BETHESDA, USA

Background. Dasatinib (Sprycel®, BMS-354825, Bristol-Myers Squibb) is a novel inhibitor of BCR-ABL, SRC kinases, c-kit, PDGF receptor and other kinases. It has been demonstrated to be safe and more effective in CML patients than Imatinib (Glivec®, STI571, Novartis) and has been approved in 2006. An increased infection rate, which has been described in patients undergoing dasatinib treatment, might be due to inhibitory effects on LCK and FYN, since dasatinib targets tyrosine kinases (TK) that play an important role in T cell development and function. A recent case report also demonstrated dasatinib's efficacy in the treatment of a patient with thymoma. *Aims.* We have now evaluated dasatinib's effects on human purified T cells from healthy blood donors and compared them with the effects of the promiscuous TK inhibitor staurosporine, which has been the base for several SRC kinase inhibitors in clinical development. Methods and *Results.* All assays described herein were performed at clinically relevant doses between 1nM and 100nM. CFSE labeled T cells were stimulated with the murine monoclonal CD3 antibody OKT-3 for four days. A dose-dependent inhibition of T cell proliferation was detected (EC50=7 nM) and almost complete inhibition (96% inhibition) occurred at a concentration of 20 nM. T cells incubated with dasatinib for 24h, and then removed from dasatinib, proliferated as well as untreated T cells (p=0.118). This argues for a reversible blockade of T cell proliferation, in contrast to staurosporine that led to a dose-dependent but irreversible inhibition of proliferation at a dose of 10 nM (on average 90% inhibition). We further investigated the functional effects of dasatinib on T cells. A statistically significant inhibition of OKT-3 induced up-regulation of the T cell activation marker CD69 was

observed at a concentration as low as 10 nM, and almost complete inhibition (99%) occurred after 24h at a concentration of 50nM (EC_{50}=11 nM). In line with these results, we also observed reduced IL-2 production in dasatinib treated purified T cells (EC_{50}=1.3nM, measured by ELISA), while 1nM staurosporine led to a 70% inhibition of IL-2 release, and 10nM almost to a complete inhibition (99.9%). $CD4^+$ T cells were more sensitive than $CD8^+$ T cells to the inhibitory effects of staurosporine on activation and proliferation (89% proliferation inhibition for $CD4^+$ cells vs. 81% for $CD8^+$ cells at 10 nM). The same held true for dasatinib (activation: EC_{50} 9 nM for $CD4^+$ cells and 15 nM for $CD8^+$ cells, proliferation: EC_{50} 5 nM for $CD4^+$ cells and 14 nM for $CD8^+$ cells). Since $CD8^+$ T cell-mediated immunity is essential for long-term control of persistent DNA viruses, we evaluated dasatinib's impact on antigen-specific T-cell responses to CMV and EBV. Proliferation inhibition of CFSE-labeled CMV- and EBV-specific $CD8^+$ T cells was observed, which might explain the increased frequency of viral infections in dasatinib treated patients besides the described induction of myelosuppression. *Conclusions.* Close monitoring of patients under TK inhibitor treatment seems warranted with respect to reactivation of persistent viral infections and newly acquired opportunistic infections. However, these findings also indicate dasatinib's potential as an immunosuppressant in the fields of transplantation and rheumatology.

0321

BOSUTINIB (SKI-606) EXHIBITS CLINICAL ACTIVITY IN PATIENTS WITH PHILADELPHIA CHROMOSOME POSITIVE CML OR ALL WHO FAILED IMATINIB

T. Brummendorf,[1] J. Cortes,[2] H. Kantarjian,[2] G. Martinelli,[3] D. Liu,[4] T. Fischer,[5] B. Hewes,[6] A.D.G. Volkert,[6] R. Abbas,[6] C. Gambacorti-Passerini[7]

[1]Universitaetsklinikum Hamburg, HAMBURG, Germany; [2]MD Anderson Cancer Center, HOUSTON, USA; [3]University of Bologna, BOLOGNA, Italy; [4]New York Medical College, VALHALLA, USA; [5]Universitaetsklinikum Mainz, MAINZ, Germany; [6]Wyeth Research, CAMBRIDGE, USA; [7]Opedale San Gerardo-Monza, MONZA, Italy

Background. Bosutinib (SKI-606) is an orally available, dual Src/Abl kinase inhibitor. *Aims.* To assess safety and preliminary clinical activity of bosutinib, we conducted a phase 1/2 study in patients (pts) with Philadelphia chromosome positive (Ph^+) chronic myelogenous leukemia (CML) or acute lymphocytic leukemia (ALL) who were imatinib resistant/intolerant. *Methods.* In part 1, 18 pts with imatinib-relapsed/refractory chronic phase (CP) CML received bosutinib 400 mg/day (3 pts), 500 mg/day (3 pts), or 600 mg/day (12 pts). Part 2 was an expanded cohort of 51 pts with all phases of Ph^+ CML and ALL dosed at 500 mg daily. Timed blood samples were collected on days 1-3, 15 for PK analysis. *Results.* Of 69 pts, median age was 59 yrs; 48 were CP; 90% imatinib resistant. Drug-related grade 1/2 adverse events (AEs) occurring in ≥10% of CP pts: diarrhea (69%), nausea (44%), vomiting (19%), abdominal pain (13%), rash (13%). Grade 3/4 AEs occurring in ≥5% of CP pts: rash (6%), thrombocytopenia (6%). 17 pts required dose reductions. In evaluable imatinib-resistant CP-CML pts with no prior exposure to other Abl inhibitors, 16/19 (84%) had complete hematologic response (CHR); 4/21 had partial and 7/21 had complete cytogenetic responses for major cytogenetic response (MCyR) rate of 52%. Of 58 pts evaluable for mutations, 13 different imatinib-resistant mutations were found in 32 pts. 12/14 CP pts with non-P-loop mutations and 3/3 with P-loop mutations achieved CHR. 5/11 CP pts with non-P-loop mutations and 1/1 with P-loop mutation achieved MCyR. 4/9 evaluable advanced leukemia pts had CHR, 2 had MCyR. After oral administration, steady state exposure of bosutinib was nearly 2-fold higher than single-dose exposure. Mean elimination half-life was approximately 22-27 hours, supporting a once-daily dosing regimen. *Conclusions.* Bosutinib was well tolerated in pts with CML, with primarily low-grade gastrointestinal and dermatologic AEs. Bosutinib showed clinical activity in imatinib-resistant pts with cytogenetic responses and CHR across a range of mutations. Durability of response continues to be assessed.

0322

SULINDAC SULFIDE REVERTS THE ACTIVATION OF THE WNT-SIGNALING AND ABERRANT SELF RENEWAL INDUCED BY THE AML-ASSOCIATED FUSION PROTEINS PML/RAR AND PLZF/RAR

M. Ruthardt,[1] E. Puccetti,[1] G. Steinert,[1] G. Steinert,[2] M. Ruthardt,[2] E.Puccetti[2]

[1]Klinikum der J. W. Goethe Universität, FRANKFURT, Germany; [2]Laboratory for Tumor Stem Cell Biology, Department of Hematology, J. W. Goethe University Frankfurt, Germany

Background. More than 60% of acute myeloid leukemias (AML) harbor specific chromosomal aberrations mainly translocations. Translocations such as t(15;17), t(11;17), or t(8;21) lead to the formation of chimeric genes encoding for fusion proteins such as PML/RAR, PLZF/RAR and AML-1/ETO (leukemia associated fusion proteins - LAFP). LAFP are able to induce and to maintain the leukemic phenotype by blocking terminal differentiation of early hematopoietic progenitors and by increasing the self renewal potential of the leukemic stem cells (LSC). The key mechanims by which LAFP increase LSC self renewal is the activation of the Wnt-signaling pathway. PML/RAR, PLZF/RAR or AML-1/ETO activate Wnt-signaling by up-regulating γ-catenin and β-catenin at a transcriptional level. Activation of the Wnt signaling augments self renewal of normal HSC and LSC. We and others have recently shown that the aberrant activation of Wnt-signaling by the LAFP decisively contributes to the pathogenesis of AML. *Aim.* To disclose whether a *leukemic stem cell therapy* is effective we targeted the Wnt-signaling by Sulindac Sulfid (SuSu) in PML/RAR- or PLZF/RAR- (X-RAR) positive stem cell models. SuSu represents the active metabolite of Sulindac, a nonsteroidal anti-inflammatory drug (NSAID), known to inactivate the Wnt-signaling. *Methods.* SuSu was used at a concentration of 50-100 μM which is achievable in patients at a dosage of 0.2-0.4g. As leukemia models we used U937 cells stably expressing PML/RAR or PLZF/RAR and the PML/RAR-positive cell line NB4. As stem cell models we used i.) the $CD34^+/CD38^-$ fraction of the KG-1 cells stably expressing PML/RAR or PLZF/RAR under serum free culture conditions; ii.) Sca-1+/lin- murine HSC retrovirally transduced with PML/RAR or PLZF/RAR and plated in methyl cellulose containing mIL-3, mSCF and mIL-6. The amount of total γ-catenin and β-catenin and activated β-catenin was determined by immunoblotting. *Results*. Here we report that SuSu i.) down-regulated not only β-catenin but also γ-catenin in X-RAR expressing U937 and KG-1 cells; ii.) reduced the active form of β-catenin in the presence of X-RAR; iii.) induced a high apoptosis rate in PML/RAR-positive NB4 cells; iv.) reduced the $CD34^+/CD38^-$ *stem cell fraction* of KG-1 cells expressing X-RAR but not of mock transfected controls; iv.) reduced the self renewal potential of X-RAR-positive HSC as revealed by a significantly reduced replating efficiency. *Conclusions*. Here we provide first evidence that it is possible to the exposure to therapeutically achievable dosages of a NSAID revert the aberrant activation of the Wnt-signaling by LAFP. The significant reduction of the aberrant self renewal potential of HSC in the presence of X-RAR further support that the inhibition of the aberrantly activated Wnt signaling in AML might be a valid molecular therapy approach which has to further validated in *in vivo* leukemia models and in a clinical setting.AML-1/ETO activate Wnt-signaling by up-regulating γ-catenin and β-catenin at a transcriptional level. MTORC1 INHIBITION ACTIVATES PI3K/AKT BY UP-REGULATING THE IGF-R SIGNALLING IN ACUTE MYELOID LEUKAEMIA: RATIONAL FOR INHIBITION OF BOTH PATHWAYS

J. Tamburini,[1] N. Chapuis,[1] V. Bardet,[1] S. Park,[1] N. Ifrah,[2] F. Dreyfus,[3] P. Mayeux,[1] C. Lacombe,[1] D. Bouscary[1]

[1]Institut Cochin, PARIS; [2]Service des Maladies du Sang CHU, ANGERS; [3]Service d'hématologie Hopital Cochin, PARIS, France

Background. The PI3K/Akt and mTORC1 pathways are frequently activated in acute myeloid leukaemia (AML) cells and represent potential therapeutic targets. *Aims.* In this report, we studied the interactions between PI3K and mTORC1 pathways in primary blast cells from the bone marrow of patients with AML at diagnosis after 4 hours of cytokine and serum starvation. *Methods.* Bone marrow samples were obtained from 22 newly diagnosed AML patients before induction of chemotherapy. Blast cells were starved 4 hours in cytokine and serum free media. Cells were then incubated with or without inhibitors: IC87114 (p110delta specific inhibitor), RAD001 (rapamycin derivative inhibitor of mTORC1), LY294002 (multiple kinases inhibitor including mTORC1 and PI3K), ?IR3 (inhibitory anti-IGF-1 receptor monoclonal antibody) and Western blot analysis and cell proliferation assays were performed. To purify the blast cell population, cells were sorted according to CD45 expression and side scatter. Immunofluorescence on cytocentrifuge preparations and quantitative RT-PCR for IGF-1 expression on CD45low blast cells were performed. *Results.* We observed that specific inhibition of mTORC1 activity with RAD001 upregulated PI3K activity, as evidenced by an increased phosphorylation of AKT (Ser 473) on Western blot analysis. The mean increase of AKT phosphorylation in the presence of RAD001 was 186% (130-500%). The increase was maintained after 24 hours of blast cell incubation with RAD001. This mTORC1-mediated Akt up-regulation was explained by an IGF-1/IGF-1 receptor autocrine loop: a/ blast cells expressed a functional IGF-1 receptor and IGF-1-induced Akt activation was increased by RAD001, b/ a neutralizing anti-IGF-1R α-IR3 monoclonal antibody reversed the RAD001-induced Akt phosphorylation, c/ autocrine production of IGF-1 was detected in highly purified CD45low blast cells from 8 patients by quantitative RT-PCR and immunofluorescence. d/ Activation of the IGF-1 receptor paralleled an up-regulation of the IRS2 adaptor protein. Finally, we observed, in AML blast cells, a dissociation of the mTORC1 and PI3K pathways: IC87114, a specific p110delta PI3K inhibitor, had no inhibitory effect on mTORC1 signalling. This was confirmed by the fact that RAD001 and IC87114 induced additive anti-proliferative effects on AML blast cells. *Conclusions.* Our results suggest that dual inhibition of mTORC1 complex and IGF1/IGF-1R/PI3K/Akt axis may enhance the efficacy of mTOR inhibitors in AML.

DISCOVERY AND PRECLINICAL DEVELOPMENT OF SELECTIVE JAK INHIBITORS FOR THE TREATMENT OF HEMATOLOGICAL MALIGNANCIES

S. Fridman, J. Li, P. Liu, E. Caulder, E. Crowgey, M. Favata, G. Guoen, Y. Li, M. Covington, J. Rodgers, A. Combs, S. Yeleswaram, R. Newton, P. Scherle, K. Vaddi

Incyte Corporation, WILMINGTON, USA

Background. Increased kinase activity is a common occurrence in malignant cells and is associated with the activation of multiple downstream pathways implicated in the pathobiology of various diseases. The identification of activating genetic mutations in multiple members of the Janus kinase (JAK) family of non-receptor tyrosine kinases has recently been described in numerous malignancies, including the majority of Philadelphia chromosome negative (Ph^-) myeloproliferative disorders (MPDs). Mouse experiments have suggested a causal role for these mutated JAKs implicating them in the pathogenesis of the human conditions. This suggests that JAK inhibition may be a promising therapeutic strategy for the treatment of diseases associated with elevated JAK kinase activity. *Aims.* To identify and characterize potent, selective, orally bioavailable inhibitors of the JAK kinases. *Methods.* A compound library was screened for inhibition of JAK kinase activity. Structure-activity relationship based lead optimization was conducted to identify novel, potent and selective JAK inhibitors. Further characterization of *in vitro* and *in vivo* pharmacokinetic, pharmacological and toxicological properties was performed to identify molecules suitable for further advancement into animal models of cancer and MPDs. *Results.* Incyte has identified multiple novel, potent, and selective inhibitors of the JAK kinases, including the recently described JAK2 V617F mutant common to the majority of the Ph- MPDs. These compounds are active against JAKs at nanomolar concentrations while demonstrating excellent selectivity against a broad panel of unrelated kinases. In cell-based assays, these compounds retain their nanomolar potency and selectivity and reduce JAK-mediated tumor cell growth and survival. In contrast, these compounds do not impact the growth or survival of cells dependent on alternative signaling pathways (e.g. Bcr-Abl), even at micromolar concentrations. *in vivo*, in a mouse model of MPD-associated mutant JAK2 driven organomegaly (BaF/3-JAK2V617F cells), Incyte JAK inhibitors markedly reduce the splenomegaly common to both the model and the human disease (Figure 1). A detailed characterization of the activity of these molecules will be presented. *Summary.* Increased JAK signaling has been associated with various malignancies, including the majority of Ph-MPDs. Incyte has identified multiple potent and selective inhibitors of the JAK kinases. These compounds are orally bioavailable and are efficacious *in vivo* at well tolerated doses. As such, these compounds may be promising new therapeutics for the treatment of MPDs and other disease states associated with elevated JAK activity.

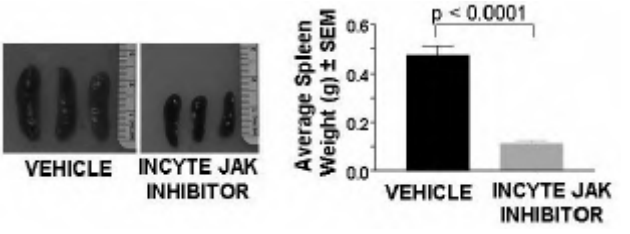

Figure 1. Normalization of MPD-related splenomegaly.

GEMTUZUMAB OZOGAMICIN (MYLOTARG) AS MAINTENANCE THERAPY AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

N. Cascavilla, C. Bodenizza, A.M. Carella, M. Dell'Olio, A.P. Falcone, M.M. Greco, A. La Sala, S. Mantuano, L. Melillo, E. Merla, M. Nobile, G. Sanpaolo, P. Scalzulli

Hematology CSS Hospital, SAN GIOVANNI ROTONDO, Italy

Background. Acute Myeloid Leukemia (AML) is a disease predominantly affecting older adults, with a median age of 65 years. These patients represent a poor risk population with a high chemotherapy-related mortality. Standard of care in the management of elderly patients with AML includes combination therapy with cytarabine plus fludarabine and an anthracycline and can result in complete remission (CR) rate of 40% to 60%. Even if successful, patients relapse quickly. Aggressive postremission therapy does not appear to improve survival. Future directions include therapies targeted at immunomodulation, and, among newer treatments, Gemtuzumab ozogamicin (GO) has given promising results in relapsed, refractory and untreated $CD33^+$ AML as monotherapy or combination regimens or adjunct to conditioning regimens for Stem Cell Transplantation (SCT). *Patients and Methods.* In this study we analyzed the efficacy and the safety of GO as maintenance treatment after Autologous-SCT in three elderly patients (2 males and 1 female; 64, 67 and 69 years, respectively) with $CD33^+$ AML in 1st (2 patients) or in 2nd (1 patient) CR. After a complete hematopoietic engraftment (at least 6 weeks from ASCT), GO was administered alone for 4 doses with 28 days between doses (two patients received 6 mg/mq for the two first doses and 3 mg/mq for the two last doses; the last received 3 mg/mq for four doses). Patients were evaluated for Continue Complete Remission (CCR) and therapy-related adverse events. *Results.* All patients are in CCR at +17, +13, +11 months, respectively. Neutropenia (between 500 and 1000/microl) and thrombocytopenia (between 50.000 and 100.000/microl) were observed in two (when GO was given at a dose of 6 mg/mq) and in three patients, respectively. No grade 3 or 4 liver toxicity was observed. *Conclusions.* GO administered in fractionated doses as maintenance treatment after ASCT in older patients with $CD33^+$ AML in first or second CR demonstrated a good efficacy and an acceptable safety profile.

THE SIMILARITIES OF HUMAN MESENCHYMAL STEM CELLS AND PERICYTES

D. Covas, R.A. Panepucci, A.M. Fontes, W.A. Silva-Jr, M.D. Orellana, L. Neder, A.R.D. Santos, L.C. Perez, M.C. Jamur, M.A. Zago

University of S. Paulo, RIBEIRAO PRETO, Brazil

Background. Multipotent mesenchymal stromal cells (MSC) can be isolated from a variety of tissues. Their relationship with pericytes and fibroblasts has not been established thus far, although they share many functional properties. Aims. To evaluate the relationship between MSC and pericytes on the basis of gene expression. Materials and Methods. We analyzed 14 samples of MSCs from adult or fetal tissues, two MSC cultures differentiated *in vitro*, and two cultures of retinal pericytes obtained either by immunological separation with anti-CD146 or adhesion, respectively. Cells were cultured under appropriate conditions to promote osteogenic, adipocytic or chondroblastic differentiation, evaluated both by morphology and by specific histochemical staining. Global gene expression was analyzed by SAGE for human retinal pericytes and MSC from BM and from umbilical cord vein. The expression of 39 selected genes was evaluated by serial dilutions of the cDNA in RT-PCR reactions for 31 different cell cultures including undifferentiated and differentiated MSC from adult and fetal sources, pericytes, fibroblasts, endothelial cells, and cells from bone marrow, liver, brain, skeletal muscle, skin and heart. Real time PCR for five genes confirmed the results obtained by serial dilution. Cluster analysis of gene expression data was performed using the Cluster 3.0 software, both for gene expression of 31 cell cultures evaluated by serial dilution and for 17 SAGE libraries from MSCs, endothelial cells, skeletal and heart muscles, $CD34^+$ cells, pericytes, skin fibroblasts, stellate hepatic cells and myofibroblasts differentiated from stellate cells. The use of human cells in these experiments has been approved by the institutional research review committee. *Results.* Cell morphology of MSCs and pericytes were very similar, both under light and transmission electron microscopy, as well as the phenotypes defined by 23 markers, especially negativity for CD34, CD33, CD45, CD14, HLA-DR, KDR and CD31, and positivity for CD73, CD90, CD29, CD44 and HLA-I. Osteogenic and adipocytic differentiation was documented for most MSC cultures and for pericytes; chondrocytic differentiation was positive for the MSCs that were tested. Cluster analysis of SAGE gene expression profiles showed that MSC, pericytes and stellate hepatic cells form a consistent group, separated from another consistent group formed by fibroblasts, smooth muscle cells and myofibroblasts differentiated from stellate cells. Cluster analysis of semi quantitative expression data of the 39 selected genes confirmed that all the MSC lines, pericytes and fibroblast share a common expression profile distinct from other normal cells. Despite the similarity, FSP-1 was more frequently expressed on fibroblasts and NG-2 on pericytes as compared with MSCs. *Conclusions.* We conclude that human MSC and pericytes, as operationally defined by culture methods, are similar cells located in the wall of the vasculature where they function as a source of precursor cells for repair and tissue maintenance. Additionally, the close relationship of fibroblasts and smooth muscle cells with myofibroblast differentiated from stellate cells further indicates that these functionally compromised cells may be closely related to these precursor cells, a proposition that has conceptual and practical implications.

STUDY OF FUNCTIONAL AND MOLECULAR CHARACTERISTICS OF THREE DIFFERENT BONE MARROW CELL POPULATIONS FOR EXPANSION OF MESECHYMAL STEM CELLS

H. Papadaki, M.C. Kastrinaki, A. Damianaki, V.M. Vlahava, P. Fragioudaki, E. Stavroulaki, G.D. Eliopoulos

University of Crete School of Medicine, VOUTES, HERAKLION, Greece

Background. There is currently great interest in exploring the use of mesenchymal stem cells (MSCs) for clinical purposes. Identification of markers and sources for MSC isolation is, therefore, of particular importance. *Aims.* To compare the colony/cloning efficiency, expression of *stemness* markers and differentiation potential of three different bone marrow (BM) derived cell populations, namely the $CD105^+/CD45^-$, the Glycophorin A $(GlycoA)^-/CD45^-$ and BM mononuclear cells (BMMCs). *Methods.* Normal human BM cells were isolated from posterior iliac crest aspirates. A colony forming unit-fibroblast (CFU-F) assay was used for the determination of the colony efficiency of the BMMC or the immunomagnetically sorted $CD105^+/CD45^-$ and GlycoA-/CD45- BM cell fractions. CFU-F colonies derived from the three different cell subpopulations were isolated with clone-rings and further expanded using a standard MSC culture protocol. Clone efficiency was determined by evaluating the number of clones survived after full *in vitro* expansion versus the number of initially expanded clones. The adipogenic, osteogenic, and chondrogenic (AOC) differentiation potential of MSCs expanded from these clones and cultured under defined culture conditions, were assessed by using Oil red O, Alkaline phosphatase/Von Kossa and Alcian Blue immunohistochemical stains respectively, as well as by evaluating the expression of specific differentiation-associated gene expression by RT-PCR. Finally, the immunomagnetically sorted $CD105^+/CD45^-$ and $GlycoA^-/CD45^-$ cell populations were assessed at day-0 for the expression of Oct4 and Nanog *stemness* genes using real-time RT-PCR. *Results.* In the CFU-F assay, the colony efficiency was statistically significantly higher when $CD105^+/CD45^-$ cells were used in the culture (144.8±62.8) compared to $GlycoA^-/CD45^-$ cells (21.5±16.2) or BMMCs (10.9±11.6) ($p<0.0001$, one-way ANOVA; colony numbers are expressed as CFU-F per 100000 cells cultured). By determining clone efficiency as the number of clones survived after full *in vitro* expansion versus the number of initially expanded clones, we found that clone recovery by $CD105^+/CD45^-$ cells (47.0%±23.86%), although higher, was not statistically significant compared to the respective of BMMCs (40.2%±32.21%) and $GlycoA^-/CD45^-$ (39.61%±38.62%) derived clones ($p=0.9018$, one-way ANOVA). The AOC differentiation capacity of clones generated from the three different cell sources were similar as evaluated my the immunohistochemical staining and the expression of aP2 and PPAR-γ for adipogenic, CBFA1 and ALP for osteogenic, aggrecan and coll-II for chondrogenic differentiation. Expression of Oct4 and Nanog was found 16-fold and 47-fold higher, respectively, in $CD105^+/CD45^-$ cells compared to $GlycoA^-/CD45^-$ cells ($p<0.05$ and $p<0.05$, Mann Whitney test). *Summary and Conclusions.* The data presented above suggest that the $CD105^+/CD45^-$ BM cell fraction contains a more immature MSC population compared to $GlycoA^-CD45^-$ cells with higher colony-forming efficiency and higher Oct4 and Nanog expression. The $CD105^+/CD45^-$ BM cells display also the potential to differentiate towards the AOC lineages and accordingly, represent a better source for MSC studies compared to BMMCs or $GlycoA^-/CD45^-$ cells. Comparison between the molecular and proteomic profile of $CD105^+/CD45^-$ and $GlycoA^-/CD45^-$ cells is an interesting field for further investigation.

0328

COMPARATIVE ANALYSIS OF ANGIOGENIC CAPACITY OF MONOCYTES AND CD 133+ CELLS IN A MURINE MODEL OF HINDLIMB ISCHEMIA

N. López-Holgado,[1] M. Alberca,[1] F.M. Sánchez-Guijo,[1] J. Almeida,[2] E. Villaron,[1] J.V. Rivas,[3] J.M. López-Novoa,[3] C. Garcia,[1] J.F. Pérez-Fontán,[1] B. Blanco,[1] L.I. Sánchez-Abarca,[1] S. Tabera,[1] J.A. Pérez-Simón,[1] J.F. San Miguel,[1] M.C. Cañizo[1]

[1]University Hospital of Salamanca, SALAMANCA; [2]Cancer Research Center, SALAMANCA; [3]Physiology Department. U of Salamanca., SALAMANCA, Spain

Background. The presence of endothelial progenitor cells (EPC) in adult humans has been recently described. Two cell sources, $CD133^+$ cells and monocytes have been shown to have angiogenic capacity. *Aims.* To perform a prospective study comparing the angiogenic capacity of monocytes and $CD133^+$ cells in a murine model of hindlimb ischemia. *Material and Methods.* Cells were obtained from voluntary healthy donors, monocytes by adherence from buffy-coats of blood donations and $CD133^+$ cells from leukapheresis products for allogeneic transplantation after immunomagnetic selection (Variomacs, Miltenyi). *In vivo* studies were performed in a mouse model of acute hindlimb ischemia. It was induced after ligation and excision of the left femoral artery in 42 Swiss-nu/nu 6-8 weeks old mice. The day of ischemia monocytes (10^5 or 10^6 cells; n=14) or $CD133^+$ cells (10^5 or 10^6 cells; n=14) or only saline serum (control group; n=14) were IV infused into the mice. Revascularization was analysed using two different approaches: blood flow by laser Doppler analysis (moor LAB server) and capillary density studies (number vessels/μm^2) (Visilog programme). In order to know where the infused cells were localized immunofluorescence and immunocytochemistry techniques were performed and analysed by light (Olympus CX40), fluorescence (Olympus Provis) and confocal (Leica TCS SP) microscopes. The following markers were used: human CD34 (Novocastra TM), human CD31 (Dakocytomation) and mouse CD31 (BD). *Results.* Monocytic and $CD133^+$ cell purity was 80% (73-85) and 82%

(50-99) respectively. Serial analysis showed a progressive recovery of limb perfusion in all animal groups analysed. From day +4 until day +28 a significant improvement in limb perfusion (p<0,05) was observed in both, mice treated with monocytes and CD133$^+$ cells when compared with non treated mice. However, no differences were observed between the two experimental groups of mice (treated with monocytes or CD133$^+$cells). Capillary density also increased in mice treated with both monocytes (48 (14-56) capillaries//∝m^2) and CD133$^+$ cells (51 (18-61) capillaries/∝m^2) versus non treated mice (20 (8-51) capillaries//∝m^2). With significant differences in mice receiving CD133$^+$ (p=0,02). By contrast, in ischemic muscles not receiving cells the number of capillaries was lower than in control mice (p=0,01). When we looked if the infused cells were or not incorporated in mice vessels we could observe that, when a low number of monocytes or CD133$^+$ cells was infused (10^5), no cells were observed into the vessels suggesting that cells could act throughout a paracrine mechanism. However, when higher doses were used (10^6 cells) few cells from both cell sources could be observed into the mice vessels. *Conclusions.* Our data show that treatment with both, monocytes or CD133$^+$ cells, improves blood perfusion in a murine model of hindlimb ischemia increasing the number of capillaries in a very similar way, probably mainly by a paracrine mechanism but some cells from both sources can incorporate into the endothelium.

REGULATION BY TGFβ SUPERFAMILY OF HUMAN B LYMPHOPOIESIS IN A NEWLY ESTABLISHED LYMPHOCYTE CULTURE SYSTEM USING HUMAN MESENCHYMAL STEM CELLS AS A SUPPORTIVE MICROENVIRONMENT

M. Ichii, K. Oritani, T. Yokota, I. Takahashi, T. Shirogane, N. Saitoh, R. Tanigawa, Y. Kanakura

Osaka University Graduate School of Medi, SUITA, Japan

Background and Aims. Recently, the analysis of human B lymphocyte developmental biology using human origin hematopoietic cells has been progressing. However, in many of these studies, murine stromal cell lines were utilized as microenvironment to support B lymphopoiesis. Previous studies showed that there are some differencet mechanism between murine and human B cell differentiation. Hence, there is a great need for a more biologically relevant model system to determine the role and function of various mediators in human B lymphopoiesis. *Methods.* Using human mesenchymal stem cells (hMSCs) as stromas, we have developed a long-term culture system to produce B lymphocytes from human CD34$^+$ cells purified from umbilical cord blood (CB). To determine the effects of various regulators on the growth of B progenitor cells, we tested effects of several low molecular weight inhibitors, neutralizing antibodies, as well as recombinant proteins in this culture system. *Results.* HMSCs can support more efficiently the commitment and differentiation of CB CD34$^+$ cells into B lineage compared to the murine bone marrow stromal cells, MS-5 and human umbilical vascular endothelial cells (HUVEC). In various combinations of recombinant human growth factors, the addition of stem cell factor (SCF) and Flt-3 ligand (FL) efficiently enhanced the growth of surface μ$^+$ immature B cells. The addition of interleukin 7 (rhIL-7) is not required for this culture system, and the addition of rhIL-7 suppress the emergence of surface IgM expression from CD34$^+$ CB cells. Thus, our co-culture of 2,000 CB CD34$^+$ cells with hMSC in the presence of SCF and FL successfully produced approximately 5×10^5 CD10$^+$ B lymphocytes at 4 weeks. When various small molecules inhibitors were added to this culture system, NAC (ROS inhibitor) and DUP697 (COX2 inhibitor) exerted no effect on B lymphopoiesis with this culture. Addition of BIO (GSK-3 inhibitor) diminished the emergence of CD10$^+$ cells. SB431542 (ALK4/5/7 inhibitors) showed significant effect of the expansion of CD10$^+$ cells. With regard to the regulation of TGFβ superfamily, follistatin (physiological antagonist of Activin A) or a neutralizing antibody for Activin A enhanced B lymphocyte production approximately 2.5-fold and 3-fold, respectively. The neutralizing antibody for TGFβ1 had no effects. The B lymphocyte production tended to be suppressed by the addition of recombinant TGFβ1, but not Activin A. The differential effects of inhibitors andfactors on B lymphocyte production seemed to be related to the fact that much higher concentration of Activin A was contained in culture supernatant than TGFβ1. With regard to the expression of TGFβ superfamily, RT-PCR revealed that hMSC expressed TGFβ family, Activin family; CB CD34$^+$ cells expressed their cognate receptors. Immunohistocal analysis revealed that both Activin A and TGFβ1 were produced in bone marrow. *Conclusions.* We established a useful co-culture system of CB CD34$^+$ cells with hMSCs for analyzing regulatory mechanisms of human B lymphocytes. With this system, we showed that members of TGFβ superfamily, Activin A and TGFβ1, are negative regulators for the early onset of normal human B lymphopoiesis.

0330

MESENCHYMAL STEM CELLS (MSC) REGULATE IMATINIB RESISTANCE: NO EFFECT OF IMATINIB ON MSC CYTOKINE SECRETION

D. Cai, Y. Wang, C. Brendel, A. Neubauer, A. Burchert

Philipps-University of Marburg, MARBURG, Germany

Imatinib mesylate (IM) specifically blocks BCR/ABL tyrosine kinase and has become standard therapy of BCR/ABL positive leukemias such as chronic myeloid leukaemia (CML). However, occurrence of IM-resistance and persistence of minimal residual disease (MRD) are major obstacles to the issue of potential cure of CML. The hematopoietic microenvironment closely regulates normal and abnormal hematopoiesis. Mesenchymal stem cells (MSC) are an important component of the bone marrow microenvironment, and control hematopoiesis via cytokine secretion and adhesion. We and others have recently reported that cytokines can mediate BCR/ABL-independent resistance to IM and Nilotinib (NI), a novel more potent BCR/ABL-kinase inhibitor (Wang Y et al, Blood 2007). Here we ask, whether IM controls the growth and changes cytokine secretion pattern of CML MSC, thereby potentially contributing to IM resistance development or persistence. In an attempt to address these questions, we isolated MSC of 4 healthy donors and 7 CML patients before and 3-12 months after commencing IM. IM potently inhibited not only proliferation of healthy donor bone marrow-derived MSC, but also CML MSC in both dose-dependent and time-dependent manners *in vitro* and NI exposure had a similar effect. Growth arrest occurred in G1 phase of the cell cycle and was associated with accumulation of the cyclin-dependent kinase (CDK) inhibitor p27kip1 and decrease of p45skp2, a negative regulator of p27kip1. Knocking down p27kip1 with a p27kip1 specific siRNA could partially overcome growth arrest by IM, indicating p27kip1 is not the only effector for the growth inhibition. Next, by scanning 120 cytokines in conditioned media made from MSC of the same CML patients before and after IM therapy via a cytokine antibody array, we found no impact of IM on differential cytokine secretion in CML MSC. Additionally, BCR/ABL positive cell line LAMA or K562 exhibited no apoptotic difference in conditioned media from MSC pre- and post-IM therapy in response to IM. However, both the conditioned media and co-cultivation between MSC and K562 could significantly prevent IM induced apoptosis of leukaemia cells, respectively, as compared with fresh culture medium, indicating that the interaction of MSC and leukaemia cells has the potential to regulate IM resistance/persistence. In summary, our data suggest that even though IM can reduce MSC pool in bone marrow, leading to decreased overall cytokines secretion, individual MSC after long term of IM treatment *in vivo* still possesses the same protection of leukemic cells nearby as the one before IM therapy due to unchanged cytokine secretion pattern and ability.

0331

WNT/β-CATENIN PATHWAY MODULATES MULTIPOTENCY OF HEMATOPOIETIC STEM/PROGENITOR CELLS REGULATING THE ACTIVITY OF VARIOUS ESSENTIAL TRANSCRIPTION FACTORS

H. Tanaka,[1] I. Matsumura,[2] K. Itoh,[3] T. Nakahata,[4] Y. Kanakura[2]

[1]Biomedical Research and Innovation, KOBE; [2]Osaka Univ.Grad. Sch.of Med., SUITA; [3]Institute of Biomedical Research and Inn, KOBE; [4]Grad. Sch. of Med. Kyoto Univ., KYOTO, Japan

Background. Wnt/β-catenin pathway has been well known as an important regulator of hematopoietic cell proliferation and differentiation. Purified Wnt3a that activates the canonical Wnt/β-catenin/TCF/LEF pathway was shown to expand murine and human hematopoietic stem/hematpoietic progenitor cells (HSC/HPCs) *ex vivo*. Also, it was reported that post transplantation treatment with an ATP-competitive GSK-3 inhibitor, which leads to activation of intrinsic β-catenin increases repopulation of HSCs *in vivo*. In this way, activation of Wnt/β-catenin pathway modulates the *in vitro* and *in vivo* self-renewal ability and mulitipotency of HSCs. However, the precise regulatory mechanisms have not been elucidated. *Aims.* In this study, we examined the effects of GSK-3 inhibitor 9 (6-bromoindirubin-3-oxime) (GI9) on the growth and differentiation of human HSC/ HPCs *in vitro*. *Methods*. Human umbilical cord blood (CB) was obtained at normal full-term deliveries after informed consent was given and CD34$^+$ HSC/HPCs were derived from CB using a MACS system. CD34$^+$ HSC/HPCs were cultured for 7 days in a serum-free medium containing with cytokines (SCF, FL, TPO, IL-6 and sIL-6R) and also with 2 μM ,10 μM of GI9, or vehicle (negative control; NC). After the culture, viable cell numbers, the distribution pattern of immunophenotype (CD34 and lineage specific markers), and the colony

forming ability were evaluated. *Results*. The expression and localization of β-catenin in CD34+ HSC/HPCs treated with GI9 was observed with confocal microscopy. After the treatment for 24 hrs, expression of β-catenin in NC cells was scarcely detected except for the membrane-bounded form, which constitutes the cytoskeleton. On the other hand, in GI9-treated cells, β-catenin accumulated in their nucleus in a dose dependent manner. These results suggested that GI9-treatment activates intrinsic β-catenin in human HSC/HPCs. After 7 days culture in a serum-free medium containing with cytokines, total viable cells and CD34+ cells were expanded 31.6±4.6 and 17.9±3.8 fold in NC cells, respectively (n=3). However, GI9-treatment could not maintain a proportion of CD34+ cells compared with NC and significantly caused the growth inhibition in a dose dependent manner. About 80% of expanded cells expressed myeloid marker, CD33 in our culture system, however, GI9-treatment perturbed myeloid differentiation of CD34+ HSC/HPCs but induced the differentiation toward to megakaryocyte and erythroid lineages. Furthermore, in methylcellulose assay, although expanded cells with GI9-treatment generated all types of progenitors, GI9-treatment was inferior significantly in terms of expansion rate of myeloid progenitor, CFU-GM and superior in formation of erythroid progenitor, BFU/CFU-E compared with NC (No. of CFU-GM/1000 cells 151±65.8 vs. 284±17.0, No. of BFU/CFU-E/1000 cells 132±18.5 vs. 32.7.±7.0, respectively) (p<0.05, n=3). As for this mechanism, we found that activated β-catenin suppresses the transcriptional activity of C/EBPα, which is essential transcription factor for granulocyte development, while it promotes the function of GATA1, essential transcription factor for megakaryocyte and erythrocyte development during the differentiation of HSC/HPCs. *Summary and Conclusions*. Wnt/β-catenin pathway was supposed to play an important role in multipotency of HSC/HPCs and control the balance of lineage commitment of HSC/HPCs, presumably by regulating the interaction with essential transcription factors.

ACUTE MYELOGENOUS LEUKEMIA CELLS CHANGE INTO FIBROBLAST CELLS MORPHOLOGICALLY AND FUNCTIONALLY DURING *IN VITRO* LONG-TERM CULTURE

H. Tashiro, M. Noguchi, R. Shirasaki, N. Shirafuji

Teikyo University School of Medicine, TOKYO, Japan

Introduction. Recently controversial results are reported on stromal cells generated from MDS patients' bone marrow, in which stromal fibroblasts are originated from normal clone or the abnormal MDS clone. We observed various kinds of de novo acute leukemia cells which were cultured long-term in liquid, and the generated stromal cells were characterized biologically and molecularly. *Materials and Methods.* Bone marrow cells or blood from patients with acute leukemia whose abnormal clones were identified with RT-PCR products for the translocated chimeric molecules, were separated with gravity sedimentation, and the obtained non-adherent mononuclear cells were cultured in DMEM with 10% FCS in the humidified 5% CO2 incubator. Morphological changes of the cultured cells were observed, and when cells were converted into stromal fibroblastoid cells, they were treated with tripsin, and re-cultured until whole cells became stromal cells. Then, cells were divided into sub clones in a 96-well plate and after culturing to be confluent, RNAs from each sub clone were extracted, cDNAs were synthesized, and RT-PCR was performed to select clones. When the abnormal translocation products, which were identified in the original leukemia blasts, were observed, the clones were examined on DNA levels with FISH or southern blotting, and when the clones were identified on DNA level, cells were characterized on their expression of cell-surface molecules, the activities on cytokine production and growth-promotion activities for the normal bone marrow-derived cells or leukemia blasts. *Results and Discussions.* Morphological changes into stromal fibroblastoid cells were observed in acute myelogenous leukemia cells except AML (M3), and acute biphenotypic leukemia cells, but not in acute lymphocytic leukemia cells. The fibroblastoid cells expressed the abnormal molecular translocation markers which were identified in the parental leukemia cells on RNA and DNA levels. The probability to identify the abnormal leukemia clones in the whole fibroblastoid sub clones was 2-56%. These fibroblastoid cells with leukemia markers expressed CD 106, fibronectin, smooth muscle actin and FSP1 which is expressed specifically in myofibroblasts not in macrophages. CD13, 33 and myeloperoxidase were also expressed which are the myeloid markers. CD34 and CD133 were expressed in these fibroblastoid cells, which are stem cell markers. These cells produced VEGF, IL-6 and G-CSF more than that produced by the normal bone marrow-derived fibroblast cells, and when leukemia blast cells were cultured onto the generated fibroblastoid cells, the proliferation activities were elevated significantly with 3H-thymidine incorporation assays. These data indicate that acute myeloid leukemia cells have the capacity to be changed into stromal fibroblastoid cells and create the microenvironment for the proliferation by themselves. Cancer stem cell hypothesis is that leukemia stem cells can have the activity for self-replication and abnormal differentiation as is observed in normal hematopoietic stem cells. Our observation suggests that leukemia stem cell may also produce the stromal microenvironment for the growth of leukemia stem cells.

INVOLVEMENT OF TNF-ALPHA IN LEUKAEMIA ONSET AND BONE MARROW TURNOVER

A.S. Cachaço,[1] A.C. Santos,[2] S. Dias[1]

[1]Portuguese Institute of Oncology, LISBON; [2]Pathologic Anatomy Inst., F. Medicine, LISBON, Portugal

Leukaemia is characterized by abnormal ratios of bone marrow cells from several hematopoietic lineages, meaning that normal tissue turnover is impaired in this situation. Bone marrow diseases have also been associated with an increase in bone marrow angiogenesis. It is known that changes in bone marrow microenvironment may lead to a loss of homeostasis; important players in this process may be cytokines and extracellular matrix (ECM) molecules present in the stroma of this organ. TNF-α is involved in bone marrow cell turnover, in normalcy and in disease, thus our study is focused on the functions of this cytokine in regulating cell apoptosis within the bone marrow microenvironment and also in regulating extracellular matrix (ECM) turnover. Whilst studying bone marrow recovery following sublethal irradiation, we observed that TNF-α undergoes significant variations, acutely increasing following irradiation, and decreasing to normal values 5 days after the stimulus. To understand the possible role of TNF-α in leukaemia development, we irradiated TNF-α knock-out (KO) and wild-type (wt) mice thrice (each irradiation was separated 1 month apart), a model that has been shown to result in leukaemia induction. From the five mice we irradiated from each genotype, four wt mice died 6-7 months after the last irradiation as a result of leukaemia, while in the KO group only one mouse succumbed to a possible bone marrow deficiency (although not overt leukaemia). FACS analysis of peripheral blood and bone marrows from the different mice, revealed that wt mice had increased endothelial progenitors and endothelial cells, suggesting that the vascular lineage was increased in these mice, following the irradiation schedules. In addition, the bone marrows of TNF-α KO mice were smaller in diameter, but after irradiation, while wt bone marrows undergo a notorious reduction, the KO bone marrows remain with more or less the same size, meaning that probably, the altered mice are more resistant to irradiation. KO bone marrow (irradiated and control) also exhibited increased megakaryocyte numbers, accompanied by a decrease in fibronectin and laminin levels, in irradiated KO mice. Another important observation is that irradiated wt mice, which developed a bone marrow disease phenotype, have increased bone marrow angiogenesis, which consisted of dilated blood vessels. Taken together, these results suggest that TNF-α plays a role in bone marrow homeostasis, which is more clearly linked with angiogenesis and ECM turnover. In KO mice, selective apoptosis may contribute to select leukaemia clones; in parallel, TNF-α is also crucial in modulating MMP activity and, as a result, its absence may contribute towards a global reduction in bone marrow MMP activity. Reduced MMPs may in turn lead to a reduced availability of ECM-bound VEGF, thus regulating bone marrow angiogenesis. Globally, our data point out for a crucial role of TNF-α in modulating bone marrow turnover and angiogenesis, which may contribute to leukaemia onset.

EXPRESSION OF SURFACE MARKERS INVOLVED IN CELL-CELL-INTERACTIONS, ADHESION AND ACTIVATION ON ENDOTHELIAL PROGENITOR CELLS

M. Satler, K. Klein, R. Koppensteiner, G.H. Schernthaner

Medical University Vienna, VIENNA, Austria

Background. Human peripheral blood contains bone-marrow derived progenitor cells which differentiate into mature endothelial cells (EC) and are thought to promote tumour neoangiogenesis as well as vascular homeostasis in adults. These endothelial progenitor cells (EPC) are characterized as CD34, CD133 and CD309 positive. However, phenotyping of circulating EPC *in vivo* still remains unclear and information about EPC function and factors that determine their cell-cell-interactions, homing and tissue distribution are scarce. *Aims.* We analysed the expression of ten surface markers on EPC involved in endothelial cell-

cell-interaction, adhesion and activation. To study EPC phenotype in health *in vivo*, two sources of cells were compared: naïve cells from umbilical cord blood and circulating cells out of peripheral blood from young, healthy adults. *Methods.* Classic Ficoll isolation was used to enrich mononuclear cells (MNC) from peripheral blood of twenty young healthy donors (between 20 and 30 years) and cord blood of twenty newborns. To identify EPC MNC were stained with monoclonal antibodies (mAb) against CD34, CD133 and CD309 and analysed by fluorescence activated cells sorting (FACS). In the same analysis tubes MNC and thereby EPC were stained with additional mAb against surface molecules involved in activation, adhesion, rolling and migration of leucocytes and mature EC. Therefore, MAbs used were: CD9, CD29, CD31, CD44, CD47, CD49, CD51/CD61, CD54, CD58, CD62e and CD63. *Results.* Expression of the β-1 integrin (CD29), Pgp-1 (CD44) and gp42 (CD47) on EPC did not differ between naïve cord blood from newborns and young healthy donors. PECAM-1 (CD31), which has been reported to be upregulated to nearly 100% in cardiovascular disease was only expressed of 53.7% on all EPC (donors and naïve did not differ), suggesting a non-activation state. Expression of MRP-1 (CD9) and LFA-3 (CD58) did significantly differ between the two cohorts: MRP-1: 81% versus 68%, and LFA-3: 34% versus 10% (donors versus naïve). Molecules reported to be expressed on mature EC and involved in activation, adhesion, rolling and migration like α-V-β-3 integrin (CD51/61), ICAM-1 (CD54), E-selectin (CD62e) and LIMP(CD63) could only be weakly detected on EPC (0-10%). *Summary and conclusions.* Significant difference of CD58 expression between donors and naïve cells might be attributed to an ongoing differentiation of circulating EPC as mature EC show an expression of CD58 up to 80%. Likewise, the upregulation of CD9 in donors versus naïve might resemble an increased proliferation potency of EPC since CD9 is likely under the regulation of the LIF/STAT3 pathway, which is critical for self-renewal of ES cells. The high expression of CD29, CD44 and CD47 may reflect the important role of these molecules in recruitment of EPC, which will be investigated in a future study. Low to not existing expression of CD51/61, CD54, CD62e and CD63 might lead to upregulation during e.g. acute ischemia. However, this cannot be proved from this data. Limitations of our study are the small sample size. Nevertheless, to our knowledge, this is a first report of EPC phenotyping in health *in vivo*.

IN VITRO CHARACTERIZATION OF CORD BLOOD MESENCHYMAL STROMAL CELLS (CB-MSC): IMMUNOMODULATORY PROPERTIES AND HAEMATOPOIESIS SUPPORTING ACTIVITY

L.D. Dorotea,[1] M. Gabelli,[2] E. Magro,[2] C. Messina,[1] R. Destro,[2] M.V. Gazzola[1]

[1]*Clinica di Oncoematologia Pediatrica, PADOVA;* [2]*Banca del Sangue di Cordone, PADOVA, Italy*

Introduction. In vitro studies and some encouraging clinical results have demonstrated that bone marrow derived MSC (BM-MSC) might play an important role in haematopoietic stem cells transplantation (HSCT), reducing Graft Versus Host Disease (GVHD) and improving haematopoietic engraftment. The aim of this study is to evaluate the immunomodulatory properties and the haematopoiesis supporting activity of CB-MSC in comparison with those of BM-MSC. *Material and Methods.* CB-MSC and BM-MSC were isolated by lineage-depletion negative immuno-selection (RosetteSep) and density gradient separation (Ficoll) respectively. Both sets of cells were cultured in aMEM with 20%FCS and 2 mM L-glutamine. CB derived CD34$^+$ haematopoietic progenitor cells (HPC) were isolated by positive immunoselection using the MidiMACS system. CD 34$^+$ cells were seeded on the MSC feeder layers at 40.000 cells/ml in RPMI medium+10%FCS and co-cultured for 12 days. Cytokine production in the culture supernatants was quantified by enzyme linked immunoadsorbent assay (ELISA) when cells achieved confluence after 3 passages, corresponding to the initial phase of their exponential growth. *Ex vivo* expanded CB and BM MSC were co-cultered with allogeneic lymphocytes (PBLs) to assess their capacity to elicit an immunoresponse. Moreover, CB and BM-MSC were added at different doses (105, 5×10^4, 104) to PBLs stimulated with Phytohaemagglutinin (PHA) and to Mixed Lymphocyte Cultures (MLC). Lymphocytes proliferation was measured by 3H-Thymidine incorporation. *Results*. CB and BM-MSC produced substantial amounts of SCF, IL-3, IL-6, TPO but almost undetectable Flt-3L. IL-6 production was significantly higher in BM-MSC cultures than in CB-MSC (p<0.05), whereas there was no statistical difference for SCF, IL-3 and TPO. Moreover, CB and BM-MSC supported ex-vivo expansion of HPC (2,0±0,3 and 2,3±0,5 NC fold expansion respectively) and their proliferation in CFU assay, whereas, as expected, CD34$^+$ cells alone were not able to grow in culture. CB-MSC did not induce T cell allo-response and they did inhibit mitogenic lymphocyte proliferation by PHA (48-88%) in a dose dependent manner (Figure 1a). Suppression of T cell proliferation was observed after the addition of different CB-MSC doses to MLC but, as shown in Figure 1b, CB-MSC seemed to have a less consistent inhibitory effect. *Conclusions.* Our experiments demonstrated that both CB and BM-MSC have the capacity to secrete some of the most important cytokines involved in expansion of HPC and show an interesting immunomodulatory capacity. Although further studies are needed to investigate more extensively their properties, CB-MSC could represent an alternative source of MSC for improving HSCT outcome.

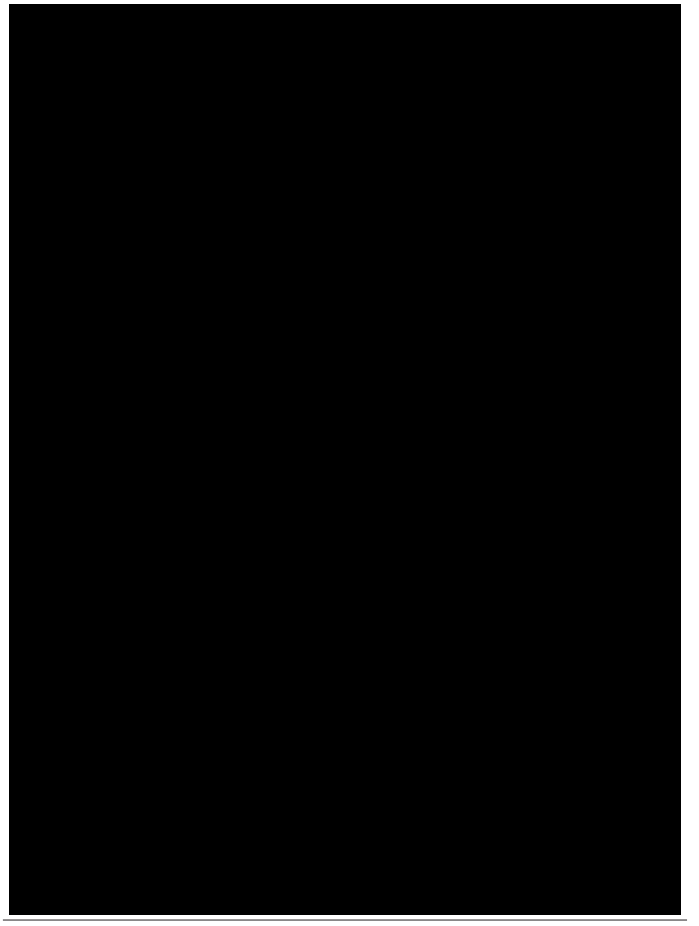

Figure 1. a) Effects of various amounts of CB and BM-MSC on PBL mitogenic stimulation. Data were expressed as percentage of the maximum proliferative response (A+PHA), mean±SEM.b) Effects of various amounts of CB and BM-MSC on MLCs. Data were expressed as percentage of the maximum proliferative response (A+B), mean±SEM.

CXCR4$^+$ CIRCULATING PROGENITOR CELLS COEXPRESSING MONOCYTIC AND ENDOTHELIAL MARKERS MAY BE INVOLVED IN THE PATHOGENESIS OF FIBROSIS IN SYSTEMIC SCLEROSIS

F. Lanza,[1] D. Campioni,[1] A. Lo Monaco,[2] S. Moretti,[1] L. Ferrari,[1] M. Fotinidi,[2] A. Lacorte,[2] F. Trotta,[2] A. Cuneo[1]

[1]*Hematology Section, FERRARA;* [2]*Rheumatology Unit, FERRARA, Italy*

Background. Although high level of circulating endothelial progenitor cells has been reported in patients affected by systemic sclerosis (SSc), there are ongoing controversies regarding the role played by circulating endothelial mature and progenitor cells (CECs/CEPs) in the pathogenesis of this disease. *Aims.* To better characterize the immunophenotype and the clonogenic potential of circulating progenitor cells (CPCs), CECs and CEPs in SSc. The presence of the various cell subsets are correlated to the disease activity score and the severity of pulmonary dysfunction. *Methods.* A multiparametric 4-color flow cytometric protocol, in combination with different progenitor cell replating assays, were used to

analyse peripheral blood specimens obtained from 40 patients (pts) with SSc, and 10 healthy subjects. Data were compared with patient's clinical features and serum levels of angiogenic factors (VEGF, PDGF, EGF, IGF and SDF-1 chemokine). *Results.* An increased number of viable (7-AADneg) $CD34^+/CD45^+/CD184^+$ (CXCR4) and $CD34^+/CD45^+/CD117^+$ (c-kit-R) CPCs subsets coexpressing endothelial and monocytic markers were detected in SSc, as compared with normal subjects. No circulating $CD45^-$ CEPs and CECs were observed. Clonogenic assays confirmed the differentiation of the CPCs towards hematopoietic-erythroid lineage (BFU-E) but not endothelial cells even after extensive culture expansion. Interestingly, in 27% of SSc patients, the *in vitro* presence of adherent endothelial-like cells, having a reduced adherent expansion capacity, with a spindle shaped morphology (SELC) that resulted positive for endothelial, and myelomonocytic markers, was observed. The presence of $CXCR4^+$CPC resulted correlated either to SDF-1 and VEGF serum level or to some clinical features related to a more fibrotic clinical subset of the disease, thus supporting a possible role of these cells in fibrosis. *Conclusions.* In SSc patients, the mobilization of endothelial-like $CXCR4^+$CPCs suggests an unreported contribution of the hematopoietic progenitor cells in the pathogenesis of the disease. Angiogenic factors could play a role in facilitating their organ homing and their perivascular positioning and retention. These findings could have clinical and biological implication, and may help in refining the sequence of the pathogenetic events in SSc .

0337

THE ANABOLIC EFFECTS OF STRONTIUM INCREASE THE NUMBER OF PROGENITOR BUT NOT PRIMITIVE HAEMOPOIETIC STEM CELLS

S. Lymperi, N. Horwood, A. Cope, F. Dazzi

Imperial College London, LONDON, United Kingdom

The regulation of haemopoietic stem cells (HSC) fate requires a specialized microenvironment in the bone marrow (BM) cavity called the HSC niche. Recent evidence indicates that osteoblasts (OB) are a key component of this niche, modulating HSC quiescent and proliferation. In this study the role of OB in the niche was further investigated by manipulating their activity with strontium (Sr); a substance that enhances osteoblast function and inhibits osteoclast activity *in vitro* and likewise stimulates bone formation and decreases bone resorption *in vivo*. Alizarin red S staining revealed that Sr promotes the mineralization of bone nodules in primary OB cultures. RT-PCR analysis demonstrated increased production of runx2 mRNA in primary OB cultures treated with Sr. Administration of Sr to mice resulted in elevated levels of serum osteocalcin measured by ELISA. Sr-treated mice showed increased bone volume, trabecular separation and trabecular thickness defined by micro-CT analysis. In regard to haemopoiesis CFU-C assay revealed increased numbers of haemopoietic progenitor cells in Sr-treated mice as compared to untreated control mice. However, no difference in the primitive HSC numbers was detected between the two groups evaluated by LTC-IC assay and by FACS analysis. When Sr-treated mice were used as donors in HSC transplantation experiments no difference in the HSC engraftment ability was observed. These results verify that Sr increases OB function and number both *in vitro* and *in vivo*. They also indicate that Sr affects an OB subset which interacts with more differentiated but no primitive HSC and that its effect on OB is not sufficient to increase the stem cell pool size or alter HSC function. In summary, this study underlines that although OB are indeed a key component of the niche, they cannot solely account for the regulation of primitive HSC numbers. In fact, a simple increase in OB number/activity is not enough to expand the stem cell pool size and other cell types may be required.

ANTI- PLASMINOGEN MONOCLONAL ANTIBODY(MC2B8) INHIBITES ANGIOGENESIS

Mansouri K,[1] Mirshahi M,[2] Pourfathollah A,[3] Hassan ZM,[3] Taheripak R[4]

[1]Ilam Medical Biology Research Center, University of Medical Sciences,ILam; [2]Biochemistry Departmet, Faculty of Science, Tarbiat Modarres University, Tehran; [3]Immunology Deparatment, Faculty of Medical Sciences,Tarbiat Modarres University,Tehran; [4]Haematology Deparatment, Faculty of Medical Scienes,Tarbiat Modarres University,Tehran ,Iran

*Abstract. Background.*Angiogenesis is a complex process during which of new blood vessels are produced from the pre-existing blood vessels. Formation and growth of new vessels play an important role in the physiologic process (embryonic growth, tissue repair) and pathologic process (tumor growth, inflammation) for surviving of the tissues. In fact, the development of tumors is depended upon new vessel formation through which the tumor is provided with nutrient and oxygen. *Aims.* In this research, the role of plasminogen conformation with MC2B8 mAb (an antibody directed against C-terminal part of plasminogen) in clot lysis and angiogenesis is observed. *Methods.* In experimental model of angiogenesis, beads, covered with endothelial cells of bone marrow capillaries, are the source of endothelial cells. It coated in three-dimensional structure to be provided through fibrin gel. Different titers of monoclonal antibody (30-480 μg/mL) MC2B8 were added in fibrin gel. *Results*. 3-5 days after culturing of endothelial cells, growth and migration was seen as the result of capillary formation MC2B8 mAb delayed clot lysis and inhibited angiogenesis at the concentration of 240 μg/mL.*Conclusions.*Our findings suggest that these effects on capillary tube formation and clot lysis caused blockage or conformational changes in plasminogen epitopes involved in angiogenesis and fibrinolysis.

0339

OUTCOMES OF THROMBOLYSIS FOR REPEATED COURSES OF SYSTEMIC TISSUE PLASMINOGEN ACTIVATOR FOR INTRAVASCULAR THROMBOSIS IN CHILDREN

C. Traivaree, L. Brandao, A.K. Chan, S. Williams

Hospital for Sick Children, TORONTO, Canada

Background. Systemic tissue plasminogen activator (tPA) has been used for treatment of life or limb-threatening intravascular thrombosis. Previous reports have varied in the rates of hemorrhagic complications. *Aims.* To summarize the outcome and safety of repeated courses of tPA thrombolysis for intravascular thrombus in the critical care unit at a single institution. *Methods.* Retrospective analysis of hospital records was completed for patients who received systemic tPA, according to institutional protocol over a 7 year period (1999-2006) at the Hospital for Sick Children, Toronto. *Results.* 51 patients received systemic tPA in doses of 0.1-0.6 mg/kg/hr for up to 6 hours per course. There were 82 courses of systemic tPA in 51 patients. Patients received from 1 to 4 courses of tPA. The indications for tPA were venous thrombi (n=63) and arterial thrombi (n=19). After the first course of tPA (n=51), there was complete resolution in (13/51) 25%, partial resolution in (17/51) 33%, no change in (20/51) 39% and progression in (1/51) 2%. After the second course of tPA (n=23), there was complete resolution in (11/23) 48%, partial resolution in (5/23) 22%, no change in (7/23) 30% and progression in (0/23) 0%. After the third course of tPA (n=6), there was complete resolution in (3/6) 50%, partial resolution in (2/6) 33%, no change in (0/6) 0% and progression in (1/6)17%. After the fourth course of tPA (n=2), there was complete resolution in (0/2) 0%, partial resolution in (1/2) 50%, no change in (0/2) 0% and progression in (1/2) 50%. Overall, major bleeding occurred in (4/82) 5%, minor bleeding in (11/82) 13% of the tPA courses. Major bleeding and minor bleeding occurred in 3/51 (6%) and 4/51 (8%) at first course, 1/23 (4%) and 6/23 (26%) at second course, 0/6 (0%) and 1/6 (17%) at third course respectively. No bleeds occurred with the fourth course. Bleeding complications were more frequent with arterial [(7/19), 37%] than venous clots [(8/63), 13%]. *Conclusions.* Repeated courses of systemic tPA therapy may improve complete resolution rates, and increase the risk of minor but not major bleeding. Bleeding complications may be more common with arterial thrombi than venous thrombi in children treated with tPA thrombolysis.

0340

ALTERED FIBRIN CLOT STRUCTURE IN PATIENTS WITH ISCHEMIC STROKE ASSOCIATED WITH FORAMEN OVALE

K. Zawilska,[1] A. Undas,[2] P. Podolec,[2] M. Pieculewicz,[2] E. Stepien,[2] I. Jedlinski,[3] M. Duszynska,[3] E. Hanschke[1]

[1]University of Medical Sciences of Poznan, POZNAN; [2]Jagiellonian University, KRAKOW; 3J.Strus Hospital, POZNAN, Poland

Background. A patent foramen ovale (PFO) has been implicated with embolic stroke. The mechanism underlying this association remains elusive. Dense fibrin clot structure, resistant to fibrinolysis, has been found to be related to thromboembolic complications of coronary artery disease. *Aims.* to test the hypothesis that altered fibrin clot architecture might characterize individuals with stroke associated with PFO. *Materials and Methods.* 62 patients (22 M, 40 F; mean age 40.5 [SD 13.7] years) with documented PFO, divided into two groups based on the presence of documented ischemic stroke or not (S^+ and S^-). Forty-two age- and sex-matched apparently healthy individuals served as controls (n=42). Plasma fibrin clot permeability (expressed as Ks, a measure of the pore size), turbidity (lag phase and maximum absorbancy [max Abs]) and tissue plasminogen activator (tPA)-induced fibrinolysis efficiency (expressed as lysis time in a turbidimetric assay and maximum D-dimer levels, along with their maximum rate of increase in a pressure-driven clot system) were determined. Genotyping for the factor (F)XIII Val34Leu and fibrinogen α chain Thr312Ala polymorphisms was performed. *Results.* In the S^+ group, clot permeability was lower compared with the S- group (median [IQR], Ks, 9.3 [1.4] vs 10.5 [1.3]$\times 10^{-9}$ cm^2; $p<0.0001$), while clot lysis was prolonged (8.45 [3] vs 7.1 [1] min;$p<0.0001$). Maximum absorbancy was higher and the lag phase shorter in the S+ group than in the S^- group (0.865 [0.07] vs 0.7 [0.065]; $p<0.0001$, and 35.5 [2.6] vs 47 [5] seconds; $p<0.0001$, respectively). Maximum D-dimer levels, measured at 120 min before the clot collapse in the S^+ group, were elevated compared with those in the S^- group (3.67 [0.14] vs 3.36 [0.13] mg/L; $p<0.0001$, respectively). Maximum rate of increase in D-dimer levels were also higher in the former group (0.081[0.008] vs 0.069 [0.0085] mg/L/min;$p<0.0001$, respectively). Variables describing clot properties in the S^- group were similar to those obtained in healthy controls with the exception of decreased rate of D-dimer increase in the former group ($p=0.01$). Genetic analysis showed no difference in the genotype frequencies among all the groups. After adjustment for fibrinogen levels, Ks, turbidity variables and lysis time remained significantly different between the S^+ group and both S^- group and healthy controls. *Conclusions.*decreased permeability of fibrin clots, composed of thicker fibers, and their relative resistance to fibrinolysis observed in subjects with PFO who experienced stroke, may represent a novel mechanism that might explain why only a small percentage of individuals with PFO suffer from thromboembolic complications.

0341

THE RISK OF PREGNANCY-RELATED VENOUS THROMBOEMBOLISM IN DOUBLE CARRIERS OF FACTOR V LEIDEN AND PROTHROMBIN G20210A

T. Battaglioli,[1] V. De Stefano,[2] D. Tormene,[3] L. Valdré,[4] E. Grandone,[5] A. Tosetto,[6] I. Martinelli[1]

[1]IRCCS Maggiore Hospital, MILAN; [2]Catholic University, ROME; [3]University of Padua Medical School, PADUA; [4]S. Orsola-Malpighi University Hospital, BOLOGNA; [5]IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO (FOGGIA); [6]San Bortolo Hospital, VICENZA, Italy

Background. The rate of venous thromboembolism (VTE) during pregnancy in double heterozygotes for factor V Leiden (FVL) and prothrombin G20210A (PT) is not established. The optimal management of these women in terms of antithrombotic prophylaxis is unknown. *Aims.* To assess the rate of VTE in double heterozygotes for FVL and PT during pregnancy. *Methods.* The source population were relatives of probands with VTE, who remained pregnant at least once before diagnosis of thrombophilia. Fifty-two double heterozygotes were compared to 104 single heterozygotes for FVL and 104 for PT. The rate of VTE during pregnancy and puerperium was recorded. *Results.* Double heterozygotes had 135 pregnancies, FVL 208 and PT 216. Double heterozygotes had a median age (range) at blood sampling of 50y (22-78), at first pregnancy of 24y (12-36); the median number (range) of pregnancies was 3 (1-8) with a rate of pregnancy loss of 20%. Single heterozygotes had similar characteristics. No VTE occurred in pregnancy. VTE was observed in 2% of puerperia (4% of women) in double heterozygotes, 3% (7%) in single FVL and 4% (9%) in single PT (p=ns). No double heterozygote, 43% of single FVL and 78% of single PT were primiparous at the time of thrombosis. *Conclusions.* The risk of first VTE during pregnancy and puerperium in double heterozygotes of FVL and PT is not different from that of single heterozygotes. As for single heterozygotes, antithrombotic prophylaxis during pregnancy does not appear to be justified in double heterozygotes.

0342

INTRACARDIAC THROMBOSIS IN CHILDREN

N. Ozbek, B. Alioglu, B. Atac, Z. Avci, B. Malbora, K. Tokel

Baskent University, Faculty of Medicine, ANKARA, Turkey

Background. Intracardiac thrombosis (ICT) in children is rare. It usually associates with congenital heart disorders (CHD), central venous catheters (CVC), surgery, and infections. *Aims.*We aimed to investigate clinical and laboratory findings, risk factors, and treatment of children with ICT. *Methods.*Clinical and laboratory characteristics of 35 children with ICT who followed in our hospital from January 1997 to May 2006 were retrospectively investigated from their files. *Results.* During study period, a total of 122 patients diagnosed with thrombosis. Among them, 35 (28,7%; mean age 5.4) had intracardiac thrombosis. Most of the patients (n=23) were above 1 year of age (p=0,04, OR=4,8). 31 patients had ICT on one anatomic site and 4 patients on more than one site. Twelve patients also had extracardiac site thrombosis. Congenital heart disease (CHD) was the most frequent associated factor (19 patients;10 cyanotic and 9 acyanotic; p=0.008, OR=8.8). Acquired risk factors were present in 30 patients; CVC in 21 patients (p=0.023, OR=5.4); infection in 16 patients (p=0.042, OR=3.1), corrective surgery in 10 patients (p=0.027, OR=5.8) and cardiac catheterization in 8 patients (p=0.022, OR=6.8). When we investigated the presence of some thrombophilic mutations [Factor V Leiden (FVL), methylene tetrahydrofolate reductase 677C-T, and prothrombin 2021 G-A], 13 patients had one and 2 patients had 2 mutations. Among them, 8 patients had FVL mutation (25%) and this percentage was higher than those obtained in the normal Turkish population (7-9%). 16 patients were treated with thrombolitic agents (11 with t-PA, 5 with streptokinase) and 7 with surgical embolectomy. *Conclusions.* In our study, we found close relation between ICT and congenital (FVL) and acquired risk factors. We suggest close monitoring and effective anticoagulation in these patients in order to prevent ICT.

0343

COMPARISON OF HEMOSIL HOMOCYSTEINE ASSAY WITH ABBOTT IMX IMMUNOASSAY FOR MEASUREMENT OF PLASMA TOTAL HOMOCYSTEINE

M. Cattaneo, M.L. Zighetti

Ospedale San Paolo, Università di Milano, MILANO, Italy

Background. The demonstration of an association of hyper homocysteinemia with heightened risk of thrombosis lead to increasing demand for measurement of plasma total homocysteine (tHcy) in clinical laboratories. Since patients at risk of thrombosis are often screened for hemostasis abnormalities that are associated with thrombophilic states, it would be very useful to measure tHcy using the same blood sample and the same instrument that are used for hemostasis screening. *Aims.* The aim of our study was to compare the performance of HemosIL™ Homocysteine assay of tHcy on the ACL 9000 coagulometer (Instrumentation Laboratory) to that of an established immunoassay for plasma tHcy measurement (Abbott IMx Immunoassay). *Methods.* Blood samples from 64 fasting patients with previous venous and/or arterial thrombosis and 12 fasting healthy controls were collected in 10.9 mM sodium citrate (HemosIL™ Homocysteine), and in EDTA (Abbott IMx immunoassay). All samples were immediately placed on ice and centrifuged at 2200xg at 4°C for 20 min; the supernatant plasma was stored at -80° C until assay. Plasma samples were reduced with dithiothreitol and incubated with S-adenosyl homocysteine (SAH) hydrolase in the presence of excess adenosine, to convert Hcy into SAH. In both assays, sample and SAH tracer interact with a specific monoclonal antibody. Detection of SAH is based on fluorescence polarization immunoassay (Abbott IMx Immunoassay) or agglutination of SAH/latex particles (HemosIL™ Homocysteine): the concentration of tHcy in plasma samples is inversely related to the intensity of polarized light or the intensity of light transmission. *Results.* The inter-run CV of HemosIL™ Homocysteine was 3.83 for a 18.8 μM tHcy sample and 3.95 for a 9.9 μM tHcy sample (n=10). The concentration of tHcy in tested samples ranged between 4.8 and 60 μM. The correlation between measurements obtained by Abbott IMx Immunoassay and HemosIL™ Homocysteine was very good (r=0.9915). Values of plasma tHcy tended to be slightly lower when

tested with HemosIL™ Homocysteine (y=0.8292x+0.3503). Since blood samples for HemosIL™ Homocysteine assay are collected in 1/10 (v/v) sodium citrate, the observed discrepancy could be due to dilution of blood sample by citrate. After correction for dilution factor, the regression line between the two measurements was almost superimposable to the identity line (y=0.9711x + 0.4135). *Summary and Conclusions.* The HemosIL™ Homocysteine assay for tHcy on ACL 9000 compares well with the established Abbott IMx immunoassay and can be used for routine measurement of plasma tHcy, especially in subjects who undergo screening for abnormalities of hemostasis that are associated with thrombophilic states. As expected, a proportional bias, due to different plasma dilutions between the EDTA and citrated samples (pendent 0.8292), was corrected applying the appropriate volume correction factor (pendent 0.9708).

0344

ROLE OF THE PAI-1 GENE 4G/5G POLYMORPHISM ON PAI-1 LEVEL AND RELATIONS AMONG PAI-1, TNFα AND TGFβ LEVELS IN OBESE CHILDREN

N. Ozbek, S. Tulgar Kinik, B. Atac, M. Yüce, A.C. Yazici, H. Verdi

Baskent University, Faculty of Medicine, ANKARA, Turkey

Objective. Obesity is a metabolic disorder that is associated with changes of plasminogen activator inhibitor-1 (PAI-1), tumor necrosis factor-alpha (TNFα) and transforming growth factor beta (TGFβ) levels. These changes are related to insulin resistance, dyslipidemia and cardiovascular disease. However the precise effect of the PAI-1 gene 4G allele is still contradictory. *Aims.* In this study we aimed to elucidate the role of the 4G/5G polymorphism of PAI-1 gene on PAI-1 level and determine the associations between cytokines α (TNFα and TGFβ), glucose and lipid metabolism parameters in Turkish obese children. *Methods.* Thirty nine obese children [12 male and 27 female; mean age of 11.4±3.3 (5.9-17.4) years] and 38 age-matched healthy control group [(19 male and 19 female; mean age of 10.3±3,5 (4.7-17.0) years] were included in the study. In all cases, serum levels of glucose, lipid and insulin were measured, homeostasis model assessment of insulin resistance (HOMA-IR) was calculated, and 4G/5G polymorphism of PAI-1 gene, plasma PAI-1 level and serum TNFα and TGFβ levels were studied. *Results.* The mean of relative body mass index (BMI) and HOMA-IR score VLDL, TG, insulin, PAI-1, TNFα levels were higher and HDL and TGFβ levels were lower in obese group. The frequency of the PAI-1 gene 4G/4G genotype was considerably higher in obese children than in controls. There was a significant interaction between groups and genotypes with regard to PAI-1 levels in obese children (p<0.001). However, PAI-1 genotype had no effect on PAI-1 level in healthy-lean children. Also, a positive correlation was found between PAI-1 and TNFα levels, and relative BMI, HOMA-IR score, insulin, TG, HDL levels. TGFβ was inversely correlated only with relative BMI. There was no correlation among three cytokines. *Conclusions.* From these results, we hypothesized that genetic background might play an important role having adiposity. Besides genetic background, cytokine disturbances such as elevated PAI-1 and TNFα originated from increased adipose tissue may be associated with metabolic disorders such as insulin resistance and dyslipidemia. Since these are not true for lean children, we conclude obesity should be treated as early as possible.

0345

THROMBOSIS IN CHILDREN WITH CARDIAC PATHOLOGY: ANALYSIS OF ACQUIRED AND INHERITED RISK FACTORS

N. Ozbek, B. Alioglu, B. Atac, Z. Avci, B. Malbora, K. Tokel

Baskent University, Faculty of Medicine, ANKARA, Turkey

Background. Thrombosis is one of the most frequent secondary complications seen in children treated for major primary illnesses. Several cardiac disorders are associated with thrombosis in children, including congenital heart diseases (CHD), cardiomyopathy (CMP), intracardiac defects, cardiac procedures, and acquired heart disease. *Aims.* In this retrospective study, we aimed to investigate the association between thrombosis and genetic and acquired risk factors in children with CHD or CMP during January 1997-May 2006. *Methods.* Clinical and laboratory characteristics of children with cardiac pathology (CHD or CMP) and thrombosis were retrospectively investigated from their files. *Results.* There were 58 children who had CHD (n=54) or CMP (n=5) and thrombosis (mean age 3.5 years). During study period, thrombosis incidence in patients with cardiac pathology (CHD or CMP) was calculated at 205/10,000 whereas the incidence of thrombosis in all hospitalized patients aged 0-18 years was 88.6/10,000. Thirty-two patients had cyanotic CHD, 22 patients had acyanotic CHD. Thirty-one (52.5%) children had venous system, twenty-one (35.6%) children had arterial system thrombosis, and 7 (11.9%) children had both. Eighty-one major anatomic thrombosis sites were detected in the enrolled study. Fourty children (67.8%) had one and 22 children had more than one anatomic site involved in thrombosis. The presence of CHD was significant risk factor for the development of intracardiac thrombosis (p=0.022, OR=6.3), and central nervous system thrombosis (p=0.020, OR=8.9). The presence of pulmonary stenosis (p=0.047, OR=8.3) and aort coarctation (p=0.004, OR=11) were significant risk factors for the development of peripheral arterial system thrombosis. Acquired risk factors were identified in 49 of the 59 patients (p=0.000, OR=20), including major surgery (p=0.000, OR=13 for all surgical interventions; p=0.045, OR=3.4 for corrective surgery of Tetralogy of Fallot; p=0.007, OR=6.7 for Blalock Taussig shunt operation), systemic infection (p=0.04, OR=1.9), cardiac catheterization (p=0.000, OR=60), central venous catheter, and hypoxia. Many patients had more than one of these acquired risk factor (n=33, p=0.000, OR=4.7). Also, polycytemia was identified significant risk factor for thrombosis in patients with Tetralogy of Fallot (p=0.001, OR=21.8). One patient had protein C and another had combined PC and PS deficiency. Fifty-two of 59 patients were analyzed for 3 thrombophilic mutations; Factor V Leiden, methylene tetrahydrofolate reductase 677C-T, and prothrombin 20210G-A. Twenty-three of these patients had at least one of these thrombophilic mutations. *Conclusions.* In summary, the data presented here underline the multifactorial cause of symptomatic thrombotic events in children with cardiac pathology. Further multicenter studies are needed to clarify in an evidence-based model the unanswered questions, eg, rate of recurrence, thrombosis locations, involvement of prothrombotic risk factors, underlying clinical conditions, and the preventive use of different treatment modalities.

0346

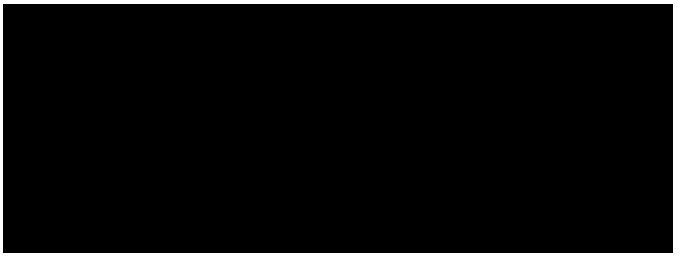
HEMOSTATIC FACTORS AND MORTALITY IN SEVERE SEPSIS

O. Gutiérrez Pérez,[1] A. Muriel,[2] A. Silvestre,[3] A. Cantalapiedra,[3] P. Martín,[4] J. Tortosa,[3] J. Blanco,[2] L.J. García Frade[3]

[1]Hospital Universitario Rio Hortega, VALLADOLID; [2]Intensive Care Unit. H.U. Rio Hortega, VALLADOLID; [3]Hematology. H.U. Rio Hortega, VALLADOLID; [4]Statistics, VALLADOLID, Spain

Background. Sepsis often is complicated by disseminated intravascular coagulation, related to severity of the disease. The aim of this study is to evaluate the dynamics and magnitude of hypercoagulability and fibrinolysis plasma markers in severe sepsis and its relation to global mortality. *Methods.* 2619 patients in 14 intensive care units were studied at admission for severe sepsis. 324 episodes in 311 septic patients were included during a 6 months period, according to definition of ACCP Consensus Conference 1992. The coagulation state was assessed by measurements of thrombin-antithrombin complexes (TAT) and Protein C (PC). The fibrinolytic system was assessed by the measurement of plasmin-antiplasmin complexes (PAP) and plasminogen-activator inhibitor type 1 (PAI-1). All the assays were performed using an enzyme linked immuno-assay method (ELISA). Samples were collected at diagnosis, and on 3rd and 7th days since the first episode of severe sepsis in a sample of 145 patients. A control group of 100 normal plasma samples was used. Statistics were analyzed using the non-parametric Mann-Whitney test. *Results.* There was an increased procoagulant response, with high values of TAT and an increased fibrinolytic response measured as PAP related to controls (p<0,001). We also found at diagnosis very low levels of anticoagulant Protein C and very high plasma concentration of fibrinolytic inhibitor PAI-1 (p<0,001). The severity of the disseminated intravascular coagulation decreased during 3rd and 7th days after treatment. Non survivors had higher values of PAI-1 (p=0,018) and lower levels of protein C (p=0,024) related to survivors. (Table 1).

Table 1. Median values at diagnosis.



Conclusions. This study demonstrates a marked prothrombotic status in severe sepsis, with hypercoagulability and impaired fibrinolytic response. The prognosis in severe sepsis is related with the magnitude of PAI-1 and Protein C at diagnosis.

0347

THE ANGIOTENSIN-CONVERTING ENZYME INSERTION/DELETION POLYMORPHISM AND SERUM LEVELS OF ANGIOTENSIN-CONVERTING ENZYME IN VENOUS THROMBOEMBOLISM: DATA FROM A CASE-CONTROL STUDY

C. Ay,[1] P. Bencur,[1] R. Vormittag,[1] T. Sailer,[1] C. Jungbauer,[2] T. Vukovich,[1] M. Mannhalter,[1] I. Pabinger[1]

[1]Medical University Vienna, VIENNA; [2]Austrian Red Cross, VIENNA, Austria

Background. The angiotensin-converting enzyme (ACE) has been suggested to affect blood coagulation and fibrinolysis. Results from literature on the role of the frequent insertion/deletion (I/D) polymorphism in the ACE gene in venous thromboembolism (VTE) are controversial. Only limited data on ACE serum levels in VTE exist. *Aims.* The purpose of our present study was to investigate the association of the ACE I/D polymorphism and of ACE serum levels in a population of selected patients with VTE. *Methods.* We determined the ACE I/D polymorphism by genotyping and ACE serum levels by an enzymatic assay in 100 high risk patients (45 female/55 male; mean age ±SD: 55 ±12 years) with objectively confirmed recurrent VTE and at least one event of an unprovoked deep venous thrombosis or pulmonary embolism. One-hundred-twenty-five age- and sex-matched healthy individuals (64 female/ 61 male; mean age ±SD: 53 ±11 years) served as controls. *Results.* ACE genotype frequencies were not significantly different between patients (DD: 26.0%, ID: 52.0%, II: 22.0%) and controls (DD: 29.6%, ID: 44.8%, II: 25.6%; p=0.56). Neither individuals with ACE DD genotype nor those with ACE ID genotype had a higher risk for VTE in comparison to those with ACE II genotype (odds ratio and [95% confidence interval]: 1.0 [0.5-2.1] and 1.4 [0.7-2.6], respectively). Serum ACE levels (U/l) did not differ between patients (median [25th -75th percentile]: 25.25 [20.20-33.70]) and controls (24.20 [17.85-34.50], p=0.49). In the total population involved in the study the ACE DD genotype (n=63: 36.00 [26.40-43.00]) was associated with higher ACE levels than the ACE ID genotype (n=108: 24.10 [19.80-31.48], p<0.001) and the ACE II genotype (n=54: 19.35 [15.00-22.95], p<0.001). *Summary and Conclusions.* We found a significant association of the ACE I/D polymorphism with ACE serum levels. However, neither the serum levels nor the I/D genotype were associated with VTE.

0348

NON ADHERENCE TO DOSING GUIDELINES FOR LMWH IN RENAL IMPAIRMENT LEADS TO A HIGH INCIDENCE OF SIGNIFICANT BLEEDING EVENTS - RESULTS OF A PROSPECTIVE AUDIT

W. Marshall,[1] A. Cole,[2] J. Smyth,[1] M. El-Agnaf[2]

[1]Ulster Hospital, BELFAST; [2]Haematology Department, Ulster Hospital, BELFAST, United Kingdom

Background. Recently Guidelines have been developed for dose reduction in LMWHs in the treatment of patients with renal impairment. Following a number of significant bleeding events related to LMWH (Enoxaparin) usage in Medical admissions to this hospital we prospectively audited Enoxaparin usage in patients with renal impairment and the incidence of adverse events over a three month period. All patients included were receiving therapeutic doses of Enoxaparin for the treatment of thromboembolic events or ischaemic heart disease. *Aims.* To determine adherence or otherwise to LMWH prescribing guidelines in patients with renal impairment. *Methods*. Estimated GFR (eGFR) was calculated using the 4 variable MDRD formula. 20 patients with an eGFR <30 mL/min/1.73m^2 who were commenced on a therapeutic dose of Enoxaparin over the three month period were included. Patients were assessed as to whether they were weighed prior to commencing treatment and if Enoxaparin dose was reduced appropriately as per established guidelines. The number of adverse bleeding events was recorded. Antifactor Xa levels were measured on each patient. Concurrent anitplatelet drug usage was also recorded. *Results.* The mean age of the 20 patients included (9 male, 11 female) was 75. 15/20 (75%) patients were incorrectly prescribed a higher initial dose than appropriate based on their weight and renal function. Of these patients 5/15 (33%) developed significant GI haemorrhage. 1 patient developed a haematoma at the injection site. Of the 6 patients who developed bleeding complications 5 had therapeutic Antifactor Xa levels and only one had an elevated level > 1u/mL. 11/20 (55%) patients were commenced on initial treatment without a recorded weight. *Conclusions*. Failure to record weight and to appreciate renal impairment can lead to excessively high dosing of LMWHs in patients admitted to general medical and cardiology wards. Renal function frequently changes over the duration of medical admissions and the dose of LMWHs should be reviewed daily and altered accordingly in order to avoid serious complications. Routine measurement of Antifactor Xa does not identify patients at risk of bleeding and should not be routinely measured.

0349

PREGNANCY OUTCOME IN WOMEN WITH THE LUPUS ANTICOAGULANT AND A HISTORY OF THROMBOEMBOLISM

G. Alguel,[1] G. Kostova,[2] S. Koder,[1] R. Vormittag,[1] R. Simanek,[1] C. Kurz,[1] I. Pabinger[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]University Clinical Center, SKOPJE, Macedonia

Background. Scarce data are available on the pregnancy outcome in patients with the lupus anticoagulant (LA) and a history of TE. The aim of this study was to evaluate the outcome of pregnancy in a cohort of women with persistent LA and previous TE. *Aims.* To evaluate the pregnancy outcome in women with the lupus anticoagulant and a history of thromboembolism (TE). *Methods*.This is a report from an ongoing observational study in which patients with LA are prospectively followed. Criteria for inclusion into the present evaluation was persistent LA before onset of pregnancy and previous TE. *Results*. Nine women (age m=32 years) had 12 pregnancies, five of these had a history of pregnancy complications (3 abortion, 1 stillbirth and 1 HELLP). Patients received a combination of low molecular weight heparin (LMWH, median 71 U/kg/day, range 41-114 antiXa U) and aspirin 100 mg) during 8 pregnancies, only LMWH (82 and 75 U/kg/day) and danaparoid (26 antiXa U) and aspirin during 2 pregnancies, respectively. Pregnancy outcome was favourable with a viable infant in 10 pregnancies born at a median of 34 weeks of gestation (range 28-40), 7/10 pregnancies ended prematurely. There was 1 abortion (6th week), 1 preeclampsia and stillbirth (27th week) and 1 HELLP-syndrome (34th week). The mean weight of viable infants was 2665g (range 700-3950 g). In one woman a post-partum pulmonary embolism occurred. *Conclusions*. The outcome of pregnancy was favourable in most pregnancies, the risk for pregnancy-associated recurrent TE events seems to be low with the applied treatment regimen. However, despite anticoagulant treatment pregnancy ended prematurely in most patients. Women should be closely followed for signs of fetal growth retardation, preeclampsia and HELLP-syndrome.

Table 1. Table of positive JAK2-V617F DNA samples.

0350

JAK2-V617F MUTATION IS PRESENT IN PATIENTS WITH IDIOPATHIC DVT

M.N. Lauw,[1] E.B. Bus,[2] A.F.Y. van Wulfften Palthe,[1] C.H. Homburg,[2] M. Coppens,[1] S. Middeldorp,[1] C.E. van der Schoot,[2] H.R. Koene[1]

[1]Academic Medical Center, AMSTERDAM; [2]Sanquin Research at CLB, AMSTERDAM, Netherlands

Background. In 30% of patients with venous thrombo-embolism (VTE), no environmental or genetic risk factors can be identified. A mutation in the JAK2 gene is present in 60-97% of patients with polycythemia vera (PV) and is considered the cause for the disease phenotype. The muta-

tion is probably absent in the healthy population. *Aims.* Since PV-patients are at increased risk for VTE, we set out to investigate whether the JAK2-V617F mutation constitutes a risk factor for VTE in non-PV patients. *Methods.* The presence of the JAK2-V617F mutation was retrospectively assessed in 188 consecutive patients with objectively diagnosed deep venous thrombosis (DVT), using a quantitative ASO Taqman PCR. Clinical parameters of mutation-positive patients at the time of DVT were analyzed. *Results.* Of the 188 samples, 180 (96%) were evaluable. A positive signal was observed in 6 VTE patients (3.3%). Quantitative analysis revealed that between 0.12 and 1.0% of cells were JAK2-V617F positive. Sensitive measurement of samples from age-matched healthy blood bank donors is currently being performed and will be presented at the meeting. *Conclusions.* We found the JAK2-V617F mutation in 3.3% (95%CI 1.5-7.0) of DVT patients, who did not fulfill diagnostic PV criteria. It is possible that in these patients DVT is a first symptom of a myeloproliferative syndrome. Investigation in an appropriate control group will determine the strength of this relationship.

0351

A PROPOSAL OF SCORING SYSTEM IN ASSESSMENT OF THROMBOTIC RISK IN CANCER PATIENT. A MONOCENTRIC STUDY

G. Giordano, G. Farina, R. Tambaro, M. Specchia, S. Papini, M. Piunno, C. Antonelli, B. Zappacosta, S. Storti

UCSC Campobasso, CAMPOBASSO, Italy

Background. Deep venous thrombosis (DVT) is present in about 3-15% of cancer patient. Paraneoplastic thrombosis pathogenesis is multifactorial. Antithrombotic prophylaxis frequently is not oriented to real thrombotic or haemorragic risk of patient. *Aims.* Aim of our study is to define the real thrombotic risk in neoplastic patient. With this purpose we considered in our patient complement fraction C3 and C4 and immune circulating complex (ICC) because they activate macrophage and platelets and increase tissue factor level. Moreover we recognize also total cholesterol and triglycerides level, because they are linked with factor VII activation. *Methods.* We considered C3, C4, ICC, cholesterol and triglycerides level in 92 patients with solid neoplasm (52 colon, 20 lung, 10 gastric, 10 others) and without anticoagulant prophilaxis. Of these only 76 were evaluable because in these complete data were available. Median age was 67.5 years (R 57-83). M/F ratio was 55/37. The threshold value of third quartile was chosen as risk cut-off (C3: 130 mg/dL; C4: 32 mg/dl; ICC: 2.9 mcg/mL; total cholesterol: 205 mg/dL; triglycerides 123 mg/dL). We elaborate a scoring system in which 1 point was attributed to each value inferior to third quartile. The statistical analysis was conducted with Yates corrected chi square test, Odds Ratio (OR), realtive risk (RR). *Results.* 15 patients (16%) showed DVT. Of these 12(80%) had a score inferior/equal to 3 and 3 superior/equal to 4. 77 patients (84%) did not show DVT. Of these 35 (46%) had a score superior/equal to 4 and 26 inferior/equal to 3. Yates corrected chi square test is 5.1 (p 0.02), with an OR of 5.4 (95%CI 1.4-21) and a RR of 4 (95%CI 1.2-13). Negative predictive value is 0.57 (95%CI 0.52-0.60) and positive predictive value is 0.80 (95%CI 57-93). Sensitivity was 0.32 (95%CI 0.23-0.37) and specificity was 0.92 (95%CI 0.83-0.97). *Summary and conclusions*. Neoplastic patient frequently shows haemorragic risk (eg in chemotherapy induced thrombocytopenia). Therefore antithrombotic prophylaxis should be used considering the effective thrombotic and haemorragic risk of neoplastic patient. Our scoring system is useful in distinguishing cancer patient with low thrombotic risk and consent to avoid antithrombotic prophylaxis in patient with higher bleeding and lower thombotic risk. Nevertheless these data need confirmation on a larger cohort of patients.

0352

PLASMA THROMBOMODULIN: A POTENTIAL MARKER FOR PRE-ECLAMPSIA

B. Lwaleed,[1] L. Dusse,[2] M. Carvalho,[2] D. Voegeli,[3] A. Cooper,[4] B. Lwaleed[3]

[1]Southampton University Hospitals NHS Tru, SOUTHAMPTON, United Kingdom; [2]Federal University of Minas Gerais, MINAS GERAIS, Brazil; [3]University of Southampton, SOUTHAMPTON, United Kingdom; [4]Portsmouth University, PORTSMOUTH, United Kingdom

Background. Thrombomodulin (TM) is an endothelial cell membrane glycoprotein which functions as a thrombin receptor. The thrombin-thrombomodulin complex initiates the protein C anticoagulant pathway. It activates protein C rapidly which together with protein S can inactivate factor Va and factor VIIIa. Pre-eclampsia (P-Ec) is a complex multisystem disorder characterized by hypertension, proteinuria and edema. It occurs after the 20th week of pregnancy. P-Ec has no cure, except by pregnancy interruption. In more severe cases, conditions such as eclampsia and HELLP syndrome (hemolysis, elevated liver enzyme, low platelets) or DIC (disseminated intravascular coagulation) may develop. *Aims.* To quantify plasma TM levels in pre-eclamptic women and compare these to the plasma TM levels in non-pregnant women and healthy pregnant women. *Methods.* Plasma TM levels were measured using an enzyme-linked immunosorbent assay (ELISA). A total of 57 subjects were studied. These include non-pregnant women (n=22), healthy pregnant women (n=15), and pre-eclamptic women (n=20), at the third trimester. *Results.* The mean and standard deviation (mean±SD) for the three groups were: non pregnant women (0.609±0.311), healthy pregnant women (0.692±0.267) and pre-eclamptic women (0.917±0.324). Plasma TM levels showed a statistically significant difference when women with pre-eclampsia were compared to the non-pregnant women group ($p<0.05$). However, we observed no significant difference when the pre-eclamptic women group was compared with the pregnant women group. *Conclusions.* Plasma TM levels are significantly elevated in women with pre-eclampsia. Endothelial cell injury and/or inflammatory reaction could have resulted in the increased plasma TM levels seen in our study. This finding may have a significant clinical ramification in the management of such patients. Detailed studies are required to address such an important relationship further.

0353

TISSUE FACTOR AND TOTAL TISSUE FACTOR PATHWAY INHIBITOR IN CORONARY ARTERY DISEASE: CORRELATION WITH THE SEVERITY OF ATHEROMATOSIS

B. Lwaleed,[1] L. Lima,[2] M. Sousa,[2] L. Dusse,[2] M. Lasmar,[2] B. Lwaleed,[3] M. Carvalho[2]

[1]Southampton University Hospitals NHS Tru, SOUTHAMPTON, United Kingdom; [2]Federal University of Minas Gerais, MINAS GERAIS, Brazil; [3]University of Southampton, SOUTHAMPTON, United Kingdom

Background. Atherosclerosis and its subsequent thrombotic complications are a major cause of morbidity and mortality in the western world. Tissue factor (TF) may contribute to the atherothrombosis process. *in vivo* TF-procoagulant activity is restrained by its major physiological inhibitor commonly known as tissue factor pathway inhibitor (TFPI). *Aims.* To determine plasma TF and total TFPI levels in subjects undergoing coronary angiography and to assess the relationship between these and the severity of coronary artery disease (CAD). Materials and *Methods.* Using an enzyme-linked immunosorbent assay (ELISA) assays, plasma TF and total TFPI levels were measured in subjects with normal coronary arteries (n=20; controls), mild/moderate atheromatosis (n=18) and severe atheromatosis (n=30). In addition, plasma lipoprotein(a) and D-Dimer (D-D) were analysed in all samples using ELFA and turbidimetric assays, respectively. The extent of CAD was assessed using coronary angiography. *Results.* The severe atheromatosis group showed significantly high TF levels compared to controls ($p<0.01$). Increased TF levels were associated with coronary stenosis of more than 70% of the luminal diameter. Plasma lipoprotein(a) levels were also significantly increased in subjects with severe atheromatosis compared to those with mild/moderate atheromatosis ($p<0.001$) or controls ($p<0.0001$). The difference in lipoprotein(a) levels between controls and mild/moderate atheromatosis group was also significant ($p<0.0001$). However, no such a significant difference was observed for TFPI and D-D. The presence of CAD was associated with increased TF (r=0.42, $p<0.0001$) and raised lipoprotein(a) levels (r=0.63, $p<0.0001$). For all groups there was a positive and significant association between TF and TFPI (r=0.34; $p<0.01$), TF and D-D (r=0.28, $p<0.05$) and TF and lipoprotein(a) (r=0.33, $p<0.01$). *Conclusions.* Increased plasma TF levels but not plasma TFPI levels in subjects with coronary artery disease are associated with the severity of atheromatosis. We observed an association between increased plasma TF levels and coronary stenosis of more than 70% of the luminal diameter. The advanced atherosclerotic injuries, the fatty core of the disrupted plaque and the increase in the macrophages and smooth muscle cells may have resulted in the observed rise in plasma TF levels.

0354

FACTOR V LEIDEN HOMOZYGOUS GENOTYPE IS ASSOCIATED WITH LATE PREGNANCY LOSS IN THE PROCARE-GEHT COHORT

C. Biron-Andreani,[1] Y. Gruel,[2] B. Delahousse,[2] M.-F. Aillaud,[3] I. Juhan,[4] V. Le Cam - Duchez,[5] C. Saladin - Theron,[6] J.Y. Borg,[5] A. Bauters,[2] B. Jude,[2] F. Dutrillaux,[7] F. Vollot,[7] J.-L. Lorenzini,[7] A. Lequerrec,[2] C. Boinot,[8] J.-F. Schved,[8] P.E. Morange[4]

[1]Laboratoire d'hematologie CHU Saint-Eloi, MONTPELLIER; [2]CHRU, TOURS; [3]Hopital LA Timone, MARSEILLE; [4]Hopital La Timone, MARSEILLE; [5]Hopital C. Nicolle, ROUEN; [6]CH, LE HAVRE; [7]Hopital Le bocage, DIJON, France; [8]CHU, POITIERS, France;

Background. A role for inherited maternal thrombophilia in the occurrence of pregnancy loss has been suggested by prevalence studies. However, limited data are available about the impact of the Factor V Leiden (FVL) homozygous genotype on early and late foetal losses. *Objectives.* We performed a retrospective multicentre study to evaluate the relationship between FVL homozygous genotype and foetal loss. *Aims.* The obstetrical history of 133 women homozygous for the FVL, included in the PROCARE-GEHT cohort, and who had initiated at least one pregnancy was carefully recorded. The frequencies of early (first trimester) and late (second/third trimester) foetal losses were analysed. All data obtained were compared with those obtained in 256 women heterozygous for the FVL recruited in Marseille centre and who also had been pregnant at least once. *Results.* 306 pregnancies were initiated in the 133 FVL homozygous women vs. 686 in the heterozygous patients. One late foetal loss occurred more frequently in homozygous FVL women than in heterozygotes (17/306 (6%) vs. 6/686 (1%); OR=6.7, 95% CI 2.6-17.1; $p<0.001$). On the other hand, the rate of early foetal loss i.e. occurring in the first trimester of pregnancy, was similar in both groups of women (38/306 (12%) vs. 73/686 (11%); OR=1.2, 95% CI 0.78-1.80; $p=0.41$). *Summary and conclusions.* The observed rates of foetal losses were similar with those previously reported1. This study supports that the homozygous status for the FVL increases the risk of foetal loss in the second-third trimesters of pregnancy. Therefore, further studies are mandatory to evaluate whether a specific monitoring of these women is useful together with anticoagulant prophylaxis.

SPONTANEOUS DEEP VEIN THROMBOSIS OF THE UPPER EXTREMITIES: RISK FACTORS AND LONG TERM FOLLOW UP

D. Lechner, C. Wiener, S. Eichinger, A. Weltermann, L. Eischer, P.A. Kyrle

Medical University of Vienna, VIENNA, Austria

Background. Risk factors of lower limb deep vein thrombosis (DVT) have been well established in large clinical studies. *Aims.* (1) To investigate whether these factors also confer an increased risk of upper limb DVT. (2) To evaluate the risk of recurrence of upper limb DVT. *Methods.* We followed 52 patients with upper limb DVT and 875 patients with lower limb DVT after discontinuation of secondary thromboprophylaxis. Exclusion criteria were previous or secondary venous thromboembolism, isolated pulmonary embolism, need for long term antithrombotic therapy, cancer, pregnancy, lupus anticoagulant and antithrombin, protein C, or protein S deficiencies. Symptomatic recurrent DVT was prospectively recorded over a mean follow-up of 44 months. *Results.* Patients with upper limb DVT were younger (38 vs. 49 years, $p<0.001$) and had a lower BMI (24 vs. 27, $p<0.001$) than those with lower limb DVT. Pulmonary embolism occurred in only 10% of patients with an upper limb DVT (lower limb DVT: 34%; $p<0.001$). No difference was found regarding sex distribution (male: 45% vs. 48%, $p=0.7$). The prevalence of Factor V Leiden was lower among patients with upper limb DVT than among those with lower limb DVT (12% vs. 30%, $p=0.005$). In addition, patients with upper limb DVT had lower levels of factor VIII (143 vs. 167 IU/mL, $p<0.001$) and factor IX (109 vs. 117 IU/mL, $p=0.015$). Low D-dimer (<250 ng/mL) was more frequent among patients with upper limb DVT than among those with lower limb DVT (60% vs. 32%, $p=0.001$). After 5 years, the probability of recurrence was 2.0% (95% CI 0%-6.0%) among patients with upper limb DVT compared with 19.6% (95% CI 16.4%-23.0%) among patients with lower limb DVT ($p<0.001$). *Conclusions.* Prevalence of thrombophilia among patients with a first upper limb DVT is low. The risk of recurrence among these patients is very low.

EFFICACY OF DASATINIB IN CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA PATIENTS AFTER IMATINIB FAILURE ACCORDING TO BASELINE BCR-ABL MUTATIONS

M.C. Mueller,[1] S. Branford,[2] J. Radich,[3] N. Shah,[4] P. Erben,[1] T. Ernst,[1] M. Acevedo,[5] C. Nicaise,[5] T. Hughes,[2] A. Hochhaus[1]

[1]Universitaetsklinikum Mannheim, MANNHEIM; [2]IVMS, ADELAIDE, Australia; [3]FHCRC, SEATTLE, USA; [4]UCSF, SAN FRANCISCO, USA; [5]Bristol Myers Squibb, WALLINGFORD, USA

Background. Dasatinib is an oral, multi-targeted BCR-ABL and SRC kinase inhibitor with preclinical activity against 20/21 imatinib resistant BCR-ABL mutations. Clinical efficacy was demonstrated in phase I, II, and III studies in patients (pts) with chronic myelogenous leukemia (CML) in all phases of the disease and with BCR-ABL positive acute lymphoblastic leukemia (ALL). *Aims.* We sought to establish a relationship between the type of BCR-ABL mutations associated with imatinib resistance and efficacy of dasatinib in chronic phase (CP) CML pts. *Methods.* Between 10/03 and 03/06, dasatinib was commenced in 1,093 CP-CML pts recruited for three consecutive trials and administered for a median period of 8.7 months (range <1-25.9). BCR-ABL mRNA was screened for mutations of amino acids 207-517 by D-HPLC and regular sequencing and data are available from 961 cases (88%). ABL polymorphisms K247R and E499E were excluded from analysis. *Results.* Prior to dasatinib, 75 different BCR-ABL mutations involving 56 amino acids were detected in 18/240 imatinib intolerant (7.5%) and 324/721 (45%) imatinib resistant pts. 267 pts showed one, 53 pts two, 16 pts three, and six pts four mutations. In imatinib resistant pts, response was not different between 370 pts with and 351 pts without baseline mutations: Complete hematologic response (CHR) was achieved in 89% vs 92%; major cytogenetic response (MCR) in 48% vs 52% being complete (CCR) in 38 vs 36%, respectively. Response dynamics was associated with preclinical activity of dasatinib: Classifying mutations for IC_{50} values <2, 2-20 and >1,000nM (T315I), CHR was achieved in 93, 85 and 28%; MCR in 48, 42 and 0%; and CCR in 37, 35 and 0% of cases, respectively. During follow up, new mutations were detected in 30 cases, predominantly T315I (n=10), Y253H/F (n=4), and F317L (n=3). *Conclusions.* We conclude that dasatinib is capable of inducing hematologic and cytogenetic remissions in a significant proportion of imatinib resistant pts associated with BCR-ABL mutations, except T315I, but also in pts with BCR-ABL independent causes of resistance. Quality of response depends on the individual type of mutation which is consistent with preclinical observations.

0357

CYTOGENETIC RESPONSE AND DISCONTINUATIONS FROM IRIS STUDY WITH LONG-TERM IMATINIB THERAPY IN NEWLY DIAGNOSED PH+ CHRONIC MYELOGENOUS LEUKEMIA

F. Guilhot,[1] B. Druker,[2] S.G. O'Brien,[3] R. Larson[4]

[1]Clinical Research Centre, POITIERS, France; [2]Oregon Health and Science University, PORTLAND, USA; [3]University of Newcastle upon Tyne, TYNE, United Kingdom; [4]University of Chicago Hospital, CHICAGO, USA

Background. The 5-year follow-up analysis of the International Randomized Interferon versus STI571 (IRIS) study was recently published. *Aims.* Here we focus on response rates for patients (pts) in long-term follow-up and provide details regarding those who discontinued prior to 31 Jan 2006 (analysis data cutoff). *Results.* Survival: In the IRIS study, routine follow-up data were collected for all randomized pts, including overall survival. For those who discontinued study treatment, quarterly assessments included whether pts were alive, deceased, lost to follow-up, or had received transplant. By the median 5-year cutoff (range: 5-5.5 years), after the last patient had been recruited into the study, 57 (10%) of the 553 pts initially randomized to imatinib (IM) were documented to have died. Of the remaining 496 pts, 333 (67%) had follow-up data of greater than 5 years, 126 (25%) pts had follow-up data between 4.5 and 5 years, 11 (2%) pts had follow-up data between 4 and 4.5 years, and only 26 (5%) pts were prematurely lost to follow-up with available survival data of less than 4 years. Using the Kaplan-Meier method, in which available data for each pt are considered, and survival is censored

at the last follow-up when pts are known to be alive, the probability of overall survival at 5 years was 89%. *Response.* Of all 553 pts, 454 (82%) achieved a complete cytogenetic response (CCyR) during IM study treatment. Of these CCyR pts, 86 discontinued IM treatment for reasons indicated in Table 1. Of the remaining 368 pts, 11 had a documented loss of CCyR while on study, but were still in MCyR at last follow-up. *Discontinuations*. At data cutoff, 382 (69%) of 553 pts remained on IM study; a total of 171 (31%) of the 553 pts had discontinued. Ten pts died for reasons other than CML while on IM treatment. Of the remaining 161 pts who discontinued IM on the IRIS protocol, 47 had died by the current follow-up (Table 1). Routine follow-up of the 79 pts who had achieved a CCyR while on IM and then discontinued due to reasons other than death revealed that 19 pts subsequently died (4 after BMT, 7 due to CML, and 8 due to other causes). *Summary and conclusions.* More detailed data from the 5-year IRIS follow-up will be presented including long-term MCyR and CCyR rates.

Table 1. Discontinuations from IM in the IRIS study (5-year analysis)

Reason	All pts (N=553) n (%)	CCyR during treatment, n	Deaths after discontinuation, n
Unsatisfactory therapeutic effect	59 (10.7)	31	20
Adverse event	23 (4.2)	15	10
Death	10 (1.8)	7	-
BMT	16 (2.9)	4	6
Withdrew consent	25 (4.5)	15	3
Lost to follow-up	5 (0.9)	3	1
Protocol violation	15 (2.7)	5	1
Other reasons	4 (0.7)	3	1
Discontinuations from first-line IM	157 (28.4)	83	42
Crossed over to IFN-α + Ara-C	14 (2.6)	3	5
Total discontinuations	171 (31)	86	47

DASATINIB INDUCES DURABLE CYTOGENETIC RESPONSES IN PATIENTS WITH CHRONIC-PHASE CML WITH RESISTANCE OR INTOLERANCE TO IMATINIB: UPDATED RESULTS OF THE CA180013 (START-C) TRIAL

F. Guilhot,[1] J. Apperley,[2] T. Facon,[3] D. Niederwieser,[4] C. Gambacorti,[5] T. Fischer,[6] A. Countouriotis,[7] R. Ezzeddine,[7] A. Hochhaus,[8]

[1]CHU La Miletrie, POITIERS, France; [2]Hammersmith Hospital, LONDON, United Kingdom; [3]University of Lille, LILLE, France; [4]University of Leipzig, LEIPZIG, Germany; [5]University of Milano Bicocca, MILANO, Italy; [6]University-Hospital, MAINZ, Germany; [7]Bristol-Myers Squibb Co, WALLINGFORD, CONNECTICUT, USA; [8]University Heidelberg, MANNHEIM, Germany

Background. Dasatinib is a potent inhibitor of BCR-ABL (325-times more potent than imatinib and 16-20-times more potent than nilotinib *in vitro*) and other tyrosine kinases, and is approved in both the EU and US for the treatment of all phases of chronic myelogenous leukemia (CML) with resistance to or intolerance of prior therapy, including imatinib. *Aims.* This study was designed to establish the efficacy and safety of dasatinib; the longer-term follow-up presented here allow for a more definitive assessment. *Methods.* In this Phase-II, open-label study, patients with CP-CML with resistance or intolerance to imatinib received treatment with dasatinib 70 mg BID. Dose escalation to 90 mg BID was allowed for patients with an inadequate response, and dose reduction to 50 mg or 40 mg BID for toxicity or intolerance. All patients provided written informed consent. *Results.* From February through July 2005, 387 patients (median age 58 years; 49% male) were enrolled and treated at 75 centers worldwide. Median time from CML diagnosis was 61 months (range 3-250). Prior therapy included: interferon-a in 65% of patients; stem-cell transplantation in 10%; 55% had received prior imatinib therapy at >600 mg/day; and 53% had received imatinib for durations in excess of 3 years. Best response prior to imatinib failure was CHR in 82%, and major (MCyR) and complete (CCyR) cytogenetic response in 37% and 19%, respectively. With median follow-up now extending to 15.2 months, CHR was seen in 91% of patients. MCyRs were attained by 59% of patients, these were CCyRs in 49%. Cytogenetic response rates were higher for patients with intolerance to imatinib (MCyR 80%, CCyR 75%) than for those with resistance (MCyR 52%, CCyR 40%). MCyRs were consistently reported across subgroups: imatinib duration (″3 years 65%, >3 years 55%), prior imatinib dose (″600 mg 63%, >600 mg 57%), prior CHR (yes 63%, no 59%), prior CyR (yes 71%, no 42%), BCR-ABL mutation (yes 57%, no 48%). MCyRs were durable, with only 7 of the 230 patients (3%) with a CyR progressing. The 15-month progression-free survival rate was 88%, where progression was defined as confirmed accelerated- or blast-phase disease, loss of CHR/MCyR, or increasing WBC count. Grade 3-4 neutropenia or thrombocytopenia were both reported in 48% of patients. Dose interruptions occurred for 87% of patients, and reductions for 73%, with a median daily dose of 101 mg (range 11-171 mg). Non-hematologic toxicity consisted mainly of grade 1-2 diarrhea, headache, fatigue, dyspnea, rash, and pleural effusion (with 6% grade 3-4 pleural effusion). *Summary and conclusions.* Longer'term data confirm the durability of cytogenetic response with dasatinib 70 mg BID. Consistent responses were observed across subgroups.

0359

DASATINIB DOSE AND SCHEDULE OPTIMIZATION IN CHRONIC-PHASE CML RESISTANT OR INTOLERANT TO IMATINIB: RESULTS FROM A RANDOMIZED PHASE-III TRIAL (CA180034)

A. Hochhaus,[1] D.-W. Kim,[2] P. Rousselot,[3] H.M. Kantarjian,[4] A. Charbonnier,[5] D. Heim,[6] N. Khoroshko,[7] E. Bleickardt,[8] S. Francis,[8] N.P. Shah[9]

[1]University Heidelberg, MANNHEIM, Germany; [2]The Catholic University of Korea, Uijeon, KYUNGGI-DO, South-Korea; [3]Hôpital Saint-Louis, PARIS, France; [4]MD Anderson Cancer Center, HOUSTON, USA; [5]Institut Paoli-Calmettes, MARSEILLE, France; [6]Dept. of Hematology, University Hospital, BASEL, Switzerland; [7]National Research Centre, MOSCOW, Russian Federation; [8]Bristol-Myers Squibb Co., WALLINGFORD, USA; [9]Jonsson Comprehensive Cancer Center, LOS ANGELES, USA

Background. Dasatinib, a potent inhibitor of BCR-ABL (325-times more potent than imatinib and 16-20-times more potent than nilotinib *in vitro*) and other tyrosine kinases, has been shown to be both safe and effective at doses of 70 mg BID in patients with chronic-phase CML resistant or intolerant to imatinib. Nonetheless, notable major cytogenetic responses (CyRs) were also observed in the phase-I program for patients with CP-CML at 100-mg and 140-mg total daily doses when administered as either a QD or BID schedule; this was despite the achievement of only transient inhibition of phospho-CRKL by dasatinib in patients receiving QD therapy. Long-term phase-I follow-up data also demonstrated that pleural effusions were less frequent with the QD schedule than with BID dosing. *Aims.* This study was designed to compare the CyR rates associated with QD and BID regimens of dasatinib. Secondary objectives included estimating differences in CyR between the 100-mg and 140-mg dose regimens and an ongoing evaluation of safety to optimize the dose and schedule for this drug. *Methods.* In this phase-III, randomized, prospective, open-label study, patients with imatinib-resistant or 'intolerant CP-CML were randomized to one of four dasatinib treatment groups: 100 mg QD, 50 mg BID, 140 mg QD, or 70 mg BID. Dose escalation to 180 mg QD or 90 mg BID and reduction to 80 mg QD or 40 mg BID were allowed for inadequate response or adverse events (AEs), respectively. All patients provided written informed consent.

Table 1.

Results. From July 2005 through March 2006, 662 patients (median age 55 years; 47% male) were randomized and received treatment. Median time from CML diagnosis to randomization was 54 months. With a median duration of treatment of 8 months, marked and similar hematologic and cytogenetic response rates were seen across all four treatment groups (Table 1). Duration of CyR and progression-free survival were also similar across all treatment groups. Toxicities identified as being of special interest were fewer for the 100-mg QD regimen (Table 1); pleural effusions (p=0.024) and thrombocytopenia (p=0.004) were both markedly reduced in the 100-mg QD group compared with the 70-mg BID arm. There were fewer dose interruptions and reductions and the lowest number of patients discontinuing treatment for drug-related toxicity in the 100-mg QD treatment group. *Summary and Conclusions.* Dasatinib 100 mg QD offers the most favorable overall benefit-risk assessment in this CP-CML patient population.

0360

DASATINIB IS SAFE AND EFFECTIVE IN PATIENTS WITH PREVIOUSLY UNTREATED CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE

A. Quintas-Cardama,[1] H. Kantarjian,[1] S. OBrien,[1] D. Jones,[1] G. Borthakur,[1] C. Nicaise,[2] J. Cortes[1]

[1]*MD Anderson Cancer Center, HOUSTON;* [2]*Bristol-Myers Squibb Co., WALLINGFORD, CT, USA*

Background. Dasatinib is a multi-targeted kinase inhibitor of BCR-ABL and SRC. Based on its high level of activity in patients with imatinib-resistant or -intolerant CML-CP, the present phase-II trial was designed to assess the efficacy and safety of dasatinib in previously untreated CML-CP patients. The primary objective was to estimate the proportion of patients attaining major molecular response (BCR-ABL/ABL ratio <0.05% by qPCR) at 12 months. *Methods.* All patients received dasatinib orally at 100 mg/day, and were randomized to either a 50-mg-twice-daily or a 100-mg-once-daily schedule. Dose escalation to 140 mg/day and 180 mg/day for poor response or dose reduction to 80 mg/day and 40 mg/day for toxicity, maintaining the same schedule, was allowed. *Results.* Of the 34 patients enrolled between 11/05 and 2/07, 50% were female; median age was 41 years (range 18-76). At 3 months, complete hematologic response (CHR) and major cytogenetic response both occurred in 23 (88%) of 26 evaluable patients and complete cytogenetic response (CCyR) in 20 (77%) patients. After 6 months of therapy, 24/26 (92%) evaluable patients had achieved CCyR; this compares favorably with a CCyR at 6 months of 54% with imatinib 400 mg/day and 85% with imatinib 800 mg/day, for historical data of similar patients treated in studies at MD Anderson. At 12 months, 5/11 (45%) evaluable patients achieved a major molecular response in the present study (1 of which was complete). The most common non-hematologic adverse events (AE) included dyspnea (8 patients), fatigue (7), muscle pain (6), and headache (5) and were predominantly grade (gr) 1-2. Pleural effusion occurred in 3 patients (gr 1-2 in all). Grade 3-4 hematologic toxicity (transient) included anemia in 4 patients, neutropenia in 7 patients, and thrombocytopenia in 4 patients. With a median duration of therapy of 10 months, 13 patients required transient treatment interruption, 9 due to non-hematologic toxicities, 3 due to hematologic toxicities, and 1 as a result of both. The actual median daily dose for all pts is 100 mg. No difference in AEs has been observed between dose schedules. *Conclusions.* Rapid, complete cytogenetic responses to dasatinib 100 mg/day have been observed in a high percentage of patients with previously untreated CML-CP. Accrual to this trial continues.

Chronic lymphocytic leukemia and related disorders - Clinical

0361

MAINTENANCE IMMUNOTHERAPY WITH LOW-DOSE RITUXIMAB IMPROVES OUTCOME IN 'HIGH RISK' CHRONIC LYMPHOCYTIC LEUKEMIA

G. Del Poeta,[1] M.I. Del Principe,[1] L. Maurillo,[1] F. Buccisano,[1] P. Niscola,[1] E. Ammatuna,[1] V. Gattei,[2] A. Venditti,[1] P. De Fabritiis,[1] F. Lo-Coco,[1] S. Amadori[1]

[1]*University Tor Vergata, ROME;* [2]*Centro di Riferimento Oncologico, AVIANO (PN), Italy*

Monoclonal antibodies combined with chemotherapy have allowed us to achieve both more complete responses and longer response duration in B-cell chronic lymphocytic leukemia (CLL), reducing disease burden to levels detectable only by immunophenotypic methods. Moreover, low-dose rituximab may decrease CD20 antigen loss via shaving and promote enhanced targeting in CLL (Williams ME et al, 2006). We performed a phase II study that added rituximab to fludarabine (Flu) as therapy for symptomatic, untreated CLL. Remission status was assessed by a multiparametric flow cytometric method based on the detection of CD19+CD5+CD79b- residual B-CLL lymphocytes. VH mutational status, CD38, ZAP-70 and cytogenetics were obtained in all patients before treatment. We defined as *high risk* patients having at least two of the following markers: unmutated IgVH, CD38 >30%, ZAP-70 >20%, unfavourable cytogenetics (trisomy 12 or del11q or del17p). Seventy-nine CLL patients, median age 60 years (range 37-74) received six monthly courses of Flu (25 mg/m^2 for 5 days) and four weekly doses of rituximab (375 mg/m^2) starting after completion of Flu therapy. According to modified Rai stages, 9 patients had a low stage, 67 an intermediate stage and 3 a high stage. Based on NCI criteria, 63/79 (80%) patients achieved a complete remission (CR), 12/79 (15%) a partial remission (PR) and 4/79 (5%) a stable disease (SD) or no response or progression. Three patients presented grade 3 (WHO) infective lung toxicity and 1 patient acute fatal B hepatitis. Hematologic toxicity included mainly neutropenia (grade 3 and/or 4 in 41 pts) and thrombocytopenia (grade 3 and/or 4 in 4 pts). Thirty-five patients in clinical CR or PR, either with CD5$^+$CD19$^+$CD79b$^-$ (MRD) bone marrow (BM) cells >1% (n=20 pts) or with MRD peripheral blood lymphocytes (PBL) >1000/mL (n=15 pts) within 1 year after completion of the induction treatment, underwent consolidation/maintenance therapy with four monthly cycles of rituximab at 375 mg/m^2 followed by twelve monthly low doses of rituximab at 150 mg/m^2. The median follow-up duration was 38 months. Noteworthy, all B-CLL pts experienced a long progression-free survival (PFS) from treatment (69% at 6 years). Nevertheless, CLL patients that underwent consolidation therapy (n=35) showed a significant longer duration of response in comparison with the subset of not consolidated and BM or PBL MRD positive (n=13) patients (85% vs 20% at 5 years, p=0.00001, Figure 1).

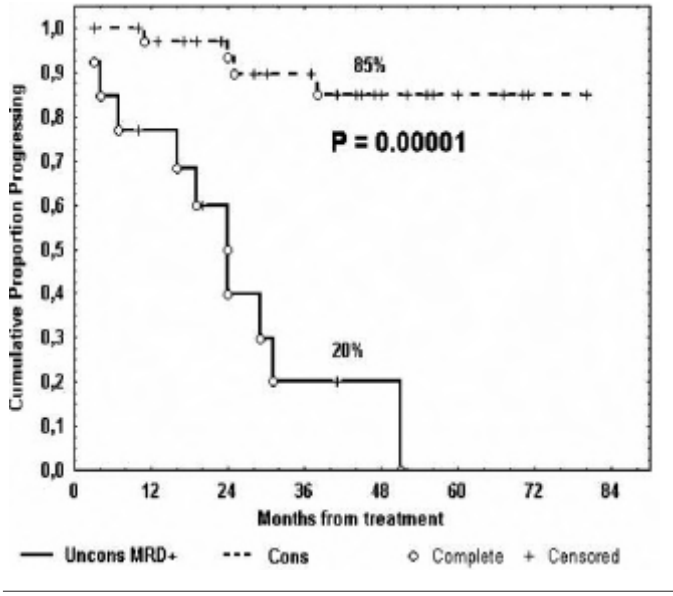

Figure 1. Duration of response in consolidated vs unconsolidated pts.

Of note, BM and PBL MRD negative patients (n=27) showed a duration of response similar to that of the consolidated pts. Moreover, a significant shorter PFS was observed within CD38+ pts (43% vs 79% at 5 years, p=0.005), unmutated pts (45% vs 94% at 2.5 years, p=0.001) and ZAP-70+ pts (39% vs 88% at 5 years; p=0.00004). Interestingly, within the *high risk* subset (n=30), the consolidated patients (n=11) showed a significant longer duration of response (64% vs 13% at 2 years, p=0.006) in comparison with MRD+ unconsolidated patients (n=9). Therefore, the addition of maintenance therapy with low dose rituximab prolongs significantly the duration of response also improving the outcome of *high risk* B-CLL pts subset.

0362

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION CURES CLL: A RETROSPECTIVE ANALYSIS FROM THE SFGM-TC REGISTRY

M. Michallet,[1] Q.H. Le,[1] N. Raus,[1] J.P. Vernant,[2] F. Nicolini,[1] L. Sutton,[3] J.L. Harousseau,[4] P. Colombat,[5] E. DeConinck,[6] B. Cazin,[7] D. Blaise[8]

[1]Hôpital Edouard Herriot, LYON; [2]Hôpital de la Pitié-Salpétrière, PARIS; [3]Centre Hospitalier Victor Dupuy, ARGENTEUIL; [4]Centre Hospitalier de l'Hotel-Dieu, NANTES; [5]Hôpital Bretonneau, TOURS; [6]Hôpital Jean Minjoz, BESANCON; [7]Hôpital Claude Huriez, LILLE; [8]Institut Paoli Calmettes, MARSEILLE, France

This retrospective study concerned 471 B-CLL patients registered in the SFGM-TC registry from 1984 to 2005: 313 patients underwent autologous transplantation, 138 females (F) and 175 males (M) with a median age of 54 years, 236 received peripheral blood stem cell (PBSC) and 77 bone marrow (BM); 158 patients underwent allogeneic transplantation, 78 F and 80 M, median age = 49 years, 77 PBSC, 81 BM from 17 related and 141 unrelated donors. Before conditioning, 302 autoT and 143 alloT were evaluated for disease status: 100 and 26 patients were in CR, 170 and 55 in PR, 4 and 13 in stable disease, 28 and 49 in progressive disease for autoT and alloT respectively. Among alloT patients, 73 received reduced intensity conditioning and 85 standard conditioning (72 Cyt+TBI, 33 Fluda+TBI, 23 Fluda+Bu+ATG, 8 Cyt+Bu and 21 other). Before autoT the conditioning consisted of 224 Cyt+TBI, 45 BEAM and 44 other. After alloT, 71 patients developed an acute GVHD ≥grade II and 60 developed a chronic GVHD. The non-relapse mortality at 1 year was 29%. With a mean follow-up of 28 months for autoT and 40 months for alloT, the probabilities of 3-year, 5-year and 8-year overall survival were 80%, 66%, 45.5% after autoT and 52%, 48% and 35% after alloT respectively. An analysis aimed to determine the percentage of long-term survivors, or patients focused on the final plateau of survival curves was performed on alloT and autoT groups. A mixture model, gfcure with Splus statistical package determined the percentages of long-term survivors and its adequacy was verified graphically.

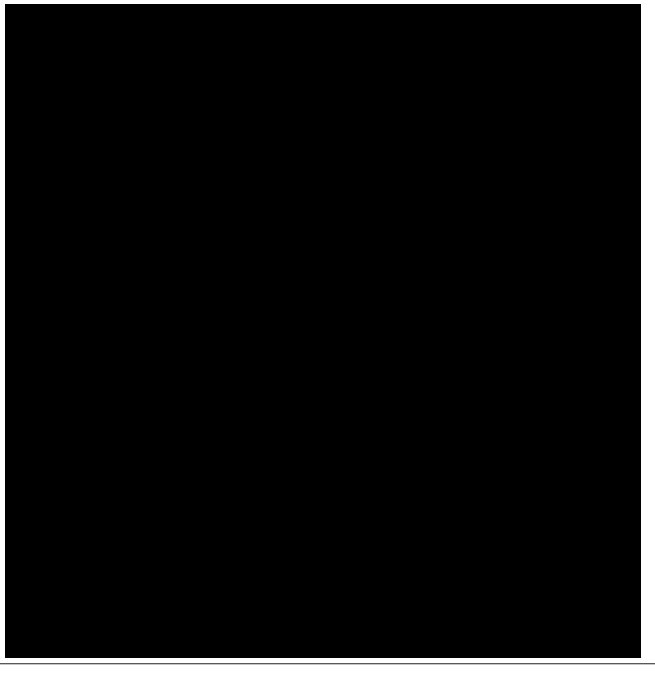

Figure 1-2. Autograft Long-term survivors prediction model [Cure Rate (Peng-Stat Med 1998)].

The percentage of long-term survivors for the autoT group was 1.2%, with a mean survival length for uncured population of 160 months, both curves were close and consequently show good adequacy and the absence of a final plateau (Figure 1). The percentage of long-term survivors for alloT was 34% (Figure 2) showing rather good adequacy. The study of the impact of usual prognosis factors (age, time diagnosis-transplant, sex match, HLA match, CMV status, type of conditioning, BM or PBSC, ABO compatibility and disease status before transplantation) on the percentage of long-term survivors showed that only the status of disease at transplant had a significant impact: (CR vs SD or PD, HR: 0.11 [0.02-0.5] p=0.01 and PR vs SD or PD, HR: 0.30 [0.09-0.96] p=0.04). This study pointed out the possibility of curing B-CLL patients who responded to conventional chemotherapy with allogeneic transplantation.

LENALIDOMIDE IS AN ACTIVE AGENT IN RELAPSED AND TREATMENT-REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

A. Ferrajoli, S. O'Brien, S. Faderl, W. Wierda, B. Lee, J. Reuben, E. Schlette, Z. Estrov, M. Keating

University of Texas M.D. Anderson Cancer, HOUSTON, USA

Lenalidomide is an immunomodulatory agent that stimulates T-cells, inhibits the production of TNF-α and VEGF, and impairs the interaction between bone marrow stroma and hematopoietic cells. These properties prompted us to initiate a phase II clinical trial of lenalidomide in patients with advanced CLL. In this study lenalidomide was given orally at 10 mg/day for the first four weeks and its dose was escalated by 5 mg every 28 days to a maximum of 25 mg/day. Thus far, 45 patients have been enrolled and data of the first 35 patients with a median follow up of 9 months was analyzed. The remaining 10 patients have been on treatment for < 3 months. All patients had received at least one purine-analogue-based regimen. The median age of the patients was 64 years (range 49-86), the median number of prior treatments was 4 (range 1-15), the median b2M was 4.1 mg/dL (range 1.6-10), 60% of the patients carried unfavorable genomic abnormalities (deletion of 17p or 11q23) and 71% had unmutated IgVH. Responses were evaluated according to the NCI-WG criteria: 13 patients (38%) responded [3 CR (9%), 1nPR (3%) and 9 PR (26%)]. The median response duration is 11+ months. Eight patients with stable disease continue on treatment. Twelve patients failed and 2 died early of infectious complications (on days 11 and 22). Minimal residual disease (MRD), as assessed by flow cytometry, was not detected in 2 of the 3 patients who attained CR. The most common toxicity was myelosuppression with grade >3 neutropenia and thrombocytopenia in 17% and 14% of the patients, respectively. Remarkably, our patients did not develop lymphopenia and the T cell count remained stable or increased during treatment. Grade >3 fatigue, diarrhea and tumor flare were observed in 9%, 6% and 6% of the patients, respectively. Twelve serious infectious episodes occurred: 8 pneumonias (PCP in 2), 2 FUOs, 1 mucormycosis (fatal) and 1 enteric cryptosporidiosis. None of the patients received routine antibiotic prophylaxis. The median dose of lenalidomide tolerated was 10 mg/day. Plasma levels of angiogenic factors and inflammatory cytokines were measured at baseline, day 8, day 28, and at 3 months in 18 patients. A significant increase in the levels of TNF-α and its soluble receptor, TNFR1, was noted on day 8, followed by a decline to basal level at 3 months. Similarly, a transient increase in the levels of IL-6, IL-10, IFN-γ, and soluble IL-2 receptor was observed on day 8, suggesting that lenalidomide activates the immune system in CLL, as previously described in multiple myeloma. We also showed that VEGF and β-FGF levels were significantly reduced at three months and the measurement of bone marrow microvessel density is ongoing. We conclude that lenalidomide, given in a low-dose continuous schedule, induces complete (MRD-negative) and partial responses in patients with advanced CLL. Ongoing correlative studies suggest a unique mechanism of action of this agent in CLL.

0364

CLINICAL EFFICACY OF OXALIPLATIN, FLUDARABINE, CYTARABINE, AND RITUXIMAB COMBINATION THERAPY IN PATIENTS WITH RICHTERS SYNDROME OR FLUDARABINE-REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE I-II CLINICAL TRIAL

A.M. Tsimberidou,[1] W.G. Wierda,[1] W.W. Plunkett,[1] S. O'Brien,[1] T.J. Kipps,[2] J.R. Brown,[3] S. Lerner,[1] H.M. Kantarjian,[1] M.J. Keating[1]

[1]U. T. M. D. Anderson Cancer Center, HOUSTON; [2]UCSD Moore's Cancer Center, SAN DIEGO; [3]Dana-Farber Cancer Institute, BOSTON, USA

Background. Oxaliplatin is a platinum compound that covalently binds DNA, inducing DNA intra- and interstrand cross-links. Fludarabine and cytarabine act synergistically to inhibit excision repair of DNA cross-links. The clinical efficacy of oxaliplatin in patients with Richter's syndrome (RS) and fludarabine-refractory chronic lymphocytic leukemia (CLL) has not been investigated previously. We conducted a phase 1-2 trial of oxaliplatin, fludarabine, cytarabine, and rituximab (OFAR) in these diseases. *Aims.* The objectives of this trial were to identify a safe, tolerated dose and any dose-limiting toxicities (DLT) of oxaliplatin, to assess pharmacodynamic endpoints (phase 1), and to assess the complete (CR) and partial remission (PR) rates for the OFAR regimen (phase 2). *Methods.* The OFAR regimen consisted of increasing doses of oxaliplatin (17.5, 20, or 25 mg/m^2/d), days (D) 1-4 (phase 1); 30 mg/m^2 of fludarabine, D2-3; 1 g/m2 of cytarabine, D2-3; 375 mg/m^2 of rituximab, D3 on course 1 and D1 on subsequent courses; and 6 mg of pegfilgrastim, D6, every 4 weeks for a maximum of 6 courses. Prophylaxis for PCP pneumonia and DNA virus were given. DLT was defined as any non-hematologic, treatment-related toxicity > grade (G) 3. *Results.* From November 2004 to January 2007, 64 patients (26 RS, 38 fludarabine-refractory CLL) were treated with OFAR (phase 1, 19 pts). The highest tolerated oxaliplatin dose identified was 25 mg/m^2. No DLT was observed. Pharmacodynamic analyses demonstrated enhanced leukemia cell killing by oxaliplatin in the presence of fludarabine and cytarabine. For patients with RS and CLL, the median ages were 66 yrs (range, 41-78) and 62 yrs (range, 34-78) and the median numbers of prior therapies were 3 (range, 0-10) and 4 (range, 1-11), respectively. Among patients with fludarabine-refractory CLL, 24 (63%) had Rai stage 3-4. The median number of OFAR cycles was 2 (range, 1-6). Sixty patients are currently evaluable for response. The overall response rates were 44% (11 of 25; CR= 3, PR= 7) in RS and 43% (15 of 35; CR=1, nodular CR= 2, PR=12) in fludarabine-refractory CLL. Responses included 9 of 22 (41%) patients with 17p deletion, 5 of 9 (56%) patients with 11q deletions, 5 of 5 (100%) patients with trisomy 12, 2 of 5 (40%) patients with 13q deletions, and 4 of 12 (33%) patients with no genomic aberrations. Fifteen of 31 (48%) patients with tumors greater than 5 cm compared to 9 of 27 (33%) patients with tumors *less than or equal to* 5 cm (tumor size was not recorded in 2 patients) responded to OFAR therapy (p=0.16). Toxicities were mainly hematologic, but no prolonged myelosuppression was observed. Grade 3-4 infections occurred in 14 patients. *Conclusions.* OFAR is clinically active in patients with Richter's syndrome and fludarabine-refractory CLL. These results are encouraging and warrant further investigation of the OFAR regimen in the treatment of these disorders.

ERADICATON OF MINIMAL RESIDUAL DISEASE IN CHRONIC LYMPHOCYTIC LEUKEMIA IS ASSOCIATED WITH PROLONGED SURVIVAL. LONG TERM FOLLOW UP OF PATIENTS TREATED WITH ALEMTUZUMAB

H.A. Sayala,[1] P. Moreton,[2] B. Kennedy,[3] G. Lucas,[4] M. Leach,[5] S.M.B. Rassam,[6] A. Haynes,[7] J. Tighe,[8] D. Oscier,[9] C. Fegan,[10] A.C. Rawstron,[1] P. Hillmen[1]

[1]HMDS, Leeds General Infirmary, LEEDS; [2]Pinderfields general Hospital, WAKEFIELD; [3]Leicester Royal Infirmary, LEICESTER; [4]Manchester royal Infirmary, MANCHESTER; [5]Stobhill Hospital, GLASGOW; [6]Maidstone Hospital, KENT; [7]Notingham City Hospital, NOTTINGHAM; [8]Aberdeen Royal Infirmary, ABERDEEN; [9]Royal Bournemouth Hospital, BOURNEMOUTH; [10]University Hospital Wales, CARDIFF, United Kingdom

Eradication of minimal residual disease (MRD) in chronic lymphocytic leukemia (CLL) is increasingly emerging as a desirable therapeutic end point predicting for better outcome. The monoclonal antibody alemtuzumab (Mabcampath) is licensed for the treatment of patients with CLL refractory to fludarabine-based therapies and results in the eradication of MRD in a proportion of patients. We previously published a series of ninety one (74 men and 17 women, median age 58 years [range, 32 to 75 years]) relapsed CLL patients who received a median of 9 weeks (range 1 to 16 weeks) of alemtuzumab treatment between 1996 and 2003 (Moreton et al, J Clin Oncol 2005 May 1;23(13):2971-9). 44 were refractory to purine analogues. Responses to alemtuzumab according to National Cancer Institute sponsored working group response criteria were complete remission (CR) in 32 patients (36%), partial remission (PR) in 17 patients (19%), and no response (NR) in 42 patients (46%). Detectable CLL to a level of less than a single CLL cell in 10,000 leucocytes, assessed by four-colour MRD flow cytometry, was eradicated from the blood and marrow in 18 patients (20%). 8/18 of these patients were refractory to prior therapy with purine analogues (fludarabine refractory). We report here the results of long term follow up of this cohort of patients after a median follow up of 7.3 years (range 4 to 10.6 years). Median survival was significantly longer in those patients achieving MRD negative responses compared with those who had detectable CLL at the end of therapy (MRD positive CR, PR, or NR). The median survival for all 18 MRD negative responders has not been reached but was 87 months for the 8 fludarabine-refractory patients who achieved MRD negativity following alemtuzumab. Overall survival for the 18 patients with MRD-negative remissions was 72% at 79 months (see Figure 1). Patients achieving an MRD positive complete response had a median survival of 41 months, an MRD positive partial response a median survival of 30 months and non-responders a median survival of 15 months. The median treatment-free interval prior to alemtuzumab for the 18 MRD negative patients was 6 months (range 1 to 28 months). We conclude that alemtuzumab can induce MRD negative remissions in CLL resulting in a clear survival advantage with 72% patients alive 10 years after alemtuzumab therapy.

ALLOGENEIC STEM CELL TRANSPLANTATION FROM MATCHED RELATED AND UNRELATED DONORS IN THALASSEMIA MAJOR PATIENTS USING A REDUCED TOXICITY FLUDARABINE BASED REGIMEN

I. Resnick,[1] I. Zilberman,[2] P. Tsirigotis,[2] M. Aker,[2] M.Y. Shapira,[2] M. Bitan,[2] B. Gesundheit,[2] A. Amar,[2] A. Ackerstein,[2] S. Samuel,[2] S. Slavin[2], R. Or[2]

[1]Hadassah Medical Center, JERUSALEM, Israel [2]Hadassah, Hebrew Univ. Medical Center, JERUSALEM, Israel

Introduction. The only radical cure for thalassemia major patients today is the replacement of the defective hematopoietic system by allogeneic stem cell transplantation (allo-SCT). The major obstacles for the application of allo-SCT even from matched family members have been the transplant related morbidity and mortality and graft failure that is usually associated with the recurrence of the thalassemia hematopoiesis. The outcome of allo-SCT from HLA-identical family donors is largely dependent on the age of the recipient as well as on pre-transplant parameters reflecting the degree of organ damage from iron overload. We hereby report our experience of allo-SCT from matched related and unrelated donors, using a reduced toxicity conditioning. *Methods*. We analyzed a cohort of 20 patients with thalassemia major. Reduced-intensity conditioning consisted of fludarabine 30 mg/m^2/day from day -9 to day -4, p. o. busulfan 4 mg/kg/day or i. v. busulfex 3.2 mg/kg/day from day -7 to day -4, and antithymocyte globulin (ATG, Fresenius) 10 mg/kg/day from day -4 to day -1. The first two patients received a decreased total dose of busulfan 8 mg/kg, and one of them had a late rejection. Donors were fully HLA-matched siblings in 17 cases, a fully matched grandfather in one case, and the other two were matched unrelated donors. Unmanipulated PBSC and BM served as the source of stem cells in 8 and 12 patients respectively. *Results*. The regimen related toxicity was minimal. Engraftment of neutrophils was observed at median 15 days (range 10-27 days); engraftment of platelets was achieved in a median 15 days (range 9-35). Six patients never required any platelet transfusion support. The incidence of acute grade II-IV, and chronic GVHD was 25%, and 25%, respectively. With a median follow-up period of 39 months (range 5-112 months) the overall survival was 100%, while thalassemia free survival was 80% (Figure 1). At two months after BMT, 12 patients had complete donor chimerism; 7 mixed chimerism and one patient suffered prime graft failure. One out of 12 patients with complete donor chimerism and 1 out of 7 with mixed chimerism experienced recovery of host-type hematopoiesis. Three patients remained in a state of stable mixed chimerism. *Conclusions.* It appears that substitution of high dose cyclophosphamide with fludarabine and ATG is effective and results in minimal regimen-related toxicity without compromising the rate of engraftment.

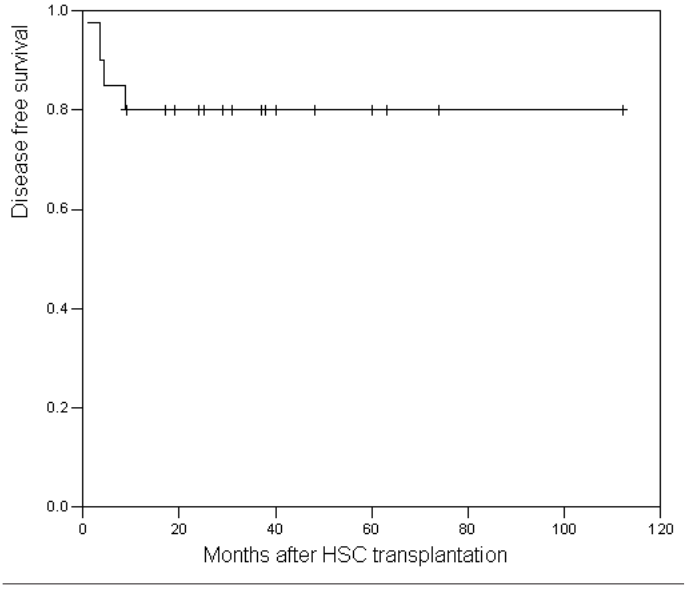

Figure 1. Disease-free survival (Kaplan-Meier Curve).

Bader[2]

[1]Children´s Cancer Research Institute, VIENNA, Austria; [2]University Frankefurt, FRANKFURT, Germany; [3]UMC Utrecht, UTRECHT, Netherlands; [4]Hopital Robert Debré, PARIS, France; [5]St.James´s Hospital, DUBLIN, Ireland; [6]University Turin, TURIN, Italy; [7]Fondazione Tettamanti, MONZA, Italy; [8]University Rotterdam, ROTTERDAM, Netherlands; [9]University Salamanca, SALAMANCA, Spain; [10]University Uppsala, UPPSALA, Sweden; [11]University Geneva, GENEVA, Switzerland; [12]University Bristol, BRISTOL, United Kingdom; [13]National Blood Service, BRISTOL, United Kingdom

We present the results of a collaborative study supported by a grant from the European Commission, the EuroChimerism Concerted Action. The aim of this Concerted Action was the development of a standardized diagnostic methodology for the detection and monitoring of chimerism in patients undergoing allogeneic stem cell transplantation. A set of microsatellite markers, selected on the basis of their excellent performance in chimerism analysis at the reference centers involved, have been carefully evaluated and optimized for quantitative chimerism testing under standardized experimental conditions. A EuroChimerism panel designed to optimally meet the specific requirements of quantitative chimerism analysis was established utilizing 13 markers (D2S1360, D7S1517, D8S1132, D9S1118, D10S2325, D11S554, D12S1064, D12S391, D17S1290, D19S253, MYCL1, P450CYP19 and SE-33), which best satisfied the criteria of the EuroChimerism consortium. Individual microsatellites from the panel can be analyzed in multiplex reactions to facilitate the identification of one or more markers optimally suited for the monitoring of chimerism during the post-transplant period. Extensive testing of related individuals (>500 pairs) revealed that the EuroChimerism marker panel will provide at least two informative markers which meet the stringent criteria of eligibility defined by the EuroChimerism consortium (Watzinger *et al.*, Leukemia 2006) in >99% of all patient/donor constellations. In addition to the outstanding informativeness of the marker panel, chimerism testing by singleplex assays permitted sensitive detection of residual cells of patient or donor origin at levels ranging between 0.8-1.6% in about 90% of instances. The assay also facilitates accurate and reproducible quantification of donor and recipient hematopoietic cells in peripheral blood or bone marrow specimens and in specific cell lineages isolated by flow-sorting. The precision in determining the relative contribution of donor/recipient cell populations to mixed chimerism was high within the range between 10-90% donor- or recipient-derived cells, while there was a tendency to overestimate the percentage of the subdominant cell population within the range between 1-10%. Wide use of the EuroChimerism assay will provide a basis for international standardization of chimerism testing, which will ultimately contribute to improved clinical management of patients undergoing allogeneic stem cell transplantation.

0368

LONGTERM FOLLOWUP AND SAFETY OF BONE MARROW AND PERIPHERAL BLOOD STEM CELL DONORS: A SINGLE INSTITUTION / DONOR REGISTRY REPORT

M. Stadler,[1] B. Behrens,[1] A. Schmitt-Thomssen,[1] E. Dammann,[1] A. Breithaupt,[1] E Wilkens-Aktürk,[2] M. Eder,1 K.W. Sykora,[1] R. Blasczyk,[1] M. Robin-Winn,[2] A. Ganser,[1] H.G. Heuft[1]

[1]Hannover Medical School, HANNOVER; [2]Northern Germany Marrow Donor Registry, HANNOVER, Germany

Background. The safety of bone marrow and peripheral blood stem cell donation is an issue of utmost importance to ensure continuous motivation of volunteer donors for hematopoietic stem cells and the high standing of this procedure in modern civilisation. Procedures have been standardised to guarantee minimal risk during both donor preparation and stem cell harvest. However, recent single reports of leukemias emerging in related donors several years after G-CSF stimulated peripheral blood stem cell mobilisation have raised concern about the long-term safety of this approach. *Subjects and Methods.* Here we report our twelve years experience (March 1994 - January 2007) of 596 consecutive

bone marrow and peripheral blood stem cell donors who were recruited, screened, harvested and followed at our institution and the associated donor registry. 40% were females and 60% males, with a median age of 37 years (range: 1-71 years). 318 were family donors and 278 unrelated volunteer donors. 110 donated bone marrow, 472 peripheral blood stem cells after mobilisation with G-CSF, and 14 both. 33 donors underwent two harvests, four donors even three. Our preparative procedure consisted of a medical work-up including history, examination, blood and clinical chemistry tests, infectious disease markers, electrocardiogram, chest X-ray, lung function test, and abdominal ultrasound. Follow-up was scheduled at 1 and 6 months, as well as 1, 2, 5, and 10 years after donation of hematopoietic stem cells. *Results.* Within the twelve year period of evaluation, no donor death was recorded, no single case of leukemia has been reported, and no splenic rupture occurred in any of our donors. Five donors experienced severe adverse events: In one female bone marrow donor, post-harvesting pain persisted for more than twelve months. A 42 year old female donor developed breast cancer 3 years after G-CSF mobilised stem cell apheresis; however, this was not considered to be of causal relationship. In two donors of peripheral blood stem cells, vascular complications occurred: one donor had to be admitted to hospital during G-CSF mobilisation for symptoms and signs of pulmonary embolus (which, however, could be ruled out), and subsequently was able to donate bone marrow. Another donor had recurrence of a deep vein thrombosis eleven days after stem cell apheresis, despite sufficient anticoagulation with low molecular weight heparin during G-CSF stimulation. Finally, a donor with sporadic epilepsy, who donated twice, had a generalised seizure few days after each G-CSF mobilised harvest. This is particularly interesting in view of recent *in vitro* and animal findings of G-CSF receptors on neural tissues and pleiotrophic neurostimulatory functions of G-CSF. *Conclusions.* In our experience, bone marrow and peripheral blood stem cell donations are safe and generally well tolerated, with very few early and virtually no late complications.

0369

ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH WALDENSTRMS MACROGLOBULINAEMIA. ANALYSIS OF 106 CASES FROM THE EUROPEAN BONE MARROW REGISTRY (EBMT)

C. Kyriakou,[1] C. Kyriakou,[1] C. Canals,[2] G. Taghipour,[2] J. Cornelissen,[2] R. Willemze,[2] G. Socie,[2] K. Thompson,[2] H. Greinix,[2] J. Harousseau,[2] N. Ifrah,[2] J. Kienast,[2] R. Hamladji,[2] M. Kazmi,[2] P. Jacobs,[2] A. Sureda,[2] N. Schmitz[2]

[1]University College London, LONDON; [2]Lymphoma WP of the EBMT, LONDON, United Kingdom

Background. Despite effectiveness of standard chemotherapy regimens, complete response is infrequent in Waldenström's Macroglobulinaemia (WM) patients and there is no cure. The role of allogeneic stem cell transplantation (Allo-SCT) has not been explored extensively and the available data are limited. *Aims.* We retrospectively analyzed the results and long-term outcome of a group of 106 WM patients from 65 European centres who underwent an Allo-SCT between 1989 and 2005 and were reported to the database of the Lymphoma WP of the EBMT. *Patients and Methods.* There were 69 males and median age at transplantation was of 49 years (range, 21-65). Time interval between diagnosis and Allo-SCT was 34 months (5-310) and the median number of lines of therapy prior to Allo-SCT was 3. Nineteen patients (18%) had failed a prior autograft. At Allo-SCT, 10 patients (10%) were in CR≥2, 35 patients (33%) in PR1, 29 patients (27%) in PR≥2 and 32 patients (30%) had relapsed or refractory disease. Seventy-nine patients (74%) were allografted from an HLA-identical sibling donor, 18 (17%) from a matched unrelated donor and the remaining 9 patients from other donors. Conventional conditioning protocols (CT) were used in 44 (41%) patients and reduced intensity conditioning (RIC) regimens in 62 (59%) patients. *Results.* Forty-eight (45%) patients developed acute graft versus host disease [Grade III-IV (n=14)] with no statistically significant differences between CT and RIC regimens. After a median follow up of 31 months (3 to 169), 17 (16%) patients had relapsed at a median time of 8 (1-89) months post Allo-SCT. The incidence of relapse at 3 years was 18%, 12% after CT and 25% after RIC. Thirty-five (33%) patients died, 5 (5%) from disease progression and 30 (28%) from non-relapse mortality (NRM), with an incidence of NRM of 27% and 31% at 1 and 3 years. The progression free survival (PFS) rates were 61%, 50% and 48% at 1, 3 and 5 years and the overall survival rates were of 69%, 63% and 63%, at 1, 3 and 5 years, respectively. In a multivariate analysis, conditioning regimen had no impact either on NRM or on relapse rate. Refractory patients presented with a higher risk of relapse (p=0.03). The use of TBI in the conditioning regimen was associated with a lower relapse risk (p=0.02) and a trend to a better PFS (p=0.1). *Conclusions.* Allogeneic stem cell transplantation is a feasible and well tolerated procedure in this heavily pre-treated group of patients. Relapse rate is low and long-term outcome seems promising, with half of the patients being alive and disease-free 5 years after the procedure.

0370

HEMATOPOIETIC STEM CELL TRANSPLANTATON FOR OSTEOPETROSIS

P.J. Orchard,[1] M. Eapen,[2] J. Tolar,[1] E. Horwitz,[3] P. Veys,[4] F. Fasth[5]

[1]University of Minnesota, MINNEAPOLIS, USA; [2]CIBMTR/Medical College of Wisconsin, MILWAUKEE, WI, USA; [3]St. Jude Children's Research Hospital, MEMPHIS, TN, USA; [4]Great Ormond St Hospital for Children, LONDON, United Kingdom; [5]Göteborg University, GÖTEBORG, Sweden

Autosomal recessive osteopetrosis is a disorder of osteoclast function, generally lethal in the first decade of life without allogeneic hematopoietic stem cell transplantation (HCT). To determine the outcomes of patients with this disorder undergoing transplantation, we examined long-term survival after HCT in 124 children with infantile osteopetrosis reported to the Center for International Blood and Marrow Transplant. The data reflected outcomes of transplantation for patients with osteopetrosis from 1978-1999. The median age at transplantation was 8 months and median time from diagnosis to transplantation 4 months. Forty percent of allografts were from HLA-matched siblings, 34% from unrelated donors and 26% from alternative related donors. Busulfan and cyclophosphamide was the most commonly used conditioning regimen (74%) and bone marrow the predominant graft source (87%). The cumulative incidence of neutrophil recovery at day +100 was 75% (93/124) with similar rates across the three donor sources. Fifty-four children are alive with a median follow up of 7.5 years and an 8-year probability of survival of 43%. The 8-year probabilities of survival were 54%, 39% and 35% after HLA-matched sibling, alternative related and unrelated donor transplantation, respectively. Early mortality rates were high after HCT regardless of donor type; 34% at day +100 and 50% at 1- year after transplantation. Common causes of mortality were graft failure (33%), interstitial pneumonitis or adult respiratory distress syndrome (34%), infections (12%) and graft-versus-host disease (10%). Nineteen patients underwent a second transplant for either primary or late graft failure. Six of these patients are alive. Most second transplants occurred within 6 months from the first transplant (n=15) and the remaining 4 occurred at 4, 4.5, 5 and 9 years after the first transplant. We conclude that long term survival for autosomal recessive osteopetrosis can be obtained with HCT. Peri-transplant mortality and graft failure remain significant obstacles in this population. Second transplantation is a viable option if engraftment is not initially achieved.

Acute lymphoblastic leukemia - Clinical

0371

HIGH INTERLEUKIN-15 EXPRESSION LEVELS IN INITIAL DIAGNOSTIC LEUKEMIC CELLS OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA ARE ASSOCIATED WITH SUBSEQUENT RELAPSE INVOLVING THE CENTRAL NERVOUS SYSTEM

G. Cario,[1] S. Izraeli,[2] A. Teichert,[3] P. Rhein,[4] J. Skokowa,[3] A. Möricke,[1] M. Zimmermann,[3] A. Schrauder,[1] W.D. Ludwig,[4] K. Welte,[3] H. Schünemann,[5] B. Schlegelberger,[3] M. Schrappe,[1] M. Stanulla[3]

[1]University Hospital Schleswig-Holstein, KIEL, Germany; [2]Chaim Sheba Medical Center, Tel-Hashomer, TEL-AVIV, Israel; [3]Hannover Medical School, HANNOVER, Germany; [4]Robert-Rössle-Clinic, Charite, BERLIN, Germany; [5]Italian National Cancer Institute, ROME, Italy

Background. Central nervous system (CNS)-targeted therapy as part of treatment for childhood acute lymphoblastic leukemia (ALL) is highly effective in the prevention of CNS relapse, but is associated with significant toxicity. The intensity of CNS-targeted treatment is adjusted according to the risk of ALL relapse originating from the CNS, the most important risk factor being overt CNS involvement at diagnosis. However, most ALL relapses involving the CNS occur in patients classified as CNS-negative at initial diagnosis. Although there are some known risk factors for CNS involvement of ALL such as T-cell-precursor immunophenotype and high initial white blood cell (WBC) count, the underlying biology leading to CNS disease is poorly understood. *Aims.* To improve patient characterization and to explore potential distinct biological properties of leukemic cells that migrate into the CNS by comparing gene expression profiles of childhood ALL patients with initial CNS involvement to CNS-negative patients. *Methods.* Leukemic gene expression profiles from bone marrow of 17 CNS-positive patients and 26 CNS-negative patients frequency-matched for risk factors associated with CNS involvement were analyzed using microarrays containing more than 39,000 distinct cDNA clones (SFGF, Stanford CA). Data were analyzed applying Significance Analysis of Microarrays (PNAS 2001, 98, 5116-5121). Results were confirmed by real-time quantitative polymerase chain reaction analysis and validated using independent patient samples. *Results.* Our analytical approach identified several differentially expressed genes. To control for possible T-cell contamination of the samples, we purified leukemic cells from four samples and repeated the analysis. Interleukin 15 (IL-15) was one of the genes for which differential expression could be confirmed with an up to 10-fold higher expression in CNS-positive patients. The high expression of IL-15 in patients with CNS involvement was validated in an independent set of 13 CNS-positive and 26 CNS-negative patients by quantitative RT-PCR in a similar range as described above (P Mann-Whitney U-Test "0.001). In multivariate analysis, IL-15 expression levels above the median were associated with CNS involvement compared to expression equal to or below the median (odds ratio (OR) = 10.70, 95% confidence interval (CI) 2.95-38.81). Diagnostic likelihood ratios for CNS-positivity were 0.09 (95% CI 0.01-0.65) for the first and 6.93 (95% CI 2.55-18.83) for the fourth IL-15 expression quartile. Next, we compared IL-15 expression at initial diagnosis of CNS-negative patients subsequently relapsing with CNS involvement (n=22) to those without CNS disease and being in long-term remission (n=44). In patients CNS-negative at diagnosis, IL-15 levels above the median were associated with subsequent CNS relapse compared to expression equal to or below the median (OR=13.80, 95% CI 3.38-56.31). *Conclusions.* We conclude that measurement of IL-15 expression levels could serve as an additional tool to further tailor CNS-directed therapy in children newly diagnosed with ALL. Additional studies are needed to finally elucidate the role of IL-15 in the pathogenesis of CNS disease in childhood ALL.

FINAL RESULTS OF THE TREATMENT OF ADOLESCENTS AND YOUNG ADULTS WITH STANDARD-RISK ALL WITH THE PEDIATRIC-BASED PROTOCOL PETHEMA ALL-96

J.M. Ribera,[1] J.M. Ribera,[1] A. Oriol,[1] M.A. Sanz,[2] P. Fernandez-Abellan,[2] E. Del Potro,[2] E. Abella,[2] J. Bueno,[2] C. Grande,[2] C. Calvo,[2] C. Bethencourt,[2] J. Fernandez-Calvo,[2] J.M. Martí,[2] I. Heras,[2] R. Parody,[2] E. Feliu,[2] J.J. Ortega[2]

[1]Institut Català d'Oncologia- Hospital Ge, BADALONA; [2]PETHEMA Group, BARCELONA, Spain

Background. Recent retrospective comparative studies have shown that adolescents and young adults with standard-risk (SR) ALL are better managed with pediatric-based than adult-based chemotherapeutic schedules. *Aims.* To report the final results of the PETHEMA ALL-96, a pediatric-based protocol, in adolescents and young adults with SR ALL. *Patients and therapy.* Criteria for SR-ALL: age 15-30 yr., WBC count $<25\times10^9$/L and absence of t(9;22)(or BCR/ABL), t(1;19) or 11q23 rearrangements. Induction: VCR, DNR, PDN, ASP and CPM over 5 weeks. Consolidation-1 (C1): MP, HD-MTX, VM26 and ARA-C. Consolidation-2/reinduction (C2): VCR, DNR, DXM, ASP and CPM. Maintenance-1 (M1): MP+MTX with monthly reinduction cycles (VCR, PDN, ASP) up to 1 yr. Maintenance-2 (M2): MP+MTX up to 2 yr. in continuous CR. CNS prophylaxis consisted of triple i.t. therapy (MTX+ARA-C+DXM), 14 doses over the 1st yr. *Results.* 86 patients included, mean (SD) age 20 (4) yr. 54 males, WBC count 7.6 (8.0)$\times10^9$/L. Phenotype: pro-B 6, Common+pre-B: 61, T: 19. Cytogenetics (61 evaluable cases, after review): normal 37, hyperdiploid 13, hypodiploid 1, other 10. Evaluable for response: 84 pts. CR 80 (95%), slow response (>10% of BM blast cells on day 14) 10 pts, early death 2, resistance 2, relapse 18 (1 CNS, 17 BM isolated or combined, 6 during therapy), death 16 pts (2 induction, 1 C2, 13 relapse/progression). With a median follow-up of 35 mo. 5-yr (95%CI) OS and DFS probabilities were 74% (63-85) and 66% (54-78). No pretreatment variables influenced CR, DFS and OS. The slow response to therapy was the only prognostic factor for CR (80% vs. 99%, p=0.04) and survival (40% vs. 85%, p=0.001). Overall toxicity was acceptable, although there were dose modifications or delay in therapy in 10% pts in induction, 26% pts in C1, 15% in C2, 22% in M1 and 21% in M2. *Conclusions.* The results of the pediatric-based PETHEMA ALL-96 study for adolescents and young adults with SR ALL treated in adult hematology units are identical to those reported in national series from pediatric centers. Slow response to therapy was the only prognostic factor for remission and survival.

TWO DECADES OF PROGRESS IN ADOLESCENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIAS TREATED IN THE FRALLE PROTOCOLS: ADOLESCENCE IS NO MORE A BAD PROGNOSTIC FEATURE IF AN INTENSIVE CHEMOTHERAPY IS APPLIED

A. Baruchel,[1] M.F. Auclerc,[2] Y. Perel,[3] F. Mechinaud,[4] A. Auvrignon,[5] C. Schmitt,[6] C. Piguet,[7] O. Lejars,[8] C. Berthou,[9] F. Demeocq,[10] P. Schneider,[11] V. Gandemer,[12] G. Michel,[13] J.M. Cayuela,[14] T. Leblanc,[15] G. Leverger,[5] F. Fralle Group[14]

[1]AP-HP, Paris 7 University, PARIS; [2]INSERM, PARIS; [3]CHU Bordeaux, BORDEAUX; [4]CHU Nantes, NANTES; [5]Hôpital Trousseau, PARIS; [6]CHU Nancy, NANCY; [7]CHU Limoges, LIMOGES; [8]CHU Tours, TOURS; [9]CHU Brest, BREST; [10]CHU Clermont-Ferrand, CLERMONT-FERRAND; [11]CHU Rouen, ROUEN; [12]CHU Rennes, RENNES; [13]CHU Marseille, MARSEILLE; [14]Hôpital Saint-Louis, PARIS; [15]Hôpital St-Louis, PARIS, France

Adolescence has been claimed since the seventies to be associated to a a bad prognosis in childhood ALL. Out of 4658 patients with ALL, 258 adolescents (15-20 year old)(5.5%) were treated in the successive FRALLE 83, FRALLE 87-89, FRALLE 92 (pilot phase), FRALLE 93 and FRALLE 2000 protocols. The main characteristics were: a sex ratio of 1.8 (M/F), a B-lineage in 71% of the cases vs T lineage in 29%, and a median WBC of 12 G/L (9-1000). Translocation and fusion transcripts were searched for in 120 evaluable BCP-ALL: t(9;22)/BCR-ABL, 8 pts (6%); t(1;19)/E2A-PBX1, 12 pts (10%); t(4;11)/MLL-AF4, 4 pts (3%). Out of 75 evaluable pts t(12;21)/TEL-AML1 was found in only 4 pts (3%). 242 out of 258 adolescents were in CR at the end of induction therapy (EOI) (94%) without any significant difference according to the era. Nevertheless a major difference in the 3y and 5y EFS was found ans is shown in Table 1. The main modification introduced in the nineties was the adoption of a double delayed intensification for the good early responders. Autologous BMT or allogenic BMT were indicated in bad early responders (D8 poor prednisone response, D21 marrow M3 response) and/or unfavourable cytogenetics. The better results of the 2000 protocol can mainly be explained by the intensification of chemotherapy in most phases and especially between induction and delayed Intensification 1 and before delayed Intensification 2. These better results were obtained despite decreasing the indications of allo BMT (6 performed vs 20 in the nineties) and of CNS irradiation (100% in the nineties vs 35% in the current era, including the TBI for BMTs). ABMT was no more indicated. *Conclusions.* 1) excellent results can now be achieved in adolescents with ALL 2) this works emphasizes again the need to treat adolescents according to pediatric intensive protocols and not *adult type* protocols, as we

recently suggested (Boissel *et al.,* J Clin Oncol 2003). 3) Whether this could also be applied to young adults is currently under testing.

Table 1.

	Number of pts	CR at end of induction	3y EFS (%)	5y EFS (%)	10y EFS (%)
Eighties (F83, 87-89)	100	93	42 ± 5	35 ± 5	35 ± 5
Nineties (F92, F93)	84	93	71 ± 5*	67 ± 5**	67 ± 5

RISK ADAPTED TREATMENT OF ADOLESCENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) ACCORDING THE GERMAN MULTICENTER STUDY GROUP (GMALL) STUDIES 06/99 AND 07/03 YIELDS SIGNIFICANTLY DIFFERENT OUTCOME FOR SUBGROUPS

N. Goekbuget,[1] R. Arnold,[2] A. Böhme,[1] R. Fietkau,[3] M. Freund,[3] A. Ganser,[3] M. Kneba,[3] T. Lipp,[4] W.-D. Ludwig,[3] G. Maschmeyer,[5] D. Messerer,[6] H. Rieder,[3] E. Thiel,[2] D. Hoelzer[1]

[1]J.W.Goethe University, FRANKFURT AM MAIN; [2]University Hospital Charité, BERLIN; [3]University Hospital, ROSTOCK; [4]Krankenhaus Schwabing, MÜNCHEN; [5]Klinikum Ernst von Bergmann, POTSDAM; 6IBE, University, MUNICH, Germany

In the recent years several groups have reported treatment results in adolescents with ALL. Outcome with protocols for adults (EFS 34-71%) were generally inferior compared to pediatric protocols (EFS 64-80%) (S.Sallan, ASH Education 2006). The conclusion was that pediatric trials include higher doses of VCR, ASP and HDMTX and a higher time-dose intensity. However the poor outcomes of most compared adult protocols are probably also due to suboptimal approaches in these specific studies e.g. stem cell transplantation (SCT) in all pts with donor. The GMALL started in 1999 the study 06/99 followed by 07/03 with minor changes. Induction is based on DEXA, DNR, VCR, PEG-ASP and standard phase II. All pts received HDMTX/HDAC based consolidation1. High risk (HR) pts (B-lineage ALL with WBC>30.000 or late CR, pro-B, earlyT, mature T, t(4;11), t(9;22)) were allocated to allogeneic SCT. Standard risk (SR) pts received consolidation with HDMTX/ASP (3x), VM26/ARAC, CYCLO/ARAC and reinduction. Since 2003 most pts with Ph+ received Imatinib. Between 9/99 and 12/06 1514 pts were included. 417 (28%) were adolescents aged 15-25 yrs (18% 15-17, 41% 18-20 and 41% 21-25 yrs). Of those 58% were SR, 34% HR and 8% Ph+. Immunophenotypes were c/preB(63%), proB(5%), earlyT(7%) matureT(7%) and thymicT(18%). Entry criteria showed no differences for the three age groups. The CR rate was 90% (87% after phase I; 93%, 92% and 88% for the 3 age groups). 2% died in induction; 7% failed. The overall survival (OS) was 64%, 67% in CR pts and the relapse free survival 54%. OS according to age was 68%, 62% and 65%. CR rates and OS differed significantly for risk groups and subtypes. OS was 74% for SR, 49% for HR and 55% for Ph^+ ($p<.05$). For subtypes OS ranged from 36% for HR c/pre-B-ALL to 70% for thymic and 74% for SR c/pre-B-ALL ($p<.05$). SCT in CR1 was realised in 73% of HR/VHR pts. OS was 57% with significant differences for subtypes (range from 46% for HR B-lin to 76% for early T). TRM for allo SCT (sibling, MUD) was 25%. We present here the results of the largest cohort of adolescent ALL pts treated according to adult protocols so far. CR rate and OS are superior to most of those reported from adult protocols but still at the lower end of range for pediatric trials. There are two major problems: The high relapse rate in SR and the TRM in HR. Further chemo intensification is planned for SR pts. Imatinib is added for Ph^+ and Rituximab for $CD20^+$ ALL. SCT leads to improvement of OS in subgroups of HR ALL, although not in all subtypes. The indication fo SCT should therefore even in young pts be defined carefully considering the TRM and late effects. Several studies with pediatric protocols used in adults are ongoing. The CR rates (82-92%) and EFS (66-72% (ASH 2006, #147, #1858, #1875) are promising but considerable toxicity e.g. neuropathies, thrombosis was observed indicating that these protocols may probably be not be transferred to all adults.

DIFFERENT OUTGROWTH KINETICS OF CLONES WITH BCR-ABL KINASE DOMAIN MUTATIONS IN DE NOVO VERSUS RELAPSED PHILADELPHIA-POSITIVE ALL IMPLY AN ADDITIONAL ROLE OF NON-MUTATIONAL RESISTANCE MECHANISMS

H. Pfeifer,[1] B. Wassmann,[1] S. Wystub,[1] T. Lange,[2] A. Hochhaus,[3] D. Hoelzer,[1] O.G. Ottmann[1]

[1]University Hospital Frankfurt, FRANKFURT; [2]University Hospital Leipzig, LEIPZIG; [3]University Hospital Mannheim, MANNHEIM, Germany

Background. Approximately 80% of patients with newly diagnosed Ph+ALL who relapse during imatinib-based therapy express a BCR-ABL Tyrosine Kinase Domain TKD mutation in the dominant cell population. Nearly all of these mutations are associated with high-level imatinib resistance. We recently showed that the same mutation found at relapse can already be detected prior to first imatinib exposure in 30% to 40% of patients with de novo Ph+ALL but that it is not associated with an inferior response: approximately 95% of patients achieve a complete remission (CR) with imatinib alone. In contrast, the CR rate with imatinib salvage therapy in patients who failed previous chemotherapy is only 20-30% and the median time to progression only 2.2 months. Possible reasons for this difference are a higher frequency of pre-existing mutations, a preponderance of mutations with greater transforming activity, a larger mutant clone or a contribution of non-mutational resistance mechanisms. *Aims.* We therefore examined the frequency and pattern of up-front mutations, the level of mutant clones, and the outgrowth kinetics of mutations during the first 4 weeks of imatinib monotherapy in de novo Ph+ALL patients and in patients who had failed prior chemotherapy. *Patients and Methods.* By denaturing high-performance liquid chromatography (D-HPLC) and cDNA sequencing, we examined bone marrow and/or peripheral blood samples collected pre-treatment, during therapy and at relapse from 48 pts. with newly diagnosed Ph+ALL (>55 yrs.) enrolled in a GMALL study of combined IM and chemotherapy, and from 67 Ph+ALL pts. who were enrolled in the initial phase II studies of single-agent imatinib as salvage treatment after prior chemotherapy. *Results.* The frequency of TKD mutations pre-IM was 38% (23/59) in pts. with advanced Ph+ALL and 37,5% (12/32) in newly diagnosed Ph+ALL. The incidence of mutations observed at relapse was substantially higher but did not differ significantly between the two cohorts: 70% in pts. with advanced disease who relapsed on IM monotherapy (36 of 51 pts.; P-loop 76%, T315I 21%, A-loop 2%) and 84% in de novo ALL pts. (n=26), treated with combination therapy (P-loop 47%, T315I 15%, A-loop 9,5%). In contrast, the outgrowth of cells expressing mutated bcr-abl during the first four weeks of imatinib therapy was considerably more rapid in Ph+ALL patients who had failed prior chemotherapy: mutations were detected after 2 and/or 4 weeks imatinib in only 34% of patients (6/18 evaluable) with newly diagnosed Ph+ALL, whereas 69% of patients (27/39) with advanced Ph+ALL expressed mutant BCR-ABL on at least one of these timepoints. Moreover, the percentage of mutated BCR-ABL was below 1% in all 6 pts. with a mutation in the former cohort (de novo Ph+ALL), but higher than 5% (range: 5-100%) in 16 of the 27 advanced disease patients (59%) who had a TKD mutation. *Conclusions.* In Ph+ALL, prior treatment with chemotherapy is not associated with a higher incidence, different spectrum or higher level of TKD mutations, either pre-imatinib or at relapse, when compared to patients with newly diagnosed leukemia. However, outgrowth kinetics of leukemic cells expressing BCR-ABL mutations are considerably more rapid in patients with advanced disease, providing clinical-translational evidence for a cooperative effect between mutational and non-mutational resistance mechanisms.

RITUXIMAB THERAPY FOR IMMUNE ANEMIA AND THROMBOCYTOPENIA: A BELGIAN REGISTRY RUN BY THE RED CELL SUBCOMITTEE OF THE BELGIAN SOCIETY FOR HEMATOLOGY

D. Dierickx,[1] A. Triffet,[2] P. Mineur,[3] A. Kentos,[4] A. Ferster,[5] D. Boulet,[6] C. Vermylen,[7] B. Deprijk,[6] Y. Beguin,[2] M.F. Dresse,[6] K. Kargar,[6] G. Verhoef,[1] A. Delannoy[8]

[1]Gasthuisberg, LEUVEN; [2]CHU, CHARLEROI; [3]CH Gilly, CHARLEROI; [4]CHU Erasme, BRUSSELS; [5]HUDERF, BRUSSELS; [6]CHR, MONS; [7]UCL St Luc, BRUSSELS; [8]CHJolimont and UCL St Luc, LA LOUVIÈRE, Belgium

Background. Immune thrombocytopenic purpura (ITP) and autoimmune hemolytic anemia (AHA) may respond to the chimeric anti-CD20 monoclonal antibody rituximab, even when refractory to conventional therapy. Aims. To collect data on Belgian patients given rituximab in the setting of ITP or AHA in order to assess the response rate and the factors predictive for response in a multicenter study. Method. Belgian hematology centers were invited to fill a questionnaire specifying the major characteristics and quality of response of ITP and AHA patients given rituximab. For ITP, complete response (CR) was defined as a platelet count >100,000/µL without immunosuppressive therapy, and a partial response as a platelet count 50-100,000/µL without immunosuppressive drugs. For AHA, CR was defined as a normal hemoglobin in the absence of hemolysis, and a PR as a 2g increase of the hemoglobin concentration. *Results.* Patient characteristics and response to therapy are presented in the attached Table 1. In practically all the patients reported here, rituximab was given at the dose of 375 mg/m^2 weekly for 4 weeks. In both ITP and AHA patients we could find no significant correlation between response and sex, age, prior splenectomy, platelet count or hemoglobin concentration when rituximab was started. *Conclusions.* In this still open registry, we could confirm that rituximab induces responses in a majority of previously treated patients with ITP or AHA. Responses could not be predicted from pre-treatment patient characteristics. As data are accumulating in the registry, more information on the duration of response will be made available.

Table 1.

	ITP	AHA
n	23	44 episodes in 35 patients
Male/Female	14/9	18/17
Median age (range)	44 (9-86)	57 (1-82)
Underlying lymphoma/leukemia	3	15
Median n of previous therapies	3 (1-4)	2 (0-5)
Previous splenectomy	14	10
Median platelet/hemoglobin at start of rituximab	24,000/µL (3-250)	8.4 g/dL (4-14.2)
CR/PR/Failure	13/2/8	15/20/9

0377

RESULTS FROM A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF DARBEPOETIN ALFA FOR THE TREATMENT OF ANEMIA IN CANCER PATIENTS NOT RECEIVING CHEMOTHERAPY OR RADIOTHERAPY

J.A. Glaspy,[1] R.E. Smith,[2] M. Aapro,[3] H. Ludwig,[4] T. Pintér,[5] M. Smakal,[6] T. Ciuleanu,[7] L. Chen[8]

[1]UCLA Medical Center, LOS ANGELES, USA; [2]South Carolina Oncology Associates, COLUMBIA, USA; [3]Clinique de Genolier, GENOLIER, Switzerland; [4]Wilhelminenspital, VIENNA, Austria; [5]Petz Aladar County Teaching Hospital, GYOR, Hungary; [6]Ustav Onkologie a Pneumologie Na Plesi, PLEœI, Czech Republic; [7]Institutul Oncologic Ion Chiricuta Onc, CLUJ-NAPOCA, Romania; [8]Amgen Inc., THOUSAND OAKS, USA

Background. Patients with cancer, not receiving chemotherapy or radiation, often develop anemia as a result of the disease itself. *Aims.* This phase 3 study was designed to evaluate the efficacy and safety of darbepoetin alfa (DA) 6.75 mcg/kg administered every 4 weeks (Q4W) for the treatment of anemia of cancer (AoC). *Methods.* Pt eligibility included: ≥18 years, non-myeloid malignancy (with active disease), hemoglobin ″11 g/dL, ECOG status score of 0-2, receiving neither chemotherapy nor radiotherapy within 4 weeks of screening or during the study, and providing informed consent. Patients (n=985) were randomized to DA 6.75 mcg/kg or placebo Q4W for 16 weeks, with an end of study visit at week 19, and 2 years of follow up to evaluate survival. Patients were stratified by screening hemoglobin (<10 vs≥10 g/dL), geographic region (Europe vs rest of world), red blood cell transfusion in the prior 12 weeks (yes vs no), tumor type/treatment (chronic lymphocytic leukemia or low grade lymphoma, ongoing hormonal or antibody therapy, or all other eligible patients), and ECOG status (0-1 vs 2). DA dosing was withheld if hemoglobin increased >13 g/dL and reinstated at 25% dose reduction once hemoglobin <12 g/dL. The primary endpoint was all occurrences of transfusions from weeks 5 to 17. Secondary endpoints were: incidence of transfusions from week 5 to 17 (including a prespecified sensitivity analysis of incidence of either transfusion or hemoglobin ″8 g/dL), change in hemoglobin from baseline (BL) to end of treatment period, and safety. *Results.* Demographics were broadly similar between the groups: mean (SD) age was 64.1 (11.6) years; the most common cancers were non-small cell lung (18%), breast (13%), and prostate (11%); most patients had disease stage III/IV (82%), most had an ECOG score of 0 or 1 (72%); BL hemoglobin was 9.5 g/dL in each group. However, there were more men in the DA group (56% vs 47% in placebo), and more patients received prior chemotherapy in the DA group (73% vs 66% in placebo). The mean (SD) number of days between prior chemotherapy and first study drug dose was 262 (572) days for the DA group vs 315 (660) for placebo. The Table 1 shows efficacy endpoints and safety data. *Summary and conclusions.* This study did not meet its primary endpoint of reducing transfusions in the DA treatment group. More deaths occurred in the DA vs. placebo group. Based on the observed results and additional analyses, the risk/benefit profile of DA in anemic patients with active cancer not receiving chemotherapy is at best neutral and possibly negative. Results of long-term follow up are awaited.

Table 1. Summary of results.

0378

SAFETY AND EFFICACY OF THE TERMINAL COMPLEMENT INHIBITOR ECULIZUMAB IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: SHEPHERD PHASE III CLINICAL STUDY RESULTS

H. Schrezenmeier,[1] L. Luzzatto,[2] B. Rotoli,[3] N.S. Young,[4] J. Schubert,[5] A. Urbano-Ispizua,[6] L. Coyle,[7] C. DeCastro,[8] C.L. Fu,[9] J.P. Maciejewski,[10] H.A. Kroon,[11] R.P. Rother,[11] P. Hillmen[12]

[1]University Hospital Ulm, ULM, Germany; [2]Istituto Toscano Tumori, FIRENZE, Italy; [3]Policlinico di Napoli Federico II, NAPLES, Italy; [4]National Heart, Lung, & Blood Institute, BETHESDA, MD, USA; [5]Saarland University Medical School, HOMBURG/SAAR, Germany; [6]Hospital Clinic i Provincial, BARCELONA, Spain; [7]Royal North Shore Hospital, ST LEONARDS, Australia; [8]Duke University Medical Center, DURHAM, NC, USA; [9]Cleveland Clinic Florida, WESTON, FL, USA; [10]The Cleveland Clinic Foundation, CLEVELAND, OH, USA; [11]Alexion Pharmaceuticals, Inc., CHESHIRE, CT, USA; [12]Leeds Teaching Hospitals NHS Trust, LEEDS, United Kingdom

Background. In paroxysmal nocturnal hemoglobinuria (PNH), lack of the GPI-anchored terminal complement inhibitor CD59 from erythrocytes renders these cells susceptible to chronic hemolysis resulting in anemia, fatigue, thrombosis, poor quality of life (QoL), and transfusion dependency. Eculizumab, a terminal complement inhibitor, reduced hemolysis and transfusion requirements in transfusion dependent patients with normal or near-normal platelet counts in a randomized placebo-controlled phase III study (TRIUMPH). *Aims.* To evaluate the safety and efficacy of eculizumab in an open-label non-placebo controlled global phase III study (SHEPHERD) in a broad PNH population including patients with significant thrombocytopenia (platelet counts as low as 30×10^9/L) and/or minimal transfusion requirements (at least 1 transfusion in the preceding 2 years). *Methods.* Eculizumab was dosed as follows: 600 mg IV every 7±2 days × 4; 900 mg 7±2 days later; and then 900mg every 14±2 days for a total of 52 weeks of therapy. *Results.* Eculizumab was administered to 97 patients at 33 international sites. The most frequent adverse events were headache (53%), nasopharyngitis (32%), and upper respiratory tract infection (30%). Most adverse events were mild to moderate in severity and not considered related to eculizumab. No serious adverse events were reported as probably or definitely related to drug. Eculizumab did not increase infections relative to the incidence of infections in placebo-treated patients from the TRIUMPH study. Intravascular hemolysis, the central clinical manifestation in PNH and the primary efficacy endpoint of the trial, was rapidly and significantly reduced in eculizumab patients as assessed by change in lactate dehydrogenase (LDH) area under the curve ($p<0.001$) from baseline. LDH levels decreased 87% from a median of 2,051 U/L at baseline to 269 U/L at 52 weeks ($p<0.001$; normal range 103-223 U/L). Eight of 97 patients had incomplete complement blockade and return of hemolysis during the 14-day dosing interval; shortening the dosing interval to 12 days per protocol led to sustained inhibition of complement and hemolysis in 6 of 6 patients. Control of hemolysis resulted in improvement in anemia as transfusion requirements decreased from a median of 8.0 (mean, 12.3±1.25) PRBC units/patient during the 12-month pre-treatment period to 0.0 (mean, 5.9±1.06) during 12 months of eculizumab treatment ($p<0.001$). Reduction in units transfused was demonstrated in each of four 12-month pre-treatment transfusion strata, reaching statistical significance in 3 strata. Approximately 50% of the patients were rendered transfusion independent ($p<0.001$), and hemoglobin levels increased from baseline ($p<0.001$) during the study. Fatigue levels, as measured by both the FACIT-Fatigue instrument and the fatigue scale of the EORTC QLQ-C30 instrument, were rapidly and significantly improved with eculizumab treatment ($p<0.001$ for each). Other EORTC-QLQ-C30 patient reported outcomes demonstrating improvement included global health status ($p<0.001$), all 5 patient functioning subscales ($p<0.001$) and 7 of 9 symptom/single item subscales ($p<0.003$). *Summary and conclusions.* Eculizumab appears to be safe and well tolerated. Beneficial effects of eculizumab in PNH are observed in a broader patient population than previously studied including those with thrombocytopenia and/or minimal transfusion requirements. This further underscores that eculizumab markedly reduces hemolysis, thereby providing significant clinical benefit to treated patients.

0379

THE CLINICAL BENEFIT OF ECULIZUMAB IS DEMONSTRABLE IN ALL SUBPOPULATIONS OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) WITH HEMOLYSIS

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a rare and life-threatening blood disease characterized by complement-mediated destruction of red blood cells (RBCs). Overall results from two Phase 3 clinical studies enrolling a heterogeneous group of PNH patients with hemolysis show that the terminal complement inhibitor eculizumab (Soliris™) significantly reduces hemolysis resulting in improved anemia, fatigue and other patient reported quality of life outcomes. *Aims.* Evaluate the efficacy of eculizumab across diverse subpopulations of patients with PNH. *Methods.* Efficacy outcomes with eculizumab treatment in various patient subpopulations were evaluated including hemolysis (lactate dehydrogenase, LDH, change from baseline at 6 months), transfusion requirements (median units transfused per patient 6 months before versus 6 months during eculizumab treatment), and fatigue (FACIT-Fatigue score change from baseline at 6 months) using the combined datasets from the Phase 3 clinical studies TRIUMPH and SHEPHERD.

Table 1. Effect of Eculizumab on 6-month outcomes in patients with PNH.

Sub-populations	Strata	N	Median change in LDH, U/L	N	Median units transfused pre- vs post-eculizumab	N	Median change in FACIT-Fatigue*
History of AA/MDS	Yes	38	-1379	39	7.0 vs 0.0	38	8.8
	No	99	-1879	101	7.0 vs 0.0	97	7.0
Platelets† (10^9/L)	≥151	69	-1840	70	6.0 vs 0.0	68	8.5
	<151	68	-1486	70	8.0 vs 2.0	67	6.0
Reticulocytes† (10^{12}/L)	≥0.2	68	-1973	70	8.0 vs 0.0	67	6.0
	<0.2	69	-1296	70	6.0 vs 0.0	68	9.0
Steroid Usage	Yes	33	-1954	33	6.0 vs 2.0	32	8.0
	No	104	-1795	107	8.0 vs 0.0	103	7.0
Erythropoietin Usage	Yes	8	-1560§	8	7.5 vs 1.0§	8	5.0§
	No	129	-1835	132	7.0 vs 0.0	127	7.0
PNH Type III RBCs† (%)	≥31	69	-2161	70	5.0 vs 0.0	68	8.0
	<31	68	-1486	70	8.0 vs 2.0	67	6.0
Hemolysis† (LDH, U/L)	≥2042	69	-2534	70	7.5 vs 1.5	68	8.8
	<2042	68	-1104	70	6.0 vs 0.0	67	4.7
Hemoglobin† (g/dL)	≥9.8	70	-1699	70	8.0 vs 0.0	68	5.5
	<9.8	67	-1889	70	4.0 vs 1.5	67	8.0
Pre-treatment Transfusion Strata‡	<4	21	-1798	21	0.0 vs 0.0¶	21	9.0
	4-14	61	-1500	62	5.5 vs 0.0	60	9.0
	15-25	32	-1806	32	10.0 vs 2.0	32	4.0
	25+	23	-1954	25	16.0 vs 4.0	22	6.5
Transfusion Independence on Treatment	Yes	75	-1625	75	6.0 vs 0.0	74	6.0
	No	62	-1920	65	8.0 vs 6.0	62	7.0

*Positive change is an improvement in fatigue; >3 points is clinically meaningful
†Strata are above versus below median value at baseline
‡Units packed RBCs transfused per patient over 12-months pre-treatment
All comparisons are $P<0.001$, except for §$P\leq0.031$ and ¶P=not significant

Results. Statistically significant improvements in hemolysis, transfusion requirements and fatigue with eculizumab treatment were observed for

each of multiple PNH subpopulations (Table 1) including patients with: (1) a history of bone marrow dysfunction (AA or MDS); (2) thrombocytopenia; (3) lower levels of reticulocytes; (4) different concomitant medications including steroids or erythropoietin; (5) smaller proportions of PNH cells (PNH clone size); (6) lower levels of baseline hemolysis; (7) lower levels of anemia; (8) minimal pre-treatment transfusion requirements; (9) and without complete transfusion independence during eculizumab treatment. Significant improvements in hemolysis ($p<0.001$), transfusion requirements ($p<0.001$), and fatigue ($p<0.007$) were also demonstrated regardless of age, gender, race, weight, geography, disease duration, concomitant iron/folate or anticoagulant usage, and whether or not the patient had a history of thrombosis. Summary and conclusions. All patients treated with eculizumab respond with a marked reduction in hemolysis, the hallmark of PNH. Eculizumab significantly reduced hemolysis and transfusion requirements, and improved fatigue in patients regardless of whether they become entirely transfusion independent during treatment. Finally, the improvement in hemolysis with eculizumab directly leads to significant clinical benefit across all subgroups in a broad and diverse PNH population, including patients with poor bone marrow function, smaller PNH clone sizes, low levels of hemolysis, less anemia, minimal pre-treatment transfusion requirements and those receiving steroids or erythropoietin.

School of Medicine, BALTIMORE, MD, USA; [10]Hospital Saint Louis and INSERM, PARIS, France; [11]Washington University School of Medicine, ST. LOUIS, MO, USA; [12]Alexion Pharmaceuticals, Inc., CHESHIRE, CT, USA; [13]Istituto Toscano Tumori, FIRENZE, Italy

Background. Life-threatening thromboembolism (TE) is the most feared complication in paroxysmal nocturnal hemoglobinuria (PNH). TE accounts for approximately 45% of PNH patient deaths. Rapidly fatal TE without a previous thrombotic history occurs in PNH, highlighting the importance of effective preventative therapy in this population. Primary prophylactic anti-coagulation potentially reduces the thrombotic risk in PNH, although controlled studies have not been performed and there is a risk of life-threatening hemorrhage. Three studies of the terminal complement inhibitor eculizumab in PNH recently demonstrated dramatic reductions in intravascular hemolysis and units of red cells transfused with improvements in fatigue and other patient reported outcomes. *Aims.* To determine whether treatment with eculizumab reduced TE risk in patients with PNH. *Methods.* We systematically and prospectively examined the aggregate TE event rate in eculizumab-treated patients from the three parent studies and a subsequent common extension study compared to the TE rate in the same patients pre-eculizumab. *Results.* Before receiving eculizumab, 124 TE events in 195 patients were identified; 103 patients were on antithrombotics. Pre-treatment TE events in the study group occurred in both venous (85%) and arterial (15%) sites. The most common sites of venous thrombosis were lower extremity deep veins (18.5%), mesenteric/splenic veins (18.5%), hepatic/portal veins (16.9%), and other deep veins (14.5%), while the most common site of arterial thrombosis was cerebrovascular accident/transient ischemic attack (13.7%, median age of 38). Eculizumab reduced the TE rate in each of the three parent studies. The aggregate TE event rate during eculizumab treatment was significantly reduced by 85% when compared with the same patients before eculizumab treatment (see Table 1). With restriction of the pre-treatment observation period to the 12-months immediately preceding eculizumab treatment, the TE event rate during eculizumab treatment was significantly reduced by 94%. The TE event rate in patients with TE prior to the trials was also significantly reduced by 89%. Most TE events prior to eculizumab treatment occurred in patients receiving antithrombotics either therapeutically or prophylactically, indicating that this therapy may be insufficient to prevent thrombosis. Of 103 patients on antithrombotics, there were 54 TE events in 30 patients pre-eculizumab compared to one TE event during eculizumab treatment, demonstrating that eculizumab significantly reduces the risk of thrombosis in PNH patients despite treatment with antithrombotics. Pre-eculizumab, TE was frequent in patients with lower levels of hemolysis and with mild anemia; eculizumab significantly reduced TE across these and other subgroups. *Summary and conclusions.* These data show that in PNH, TE can occur in both the arterial as well as the venous systems, in the context of lower levels of hemolysis or with mild anemia, and patients may continue to experience thrombosis during antithrombotic therapy. Long-term eculizumab treatment results in a clinically and statistically significant reduction in thrombosis in PNH, including patients with mild anemia and lower levels of hemolysis. Considering that TE contributes to the majority of deaths in PNH, it is reasonable to expect that eculizumab treatment, by decreasing the risk of TE, will increase the life-expectancy in PNH.

Paietta,[7] M.S. Tallman,[8] M.R. Litzow,[9] P.H. Wiernik,[7] J.M. Rowe,[10] A.H. Goldstone,[11] G.W. Dewald9

[1]University of Southampton, SOUTHAMPTON, United Kingdom; [2]University of Oxford, OXFORD, United Kingdom; [3]Indiana Unversity School of Medicine, INDIANAPOLIS, USA; [4]Stanford University School of Medicine, STANFORD, USA; [5]Abbott Northwestern Hospital, MINNEAPOLIS, USA; [6]Royal Free and UCMS, LONDON, United Kingdom; [7]Our Lady of Mercy Medical Center, NEW YORK, USA; [8]Northwestern University Feinberg, CHICAGO, USA; [9]Mayo Clinic, ROCHESTER, USA; [10]Rambam Medical Center, HAIFA, Israel; [11]UCLH, LONDON, United Kingdom

Pre-treatment cytogenetics is a known predictor of outcome in haematological malignancies. However, its usefulness in adult acute lymphoblastic leukaemia is generally limited to the presence of the Philadelphia chromosome (Ph) because of the low incidence of other recurrent abnormalities and the rarity of the disease in this age group. We present centrally reviewed cytogenetic data from adult patients enrolled on the Medical Research Council (MRC) UKALLXII / Eastern Cooperative Oncology Group (ECOG) 2993 Trial MRC. Cytogenetic analysis was attempted in 1,366/1,522 (90%) patients. This rate did not vary by registration centre, year of diagnosis or patient age. Cytogenetic analysis was successful in 1,003 (73%) cases but was considered unacceptable in 363 (27%) cases. Among those patients with successful cytogenetics an abnormal clone was detected in 796 (79%). There was no trend towards a higher rate of unacceptable cytogenetics in the early part of the trial compared with the later years. Patients were classified according to the presence of each of the following chromosomal abnormalities: t(9;22)(q34;q11.2) (Ph) (n=267, 19%); t(4;11)(q21;q23) (n=54, 7%); other MLL/11q23 translocations (n=15, 2%); t(1;19)(q21;p13.3) (n=24, 3%); t(8;14)(q24.1;q32) plus variants (n=16, 2%); t(10;14)(q24;q11.2) (n=16, 2%); other T-cell receptor translocations (n=18, 2%); 14q32 translocations (n=45, 6%); 6q deletions (n=55, 7%); 7p deletions (n=23, 3%); -7 (n=19, 2%); + 8 (n=23, 3%); + X (n=34, 4%); 9p deletions (n=71, 9%); 11q abnormalities (n=29, 4%); 12p deletions (n=29, 4%); -13 / 13q deletions (n=40, 5%); 17p deletions (n=40, 5%); complex karyotype (five or more chromosomal abnormalities) (n=41, 5%); low hypodiploidy (30-39 chromosomes) / near-triploidy (60-78 chromosomes) (Ho-Tr) (n=31, 4%); high hyperdiploidy (51-65 chromosomes) (n=77, 10%); tetraploidy (80 or more chromosomes) (n=15, 2%); other abnormality (n=102, 13%); normal karyotype (n=195, 25%). Ph-positive patients had a significantly inferior 5 year overall survival (OS) compared with Ph-negative patients: 22% (95% CI 17%-27%) versus 41% (38%-44%) [p=0.0001 adjusting for age, gender and white cell count (WCC)]. Within the Ph-negative cohort, the following four chromosomal abnormalities were associated with a poorer outcome: t(4;11), OS 24% (13%-36%), p<0.001; t(8;14), OS 13% (2%-33%), p<0.001; complex karyotype, OS 28% (15%-43%), p=0.027; and Ho-Tr, OS 22% (9%-38%), p=0.001). In contrast, patients with high hyperdiploidy or 9p deletions had a significantly improved outcome compared to other Ph-negative patients: OS 53% (41%-64%), p=0.015 and OS 58% (46%-69%), p=0.032, respectively. We used a Cox proportional hazards model to assess the prognostic relevance of cytogenetic variables within the Ph-negative cohort in the context of other established survival indicators: gender, age, WCC and T-cell status. The adverse effect of t(8;14), Ho-Tr and complex karyotype was shown to be independent of these risk factors both within the overall cohort and a reduced cohort which excluded patients undergoing a bone marrow transplant. The observation that Ho-Tr and, for the first time, karyotype complexity confer an increased risk of treatment failure demonstrates that cytogenetic subgroups other than the Ph can and should be used to risk stratify adults with ALL in future trials.

ETV6-NCOA2 FUSION DEFINES A NEW ENTITY OF ACUTE LEUKEMIA WITH COEXPRESSION OF T-LYMPHOID AND MYELOID MARKERS

S. Strehl,[1] K. Nebral,[1] M. König,[1] H. Strobl,[2] J. Harbott,[3] S. Struski,[4] B. Bielorai,[5] M. Lessard,[4] M. Zimmermann,[6] O.A. Haas,[7] S. Izraeli[5]

Background. In acute leukemia coexpression of T-lymphoid and myeloid markers is a rare finding and poses diagnostic and therapeutic challenges. Owing to the lack of specific genetic markers the molecular basis for a biphenotypic immunophenotype is unclear. Aims and Methods. To identify novel genetic lesions associated with biphenotypic leukemia displaying T-cell and myeloid markers determined by immunophenotyping, conventional cytogenetics, fluorescence *in situ* hybridization (FISH) and molecular analyses were employed. *Results.* We have identified a novel recurrent t(8;12)(q13;p13), which results in a fusion between the transcriptional repressor ETV6 (TEL) and the transcriptional coactivator NCOA2 (TIF2) in six cases of childhood leukemia. ETV6 encodes a transcription repressor and is frequently involved in chromosome rearrangements with a multitude of partners in acute leukemia. NCOA2 is a member of the p160 family of nuclear receptor transcriptional coactivators (NRCoAs), which have a common domain structure with a conserved N-terminal bHLH-PAS domain, a centrally located (nuclear) receptor interaction domain (RID/NID), and a C-terminal transcriptional activation domain (AD2). NCOA2 also contains a C-terminal CREB binding protein (CBP)-interaction domain (CID), and thus is a transcription factor that mediates transcriptional activation in a ligand-dependent fashion and involves chromatin remodeling. The ETV6-NCOA2 transcript encodes a chimeric protein that consists of the pointed protein interaction motif of ETV6 that is fused to the C-terminus of NCOA2 including the CBP interaction and the AD2 activation domain. The same C-terminal domains of NCOA2 are also involved in the previously identified MOZ-NCOA2 fusion, which is generated by a inv(8)(p11q13). The absence of the reciprocal NCOA2-ETV6 transcript in one of the cases, and the facts that MOZ-NCOA2 is transforming and that the reciprocal NCOA2-MOZ is not expressed, strongly suggest that the ETV6-NCOA2 chimeric protein and not the reciprocal NCOA2-ETV6 is responsible for leukemogenesis. In addition, heterozygous activating NOTCH1 mutations, which disrupt the heterodimerization (HD) or the PEST domains and are present in over 50% of childhood T-ALL, as well as in rare cases of AML, particularly in the context of lineage switch leukemia, were detected in 4 out of 5 samples analyzed. The blast cells of all six leukemias consistently expressed cytoplasmic CD3 and CD7, and additional T-cell specific markers such as CD2 and CD5 to a variable extent, and at least one myeloid marker, either MPO, CD33 or CD13 or a combination of these markers. Moreover, all blast cells of all samples were double negative for CD4 and CD8, and except for one case CD34 positive. As consequence of the myeloid antigen expression pattern and in accordance with the European Group for the Immunological Characterization of Leukemias (EGIL), the patients were assigned to different subtypes, namely three of the cases were classified as T-ALL (one as T-I My+) and three as biphenotypic leukemia (BAL). *Conclusions.* Together, these data suggest the ETV6-NCOA2 fusion defines a new entity of leukemia with T-lymphoid and myeloid features, and may either enforce a biphenotypic leukemia by reprogramming the target cell or may occur in a leukemic stem cell that precedes both T-lineage and myeloid commitment.

Background. Cytogenetics and expression studies have pointed out an increasing number of oncogenes in T-cell acute lymphoblastic leukemias (T-ALL), demonstrating the complexity of T-ALL oncogenesis and the requirement for a network of cooperative oncogenic events. Classifying T-ALL oncogenes include aberrantly activated transcription factors, namely bHLH (TAL1, TAL2, and LYL1), homeobox genes (HOXA, TLX1/HOX11, TLX3/HOX11L2), and CALM-AF10 and MLL fusion genes. These oncogenes are frequently activated by chromosomal translocation or intrachromosomal cryptic deletion. Combined analysis of the T-ALL genetic alterations and large scale gene expression has allowed the definition of several major T-ALL subtypes. *Aims.* We aimed to identify new oncogenic alterations in T-ALL and include them in the genetic and biological networks defining T-ALL. A series of 84 T-ALL including 80 primary samples from children and adults, and 4 cell lines, was investigated by conventional and molecular cytogenetics approaches. *Methods.* In order to identify new T-ALL oncogenes, TCR-related translocations were searched for using FISH flanking probes. Partner sequences were cloned using inverse circled PCR. In addition, a genome-wide copy-number analysis was performed using a customized 4K BAC/PAC array-CGH on the 84 T-ALL cases. *Results.* Two distinct recurrent genetic events were identified that both involved the C-MYB locus at 6q23. First, a reciprocal chromosomal translocation t(6;7)(q23;q34) was identified that juxtaposed the TCRB and the C-MYB loci (n=4 cases out of 84; two additional independant TCRB-MYB samples were also studied leading to a total of 6 cases). Second, the array-CGH analysis identified a cryptic duplication of a short genomic region including C-MYB (n=14 cases out of 84 T-ALL, 17%). The somatic origin of the duplication was demonstrated using paired leukemic and remission DNA, and a minimal duplicated region of approximately 230 Kb was mapped using 244K oligonucleotide array-CGH. RQ-PCR analysis showed an increased C-MYB expression in both the translocated and duplicated cases compared to other T-ALL cases and normal controls. Strikingly, the TCRB-MYB translocation occurred in very young children (median 2 years-old, p=10-4). Moreover, profiling of the T-ALL series by large scale expression analysis showed that the TCRB-MYB cases defined a unique T-ALL case cluster associated to a proliferation/mitosis signature. By contrast, the MYB-duplicated cases were found at various ages and in previously defined distinct T-ALL oncogenic subtypes (SIL-TAL1, TLX1, TLX3, CALM-AF10, MLL or Immature cases). *Conclusions.* The C-MYB gene has been a candidate oncogene in human hematologic malignancies for years, based on its homology with the viral oncogene v-Myb and frequent targeting by retroviral insertions in mouse leukemia. This work is the first clear demonstration of the recurrent involvement of the C-MYB locus in a human neoplasm, namely T-ALL, in two distinct genetic alterations. The C-MYB transcription factor is known to play a major role in early and definitive hematopoiesis, and it has been involved at several key steps throughout the normal thymic differentiation process. It is therefore likely that deregulated C-MYB expression due to genomic events is oncogenic in T-ALL. Importantly, the t(6;7) translocation defines a new subtype of T-ALL associated with a very young age and a proliferation/mitosis signature.

0384

SYSTEMATIC EVALUATION OF COPY NUMBER ALTERATIONS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA AND THEIR ASSOCIATION WITH TREATMENT RESPONSE

D. Steinemann,[1] G. Cario,[2] M. Stanulla,[1] M. Tauscher,[1] A. Weigmann,[1] G. Göhring,[1] J. Harbott,[3] B. Radlwimmer,[4] P. Lichter,[4] M. Schrappe,[2] B. Schlegelberger[1]

[1]Medical School Hannover, HANNOVER; [2]University Childrens Hospital Schleswig, KIEL; [3]Justus-Liebig-University, GIESSEN; [4]Deutsches Krebsforschungszentrum (DKFZ), HEIDELBERG, Germany

Background. in vivo response to initial therapy, as assessed by determination of minimal residual disease on treatment day 33 and at week 12 of treatment, has evolved as the strongest prognostic factor in children with acute lymphoblastic leukaemia (ALL) treated according to the BFM regime (ALL-BFM-2000). However, it is not known so far, whether the individual treatment response might be influenced by copy number alterations, i.e. small deletions or amplifications, leading to altered gene expression. *Aims.* We therefore aimed to systematically evaluate copy number alterations (CNA) using high resolution array-comparative genomic hybridization (array-CGH) in different treatment-response groups. *Methods.* Leukemic DNA of 25 patients with a poor (MRD load > 10-3 at week 12, MRD-high risk, HR) and 25 patients with a good treatment response (no measurable MRD at weeks 5 and 12, MRD-standard risk, SR) were compared. For array-CGH, a DNA chip containing more than 8000 individual BAC/PAC clones leading to a genome-wide resolution of at least 1 Mb was used. Hybridization, image analyses and data processing was performed as described recently (Steinemann et al. 2006). Selected CNA were validated by fluorescence *in situ* hybridization. *Results.* Copy number alterations (CNA) were found in 46 patients (92%), in both patient groups. Microscopic alterations affecting the whole or nearly whole chromosome arm were frequently found, e.g. gain of 21 in 11/50, loss of 9p in 5/50, loss of 8p in 3/50, loss of 20q in 3/50 and loss of 7p in 2/50 or gain of 1q in 2/50. A gain of chromosome 1q23-qter was found in 10/25 SR-patients, whereas none of the HR-patients showed this gain with a breakpoint in 1q23 (p<0.002). This gain may result from an unbalanced translocation der(19)t(1;19)(q23;p13). Cytogenetically, two forms, a balanced t(1;19)(q23;p13) and an unbalanced der(19)t(1;19)(q23;p13) exist, both giving rise to the E2A/PBX1 fusion gene. To confirm our findings and to analyse, if additional cases may carry an unrecognized balanced t(1;19), we performed RT-PCR to detect the E2A/PBX1 fusion transcript. In consistence with array-CGH, all cases with gain of 1q23-qter -but no additional cases- showed the fusion transcript. A gain/amplification of 21q21-q22 was not only observed in the context of hyperdiploidy but also seen in six additional cases as an isolated gain. 8 patients of the SR-group in comparison to 3 patients of the HR-group showed a gain of 21q21-q22 (p<0.17). Moreover, amplifications of 21q21-q22 were observed only in the SR-group. The frequency of other CNA like loss of 9p did not differ between both patient groups. No recurrent genomic imbalances (>1-2 Mb) were found in the HR-group. *Conclusions.* This is the first study to evaluate the clinical significance of CNA as detected by array-CGH in childhood ALL. Array-CGH had a very high sensitivity to detect CNA. Gains of 1q23-1qter due to an unbalanced t(1;19)(q23;p13) and gains of 21q turned out as markers for good treatment response in the context of the ALL-BFM regime.

0385

CYTOPLASMIC MUTATED NUCLEOPHOSMIN DEFINES THE MOLECULAR STATUS OF A SIGNIFICANT FRACTION OF MYELOID SARCOMAS

A. Liso,[1] D. Lenze,[2] R. Hasserjian,[3] S. Coupland,[2] D. Jaehne,[2] C. Soupir,[3] M.P. Martelli,[1] N. Bolli,[1] F. Bacci,[1] V. Pettirossi,[1] A. Santucci,[1] M.F. Martelli,[1] S. Pileri,[1] H. Stein,[2] B. Falini[1]

[1]Hematology, FOGGIA, Italy; [2]Charitè-Universitatsmedizin, BERLIN, Germany; [3]Massachusetts General Hospital, BOSTON, USA

Detection of genetic lesions is critical for classification, prognostic stratification, and monitoring of minimal residual disease of acute myeloid leukaemia (AML). Information on genetic lesions associated with myeloid sarcoma (MS), a tumor mass consisting of myeloblasts or immature myeloid cells at an extra-medullary site, is still limited. This is mainly due to the fact that fresh cells are usually not available for cytogenetic and/or molecular studies, since the diagnosis of MS is frequently unexpected and/or the size of the sample is small, such as a skin punch biopsy. Since MS is usually treated in the same way as AML, the frequent lack of available cytogenetics in MS, represents a significant disadvantage, and the availability of techniques applicable to paraffin samples to detect specific genetic lesions would be of great help both for diagnostic and prognostic purposes. Aberrant cytoplasmic expression of nucleophosmin (NPM), a multifunctional shuttling protein usually located in the nucleus, is a key property of a large subgroup of AML exhibiting distinguishing biological and clinical features, that we termed NPMc$^+$ (cytoplasmic-positive) AML (Falini B. *et al.,* NEJM 352:254-266, 2005; Falini B. *et al.*, 109:874-885, 2007). In NPMc+ AML, leukemic cells harbour NPM1 gene mutations generating NPM leukemic mutants that are exported at high rate from the nucleus and accumulate in the cytoplasm (Falini B. *et al.*, Blood 107:4514-4523, 2006). Aberrant cytoplasmic NPM expression and/or NPM1 mutations have been investigated in AML. However, there is no information on the role of NPM in MS, a tumor that may develop de novo (preceding bone marrow involvement), present concurrently with AML, or represent manifestation of AML relapse or blastic transformation of a pre-existing chronic myeloproliferative disorder. Since NPM1 mutations cause aberrant cytoplasmic dislocation of NPM that is fully predictable by immunohistochemistry (Falini B. *et al.,* Blood 108:1999-2005, 2006), we used anti-NPM monoclonal antibodies recognizing both wild-type and mutated NPM to detect cytoplasmic NPM in paraffin-embedded samples from 181 MS retrieved from the archives of four large Institutions. Reactivity was evaluable in 173/181 cases: 146 (85.0%) with nucleus-restricted NPM (predictive of unmutated NPM1) and 26 (15.0%) with aberrant cytoplasmic NPM (predictive of NPM1 mutations). The presence or absence of NPM1 mutations was confirmed in paraffin sections by immunostaining with specific antibodies against the NPM mutants and, in a subset of cases, also by a polymerase chain reaction (PCR) assay of NPM1 sequence we developed for application on paraffin-embedded formalin-fixed samples. NPMc+ MS showed the same distinctive features as NPMc$^+$ AML, including frequent M4 or M5 morphology, CD34-negativity, association with normal karyotype, and no previous history of myelodysplastic or chronic myeloproliferative disorders. Thus, immunohistochemistry can serve as a surrogate of molecular studies for detecting NPM1 mutations in MS. This study identifies NPM1 mutations as the most frequent genetic lesion so far reported in MS, accounting for 15% of cases. Our genetic findings have clear implications for the upcoming WHO classification of myeloid neoplasms. Clinical prospective studies aimed to assess the prognostic value of NPM1 mutations (in combination with FLT3-ITD) in MS are also warranted.

A PLACEBO CONTROLLED, CROSS-OVER STUDY OF CITRATE EFFECTS ON BONE METABOLISM IN HEALTH VOLUNTEERS

Y. Chen, C. Bieglmayer, H. Heinzl, P. Hoecker, M. Dettke

AKH Vienna, VIENNA, Austria

Background. Citrate is the anticoagulants of choice when performing apheresis donations. Less is known about the possible effects of citrate-induced hypocalcemia on bone turnover. *Aims.* Aim of the study was to investigate the possible effects of citrate on biochemical markers of bone metabolism. *Methods.* A placebo controlled, cross-over trial was performed in 10 male volunteers. Volunteers received two standardized infusion (80 min.) containing either citrate (1.5 mg/kg/min) or saline solution, separated by a wash-out period of 2 weeks. At each study time point blood and urinary samples were collected before, during, and after completion of the infusions. Samples were analysed for short- and long-term markers of bone turnover, PTH and electrolytes. *Results.* Application of citrate led to a profound decrease in serum level of iCa, potassium and phosphate. Decrease of iCa was inversely related to the increase in iPTH and the urinary excretion of Ca. Infusion of citrate resulted in a time-dependent steadily increased of serum levels of the bone formation marker osteocalcin (OC) and the bone resorption marker C-telopeptide of type 1 collagen (CTX). Peak levels of both bone markers were reached at the end of the citrate infusion (compared to base +34% for OC and +57% for CTX, respectively). Both bone parameters showed a positive correlation to the increase of PTH, as determined at the end of the citrate infusion. In addition, changes of OC but not CTX were related to the variations in serum iCa. Alterations in both bone markers were still detectable 90 min after completion of the citrate infusion. In contrast, no alterations were observed in the serum levels of the long-term bone markers bone specific AP, tartrate-resistant acid phosphatase 5b, osteoprotegerin or RANKL. *Conclusions.* Infusion of citrate equal to the dose used in voluntary platelet apheresis donation results in profound alterations of biochemical markers of bone turnover. The pattern of variations in the serum levels of the bone markers OC and CTX resembled to those of an increased bone resorption.

0387

A SMALL THROMBOPOIETIC MOLECULE NIP-004 IS EFFECTIVE FOR THE TREATMENT OF THROMBOCYTOPENIA INDUCED BY INTERFERON-ALPHA

A. Yamane,[1] T. Nakamura,[2] M. Ito,[3] Y. Ohnishi,[3] Y. Ikeda,[1] Y. Miyakawa[1]

[1]School of Medicine, Keio University, TOKYO; [2]Nissan Chemical Industries, LTD., SAITAMA; [3]CIEA, KANAGAWA, Japan

Background. Human interferon-α (IFN) is useful to treat chronic hepatitis C. However, doctors often reluctantly reduce the dose of IFN, or discontinue therapy, because of IFN-induced thrombocytopenia. Although IFN is believed to directly inhibit megakaryopoiesis, its mechanisms are not clearly understood. *Aims.* In this study, we evaluated the efficacy of a small non-peptidyl thrombopoietic molecule, NIP-004, for the treatment of IFN-induced thrombocytopenia and studied the inhibitory mechanisms of IFN for megakaryopoiesis. *Methods. In vivo* assay: After 2.4 Gy-irradiation, 1×10^5 of human umbilical cord blood-derived CD34$^+$ cells was intravenously injected into immunodeficient NOD/Shi-scid/IL-2Rγ-null (NOG) mice. Pegylated-recombinant human interferon-α2b (PEG-Intron®) and NIP-004 were subcutaneously administered into the mice. The number of platelets and human megakaryocyte ploidy were obtained by a flow cytometer. *in vitro* assay: The colony formation of human megakaryocytes (CFU-MK) assay was performed using human bone marrow (BM)-derived CD34-positive cells in collagen based semi-solid culture, and the proplatelet (PPT) formation assay was performed using human BM-derived CD34-positive cells in serum-free liquid culture, with the various combination of c-Mpl activator (thrombopoietin or NIP-004) and IFN. *Results.* When IFN at 30 microgram/kg was administered three times a week for 3 weeks into NOG mice transplanted with human CD34$^+$ cells, the number of human platelets was significantly reduced by 40% compared to the control mice. Seven weeks treatment with IFN resulted in 70% reduction of human platelets [$27.7\pm6.8\times10^6$/mL (control), $8.8\pm1.8\times10^6$/mL (IFN), n=5, $p<0.05$, Student t-test). When we administered NIP-004 to this IFN-induced thrombocy-

topenia model, the human platelet count was fully recovered. Interestingly, the numbers of $CD34^+CD41^+$ human megakaryoblasts and 4N to 128N human megakaryocytes in xenografted mice were not significantly changed compared to the control mice after treatment with IFN for 7 weeks. We also analyzed the inhibitory effects of IFN on megakaryocytes *in vitro*. Although IFN slightly reduced the number of CFU-MKs [146±13 colonies/5000 cells (control), 130±13 colonies/5000 cells (10 ng/mL of IFN)], the percentage of megakaryocytes bearing PPT was significantly reduced by IFN [20.4±3.0%(control), 12.5±3.6% (10 ng/mL of IFN)]. Currently, we are investigating the inhibitory mechanisms of IFN for PPT. *Conclusion*. These results indicated that NIP-004 is effective for preventing IFN-induced thrombocytopenia *in vivo*. IFN might inhibit the PPT formation rather than the proliferation of human megakaryocytopoiesis. We expect that the small thrombopoietin molecule, NIP-004, can be applied for the treatment of IFN-induced thrombocytopenia in the patients with chronic hepatitis C.

0388

IN VITRO AND *IN VIVO* MICROPARTICLE-ASSOCIATED ENDOTHELIAL PROTEIN C RECEPTOR CAN REVERSE PRO-INFLAMMATORY AND APOPTOTIC CELL SIGNALS AND EFFECTS

T. Dutt, M. Perez-Casal, C.H. Toh

University of Liverpool, LIVERPOOL, United Kingdom

Background. We have described a novel mechanism of endothelial protein C receptor (EPCR) release from cell surfaces *in vitro* and *in vivo*. Induced by Activated Protein C (APC), EPCR is released in microparticulate (MP) form. Unlike APC bound to truncated soluble EPCR, APC on MP-EPCR retains proteolytic anticoagulant activity. We now hypothesise that the MP EPCR-APC complex can also cleave endothelial protease activated receptor-1 (PAR1) to modulate inflammation and cytoprotection. *Aims.* 1. To compare the efficacy of MP EPCR-APC versus free-APC, using two different pools of endothelial cells, following exposure to a pro-inflammatory stimulus. 2. To determine if circulating MP EPCR-APC from patients can regulate gene expression in a PAR1-dependent manner. *Methods.* Using an *in vitro* system of human umbilical vein endothelial cells (HUVECs) or human coronary artery endothelial cells (HCAECs), TNFα, 10 ng/mL, was added to represent a cell model of sepsis. After 4 hours the cells were treated with an equal concentration of either free or MP-bound APC and left for a total of 24 hours. RNA was extracted from the cells and used to make probes for hybridization of GEArray Human Endothelial Cell Biology Gene Array (SuperArray). Using untreated cells as a baseline, the specificity of APC and the role of PAR1 were assessed by using the appropriate blocking antibodies and antagonist. Circulating MPs were isolated from plasma of APC treated patients by standard methods and platelet-derived MPs depleted using a CD41a antibody and magnetic beads. MP-associated APC was estimated from a standard curve and 17nM used for gene profiling. PAR1-mediated signalling was examined as above. *Results.* In TNFα stimulated cells, APC, selectively induced anti-inflammatory and suppressed pro-apoptotic gene regulation. In over 90% of these genes, MP-APC had a 2-7 fold greater effect in relation to free-APC. These observations were confirmed by Q-PCR for e-selectin, ICAM1, Bax, A20, caspase 10, GM-CSF and IL8. This translated into increased GM-CSF and interleukin 8 secretion, and cytoprotection against staurosporine-induced apoptosis. Protein C or PAR1 antagonism reversed these results to demonstrate that the induced effects by MPs were APC specific and PAR1-dependent. Further analysis using MP-associated EPCR from septic patients during APC treatment also demonstrated PAR1-mediated anti-inflammatory gene induction and anti-apoptotic function. *Conclusions.* APC on MP-associated EPCR can ameliorate TNF induced inflammatory changes and staurosporine induced apoptosis in both HUVECs and HCAECs. As these effects are reproducible with MPs isolated from patients' plasma, this may have clinical relevance in the septic patient treated with APC.

ENDOTHELIAL COLONY FORMING CELLS FROM PATIENTS WITH CML, POLYCYTEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA, DERIVE FROM A STEM CELL LACKING THE DISEASE SPECIFIC MARKER

F. Frassoni,[1] G. Piaggio,[2] M. Corselli,[1] F. Bertolotti,[1] S. Pozzi,[1] A. Parodi,[1] B. Chiavarina,[1] M. Sessarego,[3] G. Fugazza,[3] A. Garuti,[4] A. Ibatici,[1] A. Bacigalupo,[5] F. Frassoni[1]

[1]Centro Cellule Staminali, GENOA; [2]Lab Diagnostica Emato e Colture in vitro, GENOVA; [3]Laboratorio Citogenetica DIMI, GENOVA; [4]Terapie Cellulari DIMI, GENOVA; [5]Ematologia e Trapianto AO S Martino, GENOVA, Italy

Background. the persistence of a common progenitor to haematopoietic and vascular endothelial lineage in the adult haematopoietic tissue appeared to be validated when Bcr/Abl fusion gene was found in a variable proportion of endothelial like cells generated *in vitro* from the bone marrow and the peripheral blood of CML patients. However, the different colture conditions used to isolate and to expand endothelial cells (EC) *in vitro* have generated some confusion. Only recently, the existence of two EC populations has been clearly settled: early EPC, i.e. colony forming unit-endothelial cells (CFU-EC), are haematopoietic derived progeny committed to the myeloid lineage while late EPC, namely ECFCs, are vessel-forming progenitors. *Aims.* we have reconsidered the issue of endothelial cell origin (status) in CML and other MPDs to verify whether circulating EPCs, isolated and expanded from the peripheral blood of patients, bear the disease specific genetic marker of the leukaemia clone or this is restricted to the haematopoietic lineage. *Methods.* Forty-three patients and 12 normal controls were included in this study. Twenty-four samples were Philadelphia and Bcr/Abl positive CML, 19 were Philadelphia and Bcr/Abl negative MPDs, PV and ET with JAK2-V617F mutation. Peripheral blood mononuclear cells were cultured *in vitro* and expanded cells were searched for Bcr/Abl fusion gene by RQ-PCR and FISH, and for JAK2-V617F mutation by nested PCR. Flow cytometry and capillary formation assay in Matrigel were also performed. *Results.* due to the low frequency of late EPCs in the peripheral blood of patients, only 7/24 CML and 6/19 MPD samples gave rise *in vitro* to a progeny of EC. None of them carried the disease specific genetic marker. The expanded cells showed a complete outfit of endothelial associated antigens and were able to form capillary like structures *in vitro*. *Conclusions.* differently from previous reports and based on a clear distinction between early and late EPCs, this study shows for the first time that endothelial cells, derived in culture from Ph-positive, Bcr/Abl positive CML patients, lack the disease marker in the late EPC. In addition late EPCs from patients with PV or ET lack the JAK2-V617F mutation. Thus it appears that in CML , PV and ET the cell able to give rise to endothelial progenitors do not derive from the malignant clone. This finding, per se, does not exclude the possibility of a common ancestor cell for haematopoietic and endothelial lineage, and multiple explanations could be hypothesized: the leukemogenetic event that starts the CML involves a stem cells below the common ancestor cells. Indeed, most T cells in CML do not belong to the leukemic clone. Alternatively, since in the majority of newly diagnosed patients with CML, the bone marrow contains a high number of normal Ph-negative early progenitor cells (LTC-IC), one could argue that Ph-negative stem cells still give rise to EPC therefore diluting those deriving from Ph-positive ones. The same apply to MPD where it is now evident that part of haematopoietic progenitors do not carry the JAK2-V617F mutation.

ELTROMBOPAG RAISES PLATELET COUNT AND REDUCES BLEEDING COMPARED WITH PLACEBO DURING SHORT-TERM TREATMENT IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA: A PHASE III STUDY

J. Bussel,[1] A. Provan,[2] T. Shamsi,[3] G. Cheng,[4] L. Kovaleva,[5] N. Stone,[6] B. Mayer,[6] R. Poulin,[6] M. Arning[6]

[1]Weill Medical College Cornell University, NEW YORK, USA; [2]Southampton General Hospital, SOUTHAMPTON, United Kingdom; [3]Bismallah Taquee Inst. Health Sciences, KARACHI, Pakistan; [4]Chinese University of Hong Kong, SHATIN, Hongkong (China); [5]Hematology Research Center, MOSCOW, Russian Federation; [6]GlaxoSmithKline, COLLEGEVILLE, USA

Background. Chronic idiopathic thrombocytopenic purpura (ITP) is a disease characterized by increased platelet destruction and impaired platelet production. In a previous, large phase II study, eltrombopag, a novel, non-peptide, oral platelet growth factor, increased platelet counts in adults with chronic ITP. *Aims.* In this global, randomized, double-blind, placebo-controlled, phase III trial, the safety and efficacy of eltrombopag was studied in adults with chronic ITP and platelet counts <30,000/μL. *Methods.* Patients received placebo or eltrombopag 50 mg (1:2 ratio) once daily for up to 6 weeks. Dose escalation to 75 mg (or matching placebo) was allowed after 3 weeks in subjects whose platelet count continued to be < 50,000/μL. The primary endpoint was the proportion of patients with a platelet count ≥50,000/μL after up to 42 days of dosing. Secondary endpoints included bleeding, safety and tolerability. Patients were stratified by splenectomy status, use of concomitant ITP therapy and platelet count ≥15,000/μL. *Results.* Patients (N=114) were randomly assigned to placebo (n=38) or eltrombopag (n=76); 61% were female and 74% were White. All patients had received prior ITP treatment and 52% had received ≥3 prior therapies. Stratification included 43% of subjects receiving concomitant ITP therapy (primarily corticosteroids); 39% refractory to splenectomy; and 48% with baseline platelet counts ≥15,000/μL. At the end of treatment, 16% of placebo patients and 59% of eltrombopag patients achieved the primary endpoint (platelet count ≥50,000/μL), with median counts of 18,000/μL (placebo) and 69,000/μL (eltrombopag). There was a significant increase in the odds of responding in the eltrombopag versus placebo arm (odds ratio [OR] = 9.61, p<0.001). Three percent of placebo and 25% of eltrombopag patients achieved a platelet count >200,000/μL. Response to treatment was observed regardless of strata. The odds of any bleeding, measured by the WHO bleeding scale, was significantly lower in the eltrombopag arm on day 43 (OR = 0.27, p=0.029) and over the entire course of treatment (OR = 0.48, p=0.018). Clinically significant bleeding (WHO Grade 2-4) between Days 15 and 50 was observed in fewer patients receiving eltrombopag (16%) compared with those receiving placebo (36%). The most common AEs were headache (11% and 8%), nausea (0 and 8%), nasopharyngitis (8% and 7%), diarrhoea (3% and 5%) and vomiting (0% and 5%) for placebo and eltrombopag, respectively. No apparent safety concerns were identified following thorough examination of clinical chemistries, haematology, electrocardiographic findings and preliminary results of ophthalmic examinations. *Conclusions.* Daily eltrombopag 50 mg was highly effective in raising platelet counts and reducing bleeding during the 6-week treatment period. No safety concerns were identified. Long-term and repetitive treatment studies are ongoing in patients with chronic ITP.

Hodgkin's lymphoma

0391

COMBINED ESCALATED BEACOPP-ABVD THERAPY GUIDED BY PET-CT FOR ADVANCED HODGKIN'S LYMPHOMA PATIENTS WITH HIGH IPS SCORE

A. Avigdor,[1] S. Bulvik,[2] E. Dann,[3] I. Levi,[4] G. Perez-Avraham,[4] N. Shemtov,[1] A. Nagler,[1] I. Ben-Bassat,[1] A. Polliack[5]

[1]The Chaim Sheba Medical Center, TEL-HASHOMER; [2]Laniado Hospital, NETANYA; [3]Rambam Medical Center, HAIFA; [4]Soroka Medical Center, BEER-SHEVA; [5]Hadassah Medical Center, JERUSALEM, Israel

Background. The expected 5-year freedom from progression of advanced stage Hodgkin's lymphoma (HL) patients (pts) with IPS≥3, treated with COPP-ABVD, was reported as 55%. While the superiority of escalated (esc) BEACOPP regimen over COPP-ABVD was shown for all risk groups, it was more pronounced in pts with a poor IPS. However, pts receiving escBEACOPP had more acute and long-term toxicities including a higher incidence of AML/MDS. In an attempt to reduce this toxicity, while preserving improved initial tumor control in this high risk group of pts, we conducted a phase II study, which tested the feasibility, toxicity and efficacy of a regimen which utilized the combination of escBEACOPP and ABVD. *Methods.* Newly diagnosed HL pts, with unfavorable stage IIB or stages III-IV with IPS≥3 were initially received two cycles of escBEACOPP followed by reevaluation with PET-FDG/CT scans. When complete or partial response (CR, PR) was achieved, pts then continued to receive four cycles of ABVD, while pts who failed to obtain this response received salvage therapy. *Results.* Since starting in late 2001, 40 eligible pts received this regimen. Median age at diagnosis was 27 years (range 18-56) and 29 (73%) were males. Histology included nodular sclerosis (n=30), mixed cellularity (n=6) and unclassified (n=4). Stage IV, III and IIB were evident in 29 (73%), 8 (20%) and 3 (7%) pts, respectively and extranodal involvement was noted in 28 (70%). Following the first two cycles of escBEACOPP the overall response rate (CR+PR) was 100% and at the end of all therapy 36 (90%) pts were in CR, 2 (5%) in PR and 2 (5%) pts had progressive disease. After a median follow-up of 30 months (range 7-61), 38 pts are alive while two pts died from progressive HL. The estimated 5-year event free survival (EFS) and overall survival rates were 78% (95% CI, 64-92%) and 91% (95% CI, 78-100%), respectively. The 5-year cumulative incidence of relapse is 13% (95% CI, 5-33%). These survival rates are higher than those expected for ABVD containing regimens and comparable with the reported estimated long term survival rates achieved with the poor prognostic subgroup of pts, receiving eight cycles of escBEACOPP in the GHLSG HD9 trial. Furthermore, the estimated 5-year EFS rate for early PET negative pts (n=27) and for early PET positive pts (n=11) was 82% (95% CI, 66-98%) and 64% (95%, CI 35-92%), respectively (p=0.14) (in 2 pts early PET results were not conclusive). As expected, the incidence of acute hematologic toxicities was more common in the escBEACOPP than in the ABVD phase. Non hematologic adverse effects included grade III-IV infection (n=1), avascular necrosis of the hip (n=1) and cognitive impairment (n=1). *Conclusions.* Combined escBEACOPP-ABVD therapy is well tolerated and may improve the outcome in pts with advanced HL who have high IPS scores. Larger scale randomized studies, comparing this combination regimen with previously reported dose-intensified chemotherapy regimens, are required in order to verify its true merit in this high risk subgroup of pts.

0392

EARLY INTERIM FDG-PET DURING INTENSIFIED BEACOPP THERAPY FOR ADVANCED-STAGE HODGKIN DISEASE SHOWS A LOWER PREDICTIVE VALUE THAN DURING ABVD

A. Gallamini,[1] S. Viviani,[2] V. Bonfante,[2] A. Levis,[3] F. Di Raimondo,[4] F. Merli,[5] U. Vitolo,[6] S. Bolis,[7] P.F. Torchio[8]

[1]Az. Ospedaliera S. Croce e Carle, CUNEO; [2]Istituto Nazionale Tumori, MILANO; [3]Az. Ospedaliera S. Antonio e Biagio, ALESSANDRIA; [4]Ospedale Cannizzaro, CATANIA; [5]Arcispedale S. Maria Nuova, REGGIO EMILIA; [6]Az. Ospedaliera S. Giovanni Battista, TORINO; [7]Az. Ospedaliera S. Gerardo, MONZA; [8]Biomedical statistics Department, TORINO, Italy

Background. FDG-PET scan performed early during standard ABVD chemotherapy for Hodgkin's disease (HD) is a powerful prognostic tool (Hutchings: Blood 2006, Gallamini: Haematologica 2006). So far, no data have been published on the role of early FDG- PET in HD patients treated with BEACOPP. *Aims.* Starting from November 2002, 29 new,

advanced-stage HD patients consecutively admitted to seven Italian hematological institutions were enrolled in a prospective multicenter clinical trial to study the predictive role on treatment outcome of early interim FDG 'PET scan in HD patients treated with BEACOPP (4 escalated + 4 baseline cycles). Patients The mean age was 35,3 years (18-60); advanced disease (stages IIB-IVB) was present in 26, and stage IIA with adverse prognostic factor (> 3 nodal sites involved, sub-diaphragmatic presentation, bulky disease and ESR > 40) in 3. Bulky disease and extra nodal sites were recorded in 16 and 14 patients, respectively. All pts were staged at baseline, after 2 courses of chemotherapy at the end of treatment by FDG-PET scan (PET-0, PET-2, PET-8, respectively). All the PET-2 positive studies were reviewed. The mean interval between the end of the second BEACOPP course and PET-2 was 11.6 (5-20). At the end of chemotherapy in 15/29 pts. with bulky disease consolidation radiotherapy was given. All patients were given the therapy programmed at baseline. No treatment change depending on PET-2 result was allowed, except in case of overt progression. *Results.* the mean follow-up was 637 days (259-1428). Twenty-six pts attained CR while 3 were chemoresistant and showed disease progression during therapy; three patients relapsed + 55, + 224 and +266 days after CR entry. In univariate analysis, besides PET-2 (p<0.05), the clinical factors that were significantly associated with a higher probability of treatment failure were age older than 45 (p<0.05) and hemoglobin lower than 10.5 g/dL (p< 0.05). In multivariate analysis only age and hemoglobin retained their significance(p<0.05). In terms of treatment failure, the Positive Predictive Value (PPV) and Negative Predictive Value (NPV) were 60% and 88%, respectively. The sensitivity, specificity and overall accuracy of PET-2 were 50%, 91% and 83%, respectively. The 2-y Failure-Free Survival (FFS) probability for PET-2 negative and for PET-2 positive patients were 88% and 0, respectively (FFS Log Rank test = 5.0, p<0.05). *Conclusions.* With the caution due to the relatively small number of patients these results seems to indicate that early interim PET during intensified chemotherapy with BEACOPP regimen in advanced stage HD has an equivalent prognostic meaning than during standard ABVD therapy. However, PET-2 during BEACOPP showed a lower sensitivity and PPV (50% versus 86% and 60% vs. 92%, respectively, p< 0.05). This could depend on the relatively high number of false negative PET-2 results, probably due to an higher effectiveness of this intensified regimen.

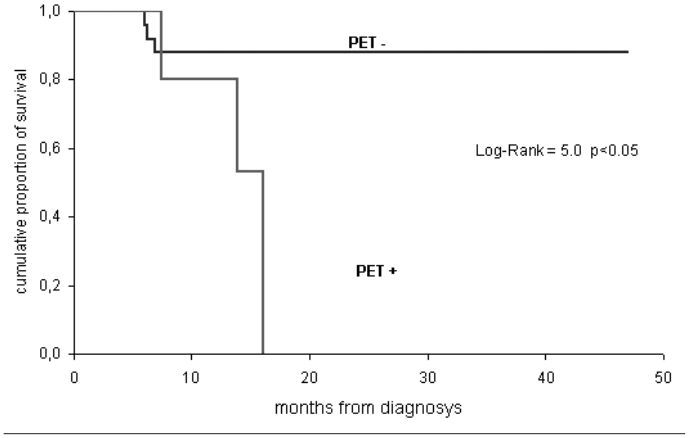

Figure 1. Failure free survival.

HIGH DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN 58 PATIENTS WITH HODGKINS LYMPHOMA. OUTCOME AND PROGNOSTIC FACTORS

H. Galani, T.P. Vassilakopoulos, P. Tsirkinidis, M. Moschogiannis, D. Boutsis, K. Anargyrou, S. Masouridis, S. Sachanas, C. Kalpadakis, A. Sarantopoulos, E. Dimitriadou, M. Dimopoulou, N. Stavrogiannis, V. Kalotychou, E. Variamis, N.A. Viniou, S.I. Kokoris, M.P. Siakantaris, M.C. Kyrtsonis, I. Rombos, G. Vaiopoulos, G.A. Pangalis, M. Angelopoulou

University of Athens, ATHENS, Greece

Backgound. HL is a potentially curable disease in at least 75% of the patients treated with ABVD chemotherapy (CT)±radiotherapy (RT). For patients either refractory to or relapsing after first line treatment, HDT/ASCT is the most widely accepted option with curative intent. *Aims.* To analyze the outcome and prognostic factors for relapsed or refractory HL patients treated with HDT/ASCT. *Methods.* We retrospectively analyzed 58 patients with refractory or relapsed HL treated with HDT/ASCT in a single Hematology Unit. Event free survival (EFS) was calculated from time of ASCT to relapse/progression, death of any cause or last follow-up. Overall survival (OS) was calculated from time of ASCT to death of any cause or last follow-up. *Results.* Median age at ASCT was 29 years (19-57) and 71% were males. At diagnosis 14%, 52%, 19% and 16% of the patients had clinical stage I, II, III and IV respectively, 43% had B symptoms, and 36% bulky disease. 97% had received an anthracycline-based regimen and 3% MOPP, while 44% had received RT. At relapse 21%, 42%, 5% and 32% of the patients had clinical stage I, II, III and IV respectively, 18% B symptoms and 4% bulky disease. 47% of the patients were transplanted in first relapse, 22% after multiple relapses and 31% were primary refractory. All patients received salvage chemotherapy before ASCT, mostly ESHAP or GIN. The median number of CT regimens prior to ASCT was 2 (2-5). Following the last salvage regimen, 36% of the patients were in complete remission (CR), 43% in partial remission (PR) and 21% were chemoresistant. The conditioning regimen was BEAM in all patients. The median time to neutrophil and platelet recovery was 10 (8-19) and 14.5 days (10-102) respectively. One patient died during the procedure for a transplant related mortality (TRM) rate of 1.7%. Two additional patients required mechanical ventilation due to respiratory and cardiac failure. 27 patients experienced an event at a median of 5.5 months (0.7-45.5) after ASCT. At a median follow-up of 25 months (0.5-104) for surviving patients the 3- and 6- year EFS were 49±7% and 39±9% respectively. The corresponding 3- and 6- year OS rates were 73±8% and 66±10% respectively. Survival analysis did not identify statistically significant prognostic factors for the outcome with the exception of bulky disease at relapse (both patients with bulky relapses progressed and died soon after ASCT, p<0.001). However, there was a non-significant trend for inferior EFS and OS in primary refractory patients. Furthermore, patients achieving CR prior to ASCT had a superior OS (p=0.02) compared to PR and unresponsive patients, although EFS was not significantly different. *Conclusions.* HDT/ASCT can salvage 40% of relapsed/refractory HL patients with a low TRM.

0394

EFFECT ON CLINICAL OUTCOME OF GENETIC POLYMORPHISMS IN HODGKIN LYMPHOMA PATIENTS

A. Gaya,[1] A. Urbano-Ispizua,[1] A. Navarro,[2] A. Pons,[2] P. Abrisqueta,[1] A. Martínez,[1] B. Gel,[2] S. Pairet,2 C. Martínez,[1] M. Granell,[1] A. López-Guillermo,[1] E. Montserrat,[1] M. Monzó[2]

[1]Hospital Clinic of Barcelone, BARCELONE; [2]University of Barcelone, BARCELONE, Spain

Background. Most drugs demonstrate an inter-patient variability in their effect These differences can be due in part to the presence of polymorphisms in genes encoding enzymes related to drug metabolism that may lead to either reduce or increase their activity. *Aims.* We investigated whether distinct patterns of functional polymorphisms in genes involved in drug metabolic pathways (SXR, GSTT1, GSTP1, SULT1C2), multidrug resistance (MDR1), DNA repair (XPD, XPA, ERCC5, XRCC5, TOP2A), apoptosis (FAS, FASL) and inflammatory cytokines (IL6, IL10) predict clinical outcome in patients with Hodgkin lymphoma (HL). *Patients and Methods.* One hundred and seventy five adult patients (median age 33, range 13-89 years; males 49%) diagnosed with HL at a single institution between January 1996 and January 2006 have been studied. Distribution according to histological subtypes was: nodular sclerosis (60%), mixed cellularity (17%), lymphocytic predominance (6%), and lymphoid depletion (3%). First-line treatment consisted of MOPPABV (38%) or ABVD (52%). Allelic discrimination of single nucleotide polymorphisms (SNPs) (ABI Prism 7500; TaqMan) of DNA obtained from formalin fixed paraffin embedded lymph nodes was performed. The characteristics considered were: age (<45 vs >45 years), gender, WHO histological classification, EBV status (LMP1+ vs LMP1-), B symptoms, bulky mass, high LDH, high β-2-microglobulin, ESR (EORTC criteria), Ann Arbor stage (I-II vs III-IV), Hasenclever prognostic index (<3 vs >3), and polymorphisms of the above-mentioned genes. Clinical outcomes analyzed were probability to achieve complete remission (CR), toxicity due to the treatment, relapse rate, disease-free survival (DFS) and overall survival (OS). *Results.* Out of 175 patients, 144 (82%) achieved CR, 10 (5.7%) a partial response, 10 (5.7%) were chemoresistant, 6 (3.4%) died during the initial treatment and 5 (2.9%) were not evaluable. After a median follow-up of 50.8 (range, 1.2-144.1) months, OS was 82% and DFS 75%. In the multivariate analysis, the only prognostic

factor for the achievement of CR was SXR -1567T>C polymorphism (RR=0.5; p=0.06). A lower probability of DFS was associated with IL10 -116A>G polymorphism (RR=0.2; p=0.02), and a lower probability of OS to higher Hasenclever prognostic index (RR=6.4; p<0.001) and MDR1 Ile1145Met polymorphism (RR=3.3; p=0.03). A close association between Asp5Glu genotype of the phase II drug-metabolizing enzyme SULT1C2 and pulmonary toxicity was found. Thus, all 9 patients with pulmonary toxicity due to bleomicine had the wild type SULT1C2 genotype (p=0.004). Thereby, 9 (12%) of the 76 wild type patients presented pulmonary toxicity (p=0.006). *Conclusions.* Germline polymorphisms in IL10, MDR1 and SULT1C2, which can easily be analyzed in paraffin embedded samples, have prognostic value in patients with HL.

0395

EARLY RESPONSE TO CHEMOTHERAPY MAY FACILITATE OMMITTING RADIOTHERAPY IN CHILDREN WITH HODGKINS LYMPHOMA

M.J. Jarrar, F. Bazzeh, M. Tawfiq, F. Madanat

King Hussein Cancer Center, AMMAN, Jordan

Background. ABVD (Doxorubicin, Bleomycin, Vinblastine Dacarbazine) chemotherapy is commonly used to treat Hodgkin's lymphoma (HL) in adults. It used less frequently in children because of the potential anthracycline related cardiotoxicity. Chemotherapy and radiation are used in most childhood HL protocols. Avoiding radiation therapy or reducing its dose may decrease its potential long-term toxicities. *Aims.* To evaluate the efficacy of 4 courses of ABVD in children with low risk HL, and 4 courses of ABVD and 2 courses of COPP (cyclophosphamide, vincristine, prednisone, procarbazine) in children with high risk HL. In addition to evaluate the efficacy of chemotherapy alone in patients who are rapid responders to chemotherapy. *Methods.* 42 children were diagnosed and treated for HL at King Hussein Cancer Center in Jordan between January 2004 and December 2006. 8 patients were excluded from analysis because they were treated on different protocols. The outcome of 34 eligible patients was retrospectively analyzed. Median age at diagnosis was 11 years (range 2-18 years). Patients were stratified into 2 risk groups: Low risk (LR) and high risk (HR). The LR group included stage IA or IIA without bulky disease or extranodal involvement, while the HR included all other patients. Patients in LR group were treated with 4 courses of ABVD, while HR patients received 4 courses of ABVD followed by 2 courses of COPP. In both groups, radiation was omitted in patients who achieved complete remission (CR) after 2 cycles of ABVD (rapid responders to chemotherapy). Patients who were slow responders to chemotherapy (i.e. achieved CR after 4 cycles of ABVD) received radiation at a dose of 25.5 Gy. CR was defined as 75% reduction in the size of each of the nodal masses, or return to normal size along with a negative gallium or PET scan. *Results.* 26/34 (75%) patients were rapid responders to chemotherapy and did not require radiation. All patients achieved CR after 4 cycles of ABVD. 6/34 (25%) patients received radiation at a dose of 25.5 Gy since they were slow responders to chemotherapy. 2 patients relapsed (one was a slow responder to chemotherapy and received radiation and one was a rapid responder and did not receive radiation during his initial therapy). At a median follow up time of 19 months (range 6-38 months), event free survival (EFS) and overall survival (OS) were 94% and 100%, respectively. No major treatment related toxicities were observed. *Conclusions.* 4 courses of ABVD chemotherapy without radiation are probably adequate in children with low risk HL who achieve CR after 2 cycles. 4 courses of ABVD followed by 2 courses of COPP chemotherapy without radiation are probably adequate in children with HR HL who achieve CR after 2 cycles of ABVD. Radiation therapy can be reserved for patients who are slow responders to chemotherapy. This can be an important issue for countries with limited resources in radiotherapy. Limiting ABVD courses to 4 by utilizing COPP may decrease the potential cardiotoxicity. These results have to be confirmed by longer follow up and larger number of patients.

Acute myeloid leukemia - Clinical

PROGNOSTIC IMPACT OF NPM1 MUTATIONS IN CYTOGENETICALLY NORMAL (CN) ACUTE MYELOID LEUKEMIA (AML) IS ADVERSELY AFFECTED BY HIGH EXPRESSION OF THE ERG GENE: A CANCER AND LEUKEMIA GROUP B (CALGB) STUDY

P. Paschka,[1] G. Marcucci,[1] K. Maharry,[1] S.P. Whitman,[1] A.S. Ruppert,[1] T. Vukosavljevic,[1] K. Mrózek,[1] B.L. Powell,[2] J.E. Kolitz,[3] R.A. Larson,[4] C.D. Bloomfield[1]

[1]The Ohio State University, COLUMBUS; [2]Wake Forest Univ. School of Medicine, WINSTON-SALEM, NC; [3]North Shore University Hospital, MANHASSET, NY; [4]The Cancer and Leukemia Group B, CHICAGO, IL, USA

Background. Mutations in the NPM1 gene (NPM1+) are the most frequent molecular lesions in patients (pts) with CN-AML and, in the absence of FLT3 internal tandem duplication (FLT3-ITD), define a subset of pts with favorable prognosis. We have recently shown that overexpression of the ETS-related gene, ERG, is predictive of poor outcome in CN-AML. However, the prognostic impact of NPM1+ has not yet been evaluated in the context of ERG expression. *Aims.* To evaluate the prognostic impact of NPM1+ in CN-AML pts when FLT3-ITD and ERG expression status are also determined. *Methods.* Diagnostic samples from 216 CN-AML pts aged <60 years and treated on one of two similar frontline CALGB trials (9621 and 19808) were analyzed by PCR amplification and subsequent sequencing for the presence of mutations in exon 12, the major mutational cluster in NPM1. The samples were also assessed for the presence (+) or absence (-) of the FLT3-ITD by GeneScan fragment analysis of PCR products encompassing FLT3 exons 14 and 15. ERG expression was measured by quantitative Real-Time RT-PCR. *Results.* NPM1 mutations were found in 65% of pts. NPM1+ pts had higher white blood cell counts (p<0.001) and higher% bone marrow blasts (p=0.01) than NPM1- pts. A trend towards worse overall survival (OS) was observed for the NPM1- pts (p=0.11). No significant differences in complete remission (CR) rates or event-free-survival (EFS) were found between the two groups. In NPM1+ pts, high ERG and FLT3-ITD were detected in 40% and 36% of the cases, respectively. Among the NPM1+ pts, high ERG expressers had worse EFS than low ERG expressers (p=.0002; estimated 3-yr rate 55% vs 15%), and high ERG independently predicted a worse EFS (p=0.003) once adjusting for FLT3-ITD status (p<.001). The subset of NPM1+/FLT3-ITD- pts (36%) tended to have a higher CR rate (p=.06; 90% vs 80%) and had significantly better EFS (p<.0001; 3-yr rate 58% vs 29%) and OS (p<.0001; 3-yr rate 70% vs 41%) when compared with the remaining pts. Importantly, when all three molecular markers were considered together, NPM1+/FLT3-ITD-/low ERG pts had better EFS than NPM1+/FLT3-ITD-/high ERG pts (p<0.001; estimated 3-yr rate 72% vs 14%). In a multivariable analysis, ERG remained the only variable independently associated with EFS (p=0.002); high ERG expressers had almost four times the risk (hazard ratio: 3.8) to experience an event compared with low ERG expressers. *Conclusions.* NPM1+ as a single molecular marker is not a strong predictor for outcome in CN-AML pts, but its prognostic value can be enhanced by further molecular characterization. Within the favorable NPM1+/FLT3-ITD- group, a subset of pts with an extremely dismal outcome can be identified based on high levels of ERG expression.

0397

PRONOSTIC VALUE OF MOLECULAR FINDINGS IN AML: RESULTS OF THE FRENCH ALFA-9802 TRIAL

V. Biggio,[1] A. Renneville,[2] J.M. Cayuela,[3] S. Hayette,[4] D. Bories,[5] X. Troussard,[6] A.L. Beanceur,[7] N. Fresnoy,[8] N. Philippe,[2] N. Boissel,[3] C. Terre,[9] M. Elhamri,[4] S. Castaigne,[9] H. Dombret,[3] X. Thomas,[4] C. Preudhomme[2]

[1]INSERM, LILLE; [2]INSERM U837, Lab of Hemat. CHRU, LILLE; [3]Dep of Hem. Hôpital Saint-Louis, PARIS; [4]Dep of Hem. Hôpital Edouard Herriot, LYON; [5]Dep of Hem. Hôpital Henri Mondor, CRETEIL; [6]Dep of Hem., Hôpital Georges Clémenceau, CAEN; [7]Dep of Hem., Institut Gustave Roussy, VILLEJUIF; [8]Dep of Hem., Hôpital des Armées Percy, CLAMART; [9]Dep of Hem., Hôpital André Mignot, VERSAILLES, France

Background and aim. Beside cytogenetics, mutations of several genes of interest have emerged as major prognostic factors in patients with acute myeloid leukemia (AML). In this study we investigated 305 of 450 patients aged 15-50 years, enrolled in ALFA-9802 protocol (median fol-

low-up: 3-y). Mutations of FLT3 (ITD and D835), NPM, and CEBPa genes were analyzed and their prognostic value evaluated. *Results.* Mutation frequencies were: FLT3-ITD 14% (#44), FLT3-D835 5% (#16), NPM 24% (#74), and CEBPa 6.8% (#21). NPM mutations were associated with female sex (p=0.004), high WBC (p=0.01), M4/M5 FAB subtypes (p=0.04), intermediate cytogenetics (p<.0001), and normal karyotype (p<0.0001) and were strongly associated with FLT3-ITD (p=0.006). FLT3-ITD was associated with high WBC (p=0.0001), intermediate cytogenetics (p=0.009), and normal karyotype (p=0.003). CEBPa mutations were associated with FAB (M1/M2) and normal karyotype (p=0.03) and were mutually exclusive with FLT3-ITD+ and NPM+ (p=0.03). Overall CR rate was 90%, with a significant correlation with FLT3-ITD (77% in FLT3-ITD+ versus 90% in FLT3-ITD-neg, p=0.008). FLT3-ITD+ patients had a worse EFS (p=0.001) and NPM+ patients a better EFS (p=0.007). FLT3-D835 or CEBPa as isolated mutation did not interfere with EFS. Only FLT3-ITD+ patients presented a shorter OS (median, 15.7 versus 60 months, p=0.0009). In the intermediate cytogenetic group (n=173), FLT3-ITD and NPM mutations showed negative (p=0.0006) and positive (p=0.0017) correlation with EFS, FLT3-ITD remaining a bad prognostic factor for OS (p=0.0006). When analyzing the normal karyotype subgroup (n=117), EFS correlations with FLT3-ITD and NPM status were still present (p=0.011 and p=0.0043, respectively). Worse OS was observed in FLT3-ITD patients (p=0.00016) and a trend for longer OS in NPM+ and CEBPa+ patients (both p=0.09). Finally we divided the intermediate cytogenetic group in 4 subgroups: CEBPa+, NPM+, FLT3-ITD-neg (G1); CEBPa+, NPM+, FLT3-ITD+ (G2); CEBPa-neg, NPM-neg, FLT3-ITD+ (G3), and the remaining patients (G4). Significant differences were found between those 4 subgroups in terms of EFS and OS (p<0.0001). Median EFS was 9.9 (G2), 4.8 (G3), and 18.8 months (G4), while not reached in the G1 group. Median OS was 16.6 (G2), 22 (G3), and 43.4 months (G4), while not reached in the G1 group. *Conclusions.* Here we confirm the good prognosis of NPM mutations and the bad prognosis of FLT3-ITD and show a negative effect of FLT3-ITD for CR achievement. The bad prognostic of FLT3-ITD is predominant in NPM+/FLT3-ITD+ patients (our G2). According to clinical data, we can observe that patients with NPM+/FLT3-ITD-neg or CEBPa+ (G1) are similar to CBF patients, while FLT3-ITD+ patients (G3) are near to those with complex karyotypes.

THE IMPACT OF THERAPY-RELATED AND SECONDARY AML IN RELATION TO KARYOTYPE AND MOLECULAR MARKERS: A STUDY OF THE AMLSG

S. Kayser,[1] K. Döhner,[1] J. Krauter,[2] S. Groner,[1] D. Späth,[1]
B. Schlegelberger,[2] G. Göhring,[2] A. Ganser,[2] H. Döhner,[1] R.F. Schlenk[1]

[1]*Uniklinik Ulm, ULM;* [2]*Hannover Medical School, HANNOVER, Germany*

Background. Patients with therapy-related acute myeloid leukemia (t-AML) or secondary AML (s-AML) after a myelodysplastic syndrome are considered to have an inferior outcome compared to *de novo* AML. Whether this is due to an adverse cytogenetic risk profile or by the fact of s/t-AML per se has not been determined yet. *Aims.* To evaluate the frequency and prognostic impact of cytogenetic abnormalities and molecular markers in t-AML and s-AML in comparison to *de novo* AML in a large cohort of adult AML patients. *Methods.* Patients were entered on several AMLSG treatment trials (AML HD93, AML HD98A, AML HD98B, AMLSG 07-04, AMLSG 06-04). The key inclusion criteria for this analysis were availability of cytogenetics and molecular markers in cytogenetically normal (CN) AML. Genotypic groups were defined as follows: favorable [t(8;21), t(15;17), inv(16)/t(16;16)], NPM1pos/FLT3-ITDneg-CN-AML, other-CN-AML, and unfavorable [all other cytogenetic aberrations]. *Results.* Between 1993 and 2006, 2530 adults (age range 16-85 years) were registered and 2287 were included in this. Of the 2287 patients, 170 (7.5%) had t-AML, 360 (16%) s-AML and 1757 (76.5%) *de novo* AML. The median age was significantly lower in *de novo* AML compared to t-AML and s-AML. Median WBC and LDH levels were significantly higher (p<.0001) in *de novo* AML compared to t-AML and s-AML. The distribution of genotypic groups was different with a lower incidence of CN-AML subsuming both CN-AML subgroups in t-AML and a lower incidence of favorable genotype in s-AML (p<0.0001). The incidence of NPM1pos/FLT3-ITDneg-CN-AML patients was nearly half in t-AML and s-AML compared to *de novo* AML (p=0.03). Response to induction therapy was significantly higher in *de novo* AML (CR 72%) compared to t-AML (59%) and s-AML (52%). Cox regression models on event-free (EFS) and overall survival (OS) revealed the genotypic groups other-CN-AML (HR 2.2 and 2.3) and unfavorable (HR 3.4 and 3.2), t-AML (HR 1.3 and 1.5) and s-AML (HR 1.4 and 1.2), age (10 years difference HR 1.4 and 1.2) and log(LDH) (HR 1.1 and 1.1) as significant unfavorable prognostic variables. To better define the role of t-AML and s-AML subgroup analyses were performed according to genotypic groups; favorable group subsuming favorable and NPM1pos/FLT3-ITDneg-CN-AML, other-CN-AML and unfavorable. These analyses revealed no impact of t-AML and s-AML within the favorable group (*de novo* n=510, t-AML n=33, s-AML n=34) for EFS (p=0.73) and OS (p=0.8), a marginal impact within the other-CN-AML group (*de novo* n=381, t-AML n=19, s-AML n=69) for EFS (p=0.02) and no impact for OS (p=0.1), and finally a marked significant impact within the unfavorable group (*de novo* n=649, t-AML n=102, s-AML n=196) for EFS (p<0.0001) and OS (p<0.0001). In t-AML and s-AML OS of patients with either favorable or NPM1pos/FLT3-ITDneg-CN-AML genotypes was 58% and 68% and was significantly superior compared to that of all other patients with 11% and 19% after 3 years, respectively. *Conclusions.* The prognostic impact of t-AML and s-AML is restricted to the group of patients defined by unfavorable cytogenetics.

0399

INCIDENCE OF RETINOIC ACID SYNDROME DURING INDUCTION THERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA (PETHEMA PROTOCOLS LPA 96 &9 99) REVEALS TWO PEAKS WITH DIFFERENT INDUCTION MORTALITY

J.M. Bergua,[1] P. Montesinos,[2] G. Guillermo,[2] J. De La Serna,[3]
E. Vallenga,[4] C. Rayón,[5] R. Parody,[6] J. Esteve,[7] M. Gonzalez,[8]

Migration-maduration of tumoral promyelocytes following treatment with All-Trans Retinoic Acid (ATRA) in Acute Promyelocytic Leukemia (APL) is the cornerstone of the pathophisiology of Retinoic Acid syndrome (RAS). RAS is a potential life-threatening complication whose incidence ranges from 2 to 30% of patients with APL treated with ATRA. We have analyzed the incidence of RAS in 733 patients with acute promyelocitic leukaemia (APL) treated *de novo* with PETHEMA protocols LPA 96 and 99 (175 and 558 patients respectively). Induction therapy consisted in all-trans retinoic acid (ATRA) plus Idarrubicin, followed with three-consolidation courses of anthracycline monochemotherapy. Treatment was risk adapted depending on the platelets and leukocytes number (three groups: low, medium and high). In LPA99 patients, ATRA was added in each cycle of consolidation, except in low risk patients ($<10\times10^9$/L leucocytes and platelets $>40\times10^9$) and oral prednisone (0.5 mg/kg) was added in induction as prophylaxis of RAS. Treatment of suspected RAS consisted in ATRA discontinuation and intravenous Dexametasone administration. Definite RAS was defined when four of the seven following criteria was found: unexplained fever (non infectious related), respiratory distress, radiological pulmonary infiltrates, pericardial/pleural effusion, hypotension, renal failure, and weight gain over 5kg. 87 out 733 patients developed RAS (11.46%). ATRA was discontinued in 63% of patients. The incidence of RAS was not statistically different between the LPA96 and LPA99 trials (15% vs 11%, p=0.16).

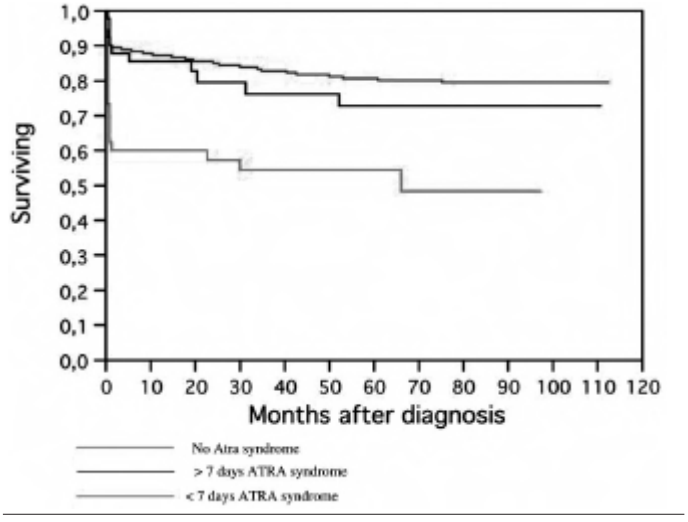

Figure 1.

The cases of RAS showed two peaks of incidence, the first one at <7 days (47 patients, 54%, median 3 days) and a second peak from 8 to 30 days (36 patients, 46%, median 22 days). Univariate analysis showed that the occurrence of the first peak was associated with high ECOG score, more leukocytes (p<0.001), more patients in high risk (p<0.001), higher LDH (p=0.025) and expression of CD2 (p=0.003). No differences in number of patients in both peaks were appreciated between LPA protocols 96 and 99. The first peak was associated with high induction mortality (36% vs. 9.11% in the second peak; 7% in no RAS patients) and decrease overall survival (p<0.001). In LPA 96 both peaks were associated with increased risk of LPA relapsed and perhaps related to ATRA discontinuation. Noteworthy, this increased risk of relapse was not observed in LPA 99 trial, in which ATRA was added in each consolidation course. In conclusion we observed a bimodal distribution incidence of RAS, in which the first peak is associated with high mortality. Patients who develop a second peak have mortality similar to patients with no RAS. The patophisiology of the second peak of RAS is intriguing since the use of Idarrubicine in induction therapy is associated with leukocyte nadir or perhaps normal leukocyte recovery.

PCR-BASED MRD DETECTION IN NPM1 MUTATED AML: A PROSPECTIVE FOLLOW-UP STUDY IN 97 PATIENTS

S. Schnittger, W. Kern, C. Haferlach, T. Haferlach

MLL, MUNICH, Germany

Background. Around 50% of all normal karyotype AML have been shown to carry mutations in the NPM1 gene that mostly are comprised of 4 bp insertions. This suggests that NPM1 may be used as an MRD marker applicable to a large subset of AML with normal karyotype. *Aims.* To evaluate the applicability of NPM1 mutations as follow up marker and to evaluate whether there is any prognostic relevance we studied 97 NPM1 mutated AML during and after therapy. *Methods.* NPM1 mutations are heterogeneous with 80% being belonging to type A, 10% to types B and D, and further 10% to more than 40 different yet described rare types. We have established NPM1 specific real time PCR assays for 10 different NPM1 variants. All assays are RNA based rendering high sensitivities between 1:100,000 to1:1,000,000. Most of these assays are specific, while in some of them a minimal detection of the wildtype allele cannot be avoided. In total 367 samples (spl) of 97 patients (pts) were analysed by quantitative real time PCR. Out of these 72 pts had type A, 7 type B, 8 type D, and 10 had 7 different rare types. 2-12 follow-up samples were analysed per patient (mean 3.7, median: 3). Mean follow-up time was 249 days (median: 175 days). *Results.* Three cases were resistant to chemotherapy as identified by non-decreasing NPM1 levels. Relapses were detected in 27 cases. All relapses had high NPM1 levels comparable to those at diagnosis. Of these 23 relapses 10 were predictable by increasing NPM1 levels 3-6 months before clinical relapse. Further four cases did not reach more than a three log reduction after consolidation and relapsed within the first year after start of therapy. In 9 cases early detection of relapse was not possible due to lack of samples within the last 6 months before relapse was diagnosed.To analyse the impact of NPM1 mutation levels on prognosis four different follow-up intervals were defined: interval 1: day 21-60 after start of therapy; interval 2: days 61-120; interval 3: day 121-365, 4: later. Using Cox regression analysis a significant impact of MRD levels on EFS was detected for interval 1 (p=0.014), interval 2 (p=0.004), and interval 3 (p=0.002). So far no impact of the initial expression ratio of the mutation on survival could be shown. In addition, the log change from diagnosis to the defined follow-up intervals was analysed. A rapid decline of median transcript ratios was observed: interval1: 2 log, interval 2: 4 log, interval 3 and 4: 6 log. *Conclusions.* 1) NPM1 mutations are highly effective and sensitive markers for PCR-based MRD detection in normal karyotype AML, 2) mutation levels highly correlate with the clinical course of the disease, 3) mutation levels during follow up have significant impact on prognosis, 4) early detection of relapse is possible by increasing MRD levels, 5) the NPM1 MRD pattern reflects a biological subgroup of AML with early response and high log reduction during follow-up.

Cervello, PALERMO; [6]Az. Osp. S. Croce e Carle, CUNEO; [7]Ospedale San Gerardo, MONZA; [8]Università Federico II, NAPOLI; [9]Ospedale S. Anna, RONCIGLIONE (VT); [10]Università La Cattolica, ROMA; [11]Centro Riferimento Oncologico Basilicata, RIONERO IN VULTURE (PZ); [12]Policlinico Monteluce, PERUGIA; 13Università Bologna, Istituto Seragnoli, BOLOGNA, Italy

Background. Since 1960, oral melphalan and prednisone (MP) has been considered the standard treatment for elderly patients. In this multicentre randomized trial we compared oral MP plus thalidomide (MPT) with MP alone in 60 to 85 years old patients. *Aims*. The primary objectives were response rates and event-free survival (EFS). Secondary end points included overall survival (OS), prognostic factors and incidence of any grade 3-4 adverse event. *Methods.* Inclusion criteria were previously untreated myeloma patients, age > 65 years of age or younger but excluded from transplant procedure, Durie and Salmon stage II or III and measurable disease. Patients agreed to use contraception, and women of childbearing age had a pregnancy test before enrolment. The criteria for exclusion were another cancer, psychiatric disease and any grade 2 peripheral neuropathy. MPT consisted of oral MP (melphalan 4 mg/m^2 and prednisone 40 mg/m^2 for 7 days) for six four-week cycles plus thalidomide 100 mg per day continuously until any sign of relapse or progressive disease (Pharmion LTD, Windsor, UK). No anticoagulation prophylaxis was administered until December 2003 when the protocol was amended and enoxaparin at 40 mg per day was delivered subcutaneously during the first four cycles of therapy. Two-hundred and fifty-five patients were randomly assigned to receive oral MPT (N=129) or MP (N=126). *Results*. Patients treated with MPT experienced higher response rates and a longer event-free survival than patients who were not. In intention-to-treat analysis, the complete and partial response rates were 76.0% for MPT and 47.6% for MP alone (absolute difference +28.3%, 95% CI 16.5 to 39.1), and the near complete and complete response rates were 27.9% and 7.2%, respectively. The 2-year EFS rate was 54% in patients receiving MPT and 27% in patients receiving MP (p=0.0006). The 3-year OS rate was 80% in patients taking MPT and 64% in patients taking MP (p=0.19). In MPT arm, no significant differences in term of OS were observed between patients with high or low B2-microglobulin (cut-off: 3.5 mg/L): at 18 months OS rate was 80% and 84%, respectively (HR 1.21, 95% CI 0.50-2.93, p=0.67). By contrast, in MP group, B2-microglobulin remained a prognostic factor: at 18 months OS rate was 71% for patients with high B2-microglobulin and 86% for patients with low B2-microglobulin (HR 2.8, 95% CI 1.26-6.18, p=0.01). Grade 3-4 adverse events were 48% in MPT patients and 25% in MP patients (p=0.0002). In the MPT group, the most frequent grade 3-4 toxicities were haematological, thromboembolism, infections and peripheral neuropathy. The introduction of enoxaparin prophylaxis significantly reduced the incidence of thromboembolism from 20% to 3% (p=0.005). *Conclusions*. Oral MPT is superior to MP as first-line treatment for elderly patients with multiple myeloma. Longer follow-up is needed to assess the effect on overall survival. Oral MPT seems to cancel the adverse prognostic effect of high β2-microglobulin.

0402

ORAL MELPHALAN, PREDNISONE AND LENALIDOMIDE FOR ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS

Osp. di Cosenza, COSENZA, Italy; [10]Celgene, SUMMIT (NJ), USA; [11]Università La Sapienza, ROMA, Italy

Background. Lenalidomide plus dexamethasone is an effective treatment in advanced and newly diagnosed multiple myeloma (MM). In newly diagnosed patients the addition of thalidomide to the standard oral melphalan and prednisone (MP) significantly increase response rate and event free-survival (EFS) compared with MP. No data are available on the potential additive and synergistic effect of the combination of MP plus lenalidomide. *Aims.* This trial was a phase 1/2 multicenter, dose-escalating, open-label study designed to evaluate the dosing, safety and efficacy of the association of MP plus lenalidomide (MPR) in newly diagnosed symptomatic elderly MM patients. Primary end points were definition of the maximum tolerated dose (MTD) and response rate; secondary objectives were EFS and overall survival (OS). *Methods.* Fifty-four patients (median age 71 years, range 57-77) were enrolled in the study and received 9 cycles of lenalidomide (5-10 mg/day for 21 days) plus melphalan (0.18-0.25 mg/kg for 4 days) and prednisone (2 mg/kg for 4 days) every 4-6 weeks, followed by maintenance therapy with lenalidomide alone (10 mg/day for 21 days every month). Four different dose-levels were tested. All patients received aspirin (100 mg/day), as antithrombotic prophylaxis. *Results*. The MTD was lenalidomide 10 mg/day for 21 days and melphalan 0.18 mg/kg for 4 days every 4-6 weeks. At this dose-level partial response (PR) was observed in 81% of patients, including 47.6% with at least a very good partial remission (VGPR) and 23.8% who showed immunofixation negative complete response (CR). The 1-year EFS and OS rates were 92% and 100%, respectively. The presence of deletion of chromosome 13 or chromosomal translocation (4;14) did not affect response rate and survival, while high values of β2-microglobulin predicted a shorter EFS. Seventy percent of patients received maintenance treatment with Lenalidomide alone (median follow-up on maintenance 3,8 months). Major grade 3'4 adverse events consisted of hematological toxicities (69.8%); major grade 3'4 non-hematological toxicities included febrile neutropenia (9.4%), cutaneous rash (7.5%), and thromboembolism (5.7%); two of three thromboembolic events occurred after aspirin discontinuation. *Conclusions*. Oral MPR is a promising first-line treatment for elderly patients with multiple myeloma. Hematological adverse were manageable and non-hematological adverse events showed a low incidence. Aspirin appears to be an effective antithrombotic prophylaxis. Un update of these data will be presented at the meeting.

Background. Allografting induces long-term molecular remissions and possibly cure in myeloma patients. The development of nonmyeloablative conditionings has reduced the transplant-related mortality (TRM) and extended the eligible age for transplantation up to 65-70 years. However, prior cytoreductive high-dose chemotherapy appears to play a key role in the achievement of high response rates. *Aims.* We report the results of a GITMO (Gruppo italiano trapianto midollo osseo) multicenter trial which evaluated efficacy and safety of a hematopoietic stem-cell autograft followed by a nonmyeloablative allograft from an HLA-identical sibling in patients with newly diagnosed myeloma. *Methods.* One hundred and six patients from 15 Italian centers were enrolled. Four patients did not complete the program because of consent withdrawal and were then excluded from the analysis. The median age was 54 years (range 30-65), 70 patients out of 102 had stage III myeloma and β2microglobulin was greater than 3,5 mg/dL in 33. All patients were initially treated with vincristine, doxorubicin, and dexamethasone, after which peripheral-blood stem cells (PBSC) mobilized by cyclophosphamide and granulocyte colony-stimulating factor (G-CSF) were collected. Upon recovery, patients were treated with 200 mg/m^2 melphalan followed by autologous stem-cell rescue. About 2 months later, they received 2 Gy total-body irradiation and infusion of G-CSF mobilized PBSC from an HLA-identical sibling. Graft-vs-host disease (GVHD) prophylaxis included cyclosporin and mycophenolate mofetil. *Results.* After autologous transplantation overall response rate was 77% (79/102), with 7/102 complete remission (CR). Following allografting, all patients promptly achieved donor engraftment. The overall response rate was 91% (93/102), with 56 patients achieving CR. Among patients progressed after allografting, 16 were treated with donor lymphocyte infusion, 8 of them received prior cytoreductive therapy, and 4/16 obtained a transient disease response. Incidence of grade 2-4 acute GVHD was 40% (41/102), including 4 patients with grade 4. Overall, chronic GVHD was observed in 74% (73/99) of patients alive at least 3 months after allografting, GVHD was graded as extensive in 50 of them. After a median follow-up of 48 months (range, 14-103) from diagnosis, median overall survival was not reached with follow-up extending to 7 years. Causes of deaths were TRM in 14 patients, disease progression in 6 and second tumor in 3. Median event-free-survival (EFS) was 38 months (range 10-103). *Summary and conclusions.* This reports shows that the combination of autologous transplant followed by allografting from an HLA-identical sibling is feasible in patients with newly diagnosis myeloma up to 65 years of age and demonstrates efficacy in terms of disease control and reduced toxicity by separating the cytoreductive effect of high dose chemotherapy from the graft-versus-myeloma effect of allografting.

0404

BORTEZOMIB PLUS MELPHALAN AND PREDNISONE (VMP) IN ELDERLY UNTREATED PATIENTS WITH MULTIPLE MYELOMA: PROGNOSTIC FACTORS INFLUENCING TIME TO PROGRESSION

M.-V.M. Mateos,[1] J.-M. Hernández,[2] M.-T. Hernández,[2] N.-C. Gutiérrez,[2] L. Palomera,[2] M. Fuertes,[2] P. García,[2] J.J. Lahuerta,[2] J. De la Rubia,[2] M.J. Terol,[2] A. Sureda,[2] J. San-Miguel[2]

[1]University Hospital of Salamanca, SALAMANCA, Spain; [2]Hematology Division, Grupo Español de MM, SPAIN, Spain; 3Millennium Pharmaceuticals, Inc., CAMBRIDGE, MA, USA; [4]Johnson & Johnson Pharmaceutical Researc, BEERSE, Belgium

Between January 2004 and April 2005, the Spanish PETHEMA group conducted a phase I/II trial in which 60 newly diagnosed MM patients older than 65 years were included and received four 6-weeks cycles of bortezomib 1.0 or 1.3 mg/m^2 on days 1, 4, 8, 11, 22, 25, 29 and 32 followed by a 10-day rest period, in combination with oral melphalan 9 mg/m^2 and oral prednisone 60 mg/m^2, both on days 1 to 4. This was followed by five cycles of weekly bortezomib in combination with melphalan and prednsone. No Dose Limiting Toxicity occurred during the phase I; therefore, the 1.3 mg/m^2 dose was expanded to the phase 2. With a median follow-up of 26 months (range: 15-38) we confirm the response rate of 88% previously reported including 32% of IF-negative CRs, 11% IF-positive CRs and 45% of PR. The median time to progression (TTP) time was 27,2 months (95% CI: 22-32) and the median overall survival (OS) time has not been reached and the estimated 3-year OS

is 85%. Seven out of the 25 relapsed patients are considered to have a biological but asymptomatic relapse and remains untreated with a median follow-up from the biological progression of 2,5 months (range: 1-8). We analyzed the influence of variables with known prognostic factors in MM in TTP and we observed that hypoalbuminemia (<3 g/dL), poor Karnofsky performance status (<70%), and high S-phase (>2,5%) of bone marrow plasma cells were associated with a significantly shorter TTP (p value < 0,05). In addition, patients with high LDH showed also a trend to have short TTP (p:0,1). By contrast neither age (similar survival for patients younger and older than 75 years) nor cytogenetics abnormalities influenced outcome in terms of TTP (p value >0,05). Toxicity was manageable and predictable; principal toxicities were haematologic, gastrointestinal, and peripheral neuropathy and were more evident during early cycles and in patients older than 75 years old. In conclusion, prognostic factors such as hypoalbuminemia, poor Karnofsky performance status and high S-phase were associated with a shorter TTP; by contrast, VMP overcomes the adverse prognosis conferred by age and cytogenetics abnormalities.

0405

POOR PROGNOSIS ASSOCIATED WITH GAIN OF CHROMOSOME 1Q21 IN MULTIPLE MYELOMA MAY BE OVERCOME BY TREATMENT WITH A BORTEZOMIB COMBINATION

V. Sagaster,[1] V. Odelga,[1] H. Kaufmann,[1] J. Ackermann,[1] M. Galhuber[1] N. Zojer,[2] H. Ludwig,[2] R. Wieser,[1] C. Zielinski,[2] J. Drach[1]

[1]Medical University of Vienna, VIENNA; [2]Wilhelminenspital, Dept. of Medicine I, VIENNA, Austria

Background. Bortezomib is an active agent for treatment of multiple myeloma (MM) and may even be effective in patients (pts) with adverse prognostic factors including unfavorable cytogenetic abnormalities. However, it is unknown whether or not bortezomib may overcome the negative prognostic impact of a chromosome 1q21 (CKS1B) gain, which has recently been reported as a negative prognostic factor even in the setting of a total therapy approach. *Aims.* We therefore evaluated chromosome 1q21 among other abnormalities in 46 pts with relapsed/refractory MM who were treated with single-agent bortezomib (1.3 mg/m^2 on days 1, 4, 8, and 11 every 3 weeks) and in 28 pts treated with a bortezomib combination (bortezomib/dexamethasone in 43%, bortezomib/ chemotherapy in 46%, bortezomib/ thalidomide/dexamethasone in 11%). *Patients and Methods.* Median age of pts was 63 years (range, 40 - 82) and median time to bortezomib therapy was 40 months (median number of prior therapies: 3; 96% of pts had high-dose pulsed dexamethasone, 61% thalidomide, 85% alkylating agents, and 41% high-dose melphalan). Chromosome 1q21 was evaluated by interphase FISH with a CKS1B-specific probe. Results were correlated with clinical outcome. *Results.* Among patients treated with single-agent bortezomib, gain of 1q21 was observed in 20 of the 46 pts (43.5%). Treatment outcome after bortezomib was negatively affected by presence of a 1q21 gain: The overall response rate was 30% (versus 58% in pts with normal 1q21; p=0.06) and the CR/near-CR rate was 10% (versus 23%). Moreover, gain of 1q21 was associated with shortened time to treatment failure (TTF) (median, 2.4 versus 6.6 months; p=0.043) and overall survival (OS) (median, 4.4 versus 19.8 months; P = .003) compared to pts with normal 1q21. β-2-microglobulin and 14q32 translocations were unrelated to treatment outcome after single-agent bortezomib, but median OS was short in the presence of low serum albumin (4.8 versus 17.8 months; p=0.036). In the group of pts treated with a bortezomib-combination, 11 of the 28 pts had a 1q21 gain (39%). There were no significant differences between pts with 1q21 gain and normal 1q21 regarding overall response (54.5% versus 64.7%), CR/near-CR rate (27% versus 29%), median TTF (8.2 versus 6.9 months; p =0.57) and median OS (not reached versus 17.8 months; p=0.49). *Conclusions.* FISH-defined gain of 1q21 is associated with poor response, short TTF and short OS after single-agent bortezomib; however, these differences disappeared in the context of a bortezomib-combination therapy. These results provide further evidence for the efficacy of bortezomib-combinations in MM patients with high-risk features.

Background. The superiority of intensified chemotherapy with autologous stem cell transplantation (ASCT) as the first-line treatment in follicular lymphoma (FL) is uncertain, particularly since the introduction of rituximab. The GITMO-IIL trial evaluated if an intensified treatment with ASCT is better than conventional chemotherapy (both supplemented with Rituximab) in high-risk FL at diagnosis. Objectives. This is a multicenter randomized open-label phase III trial. The analysis was intention to treat with event-free survival (EFS) as the primary endpoint. Crossover from CHOP-R to R-HDS was allowed. Centralized PCR-based molecular analysis was performed. The whole patient (pt) population is now evaluable for analysis with a median follow-up of 39 months. Methods. Eligibility required a FL with aaIPI>1 or IIL>2 score and an age of 18-60. Secondary endpoints were PFS, DFS, OS, rate and prognostic value of MR. R-HDS and CHOP-R have been already described (Ladetto et al ASH 2005, Rambaldi et al Blood 2002). Planned sample size was 240 to detect a 20% absolute increase in the 3-years EFS. However the trial was stopped at 136 pts due to R-HDS EFS superiority at a planned interim analysis. Cross-over was allowed after CHOP-R failure. Centralized PCR-based molecular analysis was planned on BM cells.

Figure 1.

Results. Age, sex, histological grade, stage, LDH, bulky disease, B-symptoms, ECOG PS, frequency of bone marrow, spleen and other extranodal disease, high aaIPI and IIL scores were similar in the two arms. CRs were 62% with CHOP-R and 85% with R-HDS (p<0.001). At a median follow-up of 39 months EFS and PFS are 33% and 36% for CHOP-R and 62% and 70% for R-HDS (Figure 1A). OS is 81% in each arm. 56% of relapsed R-CHOP pts underwent R-HDS with a CR/VGPR rate of 66%. PCR analysis showed a MR rate of 44% after CHOP-R and 80% after R-HDS (p<0,001). MR was associated to a better PFS (p<0,001) (Figure 1B). Of note, 3yrs PFS of pts with or without MR was similar in the two arms (MR: 62% with CHOP-R and 80% with R-HDS) (no MR: 21% for CHOP-R and 30% for R-HDS). MR was the strongest independent prognostic factor for PFS, EFS and DFS by multivariate analysis. *Conclusions.* This is the first phase III trial including MR analysis in a high proportion of pts and comparing intensified versus conventional therapy in the Rituximab age. This trial indicates that: a) R-HDS has a better EFS and PFS in truly high-risk FL patients; b) MR is the strongest outcome predictor available in FL; c) the similar outcome in pts achieving or not MR, regardless of treatment received, indicates that the superior performance of R-HDS is due to its superior MR rate.

0407

LONG-TERM RESULTS OF THE GELA STUDY COMPARING R-CHOP AND CHOP CHEMOTHERAPY IN OLDER PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA SHOW A LONG TERM BENEFIT FOR THE ADJUNCTION OF RITUXIMAB TO CHOP

B. Coiffier,[1] P. Feugier,[2] R. Bouabdallah,[3] P. Morel,[4] G. Marit,[5] J. Gabarre,[6] E. Jourdan,[4] A. Delmer,[5] G. Lepeu,[4] H. Tilly[7]

[1]Hospices Civils de Lyon, PIERRE BENITE; [2]CHU de Brabois, NANCY; [3]Institut Paoli Calmette, MARSEILLE; [4]Centre Hospitalier, LENS; [5]CHU, BORDEAUX; [6]Hôpital de la Pitié, PARIS; [7]Centre Henri Becquerel, ROUEN, France

We present an update with 7 years median follow-up of the prospective randomized study LNH-98.5 that was first reported in the N Engl J Med and J Clin Oncol with a median follow-up of 2 and 5 years. The 399 patients included in the study had untreated diffuse large B-cell lymphoma and were 60 to 80 years old with a median age at diagnosis of 69 years. 60% had a poor risk lymphoma as defined by the aaIPI risk score of 2 or 3. 197 patients were randomized in CHOP arm and 202 in R-CHOP arm. Treatment consisted of 8 cycles of CHOP every 3 weeks with rituximab, 375 mg/m^2, the same day in R-CHOP. With a median follow-up of 7.1 years, 76% of the patients had an event in CHOP compared to 58% in R-CHOP, p=0.0002 (Table 1). 65% of patients died in CHOP arm compared to 47% in R-CHOP arm: 80% and 71% of them from lymphoma or treatment toxicity, 5% and 5% from another cancer, and 15% and 22% in CR from other causes, respectively. Survival curves show the same difference as reported before with a large difference in favour of R-CHOP (Table 1). Patients not expressing bcl-2 protein treated with R-CHOP have a statistically longer PFS but only a trend for OS because they responded better to salvage treatment. No statistically significant difference was observed for patients <70, 70-74, or >75 years old. Patients treated with R-CHOP have good survival even with poor risk parameters: 43% are alive for age >75 years, 38% for PS=2, 54% for B symptoms, 47% for stage IV, 45% for high LDH level, 54% for Hb <10 g/dL, and 42% for high aaIPI score. Death in CR was associated with high risk aaIPI score and presence of other diseases before lymphoma diagnosis. This analysis confirms the long term benefit associated with the combination of rituximab and CHOP and shows that older patients must be treated as younger patients even in presence of high risk characteristics or concomitant diseases.

Table 1. Survivals of patients treated with R-CHOP.

0408

ADDITION OF RITUXIMAB TO DOSE-DENSE AND HIGH DOSE CHEMOTHERAPY WITH AUTOLOGOUS TRANSPLANTATION IN UNTREATED POOR-PROGNOSIS DIFFUSE LARGE B-CELL LYMPHOMA: RESULTS OF PHASE II TRIAL

U. Vitolo, M.G. Cabras, G. Rossi, A.M. Liberati, A. Chiappella, A. Levis, V. Pavone, E. Angelucci, B. Botto, G. Ciccone, R. Freilone, G. Gaidano, D. Novero, L. Orsucci, I. Palumbo, E.M. Pogliani, D. Rota Scalabrini, F. Salvi, A. Tonso, A. Tucci, E. Gallo

On the behalf of GIMURELL, TURIN, Italy

Background. The efficacy of Rituximab (R) with high-dose chemotherapy in DLBCL is under investigation. *Aims.* We evaluated efficacy and safety of adding Rituximab to dose-dense and HDC as first line treatment in untreated patients with aa-IPI at Intermediate-High (IH) or High (H) risk with DLBCL. *Methods.* 94 previously untreated patients<61 years with DLBCL, stage III-IV at aaIPI IH or H risk were enrolled into R-HDC trial (study group; January 2001-December 2004). Treatment was: an induction lasting two months with 4 courses of R-MegaCEOP chemotherapy (R 375 mg/m^2 day1, CTX 1200 mg/m^2 + EPI 110 mg/m^2 + VCR 1.4 mg/m^2 day3 and PDN 40 mg/m^2 days 3-7) every 14 days with G-CSF support; 2 courses of intensified chemoimmunotherapy R-MAD (Mitoxantrone 8 mg/m^2 + ARAC 2000 mg/m^2/12h + Dexamethasone 4 mg/m^2/12h for 3 days and R 375 mg/m^2 day4 and before PBSC harvest) followed by ASCT conditioned by BEAM regimen. *Results.* median age was 47 yrs (19-60); 47% were at H risk; 28% had bone marrow involvement, 79% had LDH level >normal and 35% extranodal sites>1. Complete Response at the end of the treatment was achieved in 77 patients (82%), PR in 1 (1%) and 11 patients (12%) did not response; 5 patients (5%) died of toxicity. Few severe early toxicities (WHO grade 3-4) were reported and late toxicity was minor, with no MDS or ANLL or solid tumour. With a median follow-up of 41 months, 4-yr FFS and 4-yr OS rates were: 73% and 80%. These results were compared to those ones achieved into 41 patients, with the same clinical characteristics, enrolled in a previous phase II clinical trial with up-front HDC and ASCT but without R. Treatment in HDC control group was: an induction treatment lasting two months with MACOPB chemotherapy for 8 weekly infusions followed by the same intensified and HDC regimens (MAD x 2 courses + BEAM and ASCT). Four-yrs FFS and OS in control group were: 44% and 54%. To properly evaluate the efficacy of R-HDC therapy, a Cox's model was performed to adjust the effect of treatment for competing risk factors (age, IPI, BM involvement, number of extranodal sites). In this multivariate analysis the risk of failure and death was confirmed as significantly reduced in R-HDC group: adjusted hazard ratio (R-HDC vs HDC) was 0.46 (95% CI=0.25-0.85, p=0.01) for FFS and 0.46 (95% CI=0.23-0.93, p=0.03) for OS. PBSC harvest and time to engraftment were similar into two groups, with no statistically significant differences: all patients in both groups collected more than 2×10^6 CD34$^+$/kg; median time to neutrophils engraftment (neutrophils >500/mm^3) was 9 days in R-HDC group and 9.5 days in HDC group and median time to platelets engraftment (platelets >50000) was 13 vs 11 respectively. *Conclusions.* these results suggest that Rituximab as adjuvant to dose-dense and HDC may improve the outcome of DLBCL at poor prognosis. This promising new treatment strategy need to be compared to Rituximab dose-dense chemotherapy without HDC as R-CHOP14. Such a randomized trial is currently undergoing conducted by Intergruppo Italiano Linfomi.

0409

FRACTIONATED RADIOIMMUNOTHERAPY IN NHL WITH DOTA-CONJUGATED, HUMANIZED ANTI-CD22 EPRATUZUMAB AT HIGH CUMULATIVE 90Y DOSES

F. Morschhauser,[1] F. Kraeber-Bodere,[2] M.-O. Petillon,[1] J.-F. Chatal,[2] J.-L. Harousseau,[3] H. Horne,[4] N. Teoh,4 W.A. Wegener,[4] D.M. Goldenberg[4]

[1]Centre Hospitalier Universitaire, LILLE, France; [2]Institut de Biologie, INSERM, Research, NANTES, France; [3]Service d'Hematologie, Centre Hospitalie, NANTES, France; [4]Immunomedics, Inc, MORRIS PLAINS, NJ, USA

Background. The advantages of fractionated delivery of external radiation therapy may also apply to radioimmunotherapy. *Aims.* A phase I/II, multi-center, dose-escalation trial was undertaken to determine the maximum tolerated dose (MTD) for 2 or 3 weekly infusions of 90Y-epratuzumab in non-Hodgkin's lymphoma (NHL). *Methods.* Patients (pts) with B-cell NHL who failed >1 regimen of standard chemotherapy were eligible if they had <25% bone marrow involvement, platelets >100,000 cells/mm^3, and measurable disease by CT with no single mass >10 cm. The 90Y dose was escalated separately in increments of 2.5 mCi/m^2 (92.5 MBq/m^2) in cohorts of 3-6 pts with or without prior bone marrow transplant (BMT) until 2 occurrences of dose limiting toxicity (DLT). *Results.* Fifty-five pts (31 male, 24 female; median age 63) with a median of 3 prior therapies have now completed treatment. Therapy was well tolerated, and other than hematological DLT, no serious adverse events were considered treatment-related. For 17 pts with prior BMT, escalation stopped with 2 DLTs (platelet recovery delayed >12 wks) at 10 mCi/m2 total dose (5.0 mCi/m^2×2 wk). For 38 pts without prior BMT, no DLTs have yet occurred at 45 mCi/m^2 total dose (15 mCi/m^2×3 wk), the highest level currently administered. Of 44 pts with evaluated treatment responses, 23 (52%) had an objective response (OR) by International Working Group (IWG) criteria, across all histologies [follicular NHL, 11/20 (55%); DLBCL, 3/9 (33%); mantle cell, 6/12 (50%), marginal zone, 3/3 (100%)], and including pts after prior BMT (7/17, 41%), or pts not responding to the last rituximab-containing regimen (6/9, 67%). Most ORs were complete responses (CR/CRu, 17/23, 74%), and with long-term follow-up now available in 11 CR/CRu responders, 8 pts had responses >6 mo, including 3 pts with continuing response >1 yr. OR rates increased at higher cumulative dose for the 44 patients currently evaluated [5-10 mCi/m^2, 7/17 (41%), 15-20 mCi/m^2, 7/12 (58%), 22.5-37.5 mCi/m2, 9/15 (60%)] and remain to be determined for other pts currently being evaluated, including those who completed treatment at the highest cumulative doses, 40 and 45 mCi/m^2. *Conclusions.* Fractionated radioimmunotherapy with epratuzumab appears feasible and safe, achieving high response rates at cumulative 90Y doses several-fold higher than the 32-mCi (1200-MBq) limit approved for a single dose of Zevalin.

0410

HIGH CURE RATE OF ADULT BURKITT'S AND OTHER HIGH GRADE NHL BY THE COMBINATION OF SHORT INTENSIVE CHEMOTHERAPY CYCLES WITH RITUXIMAB

D. Hoelzer,[1] W. Hiddemann,[2] A. Baumann,[2] H. Döhner,[2] U. Dührsen,[2] R. Fietkau,[2] M.-L. Hansmann,[1] A. Hüttmann,[2] S. Irmer,[2] S. Kaun,[3] M. Kneba,[2] A. Reichle,[2] M. Schmid,[2] I. Schmidt-Wolf,[2] E. Thiel,[4] J. Walewski,[5] N. Gökbuget[1]

[1]J.W.Goethe University, FRANKFURT AM MAIN, Germany; [2]University Hospital, MUNICH, Germany; [3]Klinikum Bremen Mitte, BREMEN, Germany; [4]University Hospital Charité, BERLIN, Germany; [5]The Maria Sklodowska-Curie Memorial Canc, WARSAW, Poland

Survival rates for adults with Burkitt'S NHL and B-ALL were improved by mostly childhood derived regimens with HDMTX, HD alkylators and HDAC to CR rates of 80% and overall survival (OS) of 50-70%. Further intensification of chemotherapy in other and our study group failed to improve these results (B-NHL90 trial, Blood 100 (11), #595). Therefore the GMALL study group invented in 2002 a new B-NHL protocol including 6x Rituximab 375 mg/m^2 before each chemo cycle and of two Rituximab maintenance cycles. In addition two cycles HDAC 2 g/m^2 were included. HDMTX was reduced from 3 to 1,5 g/m^2 in the protocol for younger pts (<55 yrs) since no improvement but increased toxicity had been observed in the previous study B-NHL90. A dose reduced regimen without HDAC and with 500 mg/m^2 HDMTX was given in older pts (>55 yrs) (Figure 1).

Figure 1. Multicentre study to optimize therapy of B-ALL, Burkitt's NHL and other high-grade non-Hodgkin's lymphoma in adults (GMALL-B-ALL/NHL 2002).

In this study 376 pts with high-grade B-NHL were enrolled between 09/02 and 12/06. 272 were evaluable for response after the first two cycles. The median age was 38 (16-78) yrs; 23% (N=63) were older than 55 yrs. The distribution of subtypes was as follows: 115 Burkitt's NHL (stage III-IV 52%, extranodal inv. 78%, aaIPI >1 47%), 70 mature B-ALL, 62 DLBCL (42 mediastinal, stage III-IV 63%, extranodal inv. 77%, aaIPI >1 63%), 14 B-LBL and 11 LACL. The CR rate after two cycles was 90% in Burkitt's NHL, 81% in B-ALL and 74% in DLBCL; death under therapy occurred in 3%, 11% and 2% respectively. The OS at 3 yrs was 91% for Burkitt's NHL, 79% for B-ALL and 91% for DLBCL in pts 15-55 yrs and 84%, 39% and 67% (N=9) in pts >55 yrs. Since in elderly pts with mature B-ALL CNS relapses were observed, HDAC will be included in the future. In younger pts the overall CNS relapse rate was 0. There was no difference in OS between pts with Burkitt (92%) vs Burkitt-like NHL (86%). Since no prognostic factors could be identified in younger pts, there was no need for SCT in CR1. Major grade III/IV toxicity was hematological (28-37%) and mucositis (36%, 37%, 28% in cycles A1, B1, C1 respectively). Compared to the trial B-NHL90 with 270 pts the OS at 3 yrs improved significantly from 54% to 80% (p<0.0001) overall, 56% to 85% (p<0.0001) in younger and 39% to 65% (p=0.01) in older pts. In this largest prospective study of adult Burkitt's NHL and other high grade NHL the combination of Rituximab and 6 short intensive chemo cycles was feasible and lead to an OS of 91% in NHL and 79% in mature B-ALL in the younger patient cohort. Even in older pts with Burkitt's NHL survival was 84%. The next generation studies will mainly focus on reduction of toxicity.

Myeloproliferative disorders - Biology

ACQUIRED ISODISOMY IS COMMON IN ATYPICAL MYELOPROLIFERATIVE DISORDERS

C. Curtis,[1] F.H. Grand,[1] S. Kreil,[1] D.G. Oscier,[2] A.G Hall,[3] N.C.P Cross[1]

[1]Wessex Regional Genetics Lab, SALISBURY, United Kingdom; [2]Royal Bournemouth Hospital, BOURNEMOUTH, United Kingdom; [3]University of Newcastle Upon Tyne, NEWCASTLE UPON TYNE, United Kingdom

Recent evidence has indicated that acquired isodisomy is a novel mechanism by which mutations in cancer may be reduced to homozygosity. Typically, acquired isodisomy is associated with oncogenic changes rather than tumour suppressor genes, eg. the activating JAK2 V617F mutation in patients with myeloproliferative disorders (MPD) is often associated with acquired isodisomy for chromosome 9p. We have undertaken a screen for regions of acquired isodisomy as a means to identify genomic regions that may harbour novel oncogenes in patients with atypical MPD (n=30), blast crisis of chronic myeloid leukaemia (CML-BC; n=20) and chronic lymphocytic leukaemia (CLL; n=20). Genomewide SNP analysis was performed using Affymetrix 50K XbaI arrays and analysed for copy number changes and length of homozygous tracts. Chromosome deletions and gains identified by cytogenetic analysis were also detected by SNP analysis. Large tracts of homozygosity (defined as >20Mb running to a telomere), strongly suggesting acquired isodisomy, were seen 12 (40%) aMPD patients, a single case (5%) of CML-BC but were not seen in CLL. The homozygous tracts encompassed diverse genomic regions in aMPD, but two common regions (3 cases for each region) were identified at 7q and 11q. Because of the recurrent involvement of tyrosine kinases in MPDs, we focused our initial screen on this class of gene. The entire coding regions of EPHB6 and EPHA1 were sequenced in patients with 7q isodisomy but no sequence changes were identified. Similarly, no changes were found in selected regions of BRAF and PIK3CG. Ongoing sequence analysis is focused on other candidate genes within the two regions.

0412

JAK2V617F-NEGATIVE ET PATIENTS DO NOT DISPLAY CONSTITUTIVELY ACTIVE JAK/STAT SIGNALLING

S. H. Schwemmers,[1] H. Pahl,[1] B. Will1 C. F. Waller,[1] K. Abdulkarim,[2] P. L. Johansson,[2] B. Andreasson,[2] H. L. Pahl[1]

[1]University Hospital Freiburg, FREIBURG, Germany; [2]Sahlgrenska University Hospital, GÖTEBORG, Sweden

Background. Presence of the Jak2V617F mutation in only 40-60% of patients with Essential Thrombocythemia (ET) underscores the heterogeneity of this myeloproliferative disorder (MPD). Several distinct mutations, either in Jak2 (exon 12) or in c-Mpl (W515L) have been described in subsets of other Jak2V617F-negative MPDs, Polycythemia vera (PV) and Idiopathic Myelofibrosis (IMF). Analogous to Jak2V617F, these mutations cause constitutive Jak2 and STAT activation. It has therefore been proposed that constitutive activation of the Jak/STAT pathway underlies the molecular etiology of all MPDs. *Aims.* We investigated the alternative hypothesis that distinct alterations, separate from the Jak/STAT signal transduction pathway, underlie a subset of Jak2V617F-negative ET. We therefore compared gene expression profiles of ET patients with and without the Jak2V617F mutation. *Methods.* 32 patients with ET, diagnosed according to the PVSG criteria, were included in the study after giving informed consent. Jak2V617F allele expression was quantified in purified granulocytes by real time qRT-PCR. cDNA microarrays were processed according to the protocol of Eisen and Brown using the Lowess (Locally weighted scatter plot smoother) subgrid normalization method for comparison across slides. Statistical significance of differences was determined after correction for the false discovery rate by the method of Benjamini and Hochberg. Differences in gene expression were verified with qRT-PCR and protein phosphorylation detected by Western Blotting. *Results.* Unsupervised clustering of gene expression patterns in ET patients revealed two distinct subclasses of patients. These subclasses differed in presence or absence of the Jak2V617F mutation. Patients lacking the Jak2V617F mutation displayed significantly lower expression of the STAT target genes Pim-1 and SOCS2. In addition, Jak2V617F-negative patients showed lower levels of STAT phosphorylation. *Conclusions.* These data demonstrate that a large proportion of Jak2V617F-negative ET patients do not display constitutive Jak/STAT signaling. Hence, we propose that alterations in different signal transduction pathways can lead to the clinical phenotype of ET. Elucidation of novel ET-inducing changes will facilitate both a molecular classification of ET and the development of rationally designed therapies.

0413

MPL MUTATIONS IN PRIMITIVE MYELOFIBROSIS ARE NOT RESTRICTED TO MPL 515 MUTATIONS BUT ONLY MPL 515 MUTATIONS ARE ONCOGENIC EVENTS PRESENT AT THE STEM CELL LEVEL

S. Giraudier,[1] R. Chaligné,[2] C. James,[3] C. Tonetti,[4] J.P. Le Couédic,[2] R. Besancenot,[2] I. Godin,[2] L. Lordier,[2] K. Malloum,[5] P. Mossuz,[6] M.C. Le Bousse-Kerdilès,[7] W. Vainchenker,[2] S. Giraudier[1]

[1]INSERM, U790 and Hematology Laboratory H, VILLEJUIF AND CRÉTEIL; [2]INSERM, U790, VILLEJUIF; [3]INSERM, U217, BORDEAUX; [4]Faculté de Médecine Paris XII, CRÉTEIL; [5]AP-HP, Laboratoire d'hématologie, La pit, PARIS; [6]Laboratoire d'Hématologie, GRENOBLE; [7]INSERM, U602, VILLEJUIF, France

Background. The MPL 515 mutations have recently been described in 10% of primitive myelofibrosis (PMF) as an essential oncogenic event. Here we report other MPL mutations found in PMF patients. These new mutations raise the question whether these molecular events occur in a true stem cell (ie: lymphoid/myeloid progenitor cell), as it has already been shown for JAK2 V617F occurrence in PMF and PV. *Aims.* The aim of this work was to study the presence of MPL exon 10 mutations in a cohort of 100 PMF, determine the functions of the different mutations, and if these mutations occurred in both myeloid and lymphoid lineages in JAK2 V617F negative PMF. *Methods and Results.* We therefore sequenced MPL exon 10 in 100 PMF patients. Six different mutations were found. In order to determine whether these mutations were only genetic polymorphism or real gain of function mutations, we introduced all the mutations in Baf3 cells. We found that only the recently described MPL 515 mutations and a 506+519 mutant induced factor independence growth, activation of JAK/STAT, RAS/MAPK, and PI3K transduction pathways as well as P21 overexpression, a spontaneous cell cycling with an increase in S and G2M phases, and tumorigenesis in NUDE mice. Then we looked for the MPL 515 mutations in stem cells compartments: First in mature myeloid and lymphoid cells and second in lymphoid/myeloid progenitors progeny after $CD34^+$ and $CD34^+CD38^-$ cell isolation from peripheral blood. Three PMF patients harboring MPL515 mutations were studied. Peripheral blood granulocytes and platelets were purified by standard methods and B, T, NK cells and monocytes were isolated by combined immunomagnetic and flow cytometric procedures. The same techniques were used to sort CD34+ and $CD34^+CD38^-$ subpopulations from peripheral blood. Clonal B/NK/Myeloid differentiation from $CD34^+CD38^-$ cells and T cell differentiation from $CD34^+$ cells were performed respectively onto a MS5 layer in the presence of cytokines and in Fetal Thymic Organ Cultures (FTOC). Genotyping of mature cell populations, B/NK/Myeloid clones and $CD34^+$ derived T cells were performed by direct sequencing. Moreover, $CD34^+$ cells were cultured in a one cell per well experiment to determine the sensitivilty of these patient's cells to low dose TPO. The MPL515 mutations were present in granulocytes and platelets from all patients, and in monocytes in one. We detected the mutation in NK cells in two cases. The MPL 515L and MPL 515K mutations could be subsequently detected in $CD34^+$ cells and in B/NK/Myeloid and/or NK/myeloid $CD34^+CD38^-$ derived clones from all IMF patients. Interestingly, MPL 515L homozygous clones were detected in B/NK/Myeloid and/or NK/Myeloid clones from 1 patient. However, using the FTOC assay, the mutations were not detected in T cell fractions derived from $CD34^+$ cells. At least we found that MPL mutations induce a spontaneous megakaryocytic growth in cell culture but also a hypersensitivity to low dose TPO. *Summary.* These results demonstrate that the MPL 515 mutations occur in a lymphoid/myeloid progenitor cell and give rise to a hypersensitivity to TPO. Thus, these MPD take their origin in a true lymphoid/myeloid progenitor cell. In accordance with mouse model, this represent a good argument for a causative role of MPL mutations in PMF.

0414

COMPARATIVE ANALYSIS OF THE CONSTITUTIVE ACTIVE JAK2V617F, JAK2T875N AND MPLW515L ALLELES IN A MURINE BONE MARROW TRANSPLANT MODEL OF MYELOPROLIFERATIVE DISEASE

G. Wernig, T. Mercher, Y. Pikman, R.L. Levine, D.G. Gilliland

HMS, Brigham & Women's Hospital, BOSTON, USA

Present in the 95% of polycythemia vera (PV) patients and in 50-60% of patients with essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF), the JAK2V617F mutation, resulting in constitutive activation of the JAK/STAT pathway, is the most frequent genetic event in myeloproliferative disease (MPD). Little is know about additional mutations which contribute to JAK2V617F negative MPD. Very recently, two additional mutations were identified in JAK2V617F$^-$ patients: JAK2T857N, detected in the human AMKL cell line CHRF-288-11 and the somatic mutation in the thrombopoietin receptor, MPLW515L, detected in ~10% of patients with JAK2V617F$^-$ MF. JAK2V617F, JAK2T875N and MPLW515L were analysed in murine models of bone marrow transplantation and sufficiency for the development of MPD has been shown for each of them. Comparison of these three models provides insight into the JAK2-positive and JAK2$^-$ MPDs that may inform therapeutic strategies. Furthermore, developing murine models of disease for each of these alleles may provide novel insights into phenotypic variance among the MPDs. The JAK2V617F mouse model is characterized by a striking, longterm erythrocytosis, a strain dependent degree of leukocytosis and the development of bone marrow and splenic reticulin fibrosis. Despite the presence of megakaryocytic hyperplasia, there is impaired megakaryocytic polyploidization, and platelet counts are not augmented. JAK2T875N constitutively activates downstream effectors including STAT5 in hematopoietic cells *in vitro*. In a murine bone marrow transplantation model JAK2T875N, although the T875N substitution is localized in a different domain of the JAK2 kinase, results in a phenocopy of JAK2V617F disease, causing a MPD with features of AMKL including megakaryocytic hyperplasia in spleen, a polyploidization defect and increased reticulin fibrosis in bone marrow and spleen, with normal platelet and leukocyte counts. Similarly, the MPLW515L mutation also transformed hematopoietic cell lines to cytokine independent growth through activation of the JAK/STAT pathway. *in vivo* expression of MPLW515L, caused a rapidly fatal, fully penetrant MPD that was characterized by a marked leukocytosis, splenomegaly, bone marrow reticulin fibrosis with a strain specific disease latency. However, - in contrast to both JAK2 mutations - there was megakaryocyte hyperplasia with normal megakaryoctye ploidy and marked thrombocytosis in the 3-4 million/uL range that was accompanied by thrombotic complications. Our data demonstrate important phenotypic differences between JAK2V617F, JAK2T875N and MPLW515L induced MPDs. Most striking was the effect on the megakaryocyte lineage. JAK2V617F and JAK2T875N induced megakaryocytic hyperplasia with a block in megakaryocyte maturation and lack of thrombocytosis, whereas MPLW515L enhanced megakarypoiesis resulting in severe thrombocytosis. Furthermore, marked leukocytosis developed in MPLW515L but not in JAK2V617F and JAK2T875N expressing C57Bl/6 mice. These findings indicate that the three mutations have different impacts on proliferation and/or survival of various hematopoietic progenitors. Since all three mutations signal through the JAK/STAT pathway, these data suggest that the MPLW515L allele activates transcriptional programs not activated by JAK2 mutations that confer the ability for megakaryocytic development and thrombocytosis.

0415

EXPRESSION AND EFFECTS OF NUCLEAR FACTOR-ERYTHROID DERIVED 2 (NF-E2) IN MURINE AND HUMAN HEMATOPOIESIS

B. Will,[1] M. Mutschler,[2] C. Scholl,[3] U. Steidl,[4] E. Levantini,[4] C.S. Huettner,[5] D.G. Tenen,[4] H.L. Pahl[6]

[1]Harvard Medical School, BOSTON, USA; [2]University of Freiburg, FREIBURG, Germany; [3]Brigham and Women's Hospital, BOSTON, USA; [4]Harvard Institutes of Medicine, BOSTON, USA; [5]Medical College of Wisconsin, MILWAUKEE, USA; [6]University Hospital of Freiburg, FREIBURG, Germany

The basic region-leucine zipper transcription factor NF-E2 plays an important role in terminal erythroid and megakaryocytic maturation and regulates the differentiation of erythroblasts and megakaryocytes. NF-E2 knock out mice die at birth due to lack of platelets, but only display mild defects in the erythroid lineage. NF-E2 expression has been reported in murine cKit+/Sca-1+/Lin- (KSL) cells. However, its specific role in stem cells and early progenitors remains unclear. NF-E2 is overexpressed in patients with Polycythemia vera (PV). Several studies have demonstrated that the degree of NF-E2 overexpression in individual PV patients correlates with the proportion of Jak2V617F'positive granulocytes and the ability to form endogenous erythropoietin-independent colonies *in vitro*. Interestingly, the Jak2V617F activating mutation is present in uncommitted progenitor cells (Lin-/CD34$^+$/CD38$^-$/CD90$^+$) and results in enhanced erythroid differentiation capacity. However, the role of NF-E2 in stem and progenitor cells and its potential cooperation with Jak2V617F in PV is unclear. In an approach to clarify the function of NF-E2 in normal hematopoiesis and PV we investigated nf-e2 mRNA expression in human and murine hematopoietic cells at different developmental stages as well as the effects of NF-E2 overexpression in murine models. Nf-e2 expression was evaluated in FACS sorted human and murine stem and progenitor populations by qRT-PCR. A lentiviral construct (NF-E2-IRES-GFP) was used to transduce KSL and cKit+/Sca-1-/Lin- cells, which were subsequently assayed for colony formation in methylcellulose. A tetracycline-inducible mouse model (TET-OFF) was generated by introducing an nf-e2 transgene under control of the tetracycline responsive element and subsequent crossing to a CD34-promoter-tTA transgenic strain. Nf-e2 displayed a similar differentiation-specific expression pattern in murine and human hematopoiesis: nf-e2 mRNA was detected in LT-HSCs and ST-HSCs. During lineage commitment nf-e2 was downregulated in both CMPs and GMPs but was again upregulated in MEPs. In murine cells, highest nf-e2 expression levels were found in proerythroblasts followed by a consecutive decrease during maturation to orthochromatic erythroblasts. Enforced expression of NF-E2 following lentiviral transduction of murine KSL and cKit+/Sca-1-/Lin- progenitor cells caused markedly decreased BFU-E and CFU-E colony formation in the presence of erythropoietin. In the tetracycline-inducible mouse model NF-E2 overexpression in KSL and cKit+/Sca-1-/Lin- cells similarly led to impaired erythroid colony formation *in vitro*. Lentiviral NF-E2 overexpression did not appear to affect maturation of committed erythroid progenitor cells in *in vitro* differentiation assays of murine Ter119-spleen and fetal liver (E14.5) cells. In these assays, Jak2V617F likewise showed no effect. Our study shows that NF-E2 expression is regulated in a biphasic manner in both murine and human erythropoiesis. Forces expression of NF-E2 in various human and murine stem- and progenitor cells decreases erythroid colony cloning efficiency.

Gene therapy and immunotherapy

DUAL SYSTEM OF RNA TRANS-SPLICING ELEMENT AND SLEEPING BEAUTY TRANSPOSON CORRECTS DNA PROTEIN KINASE MUTATION IN SEVERE COMBINED IMMUNE DEFICIENCY

J. Tolar,[1] H. Zayed,[1] L. Xia,[1] A. Yerich,[1] S.R. Yant,[2] M.A. Kay,[2] M. Puttaraju,[3] S.G. Mansfield,[3] D. Wiest,[4] R.S. McIvor,[1] B.R. Blazar[1]

[1]University of Minnesota, MINNEAPOLIS, USA; [2]Stanford University School of Medicine, PALO ALTO; [3]Introni, Inc., GAITHERSBURG; [4]Fox Chase Cancer Center, PHILADELPHIA, USA

Background. Spliceosome-mediated RNA trans-splicing (SMaRT) can repair defective mRNA molecules by exon replacement between two individual RNA molecules: endogenous mutated mRNA and exogenous wild type mRNA. SMaRT technology, though, can only be effective long-term if the correcting sequence persists in target cells. While virus-mediated SMaRT delivery can be effective in achieving long-term correction, there are technical issues for production. In contrast, non-viral vectors are typically much more easily produced. Therefore, we tested whether the non-viral Sleeping Beauty (SB) transposon system could mediate stable delivery of trans-splicing molecules designed to correct the genetic defect responsible for severe combined immune-deficiency (SCID). This immunological disorder is caused by a point mutation within the 12.4 kb gene encoding the DNA protein kinase catalytic subunit (DNA-PKcs) and is associated with aberrant DNA repair, defective T- and B-cell production, and hypersensitivity to radiation-induced injury. Importantly, the currently available SB transposon plasmid vectors are not practical for delivering large genes, such as the DNA-PKcs gene mutated in severe combined immune deficiency (SCID). *Aims.* To use the SB transposon/SMaRT dual system to achieve integration and repair of the mutated mRNA endogenous transcripts in a T-cell line and in adult stem cells derived from SCID mice. *Methods.* To select the preferred trans-splicer for correction of the DNA-PKcs gene we designed six binding domains targeting a distinct region adjacent to DNA-PKcs mutation. The vector resulting in the highest radiation resistance was chosen for further studies. SB/SMaRT dual vector and transposase were nucleofected to a T-cell thymoma cell line (scid.adh) and SCID adult stem cells (ASC). ASC were derived from the bone marrow of SCID mice and induced to differentiate *in vitro* into neurons, hepatocytes and endothelium. Pyrosequencing (a quantitative sequencing method) and automated sequencing were used to determine the correction to wild type. *Results.* Gene transfer of the SB-based trans-splicing vector and radiation selection in scid.adh cells resulted in a 4.3-fold increase in number of surviving cells over irradiated untreated scid.adh cells (p=0.029). The degree of mutation correction in treated scid.adh cells was 79.1% as determined by pyrosequencing. For adult stem cells, in the presence of the SB/SMaRT dual vector and selection by radiation, 64.3% correction to wild type was achieved. Corrected DNA-PKcs protein was detected by Western blotting in radiation resistant scid.adh and ASC treated with SB/SMaRT dual vector and transposase. Multiple genomic integration sites of the SB/SMaRT dual vector were determined with splinkerette PCR in genomes of corrected SCID cells. *Summary.* Using this novel SB-based trans-splicing vector, we demonstrate stable mRNA correction, proper DNA-PKcs protein production, and conference of a radiation-resistant phenotype in a T-cell thymoma cell line (scid.adh) and SCID adult stem cells. These results suggest that SB-based trans-splicing vectors offer a potential alternative to viral gene therapy for treatment of genetic diseases, especially those involving large genes such as the DNA-PKcs mutation in SCID.

BRB and JT have contributed equally to this work.

RHAMM/CD168-R3 PEPTIDE VACCINATION OF PATIENTS WITH ACUTE MYELOID LEUKEMIA, MYELODYSPLASTIC SYNDROME, MULTIPLE MYELOMA AND CHRONIC LYMPHATIC LEUKEMIA ELICITS IMMUNOLOGICAL AND CLINICAL RESPONSES

J. Greiner,[1] A. Schmitt,[1] K. Giannopoulos,[1] J. Chen,[1] P. Liebisch,[1] M. Ringhoffer,[1] P. Guillaume,[2] G. Ritter,[2] M. Bommer,[1] M. Rojewski,[3] S. Gnjatic,[2] H. Döhner,[1] M. Schmitt[1]

[1]University of Ulm, ULM, Germany; [2]Ludwig Institute of Cancer Research, LAUSANNE, Switzerland; [3]Institute of Clinical Transfusion Med., ULM, Germany

We initiated a phase I/II R3 peptide vaccination to induce immunological and hematological responses for patients with AML, MDS, MM or CLL overexpressing the receptor for hyaluronic acid mediated motility (RHAMM/CD168). RHAMM/CD168 is expressed on tumor cells of most patients with AML, MDS, MM and CLL. We characterized RHAMM/CD168 as a leukemia-associated antigen (LAA) eliciting both humoral and cellular immune responses in patients with different hematological malignancies. CD8 positive T cells primed with the RHAMM/CD168-derived peptide R3 (ILSLELMKL) were able to lyse autologous tumor cells expressing this LAA. In this study, patients were included with positive RHAMM/CD168 expression but with a limited tumor load. At a biweekly interval, RHAMM R3 peptide (300 mcg for the first 12 patients and 1000 mcg for patients 13-24) emulsified with the incomplete Freund's adjuvant (day 3) and GM-CSF (100 mcg, days 1-5) was administrated four times subcutaneously. The primary aim of the study is safety and feasibility of this peptide vaccination, secondary aims the evaluation of a specific T cell immune response to RHAMM/CD168 R3 peptide and the assessment of the influence of the R3 peptide vaccination on the remission status. Since January 2005, 19 patients (3 AML, 8 MDS, 6 MM, 2 CLL) have been enrolled in the study. The first ten patients (2 AML, 4 MDS, 4 MM) have completed the course of four vaccinations and have been completely evaluated. Drug-related adverse events observed under R3-peptide vaccination were erythema and induration of the skin at the site of injection (CTC I°). In 5/10 patients, we detected an increase of CD8+ R3 tetramer+ CD45RA+CCR7-CD27-CD28- effector T cells in flow cytometry in accordance with R3-specific CD8+ T cells in ELISPOT analysis. In chromium release assays specific lysis of RHAMM-positive leukemic blasts were shown for AML patients responded to peptide vaccination. 3/6 patients with myeloid disorders (1/3 AML, 2/3 MDS) achieved clinical responses: one partial and one complete remission (1 PR, 1 CR), and one hematological improvement (1 HI). One patient with MDS did not need any longer erythrocyte transfusion after four vaccinations. Two MM patients responded as assessed by free light chains, two progressed (PD). Taken together, RHAMM/CD168 induced both immunological and clinical results and therefore constitutes a promising target antigen for immunotherapies in patients with hematological malignancies.

0418

FEASIBILITY STUDY OF RITUXIMAB FOLLOWED BY ANTI-IDIOTYPE IMMUNOTHERAPY WITH TUMOR-SPECIFIC IDIOTYPE-KLH (FAVID) AND GM-CSF IN INDOLENT B-CELL LYMPHOMAS

E. Zucca,[1] F. Cavalli,[1] F. Bertoni,[1] D. Rodriguez-Abreu,[1] V. Belisario Filho,[1] E. Ceresa,[1] B. Dossena,[1] L. Ponsanesi,[2] R.M. Diaz Borrell,[2] T. Terrot,[2] V. Esquibel,[3] J. Gutheil,[3] D. Johnson[3]

[1]Oncology Inst. of Southern Swtizerland, BELLINZONA, Switzerland; [2]Oncology Inst. of Southern Switzerland, BELLINZONA, Switzerland; [3]Favrille, Inc, SAN DIEGO, CA 92121, USA

Background. Anti-idiotype immunotherapy appears a promising strategy for lymphoma treatment. *Aims.* A pilot study was started at the Oncology Institute of Southern Switzerland (IOSI) with the primary objective of testing the feasibility of a idiotype-KLH vaccine (FavId®) therapeutic program in Switzerland with a patient-specific vaccine produced in the USA. *Methods.* Patients with B-cell lymphoma of the following subtypes were eligible: small lymphocytic lymphoma (CLL/SLL), lymphoplasmacytic lymphoma (LPL), follicular lymphoma (FL), marginal zone lymphoma (MZL) either nodal, splenic or extranodal (MALT type), and mantle cell lymphoma (MCL). A recent tumor biopsy from lymph nodes (LN), bone marrow (BM) or other tissues suitable for preparation of FavId® was required. Eleven patients have thus far been enrolled, 10 with pretreated disease,1 (with FL) treatment naïve. All the enrolled patients received 4 weekly Rituximab infusions (375 mg/m^2) followed approximately 8 weeks later by 6 monthly subcutaneous treatments with FavId® (1 mg on day 1) and GM-CSF (250 mcg on days 1-4). Patients with lack of disease progression following 6 doses were allowed to continue to receive additional cycles of FavId® and GM-CSF every 2 months for 6 doses and then every 3 months until disease progression. A tumor cell suspension, prepared within 2 hours after the biopsy in the IOSI laboratory in Bellinzona, was frozen and shipped by courier to the Favrille laboratories in San Diego according to CDC guidelines for shipment of biohazardous body fluids and tissues. *Results.* In all the cases viable tumor cells suitable for proper vaccine manufacturing arrived in San Diego and the patient-specific FavId® was successfully prepared and sent back to Switzerland under controlled temperature in suitable condition to be administered to the patients. Vaccine therapy has been thus far given to 9 patients. The main side effect was a transient mild erythema (grade 1-2), sometimes with itching, in the site of FavId® injection, which was observed in nearly all cycles and usually disappeared within 3-4 days. In two patients only the erythema was more severe and was

successfully managed with GM-CSF discontinuation. The table summarises the preliminary results (a final sample size of 15 patients is planned). *Conclusions.* Our experience suggests that a large scale trial of anti-idiotype vaccine (Id-KLH active immunotherapy) may be conducted in Europe with the vaccine manufacturing taking place in the USA. Clinical efficacy was not the main endpoint of the study, however, our preliminary findings indicate a possible activity in disseminated MZL, which might merit further evaluation

Table 1. Summary of preliminary results.

#	NHL type	Biopsy Site	Successful Favid® production	Response after Rituximab	Vaccine Therapy	Outcome (from start of Favid®)
02	FL	LN	yes	complete response (CR)	completed (6 cycles)	PD at 9 months

ACUTE MYELOID LEUKEMIA (AML)-REACTIVE CYTOTOXIC T LYMPHOCYTE CLONES RAPIDLY EXPANDED FROM CD8+ CD62L(HIGH)+ T CELLS OF HEALTHY DONORS PREVENT AML ENGRAFTMENT IN NOD/SCID IL2R GAMMA NULL MICE

E. Distler, C. Woelfel, S. Koehler, M. Nonn, N. Kaus, E. Schnuerer, R.G. Meyer, T.C. Wehler, C. Huber, T. Woelfel, U.F. Hartwig, W. Herr

Johannes Gutenberg-University Mainz, MAINZ, Germany

Donor-derived $CD8^+$ cytotoxic T lymphocytes (CTLs) eliminating host leukemic cells mediate curative graft-versus-leukemia (GVL) reactions after allogeneic hematopoietic stem cell transplantation (HSCT). The leukemia-reactive CTLs recognize hematopoiesis-restricted minor histocompatibility and leukemia-associated peptide antigens that are presented by HLA class I molecules on recipient cells. Current *in vitro* techniques for generating AML-reactive CTLs from unprimed healthy donors are of relatively low efficiency and yield responder populations with unknown biological significance. We established a new allogeneic mixed lymphocyte-leukemia culture (MLLC) approach by stimulating donor $CD8^+$ T cells at comparably low numbers (i.e. 10^4/well) with HLA class I-matched primary AML blasts in 96-well microtiter plates. Using this so-called mini-MLLC strategy, we aimed at creating multiple different responder-stimulator compositions in order to provide for the growth of leukemia-reactive CTL optimized culture conditions by chance. Before culture, $CD8^+$ T cells were immunomagnetically separated into $CD62L^{high}$+ and $CD62L^{low}$+/neg subsets enriched for naïve/central memory and effector memory cells, respectively. The culture medium was supplemented with interleukin (IL)-7, IL-12, and IL-15. On day 14, IL-12 was replaced by IL-2. In 8 different related and unrelated donor/AML pairs with complete HLA class I match, numerous CTL populations were isolated that specifically lysed myeloid leukemias in association with various HLA-A, -B, or -C alleles. These CTLs recognized neither lymphoblastoid B cell lines of donor and patient origin nor primary B cell leukemias expressing the corresponding HLA restriction element. CTLs expressed T cell receptors of single V-β chain families, indicating their clonality. The vast majority of CTL clones were obtained from mini-MLLCs initiated with $CD62L^{high}$+ cells. Using antigen-specific stimulation, multiple CTL populations were amplified to 10^8-10^{10} cells within 6-8 weeks. We also investigated the capability of mini-MLLC derived AML-reactive CTL clones to inhibit the engraftment of human primary AML blasts in immunodeficient nonobese diabetic/severe combined immune deficient IL-2R common γ-chain deficient (NOD/SCID IL2R gamma null) mice. The leukemic engraftment was specifically prevented if inoculated AML blasts had been preincubated *in vitro* with AML-reactive CTLs, but not with anti-melanoma control CTLs. Taken together, our results provide the first evidence that CD8+ CTL clones raised from healthy donors against AML blasts using primary *in vitro* stimulation might carry biologically significant anti-leukemic activity. The efficient *in vitro* generation and expansion of AML-reactive CTL clones from $CD8+CD62L^{high}$+ precursors of healthy donors by the mini-MLLC approach allows several potential applications. First, CTLs can be used within T cell-driven antigen identification strategies to extend the panel of molecularly defined AML antigens that are recognizable by T cells of healthy donors. Second, because these CTLs can be readily isolated from the stem cell donor by mini-MLLC prior to transplantation, they could be infused into AML patients as a part of the stem-cell allograft, or early after transplantation when the leukemia burden is low. Our current work focuses on the identification of CTL-defined AML peptide epitopes using cDNA expression cloning, and on the translation of the mini-MLLC approach into a protocol that is compatible with good manufacturing practice guidelines.

A COMPARATIVE ANALYSIS OF THE LEUKAEMIC POTENTIAL OF MATURE T CELLS VERSUS HEMATOPOIETIC STEM CELLS

S.N. Newrzela,[1] Z. Li,2 C. Baum,[2] M. Hartmann,[1] S. Hartmann,[3] M.-L. Hansmann,[3] K. Cornils,[4] B. Fehse,4 M.D. Von Laer[1]

[1]Georg-Speyer-Haus, FRANKFURT AM MAIN; [2]Hannover Medical School, HANNOVER; [3]University of Frankfurt, FRANKFURT AM MAIN; [4]University Medical Center Hamburg, HAMBURG, Germany

Background. After the report of two cases of leukaemia caused by insertional mutagenesis of a retroviral vector in children with SCID, it became clear that safety issues of therapeutic gene transfer must be addressed more thoroughly. *Aims.* We wanted to analyse whether gene transfer into mature T cells and haematopoietic stem cells bear the same risk of generating T cell leukaemia through activation of specific T cell oncogenes, such as LMO2, TCL1 and TrkA. *Methods.* To address this issue, we used the Rag-1 mouse model, which allows long term analysis of transplanted T cells and haematopoietic stem cells. We transduced mature T cells and haematopoietic stem cells of C57BL/6 (Ly5.1) donor mice with oncoretroviral vectors expressing LMO2, TCL1 and TrkA. *Results.* Transduction efficacies of up to 70% were achieved for mature T cells and approximately 90% for haematopoietic stem cells. After transplantation into Rag-1-deficient recipients, stem cell transplanted animals developed T cell lymphomas/leukemia for all investigated oncogenes after characteristic incubation times, mostly of a $CD8^+CD4^+$ double positive phenotype. T cell lymphomas were characterised by gross thymic mass, splenomegaly and heavily enlarged lymph nodes, although none of the control- vector- transduced mice developed lymphoma/leukaemia. LM PCR analysis revealed mono- or oligoclonality of the tumours. T cell transplanted animals showed no signs of leukaemia development so far. *Summary and conclusions.* Our results so far indicate that mature T cells are less susceptible to transformation by known T cell proto- oncogenes, but the studies are still ongoing.

Stem cell transplantation II

0421

GRAFT-VERSUS-LEUKEMIA INDUCED BY GRAFT-VERSUS-HOST DISEASE EARLY AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION IN CHILDREN WITH DETECTABLE LEVELS OF RESIDUAL ACUTE LYMPHOBLASTIC LEUKEMIA PRIOR TO TRANSPLANTATION

M. Bierings,[1] A. Lankester,[2] V.J.V. van der Velden,[3] E. van Wering,[4] T. Revesz,[1] A. Wijkhuis,[3] J.J.M. van Dongen,[3] M. Van Tol,[2] M. Egeler,[2] M.W. Schilham[2]

[1]Wilhelmina Children's Hospital, UTRECHT; [2]Leiden University Hospital, LEIDEN; [3]Erasmus University, ROTTERDAM; [4]Dutch Childhood Oncology Group, THE HAGUE, Netherlands

Children with high risk acute lymphoblastic leukemia who receive an allogeneic stem cell transplantation (SCT) nevertheless have a high chance of relapse (40%). It has been reported that the presence of minimal residual disease (MRD) detected by sensitive molecular techniques immediately prior to SCT predicts a very high probability of relapse (80%). This criterion was used to select patients for an intervention study. In patients with MRD levels > 1×10^{-4} in their bone marrow pretransplantation, we have attempted to induce a graft-versus-leukemia effect by early tapering of cyclosporin A (CsA, 4-5 weeks post-SCT) followed, if needed, by infusion of incremental doses of donor lymphocytes (DLI). Dosage varied between 1×10^{5} and 4×10^{6} $CD3^{+}$ cells/kg depending on transplantation characteristics. When GVHD grade II occurred, therapy was initiated to suppress GVHD. Patients with low (<1×10^{-4}) or undetectable levels of MRD were not eligible for intervention. As of October 2006, 42 patients were transplanted and included in the protocol with a median follow-up of 11 (1-65) months. In 13/42 patients MRD levels were > 1×10^{-4}. In 11 of these patients CsA was tapered 4-5 weeks after SCT. Four patients developed GVHD, grade II after tapering of CsA, which was controlled by treatment. Two relapsed, the other two are still in remission. The remaining 7 MRD-positive patients received DLI, and did not develop GVHD. Of those 7 patients, 5 had a relapse and 2 are in remission as of to date. Of the 7 relapses 4 were extramedullary. Of the remaining 29 patients in whom MRD was either below the cut-off level of 1×10^{-4}, positive but not quantifiable, or undetectable, 9 relapsed (31%) with GVHD greater than grade I, in 2 patients. As no transplant related mortality was seen, due to induction of GVHD, these data indicate that early reduction of immunosuppression and low dosis DLI can safely be performed following SCT. The timing of (mostly) extramedullary relapses in the MRD high group suggests an antileukemic effect of the intervention.

A PROSPECTIVE RANDOMIZED TRIAL OF TWO DOSE-INTENSIVE MELPHALAN REGIMENS (100 VS 200 MG/MQ) IN NEWLY DIAGNOSED MYELOMA PATIENTS

A. Palumbo,[1] S. Bringhen,[1] M.T. Petrucci,[2] A. Falcone,[3] A.M. Liberati,[4] M. Grasso,[5] F. Pisani,[6] C. Cangialosi,[7] T. Caravita,[8] F. D'Agostino,[1] F. Cavallo,[1] P. Omedè,[1] P. Musto,[9] R. Foà,[2] M. Boccadoro[1]

[1]Az. Osp. S. Giovanni Battista, TORINO; [2]Università La Sapienza, ROMA; [3]IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO (FG); [4]Policlinico Monteluce, PERUGIA; [5]Az. Osp. S. Croce e Carle, CUNEO; [6]Istituto Regina Elena, ROMA; [7]Az. Osp. Cervello, PALERMO; [8]Università Tor Vergata, ROMA; [9]Centro Riferimento Oncologico Basilicata, RIONERO IN VULTURE (PZ), Italy

Background. Several trials have shown the superiority of high-dose melphalan (usually 200 mg/m^2, MEL200) versus standard therapy in myeloma patients. Intermediate-dose melphalan (100 mg/m^2, MEL100) is also superior to the standard dose, but has not been clinically compared with MEL200 in a randomized study. In this prospective, randomized, phase III trial, we compared MEL200 with MEL100. *Aims*. The primary end points were complete remission (CR) rate, event-free survival (EFS) and incidence of gastrointestinal toxicity, infections and early deaths. *Methods*. Between January 2002 and July 2006, 298 patients were enrolled. Inclusion criteria were previously untreated myeloma, age < 65 and Durie and Salmon stage II or III. Exclusion criteria were prior treatment for myeloma, abnormal cardiac function (systolic ejection fraction <50%), respiratory disease (vital capacity or carbon monoxide diffusion <50% of normal), abnormal liver function (serum aminotransferase value >2.5 of normal), abnormal renal function (serum creatinine > 3 mg/dL), HBV, HCV, or HIV positivity, concomitant cancer or psychiatric disease. The institutional review board approved the protocol and written informed consent was obtained from all patients. All patients received: 2 DAV debulking courses (dexamethasone-doxorubicin-vincristine), 2 cycles of cyclophosphamide (4 mg/m^2) plus G-CSF followed by stem cell harvest. The MEL200 group was conditioned with 2 cycles of melphalan 200 mg/m^2. The MEL100 group was conditioned with 2 courses of melphalan 100 mg/m^2. All MEL courses were followed by stem cell infusion. *Results.* Two-hundred and forty-six patients (median age 57) were evaluable: 124 in the MEL200 arm and 122 in the MEL100. Patient characteristics were similar in both groups. In intention-to-treat analysis, the very good partial response rate was higher in MEL200 arm (38% versus 22%, p=0.011), but CR was 17% in the MEL200 group and 10% in the MEL100 group (p=0.2). The median follow-up for censored patients was 26.5 months. The 3-years EFS was 48% in the MEL200 and 31% in the MEL100 arm (p=0.31). The 3-years overall survival was 86% in the MEL200 and 71% in the MEL100 group (p=0.51). Forty-six patients did not complete tandem MEL200; 36 did not complete tandem MEL100. Severe hematologic toxicity was comparable in two arms, but 84% of MEL200 patients received more than 4×10^{6} $CD34^{+}$/Kg compared with 52% of MEL100 (p=0.0001). Grade 3-4 non-hematologic adverse events were more frequent in the MEL200 (52% versus 34%, p=0.01 in the 1st cycle and 39% versus 31%, p=0.9 in the 2nd cycle). The incidence of severe gastrointestinal toxicity was 51% after MEL200 and 21% after MEL100 (p<0.001). The incidence of grade 3-4 infections was similar in both group (54% in the MEL200 versus 45% in the MEL100 patients, p=0.25). Early deaths were 6% in the MEL200 and 4% in the MEL100 arm (p=0.9). *Conclusions.* MEL200 resulted in a significantly higher very good partial response rate but this did not translate in a superior EFS and overall survival.

0423

A RAPID CLEARANCE OF MINIMAL RESIDUAL DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION PREDICTS THE CLINICAL OUTCOME OF HIGH RISK ADULT ALL PATIENTS

O. Spinelli,[1] B. Peruta,[1] M. Tosi,[1] V. Guerini,[1] A. Salvi,[1] M.C. Zanotti,[1] E. Oldani,[1] A. Grassi,[1] T. Intermesoli,[1] C. Micò,[1] G. Rossi,[2] P. Fabris,[3] G. Lambertenghi-Deliliers,[4] E. Angelucci,[5] T. Barbui,[1] R. Bassan,[1] A. Rambaldi[1]

[1]Ospedali Riuniti, BERGAMO; [2]Spedali Civili, BRESCIA; [3]Ospedale San Maurizio, BOLZANO; [4]Fondazione IRCCS Ospedale Maggiore, MILANO; [5]Ospedale A. Businco, CAGLIARI, Italy

Background. Allogeneic stem cell transplantation represents a curative option for patients with acute lymphoblastic leukemia (ALL) with high-risk features at diagnosis. However, the percentage of relapse after transplant is still high (30-40%). The molecular analysis of Minimal Residual Disease (MRD) may provide informative results as to the risk of recurrence in patients with acute lymphoblastic leukemia. *Aims*. Objective of this study is to correlate the kinetics of MRD clearance after allogeneic transplantation with the clinical outcome. *Methods.* Patients were diagnosed and treated in the context of multicenter Northern Italian Leukemia Group (NILG) protocol for adult ALL 09-00 (ClinicalTrials.gov Identifier: NCT00358072). MRD was evaluated by Real Time Quantitative Polymerase Chain Reaction (RQ-PCR) using probes derived from fusion chimeric genes (BCR/ABL and MLL/AF4) or rearrangements of the T-cell receptor or the Immunoglobulin genes. Patients were eligible to allogeneic transplantation in first CR only if they had adverse cytogenetic abnormalities including t(9;22) or t(4;11) or persistent MRD during consolidation chemotherapy. *Results.* Diagnostic samples from 43 ALL patients were analyzed to identify a molecular probe suitable for MRD evaluation. Twenty patients with B precursor ALL were positive for the BCR/ABL chimeric transcripts and two for MLL/AF4 transcript. The remaining patients (6 T-ALL and 15 B precursor ALL) were studied for the presence of clonal Ig or TCR gene rearrangements. The sensitivity of the probes by which patients were actually monitored during the follow-up was ranging from 10-3 (7% of cases) to 10-5 (70% of cases). At day +30 after transplant, a median 3-log reduction of leukemic cells was documented so that 71% of patients converted to a molecularly negative status. At day +100 evidence of leukemia persistence/progression was documented in 44% of patients. As expected, a ten times higher median MRD value at conditioning was documented in the BM of most patients who failed to achieve the molecular remission by day +30 or +100. With a median follow-up of 23 months (range 4-138), the OS at 36 months of these patients was 48% (95% CI 31-63). The OS of patient who underwent transplant in hematological remission was 80% for those who proved PCR negative before transplant as compared to

49% for PCR positive patients (95% CI, 20-67), (p=0.17). For the same patients, the cumulative incidence of relapse was 0% for PCR negative patients and 46% in MRD positive patients (p=0.027). Moreover, the relapse rate of patients with PCR negativity at day +100 after transplantation was remarkably low (7%) as compared to patients who proved PCR positive (80%, p=0.0006). By multivariate analysis, only the molecular CR before conditioning proved to be a significant predictor for the achievement of a molecular negativity at day 100 after transplantation. *Conclusions*. These observations may help in identifying patients at high risk of leukemia relapse after allogeneic stem cell transplantation. More importantly, our results strongly suggest that patients not achieving an early molecular remission after transplantation require timely and appropriate preemptive treatments such as immunosuppression modulation, infusions of donor lymphocytes or new experimental drugs.

0424

DIRECT INTRA BONE TRANSPLANT OF UNRELATED CORD BLOOD CELLS IS ASSOCIATED WITH FAST AND COMPLETE HEMATOLOGIC RECOVERY

F. Frassoni,[1] A. Ibatici,[1] A.M. Raiola,[1] F. Gualandi,[2] N. Sessarego,[1] A. Parodi,[1] S. Pozzi,[1] M. Gobbi,[3] M. Corselli,[1] M. Podestà,[1] G. Piaggio,[2] A. Bacigalupo,[2] F. Frassoni[1]

[1]Centro Cellule Staminali, GENOA; [2]Ematologia e Trapianto AO S Martino, GENOVA; 3Clinica Ematologica, GENOVA, Italy

Background. Cord blood transplants (CBT) are associated with delayed or failed engraftment in a significant proportion of patients. Two previous our observations suggested (i) that, in the animal model, direct intrabone (i.b.) injection of hematopoietic cells improves seeding efficiency and (ii) that the delayed engraftment was not related to an insufficient number of hematopoietic stem cells but rather to a reluctance to differentiation and maturation. *Methods.* Unrelated CB (4/6 or 5/6 HLA antigen matched) were selected for 19 consecutive patients. Median cell dose was 2.6×10^7/kg (range 1.6-3.5). CB cells were concentrated in a total volume of 20 mL and infused in the supero-posterior iliac crest (SPIC) under rapid general anesthesia (10 minutes with propofol). Patients median age was 40 years (18-60), 15 had acute leukemia, 2 chronic myeloid leukemia, 2 Hodgkin disease. Fifteen patients had refractory or advanced disease, whereas 4 had high risk first remission leukemia. Most patients (n=15) were prepared with conventional CY-TBI. *Results.* The infusion of cells i.b. in supero-posterior iliac rest (SPIC), in the operating room, under short general anaesthesia, was uneventful. All patients engrafted. Cumulative incidence of neutrophil and platelet engraftment was 100% at 50 days. Median for neutrophil engraftment ($>0.5\times10^9$/L) was day 23 (14-40), whereas for platelets ($>20\times10^9$/L) it was day 38 (range 22-47). Three patients are not evaluable because died within day 10 from transplant. Two patients relapsed and two died of infection and multiorgan failure. Twelve patients are alive and well in hematologic remission at a median follow up of 6 months (range 2-11). 100% donor chimerism was documented since 30 days onward after transplant, including those in which CB cells were injected monolaterally in one SPIC. From day +60, CFC and LTC-IC had already reached the lower values of the range of normal individuals in bilateral sites. This is particularly relevant considering that hemopoietic progenitor reconstitution remains deficient years after allo-transplant. Thus, direct injection of CB cells in the bone marrow spaces, produces *in situ* proliferation and maturation, rapid recovery of peripheral blood counts, and early recirculation of stem cells to other un-injected bone marrow sites. Acute GvHD grade II was seen in 1/20 patient (5%). Since lymphocyte trafficking is known to be an essential part of immune response, two combined factors might contribute: (i) injected T cells come immediately in direct contact with mesenchymal stem cells (MSC) and osteoblasts which are known to be potent immunomodulators; (ii) the T cells present in the graft do not reach primarily in the lymphatic organs, where they would be immediately confronted with host antigen presenting cells, as it probably occurs after intra-venous injection. *Conclusions.* This study shows that CB cells injected directly into the iliac crests are associated with fast and complete hematologic recovery and almost absent acute GvHD. The direct intra-bone transplant of CB cells could now be offered to many more adult patients. This may change our policy of hemopoietic cell transplants.

0425

THE ROLE FOR AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN THE TREATMENT OF WALDENSTRMS MACROGLOBULINAEMIA PATIENTS. ANALYSIS OF 201 CASES FROM THE EUROPEAN BONE MARROW TRANSPLANT REGISTRY (EBMT)

C. Kyriakou,[1] C. Kyriakou,[1] C. Canals,[2] G. Taghipour,[2] C. Gisselbrecht,[2] P. Mazza,2 M. Kazmi,[2] E. Montserrat,2 N. Milpied,[2] D. Niederwieser,[2] K. Indrak,[2] A. Neubauer,[2] A. Kolbe,[2] P. Biron,[2] J. Bay,[2] A. Levis,[2] A. Sureda,[2] N. Schmitz[2]

[1]University College London, LONDON; [2]Lymphoma WP of the EBMT, LONDON, United Kingdom

Background. Waldenström's Macroglobulinaemia (WM) is a relatively rare lymphoma, which primarily affects elderly patients. Standard doses of alkylating agents, purine analogues and anti-CD20 monoclonal antibody produce response rates of up to 60%. Nevertheless, complete responses are infrequent and there is no cure. Due to the indolent nature of the disease and the fact that patients are old and present with comorbidities, the evaluation of the role of high-dose therapy with autologous transplantation (ASCT) has been infrequent in the past. *Aims.* Herein we report a retrospective multicenter analysis of 201 WM patients (132 male, 69 female), who an ASCT between 1992 and 2005 were reported to the database of the Lymphoma WP of the EBMT. *Patient and Methods.* Median age at transplantation was 53 years (22-73), the median time from diagnosis to transplant was of 18 months (3-239) and the patients had received a median number of 2 (1-10) lines of therapy before ASCT. Forty patients (20%) were in CR1, 24 (12%) in CR2, 83 (41%) in PR1, 27 (13%) in PR2, 21(10%) with primary refractory at the time of transplantation. Conditioning regimens used were BEAM in 44% of the cases, the combination of cyclophosphamide or melphalan/TBI in 28% of the cases, high dose melphalan in 4% and other protocols in the remaining 14% of the cases. Peripheral blood was used as the source of stem cells in 188 patients, bone marrow in 10 patients and the combination of both in 3 patients. *Results.* All patients but 3 had a successful engraftment. With a median follow-up of 26 months (5-163), 112 (56%) patients are alive and free of disease and 73 (36%) patients have relapsed after a median of 14 months (1-110) post ASCT. Fifty-two patients have died, 36 (18%) from disease progression and 16 (8%) from regimen toxicity. Non- relapse mortality was 6% at 1 year. The actuarial overall survival was 86% at 1 year, 75% at 3 years and 61% at 5 years. The probability of relapse was 20% at 1 year, 38% at 3 years and 55% at 5 years and the estimated progression free survival of 74%, 54% and 33% at 1, 3 and 5 years, respectively. *Conclusions.* In conclusion, this study shows that ASCT is a safe procedure and is able to rescue a significant proportion of heavily pre-treated patients with WM.

Myelodysplastic syndromes

0426

CYTOGENETIC HYBRIDIZATION BY ARRAY COMPARATIVE GENOMIC HYBRIDIZATION AND FLUORESCENCE *IN SITU* HIBRIDIZATION OF MESENCHYMAL STEM CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROMES

O. López Villar,[1] F. Martín Sánchez-Guijo,[1] J.L. García,[2] E. Villarón,[1] N. López-Holgado,[1] J.A. Pérez Simón,[1] J. San Miguel,[1] M.C. Cañizo[1]

[1]Hospital Universitario de Salamanca, SALAMANCA; [2]Centro de Investigación del Cancer, SALAMANCA, Spain

Background. Myelodysplastic syndromes (MDS) are a group of clonal disorders of hematopoietic stem cell (HSC). The hematopoietic microenvironment plays a role in the physiology of the hematopoietic system, and mesenchymal stem cells (MSC) are a key component of this microenviroment. Recently, some data has been published showing that these MSC could be involved in the MDS pathophysiology. Moreover, the presence of cytogenetic aberrations on these cells is controversial. The studies performed, so far, have used conventional cytogenetics and fluorescent *in situ* hybridization (FISH). *Aims*. To characterize bone marrow derived MSC from patients with MDS, by two approaches: array comparative genomic hybridization (array-CGH), and FISH, in order to know genomic changes in these cells and whether they could show clonal cytogenetic alterations. *Methods.* 13 patients with untreated MDS were included in the study. The median age was 72 years (range: 54-89) The male/female ratio was 7/6. Diagnosis of MDS was established according to the WHO classification as follows: 5q- syndrome (n=7), refractory anemia (RA) (n=2), refractory anemia with ringed sideroblasts (RARS) (n=1) and refractory anemia with excess blasts type II (RAEB-II) (n=3). Standard cytogenetic and FISH studies on hematopoietic cells were performed at diagnosis according to standard methods with the following *Results.* 5q- (n=7), 8 trisomy (n=2) and normal cytogenetics (n=4). MSC were obtained by plating mononuclear cells from BM and cultured in a DMEM + 10% fetal calf serum medium, and expanded following standard procedures, until the third passage, when adherent MSC were harvested to perform cytogenetic and phenotypical studies. Array-CGH was performed in 11 cases and FISH studies in 5 (3 cases had both techniques). To perform Array-CGH a total of 3500 genomic targets were compounded from RP-11 libraries. The PCR products after purification were arrayed onto glass slides using a BioRobot. DNA was labelled, denaturalised and hybridizated. Images were analysed by using GenePix Pro 4.0 software. *Results.* MSC showed characteristic phenotypical data and their purity was 91%. In all cases analysed MSC showed DNA genomic changes. The most frequent aberrations were 1q24q32 region gains, in 72% of the cases, and 1p13 and 11q12 losses in 55% of patients. When the cells from patients carrying the 5q- alteration were analysed we observed that in half of them 5q losses were present in MSC. FISH analysis was carried out in MSC from 3 patients with 5q- and 2 patients diagnosed of RARS and RAEB-II, who had trisomy 8, and the same changes were present in 11% of MSC. *Conclusions.* We conclude that 100% of MSC from MDS show chromosomal aberrations when CGH arrays are used for this analysis. Even clonal specific MDS alterations are also shown when both, FISH and array-CGH analysis are performed. This is the first study that has showed the gains and losses in DNA of MSC from MDS by Array-CGH. MSC aberrations were also confirmed by FISH.

0427

HAS TREATMENT WITH EPO+/- G-CSF AN IMPACT ON PROGRESSION TO AML AND SURVIVAL IN LOW/INT-1-RISK MDS? A COMPARISON BETWEEN FRENCH-EPO PATIENTS AND THE IMRAW DATABASE

S. Park,[1] S. Grabar,[1] C. Kelaidi,[2] O. Beyne-Rauzy,[3] F. Picard,[1] D. Vassilieff,[1] V. Coiteux,4 G. Leroux,[4] P. Leppeley,[4] H. Dombret,[4] M.T. Daniel,[4] S. Cheze,[4] B. Mahe,[4] L. Ades,[2] A. Ferrant,[4] C. Ravoet,[4] N. Vey,[4] M. Escoffre-Barbe,[4] L. Aljassem,[4] K. Bourgeois,[5] P. Greenberg,[6] P. Fenaux,[2] F. Dreyfus[1]

[1]Cochin Hospital, PARIS, France; [2]Hôpital Avicenne, BOBIGNY, France; [3]Hôpital de Purpan, TOULOUSE, France; [4]GFM, PARIS, France; [5]University of Rochester Medical Center, NEW YORK, USA; [6]Stanford University Cancer Center, STANFORD, USA

Backround. We recently reported the results of treatment with EPO ±G-CSF in 419 patients (Park, ASH 2006, n°522) treated between 1998 and 2005 in France. *Aims.* Here we compared the outcome (progression to AML and survival) of these French patients (French-EPO) to MDS patients who received only supportive care (IPSS/IMRAW database). *Methods.* We restricted the analysis to patients with low and int-1 IPSS and also excluded CMML, RAEB-t, unclassifiable MDS, poor- risk karyotype, and 3q26 deletion, that are classically not the best candidates for EPO treatment. Progression to death and progression to AML since MDS diagnosis were compared using Kaplan-Meier estimates and Log-rank test. Multivariate cox analyses were adjusted for the main known prognostic factors (age at diagnosis, sex,% of marrow blasts, FAB diagnosis, IPSS score and karyotype). EPO introduction was modeled as a time-dependent covariate (dependent on the delay between MDS diagnosis and EPO introduction). *Results.* In the French-EPO (F), 284 pts, and in the IMRAW database (I), 447 pts were finally compared. Median follow-up was 26 months (IQR 13-53) and 33 months (IQR 15-61) in French-EPO and IMRAW, respectively. Both cohorts were different for: age (median 71 vs 68 y, p=0.0013),% of blasts (median, 3% [IQR 2-5] vs 2% [IQR 1-4], p=0.0006), FAB diagnosis [RA= 39% vs 56%, RAEB= 22% vs 17%, and RARS=38% vs 26%, (p<0.0001)], and karyotype [favorable=90% vs 84%, intermediate= 10% vs 16%, (p=0.02)] for F and I, respectively. At 5 years, 8% pts in the F cohort vs 16% in the I cohort progressed to AML (p=0.0002). In multivariate regression analysis, EPO treatment (HR=0.2, CI 95% [0.1-0.3]) was independently associated with a lower progression to AML. Other factors significantly associated with a lower progression to AML were: feminine sex (HR=0.6, CI 95% [0.5-0.8]), RARS vs RAEB (HR=0.6, CI 95% [0.5-0.9]), and favorable karyotype (HR=0.6, [CI 95% 0.4-0.8]). Overall survival (OS) from diagnosis of MDS was also higher in the French-EPO with a 5-year OS of 82% vs 47% for F and I, respectively (p<0.0001). In multivariate analysis, the same factors were found independently associated with survival as for AML progression. EPO treatment (HR=0.26, [CI 95% 0.18-0.38)]) was also independently associated with a better survival. *Conclusions.* These results suggest that EPO treatment was associated with reduction of the risk of progression to AML and improvement of survival in MDS patients. Reasons underlying this improvement are being examined. Confirmation of these results by other studies and with prospective patient series and clinical trials are required.

0428

TREATMENT OF HIGH RISK MDS AND AML POST-MDS WITH AZACYTIDINE (AZA): CURRENT RESULTS OF THE FRENCH ATU PROGRAM

M. Sebert,[1] E. Hernandez,[1] F. Chermat,[1] D. Bordessoule,[2] M.P. Chaury,[2] C. Dartigeas,[3] S. De Botton,[4] F. Dreyfus,[5] L. Legros,[6] L. Mannone,[6] A. Marfaing-Koka,[7] M.P. Noel,[8] S. Park,[5] T. Prebet,[9] A. Stamatoullas,[10] N. Vey,[9] P. Fenaux,[1] C. Fabre[4]

[1]Hôpital Avicenne, BOBIGNY; [2]CHU Dupuytren, LIMOGES; [3]CHU Bretonneau, TOURS; [4]Institut Gustave Roussy, VILLEJUIF; [5]Hôpital Cochin, PARIS; [6]Hôpital Archet, NICE; [7]Hôpital Antoine Béclère, CLAMART; [8]Hôpital Claude Huriez, LILLE; [9]Institut Paoli Calmettes, MARSEILLE; [10]Centre Henri-Becquerel, ROUEN, France

Background. Following FDA approval of AZA for MDS, a compassionate program of AZA (ATU nominative) was started in France for higher risk MDS unfit for intensive chemotherapy and with contra indication to a phase III trial randomizing AZA to conventional treatment. Patients (pts): IPSS int-2 and high-risk MDS (and some int-1) received AZA 75 mg/mÇ/d (d 1-7) (SC) every 4 weeks. *Results.* From Sept 2004 to October 2006, 145 pts from 34 centres were included. We currently had data for 105 of them who had completed at least one course of AZA: M/F: 69/36, median age 71 y [17-102]. WHO at inclusion: 9 RAEB1, 40 RAEB2, 42 AML post-MDS, 4 CMML, 1 RAS, 2 RCMD, 7 unclassified MDS. 36 pts had previously received intensive Anth-AraC, 7 low dose AraC, 22 EPO and 9 non cytotoxic treatments. 31 (29%), 24 (23%) and 50 (48%) pts had fav, int and unfav karyotype, resp. 48 pts (46%) were IPSS high, 48 pts (46%) int-2 and 9 pts (8%) int-1. Pts received a median of 5 cycles [range 1-18+]. Response was generally assessed after 4 cycles, unless pts progressed before. Thus, 20 pts were not yet evaluable for response. Of the remaining 85 pts, 10 (12%) achieved CR (2006 IWG criteria), 29 (34%) achieved PR and 15 (18%) achieved HI (Overall response rate OR=64%). 31 pts (36%) were considered failure: 6 of them died before evaluation and 10 of them were considered failure because early evaluation after only 2 cycles showed stable disease only, and AZA was then stopped. OR was 88%, 65%, 75% and 63% for RAEB1, RAEB2, CMML and AML post-MDS resp (p<0.1); 76%, 58% and 59% for fav, int and unfav karyotype, resp (p=NS). 4/7 pts with monosomy 7 responded (2 CR+2 PR), 2/3 pts with

+8 (1 PR+1 HI) and 14/24 pts with complex karyotype (3 CR+9 PR+2 HI). OR was 59%, 65% and 75% for IPSS high (p=NS), int-2 (p<0.1) and int-1 pts (p=NS) resp and 63%, 67% in pts previously treated or not by cytoreductive agents resp (p=NS). Median survival from inclusion was 8 months [range 1-24+]. AZA induced myelosuppression lead to dose reduction in 16% pts and hospitalization in 23% pts but was not responsible for any death. Other side effects included frequent local reactions (reversible with local NSAID) (54%), grade I-II gastro-intestinal disorders (54%), unexpected cardiac arythmias (2%). *Conclusions.* AZA, in this population with overall unfavorable features, gave response rates at least similar to those of CALGB studies, that may have been higher if treatment had not been stopped in some of the pts stable after 2 courses. Pts with unfavorable karyotype (-7, complex) or +8 had about 59% response rates. Accrual in this program is continuing. Data on response duration will be presented.

PROGNOSTIC VALUE OF BONE MARROW HISTOLOGY IN MYELODYSPLASTIC SYNDROMES CLASSIFIED ACCORDING TO WHO CRITERIA

M.G. Della Porta,[1] L. Malcovati,[2] E. Boveri,[3] E. Travaglino,[4] C. Pascutto,[2] M. Maffioli,[2] R. Invernizzi,[4] A. Castello,[3] U. Magrini,[3] L. Lazzarino,[2] M. Cazzola[2]

[1]University of Pavia; [2]Department of Hematology, University of Pavia; [3]Department of Human Pathology, University of Pavia; [4]Department of Internal Medicine, University of Pavia, Italy

Background. In 2002, the WHO proposed a new classification of myelodysplastic syndromes (MDS) that has been shown to have a relevant prognostic value [J Clin Oncol 2005;23:7594, Haematologica. 2006;91:1596]. Previous studies had also shown that bone marrow (BM) histopathology is associated with outcome of MDS, but its prognostic value in patients classified according to WHO criteria has not been defined. *Aims.* To determine the prognostic value of BM histology in MDS classified according to WHO criteria. *Design and Methods.* We retrospectively evaluated 452 patients with a diagnosis of MDS formulated at the Department of Hematology, Fondazione IRCCS Policlinico San Matteo, University of Pavia Medical School, Pavia, Italy, between 1992 and 2004. Patients receiving a diagnosis before 2002 were reclassified according to the WHO criteria. BM biopsies were analyzed by independent pathologists for CD34 immunoreactivity, cellularity, and bone marrow fibrosis according to the European consensus guidelines [Haematologica 2005;90:1128]. Cox proportional hazards regression was used to identify the most significant prognostic factors, and hierarchical clustering analysis was performed to recognize subsets of patients with homogeneous clinico-pathological features. *Results.* Moderate or severe BM fibrosis (grade ≥2) was detected in 57 out of 408 evaluable cases (14%), and was significantly associated with multilineage dysplasia (p<0.001), low hemoglobin and platelet count (p<0.001), higher red cell transfusion need (p<0.001) and poor cytogenetics (p=0.001). In multivariate analysis, BM fibrosis and CD34 clusters showed a significant prognostic value on both OS (p<0.001 and p=0.03, respectively), and LFS (p<0.001 and p=0.006, respectively). The negative effect of BM fibrosis was more significant in MDS patients without excess blasts (OS p<0.001 and LFS p<0.001). A hierarchical clustering analysis allowed us to identify 3 distinct groups of patients. Two of the subsets (n=74 and n=67) included patients with no or mild BM fibrosis, clustered according to WHO classification, while a third cluster (n=67) consisted of patients with increased BM fibrosis (including the 57 patients with BM fibrosis of grade ≥2), high BM cellularity, multilineage dysplasia, and high transfusion need. Patients classified in the latter cluster had significant lower OS and LFS compared to clusters 1 and 2 (p=0.001 and p<0.001). Finally, we applied Cox regression in order to identify the most significant prognostic factors in the cluster with increased BM fibrosis: marrow blasts was the only variable with a significant effect on both OS (p=0.02) and LFS (p=0.01). *Conclusions.* BM histology provides useful clinical information in patients with MDS classified according to WHO criteria. Bone marrow fibrosis identifies a distinct subset of MDS patients with multilineage dysplasia, high transfusion requirement and poor prognosis. This parameter should be taken into account for implementing risk-adapted therapeutic strategies.

A ROLE FOR THE ENDOPLASMIC RETICULUM IN THE APOPTOSIS OF ERYTHROID PRECURSORS IN LOW RISK MYELODYSPLASTIC SYNDROMES

E.G. Gyan,[1] E. Frisan,[1] O. Beyne-Rauzy,[2] J.C. Deschemin,[1] C. Randriamampita,[1] A. Dubart-Kupperschmitt,[1] M. Pla-Brunet,[3] C. Garrido,[3] F. Dreyfus,[1] P. Mayeux,[1] C. Lacombe,[4] E. Solary,[3] M. Fontenay[1]

[1]Institut Cochin, PARIS; [2]Department of Internal Medicine, Purpan, TOULOUSE; [3]Inserm U517, Faculté de Médecine, DIJON; [4]Laboratoire d'hématologie hôpital Cochin, PARIS, France

Background. The anemia that characterizes low grade myelodysplastic syndromes (MDS) has been explained by an excessive death by apoptosis of bone marrow erythroid precursors. The pathways leading to the death of these precursors have been partially depicted, e.g. we have identified the Fas-dependent activation of caspase-8 as a key initiating event. The endoplasmic reticulum (ER) was shown to play a role in some apoptotic pathways. AIMS. The present study was designed to determine whether the ER was involved in the death of MDS erythroid precursors. METHODS. These erythroid precursors were derived in liquid culture from bone marrow $CD34^+$ progenitors. Intracellular or ER Ca^{2+} stores were measured by spectrofluorimetry. Cells were loaded with Fura-2/AM and stimulated with ionomycin or thapsigargin. These experiments were performed in the presence of the extracellular Ca2+ chelator EGTA. *Results.* We first observed that the basal ER Ca2+ stores were increased in MDS compared to normal erythroid precursors. We also specifically detected a spontaneous cleavage of the ER-associated caspase-4 in MDS erythroid precursors. To further explore the role of the ER in erythroid precursor cell death, we ectopically expressed an ER-targeted Bcl-2 protein in $CD34^+$ cells using a lentiviral vector before inducing their erythroid differentiation. We observed that ER-targeted Bcl-2 protein prevented the spontaneous death of MDS erythroid precursors by acting upstream of the mitochondrial events such as cytochrome c release in the cytosol and decrease in mitochondrial membrane potential. This observation suggested a role for the ER in the pathway to death of MDS erythroid cell precursors, upstream of the mitochondria. Thapsigargin is an inhibitor of sarcoplasmic Ca^{2+} (SERCA) pumps that can induce apoptosis through ER stress. MDS erythroid precursors did not demonstrate a higher sensitivity to thapsigargin-induced apoptosis than normal erythroid precursors. Thapsigargin enhanced mitochondrial Ca^{2+}, which was inhibitable by ruthenium red, suggesting that Ca^{2+} import into the mitochondria was operational in both cell types. ER-targeted Bcl-2 protected MDS erythroid precursors from thapsigargin-induced apoptosis. This protective effect of Bcl-2 in MDS erythroid precursors could not be related to a depletion of ER Ca^{2+} stores, as observed in other cell types including normal erythroid precursors. Rather, Bcl-2 targeted to ER appeared to prevent caspase-4 activation in MDS erythroid progenitors undergoing spontaneous and thapsigargin-induced apoptosis. *Conclusions.* Altogether, our data indicate that ER plays a central role in apoptosis of MDS erythroid precursors, upstream of the mitochondria, through a Ca^{2+}-independent and Bcl-2-sensitive pathway that appears to involve caspase-4.

INVERSE REGULATION OF HEMATOPOIETIC PROGENITOR CELL EGRESS BY MT1-MMP AND RECK

A. Avigdor,[1] Y. Vagima,[2] P. Goichberg,[2] S. Shivtiel,[2] M. Tesio,[2] A. Dar,[2] A. Kalinkovich,[2] I. Petit[2] O. Perl,[1] E. Rosenthal,[1] I. Resnick,[3] I. Hardan,[1] A. Nagler,[1] T. Lapidot[2]

[1]The Chaim Sheba Medical Center, TEL-HASHOMER; [2]The Weizmann Institute of Science, REHOVOT; [3]Hadassah Medical Center, JERUSALEM, Israel

Background. hematopoietic stem and progenitor cells continuously exit from the bone marrow (BM) reservoir to the blood circulation as part of homeostasis and host defense. Clinical recruitment of progenitors to the peripheral blood (PB) is achieved by chemotherapy and repeated G-CSF stimulations, which mimic physiological egress of stem and progenitor cells during injury and inflammation. Yet, mechanisms governing progenitor cell trafficking during steady state homeostasis and clinical mobilization are not fully understood. Membrane type-1 metalloproteinase (MT1-MMP) and its endogenous inhibitor, reversion-inducing-cysteine-rich protein with Kazal motifs (RECK), are established key regulators of tumor and endothelial cell motility. *Methods and Results.* In our study we found that egress of human hematopoietic CD34$^+$ progenitors requires cell autonomous changes in their motile properties inversely mediated by MT1-MMP and its endogenous inhibitor, RECK. By flow cytometry analysis we detected higher MT1-MMP and lower RECK expression on circulating human CD34$^+$ cells and maturing leukocytes as compared to immature BM cells. MT1-MMP expression was even more prominent on CD34$^+$ cells obtained from PB of G-CSF-treated healthy donors whereas RECK labeling was barely detected. In addition, five daily injections of G-CSF to NOD/SCID mice, previously engrafted with human cells, increased MT1-MMP and decreased RECK expression on human CD45$^+$ leukocytes, human immature CD34$^+$ and primitive CD34$^+$/CD38$^-$/low cells, in a PI3K/Akt1-dependent manner, resulting in elevated MT1-MMP activity. Inverse regulation of MT1-MMP and its inhibitor RECK by G-CSF induced mobilization was confirmed by *in situ* immuno-labeling of BM sections, as well as by human MT1-MMP and RECK mRNA expression analysis of leukocytes repopulating the BM of chimeric mice. Blocking MT1-MMP function halted mobilization, while RECK neutralization promoted egress of human CD34+ progenitors in the functional model of NOD/SCID chimeric mice. Treatment with MT1-MMP neutralizing Ab or with tissue inhibitor of metalloproteinase-2 (TIMP-2) reduced the *in vitro* chemotactic response to SDF-1 of human G-CSF-mobilized CD34$^+$ cells via matrigel coated filters. In contrast, blocking RECK function by neutralizing Ab, thus abrogating RECK-mediated inhibition of MT1-MMP, facilitated SDF-1-induced migration of steady state human BM CD34$^+$ cells. Following G-CSF-induced mobilization, we also observed a reduction in CD44 expression on human leukocytes and, specifically, on immature CD34$^+$ progenitor cells in the BM of chimeric mice. This was accompanied by accumulation of CD44 cleaved products of molecular weights, expected for MT1-MMP activity, in the BM supernatants. In chimeric mice co-injected with MT1-MMP-neutralizing Ab, less cleavage of CD44 was detected upon G-CSF mobilization, whereas in the absence of a mobilizing signal, increasing MT1-MMP activity by anti RECK Ab injection facilitated CD44 proteolysis on the BM cells. Finally, MT1-MMP expression correlated with the number of CD34$^+$ cells, collected on the first apheresis day in 29 consecutive patients with lymphoid malignancies and in 21 healthy donors treated with G-CSF. *Conclusions.* our results indicate that MT1-MMP and RECK oppositely control G-CSF induced-hematopoietic progenitor cell mobilization, by regulating CD44 surface expression and ultimately, cell adhesion and motility. These molecules might serve as targets for new approaches to improve clinical stem cell mobilization and repopulation.

SNX5, A NOVEL GENE LINKED TO FANCONI ANAEMIA CAUSES HAEMATOPOIETIC FAILURE WHEN KNOCKED DOWN IN ZEBRAFISH

C. Flynn,[1] E.M. Mendenhall,[2] C.M. Verfaillie[1]

[1]Stem Cell Institute Leuven (SCIL), LEUVEN, Belgium; [2]Dept. of Medicine & Stem Cell Institute, MINNEAPOLIS, USA

Background. Sorting nexin 5 (SNX 5) is a member of the sorting nexin family, a diverse group of cellular trafficking proteins unified by the presence of a phospholipid binding domain (PHOX) which is involved in protein-protein interactions. While the function of SNX5 is unknown, there is evidence from yeast two hybrid studies that SNX5 binds to FANCA, and SNX5 is one of the 20 genes located on a region on mouse chromosome 2 associated with accelerated stem cell aging. More recently SNX5 has been shown to be a partner of Mindbomb- an E3 ubiqitin ligase essential for notch signal activation. *Aims.* We have shown that SNX5 is significantly higher expressed in CD34$^+$CD33$^-$CD38$^-$Rho$^+$ (Rho-hi) cells from umbilical cord blood (UCB) and bone marrow (BM), depleted of SCID repopulating cells (SRCs) than in CD34$^+$CD33$^-$CD38$^-$cKIT$^+$ Rho- cells (Rholo), containing all SRCs. We are investigating the role of SNX5 in Fanconi anaemia and developmental haematopoiesis. *Results.* A large scale high throughput functional analysis was carried out in zebrafish and genes differentially expressed between Rholo and Rhohi cells were knocked down using morpholino (MO) antisense oligonucleotides. Morpholinos are useful tools which can specifically inhibit the translation of target mRNA. 16 out of 70 genes knocked down, including snx5, demonstrated decreased circulating blood in the zebrafish injected. Further analysis has shown that MO knock down of snx5 in zebrafish (n=152) results in haematopoietic failure with normal vasculature, with normal expression of scl and gata-1 by *in situ* hybridization, indicating a defect at or beyond the haematopoietic stem cell (HSC) stage. Quantitative RT-PCR was used to further confirm the phenotype. Levels of haemoglobin, l-plastin and myeloperoxidase mRNA in snx5 morphants compared to uninjected controls, were significantly lower, consistent with a multi-lineage haematopoietic differentiation defect. The decrease in circulating blood could be partially rescued by overexpressing human SNX5 cDNA, confirming specificity of the morphant phenotype. To determine whether SNX5 might be linked to Fanconi anaemia (FA), we measured levels of SNX5 mRNA and protein in EBV transformed cell lines from patients with Fanconi-complementation group A (FANCA), -complementation group C (FANCC) or unknown complementation group (FANC-NX). We have found no significant difference between SNX5 mRNA and protein expression in 11 Fanconi cell lines tested compared to Raji controls. The association of SNX5 and Fanconi anaemia in mammalian cell lines has been inconclusive. Studies examining SNX5 over expression and knockdown in human UCB using lentivirus, the impact on haematopoietic engraftment and differentiation in a NOD SCID murine model are in progress and this data will be presented. *Conclusions.* Knockdown of snx5 in zebrafish results in decreased blood, with an effect at or beyond the definitive HSC. There is no quantitative defect of SNX5 in Fanconi anaemia cell lines and mammalian studies are ongoing to determine its association with the HSC.

0433

IMPACT OF STOCHASTIC DYNAMICS ON THE ACTIVE HEMATOPOIETIC STEM CELL POOL

D. Dingli,[1] A. Traulsen,[2] J.M. Pacheco[3]

[1]Mayo Clinic, ROCHESTER, USA; [2]Harvard University, CAMBRIDGEUSA; 3University of Lisbon, LISBON, Portugal

Background. Hematopoiesis is maintained by a small group of hematopoietic stem cells (HSC) that may contribute to blood formation for many years, if not for the lifetime of the individual. HSC replicate approximately 1/year and this slow replication rate is one mechanism to minimize the risk of acquiring mutations in this important pool of cells. However, HSC do acquire mutations that can lead to either neoplastic proliferation (e.g. chronic myeloid leukemia, CML) or marrow failure (e.g. paroxysmal nocturnal hemoglobinuria, PNH). *Aims.* Given that the size of the HSC is small, we aim to determine the potential role of stochastic effects on the evolution of mutant clones that originate in this pool of cells by mathematical modeling. *Methods.* We develop a stochastic model of HSC dynamics based on the Moran process where the cell population is maintained strictly constant. Cells are chosen for reproduction based on their fitness and each time a cell is chosen for reproduction, it has a probability to mutate into a cancer stem cell (CSC). In this model we consider that one mutation is enough to lead to cancer

(e.g. bcr-abl leading to CML). CSC have a fitness advantage r compared to normal cells with fitness 1. Cells are selected for reproduction proportional to their fitness. After each reproductive event, one cell chosen at random from the pool is eliminated. We follow this birth-mutation-export process for a HSC pool of ~400 cells and perform stochastic simulations to follow the evolution of the clone and determine time probability density functions for either extinction or complete invasion by the mutant stem cells. *Results.* Stochastic dynamics leads to three possible scenarios: clonal extinction, latency/stability or complete takeover of the pool of the HSC pool by CSC. Although stochastic extinction is rare, this is possible even for mutants with a significant fitness advantage. The mutant clone can remain latent for many years. The time required for the mutant clone to reach a threshold compatible with a diagnosis of cancer varies significantly and has a very broad distribution, especially if the fitness advantage conferred by the mutation is small. As the fitness advantage increases, the time to diagnosis decreases and while extinction is still possible this becomes a rare event. *Summary and conclusions.* Stochastic considerations with respect to the active HSC pool are important and can possibly explain observations such as stability of JAK2 mutant clones in patients with essential thrombocythemia, disappearance of bcr-abl clones in healthy adults or transient leukemia in children with Down syndrome. Single mutations have to give a significant fitness advantage (r>1.7) to the cell for the disease to appear within the observed timeframes.

0434

A PUTATIVE ROLE FOR VEGFR-1 (FLT-1) IN B CELL COMMITMENT AND DIFFERENTIATION

R. Fragoso,[1] C. Igreja,[1] C. Appleton,[2] A. Henriques,[2] N. Clode,[2] Y. Wu,[3] Z. Zhu,[3] S. Dias[1]

[1]Portuguese institute of Oncology, LISBON, Portugal; [2]Hospital Santa Maria, LISBON, Portugal; [3]ImClone Systems, NEW YORK, USA

VEGF and its receptors are expressed in the hematopoietic system. A role for FLT-1 in particular was described in monocyte-macrophage migration and differentiation, megakaryocytes maturation and dendritic cell differentiation. Given that the expression of this receptor in the lymphoid lineage is not known, we studied FLT-1 expression and a its functions in normal lymphoid progenitors (B cells). To address this question we induced *in vitro* $CD34^+$ cord blood cells differentiation into the B cell lineage using a well established assay (on S17 stromal cells). With this approach, we observed that FLT-1 is expressed throughout B cell differentiation increasing along the differentiation process, and reaching its highest at the *small pre-B cell* stage. We also neutralized FLT-1 during B cell differentiation *in vitro*. Surprisingly, in the presence of the FLT-1 neutralizing antibody (6.12 monoclonal Ab, from ImClone systems), at the end of the assays (4 different experiments) a significantly higher number of $CD19^+$ cells were detected. We observed that the expression of PU.1, Pax5 and E47 was also up-regulated by FLT-1 neutralization. To understand if VEGF/PlGF signalling through FLT-1 promoted myeloid differentiation, suppressed B cell differentiation or simply regulated the quiescent state of hematopoietic stem cells, we studied the *in vitro* differentiation of $CD34^+/FLT\text{-}1^-$ and $CD34^+/FLT\text{-}1^+$ cells (10% of $CD34^+$ population) using the assay described above. Interestingly, $CD34^+/FLT$-1- differentiation *in vitro* largely promoted B cell differentiation, while $CD34^+/FLT$-1+ cells originated mostly myeloid cell differentiation. These results pointed out for a role of FLT-1 in B cell commitment. In order to confirm it, we used FLT-1 positive and negative BM precursors to reconstitute the BM of immunocompremised (sub lethally 350 rad irradiated) mice. Surprisingly, $FLT\text{-}1^+$ precursors lacked the capacity to engraft and/or reconstitute the BM of irradiated recipients and at the end of 5 days all mice in this group were dead. On the other hand, $FLT\text{-}1^-$ precursors not only reconstituted the recipient BM but also originated B cells, which were detected/quantified in both BM and in the spleen. Next, given that FLT-1 function was mainly associated with cell migration, and since it is expressed at the BM latest B cell stages, we reasoned that FLT-1 might have a role in B cells exit from the BM. For this purpose, we used LPS to induced B cells exit from BM and pre-treated some of the mice with a FLT-1 neutralizing Ab. FLT-1 neutralization not only prevented LPS-induced B cells exit from BM but also decreased the number of activated B cells in the peritoneal cavity. Taken together, our results reveal a role for FLT-1/VEGF in regulating B cell commitment from precursor cells and later during B cell differentiation as a chemoattractive signal.

0435

RXR α DIFFERENTIALLY REGULATES MYELOID SUBLINEAGE DIFFERENTIATION

S. Taschner,[1] C. Kösters,[1] B. Platzer,[2] A. Jörgl,[1] W. Ellmeier,[1] H. Strobl[1]

[1]Medical University Vienna, VIENNA, Austria; [2]Harward Medical School, BOSTON, USA

Cells of the myeloid lineage including neutrophil granulocytes (G), monocytes (M) and dendritic cells (DC) are continously regenerated by bone marrow resident hematopoietic stem cells. Nuclear receptor (NR) family members are ligand-activated transcription factors that play key roles in cellular proliferation and differentiation processes including myelopoiesis. Retinoid X receptor alpha (RXRα) represents the predominant NR type I and II homo- and heterodimerization partner in myeloid cells. RXRα partner availability regulated by intracellular RXRα abundance is thought to determine NR signaling. However its regulation in primary human neutrophil versus M versus DC differentiation remained uncharacterized. Here we show that human myeloid progenitors express RXRα protein at sustained high levels during M-CSF-induced monopoiesis. In sharp contrast, RXRα is downregulated during G-CSF-dependent late-stage neutrophil differentiation from myeloid progenitors. Downregulation of RXRα is critically required for neutrophil development since ectopic RXRα inhibited granulopoiesis by impairing proliferation and differentiation. Moreover ectopic RXRα was sufficient to redirect G-CSF-dependent granulocyte differentiation to the monocyte lineage and to promote M-CSF-induced monopoiesis. Functional genetic interference with RXRα signaling in hematopoietic progenitor/stem cells using a dominant-negative RXRα promoted the generation of late-stage granulocytes in human cultures *in vitro* and in reconstituted mice *in vivo*. Therefore, our data suggest that high levels of RXRα?are not compatible with neutrophil development but redirect common progenitors towards the M lineage. Furthermore we show that a third sublineage of myeloid origin - Langerhans-type DC (LC) - are also regulated by RXRα. RXRα activation inhibited TGFβ1-dependent LC proliferation and differentiation and arrested LC development at a CD14loCD11blo/- common LC/intDC/M progenitor stage. Ectopic expression of the myeloid transcription factor PU.1 - but not RelB - fully restored LC development from arrested progenitors in human primary cultures, suggesting that RXRα functionally interferes with PU.1 signaling Taken together we conclude that RXRα abundance and activation determine the fate of myeloid progenitors towards G, M and DC in a differentiation stage and cytokine-dependent manner.

Bone marrow failure

0436

IMPACT OF SOMATIC CELL MOSAICISM IN FANCONI ANEMIA ON DEVELOPMENT OF BONE MARROW FAILURE

J. Tolar,[1] M.L. MacMillan,[1] S.D. Batish,[2] C. Eide,[1] Y. Flit,[2] S.M. Davies,[3] B.R. Blazar,[1] A. Auerbach,[2] J.E. Wagner[1]

[1]University of Minnesota, MINNEAPOLIS; [2]The Rockefeller University, NEW YORK; [3]Cincinnati Children's Hospital Med Ctr, CINCINNATI, USA

Background. Determination of the degree of somatic mosaicism providing functional correction of Fanconi anemia (FA) hematopoiesis has direct implications for gene therapy for FA: it may help assess the percentage of FA hematopoietic cells corrected by gene therapy approaches that are needed to achieve clinically meaningful effects. *Aims.* Hypersensitivity to DNA inter strand cross-linking agents, such as diepoxybutane (DEB) and mitomycin C (MMC), is a cellular marker for diagnosis of FA. However, in some FA patients a population of DEB-resistant PHA-stimulated lymphoblasts (PHA-L) was observed, and this population sometimes varied over time. Our aim was to assess the significance of this finding on hematopoietic function. *Methods.* To that end, we evaluated the MMC sensitivity of bone marrow mononuclear cells (BMMC) and DEB sensitivity of PHA-L and cultured lymphoblastoid cell lines (LCL) in 42 consecutive FA patients referred to the University of Minnesota. In cases where LCL were DEB-resistant, cultured fibroblasts were also studied. BMMC were cultured in the presence of increasing concentrations of MMC. PHA-L and LCL were cultured in DEB at 0.1 μ/ml. *Results.* Wild type BM progenitors (N=17 subjects) proliferated regardless of increasing MMC concentrations (albeit at decreased efficiency at the highest concentrations) as follows: 0 MMC (normalized to 100%), 5 nM MMC (99% [standard deviation, SD, 16%]), 10 nM MMC (90% [SD 22%]), 25 nM MMC (77% [SD21%]), and 50 nM MMC (44% [SD 30%]). Of the 42 FA patients, BMMC failed to proliferate at 0 nM MMC in 10 patients and at 5 nM MMC in 20 patients. Twelve FA patients had MMC resistant BMMC: cells cultured in 5, 10, 25 and 50 nM MMC grew 44% (SD 28%), 35% (SD 24%), 24% (SD 30%) and 17% (SD 32%) of colony numbers in MMC free culture, respectively. Six of these 12 subjects were PHA-L mosaics as determined by DEB sensitivity testing. Four patients with no growth of BMMC at 0 or 5 nM MMC were also somatic mosaics in their PHA-L and LCL. Thus there was no clear correlation between somatic mosaicism as demonstrated by DEB testing in peripheral blood and sensitivity of BMMC to growth in MMC. Clinically, two patients with hematopoietic somatic mosaicism (out of six subjects with simultaneous sensitivity of BMMC to MMC and PHA-L to DEB) developed severe marrow aplasia, one of which received hematopoietic stem cell transplantation. The remaining four hematopoietic mosaic patients had normal or near normal peripheral blood counts. While patients with hematopoietic somatic mosaicism had mixed populations of DEB sensitive cells in their peripheral blood, all their fibroblast cultures were DEB sensitive. *Summary.* These data show that the presence of somatic mosaicism per se does not necessarily prevent bone marrow failure. Moreover, the data suggest that patients with stigmata of FA may have chromosomal breakage studies showing few cells (or no cells) with the characteristic changes of FA; in these cases, skin fibroblasts should be tested as well.

0437

INCREASED PRODUCTION OF TGF-Β1 BY BONE MARROW STROMAL CELLS IS ASSOCIATED WITH DOWNREGULATION OF IL-10 AND OVEREXPRESSION OF SOLUBLE FLT-3 LIGAND IN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

H. Papadaki, K. Pyrovolaki, I. Mavroudi, M. Spanoudakis, C. Pontikoglou, M. Ximeri, C. Kalpadaki, G. Gvazava, M. Velegraki, G.D. Eliopoulos

University of Crete School of Medicine, VOUTES, HERAKLION, Greece

Background. Chronic idiopathic neutropenia (CIN) is a bone marrow (BM) failure syndrome characterized by low number of circulating neutrophils for prolonged period of time. The disease has been attributed to low number of BM myeloid progenitor cells due to an inflammatory BM microenvironment. Among multiple cytokines normally involved in regulation of myelopoiesis, transforming growth factor-β1 (TGF-β1), interleukin-10 (IL-10), and soluble flt-3 ligand (sFL) play a significant role. The involvement of these cytokines in the pathogenesis of CIN has not been extensively studied. *Aims.* The aim of the study was to evaluate the production of TGF-β1, IL-10 and sFL in the BM microenvironment of CIN patients and investigate the possible involvement of these cytokines in the pathogenesis of neutropenia in the affected subjects. *Materials and Methods.* BM was obtained from 70 patients with CIN and 35 healthy controls. All patients fulfilled the diagnostic criteria for CIN as we have previously published (Blood 2003; 101: 2591-2600). Aliquots of BM mononuclear cells (BMMCs) were evaluated by flow cytometry for $CD34^+/CD33^+$ expression. Long-term BM cultures (LTBMCs) were initiated from BMMCs according to a standard technique and TGF-β1, IL-10 and sFL were measured in the supernatants by means of ELISA. LTBMC supernatant IL-10 and sFL were also measured in patient cultures after the addition of anti-human TGF-β1 mouse monoclonal neutralizing antibody. *Results.* The levels of TGF-β1 in LTBMC supernatants were significantly increased in CIN patients compared to controls ($p<0.0001$). Individual values of the cytokine inversely correlated with the number of circulating neutrophils (r=-0.3776, $p<0.0001$). In contrast, LTBMC supernatant IL-10 levels were significantly decreased in the patients compared to controls ($p<0.0001$), and individual values of the cytokine inversely correlated with the values of TGF-β1 (r=-0.6117, $p<0.0001$) and positively with the number of circulating neutrophils (r=0.4957, $p<0.0001$. The levels of culture supernatant sFL were significantly increased in the patients, compared to controls ($p<0.0001$). sFL values inversely correlated with the values of supernatant IL-10 (r=-0.4401, $p<0.0001$) and the number of circulating neutrophils (r=-0.4370, $p<0.0001$) and positively with the values of supernatant TGF-b1 (r=0.4807, $p<0.0001$). Moreover, culture supernatant TGF-β1 values inversely correlated with the proportions of $CD34^+$ (r=-3599, $p=0.0016$) and $CD34^+/CD33^+$ (r=-0.2613, $p=0.0243$) cells, while the levels of supernatant IL-10 correlated positively with the percentages of $CD34^+$ cells. An inverse correlation was also found between the values of LTBMC supernatant sFL and the proportions of $CD34^+$ (r=-0.4119, $p=0.0007$) and $CD34^+/CD33^+$ (r=-0.3801, $p=0.0019$) cells. Interestingly, the addition of anti-TGF-b1 neutralizing antibody in patient LTBMCs significantly increased IL-10 but not sFL levels in culture supernatants. *Summary and Conclusions.* BM stromal cells produce excessive amounts of TGF-b1 in CIN patients which affect the number of $CD34^+$ and $CD34^+/CD33^+$ cells. TGF-β1 exerts a direct inhibitory effect on the production of the anti-inflammatory cytokine IL-10. The effect of TGF-β1 on sFL production however, seems to be indirect as was shown by the neutralizing antibody experiments. We postulate that the increased sFL levels in patient LTBMC supernatants represent a compensatory effect of the BM microenvironment to the low number of granulocytic progenitor cells in CIN.

0438

TERC MUTATIONS ANALYSIS IN PATIENTS WITH APLASTIC ANEMIA: RESULTS OF A DHPLC SCREENING AND CLINICAL IMPLICATIONS

S. Pigullo,[1] C. Dufour,[1] G. Caridi,1 J. Svahn,[1] G. Santamaria,[1] M. Risso,[1] M. Van Lint,[2] D. Longoni,[3] M. Pillon,[4] A.P. Iori,[5] P. Saracco,[6] A. Bacigalupo,[7] C. Di Grazia,[2] M. Lanciotti[1]

[1]G. Gaslini Hospital, GENOA; [2]San Martino Hospital, GENOA; [3]San Gerardo Hospital, MONZA; [4]Padoa University, PADOA; [5]La Sapienza University, ROME; [6]Regina Margherita Hospital, TURIN; [7]St. Martin Hospital, GENOA, Italy

Background. Telomerase RNA Component (TERC) is an essential subunit of the telomerase ribonucleoprotein complex. TERC mutation results in a reduction of telomerase activity leading to premature telomere shortening. Heterozygous mutations of TERC gene are responsible for the autosomal dominant form of Dyskeratosis Congenita (DC). Recently TERC mutations were also described in individuals with aplastic anemia (AA) acquired apparently late in life. Denaturing High Performance Liquid Chromatography (DHPLC) is a relatively novel technique of mutation detection based on the separation of heteroduplex PCR products from their corresponding homoduplex by reverse phase liquid chromatography. *Aims.* To investigate the presence and the frequency of TERC mutations in a population of Italian AA patients including pediatric and adults subject. *Methods.* DNA from 111 AA patients (75 pediatrics and 36 adults) and 156 normal controls (94 pediatrics and 62 adults was obtained from blood or bone marrow samples previously collected and frozen. The TERC coding region (GenBank NR_001566) was amplified in 2 PCR fragments and then analyzed by DHPLC. For each abnormal elution profile PCR products were directly sequenced using ABI prism 3100 genetic analyzer. *Results.*Two new mutations, c53T>A and c210C>G, of TERC gene were identified. The c53T>A mutation results in a nucleotidic change in the template sequence inside the highly conserved region CR1, but it does not alter TERC-RNA secondary structure. This mutation was found in a 14 year old boy who, throughout his 10 year clinical follow-up, on CyA and Steroid to which he was not thoroughly compliant, maintained hypocellular marrow and a mild cytopenia (WBC 2.8-7.0×10^9/L, PMN 1.0-4.5×10^9/L, Hb 14-16 g/dL, Plt 60-80 ×10^9/L). The c210C>G mutation was found in a 47 year old woman and localized in the P1 region. This mutation gives rise to a radical conformational change of the TERC-RNA secondary structure. This patient was diagnosed 10 years ago with severe AA, she did not respond to initial treatment with ATG plus CyA. Afterwards, androgens and steroids were added to CyA, she improved her counts (Platelets 50×10^9/L, Hb 9.4 g/dL, PMN 3.0×10^9/L), after 3 years of this therapy. In the last year, without treatment, her Hb is 12 g/dL, Platelets 180×10^9/L and PMN 3.0 ×10^9/L). Marrow committed progenitors are far lower than normal controls. *Conclusions.* The frequency of TERC mutations in our cohort of AA patients is low (1.75%) but consistent with previously published data. We developed a fast, effective and low cost DHPLC-screening protocol which allows TERC gene mutation analysis in all new cases of AA. Identification of TERC mutations in AA patients has some important clinical implications: i) the genetic test is useful for a correct diagnosis and an adequate therapeutic protocol since TERC mutated patients often have no other signs of DC and invariably fail to respond to immunosuppressive therapy. ii) TERC mutation carriers, as they have a hereditary disease with an elevated cancer-susceptibility, require an adequate cancer surveillance program and genetic counseling.

ADIPONECTIN IS PRODUCED BY LYMPHOCYTES AND INHIBITS GRANULOPOIESIS

L. Crawford,[1] W. Peake,[1] S. Price,[1] T.C.M. Morris,[2] A.E. Irvine[1]

[1]Queen's University Belfast, BELFAST; [2]Haematology, Belfast City Hospital, BELFAST, United Kingdom

Background. Previous studies by our group have shown that normal unstimulated lymphocytes produce a protein which inhibits colony formation of granulopoietic progenitors, but has no effect on erythroid progenitors. Therefore, this inhibitor was initially designated GIA (granulopoietic inhibitory activity). GIA was identified as a glycoprotein of approximately 30 kDa, with a pI of 7.9-8.4. Furthermore, we demonstrated that this inhibitor may have physiological significance in that its production is altered in patients with neutropenia. GIA has proved difficult to characterise to date since it is produced in relatively low amounts although it has a high specific biological activity. *Aims.* Adiponectin is an adipokine reported to share many of the inhibitory characteristics of GIA and has been demonstrated to act as a negative regulator of haemopoiesis and immune response. This study aimed to determine whether GIA is adiponectin or if it represents an adiponectin-like molecule. *Methods.* Lymphocyte conditioned medium (LCM) from lymphocytes cultured at 1×10^6 cells/ml in HL-1 minimal medium was used as a source of GIA. Inhibition of granulopoiesis was tested by co-culturing LCM with normal bone marrow cells in a myeloid colony assay. Western blot analysis and ELISA were performed to investigate adiponectin expression in LCM. RT-PCR analysis of lymphocyte mRNA was carried out to look for expression of adiponectin at the transcript level. *Results.* Inclusion of LCM as 10% of the top layer of agar in a myeloid colony assay inhibited growth of CFU-GM by 52±11% (n=3), confirming the presence of the inhibitory activity. Western blot analysis demonstrated a distinct banding pattern in days 3-7 LCM corresponding to monomers, dimers, trimers and greater. This is consistent with adiponectin which circulates as a multimer of trimers. Characterisation of GIA at the transcript level confirmed that GIA is in fact adiponectin. The N-terminal collagenous domain, C-terminal globular domain and full length adiponectin were amplified by RT-PCR analysis and confirmed by sequencing. *Summary and conclusions*. Adiponectin is thought to be secreted exclusively from adipocytes and much of our current knowledge of this molecule relates to its metabolic functions. Our study provides evidence that adiponectin is also produced by lymphocytes and may play a role in the pathogenesis of neutropenia.

ABSENCE OF LEF-1 TRANSCRIPTION FACTOR IN MYELOID PROGENITORS OF PATIENTS WITH SEVERE CONGENITAL NEUTROPENIA RESULTED IN ABROGATED EXPRESSION OF NEUTROPHIL ELASTASE AND DEFECTIVE GRANULOPOIESIS

J. Skokowa,[1] J.P. Fobiwe,[2] L. Dan,[2] K. Welte[2]

[1]Medical School Hannover, HANNOVER; [2]Dept. Pediatric Hematology/Oncology MHH, HANNOVER, Germany

Recently we have shown that Lymphoid-enhancer binding factor 1 (LEF-1) is a decisive transcription factor in granulopoiesis controlling proliferation, proper lineage commitment and granulocytic differentiation via regulation of its target genes C/EBPα, cyclin D1, c-myc and survivin. Expression of LEF-1 and its target genes was abrogated in myeloid progenitors of severe congenital neutropenia (CN) patients (Skokowa et al., Nat Med. 2006;12:1191-7). CN is a heterogeneous syndrome with two major subtypes: 1) autosomal dominant CN defined by mutations in ELA2 gene encoding neutrophil elastase (NE) and 2) autosomal recessive CN (including Kostmann syndrome) carrying HAX-1 mutations, both characterized by an early stage maturation arrest of granulopoiesis. Interestingly, in line with LEF-1 levels, ELA2 mRNA expression in myeloid progenitors as well as NE protein levels in the blood were severely reduced in CN patients irrespective of *ELA2 or HAX1* inheritance. ELA2 gene promoter is positively regulated by direct binding of LEF-1 or C/EBPα. Transduction of LEF-1-GFP lentiviral constructs containing cDNA of either full-length or dominant negative (dn) LEF-1 into U937 myeloid cell line led to significant upregulation of ELA2 mRNA and NE protein, similar as we have shown for C/EBPα. LEF-1 rescue of CD34+ cells of two CN patients resulted in increased NE levels and in granulocytic differentiation *in vitro* . Therefore, these data confirm the importance of LEF-1 in myelopoiesis and in the pathogenesis of CN. Absence of LEF-1 is a common decisive mechanism of the defective maturation program of myeloid progenitors in CN downstream of both, ELA2 or HAX1 mutations.

PRIMARY ALLOGENEIC STEM CELL TRANSPLANTATION VERSUS BEST AVAILABLE DRUG TREATMENT IN CHRONIC MYELOID LEUKEMIA

R. Hehlmann,[1] T. Lahaye,[1] M. Pfirrmann,[2] A. Hochhaus,[1] M.C. Müller,[1] A. Reiter,[1] J. Hasford,[2] H.J. Kolb,[3] H. Heimpel,[4] D.K. Hossfeld,[5] A. Gratwohl,[6] Germany and the German CML Study Group[1]

[1]Medizinische Fakultät Mannheim, MANNHEIM, Germany; [2]IBE, LMU München, MÜNCHEN, Germany; [3]Medizinische Klinik III, LMU München, MÜNCHEN, Germany; [4]Universität Ulm, ULM, Germany; [5]Universität Hamburg, HAMBURG, Germany; [6]Kantonsspital Basel, BASEL, Switzerland

Early allogeneic hematopoietic stem cell transplantation (HSCT) has been proposed as primary treatment modality for patients (pts) with chronic myeloid leukemia (CML). This concept has been challenged by persisting transplantation mortality and improved drug therapy. In order to verify retrospective results, a randomized controlled trial was designed to compare primary HSCT and best available drug treatment in a cohort of 621 newly diagnosed CML pts in chronic phase. Assignment to treatment strategy was by eligibility for HSCT and genetic randomization according to availability of a matched related donor. Evaluation followed the intention to treat principle. 354 pts (62% male; median age 40 years, range 11-59) were eligible and randomized. 135 pts (38%) had a matched related donor of which 123 (91%) received a transplant within a median of 10 months (range 2-106) from diagnosis. 4 pts died before scheduled transplantation, 8 pts withdrew consent. 219 pts (62%) had no related donor and received best available drug treatment. Of these, 97 pts (44%) received a matched unrelated donor (MUD) transplant in 1st chronic phase and were censored at the time of transplantation. As 1st line treatment after randomization pts received interferon alpha based therapy. In the course of the study a total of 197 pts were switched to imatinib after failure of interferon alpha. Currently 31 (57%) of 54 living pts of the drug treatment group receive imatinib or 2nd generation tyrosine kinase inhibitors (dasatinib n=2, nilotinib n=1). With a median observation time of 8.9 (4.2-11.2) years median survival of all 621 pts was 8.1 years. During the first 8 years after diagnosis survival curves of drug treated patients were superior to those of transplanted patients reflecting transplant-related mortality. Beyond 8 years survival curves were no longer distinct. 5 (10) year survival was 62% (53%) for transplanted and 73% (52%) for drug treated pts, in the low risk group 68% (59%) for transplanted and 85% (62%) for drug treated pts, respectively. Survival was superior for drug treated pts up to the cutpoint of survival curves at year 8 (p=0.041) and during the study period up to 11 years from diagnosis (p=0.049), particularly so in low risk pts (p=0.027 to cutpoint, p=0.032 overall). Significantly higher proportions of complete cytogenetic remissions (91% vs 48%, p=0.002) and of major molecular responses (ratio BCR-ABL/ABL <0.1%; 81% vs 45%, p=0.001) were found in the transplant group indicating higher levels of residual disease in the group receiving drug treatment. On the basis of up to 11 years of follow-up the general recommendation of HSCT as 1st line treatment option in chronic phase CML can no longer be maintained. It should be replaced by a trial with modern drug treatment first. Exceptions may be patients´ preference, very low transplantation risk and economic reasons.

DUPLICATION OF THE MYB ONCOGENE IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

I. Lahortiga,[1] K. De Keersmaecker,[2] P. Van Vlierberghe,[3] C. Graux,[2] B. Cauwelier,[4] F. Lambert,[5] N. Mentens,[2] H.B. Beverloo,[3] R. Pieters,[3] F. Speleman,[4] M.D. Odero,[6] M. Bauters,[2] G. Froyen,[2] P. Marynen,[2] P. Vandenberghe,[1] I. Wlodarska,[1] J. Meijerink,[3] J. Cools[2]

[1]KULeuven, LEUVEN, Belgium; [2]VIB, LEUVEN, Belgium; [3]Erasmus Medical Center, ROTTERDAM, Netherlands; [4]Ghent University Hospital, GENT, Belgium; [5]University of Liege, LIEGE, Belgium; [6]CIMA, PAMPLONA, Spain;

Background. T-ALL is an aggressive T-cell malignancy that is most common in children and adolescents. Leukemic transformation of thymocytes is caused by the cooperation of mutations that affect proliferation, survival, cell cycle, and T-cell differentiation. Molecular analyses have identified a large number of genetic alterations including deletion of CDKN2A (p16), ectopic expression of transcription factors, episomal amplification of NUP214-ABL1, and mutation of NOTCH1. *Aims.* In order to detect novel unbalanced genomic rearrangements in T-ALL, we performed micro array comparative genomic hybridization (array CGH) with a resolution of 1 Mb over the entire genome and with higher resolution around oncogenes and candidate oncogenes. *Results.* We identified a duplication of the MYB gene in 2 of 27 T-ALL cases using array CGH. The duplication was confirmed using quantitative PCR (Q-PCR) and Q-PCR analysis of DNA from diagnosis and remission confirmed that that the duplication was an acquired event. We used Q-PCR to screen additional cases and identified a duplication of MYB in 9 of 107 (8.4%) T-ALL cases and in 5 T-ALL cell lines (ALL-SIL, MOLT-4, P12-ICHIKAWA, CCRF-CEM and RPMI-8402). The commonly duplicated region in all patients and cell lines only covered the MYB gene, strongly suggesting that MYB is the critical gene deregulated by the chromosomal duplication. In support of this, the average expression level of MYB was found to be significantly elevated in T-ALL cases with MYB duplication compared to cases without the duplication. In T-ALL cell lines, MYB expression was variable, with MOLT-4 and RPMI-8402 showing high level MYB expression. The MYB gene encodes a nuclear transcription factor that is implicated in proliferation, survival and differentiation of hematopoietic progenitor cells. Proper levels of MYB expression are known to be important during hematopoietic cell development, and the Myb gene is a frequent target of retroviral insertions in myeloid, B- and T-cell leukemias in the mouse. Knock-down of MYB expression using specific siRNAs resulted in an irreversible differentiation of the RPMI-8402, MOLT-4, and ALL-SIL cells, but not of T-ALL cell lines without MYB duplication, as observed by changes in expression of the CD1a, CD3, CD4 or CD8 markers. Although the downregulation of MYB expression had almost no effect on the proliferation and viability of the cells, we observed that a combined inhibition of NOTCH1, another oncogene in T-ALL, and the downregulation of MYB expression resulted in a complete block of proliferation with a strong impact on cell viability and proliferation. These data suggest that NOTCH1 mutation and MYB duplication may cooperate in the pathogenesis of T-ALL. Most of the patients with MYB duplication, and all of the cell lines with MYB duplication indeed harbour mutations in NOTCH1. *Summary.* We identified a duplication of the MYB oncogene in approximately 8% of human T-ALL, and we show that MYB expression is critically required to block differentiation in T-ALLs with MYB duplication. A combined inhibition of MYB and NOTCH1 strongly affects proliferation and survival of T-ALL cell lines, establishing MYB as a novel target for therapy in T-ALL.

THE JAK2 V617F MUTATION IS PRESENT IN A MINORITY OF HUMAN HEMATOPOIETIC STEM CELLS FROM PATIENTS WITH MYELOPROLIFERATIVE DISORDERS AND DOES NOT MODIFY THEIR SELF-RENEWAL PROPERTIES

C. James,[1] F. Mazurier,[1] R. Chaligne,[2] I . Lamrissi-Garcia,[1] S. Dupont,[2] S. Giraudier,[2] F. Delhommeau,[2] E. Lippert,[3] F.X. Mahon,[3] J.M. Pasquet,[1] H. De Verneuil,[1] W. Vainchenker[2]

[1]INSERM U876, BORDEAUX; [2]INSERM U790, VILLEJUIF; [3]Hematology Laboratory, BORDEAUX, France

Background. The JAK2 V617F mutation is the most common genetic defect observed in hematological malignancies since it is observed in essential thrombocythemia (ET), polycythemia vera (PV) and primitive myelofibrosis (PMF). Whether it is the first genetic defect in these 3 myeloproliferative disorders (MPD) remains a matter of debate. However, all these malignancies are considered to arise from a defect in a hematopoietic stem cell (HSC). *Aims.* To investigate whether the V617F mutation occurs in a true stem cell and modifies its self-renewal and differentiation properties, we repopulated immune-deficient mice with human JAK2 V617F cells. *Methods.* After informed consent was obtained, $CD34^+$ cells isolated from the blood or bone marrow (BM) of 28 patients with JAK2 V617F-positive MPDs (14 PV, 9 PMF, 4 post PV-MF, 1 ET) were intravenously injected into sublethally irradiated and anti-CD122 antibody-treated NOD/SCID mice. 3, 6, and 12 weeks after transplant, immunophenotypic analysis on BM aspirates was performed to assess human cell engraftment. 15 weeks after transplant, mice were sacrificed and hematopoietic cells were used for secondary transplants. Before transplant and 3, 6, 12, 15 weeks after, cells were seeded in methylcellulose for colony assays and each harvested colony was genotyped to assess the presence of JAK2 wild type (WT) and JAK2 V617F alleles. *Results.* 10^5 to 10^6 $CD34^+$ cells were injected in one to 3 mice per patient's sample. Three weeks after transplant, the mean percentage of human cells ($CD45^+$, $CD45^-/CD36^+$, $CD45^-/CD36^-/GpA^+$) was 22±21% but decreased to 6±6% at week 6. This decrease of engraftment was

observed in all mice. Analysis of long-term reconstitution (12 and 15 weeks post-transplant) distinguished 2 groups of mice: 1) most of them (25 patients' samples) had a progressive reduction in human cell engraftment, with a majority of CD19+ cells, such as observed in mice repopulated with normal CD34+ cells. No engraftment was detected in secondary transplant. 2) On the contrary, a small number of mice (2 repopulated with PMF cells and 1 with PV cells) developed a MPD-like syndrome characterized by an increase in human cell engraftment, a majority of CD33+ cells and even some GpA positive cells. Genotypic analysis of human colonies demonstrated that the first group of mice contained a majority of JAK2 WT colonies. However, in this group, we could also observe some heterozygous colonies at 12 and 15 weeks after transplant, in 2 mice reconstituted with cells from 2 PV patients, confirming that the JAK2 V617F mutation is indeed present in HSCs. Genotyping of the second group of mice is still under investigation and the results will be presented. *Conclusions.* Using NOD/SCID mice we demonstrated that the JAK2 V617F mutation is present in only a minority of HSCs in MPDs and that it does not induce self-renewal advantage in human HSCs. We can hypothesize that the HSCs engrafted in mice that develop a MPD-like syndrome probably have an additional genetic event that modifies their stem cell properties.

A MOLECULAR CLASSIFICATION OF LEUKAEMIA REVEALS MDS AS A DISEASE CONTINUUM WITH NON-LEUKAEMIA AND AML SUB GROUPS

KI. Mills,[1] A.F. Gilkes,[1] J. Hernandez,[2] W.-K. Hofmann,[3] A. Kohlmann,[4] M. Williams,[4] L. Wieczorek,[4] T. Haferlach[5]

[1]Cardiff University, CARDIFF, United Kingdom; [2]Haematologia, SALAMANCA, Spain; [3]Charite, BERLIN, Germany; [4]Roche Molecular Systems, PLEASANTON, USA; [5]MLL, Munich Leukemia Laboratory, MUNICH, Germany

Robust gene expression signatures associated with distinct sub-classes of paediatric and adult leukaemias have been identified from microarray studies. Recently, the MILE (Microarray Innovations in LEukemia) study group has compared the accuracy of gene expression profiling to gold standard diagnostic workup for ~2000 patients within 16 acute and chronic leukaemia subclasses, MDS, and non-leukaemia as control group in 11 centres (ELN: 7, USA: 3, Singapore: 1). The overall cross-validation accuracy was very high for the leukaemia subclasses: >95%. Based on this data set a customized AmpliChip Leukemia microarray has been designed for leukaemia classification. However, only 49.1% of the 173 MDS samples included in the study were correctly called as MDS from their underlying gene expression profiles. The remainder were approximately equally split between an algorithm classification call of *non-leukaemia* (24%) and *AML* (24.6%). Our analysis showed that neither centre nor age were a factor in differentiating between *MDS*, *MDS with an AML-like signature* or *MDS with a non-leukaemia like signature*. WHO classification was highly correlated with the microarray classification result; specifically RAEB (I or II) was associated with *AML-like signature* ($p<0.0001$) whilst, RA/RARS was highly correlated with *MDS* or *non-leukaemia-like signature*. Furthermore, IPSS was significantly correlated with classification call ($p>0.0001$): 65% of patients with an IPSS score of Int-2 or above were classified as *AML*. Individually, the blast, karyotype and cytopenia contributions were highly significant ($p<0.0001$, <0.013 and <0.0001 respectively) when comparing *MDS like AML*, *MDS* and *MDS like non-leukaemi*a samples. Survival data (available for 122 of the diagnosed MDS patients) showed that MDS patients called *MDS like AML* had a trend towards shorter survival ($2p=0.2$) than those called *MDS* or *MDS like non-leukaemia*. The mapped molecular pathways and functions between these sub-groups may give an indication of the molecular steps involved in disease evolution and lead to a molecular redefinition of MDS. An external review of the morphology slides by two experts in the field has been completed with a few samples being reclassified or excluded from the MDS analysis: mainly as a result of being reclassified as true AML. The Amplichip Leukemia is also being used in the prospective Stage II of the MILE study to further determine the molecular differences within the expression based sub groups of MDS.

MILE Study Group on behalf of Workpackage 13 of the European LeukemiaNET (ELN)

IDENTIFICATION OF THE CHROMATIN-REMODELING PROTEIN SATB1 AS A DEVELOPMENT-DEPENDENT LONG-RANGE TRANSCRIPTIONAL REGULATOR OF THE PU.1 GENE

U. Steidl,[1] C. Steidl,[2] A. Ebralidze,[1] H.J. Han,[3] B. Will,[1] F. Rosenbauer,[4] S. Kobayashi,[1] K.B. O'Brien,[1] D. Haase,[5] T. Kohwi-Shigematsu,[6] D.G. Tenen[1]

[1]Harvard Institutes of Medicine, BOSTON, MA, USA; [2]British Columbia Cancer Agency, VANCOUVER, Canada; [3]Lawrence Berkeley National Laboratories, BERKELEY, CA, USA; [4]Max Delbrueck Center for Mol. Medicine, BERLIN, Germany; [5]University of Goettingen, GOETTINGEN, Germany; [6]Lawrence Berkeley National Laboratory, BERKELEY, CA, USA

Expression of the transcriptional master regulator PU.1 is dependent on a highly conserved upstream regulatory element (URE) located many kilobases upstream of the transcriptional start site. The proximal promoter of PU.1 alone, without this enhancer, displays 100-fold reduced promoter activity in reporter assays and is not capable of driving PU.1 expression in transgenic mice. Targeted disruption of the URE reduces PU.1 expression by 80% and leads to acute myeloid leukemia (AML) in mice. However, the mechanisms mediating the long-range regulatory function of the URE are largely unknown. In this study, we identified a binding site of the chromatin remodeling special AT-rich sequence-binding protein 1 (SATB1) in the URE of PU.1. Utilizing EMSA and ChIP, we found that SATB1 binds to the URE in myeloid U937 cells *in vitro* and *in vivo*. Luciferase assays in stably transfected U937 cells demonstrated 7-fold reduced reporter activity upon disruption of the SATB1 binding site. When we transduced U937 cells or primary murine Lin-, Kit+ progenitor cells with a SATB1-IRES-GFP lentivirus, we found an upregulation of PU.1 expression in sorted GFP+ cells. We did not observe this effect in URE-/- progenitors indicating that the PU.1 regulatory function of SATB1 is mediated by the URE. 75% inhibition of SATB1 by stable transfection of a construct expressing a SATB1-directed siRNA into U937 cells led to a 3-fold decrease in PU.1 expression levels. This inhibitory effect was not seen in a myeloid cell line derived from URE-/- mice, again demonstrating that the regulatory function of SATB1 is dependent on the URE. To address the question at which stages during myeloid development SATB1 regulates PU.1, we sorted KSL-HSC (Kit+, Sca1+, Lin-), CMP (Lin-, Kit+, Sca1-, CD34+, FcgRII/IIIlow), GMP (Lin-, Kit+, Sca1-, CD34+, FcgRII/IIIhigh), and MEP (Lin-, Kit+, Sca1-, CD34-, FcgRII/III-) from SATB1 knockout mice and determined PU.1 expression levels by quantitative real-time RT-PCR. Interestingly, PU.1 expression levels were 88% and 80% reduced in SATB1-/- GMP and MEP, while KSL-HSC and CMP did not show significantly changed PU.1 levels. This finding indicates a stage-specific regulatory function of SATB1 during myelopoiesis. In conclusion, we have shown that the chromatin-remodeling protein SATB1 binds to the URE and acts as a development-dependent long-range transcriptional regulator of the PU.1 gene.

Background. Thalidomide-Dexamethasone (TD) is an active regimen both in patients with relapsing/refractory and in previously untreated patients with multiple myeloma. *Aims.* In the present trial we compare TD with standard Melphalan-Prednisone (MP) in previously untreated elderly patients with multiple myeloma. *Methods.* 276 patients have been enrolled so far (median age: 72 years, stage I: 12 (4%), stage II: 91 (33%), stage III: 173 (63%). Patients are randomized to Thalidomide 200mg/day and Dexamethasone 40 mg, days 1-4 and 15-18 (on odd cycles) and days 1-4 (on even cycles) or Melphalan 2.5mg/kg day 1-4 and Prednisone 2 mg/kg days 1-4, q 4-6 weeks. Thalidomide should be dosed up to 400 mg/day, if feasible. Patients achieving response or stabilization are randomized to maintenance treatment either with Thalidomide (maximal dose 200 mg/day)-Interferon alpha-2b (3Mega U, TIW) or Interferon alpha-2b (3Mega U/TIW). All patients are scheduled for monthly Zometa (4mg) during the entire period. Response is defined according Blade's criteria, plus nCR defined as IF positive CR and VGPR defined as >90% reduction in PP. Statistical results are given by intend to treat and per protocol analysis. *Results.* 197 patients are evaluable for response as yet. Best response to TD was: CR 7 (7%), nCR 20 (21%), and VGPR 13 (14%) PR 16 (17%), MR 10 (10%) yielding an ORR (CR-PR) of 58%. The respective results in patients on MP were: CR 4 (4%), nCR 10 (10%), VGPR 11 (11%), PR 25 (25%), MR 16 (16%), ORR 50% (ORR in TD vs. MP p=0.051). Analysis per protocol revealed an ORR of 72% in the TD and 52% in the MP group (p<0.01). Time to response and time to best response was significantly shorter in the TD (8, 11 weeks, respectively) compared to the MP group (10, 39 weeks, respectively; p<0.01, p<0.0047, respectively). There were more early treatment discontinuations in the TD arm (20 vs. 8, p<0.007). Patients on MP had statistically more frequently grade III-IV leukopenia, while for thrombocytopenia only a tendency for a higher incidence was noted (14% vs. 2%; p< 0.05, and 9% vs. 4%, p=0.252). Patients on TD had more grade II-III neuropathy (28% vs. 9%, p<0.001), psychological toxicity (18% vs. 7%, p<0.02), and a tendency for more skin toxicity (10% vs. 4%, p=0.09) compared to those on MP. Thromboembolic complications were seen in 9% of patients on TD and in 4% in those on MP (p=0.15). *Summary.* TD treatment was associated with a significantly shorter time to response and to best response, higher rate of CR-NCR, and a tendency for higher ORR in the intent to treat analysis. In the per protocol analysis, ORR was significantly higher in the TD arm. Patients on TD had more neuropathy and psychological toxicity, a tendency for more skin toxicity and thromboembolic complications, and a higher rate of early treatment discontinuations, while haematological toxicity was higher in patients treated with MP. Updated data on time to progression and survival for both groups combined will be presented at the meeting.

POSTER SESSION II

Allogeneic stem cell transplantation

0447

FAVORABLE OUTCOME FOLLOWING STEM CELL TRANSPLANTATION WITH UNMANIPULATED GRAFTS OF HLA 7-8/10 ALLELE MISMATCHED UNRELATED DONORS IN CHILDREN

P. Sedlacek,[1] R. Formankova,[1] P. Keslova,[1] M. Dobrovolna,[2] M. Vrana,[2] L. Kupkova,[3] H. Pittrova,[4] J. Stary[1]

[1]University Hospital Motol, PRAGUE; [2]Inst. of Hematol. and Blood Transfusion, PRAGUE; [3]Czech Stem Cell Registry, PRAGUE; [4]Czech National Marrow Donors Registry, PILSEN, Czech Republic

Background. Allogeneic hematopoietic stem cell transplantation (HSCT) is an efficient curative treatment for certain malignant and non-malignant diseases. Unfortunately in central Europe only 15% of the indicated children have an HLA-matched sibling available and in around 65-70% others HLA allele matched (9-10/10) unrelated donor (UD) could be identified in registries worldwide. For the rest of patients (15-20%) it is necessary to identify other alternative donors such as HLA mismatched family or unrelated donor or cord blood. Here we report our single-center clinical experience of HSCT using HLA partially mismatched (7-8/10) unrelated donors. *Patients and Methods.* 27 children (age range 0.4-18.1 years; median 9.0) were transplanted at our center between I/2001 and XII/2006 for malignant (n=20; 74%) and non-malignant disease (n=7) using unmanipulated grafts from UD mismatched in two or three HLA alleles. HLA allele mismatches were in patients and UD prospectively identified by PCR SSP four digits (A* 3x, B* 18x, Cw* 28x, DRB1* 3x, DQB1* 10x). No donor/patient pair was mismatched in more than one allele in loci A*, B* or DRB1*. The median interval between start of search till the day of graft infusion was 142 days (range 68-492). Standard myeloablative conditioning regimen was used in majority of patients. Median age of UD was 34 (range 22-49 years) with 14 males and 13 females. Serotherapy with rabbit ATG (Fresenius; 4x 10mg/kg/dose) and cyclosporine A (CsA) with standard short term methotrexate (MTX) were used as graft versus host (GvHD) prophylaxis. Primary grafts were peripheral blood stem cells (PBSC; n=16) and bone marrow (BM; n=11). Four patients later received five grafts (all PBSC) for graft failure (2) or leukemia relapse (2). Informed consent form was signed by parents and approved by local ethical committee. *Results.* Stable primary engraftment was achieved in 25/27 (93%) children, two with acute graft failure were successfully re-grafted using the same UD. 96% of patients achieved stable complete donor chimerism (VNTR/STR). Acute GvHD grade II was diagnosed in 21 (78%) of them, grade III-IV in 1 (3.7%). Extensive chronic GvHD was diagnosed in 7 of 26 evaluable patients (27%). Transplant related mortality (TRM) at day+100 is 3.7% with overall TRM 18.5% (mainly in patients with repeated transplants). Overall survival (OS) of the whole cohort is 74% with median follow-up 34.5 months (3-71 months). Altogether 7 patients died in median 289 days post-transplant (range 44-602), 2/20 (10%) died in a consequence of leukemia relapse 451 and 502 days post-transplant. OS is better in recipients of PBSC (81%) compare to 64% in those receiving BM, but this difference is not relevant due to small cohorts. *Summary and conclusions.* Combination of rATG/CsA/MTX for GvHD prophylaxis represents efficient modality even for patients transplanted with unmanipulated grafts from HLA markedly mismatched UD, enabling stable engraftment, good control of GvHD and full reconstitution of immunity. Furthermore this approach is feasible, not connected with unacceptable early or late TRM. No patient in this cohort died due to EBV related lymphoproliferative disease, one died due to CMV pneumonia.

A NOVEL MDR-DEPENDENT PHARMACOLOGICAL APPROACH FOE *EX VIVO* EXPANSION OF HEMATOPOIETIC STEM CELLS (HSCS) FROM HUMAN UMBILICAL CORD BLOOD (HUCB) FOR TRANSPLANTATION

A. Nagler, I. Bar, A. Treves, H. Galski

Chaim Sheba Medical Center, TEL HASHOMER, Israel

While HUCB is an attractive alternative source of hematopoietic stem cells (HSCs) for allogeneic transplantation (alloSCT), major disadvantage is its relative low number of HSCs. A rational approach, thus, involves

ex-vivo expansion of HUCB-derived HSCs. The multidrug transporter MDR1 (ABCB1) gene product (Pgp) and ABCG2 channel transporter reported being over-expressed in various stem cells relatively to their differentiated progeny. We, therefore, compared the expression level and activity of Pgp in HUCB-derived $CD133^+$ HSCs relatively to $CD133^-$ cells. Moreover, we reasoned that higher Pgp activity in these $CD133^+$ HSCs will make them more resistant to cytostatic agents as colchicine (COL) and thus its presence during the expansion process could be applicable to their selection and enrichment. Towards this end, we isolated $CD133^+$ HSCs from HUCB by CD133-immunomagnetic separation (MACS). Pgp-expression level was measured by flow cytometry using the Pgp-antibodies MRK-16, and its activity was measured by accumulation assay of the Pgp-substrate Rh123. We further analyzed the $CD133^+/Pgp^+$ and the $CD34^+/CD38^-/Pgp^+$ subsets during 8 weeks of standard cytokines based expansion in the presence or the absence of COL. Analyses of freshly isolated $CD133^+$ HSCs from various donors (n=6) indicated that the majority (>92%) of these HSCs express Pgp on the cell surface. Moreover, the Pgp is functional as the accumulation of Rh123 was approximately 260-fold lower relatively to CD133 negative cells and the Pgp inhibitor R-VRP inhibited the efflux of Rh123. Analyses after *ex vivo* expansion demonstrated a significant dose-dependent enrichment of $CD133^+$ cell fraction by COL. At optimal COL dose (2.5 ng/mL, the relative fold-enrichment of $CD133^+/CD34^+/CD38^-$ HSC was 5.2±2.3. At 8 weeks of expansion the $CD133^+$ cell number increased from 105 cells to $1.6\pm0.4\times10^9$ and $0.6\pm0.2\times10^9$ in the presence and absence of COL, respectively and thus the total yield of $CD133^+$ HSCs after expansion in the presence of COL was 2.9±0.5 fold higher than in its absence. The long exposure of CD133+ HSC to COL at the expansion process did not affect their ability to form hematopoietic colonies in semisolid cultures. In conclusion, we show that HUCB-derived HSCs over-express a functional Pgp that may be used as a novel tool for their expansion *ex vivo* towards clinical transplantation.

PATIENT HSP70-HOM TG HAPLOTYPE IS ASSOCIATED WITH DECREASED TRANSPLANT-RELATED MORTALITY AND IMPROVED SURVIVAL AFTER SIBLING HLA-MATCHED HEMATOPOIETIC STEM CELL TRANSPLANTATION

I. Kim,[1] J.H. Kim,[2] J.Y. Rhee,[1] E.K. Ra,[1] S.C. Park,[1] E.K. Park,[1] B.S. Kim,[1] S.S. Yoon,[1] Y.C. Hong,[2] S.S. Park,[1] M.H. Park,[1] S. Park,[1] B.K. Kim[1]

[1]Seoul National University Hospital, SEOUL; [2]Seoul National University, SEOUL, South-Korea

Background. Heat shock protein 70 hom (HSP70-hom) gene is known to play an important role in protein folding and immune responses. Therefore, HSP70-hom gene polymorphisms may act as important factors predicting prognosis in patients receiving allogeneic hematopoietic stem cell transplantation (HSCT).

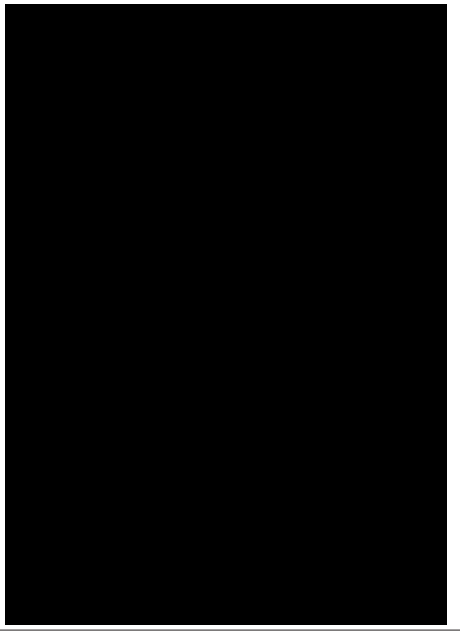

Figure 1. Overall survival and treatment-related mortality according to TG haplotype or non-TG haplotype.

Aims. The aim of this study is to evaluate the role of HSP70-hom gene polymorphisms in prognosis of patients receiving sibling human leukocyte antigen (HLA)-matched allogeneic HSCT.*Methods.* The HSP70-hom polymorphisms, T2437C and G2763A, were genotyped in 147 patients receiving sibling HLA-matched allogeneic HSCT, and individual diplotypes were estimated from genotype data of two HSP70-hom polymorphisms using the expectation maximization algorithm. *Results.* Patients with 2763GG or GA genotype showed longer overall survival compared with those with 2763AA genotype, and patients with TG haplotype (TG/TA, TG/TG or TG/CG) also showed longer overall survival compared with those without TG haplotype (TA/TA or TA/CG) (both G2763A genotype and diplotype, $p<0.01$). Moreover, 2437TT genotype was found to be protective for treatment-related death compared to 2437TC genotype, and TG haplotype (TG/TA, TG/TG or TG/CG) was found to be very protective for treatment-related death compared to non-TG haplotype (TA/TA or TA/CG) (T2437C genotype, $p=0.04$; and diplotype, $p=0.02$). *Conclusions.* Therefore, our results suggest that polymorphisms of the HSP70-hom gene play an important role in the prognosis of patients receiving sibling HLA-matched allogeneic HSCT.

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITHOUT *IN VITRO* T-CELL DEPLETION FOR THE CHRONIC MYELOID LEUKEMIA: IMPROVED OUTCOMES IN PATIENTS WITH ACCELERATED PHASE AND BLAST CRISIS PHASE

X.-J. Huang, L.-P. Xu, K.-Y. Liu, D.-H. Liu, H. Chen, W. Han, Y.-H. Chen, J.-Z. Wang, Y. Chen, X.-H. Zhang, H.-X. Shi, D.-P. Lu

Peking University Institute of Hematology, BEIJING, China

Backgroud. Allogeneic hematopoientic stem cell transplantation (Allo-HSCT) remains the only proven curative therapy for chronic myeloid leukemia (CML), but many patients have no suitably HLA matched related or unrelated donors. Recently, we developed a new method for haploidentical allo-HSCT without *in vitro* T-cell depletion, which could achieve comparable outcomes to HLA identical sibling transplantation. So good outcomes of HSCT from mismatched family donor for CML patients could be expected. *Methods.* Ninety-three patients, including 51 cases in CP1, 14 cases in CP2, 15 cases in AP and 13 cases in BC pre-HSCT, who underwent mismatched family donor HSCT were analyzed. Patients received the modified BU/CY2 regimen consisting of cytarabine, busulfan, cyclophosphamide, simustine and ATG. Both of donor G-BM (G-CSF immobilized) and G-PB were harvested and infused to recipients. All patients were given CsA/MTX and MMF for prophylaxis of GVHD. *Results.* All patients achieved full donor chimerism. The cumulative incidences of aGVHD is 64.52% (CI 55.49%-75.01%)?grade III-IV is 26.45% (CI 17.51%-39.95%). The cumulative incidence of total cGVHD was 61.79% (CI 49.33%-77.39%) and 28.93% (CI 19.25%-43.46%) for extensive chronic GVHD at 2 years after transplantation. The non-relapse mortality was 8.72% for 100 days, 20.72% for 1year and 20.72% for 2 years. 100d TRM of patients in CP1, CP2/CR2, AP, BC are 7.8%, 7.1%, 13.3%, 7.7%, 1 year TRM of patients in CP1, CP2/CR2, AP, BC are 28.3%, 16.92%, 13.33%, 7.69% respectively, there are no different among them ($p=0.622$). The probability of 1-year and 4-year LFS was 76.5%, 74.5% for CP1 patients; 85.7%, 85.7% for CP2/CR2 patients ; 80%, 66.7% for AP patients; 53.8%, 53.8% for BC patients ($p=0.221$). At present, all living patients who relapsed after transplantation achieved CMR. The probability of 4-year OS was 76.5% for CP1 patients, 85.7% for CP2/CR2 patients 73.3% for AP patients and 61.5% for BC patients ($p=0.7442$). Multivariate analysis showed that factors affecting transplantation outcomes were 3-4 aGVHD for LFS, OS, TRM, and the stage of disease at transplantation for relapse. *Conclusions.* For patients with CML without an HLA identical sibling donor, haploidentical family members can be an alternative donor for HSCT. In our HSCT protocol, survival of HSCT for CML in advanced stage was no worse than that in stable stage. The optimal time of HSCT for CML patients from MM-family donors need to be further studied.

0451

CHLORAMBUCIL AND FLUDARABINE AS A NEW PRE-TRANSPLANT CONDITIONING FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA : RESULTS OF *IN VITRO* AND *IN VIVO* EXPERIMENTS

J. Mayer,[1] J. Berankova,[2] M. Doubek,[1] D. Horky,[3] M. Trbusek,[1] J. Chumchalova,[1] S. Pospisilova[1]

[1]University Hospital Brno, BRNO; [2]Univ. of Vet. and Pharm. Medicine, BRNO; 3Masaryk University, Medical Faculty, BRNO, Czech Republic

Background. CLL, incurable by standard treatments, may by potential-

ly cured by allogeneic hematopoietic stem cell transplantation. Since CLL affects predominantly older people, there is a need for some low-toxicity conditioning with, on the other hand, strong anti-leukemia activity. Since there are very encouraging results with busulfan + F conditionings in myeloid malignancies, and since the clinical study with the combination treatment with CHL + F was stopped prematurely for myelotoxicity, we hypothesized, that this CHL + F combination might have the potential as a good conditioning for high-risk lymphoid malignancies. *Aims.* To test the CHL + F combination *in vitro* and *in vivo* (rats) for anti-leukemia effects and for toxicity. *Methods. In vitro* cell viability testing: DHL-4 (mut-p53), DOHH2 cell lines (wt-p53), and three B-CLL primary cultures (two wt-p53 and one mut-p53) were used for WST-1 viability assay. Animal experiments: Male Wistar rats were used for all experiments. First, the maximal tolerated dose (MTD) of either drug was tested. For F, doses of 0.75 - 60 mg/kg/d were used, and for CHL, doses of 0.15 - 50 mg/kg/ were used, all administered for 5 days. Then, the combination treatment was tested: 1) F+CHL, 2) F followed by CHL, 3) CHL followed by F; all drugs were administered for 5 days. *Results. In vitro* testing: Cell lines testing did not reveal significant differences between simultaneous vs. sequential drug applications. The combination treatment of CLB and FLU caused a prominent decrease of viability in p53-mut cells compared to individual drugs alone both for cell lines and for B-CLL cells, which can have significant clinical importance. Animal experiments. For F alone, the MTD has not been reached. Clinically, the rats tolerated well even the highest doses. Moreover, no myelotoxicity was seen. However, histological examination found pneumotoxicity, hepatotoxicity, nephrotoxicity, and gastrointestinal toxicity. For CHLB alone, the MTD is about 40-50 mg/kg/d. Pneumotoxicity, nephrotoxicity, gastrointestinal toxicity, and mild myelotoxicity was seen. Combination treatment tested fixed dose of F (3 mg/kg/d) and three doses of CHL (1, 2, and 4 mg/kg/d). Clinically, the combination tolerated at best was F followed by CHL. Myelotoxicity was mild, usually affecting predominantly lymphocytes, and interestingly, was most pronounced in the clinically best tolerated regimen. *Conclusions.* Rats can tolerate extremely high doses of F and CHL. Based on these experiments, for further development, hopefully into the clinical usage, we could recommend administration of fludarabine, followed by chlorambucil. This combination will be further tested together with monoclonal antibodies and total lymphoid irradiation.

0452

HAEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) FOR HIGH RISK REFRACTORY MULTI SYSTEM LANGERHANS CELL HISTIOCYTOSIS (MS-LCH) IN CHILDREN

M. Caniglia,[1] R.M. Pinto,[1] I. Rana,[1] A. Lombardi,[1] M. El Hachem,[1] F. Zinno,[1] G. Isacchi,[1] W. Arcese,[2] G. De Rossi[1]

[1]Bambino Gesù Children's Hospital, ROME; [2]Hematology Tor Vergata University, ROMA, Italy

Background/Aims. LCH is a heterogeneus proliferative disease varying between a reactive or a neoplastic process. The Histiocyte Society Working Group identified a *single system* LCH as usually associated with a favourable prognosis, while *multisystem* LCH as an extremely variable but aggressive clinical course. The LCH-II Study showed that response to initial therapy is a powerful prognostic predictor; MS-LCH patients non-responders after 6 weeks of initial therapy, have extremely poor prognosis with only 17% of survival at 3 years. The high rate of mortality in this latter subgroup justifies an early switch to salvage approaches; HSCT has been indicated as an alternative salvage therapy. Myeloablative conditioning regimens were associated with a high treatment-related morbidity and mortality while Reduced Intensity Conditioning regimen, recently reported by an Histiocyte Society Study, has an increased risk of non-engraftment and graft rejection. *Methods.* Here we describe four consecutive refractory MS-LCH paediatric patients diagnosed and treated at the Haematology Department of Bambino Gesù Children's Hospital. All patients were males with a median age at diagnosis of 9 months (4-25 months). All received first-line LCH therapy according to the study protocol LCH-II or LCH-III and all experienced severe disease progression, unresponsive to chemotherapy. All patients recived allogeneic HSCT at median of 38 months after diagnosis (10-72 months). Stem cell source was HLA-matched sibling donor in two cases and unrelated cord blood (CB) donor (1 and 2 HLA mismatched antigens) in the remaining two. Conditioning regimen included oral Busulfan (16 mg/kg) + Fludarabine (120 mg/m^2) in 4 days + Thyotepa (10 mg/kg) for 1 day. GvHD prophylaxis consisted of Cyclosporine, horse Antilymphocyte Globulin and Methylprednisolone. *Results.* Median time to neutrophil engraftment was 43 days (14-99 days), while platelets engraftment was 136 days (19-437 days). All patients reached full donor chimerism at day 25, 24, 25, 41 respectively, which persisted until the last follow-up. Three patients presented acute GvHD (two patients grade II, with skin involvement and one grade III, with skin and gut involvement). Long term follow-up showed a *peculiar* recovery from the underlying disease. In the post transplant period no additional therapy specific for LCH was administered to any patient. *Conclusions.* The literature reports enlist only 38 LCH patients who underwent HSCT. Therefore, even if limited to 4 patients, our prospective unicentric contribute could be significant to consider: HSCT is a good salvage approach for resistant LCH patients with MS organ involvement unrelated CB is a reliable alternative option in high-risk patients lacking sibling donor. By using an immune-myeloablative conditioning regimen, all patients obtained a full stable engraftment with no TRM even if a diffuse disease was present at moment of HSCT and regardless of the stem cell source . Acute GvHD did not exceed grade III. At the time of last follow-up (median 1470 days; range 990-1920), all patients are still alive in absence of active LCH disease (Lansky scale> 90%).

Table 1. HSCT characteristics and results.

CHRONIC KIDNEY DISEASE AFTER MYELOABLATIVE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Kersting, R.J. Hené, H.A. Koomans, L.F. Verdonck

UMC Utrecht, UTRECHT, Netherlands

Background. Because many recipients of hematopoietic stem cell transplantation now have long term survival, late complications become more important. Chronic kidney disease is a complication that is not well-established after stem cell transplantation. *Aims.* The aim of this study was to determine incidence of chronic kidney disease in recipients of allogeneic stem cell transplantation with a long follow up, and to determine baseline factors, complications and mortality associated with chronic kidney disease. *Methods.* We performed a single centre retrospective cohort analysis on 271 adult patients that received a hematopoietic stem cell transplantation between 1993 and 2004 and survived for more than 6 months. All patients had a myeloablative conditoning regimen that consisted of cyclophosphamide (60 mg/kg/day for two days), followed by total-body irradiation (600 cGy/day for two days) with partial shielding of the lungs (total lung dose 850cGy) and partial shielding of the kidneys (500 cGy/day for 2 days). Follow up was through February 2006. Primary outcome was the incidence of chronic kidney disease defined as a glomerular filtration rate (GFR) of < 60 mL/min/1.73 m^2, calculated using the Modification of Diet in Renal Disease (MDRD) study equation. *Results.* Chronic kidney disease developed in 62 (23%) of 271 patients. Severe kidney disease (GFR of < 30 mL/min/1.73 m2) developed in 8 (3%) of 271 patients, of which 2 patients needed dialysis. Factors associated with chronic kidney disease were lower GFR (p<0.0001, OR 0.98 95% CI 0.96-0.99) and higher age (p=0.020 OR 1.04 95% CI 1.01-1.08) at baseline, and the occurrence of hypertension after transplantation (p=0.014, OR 0.46 95% CI 0.24-0.86). Gender, diagnosis, type of transplant, mismatch, presence of high-risk malignancy, history of hypertension, previous autologous transplantation, acute renal failure, thrombotic thrombocytopenic purpura, sinusoidal occlusion syndrome, acute graft-versus-host disease, chronic graft-versus-host disease, cytomegalovirus reactivation and longer than 3 months cyclosporine use did not differ statistically between the groups with or without chron-

ic kidney disease in univariate or multivariate analysis. Mean follow-up of surviving patients was 7.0 years (range 1.7-13.1 years). Death occurred in 107 patients (40%) after a mean of 2.0 years (range 0.5-12.6 years) due to relapse (19%) or treatment related mortality (21%). There was no significant difference in survival between patients with and without chronic kidney disease. *Conclusions.* Chronic kidney disease is a common late complication of myeloablative allogeneic hematopoietic stem cell transplantation. Lower GFR and higher age at baseline and the occurrence of hypertension after transplantation are associated with development of chronic kidney disease. It is known that chronic kidney disease in general is a risk factor for cardiovascular disease. Decreased GFR is associated with high blood pressure, anemia, malnutrition, bone disease, neuropathy and decreased overall functioning and well-being. In order to prevent morbidity and mortality of chronic kidney disease, all recipients of allogeneic stem cell transplantation should be monitored lifelong for renal function and hypertension and be treated according to guidelines developed for chronic kidney disease in general.

TRANSPLANT-RELATED MORTALITY AFTER ALLOGENEIC REDUCED INTENSITY CONDITIONING HEMATOPOIETIC STEM CELL TRANSPLANTATION: A STUDY ON INFLUENCE OF PARAMETERS BEFORE AND AFTER TRANSPLANT

M. Micahllet, Q.H. Le, N. Raus, D. Revesz, A. Thiebaut, X. Thomas, Y. Chelgoum, S. Ducastelle, J. Troncy, M. Clark, F. Nicolini

Hôpital Edouard Herriot, LYON, France

We studied the impact of demographic, pre and post-transplant parameters on transplant related mortality (TRM) in 141 allogeneic reduced intensity conditioning transplant (RICT). There were 52 female and 89 male recipients [median age: 51 yrs], 71 female and 70 male donors [48.5 yrs]. There were 83 sex-mismatched pairs (59%), 48 ABO incompatibilities (34 minor, 14 major) and 68% CMV seropositive pairs. 33 patients received bone marrow, 105 peripheral blood stem cells with a median $CD34^+$ cell number of 5×10^6 /kg (0.42-64) and a median number of $CD3^+$ cells of 197×10^6 /kg (0-761) and 3 cord blood cells from 121 related donors and 20 unrelated donors (17 HLA matched and 3 mismatched), 48% of cases were previously transplanted. For conditioning, 68 patients received Fluda+Busulfan+ATG with dose varying from 2.5 mg/kg to 12.5 mg/kg, 39 Fluda+TBI (2 grays), 6 Fluda+Treosulfan+ATG and 28 other combinations. The GVHD prophylaxis consisted of methotrexate+Ciclosporine (CsA) for 41 patients, CsA alone for 50, CsA+MMF for 39 and other combinations for 11. The diagnosis pre-transplant were 30 AML, 5 ALL, 13 CML and myeloproliferative disorders, 8 Hodgkin disease, 10 CLL, 16 MDS, 43 MM and 16 NHL; 40 were in CR (28%), 54 in PR (38%), 4 in stable disease and 43 in progressive disease (30%). The median interval between diagnosis and transplant was 20 months (5-300). We observed 10 graft failures, 51 patients (39.5%) developed acute GVHD≥II and 54 (42%) chronic GVHD (28 limited - 26 extensive). At the last follow-up, 73 patients (52%) relapsed and 97 patients had died (55 from TRM causes and 42 from relapse), 43 (30.5%) received DLI. The TRM at 1 year and 3 years was 24% and 34% respectively. We analyzed in multivariate analysis using a Cox proportional hazard model the relation between TRM and (1) demographic parameters: donor and recipient age, sex-matching (2) pre and post-transplant variables: number of previous transplant, ABO compatibility, HSC source, conditioning, ATG dose, status of disease and acute GVHD. We found a significant positive impact of disease status on TRM (HR=0.17 95%CI 0.03-0.77 p=0.02) and a significant negative impact of minor ABO incompatibility (HR=4.60 95%CI 1.25-16.65 p=0.02). This retrospective analysis showed that TRM in RICT for this high risk population is significantly influenced by disease status and minor ABO incompatibility which pointed out the importance of donor choice, transfusion rules and methotrexate addition in this case.

0455

REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION) AS SALVAGE TREATMENT FOR RELAPSING MULTIPLE MYELOMA (MM): A *DONOR* VS. *NO DONOR* COMPARISON

H. de Lavallade,[1] P. Ladaique,[1] C. Faucher,[1] S. Furst,[1] J. El Cheikh,[1] A.M. Stoppa,[1] D. Coso,[1] R. Bouabdallah,[2] N. Vey,[1] D. Sainty,[1] C. Chabannon,[1] J.A. Gastaut,[1] D. Blaise,[1] M. Mohty[1]

[1]Institut Paoli Calmettes, MARSEILLE; [2]Imperial College IT Society, MARSEILLE, France

The role of RIC allo-SCT in MM is still controversial. This single centre study aimed to evaluate RIC allo-SCT for relapsed MM, using a genetic randomization through a donor vs. no donor comparison. Between 2002 and 2005, 32 patients with relapsed or refractory MM, and with an identified sibling, were referred to our centre for HLA typing. In all, 19 patients (59%; donor group) had an HLA-identical sibling donor, while the remaining 13 pts (41%; no donor group) had no HLA-identical sibling donor. There were no significant differences between these two groups that were comparable as for demographic, disease and prognosis factors. Median age was 54 (range, 37-65), and all pts had previously failed auto-SCT. Pts from the no donor group received salvage therapy including thal., bortezomib, dex., and/or additional high dose chemotherapy. Among the 19 pts from the donor group, 18 (95%) could proceed to allo-SCT. With a median overall FU of 36 m., 11 patients (85%;95%CI:54-98%) from the no donor group had disease progression despite salvage therapy, and only 6 of them are still alive, of whom 5 (80%) in progressive disease at last FU. In contrast, only 5 pts (28%; p=0.001) from the donor group progressed after RIC allo-SCT. In the RIC allo-SCT group, 10 pts (56%;95%CI;33-79%) are still alive, with 4 pts being in CR, and 5 in PR or VGPR. Only one patient is currently experiencing disease progression and receiving salvage therapy. Interestingly, 11 pts (61%;95%CI,39-83%) from the RIC allo-SCT group showed objective disease response, usually concurrent to chronic GVHD. In all, 6 pts died from TRM for an overall incidence of TRM of 33% (95%CI,11-55%) in this population of heavily pretreated and relapsed or refractory MM population. In an intention-to-treat analysis, the KM estimate of progression-free survival was significantly higher in the donor group as compared to the no donor group (p=0.01;46%vs.8% at 3 y.; Figure 1). In all, these results compare favorably with those achieved using other standard non-allo-SCT salvage therapies for relapsed MM. Therefore, RIC allo-SCT from an HLA-identical sibling is a feasible and potential therapy that should be proposed for refractory or relapsed MM, since a potent graft-vs.-MM effect can be induced despite heavy pretreatments, allowing for significantly longer PFS. Also, the latter results are expected to be further improved with the systematic and early use of maintenance therapies after RIC allo-SCT.

REDUCED INTENSITY SIBLING ALLOGENEIC STEM CELL TRANSPLANTATION AND DONOR LYMPHOCYTE INFUSIONS IN SEZARY SYNDROME AND ADVANCED MYCOSIS FUNGOIDES RESULT IN DURABLE CLINICAL AND MOLECULAR REMISSIONS

I. Gabriel,[1] A. Chaidos,[1] J. Apperley,[1] S. Whittaker,[2] R. Russell-Jones,[2] S. Morris,[2] J. Scarisbrick,[2] E. Olavarria[3]

[1]Hammersmith Hospital NHS Trust, LONDON; [2]Skin Tumour Unit, St Johns Institute, LONDON; [3]Hammersmith Hospital, LONDON, United Kingdom

Background. Prognosis for tumour stage Mycosis fungoides (MF) and Sézary syndrome (SS) is poor with a median survival of approximately 5 years. Treatment for advanced stage disease is currently largely palliative, and allogeneic stem cell transplantation (SCT) with the potential of mounting graft versus lymphoma effect (GvL) could result in long-term complete clinical and molecular remission *Aims.* In this pilot study, we looked at the role of reduced intensity conditioned (RIC) HLA matched sibling allogeneic transplants on survival in advanced stage MF/SS. We

also looked the role donor lymphocyte infusions (DLI) for post-transplant relapse in the absence of clinically significant graft versus host disease (GVHD). *Methods.*METHODS Six patients were enrolled into our programme of HLA matched sibling allogeneic haematopoietic stem cell transplantation (HSCT) for Sézary syndrome and advanced cutaneous T-cell lymphoma (CTCL). Sézary syndrome n=3, tumour stage MF n=2, and the erythrodermic variant of MF n=1. All six patients were in advanced stage disease (stage IIIA or above) at time of transplant conditioning. All patients were conditioned with a reduced intensity regime using Campath-1H Fludarabine and Cyclophosphamide. Disease status pre and post-transplant was monitored clinically, radiologically and molecularly by PCR for TCR gene rearrangement. Upon disease relapse post-transplant, and in the absence of graft versus host disease (GVHD) a programme of escalating dose DLI with a starting dose of 10×10^6/kg CD3 positive T-cells was commenced. *Results.* Of the six patients who had a RIC SCT, five demonstrated a clinical complete remission (CR), four of those also experienced a molecular CR. One patient died in CR of transplant related mortality (invasive aspergillosis). One patient developed autologous reconstitution and died of disease progression while four patients experienced early relapse with cutaneous disease and the re-emergence of a T-cell clone (median time to relapse 82.2 days (range: 28-100). One patient developed acute GVHD after withdrawal of immunosuppression and entered a molecular CR. Three patients received DLI. All three developed acute skin GVHD, and regression of the relapsed disease occurred concurrently. All three remain alive (median 32 months, range: 12-24 months) in clinical and molecular CR. The minimum dose to induce GVHD and result in CR2 was 10×10^6/kg CD3 T-cells. *Conclusions.* RIC-SCT can result in clinical and molecular remissions post-transplant in the majority of patients. However, most patients experience early relapse. Reduction of immunosuppression and donor lymphocyte infusions induce GVHD which is followed by regression of the relapsed disease and subsequent clinical and molecular complete remission. We believe that this is clear evidence of a graft versus tumour effect in patients with cutaneous T-cell lymphoma.

MULTI-DONOR STEM CELL TRANSPLANTATION (MDT) FROM HAPLOIDENTICAL MISMATCHED DONORS ENGRAFTMENT AND SAFETY DATA

M.Y Shapira, I.B. Resnick, B. Gesundheit, M. Bitan, S. Samuel, L. Dry, Y. Verkholevsky, S. Slavin, R. Or

Hadassah Hebrew University Medical Cen, JERUSALEM, Israel

Introduction. The aim of stem-cell-transplantation (SCT) is to combine tumor cytoreduction and to replace host with donor cells. For patients with no matched sibling available for allogeneic SCT (approximately 70% of patients) an alternative treatment option is SCT from a relative carrying only one identical HLA haplotype (haplo-SCT), which may provide a donor for almost every patient in need at optimal timing. Mandatory T-cell depletion (TCD) increases the risk of graft rejection and decreases the intensity and efficacy of GVT effect. In umbilical cord blood transplant, in order to overcome the delayed engraftment, the possibility of using several cord-blood units to increase the stem cell dose was investigated. In the small number of multi-cord transplants reported, it was found that usually only one unit engrafted faster, while the others were rejected. We hypothesized that multi-donors may improve the engraftment, GVT effect and immune reconstitution following haplo-SCT. *Patients and Methods.* Eleven ultra high-risk patients (median age 38 years, 9-54, mostly after 1-2 previous SCTs) were included. Conditioning regimen was fludarabine-TBI (n=8) or TLI-CY (n=3) based. All grafts were T-cell depleted. *Results.* All nine evaluable patients engrafted but one of them later rejected the graft. The time for neutrophil engraftment (0.5 and 1.0×10^9/L) was fast, 11 days (9-23) and 12 days (10-17) respectively. Platelets engrafted earlier (20 and 50×10^9/L), 9.5 days (8-11) and 11 days (9-14) respectively. Of 6 evaluable patients, all converted to single donor hematopoiesis within a median of 33 days (21-49). In 2 patients in-which the leukemia persisted throughout the conditioning, there was a noteworthy disappearance of leukemic cells during the conversion to single donor chimerism. Despite major blood type differences between the recipient and the 2 donor, no hemolysis related side-effects were noted. Two patients developed GVHD (grade 2 and 3). *Conclusions.* MDT is safe and induces fast and durable engraftment of both myeloid and thrombocyte lineages in patients undergoing haplo-SCT. Further studies should follow this report.

0458

FEASIBILITY AND OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA AFTER A FLUDARABINE-BASED INDUCTION PROGRAM

A. Candoni,[1] E. Simeone,[2] M. Battista,[2] F. Zaja,[2] F. Patriarca,[2] A. Sperotto,[2] M. Cerno,[2] A. Geromin,[2] R. Fanin[2]

[1]*Hematology Unit, UDINE;* [2]*Division of Hematology, UDINE, Italy*

There are only limited data about allogeneic stem cell transplantation (HSCT) in elderly patients (pts). In the present analysis we report the feasibility and outcome of HSCT in elderly pts with acute myeloid leukemia (AML) after a fludarabine-based induction program. Between 2000 and 2006, 62 consecutive AML pts aged 50 years or older (range 50-78) were treated with fludarabine-based induction regimen [FLAI+Mylotarg 20/62 (32%), FLAIE 28/62 (45%), FLAI 14/62 (23%)]; the median age at diagnosis was 59 years (range 50-78), high risk at onset 45/62 cases (76%). Thirty-eight of 62 pts (61%) achieved complete remission after induction chemotherapy (death during induction was only 3%). Twenty-four of these 62 pts (39%) underwent HSCT. The median time from diagnosis to transplant was 6 months. Disease status at time of transplant: high-risk 21/24 cases (88%), advanced disease 10/24 cases (42%), complete remission 14/24 cases (58%). Median age 60 years (range 50-69). Donor status: sibling donor 50% (12/24), unrelated donor 37% (9/24), haploidentical donor 13% (3/24). Twelve of 24 pts (50%) received a reduced intensity conditioning regimen (RIC). Conditioning regimen: Fludarabine + Busulfan 4/24 (17%), Thyotepa + Cyclophosphamide + ATG 8/24 (33%), Busulfan + Cyclophosphamide + ATG 7/24 (29%) and other regimens 5/24 (21%). Outcome: all patients achieved engraftment. Acute GvHD was observed in 11/24 pts (46%) with 8 having grades I-II and 3 having grades III-IV. Data on chronic GvHD was available for 14/24 pts (58%); of those 1/14 (7%) developed extensive chronic GvHD. Transplant-related mortality occurred in 3/24 pts (12%). At the time of analysis, after a median follow-up of 8 months (range 1-37), 14/24 pts (58%) were alive and in complete remission while 10/24 (42%) have died (leukemia relapse 7/10 and TRM 3/10). One and two year probability of Overall Survival (OS) was 70% and 56% respectively. The pts transplanted in complete remission have a significantly better OS and DFS compared to those transplanted with relapsed or refractory disease (log rank=0,01). These preliminary results are encouraging and compare favourably with results after conventional chemotherapy in elderly pts with AML. Related and unrelated donor HSCT is feasible in elderly pts with AML, with outcomes that are similar to younger pts. Favourable outcome was observed expecially in those transplanted in complete remission and early in the course of disease. Besides our data confirm the efficacy of fludarabide-based induction regimen for AML pts older than 50 yrs (61% of complete remission rate) allowing the treatment intensification with HSCT in a high proportion of cases (39%, 24/62).

0459

IMPACT OF ALLOGENEIC STEM CELL TRANSPLANTATION IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA PATIENTS AND CORRELATIONS WITH PGP EXPRESSION

M. Tiribelli,[1] D. Damiani,[2] A. Geromin,[2] A. Michelutti,[2] D. Russo,[3] C. Filì,[3] R. Fanin[2]

[1]*Azienda Ospedaliero-Universitaria, UDINE;* [2]*Division of Hematology and BMT, UDINE;* [3]*Unit of Blood Diseases and Cell Ther., BRESCIA, Italy*

Background. Patients with acute myeloid leukemia (AML) and normal karyotype represent about 40-50% of all AML cases. Despite being included in an 'intermediate' risk group, with a median 5-year overall survival (OS) of 35%, they display an heterogeneous clinical course. Different genetic abnormalities have been found to impact on the clinical course of these patients. We have recently demonstrated that Multidrug resistance (MDR) protein P-glycoprotein (PGP) is related with a reduced survival also in cytogenetically normal (CN) AML patients. Allogeneic hematopoietic stem cells transplantation (HSCT) is recommended in patients with unfavourable karyotype AML, while its role in CN AML cases is not yet established. *Aims.* We have retrospectively analyzed 111 patients with high-risk CN AML. We have evaluated the role of allogeneic HSCT in 51 patients who underwent transplant procedure and its relationship with different know prognostic factors, including PGP expression at diagnosis. We also compared the survival in the transplanted patients with the 60 high-risk CN AML patients who did not received HSCT. *Methods.*

One hundred eleven CN AML patients, considered at high risk according to initial clinical presentation (WBC >30×10^9/L, PGP MFI >6, secondary AML) or on the basis of poor response to induction therapy, were considered candidate to allogeneic HSCT. Fifty-one (46%) identified an HLA identical donor and underwent transplantation, while 60 patients without a donor received chemotherapy-based intensification. The two cohorts were comparable for WBC count and secondary AML, while the transplanted patients were younger (45 vs 60 years) and with a lower incidence of PGP-positive (27% vs 47%) and primary resistant (22% vs 42%) cases. HSCT was performed at a median of 7 months (range: 1-99) from diagnosis. Twenty-eight patients (55%) had a sibling donor, 23 an unrelated one. HSC source was bone marrow in 30 cases, peripheral blood in 21. Twenty-eight transplants were performed in first (n=23) or subsequent (n=5) remission. Conditioning regimen was myeloablative in 40 cases (78%), nonmyeloablative in 11. *Results.* Acute GvHD developed in 17 patients (33%), mostly in MUD recipients. Chronic GvHD occurred in 14 of 41 evaluable patients (34%). One year transplant related mortality (TRM) was 22% (11 cases). CR rate at engraftment was 90%. Sixteen of 21 patients transplanted with active disease obtained CR (76%). Relapse occurred in 17 patients, with no difference according to PGP status at diagnosis. Disease-free survival (DFS) and OS was influenced only by disease status at transplantation (p=0.027). Allogeneic SCT conferred a significant advantage in survival. Median OS was 37 months in the transplanted patients, 12 months in the non-transplanted ones (p=0.007). The advantage of transplantation was evident both in the PGP+ and in the PGP- cases. Only HSCT was able to overcome the negative impact of PGP, with an identical OS in PGP-positive and PGP-negative transplanted patients. *Summary*. Allogeneic HSCT is an effective therapy in CN AML, especially in cases with high risk, such as over-expression of PGP. Transplant overcomes the impact of PGP on survival and may be therefore pursued in patients who display this high risk feature at diagnosis.

0460

LONGITUDINAL FOLLOW-UP OF WT1 GENE EXPRESSION AS MONITORING OF MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA FOLLOWING ALLOGENEIC BONE MARROW TRANSPLANT

A. Candoni,[1] E. Toffoletti,[2] A. Chiarvesio,[2] A. Michelutti,[2] M. Cavallin,[2] D. Damiani,[2] R. Fanin[2]

[1]*Hematology Unit, UDINE;* [2]*Division of Hematology, UDINE, Italy*

Introduction. WT1 is identified as a tumor suppressor gene encoding a transcriptional regulator and playing a role in the development of Wilms Tumor. WT1 overexpression is described in several oncological diseases including leukemias. The majority of acute myeloid leukemia (AML) patients don't have a suitable specific molecular marker for monitoring minimal residual disease (MRD). Quantification of WT1 in bone marrow samples can be useful as a marker of MRD and can predict the relapse of AML. *Methods and Results.* Here we present the preliminary results of our study in which we are evaluating the dynamic expression of WT-1 in AML patients (pts) following Allogeneic bone marrow transplantation (BMT). The expression of WT-1 was measured using Real Time Quantitative RT-PCR with the specific TaqMan probe; the WT-1 expression was related to expression of the control gene ABL. The cDNA level of WT-1 was detected in bone marrow samples from 20 AML pts at diagnosis (11 males and 9 females), at the time of transplant and after the allogeneic BMT. Samples of diagnosis showed high WT1 expression levels in all cases with a mean of 5468 (SD 4025) copies of WT1/10000 Abl, median 4200 (range 658-13923) copies WT1/10000 Abl. At transplant 12 pts (60%) were in complete cytologic remission (CcR) and 8 (40%) had refractory or relapsed AML. Bone marrow samples from pts in CcR at BMT showed significantly lower WT1 expression levels (mean 74,3±126), compared to the samples from pts with relapsed or refractory disease (mean 5627±4165) (p<0,001). After BMT a rapid decline of mean and median WT1 expression levels was observed in all pts that maintained a condition of CcR, expecially in those that were in CcR at BMT (Figure 1A). After a median follow up of 7 mths from transplant, 3 out 20 pts relapsed (15%) and all of them had high expression levels of WT1 (Figure 1B). One of these pts died with leukemia and two were successfully reinduced with DLI±chemotherapy with a rapid reduction of WT1 levels.*Conclusions.* In our preliminary experience, taking into account the small number of cases, there was a complete concordance between WT1 levels and status of leukemic disease before and after BMT. WT1 (from bone marrow samples) may be useful as a non-specific leukemia marker (NSLM) for monitoring of MRD and as a possible predictor of AML relapse. Besides WT1 levels before and after BMT could help to measure the burden of neoplastic disease.

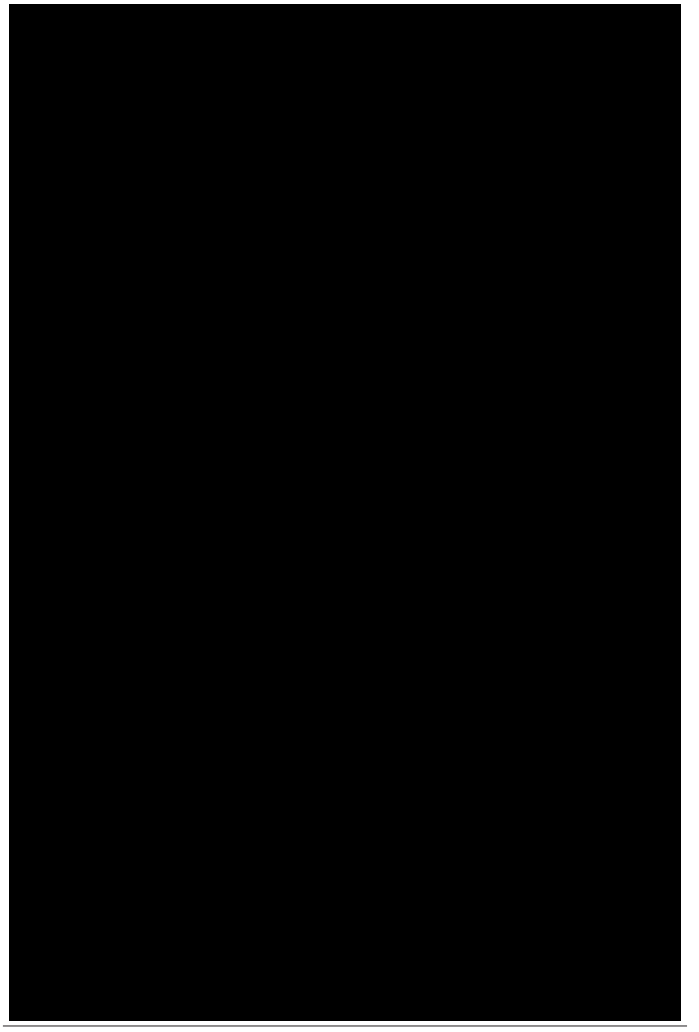

Figure 1. A) WT1 in pts transplanted in CcR that mantained CcR after BMT. B) WT1 in 3 pts t (one in CcR and two with active AML at BMT) that relapsed after BMT.

0461

BONE MASS IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION (SCT)

J.M. Sancho,[1] S. Holgado,[2] C. Biosca,[2] A. Olive,[2] M. Morgades,[1] J. Grau,[1] C. Ferra,[1] L. Mateo,[2] A. Oriol,[1] E. Riera,[2] B. Xicoy,[1] M. Batlle,[1] F. Milla,[1] E. Feliu,[1] X. Tena,[2] J.M. Ribera[1]

[1]*ICO-Hospital Germans Trias i Pujol, BADALONA;* [2]*Hospital Germans Trias i Pujol, BADALONA, Spain*

Background and Aims. Organ transplantation is associated with bone loss. There are scarce studies on bone mass in patients undergoing SCT. The aims of the study were: 1 To determine the changes in bone mineral density (BMD) of patients receiving SCT. 2 To study the differences in BMD between allogeneic and autologous SCT. 3 To determine serum osteoprotegerin levels and to correlate them with BMD. *Patients and Methods.* Prospective study of 98 consecutive patients with hematologic malignancies undergoing SCT. BMD prior to SCT and at 6 and 12 months after SCT were measured by dual-energy x-ray absorptiometry (Lunar Prodigy, Madison WI) at the lumbar spine and the proximal left femur. Bone formation/resorption markers (N-terminal propeptide of human procollagen tipe I [P1NP]/ N-telopeptide cross-links of tipe I collagen [NTX]) were measured at baseline and after 3, 6 and 12 months. Osteoprotegerin was determined prior to SCT and at 6 months after SCT. *Results.* Mean (SD) age was 44 (12) yr, 45 females; 54 autologous SCT and 44 allogeneic SCT. Prior to SCT, 36 patients (37%) had low BMD (25 osteopenia and 11 osteoporosis). BMD values can been

observed in Table 1. Osteoprotegerin levels showed a non significant increase after 6 months, both in autologous (4.33 vs 5.35 pmol/L, p=0.093) and allogeneic SCT (5.16 vs 5.84 pmol/L, p=0,258) and there was no correlation with BMD. P1NP levels showed a significant increase after 3 months in autologous SCT group (80.02 vs 113.85 ng/mL, p=0.002) and a decrease in allogeneic SCT at 3 months (112.47 vs 81.23 ng/mL, p=0.033), 6 months (130.28 vs 87.40 ng/mL, p=0.029) and 12 months (123.07 vs 90.98 ng/mL, p=0.111). No changes in NTX were observed in these patients. *Conclusions.* Hematopoietic SCT (autologous and allogeneic) is associated with bone loss, specially in femoral neck. Patients undergoing allogeneic SCT showed a significant decrease in bone turnover markers, which are involved in the reduction of BMD. Changes in osteoprotegerin levels were not correlated with changes in BMD.

ROLE OF PRIMACY OF BIRTH IN HLA-IDENTICAL SIBLING TRANSPLANTATION

C. Bucher,[1] M. Stern,[2] A. Buser,[2] D. Heim,[2] M. Paulussen,[2] J. Halter,[2] D. Tsakiris,[2] S. Meyer-Monard,[2] D. Droll,[2] A. Tichelli,[2] J. Passweg,[2] A. Gratwohl[2]

[1]University of Minnesota, Minneapolis, MINNEAPOLIS, USA; [2]Haematologie Universitaetsspital, BASEL, Switzerland

Role of sibling primacy in HA-identical sibling transplantation. HLA-identical siblings are prime donors for allogenic hematopoietic stem cell transplantation (HSCT). Despite matching for MHC antigens, the risk for GvHD remains high. Fetomaternal microchimerism has been associated with better survival of maternal compared to paternal grafts in non-T-cell depleted, haploidentical HSCT. Fetomaternal and transmaternal sibling microchimerism have been associated with autoimmune diseases. In analogy, we hypothesized that pretransplant encounters of recipient cells with their later donors through fetomaternal trafficking should have an impact on outcome in HLA-identical sibling HSCT. This retrospective single-center cohort study analyzed overall survival (OS) transplant related mortality (TRM), relapse mortality (RM), and incidence and severity of acute and chronic GvHD after HLA-identical sibling HSCT. We defined based on birth sequence, three groups: Firstborn donor (FD), firstborn recipient (FR) and others (FO). 311 consecutive patients with complete information on sibling sequence, transplanted from 1980 to 2004 were included. Recipient and donor age and sex, diagnosis, stage of the disease, transplantation date and conditioning regimen, stem cell source (bone marrow vs. peripheral blood stem cells), graft manipulation (T-cell depletion), acute and chronic GvHD, date of relapse and of last clinical visit or death were recorded. 97 patients were firstborn recipients (FR) and 107 recipients received a graft from a firstborn donor (FD). 107 patients were neither firstborn nor received a graft from a firstborn sibling (FO) and served as a control group. FR patients were by definition older than FD patients, FO patients had more siblings. No other significant differences for pretransplant variables were observed. 187 (60.1%) patients were alive with a median follow-up of 8.9 years. OS at 10yrs was better in FR than FD patients (49.6% vs. 63.7%, p=0.014) and cumulative incidence of death from relapse was lower in FR. Cumulative incidence of grade II or higher aGvHD was 41.2% in FR vs. 57.0% in FD (p=0.035). FO showed intermediate *Results.* Chronic GvHD was not different among groups. Multivariate analyses strongly confirmed the findings of the univariate tests and excluded recipient/donor age or sibling number as reasons for the observed *Results.* We describe a significant impact of sibling primacy on the incidence of acute GvHD, relapse incidence and overall survival in HLA-identical HSCT: Patients who were born as a first child in a family had the best survival with a significant reduction in acute GvHD and relapse mortality. Possible mechanisms include fetomaternal and transmaternal sibling cell trafficking and tolerisation of the donor. If confirmed, birth order could be integrated into the donor selection algorithm in HLA identical sibling HSCT or matched unrelated donors might be preferred over a high-risk HLA-identical sibling in some cases.

0463

PALIFERMIN IN UNRELATED DONOR TRANSPLANT RECIPIENTS

S. Langner,[1] P. Staber,[1] N. Schub,[2] M. Gramatzki,[2] W. Grothe,[3] G. Behre,[3] W. Rabitsch,[4] W. Linkesch,[1] P. Neumeister[1]

[1]Medical University Graz, GRAZ, Austria; [2]University Hospital of Schleswig-Holstei, KIEL, Germany; [3]Martin-Luther-University Halle-Wittenber, HALLE, Germany; [4]Medical University of Vienna, VIENNA, Austria

Background. Within a compassionate use program in Austria (Medical University of Graz and Medical University of Vienna) and Germany (University Hospital of Schleswig-Holstein, Campus Kiel and Martin-Luther-University, Halle) we retrospectively analysed data on 39 palifermin (keratinocyte growth factor, KGF) treated patients receiving an allogeneic hematopoietic stem cell transplantation (allo-HSCT) for hematologic malignancies. Since 24 patients had an unrelated donor we evaluated a possible acute graft versus host disease (aGVHD) protective effect of palifermin, as indicated in several animal models, in dependence on donor status. *Methods.* Palifermin was administered 60µg/kg per day for three consecutive days before the initiation of conditioning therapy and after graft infusion as previously published in autologous HSCT. The conditioning included TBI-based regimens in two-thirds of the cases, one third was treated with chemotherapy only. Baseline demographics and disease characteristics are listed in Table 1.

Table 1.

	unrelated donor	sibling donor
No. patients	24	15
Sex, no. (%)		
Male	17 (71)	9 (60)
Female	7 (29)	6 (40)
Median age, y (range)	41 (18-67)	42 (21-68)
Disease, no. (%)		
AML	12 (50)	9 (60)
ALL	2 (9)	3 (20)
CML	1 (4)	0
MDS	1 (4)	0
NHL	6 (25)	3 (20)
Hodgkin	1 (4)	0
other malignancies	1 (4)	0
Conditioning regimen, no.(%)		
Chemo + TBI	15 (63)	11 (73)
Chemo only	9 (37)	4 (27)

Results. Age, sex, disease and conditioning regimen allocation were balanced between patients transplanted with an unrelated or sibling donor. Adverse events - mainly skin rash, erythema, swelling of lips and tongue and taste alteration - were comparable in both groups, mild to moderate in severity and transient. One patient with a sibling donor died before day 30 due to sepsis. No statistically significant difference was observed in the incidence of grades 2 to 4 (38 vs 36%, p=ns) or grade 3 to 4 (30 vs 29%, p=ns) aGVHD on day 100 after allo-HSCT. Although the incidence of grade 3 and 4 oral mucositis was lower in unrelated donors (25 vs 40%, p=0.016) both groups showed a similar median duration of febrile neutropenia (3.7 vs 4.1days, p=ns). In order

to asses intestinal epithelial damage we prospectively measured serum citrulline levels - a marker of small bowel enterocyte mass - once weekly during the course of HSCT (timepoints: day-12, -6, 0, +7, +14, +21) in 11 consecutive palifermin treated patients receiving either an unrelated or related donor. In a mouse model administration of palifermin reduced aGVHD documented by preserved citrulline levels, indicating a reduced injury to the gastrointestinal tract. In our patients median citrulline serum concentration showed an expectable decline until day+7 (7.70 µM) - reflecting a maximal intestinal barrier injury - followed by an adequate increase at day+21 (14.86 µM) which is in accordance with untreated patients at our site (day+7: 9.02 µM, *p*=ns and day+21: 16.33 µM, *p*=ns) and a historical cohort receiving allo-sibling-HSCT following myeloablative therapy. This lack of preserved gut integrity shown by an equal decline of citrulline concentration may explain the absent reduction of aGVHD rates. *Conclusions.* Palifermin in unrelated HSCT shows a comparable safety profile to sibling donor transplants. However, we could not find a favourable effect of palifermin on the incidence and severity of aGVHD.

0464

THE DEVELOPMENT OF CELLULAR IMMUNITY TO ASPERGILLUS FUMIGATUS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

D. Bensoussan, L. Clement, N. Daguindau, A. Salmon, F. Namour, M. Machouart, V. Latger Cannard, V. Decot, C. Andre Botté, B. Fortier, J.L. Guéant, T. Lecompte, J.F. Stoltz, P. Bordigoni

CHU de Nancy, NANCY, France

Background. Slow immune reconstitution after mismatched and match unrelated donor transplantation results in a high mortality from viral and fungal infections. Invasive aspergillosis (IA) is one of the major fungal infections after hematopoietic stem cell transplantation (HSCT), although new antifungal drugs have emerged. Part of the problem is the failure to make an early molecular diagnosis, as for CMV. Invasive aspergillosis incidence after HSCT is about 10%, variability depending on environmental conditions. The mortality rate of IA is about 50 to 80%. It has been previously reported that a Th1-type cellular immune response could favourably influence the IA evolution. *Aims.* We initiated a study of cellular immune reconstitution against Aspergillus fumigatus after HSCT where 70 patients have to be included. We present hereafter the results of the 41 one first patients. *Methods.* Cell phenotype analysis and proliferation capabilities against mitogens and Aspergillus fumigatus conidies were performed at day 60, 100, 180 and 360 after HSCT. Secretion of IL10 and IFNγ cytokines was also investigated. Finally, antigen and molecular monitoring of aspergillosis infection were performed. *Results.* Six patients presented antigenic or molecular evidence of infection but only one developed an IA. Proliferation response against Aspergillus fumigatus conidies improved regularly after day 60 to be completely recovered at day 360. IFNγ level seemed to decrease during the first year post-HSCT whereas IL10 level remained constant. The patient who presented an IA at day 15 after HSCT was first unsuccessfully treated with anti-viral drugs. He underwent two surgical procedures at day 110 and day 160 which finally resulted in negativation of biological evidence of aspergillosis and development of a proliferation response against Aspergillus fumigatus conidies at day 265. However, no cytokine secretion could be detected. *Conclusions.* The analysis of such a cohort is interesting to better characterise how immune reconstitution against Aspergillus fumigatus happens depending on transplantation conditions.

FLUDARABINE PHOSPHATE-BASED REDUCED INTENSITY CONDITIONING FOR ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA, MYELODYSPLASIA AND CHRONIC MYELOID LEUKEMIA: UPDATE OF A NATIONAL DOSE- FINDING STUDY

M.C. Ngirabacu,[1] P. Zachee,[2] J. Maertens,[3] K. Theunissen,[4] A. Ferrant,[5] C. Doyen,[6] L. Noens,[7] W. Schroyens,[8] D. Selleslag,[9] H. Demuynck,[10] R. Schots,[11] N. Meuleman,[1] D. Bron[1]

[1]Institue Jules Bordet, BRUXELLES; [2]ZNA Campus Stuivenberg, ANTWERPEN; [3]U.Z. Gasthuisberg, LEUVEN; [4]UZ Gasthuisberg (Hematologie), LEUVEN; [5]Cliniques universitaires Saint-Luc, BRUXELLES; [6]UCL Mont Godinne, YVOIR; [7]UZ Gent, GENT; [8]UZ Antwerpen, EDEGEM-ANTWERPEN; [9]AZ St Jan, BRUGGE; [10]Heilig Hartziekenhuis vzw, ROESELARE; [11]AZ-VUB, BRUXELLES, Belgium

Objectives. We prospectively studied the role of ATG in a Fludarabine phosphate (F)-based non myeloablative conditioning regimen to control the development of graft-versus-host-disease (GVHD), to accelerate donor engraftment and to maintain graft-versus-leukemia (GVL) effects in patients with myeloid malignancies not eligible for classical allogeneic transplant. We also analyzed the outcome of the patients (pts) according to their age and to the status for disease before transplantation. *Population*. A total of 61 pts were enrolled in this phase I-II study. Pts were conditioned with F (30 mg/m^2/day for 4 days) plus cytarabine (2 mg/kg/d for 4 days) or cyclophosphamide (1g/m^2/day for 3 days). All pts received cyclosporine (3-5 mg/kg IV, daily) and ATG 10 mg/kg/day either for 4 days (n=13), or for 2 days (n=7), or for 2 days + mycophenolate mofetyl (n=38) or no ATG (n=3). Chimerism analyses were performed on d30, 45, 60 and 90. *Results.* 23AML, 22 MDS, 13 CML and 3 Myelofibrosis (MF) were enrolled in this trial. The median age was 56.5 (18-75) years. 22 pts (36%) had 60 y.o. or more. The median follow-up is 41 (13-81) months. Prior to transplantation, 51% of pts were in complete remission. 49% had persistent disease (PR, PD). Engraftment rate was 97%. The occurrence of Acute GVHD (aGVHD) grade II-IV at day 90 was very low in all groups (<20%). Chronic GVHD rates are similar in all groups (30%).The low number of pts /group does not allow to find a statistical difference between the different doses of ATG. At d90, full T-cell (>90%) donor chimerism was achieved in 85% of the pts. 3 years OS and EFS in all patients were respectively 55% and 44%. According to the age, OS at 3 years seems to be better in young pts (60.5%) than in pts above 60 y.o (39%), *p*=0.07. For CML, OS and EFS at 3 year were 80% and 60% respectively in young patients versus 0% in elderly pts. The comparison of high risk pts (not in CR) and pts in CR didn't show any difference in term of OS or EFS. Primarily in diseases very sensitive to the GVL effect (AML and CML), there were no significant differences in OS and EFS curves according to the status before transplant. In AML and MDS pts, a plateau in the EFS curve (respectively 43% and 40% /3 years) suggests a cure in these pts. *Conclusions.* Although this series is too small to draw definite conclusions, these observations suggest that in AML and CML pts, RIC transplantation can be a curative option whatever the status of disease before transplant. In MDS pts, the status before transplant remains a prognostic factor and in CML pts, age (above 60) also has a negative impact.

Acute myeloid leukemia - Biology II

ROLE OF MONOCYTE CHEMOATTRACTANT PROTEIN-1 IN THE CHEMOTACTIC MIGRATION OF ALL-TRANS RETINOIC ACID-TREATED PROMYELOCYTIC LEUKEMIC CELLS TOWARD ALVEOLAR EPITHELIAL CELLS

H.Ch. Hsu,[1] W.H. Tsai,[2] C.C. Lin,[1] C.H. Shih,[3] C.K. Ho,[1] Y.R. Kou[2]

[1]Taipei-Veterans General Hospital, TAIPEI; [2]National Yang-Ming University, TAIPEI; [3]Taipei Medical University, TAIPEI, Taiwan

Background. Although all-trans retinoic acid (ATRA) can treat acute promyelocytic leukemia (APL), it also causes retinoic acid syndrome with presentations similar to acute respiratory distress syndrome. Our previous study has demonstrated that IL-8 and GRO-α secreted from alveolar epithelial cells play an important role in the cell-cell interaction involved in the chemotactic transmigration of ATRA-treated APL cells toward alveolar epithelial cells.(Critical Care Medicine-10.1097/01.CCM.0000256844.38259.27). *Aims.* In this study, we further investigated the role of monocyte chemoattractant protein-1 (MCP-1; CCL2) involved in the chemotactic transmigration of ATRA-treated NB4 (ATRA-NB4) APL cells toward A549 alveolar epithelial cells. *Methods.* Co-culture and transmigration assay were used in this study. NB4 and A549 cells were separately cultured with ATRA and/or dexamethasone for 1-3 days. NB4 or ATRA-NB4 cells were then placed in an upper insert and co-incubated with A549 cells or their conditioned medium (CM) located in a lower plate. *Results.* We firstly determined the MCP-1 level in the CM by ELISA. Only A549 cells constitutively secreted MCP-1. However, ATRA treatment markedly enhanced the secretion of MCP-1 in both A549 and NB4 cells. Exogenous administration of MCP-1 also promoted the ATRA-NB4 transmigration. Neutralization of MCP-1 in CM of A549 cells with its specific antibodies reduced ATRA-NB4 transmigration by about 38%. Pretreatment of ATRA-treated NB4 cells with antibody directed against MCP-1 receptor (CCR2) significantly reduce the transmigration of ATRA-treated NB4 cells by about 45%. Dexamethasone did not affect the secretion of MCP-1 in untreated- or ATRA-treated NB4 cells. However, when dexamethasone was applied to A549 cells, MCP-1 secretion was suppressed in both untreated- or ATRA-treated A549 cells, and there was attenuation of ATRA-NB4 transmigration. *Conclusions.* MCP-1 secreted from alveolar epithelial cells also play an important role in the cell-cell interaction involved in the chemotactic transmigration of ATRA-treated APL cells toward alveolar epithelial cells.

Background. Large hyperdiploidy (49 or more chromosomes) is a rare abnormality in AML and no large series describing the feature of such population of patients are available. Applying the definition of complexe caryotypes, all patients with hyperdiploid AML fall in the high risk cytogenetic cohort. *Aims.* We report here the first large cohort of 38 patients with more than 48 chromosomes and without karyotypic structural abnormality to better define the incidence, the clinical and morphological characteristics, and the prognosis of this rare group of patients. *Methods.* 4884 cytogenetic studies performed in laboratories members of the GFCH were screened. This corresponds to AML patients (adults and pediatrics) diagnosed in 19 French and Belgium institutions during A retrospective and one year prospective survey (February 2005-February 2006). We were able to select 38 AML patients with hyperdiploid karyotypes without structural abnormality under conventional cytogenetic. *Results.* Large hyperdiploidy is rare in AML with an incidence inferior to 1% (0.78%). Sex ratio F/M was 2.2 and median age 65 years (ranging from 1 to 91 years). All AML FAB subtype was represented. Although all chromosomes are involved, some seems to prevail: gains of chromosome 8 (68%), 21 (47%) and 19 (39%) are the most frequent followed by gains of chromosome 14 (34%), chromosomes 10 and 13 (29% each) and chromosomes 4 and 11 (26% each). Interestingly, some chromosomes involved in hyperdiploid ALL (4, 6, 8 , 10, 14, 18, 21 and X) are also found in our hyperdiploid AML patients, suggesting that these gains are not lineage restricted. Monosomie was uncommon and we report only two X chromosome losses in women. A cryptic rearrangement of MLL was found in 15% of these patients leading them in a subcategory in the WHO classification with an unfavorable prognosis. Therefore detection of MLL rearrangement should be systematically search in AML without a well cytogenetically established prognosis. When we applied the most frequent definition of complexe karyotypes (3 or more abnormalities), all patients with large hyperdiploid AML fall in the unfavorable category. Among the 18 patients without ML rearrangement receiving an induction therapy, 16 (89%) reached CR and 6 (33%) were still alive after a 26 months median follow-up (10-56 months). The median time to relapse is 658 days for the 16 patients in CR including 3 patients censored at the time of bone marrow transplantation. *Conclusions.* Although this study was retrospective these results suggest that hyperdiploid AML may be better classified in the intermediate prognostic group when hyperdiploidy is the only cytogenetic abnormality.

Orsola Malpighi Hospital, BOLOGNA, Italy; [6]Dept. Hematology S. Martino H., GENOVA, Italy; [7]DOBIG University of Genoa, GENOVA, Italy

Background and Aims. We previously reported that about 80% of acute myeloid leukemia (AML) samples tested at diagnosis constitutively expressed CTLA-4. In this study, we compared CTLA-4 expression and function of leukemic cells from AML patients at diagnosis with those from AML patients resistant to conventional chemotherapy. We also explored the possibility of targeting CTLA-4 for apoptosis induction in chemoresistant AML cells. *Results.* AML cells either from untreated patients (n=15) or in chemoresistant phase (n=10) were analysed for CTLA-4 protein and transcript expression by flow cytometry and RT-PCR, respectively. CTLA-4 expression was similar in untreated and in chemoresistant samples and not associated with patients' clinical features. CTLA-4 expressed by chemoresistant AML cells was able to transduce an apoptotic signal on engagement with its recombinant ligands r-CD80/r-CD86 which induced an average of 71% and 62% apoptotic cells respectively, at highest concentration. Apoptosis was equally induced in untreated leukemic cells accompanied by cleavage of procaspase-8 and -3. *Conclusions.* this study provides the first evidence that killing of leukemic cells from AML patients may be obtained upon engagement of CTLA-4 with its ligands opening the way to a novel potential therapeutic approach based on triggering the CTLA-4 molecule to circumvent chemoresistance in AML.

0469

PROTEOMICS ANALYSIS TO IDENTIFY BIOMARKERS AND PHARMACOLOGICAL TARGETS IN ACUTE MYELOID LEUKEMIAS WITH FLT3/ITD MUTATIONS

N. Barbarroja,[1] L.A. Torres,[1] V. Hernandez,[1] E. Siendones,[2]
J.M. Villalba,[3] A. Torres,[1] F. Velasco,[1] Ch. López-Pedrera[1]

[1]Hospital Reina Sofia, CÓRDOBA; [2]Centro Andaluz Biologia del Desarrollo, SEVILLA; [3]Universidad de Córdoba, CÓRDOBA, Spain

The Flt3 receptor tyrosine kinase is a critical mediator in the patho-

genesis of acute myeloid leukaemia (AML). Flt3-activating mutations have been associated with poor prognosis and decreased overall survival of AML patients. Among them, internal tandem duplications (ITD) of Flt3 are found in a high proportion of cases with acute myeloid leukemia (AML). These genetic aberrations may lead to the constitutive activation of the receptor, thus providing the molecular basis for a persisting growth stimulus. On the other hand, alterations of transcriptional regulators are also key events in leukaemogenesis. Constitutive activation of MAP/Akt/STAT/NF-κB signal transduction pathways have been described in AML and they are commonly attributed to Flt3 activity. With the aim of better understanding the molecular mechanisms accompanying the acquisition of Flt3 activating mutations, a comparative proteomic approach was undertaken on Flt3/ITD and wild-type Flt3 AML cells. Proteomic analyses of three AML samples showing Flt3/ITD and three samples with wild-type Flt3 were carried out using 2-DE and MALDI-TOF mass fingerprinting analysis. Proteins identified as more significantly altered between the different AMLs analyzed belonged to the group of suppressor genes, metabolic enzymes, antioxidants and signal transduction mediators. Among them, four identified proteins were found significantly deregulated in Flt3/ITD leukemic cells in comparison to wild-type Flt3 AML cells, including two up-regulated proteins (peroxirredoxin and catalase) and two down-regulated proteins (calreticulin and RhoGDI). These proteins were widely involved in differentiation and cell survival. Furthermore, several intracellular pathways and transcription factors also implicated in differentiation and cell survival such as ERK 1/2, p38 MAPK, Akt, STAT5 and NFkB were found constitutively activated in the Flt3/ITD AML samples. Employing methods of cell biology and proteome analysis tools, we examined the effects of an inhibitor of Flt3 phosphorylation, AG1296 (AG), on the proliferation/apoptosis characteristics of myelomonocitic leukemia-derived cells MV411, which carried the Flt3/ITD mutation. AG induced apoptosis by suppressing Flt3 activity, which was followed by p38 MAPK and Akt inhibition. The proteomic analysis revealed several proteins that were differentially expressed due to AG treatment namely, calreticulin, eIF-5a, nucleophosmin, protein disulfide isomerase, glutamate dehydrogenase, peroxirredoxin and RhoGDI, all of them involved in the regulation of cell differentiation, proliferation and apoptosis. The further investigation of the relationship between the altered protein expression found in FLT3/ITD AML cells and the constitutive activation of those intracellular pathways, will uncover new clues to understanding leukemogenic effects of FLT3 activating mutations. This study shows the power of proteomic profiling for the discovery of novel molecular targets and a better understanding of the actions of Flt3/ITD at the molecular level in AML cells. LOW DOSE RAPAMYCIN IS NOT EFFLUXED BY P-GLYCOPROTEIN IN AML

M. Pallis,[1] S. Shang,[2] C.H. Seedhouse,[2] N.H. Russell[2]

[1]*Nottingham University Hospitals, NOTTINGHAM;* [2]*University of Nottingham, NOTTINGHAM, United Kingdom*

Background. A clinical trial of rapamycin in elderly patients with AML is currently underway in Nottingham, UK. A potential confounding factor to the clinical effectiveness of rapamycin is its reported interaction with the drug efflux pump p-glycoprotein. *Aims.* We investigated the effect of rapamycin on mTOR targets and on pgp in a single cohort of AML cells in order to determine whether the mTOR target-modulating dose of rapamycin is above or below the threshold for interaction with pgp. *Methods.* Three pgp positive cell lines - KG1, KG1a and TF-1 were used. MTOR targets p70 S6K(phosphothr389) and 4E-BP1 (phosphoser65) were measured by Western blotting. Pgp function was measured using the UIC2 shift assay and the rhodamine 123 accumulation assay with cyclosporin A and vinblastine as positive controls. *Results.*10 nM rapamycin induced a complete loss of phospho-p70 S6K in KG1 and KG1a cells. TF-1 cells had undetectable basal levels. At 10 nM, rapamycin also reduced phospho-4E-BP1 levels to 56% of control values in KG1a, 26% of control in KG1 and 39% of control in TF-1 cells. At this dose, rapamycin failed to induce a UIC2 shift, indicating that there was no interaction with pgp. 10 nM rapamycin also failed to increase rhodamine 123 accumulation, whether added concurrently or up to one hour before the rapamycin, indicating that pgp has no significant interaction with 10 nM rapamycin. Higher doses of rapamycin did induce a small increase in rhodamine 123 accumulation (by approximately 30% in all 3 cell lines at 100 nM). Similarly, at 100 nM there was an approximately 20% increase in UIC2 binding in KG1a and TF-1, but not KG1 cells. Many drugs are documented to upregulate pgp within 48 hours. 72 hours' incubation with 10 nM rapamycin did not upregulate pgp protein expression in the three cell lines. *Conclusions.* We conclude that pgp-mediated drug resistance is unlikely to be a significant factor in the response of AML cells to rapamycin.

0471

SEPT2 IS A NEW FUSION PARTNER OF MLL IN ACUTE MYELOID LEUKEMIA WITH T(2;11)(Q37;Q23)

N. Cerveira, C. Correia, S. Bizarro, C. Pinto, S. Lisboa, J.M. Mariz, M. Marques, M.R. Teixeira

Portuguese Oncology Institute, PORTO, Portugal

Background. Abnormalities of 11q23 involving the MLL gene are found in several hematological malignancies, including acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML), and also in a proportion of patients with therapy-related leukemia after treatment with topoisomerase II inhibitors. *Aims/Methods.* Cytogenetic, fluorescence *in situ* hybridization, and molecular studies were used to identify a new fusion partner of the MLL gene in a patient with a diagnosis of therapy-related acute myeloid leukemia with a t(2;11)(q37;q23). *Results/Discussions*. Fluorescence *in situ* hybridization demonstrated a rearrangement of the MLL gene with the chromosome band 2q37. RNA and DNA analyses showed the existence of an in-frame fusion of MLL exon 7 with SEPT2 exon 3, with the genomic breakpoints located in intron 7 and 2 of MLL and SEPT2, respectively. Search for DNA sequence motifs revealed the existence of two sequences with 94.4% homology with the topoisomerase II consensus cleavage site in MLL intron 7 and SEPT2 intron 2. SEPT2 is the fifth septin family gene fused with MLL, making this gene family the most frequently involved in MLL-related AML (about 10% of all known fusion partners). *Conclusions.* We have identified a new MLL gene fusion partner in a patient with treatment-related AML presenting a t(2;11)(q37;q23) as the only cytogenetic abnormality. SEPT2 is the fifth septin that has been found fused with MLL in acute leukemia, but the precise role played by this family of genes in this disease remains incompletely known.

0472

PROGNOSTIC VALUE OF CYTOCHROME C RELATED ACTIVATION OF CASPASES IN PEDIATRIC ACUTE MYELOID LEUKEMIA

H. Meyer, S.M. Eckhoff, M. Queudeville, K. Stahnke, K.-M. Debatin

University of Ulm, ULM, Germany

Background. Deficient activation of apoptosis signaling pathways has been considered to be responsible for treatment failure in acute leukemia. Studies have been performed to analyze the expression of apoptosis molecules with respect to their prognostic value for treatment outcome but could not establish a correlation with response to treatment and prognosis. In a previous study we investigated functionally the importance of intact apoptosis signaling for treatment response in childhood lymphoblastic leukemia by analysis of two key apoptogenic events, caspase-3 activation and mitochondrial cytochrome c release. By combining both parameters, we identified the novel indicator CRAC (cytochrome c related activation of capase-3) which directly connects the extent of caspase-3 activation to cytochrome c release in single cells in an individual patient sample. Pediatric B-ALL patients with positive CRAC values were found to be good responding to initial treatment and showed a significantly higher probability of relapse free survival in contrast to patients with negative CRAC values (Meyer *et al.,* Blood, 2006, 107(11): 4524-31). *Aims.* Since the investigation of cytochrome c release and caspase activation and the calculation of its relation as expressed by the parameter CRAC is of prognostic value in childhood lymphoblastic leukemia we were interested in the significance of intact apoptosis signaling represented by this parameter in pediatric patients suffering from acute myeloid leukemia. *Methods.* Myeloid leukemia cells identified by surface staining in samples (cryopreserved bone marrow or peripheral blood) obtained at diagnosis from pediatric AML patients were analyzed for active caspase-3 and released cytochrome c flowcytometrically. The relation between these two key apoptogenic events was analyzed upon induction of apoptosis by factor withdrawal and the parameter CRAC was calculated for each patient sample. *Results.* In the samples investigated a heterogenous pattern of caspase activation and cytochrome c release was observed. Especially insufficient caspase activation in the presence of mitochondrial released cytochrome c was found in a number of samples resulting in negative values for the CRAC parameter. This indicates deficient apoptosis signaling in this subset of AML patient samples. 16 of the 34 AML patients (47,1%) showed negative CRAC val-

ues whereas 18 (52,9%) revealed a positive value for CRAC. This distribution is comparable to the pattern found in the analysis of acute lymphoblastic leukemia in our previous study (N=78, CRAC positive n=35, 44,9%; CRAC negative n=43, 55,1%). *Conclusions.* The analysis of cytochrome c related caspase activation (CRAC) identifies leukemia samples with deficient apoptosis signaling in a group of pediatric AML patients. The detection of such patients by assessment of the parameter CRAC may be used for additional treatment stratification in childhood acute myeloid leukemia.

This work is supported by an EHA research fellowship grant to L.H. Meyer.

FLT-1 ACTIVATION BY VEGF/PLGF INDUCES LEUKEMIA CELL MIGRATION VIA P38/ERK1/2 KINASE PATHWAY, RESULTING IN RHO GTPASES ACTIVATION AND CAVEOLAE FORMATION

C. Casalou, R. Fragoso, J.F. Nunes, S. Dias

Portuguese Institute of Oncology, LISBON, Portugal

Vascular endothelial growth factor (VEGF) receptors -1 (FLT-1) and -2 (KDR) are expressed by subsets of malignant hematopoietic cells, where they signal in a paracrine and/or autocrine manner to induce cell survival, proliferation and migration. We recently demonstrated that acute lymphoblastic leukemia (ALL) migration in response to VEGF via FLT-1 modulates the onset of extramedulary disease, and thus has clinically predictive value. However the molecular mechanisms involved in leukaemia cell migration were not yet characterized and are the subject of this study. We demonstrate that FLT-1 activation by VEGF or PLGF stimulation results in a significant increase of AML migration, having a minor proliferative effect. This FLT-1 mediated migration of AML cells resulted in the formation of actin membrane protrusions (as assessed by phalloidin/FLT-1 immuno-staining and confocal microscopy) with concomitant increased ERK1/2 and P38 phosphorylation and activation of Rho-GTPases and PAK/Cofilin. Also, by immunoprecipitation studies, we have shown that PLGF promoted the recruitment of Hsp90 and its binding to FLT-1, actin and caveolin-1. While PLGF stimulation of AML cells induced the formation of caveolae-like structures, cytochalasin D treatment, used as control to block cell migration, was shown to block the molecular interactions between FLT-1, actin, Hsp90 and caveolin-1.Taken together, these data highlight some of the molecular mechanisms whereby VEGF/PLGF stimulation of FLT-1 on AML cells results in cell migration. As such, our data reveal important biological and mechanistic outputs that may be used to monitor leukemia responses to cytoskeleton-disrupting agents or anti-angiogenic therapies. Our ongoing studies are know focusing on a screening of kinases/phosphatases that affect VEGF production in acute leukemia cells, using a system of retrovirus-based vectors that achieve with high-efficient siRNA-dependent silencing in leukaemia cells.

0474

A RECURRENT IN-FRAME INSERTION IN CEBPA TAD2 REGION IS A POLYMORPHISM THAT DOESNT HAVE A PRONOSTIC VALUE IN AML. A STUDY FROM THE FRENCH ALFA GROUP

V. Biggio,[1] A. Renneville,[2] O. Nibourel,[2] N. Philippe,[2] L. Terriou,[2] C. Roumier,[2] P. Amoyuel,[3] D. Cottel,[3] D. Cottel,[3] S. Castaigne,[4] H. Dombret,[5] X. Thomas,[6] C. Preudhomme[2]

[1]INSERM, LILLE; [2]INSERM U837, Lab of Hemat. CHRU, LILLE; [3]INSERM U744, INSTITUT PASTEUR, LILLE; [4]Dep of Hem., Hôpital André Mignot, VERSAILLES; [5]Dep of Hem. Hôpital Saint-Louis, PARIS; [6]Dep of Hem. Hôpital Edouard Herriot, LYON, France

Background. CCAAT/enhancer-binding protein-α (CEBPa) is a transcription factor strongly implicated in myelopoiesis through control of proliferation and differentiation of myeloid progenitors. In patients with acute myeloid leukemia (AML), this gene is often mutated (about 8%). Those mutations are in-frame or out of frame types and the consequences are a loss of function of CEBPa. Among those mutations, an in-frame insertion of 6bp in the TAD2 domain, resulting in a His-Pro duplication (HP196-197ins), was found in patients at diagnosis and remission time, letting think of a constitutive abnormality, that may induce AML susceptibility. Surprisingly this 6bp insertion was observed in healthy voluntaries too. Recently Delwel *et al.* have described this insertion as being a polymorphism. They report that 6bp insertion frequency in AML patients is between 3.2% (9/282) and 3.9% (12/305), while in non-leukemic blood samples, the frequency is 8% (22/274). Further, they didn't found any correlation with CEBPa gene expression signature and more, patients with insertion didn't show any particular expression profile. *Aim of study and Methods.* In our study we have investigated 325 AML patients enrolled in ALFA 98-02 protocol and 994 healthy voluntaries for the presence of this insertion by nucleotide sequencing, and we studied its prognostic value. *Results*. First, we looked for the frequency of this insertion between the healthy whole population and the AML cohort; we didn't found any difference between AML patients and healthy voluntaries: 6.5% (21/325) versus 6.6% (66/994) respectively. This data strongly suggest that this insertion is a polymorphism, but familiar molecular study should be performed to confirm this hypothesis. Second, we made a comparison between true mutation of CEBPa and this 6bp polymorphism. Patients who harbored only the polymorphism have heterogeneous cytogenetic finding (8 normal, 5 complex and 1 intermediate karyotypes, 4 CBF-AML and 4 unknown), while patients with a true abnormality of CEBPa gene (n=23) show significant association to normal karyotypes (p=0.03). Mutations of CEBPa are often associated to M1 and M2 FAB subtypes, but we didn't find an association to FAB subtype for the group of patients with 6bp polymorphism. Regarding other molecular prognostic factors, CEBPa is rarely associated to NPM mutations (p=0.03) while polymorphism doesn't show this particularity (p>0.2). Regarding the EFS, we didn't find any correlation between this polymorphism, true CEBPa mutations and others patients. However regarding the OS only the true CEBPa mutation patients presented a trend for longer survival. *Conclusions.* In conclusion, we confirm that HP196-197ins is a common polymorphism spread in normal population and AML patients, without any prognostic value in our cohort of AML patients.

CAN HYPERACTIVE SIGNALLING THROUGH THE RAS PROTEINS INDUCE AML IN MICE?

A. Cutts, A.M. Wahlstrom, C. Karlsson, B. Swolin, M.O. Bergo

Sahlgrenska University Hospital, GÖTEBORG, Sweden

Background. Mutationally activated forms of the RAS proteins, especially the N and K isoforms, are implicated in the pathogenesis of several haematological malignancies, including acute myeloid leukaemia (AML). However, in AML, the mutations in RAS genes are always accompanied by other genetic abnormalities (e.g. MDR1). In mice, hyperactive signalling through the RAS proteins, e.g., via expression of endogenous oncogenic K-RAS or inactivation of the tumor suppressor NF1, results in myeloproliferative disorders (MPD). At this point, it is unclear if hyperactive RAS signalling can induce AML in the absence of other genetic abnormalities. *Aims.* To test the hypothesis that hyperactive signalling through the RAS proteins can induce AML in mice, without other genetic abnormalities. To accomplish this, we will determine if inactivation of Nf1 - which increases signalling through the N- and K-RAS proteins - will transform a K-RAS-induced MPD into AML. *Methods.* For these studies, we use Cre-loxP techniques in mice. Cre-induced activation of endogenous oncogenic K-RAS in bone marrow cells results in a rapidly progressing MPD with leukocytosis, splenomegaly, and tissue infiltration; without an increase in blasts in peripheral blood. Similarly, Cre-induced inactivation of the RAS-GAP NF1 results in increased levels of RAS-GTP, hyperactive RAS signalling, and a slowly progressing MPD; without an increase in blasts. In this study, we simultaneously activate the expression of oncogenic K-RAS and inactivate the tumour suppressor NF1 in myeloid cells. This approach allows us to determine if higher levels of RAS-GTP would result in transformation of MPD into AML with > 20% blasts in peripheral blood. *Results and Conclusions.* This is an ongoing project. By June, 2007, we will have all the necessary data that will allow us to accept or reject our hypothesis.

INCREASED RISK AND EARLY ONSET OF ACUTE MYELOID LEUKAEMIA IN BRAZILIAN INDIVIDUALS WITH NAD(P)H:QUINONE OXIDOREDUCTASE 1 (NQO1) AND CYTOCHROME P450 A1 (CYP1A1) GENE DEFECTS

G.G. Yamaguti

State University of Campinas (UNICAMP), CAMPINAS, Brazil

Background. Acute myeloid leukaemia (AML) has been linked to chronic exposure to benzene and tobacco's polycyclic aromatic hydrocarbons (PAH). NAD(P)H:quinone oxidoreductase 1 (NQO1) is an enzyme that detoxifies benzene-derived quinones and reduces oxidative stress on hematopoietic cells. A C-->T substitution polymorphism at nucleotide 609 of the NQO1 gene has been linked to a decreased activity of the coded enzyme. On the other hand, PAH are bioactivated by the cytochrome P450 A1 (CYP1A1) enzyme. An A-->G substitution

polymorphism at nucleotide 4889 of the CYP1A1 gene leads to the production of an enzyme with increased activity in PAH metabolism. Moreover, environmental-related diseases resulting from exposure to benzene and tobacco-related diseases have been described as serious health problems in south-eastern Brazil. *Aims.* The aim of this study was to evaluate the influence of the NQO1 C609T and CYP1A1 A4889G polymorphisms for AML risk and its clinical manifestations in individuals of the south eastern region of Brazil. *Methods.* Genomic DNA from 133 AML patients and 133 age, gender and race-matched controls were analysed using the polymerase chain reaction (PCR) and enzymatic digestion. The differences between the groups were calculated by the chi-square or Fischer exact test. *Results.* Controls samples (X^2=3.69, p=0.07) but not patients samples (X^2=6.52, p<0.02) were in Hardy-Weinberg equilibrium at the NQO1 C609T locus. Both the patients (X^2= 2.54, p=0.12) and controls (X^2= 0.89, p=0.34) samples also confirmed the Hardy-Weinberg expectations at the CYP1A1 A4889G locus. The frequency of the NQO1 609CT+TT genotype was significantly higher in AML patients than in controls (41.4% vs 28.6%, p=0.04). Carriers of the NQO1 wild allele (T) were under a 1.7-fold increased risk of AML (95% CI: 1.01-2.89). The frequency of the combined variant genotype was higher in patients under 47 years of age than in older patients (63.6% vs 36.4%, p=0.03). Similar frequencies of the CYP1A1 4889AG+GG genotype were seen in patients and controls (43.6% vs 30.8%, p=0.10). Similar risks for the disease were seen in carriers and non-carriers of the variant allele (G) (95% CI: 0.92-2.60). However, the frequency of the combined variant genotype was higher in patients under 47 years of age than in older patients (63.8% vs 36.2%, p=0.02). *Conclusions.* These results suggest a role for the NQO1 609TT+CT genotype in increased risk for AML and early onset of the disease and the CYP1A1 4889GG+AG genotype in the early age of disease onset in individuals of south eastern Brazil. Financial support: CNPq

HALOFUGINONE INHIBITS TGF-β/VEGF SIGNALING IN ACUTE PROMYELOCYTIC LEUKEMIA

L. Figueiredo-Pontes,[1] A.S.G. Lima,[1] A.B. Garcia,[1] M.S. Baggio,[1] L.F.F. Dalmazzo,[1] M.A. Zago,[1] R.P. Falcão,[1] A. Nagler,[2] E.M. Rego[1]

[1]Medical School of Ribeirão Preto - USP, RIBEIRÃO PRETO, Brazil; [2]Chaim Sheba Medical Center, TEL HASHOMER, Israel

Acute Promyelocytic Leukemia (APL) is a distinct subtype of Acute Myelogenous Leukemia on morphologic, clinical and molecular bases. APL bone marrow biopsies showed increased microvessel density, which was reduced by all-trans retinoic acid (ATRA), suggesting that aberrant angiogenesis may be relevant to APL pathogenesis. In addition, NB4 cells, an APL cell line harboring the t(15;17) translocation, were shown to secrete high levels of the pro-angiogenic factors VEGF and bFGF. TGF-β is known to regulate VEGF production, and Lin, Bergman & Pandolfi have recently shown that PML is an essential regulator of the TGF-β pathway. Therefore, our aim was to determine if the increased VEGF production observed in APL was related to PML/RARα protein effect on the TGF-β signaling. We analyzed the effect of Halofuginone (HF), a low molecular weight alkaloid that has been shown to inhibit TGF-β, reduce fibrosis and tumor progression in a variety of experimental models. NB4 and NB4-R2 cell lines, this latter resistant to ATRA, were treated with increasing doses of HF (6.25, 12.5, 25, 50, 100 ng/mL) and 10-6M of ATRA. VEFG production was measured by ELISA in culture supernatants, and a significant reduction of its levels was detected in samples treated with HF at doses higher than 25 ng/mL or ATRA. Western blot analysis showed that smaller doses of HF (6,25 to 25 ng/mL) and ATRA induced TGF-β expression while higher doses (50 to 100 ng/mL) were found to reduce its expression. We then evaluated the expression of p21 and CDC25A genes, TGF-β target genes involved in cell cycle regulation. HF treatment resulted in inhibition and increase of p21 and CDC25A expression, respectively. Cell proliferation and apoptosis were accessed by flow cytometry using a immunofluorescent staining of incorporated bromodeoxyuridine and 7AAD labeling, simultaneously. In both cell lines, HF progressively inhibited cellular proliferation and induced apoptosis, after 24 hours of treatment, in a dose-dependent fashion. In NB4, there was significant cell growth inhibition with all the HF doses superior to 25 ng/mL (p<0.001). In addition, a 1.5 fold increase in apoptosis was seen with 100 ng/mL after 24 hour incubation (p<0.001). In NB4-R2, cell growth inhibition was observed with 50 and 100 ng/mL and apoptosis with 100 ng/mL of HF (p<0.001). Results also showed that the drug was able to block the cell cycle progression at G1/S transition. Simultaneously, progressive reduction of Bcl2 protein expression in samples of both cell lines treated with increasing doses of HF was seen by flow cytometry analysis. Our results indicate that HF inhibits TGF-β signaling and its consequent VEGF production and thus may revert APL aberrant angiogenesis. TGF-β inhibition resulted in p21 and Bcl-2 downregulation leading to block of cell cycle, reduction of cell proliferation and induction of apoptosis. These effects were independent of ATRA sensitivity. We hypothesize that although the disruption of TGF-β signaling itself is not sufficient to initiate malignant transformation, it may be a critical second step that contributes to leukemia progression. In this context, HF may have therapeutic potential in APL.

SIGNAL REGULATORY PROTEIN-α AS A POTENTIAL NEW TREATMENT TARGET IN ACUTE MYELOID LEUKEMIA

I. Hubeek,[1] J. Cloos,[1] E.M. van Beek,[2] K. Schornagel,[2] A.J.F. Broekhuizen,[1] A.A. van de Loosdrecht,[1] R. Delwel,[3] P. Valk,[3] P. Kearns,[4] H. Martin,[4] U. Creutzig,[5] G.J.L. Kaspers,[1] T.K. van den Berg[2]

[1]VU University Medical Center, AMSTERDAM, Netherlands; [2]Sanquin Research, AMSTERDAM, Netherlands; [3]Erasmus MC, ROTTERDAM, Netherlands; [4]University of Bristol, BRISTOL, United Kingdom; [5]AML BFM Study Group, MUNSTER, Germany

Background. Signal regulatory protein-alpha (SIRP α) is a transmembrane receptor selectively expressed on myeloid and neuronal cells. The broadly expressed cell surface CD47 molecule acts as a major extracellular ligand. The SIRP α cytoplasmic tail contains ITIM motifs that upon CD47 binding mediate the recruitment and activation of the cytosolic tyrosine phosphatases SHP-1 and SHP-2. SIRP α signaling negatively regulates many signaling pathways leading to reduced tumor migration, survival and cell transformation. Indirect evidence has suggested that SIRP α may be downregulated in acute myeloid leukemic (AML). *Aims/Results.* We studied SIRP α mRNA levels in a micro-array data set of 285 AML samples and found a strong association with AML subtypes. (Minimal/poorly) differentiated myeloblastic and promyelocytic AMLs expressed low SIRP α mRNA levels. mRNA expression was higher in myelomonocytic/monocytic AMLs (comparable to normal bone marrow). These findings were confirmed by Western blotting on representative AML cell lines and 25 AML patient samples. SIRP α protein expression was low in AML cell lines KG1a (FAB M0) and Kasumi-1(FAB M2), while HL60 (FAB M3), U937 and THP1 (FAB M5) cells expressed higher protein levels. In the patient samples, SIRP α protein expression was absent/low in FAB M1/2 cases and high in FAB4/5 cases.We investigated whether SIRP α down-regulation in specific AML subsets, such as t(8;21) FAB M2 AML, resulted from epigenetic promoter hypermethylation. Although exposure to demethylating agents and HDAC inhibitors did increase SIRP α expression in t(8;21) Kasumi-1 cells, only limited methylation of the SIRP α gene promoter in these cells and primary t(8;21) AML patient samples was observed. In addition, we studied the functional significance of SIRP α by retroviral reconstitution of Kasumi-1 cells and incubation with an agonistic SIRP α antibody (ED9; 10 μg/mL for 7 days). Daily cell counting and annexin V/7-AAD FACS staining demonstrated significant growth inhibition (p=0.02) and promoted apoptosis (p=0.005). No effect was seen in Kasumi-1 empty vector control cells. Finally, we determined the efficacy of ED9 in combination with 6 concentrations of cytarabine (ara-C; 0.625-0.00061 μg/mL), daunorubicin (DNR; 2.56-0.0025 μg/mL) and etoposide (VP16; 10-0.0098 μg/mL) in these Kasumi-1 cells, by 4-day MTT assay. Calcusyn analysis demonstrated synergism between ED9 and ara-C (CI=0.46±0.32), DNR (CI=0.74±0.06) and VP16 (CI=0.60±0.05). *Summary and conclusions.* In conclusion, SIRP α expression appears to be reduced in specific AML subsets. SIRP α -derived signals can directly control myeloid cell growth and induce apoptosis in AML M2 t(8;21) Kasumi-1 cells. Moreover, agonistic SIRP α triggering synergized with conventional chemotherapeutic agents. Our results create a rational basis for the design of anti-leukemic therapies targeting SIRP α.

0479

ARHGAP21 INTERACTS WITH FOCAL ADHESION KINASE AND IS OVEREXPRESSED IN LEUKEMIA CELLS

FT Traina, S.M.B. Winnischofer, L. Borges, M. Lazarini, C.L. Bigarella, F.F. Costa, S.T.O. Saad

State University of Campinas, CAMPINAS, Brazil

Background. ARHGAP21 is a new protein recently described by us and characterized as a Rho-GTPase activating protein (Rho-GAPs), a negative regulator of RhoGTPase signaling pathways. RhoGTPases mediate many aspects of cell biology, including proliferation, apoptosis, survival, adhesion and actin cytoskeleton dynamics. Recently, ARHGAP21 was

identified as a new component of cell-cell junctions that controls α-catenin recruitment and is able to interact with α-catenin, ARF1 and ARF6, important proteins in the cytoskeleton assembly and adherent junctions. Cell-to-cell adhesion is one of the major factors that restrict cellular invasion and metastasis in malignant diseases. FAK is a non-receptor tyrosine kinase, and coordinates signals from integrins, cytokines, growth factor receptors, and oncogenes. In AML cells, FAK has been found to be overexpressed and associated with enhanced blast migration, increased cellularity, and poor prognosis. *Aims.* In the attempt to verify the role of ARHGAP21 in leukemogenesis, we aimed to verify the expression level of ARHGAP21 mRNA and protein in normal hematopoietic cells and in leukemia cells. In addition, we attempted to verify a possible interaction of ARHGAP21 with proteins involved in cell adhesion, as Focal adhesion kinase (FAK). *Methods.* Marrow aspirates were obtained from 5 normal donors, 37 patients with Acute Myeloid Leukemia (AML) and 9 patients with Acute Lymphoblast Leukemia (ALL). The National Ethical Committee Board approved the study and informed-written consent was obtained from all patients and donors. Total cells were submitted to RNA extraction and the expression level of mRNA was detected by real time RT-PCR. The relative quantification value of gene expression was calculated using 2'DDCT. Leukemia cell lines (Jurkat, Molt-4, K562, HL60) and normal peripheral blood mononuclear cells (PBMC) obtained from 5 normal donors were submitted to immunoprecipitation and Western blotting analysis to detected protein expression and protein interactions. Pull down assays using three different FAK-GST fusion proteins: C-terminal (residues 687-1054), FERM domain (residues 60-349) and catalytic domain (residues 390-696) were performed to confirm the interaction between ARHGAP21 and FAK. *Results.* ARHGAP21 mRNA expression was found to be significantly higher in AML and ALL samples when compared with normal hematopoietic cells (medians: AML: 3.01 vs 0.25, $p<0.0001$; ALL: 4.47 vs 0.25, $p=0.0010$; Mann-Whitney test). Western blotting analysis showed higher ARHGAP21 expression in acute leukemia cell lines in comparison to normal PBMC. Immunoprecipitation and Western blotting assays using anti-ARHGAP21 and anti-FAK antibodies detected the interaction between ARHGAP21 and FAK in protein extracts of Jurkat cells and normal PBMC. Pull down assays, using three different FAK-GST fusion proteins, showed that ARHGAP21 is associated with the C-terminal region of FAK in protein cell lysates of HL-60 and normal PBMC. *Conclusions.* In conclusion, our data show that ARHGAP21 is overexpressed in AML and ALL cells and is associated with FAK in leukemia cell lines and in normal PBMC. These findings give rise to the hypothesis that ARHGAP21 may be involved in leukemogenesis, aiming this gene as a candidate for anti-tumor therapy.

0480

THE FOUR AND A HALF LIM DOMAIN PROTEIN 2 (FHL2) INTERACTS WITH CALM AND IS HIGHLY EXPRESSED IN AML WITH COMPLEX ABERRANT KARYOTPES

Z. Pasalic, B. Tizazu, L. Fröhlich-Archangelo, A. Krause, P. Greif, S. Bohlander

GSF, KKG-Leukemia, MUNICH, Germany

Background. The balanced chromosomal translocation t(10;11)(p13;q14) results in the CALM/AF10 fusion gene. This translocation is found in acute myeloid leukemia (AML), T-cell acute lymphoblastic leukaemia (T-ALL) and malignant lymphoma. The CALM/AF10 fusion gene has recently been shown to cause aggressive biphenotypic leukemia in a murine bone marrow transplant model. The CALM (Clathrin Assembly Lymphoid Myeloid leukemia gene) gene product is a clathrin assembly protein which plays a role in clathrin mediated endocytosis and trans Golgi network trafficking. AF10 is a putative transcription factor most likely involved in processes related to chromatin organization and has polycomb group gene like properties. Known FHL2 interactors are BRCA1, PLZF (promyelocytic leukemia zinc finger protein), SKI1, β-catenin and Runx2. Deficiency of FHL2 causes decreased osteoblast activity. High expression of FHL2 in breast cancer has recently been shown to be associated with an adverse prognosis. *Aims.* The CALM/AF10 translocation is associated with a variety of acute lymphoid and myeloid leukemias. To learn more about the CALM/AF10 translocation we searched for protein interaction partners of CALM. *Methods and Results.* In a yeast two hybrid screen the four and a half LIM domain protein (FHL2) was identified as putative CALM interacting partner. The CALM-FHL2 interaction was confirmed by co-transformation assay in yeast, GST-pulldown and co-immunoprecipitation. In co-localization studies with transiently expressed fluorescent protein tagged CALM and FHL2, both proteins showed cytoplasmatic localization. Expression analysis (Affymetrix based) in different AML subtypes showed a significantly higher expression of FHL2 in AML with complex aberrant karyotypes compared to AML with normal karyotypes or balanced chromosomal translocations like the t(8;21), inv(16) or t(15;17). Reporter assay is being performed to test transcriptional activities of FHL2 on CALM. *Summary.* The observation that FHL2 has been shown to modify the transcriptional properties of other proteins suggests that FHL2 might regulate the nuclear function of CALM and it is thus conceivable that FHL2 is playing role in CALM/AF10-mediated leukemogenesis by tethering the CALM/AF10 fusion protein to various nuclear transcription factor complexes.

SULFASALAZINE SENSITIZES ACUTE MYELOID LEUKEMIC THP-1 CELLS TO CYTARABINE

N.E. Franke, J. Vink, R. Oerlemans, Ch. van Zantwijk, I. Hubeek, G.J.L. Kaspers, G. Jansen, J. Cloos

VU university medical centre, AMSTERDAM, Netherlands

Introduction. In spite of the advances made in the last decades, the prognosis of primary and relapsed pediatric acute myeloid leukemia (AML) is still poor, 60% and 40%, respectively. Resistance to chemotherapy including cytarabine (ara-C), etoposide and daunorubicin is partially responsible for this poor response. Ara-C is the most effective agent for the treatment of AML. Aberrant expression of enzymes involved in the transport/metabolism of ara-C including down-regulation of human equilibrative nucleoside transporter (hENT1) and deoxycytidine kinase (dCK) and upregulation of cytidine deaminase (CDA) is correlated with ara-C resistance. It has been suggested that activation of the nuclear factor κ-B (NF-κB) pathway is also associated with ara-C resistance by inhibiting apoptosis and stimulating cell proliferation. *Aims.* The aim of our study was to investigate whether inhibition of NF-κB by sulfasalazine (SSZ), an anti-inflammatory drug and inhibitor NF-κB, could increase the sensitivity of AML cell lines to chemotherapy. *Methods.* Two human myeloid leukemia cell lines AML cell lines, one being relatively resistant to ara-C (THP-1 cells from relapse AML patient) and one being ara-C sensitive (U937 cells) were chronically exposed to SSZ for 1-2 months. Subsequently, the drug sensitivity was determined by MTT assay, mRNA expression profiles were analyzed by microarray analysis and protein expression was measured by Western blot analysis. *Results.* U937 cells showed marginally altered changes in sensitivity to ara-C, etoposide and daunorubicin after prolonged exposure to SSZ. In contrast, SSZ-exposed THP-1 cells showed a 200 fold increased sensitivity to ara-C (see Figure 1A) and nearly unchanged etoposide and daunorubicin sensitivity.

Figure 1. A) Ara-C sensitivity measured by MTT comparing wild type (wt) cells with SSZ exposed cells. (B) Western blot analysis of these cells showing deoxycytidine kinase (dCK) and β-actin (β-act) protein expression.

Subsequently microarray analysis revealed a slightly decreased hENT1, dCK and CDA mRNA expression in SSZ-exposed U937 cells while SSZ-exposed THP-1 cells showed an increased hENT1 and dCK

expression along with a decreased CDA expression. For dCK, these results were confirmed at protein level by Western blot analysis (see Figure 1B), for the other parameters this remains to be established. Finally, unbalanced protein levels of NF-κB p65 and IkB (markedly increased) relative to NF-κB p50 (unchanges) of the NF-κB complex were indicative for an inactive state of the NF-κB pathway. *Conclusions.* These data suggest that chronic SSZ exposure decreases the NF-κB activity, increases the proteins involved in ara-C transport/metabolism and thereby increasing the ara-C sensitivity. Whether the dCK upregulation is caused by the NF-κB inhibitory effect of SSZ or by other mechanisms of SSZ is yet to be elucidated. In general, these data indicate that treatment of AML might be improved by combination with the NF-κB inhibitor SSZ, especially in relapsed AML.

ABROGATION OF THE DNA-DAMAGE RESPONSE IN AML VERSUS MDS CELL LINES

S. Boehrer, L. Adès, T. Braun, J. Grosjean, C. Fabre, P. Fenaux, G. Kroemer

Institut Gustave Roussy, VILLEJUIF, France

Introduction. The increasing evidence that activation of the DNA-damage-response (DDR) pathway in preneoplastic lesions of solid neoplasms hinders tumorigenesis prompted us to evaluate the same hypothesis in cell line models representing different subtypes of MDS and AML. *Methods.* Myeloid cell lines corresponding to prognostically different subgroups of MDS/AML (P39, MOLM-13, MV4-11, and KG-1) were assessed for their capacity to undergo a DDR. Using the quintessential inducer of a DDR, the cell lines were gamma-irradiated (2, 5 and 10Gy) and their ability to arrest the cell cycle in G2/M and/or to undergo apoptosis were assessed by FACS-measurement. Concomittantly changes in the expression levels of crucial proteins conferring the DNA-damage response were evaluated by immunoblotting. *Results.* Thus we show, that - in contrast to the *de novo* AML-derived KG-1 cells - the irradiated MDS/AML-derived cell lines P39 and MOLM-13 exhibit an earlier and more pronounced arrest of the cell cycle in G2/M, as well as a higher percentage of apoptotic cells. Assessing the underlying molecular determinants we demonstrate that irradiated P39 and MOLM-13 cells retain the ability to activate crucial mediators of the DDR, whereas this ability is decreased in the AML cell line KG-1. In contrast to KG-1 cells, irradiated P39 and MOLM-13 cells exhibit an increased upregulation of the crucial cell cycle/checkpoint regulators Chk1-P-Ser317 and Cdk1-P-Tyr15. To investigate the functionality of the DDR-pathway, cell lines were γ-irradiated in the presence of the ATM-inhibitor KU-55933 and the Chk-1 inhibitor UCN-01. Whereas inhibition of Chk1 (and to a lesser extent inhibition of ATM) is able to hinder G2/M-progression in irradiated MDS cells, it remained without effect in the AML cell lines KG-1 and MV4-11. Noteworthy, whereas irradiated P39/MDS cells hindered to activate Chk1 decrease expression of Plk-1 - which not only governs mitotic entry and exit, but also functions as an oncogene - KG-1 cells maintained a high expression, comparable to that observed in non-irradiated cells. *Conclusions.* We demonstrate the different capacities of MDS and AML cell lines to activate the DDR and thus provide evidence, that the DDR-pathway is abrogated in AML as compared to MDS cells.

Acute myeloid leukemia - Clinical II

TREATMENT FOR ELDERLY PATIENTS (>70 YEARS) WITH *DE NOVO* ACUTE MYELOBLASTIC LEUKEMIA (AML). STUDY OF EFFICACY AND OUTPATIENT FEASIBILITY

S. Piernas Pontanilla,[1] A. Oriol,[2] S. Brunet,[2] D. Gallardo,[2] S. Vives,[2] E. Plensa,[2] J. Sierra,[2] J.M. Ribera[2]

[1]Hospital Germans Trias i Pujol-ICO, BADALONA; [2]CETLAM Group, BARCELONA, Spain

Background. The results of therapy for elderly patients with AML is dismal. Several intermediate dose cytarabine schedules have been introduced in an attempt to reduce toxicity. *Aims.* To evaluate the outpatient feasibility, tolerability and effectiveness in terms of rate of complete remissions (CR), overall survival (OS) and leukemia-free survival (LFS) of an oral (fludarabine and idarubicin) and subcutaneous (cytarabine and filgastrim) combined treatment in elderly patients (>70 years) with *de novo* AML. *Methods and patients.* Elligible patients: 70 years of age or older with a newly diagnosed AML, ECOG 0-2 and able to attend weekly hospital visits on an outpatient basis at baseline. Treatment schemes: FAG: fludarabine 25 mg/m^2 po days 2 to 5, cytarabine 200 mg/m^2 sc days 2 to 8, filgastrim 300 mcg sc days 1 to 7. IAG: idarubicin 20 mg/m^2 po days 2 to 4,cytarabine 200 mg/m^2 sc days 2 to 8, filgastrim 300 mcg sc days 1 to 7. Schedule: FAG induction followed by FAG and IAG consolidation in case of CR achievement. In case of partial remission (PR), FAG induction was repeated followed by the same consolidations in case of CR. If disease proved resistant after 1 or 2 FAG inductions, 1 to 2 inductions with IAG were attempted, followed by 2 IAG consolidations in case of CR. *Results.* From april 2004 to december 2007, 26 patients have been included (target 30 patients). Median age 74 (range 70-77) years. 8 (50%) males. AML characteristics: poor risk cytogenetics 4 (25%), trilineage dysplasia 5 (31%), FLT3 internal tandem duplication 2 (12%). Outcome: induction related deaths 4 (25%), CR after 1 (6) or further (1) induction cycles 44%. Consolidation related deaths 1 (6%). Patients completing the scheduled treatment 5 (31%). After a median follow-up of 7 months 1-yr (95%CI) OS and LFS probabilities are 24% (0-50) and 51% (12-90). Toxicity: The median duration of thrombocytopenia (<20×10^9/L) and neutropenia (<1×10^9/L) was 2 weeks (range 1-5) per cycle. Fever and infections grade 3-4 appeared in 70% and 27% of cycles respectively. Other toxicities were mild. Thirty-two percent of cycles could be managed in a completely outpatient basis and median hospital stay per cycle was 3.5 days (range 0-21). *Conclusions.* Selected elderly patients with AML could be managed on an outpatient basis with the proposed protocol. Although hospital admission was necessary in two thirds of the cycles, mainly due to infections, hospital stay was considerably shortened compared with standard dose cytarabine schedules while effectiveness is not importantly hampered by the cytarabine dose reduction.

MARROW OSTEOPONTIN LEVEL AS A PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

C.Y. Lee,[1] H.F. Tien,[2] L.I. Lin[1]

[1]National Taiwan University, TAIPEI; [2]National Taiwan University Hospital, TAIPEI, Taiwan

Background. Osteopontin (OPN) is a glyco-phosphoprotein expressed in osteoblasts, osteoclasts, vascular smooth muscle cells, nerve cells, endothelial cells, epithelial cells, and activated immune cells. Secreted form of OPN is widely distributed in the body fluid. It could function in cell adhesion, chemotaxis, angiogenesis, apoptosis prevention, and tumor cell growth. OPN expression has been detected in many solid tumors, and its overexpression in tumor tissues has been shown to be associated with poor prognosis. Plasma or serum OPN levels were higher in patients with lung, breast, prostate, liver, and ovarian cancer than in normal controls. In many tumors, OPN blood levels were suggested as a prognostic or diagnostic marker. *Aims.* Previous studies in hematological malignancies demonstrated that OPN was overexpressed in chronic myeloid leukemia (CML) and multiple myeloma (MM). OPN concentration increased significant in CML and MM patients, as compared to normal controls. In the present study, we investigated whether marrow OPN level could be a diagnostic and/or a prognostic factor in acute myeloid leukemia (AML) patients. *Methods.* We determined the marrow OPN level in 52 AML patients before chemotherapy and 20

healthy controls at National Taiwan University Hospital (Taipei, Taiwan). All the molecules were quantified using ELISA. Concentrations in the AML patient and healthy control groups were compared using Student's t test. The receiver operating characteristic (ROC) curve was constructed, and the area under the ROC curve (AUROC) was calculated. Survival status was investigated by using the Kaplan-Meier survival curve and log-rank test. Multivariate Cox regression analyses were also used to estimate prognosis. *Results.* The OPN level was significantly higher (p<0.001) in the AML patients than in the healthy controls, while mean value was 19.46 ng/mL (range: 1.46-83.55 ng/mL) in patient group and 4.25 ng/mL (0.72-37.60 ng/mL) in control group. The ROC curve was illustrated to differentiate AML patients from controls. With a cut-off value of 4.3 ng/mL, OPN displayed a good result (AUROC = 0.896, 95% confidence interval, 0.802-0.956, p<0.001). Of the 52 patients, 31 patients undergoing conventional induction chemotherapy were further subjected to survival analysis. Patients with lower OPN (< 26 ng/mL) displayed a longer survival time than those with higher levels in one-year analysis (p=0.006, 12.0 vs. 2.5 months). In addition, it also demonstrated a borderline significant in five-year analysis (p=0.067, 22.1 vs. 2.5 months). Multivariate Cox regression models revealed that patients with higher OPN level displayed poor prognosis, with a hazard ratio of 4.96 (95% CI, 1.40-17.57, p=0.014) in one-year analysis and 2.99 (95% CI, 1.06-8.44, p=0.040) in five-year analysis. *Summary and conclusions.* In the present report, we demonstrated marrow OPN level in AML patients was not only higher than healthy controls, but patients with high OPN level also had significantly poor prognosis in one-year and five-year periods. As a conclusion, marrow OPN level is closely associated with the clinical outcome of AML patients and may be valuable in disease prognosis.

CP-4055 IN PATIENTS WITH HAEMATOLOGIC MALIGNANCIES - A PHASE I STUDY

F. Giles,[1] D. Rizzieri,[2] T. Prebet,[3] A. Charbonnier,[3]
M. Liland Sandvold,[4] K. Hernes,[4] T. Flem Jacobsen,[4] N. Vey[3]

[1]University of Texas, MD Anderson, HOUSTON, USA; [2]Duke University Medical Center, DURHAM, USA; [3]Institut paoli-Calmettes, MARSEILLE, France; [4]Clavis Pharma, OSLO, Norway

Background. CP-4055 (cytarabine 5'-elaidic acid ester) is a novel cytotoxic nucleoside analogue. Cytarabine is the backbone of therapy in leukaemia. CP-4055 has similar mechanism of action to cytarabine but, unlike cytarabine, it is independent of nucleoside transporters for cellular uptake. CP-4055 is currently in Phase II in solid tumours and the recommended dose is 200 mg/m^2/day in a day 1-5 q4 weeks (1-5 q4w) schedule. Myelosuppression was the main dose limiting toxicity (DLT). *Aims.* Determination of the maximum tolerated dose and the preferred infusion time in patients (pts) with haematologic malignancies. *Methods.* Pts received IV CP-4055 over 2 hours (Arm A) or 24 hours (CIV, Arm B) in a day 1-5 q3w schedule. The starting dose in Arm A was 300 mg/m^2/day and in Arm B 200 mg/m^2/day, with standard definitions of DLT for haematologic malignancies. Dosing increments were by 50% (or by 30% in case of grade 2 non-haematologic toxicities). *Results.* In the ongoing study, 22 pts [14 male, median age 61.5 yrs (range 34-77); ECOG PS 0-1: 18 pts, ECOG PS 2: 4 pts; AML 18 pts, MDS 1 pt; ALL 2 pts, CML-BP 1pt, mean 2 lines prior chemotherapy (range 0-7)] have been treated at 2 US and 1 European centres. Seven pts are ongoing, 6 pts withdrawn with minimal response and 9 pts discontinued due to progressive disease. No treatment-related serious adverse events (SAE) have been observed. No DLT has been observed and dose escalation is ongoing at doses 875 mg/m^2/day in Arm A and at 675 mg/m^2/day in Arm B. Safety: Nausea and vomiting were the most common possibly related AEs. One patient experienced rash possibly related to study drug. Efficacy: Two pts (both AML) with stable disease/mild myelosuppression received a third cycle with CP-4055. One of these pts was referred to stem cell transplantation. Twelve pts received 2 cycles of therapy of whom 4 pts are ongoing. *Summary and Conclusions.* Patients with haematologic malignancies tolerated CP-4055 well up to a dose of 875 mg/m^2/day in a d1-5 q3w schedule (2 hrs infusion). Myelosuppression has been observed with minimal toxicity. Accrual is ongoing.

OPTIMAL POST-REMISSION THERAPY FOR FLOW-CYTOMETRY MINIMAL RESIDUAL DISEASE POSITIVE PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Venditti, F. Buccisano, L. Maurillo, M.I. Del Principe,
G. Del Poeta, L. Ottaviani, C. Sarlo, E. Ammatuna, D. Fraboni,
M. Irno-Consalvo, S. Amadori

University Tor Vergata, ROME, Italy

Background. Autologous (AuSCT) and allogeneic stem cell transplantation (SCT) are well established post-remissional strategies for patients with Acute Myeloid Leukemia (AML). However, there is still a debate ongoing about the relative merit of each of these options in first CR. *Aims.* Minimal residual disease (MRD) may be a useful tool to stratify AML patients into categories of risk which can benefit from differentiated post-remissional approaches. To address this issue, we analysed retrospectively, a series of patients affected with AML in whom flow-cytometry serial determinations of MRD were available, at established time-points (post-induction, post-consolidation, post-stem cell transplantation). *Methods.* 123 patients were entered into the EORTC/GIMEMA protocols AML10/AML12 (age <61 yrs) or AML13 (age>61 yrs), all consisting in intensive induction and consolidation cycles, and, for patients aged <61 years, AuSCT or SCT. Median age was 52 years (range 18-78), no APL cases were included in the study. The *Maximally Selected Rank Statistic* (MSLRS) analysis was used to select the MRD level and the time-point of analysis achieving the best prognostic significance in terms of overall survival (OS) and relapse free survival (RFS). This test was specifically developed to find out the optimal cut-off for a given biological variable correlating with clinical parameters of interest. *Results.* The MSLRS indicated the threshold of 3.5×10^{-4} residual leukemic cells after consolidation therapy, as a discriminator between MRD$^-$ and MRD$^+$ cases with different 5-years OS (64% vs. 14%, p<.001) and RFS (68% vs. 13%, p<.001). Therefore, among these 123 patients, we enucleated 2 groups of patients which underwent stem cell transplant procedure, 53 AuSCT and 11 SCT. The two subgroups were balanced in terms of FAB categories, WBC count, karyotype and expression of MDR-1 phenotype; 34/64 (53%) were MRD$^+$ (9 SCT, 25 AuSCT) and 30/64 (47%) were MRD$^-$ (1 SCT, 28 AuSCT). Among the 53 patients submitted to AuSCT, MRD$^-$ had a significant better outcome than those MRD$^+$, both in terms of 5-years OS (68% vs. 24%, p=0.003) and RFS (68% vs. 11%, p<.001). In the SCT group the low numbers hampered any firm conclusion; however, when the category of post-consolidation MRD$^+$ patients was separately analysed, the use of SCT was associated with a better RFS (40% vs. 12%, p=NS), (Figure 1); we assume that the lack of statistical significance was merely due to the few cases in the SCT group. *Conclusions.* 1) the threshold of 3.5×10^{-4} at post-consolidation check-point is critical to predict disease outcome; 2) MRD$^-$ patients have an excellent outcome regardless of the post-consolidation therapy; 3) in the MRD$^+$ group, AuSCT seems not to improve the prognosis whereas the use of SCT is associated with a superior outcome, although a larger number of patients is required to confirm this assumption.

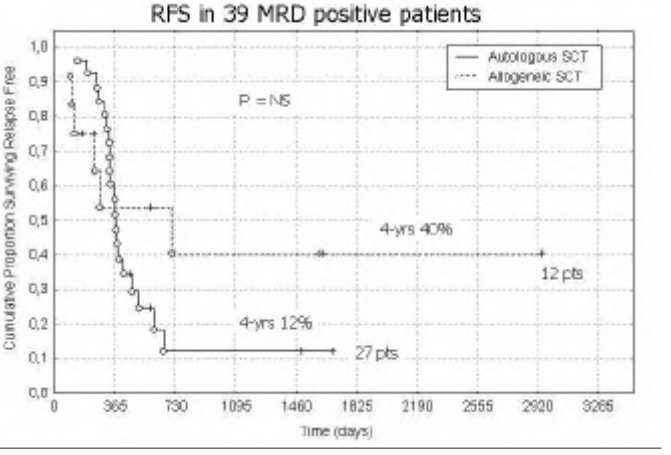

Figure 1. Duration of RFS according to type of SCT received.

0487

MUTATIONAL STATUS OF NUCLEOPHOSMIN (NPM1) AND FLT-3 GENES ARE STRONG PREDICTORS OF THE OUTCOME IN PATIENTS WITH CYTOGENETIC INTERMEDIATE-RISK ACUTE MYELOID LEUKEMIA UNDERGOING AUTOLOGOUS STEM-CELL TRANSPLANTATION

M. Torrebadell,[1] M. Camós,[2] S. Brunet,[3] M. Rozman,[2] M. Pratcorona,[2] J. Nomdedeu,[3] A. Carrio,[2] D. Costa,[2] D. Colomer,[2] E. Carreras,[2] E. Campo,[2] J. Sierra,[3] E. Montserrat,[2] J. Esteve[2]

[1]Hospital Clinic, BARCELONA; [2]Hospital Clínic, BARCELONA; 3Hospital de Sant Pau, BARCELONA, Spain

The modality of post-remission therapy in AML is mainly based on cytogenetics. However, there are several cytogenetic categories, such as the intermediate-risk subgroup, that include patients with a highly heterogeneous prognosis. In this subset of patients, molecular markers such as mutations of NPM1 and flt-3 genes might be useful to determine prognosis more precisely. We analyzed the predictive value of these molecular markers in patients with AML receiving autologous stem-cell transplantation (autoSCT). Thirty-seven patients (age: 53, 15-66; 51% female) diagnosed with AML of intermediate-risk cytogenetics (normal karyotype, n=23) and submitted to autoSCT in first complete remission (CR1) during 1995-2006 were included in the analysis. Pre-transplant therapy was similar in all patients, consisting of one (n=32) or two cycles (n=5) of standard induction chemotherapy (ICE, n=8, IDICE, n=29) and one cycle of high-dose ara-C-based consolidation chemotherapy, according to three sequential trials (CETLAM protocols LMA-94, LMA-99, and LMA-2003). Conditioning regimen contained TBI in most cases (86%) and the stem-cell source was peripheral blood in all patients. Internal tandem duplication of flt-3 (flt-3 ITD) and exon 12 NPM1 mutations were studied in diagnostic samples by either PCR or RT-PCR following standard methods and visualized by means of Genescan analysis. After a median follow-up of 66 months (6-122), 12 patients relapsed after autoSCT, this resulting in a 5-year OS and LFS of 56±9% and 50±9%, respectively. According to molecularly-defined risk, three different subgroups of patients were considered: group 1 (NPMmut: n=12, 32%), constituted by patients with mutated NPM1 without flt-3 ITD; group 2 (NPM-neg: n=20, 54%), which included patients without NPM1 or flt-3 ITD; and group 3 (flt-3 ITD: n=5, 13%), defined by flt-3 ITD regardless NPM1 mutational status. The only variables with prognostic value for survival after autoSCT were flt-3 ITD, which conferred an adverse prognosis (5-yr OS: 62%±10% vs. 20%±18%, p=0.028), and molecular NPM1/flt3 category (5-yr OS: 90%±10% [group 1] vs. 48%±13% [group 2] vs. 20%±18% [group 3], p=0.02; see Figure 1). In conclusion, autoSCT is an effective post-remission strategy in patients with NPM1-mutated AML, whereas flt-3 ITD identifies a high-risk population who does not benefit from this procedure. For the subgroup of patients lacking NPM1 and flt-3 mutations, search of other molecular markers adding prognostic information is warranted in order to assess the role of different post-remission options.

ANALYSIS OF THE ASSOCIATION OF ICAM-1 AND PECAM-1 POLYMORPHISMS AND THE DEVELOPMENT OF DIFFERENTIATION SYNDROME IN ACUTE PROMYELOCYTIC LEUKEMIA

A.I.D. Dore,[1] B.A.A. Santana-Lemos,[1] L.F.F. Dalmazzo,[1] V.M. Coser,[2] F.L.S. Santos,[1] A.S.G. Lima,[1] R.H. Jacomo,[1] L.L. Figueiredo-Pontes,[1] J. Elias Junior,[1] R.P. Falcao,[1] W.V. Pereira,[2] E.M. Rego[1]

[1]University of Sao Paulo, RIBEIRÃO PRETO; [2]University os Santa Maria, SANTA MARIA, Brazil

The use of all trans-retinoic acid (ATRA) is the base of treatment of Acute Promyelocytic Leukemia (APL) and constitutes the paradigm of differentiation therapy. In general, ATRA is well tolerated, but may be associated with a potentially lethal side effect, referred to as Retinoic Acid or Differentiation Syndrome (DS), which is characterized by fever, pleural and pericardial effusions, respiratory distress, weight gain and pulmonary infiltrates on chest radiography. The cellular and molecular mechanisms of DS are poorly understood, and involve changes in the adhesive qualities and cytokine secretion of leukemic cells during ATRA-induced differentiation. Since leukocyte extravasation is a key event in DS pathogenesis, we analyzed the association between the polymorphisms at exon 6 of ICAM-1 (K469E) and exon 3 of PECAM-1 (L125V) genes and DS development in APL patients treated with ATRA and anthracyclines. Bone marrow (BM) or peripheral blood (PB) specimens from 127 patients with APL were collected at diagnosis. PB samples from 248 healthy volunteers were used as controls. The genetic confirmation of the PML/RARα rearrangement was done by RT-PCR using the BIOMED-1 protocol. DS was diagnosed in 23/127 (18.1%) APL patients, at an average of 11.5 days after the start of ATRA (between the 4th and 20th days). We did not demonstrate any difference between the group of leukemic patients with and without DS regarding age, gender, white blood cells counts, hemoglobin value or platelets counts. All patients who developed DS presented respiratory distress associated with increased ground-glass opacity in chest radiographies and, other accompanying symptoms were: fever not attributable to infection (65.2%), generalized edema (37.5%), weight gain (37.5%) and impairment of renal function (8.6%). The genotype frequencies of ICAM-1 were GG 33.0%, GA 50.8% and AA 16.2% in APL patients and GG 8.0%, GA 54.6% and AA 37.4% in control group. For PECAM-1, these frequencies were CC 10.2%, CG 60.2% and GG 29.2% in APL patients and CC 22.3%, CG 57.0% and GG 20.7% in control group. These genotype frequencies of both groups did not deviate significantly from the predicted frequency using Hardy-Weinberg equilibrium. APL patients presenting the AA genotype at exon 6 of ICAM-1 had a significantly increased risk of developing DS with a relative risk of 2.6 (95% confidence interval: 1.2-5.6). The AA genotype frequency in APL patients with and without DS was, respectively, 33% and 12.6% (p=0.04). On the other hand, no significant association was detected between L125V polymorphism at exon 3 of PECAM-1 and DS development. Our results suggest that susceptibility to DS in APL patients may be influenced by genetic variation in adhesion molecules loci.

0489

PHARMACOKINETIC/PHARMACODYNAMIC CORRELATION WITH CLINICAL RESPONSES IN A PHASE 1 STUDY OF PATIENTS WITH RELAPSED/REFRACTORY ACUTE LEUKEMIAS TREATED WITH SNS 595

M.R. Arkin,[1] R. Ricklis,[2] J. Lancet,[3] F. Giles,[4] U. Hoch,[1] D. Stockett,[1] Y Zhu,[1] G. Michelson,[1] J.A. Fox,[1] J.E. Karp[2]

[1]Sunesis Pharmaceuticals, SOUTH SAN FRANCISCO; [2]Sidney Kimmel Comprehensive Cancer Cente, BALTIMORE; [3]H. Lee Moffitt Cancer Center and Researc, TAMPA; 4MD Anderson Cancer Center, HOUSTON, USA

Background. SNS-595, a novel cell-cycle active compound that disrupts DNA replication forks and triggers DNA damage responses, G2 arrest, and apoptosis, is in phase 1 and 2 clinical trials in hematologic and solid malignancies. Preliminary clinical, pharmacokinetic (PK) and correlative results from an on-going escalating-dose phase 1 trial of SNS-595 in refractory acute leukemias are presented. *Aims.* Objectives: 1) establish safety, tolerability and MTD of SNS-595 given on 2 schedules; 2) characterize PK; 3) assess clinical activity; 4) explore potential biomarkers of mechanism-based activity and patient stratification. *Methods.* SNS-595 IV dosing: Arm A: days 1, 8 and 15; Arm B: days 1, 4, 8 and 11; minimum cycle lengths were 42 days and 39 days, respectively. Starting doses were18 mg/m^2 (Arm A) and 9 mg/m^2 (Arm B), with escalation by cohort. PK samples and pretreatment blood and bone marrow aspirates were collected from all patients for exploratory analyses

of the level of DNA damage repair proteins DNA-PKcs, Ku70 and Ku80. Post-dose blood and bone marrow aspirate samples were obtained from a subset of patients to determine sensitivity to SNS-595 *ex vivo* as well as evidence for DNA damage, apoptosis, and cell-cycle response. H2AX phosphorylation, PARP cleavage, and G2 arrest were evaluated. *Results.* 21 patients (Arm A) and 14 patients (Arm B) were evaluable. All patients were consented and had refractory and/or relapsed disease (median 3 prior regimens (range 1-6)). Accrual and dose-escalation have continued at 60 mg/m^2 for Arm A and 30 mg/m^2 for Arm B. Diagnoses: AML 32 patients, ALL 3 patients. One dose-limiting toxicity, prolonged neutropenia, was observed. Non-dose limiting adverse events included nausea/vomiting, diarrhea, and mucositis; grade 4 neutropenic fever was observed in only 1 patient. SNS-595 PK were dose proportional (dose range characterized: 9-50 mg/m^2) and volume of distribution and clearance values were unchanged across the dose range. Evidence of DNA damage was observed in patients treated with <25 mg/m^2 SNS-595. Increased H2AX phosphorylation was observed 2-4 hours post-dose. H2AX phosphorylation was unaffected at 18 mg/m^2 (Arm A). Estimated EC90 levels (10-fold the for cytotoxicity in leukemic cell lines) of SNS-595 were present on average for at least 4 hours for the 25 and 50 mg/m^2 cohorts, but for less than 2 hours at the 18 mg/m^2 dose level. Patient bone marrow samples were sensitive *ex vivo* to SNS-595 induced cytotoxicity. Clinical responses were observed at 50 mg/m^2, including one patient with CRp. At this dose level, four out of six patients with relapsed and/or refractory AML had decreases in marrow blasts to <5%. Clinical activity was observed at a dose where EC90 concentrations were maintained on average for over 24 hr. *Summary and Conclusions*. SNS-595-induced DNA damage responses are observed in bone marrow at doses <25 mg/m^2. In patients with advanced leukemia, SNS-595 demonstrates promising clinical activity, including significant blast reductions (<5%) and a CRp at 50 mg/m^2, a dose level where EC90 concentrations of SNS-595 were maintained over 24 hr. An MTD has not yet been reached in either schedule.

0490

HIGH RELAPSE RATE OF ACUTE MYELOID LEUKEMIA WITH TRANSLOCATION (8;21) OR INVERSION (16) IN ELDERLY PATIENTS TREATED WITH CONVENTIONAL CHEMOTHERAPY

T. Prebet,[1] F. Bernard,[2] A. Charbonnier,[2] M.J. Mozziconacci,[2] D. Coso,[2] A.M. Stoppa,[2] D. Sainty,[2] J.A. Gastaut,[2] D. Blaise,[2] N. Vey[2]

[1]Instiut Paoli Calmettes, MARSEILLE; [2]Institut Paoli Calmettes, MARSEILLE, France

Background. AML with rearrangements of CBF α or β (CBF-AML) are associated with a good prognosis when treated with intensive chemotherapy. Such treatments cannot be offered to elderly patients and previous reports (Schoch et al, Haematologica 2004) showed that aging was an independent adverse prognosis factor in CBF-AML patients. Nevertheless only few specific data are available on the characteristics and outcome of CBF-AML in the elderly. *Aims.* To describe the clinical characteristics of CBF-AML in the elderly and to analyze their outcome. *Methods.* A retrospective analysis was performed on 27 patients with t(8;21) or inv(16) older than 60 years who received conventional induction chemotherapy in our institution. CBF leukemia was confirmed by cytogenetics and/or transcript specific PCR. A predefined set of data was collected including medical history, disease related variables and treatments. A comorbidity index was calculated for each patient as described by Sorror et al (HCT-CI, Blood 2005). *Results.* Median age was 68 years (60-76). Eight patients (30%) were older than 70 years. Seven patients had t(8;21), 20 patients had inv(16) and 9 patients (33%) presented additional chromosomal abnormalities. 24 patients achieved CR after 1 or 2 induction courses (89% CR rate). There were 3 early deaths (11%) and 7 patients were referred to ICU (3/7 had a high HCT-CI). Post-remission therapy consisted of low dose maintenance chemotherapy (14 patients) or intensive consolidation (high dose cytarabine: 10 patients; HD Melphalan with autologous SCT: 4 patients). With a median follow-up of 14 months, 16 patients have relapsed (3-year cumulative incidence of relapse: 82%). Overall Survival and Leukemia Free Survival were respectively 22 and 18 months. There was a trend to a better OS for patients without initial high WBC count (p=0.1). No impact of other initial demographic or biological variables, post induction regimen or molecular minimal residual disease monitoring could be put in evidence. *Conclusions.* Elderly patients with CBF-AML must be offered standard induction which leads to high CR rate. Nevertheless, the majority of them relapse with conventional post-remission treatment and the administration of one cycle of HDAC did not seem to improve prognosis. Alternative strategies of post-remission therapy are thus warranted. New cytotoxic drugs as well as targeted molecules need to be investigated.

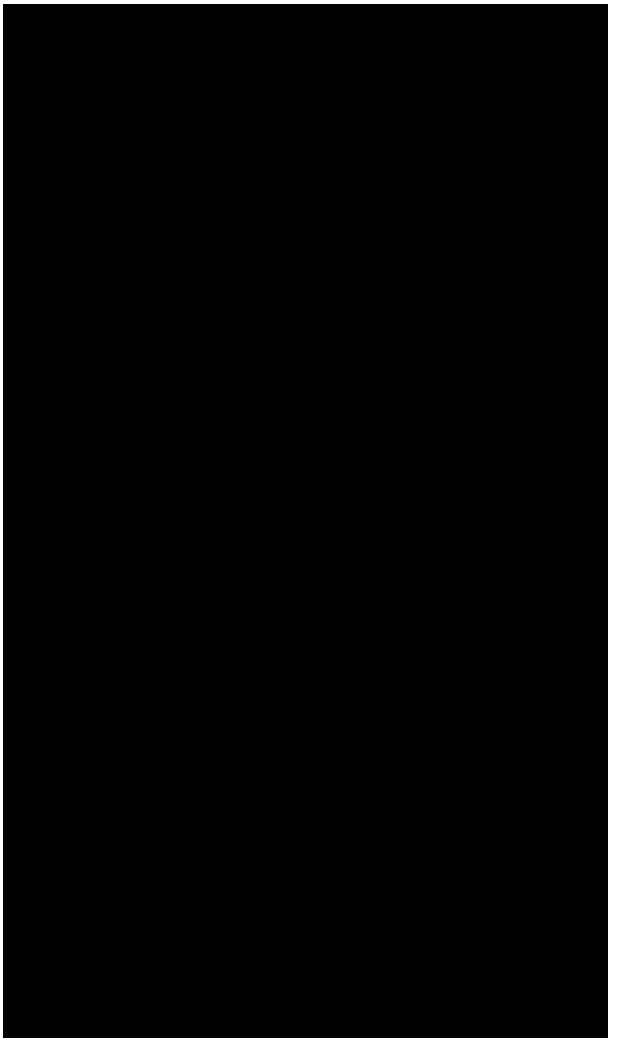

Figure 1. Overall survival and incidence of relapse.

0491

IMPROVED SURVIVAL IN ELDERLY ACUTE MYELOID LEUKAEMIA PATIENTS GIVEN CLADRIBINE IN COMBINATION WITH STANDARD REMISSION INDUCTION (DA 3+7) AND CONSOLIDATION TREATMENT (HD ARAC). SEVEN YEAR FOLLOW-UP OF PROSPECTIVE, COOPERATIVE PALG STUDY

S. Grosicki,[1] J. Holowiecki,[1] T. Robak,[2] S. Kyrcz-Krzemien,[1] S. Giebel,[1] A.H. Andrzej,[3] A.S. Skotnicki,[4] W.W. Jedrzejczak,[3] L. Konopka,[5] K. Kuliczkowski,[3] B. Zdziarska,[3] A. Dmoszynska,[3] B. Stella-Holowiecka[1]

[1]Silesian Medical Academy, KATOWICE; [2]Medical University, LODZ; [3]Medical Academy, GDANSK; [4]Jagiellonia University, CRACOW; [5]Institut of Hematology and Transfusiology, WARSAW, Poland

The aim of this study was to evaluate long-term outcome of acute myeloid leukemia (AML) patients treated within the PALG 1999 DAC vs. DA Study. Within 3 years (1999-2002) 400 patients, aged 18-60, were randomized 1:1 to the induction treatment DAC-7: daunorubicin 60 mg/m^2/d iv 1-3; cytarabine 200 mg/m^2/d ci d 1-7; cladribine (2-CdA) 5 mg/m^2 2h inf. iv d 1-5 and standard DA-7 regimen (the same therapy excluding cladribine). Patients achieving CR received two courses of subsequent intensive consolidation: 1) HAM (HD AraC, mitoxantrone) 2) HD AraC with or without cladribine in the DAC-7 or DA-7 arm, respectively. In case of PR after the first induction course the same regimen was repeated, Post-consolidation therapy was comparable in both arms with following proportions of autoHCT, alloHCT and maintenance: DAC-7 17%, 14%, 69%; DA-7 21%, 14%, 65%, respectively. As

previously reported, a single course of DAC-7 induction resulted in 17% higher CR rate compared to the DA-7 treatment (p=0,0008). The difference was particularly pronounced in patients: aged >40 years and with initial WBC >100×10^9/L. In the latter subgroup also the overall CR rate (achieved after entire induction program) was higher in the DAC-7 arm (71% vs. 43%). [Leukemia 2004;18:989-97] In the present report we analyzed seven-year long-term outcome (median follow-up 5 yrs) in the whole study population and in subgroups stratified according to age, initial WBC, cytogenetics, sex, FAB subtype, and preceding myelodysplasia. In the whole group the overall survival (OS) rate equaled 29,5% for DAC-7 and 24% for DA-7 arm (p=NS) and leukemia free survivall (LFS) 30% vs. 28% (p=NS), respectively. Of note, in patients aged >40 years, the therapy containing cladribine was associated with improved OS (26% vs. 14,5%, p=0.03), and LFS (28% for DAC-7 vs. 18,5% for DA-7, p=0.02). Other subgroup analyses revealed higher probability of the OS in patients with initial WBC ≤50 G/L assigned to DAC-7 compared to DA-7 arm (32% vs. 20,5%, p=0.04). The LFS rate equaled 35% and 27% (p=NS), respectively. In women receiving DAC-7 induction therapy in comparison with those treated in arm without 2-CdA reached higher OS: 29% vs. 19,5%, p=0,03, respectively. LFS in these subgroups was comparable: 25% vs. 22%, p=NS, respectively. We conclude that addition of cladribine to induction and consolidation therapy of AML improves long-term outcome in patients: older than 40 y, as well as in those with high tumour burden. The better outcome in older patients results mainly from reduced risk of relapse, whether that in cases with high WBC seems to be linked to a higher CR rate.

0492

INFANT LEUKEMIAS: TRANSIENT MYELOPROLIFERATIVE SYNDROMES IN CHILDREN WITH TRISOMY 21 MOSAIC

K. Reinhardt,[1] A. Pekrun,[2] A. Sauerbrey,[3] D. Reinhardt[1]

[1]Hannover Medical School, HANNOVER; [2]Prof.-Hess Kinderklinik, BREMEN; [3]Helios-Klinikum Children's Hospital, ERFURT, Germany

Introduction. Children with Down syndrome have a 10- to 20-fold increased risk of leukemia and a 10%-incidence of transient myeloproliferative disorders (TMD). TMD may also occur in neonates without any stigmata of Down syndrome but with trisomy 21 mosaic. About 20-30% of DS-neonates with TMD developed myeloid leukemia of Down syndrome (ML-DS) during the first 4 years of life. TMD blasts are indistinguishable from ML-DS blasts in both morphology and immunophenotyping. In almost all patients with TMD or myeloid leukemia of Down syndrome mutations in exon2 or exon3 or the hematological transcription factor GATA1, leading to a truncated GATA1s, have been detected. *Materials and Methods.* We performed polymerase chain reaction (PCR) on exons 2 and 3 using primers that flanked each of the exons. DNA sequencing was done directly on purified PCR products. Each identified mutation was confirmed using sense and anti-sense primers. *Patients*. All three children were mature newborns without any obvious stigmata of Down syndrome. The clinical symptoms of leukemia occurred within the first weeks of life. Due to typical morphology and immunophenotype of the leukemic blasts (CD34/CD117/CD13/CD33/CD7/CD56/CD36/CD42b), a TMD was considered and no intensive anti-leukemic treatment initiated. Detection of GATA1 mutations in all children and the karyotyping of fibroblasts and hematopoietic cells, which revealed trisomy 21 mosaic, confirm the diagnosis of TMD. Due to clinical symptoms caused by the TMD, two children were treated with low-dose cytarabine (1 to 1.5 mg/KBW). All infants experienced complete remission within 6 weeks. During follow-up no evidence of relapse or development of a myeloid leukemia of Down syndrome was observed. *Results.* Table 1.

Table 1.

Patient	Sex/Age diagnosis	Symptoms	WBC/μL	Blasts (BM)	DNA source	Mutation	Consequence
P.M.	F/5 weeks	Leukemia cutis anemia, thrombocytopenia, hepatosplenomegaly	74,700	24%	blasts	IVS2+2 T>C	Splice mutant
K.V.	M/0	Pulmonal insufficiency, hepatosplenomegaly	130,000	13%	blasts	261 dup 156-261	Stop codon before Met84
A.S.	M/6 weeks	Anemia, thrombocytopenia, pericardiac effusion	40,600	65%	smears	328 del 12	Splice mutant

Conclusions. In newborns and infants, diagnosed with acute megakaryoblastic leukemia, the possibility of TMD and trisomy 21 mosaic should be considered. Analysis of the GATA1 mutation should be performed to prevent overtreatment. If clinical symptoms due to TMD occur, low-dose cytarabine is recommended. Due to the possible risk of developing myeloid leukemia, close follow-ups should be performed.

0493

CLAG-M IS HIGHLY EFFECTIVE SALVAGE REGIMEN IN PATIENTS WITH RELAPSED AND REFRACTORY ACUTE MYELOID LEUKEMIA. THE FINAL RESULTS OF MULTICENTER PHASE II STUDY OF THE POLISH ADULT LEUKEMIA GROUP (PALG)

A. Wierzbowska,[1] T. Robak,[1] A. Pluta,[1] E. Wawrzyniak,[1]
J. Holowiecki,[2] S. Kyrcz-Krzemien,[2] S. Grosicki,[2] A. Skotnicki,[2]

A. Wrzesien-Kus[1]

[1]Copernicus Memorial Hospital, LODZ; [2]Department of Hematology, KATOWICE, Poland

Objectives. Cladribine (2-CdA) in addition to cytosine-arabinoside (Ara-C) increases the accumulation of Ara-C-5' triphosphate which is responsible for the cytotoxic effect in leukemic blasts. Our preliminary results have suggested that addition of Mitoxantron (MIT) to 2-CdA, Ara-C and granulocyte colony-stimulating factor (G-CSF) CLAG-M improves the treatment results in refractory/relapsed patients with acute myeloid leukemia (AML). In this cooperative phase II study we evaluated the efficacy and toxicity of salvage regimen CLAG-M in refractory/relapsed AML patients with poor risk. *Materials and Methods.* The patients were qualified to high risk group if they represent: i) primary refractory AML, ii) AML in first relapse with duration of complete remission (CR) <6 months iii) second or greater relapse and iv) relapse after autologous or allogeneic stem cell transplantation (SCT). All patients were previously treated according to the Polish Adult Leukemia Group clinical research protocols. The patients received 2-CdA 5 mg/m^2 (days 1-5), Ara-C 2 g/m^2 (days 1-5), G-CSF (days 0-5) and MIT 10 mg/m^2 (days 1-3). In case of partial remission a second CLAG-M was administered. Patients with CR received consolidation courses based on high dose of Ara-C and MIT and allogeneic SCT if donor was available. *Results.* From November 2002 to November 2006, 112 patients (72 primary resistant and 40 relapsed) from 11 centers were registered. The median age was 43 years (range 20-66). CR was achieved in 63 (56%) patients 43 (38,5%) were refractory and 6 (5,5%) died early. Forty six out of primary resistant patients received daunorubicine (DNR) and Ara-C as the first line induction therapy (DA), 26 received additionally purine analogues: Cladribine (n=13; DAC) or Fludarabine (n=13; DAF). The CR rates after CLAG-M were 52%, 61% and 53% respectively (p=NS). Cytogenetic analysis was available in 89 patients. Two patients (2%) had a favourable karyoytype, 49 (55%) an intermediate, 26 (29%) an unfavourable and 12 (14%) were classified as unknown according to SWOG classification. The CR rate of 100%, 57% and 46% were achieved in favourable, intermediate and unfavourable cytogenetics respectively (p=NS). The only factors influencing the probability of achieving CR were WBC<30 G/L (66% vs. 41%; p<0.04) and LDH <500 U/l (65% vs. 47%; p<0,03). The hematological toxicity was the most prominent toxicity of this regimen. The overall survival (OS; 1 year) for the 112 patients as a whole and the 63 patients in CR were 42% and 62% respectively. In the univariate analysis WBC>30 G/L, lack of transplantation in CR and unfavourable cytogenetics were poor prognostic factors for OS (p<0.02; p<0,001 and p=0,051 respectively). In multivariate Cox regression model lack of transplantation in CR was the only factor influencing OS (p<0,01). *Conclusions.* CLAG-M is well tolerated and very effective salvage regimen in high risk refractory/relapsed AML. The toxicity is acceptable enabling most patients to receive futher treatment including transplantation procedures. SCT is the only factor influencing overall survival and should be treatment of choice.

MONITORING OF MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA USING PERIPHERAL BLOOD AS AN ALTERNATIVE SOURCE TO BONE MARROW

L. Maurillo,[1] F. Buccisano,[2] G. Del Poeta,[1] A. Spagnoli,[1] B. Neri,[1]
M.I. Del Principe,[2] L. Cupelli,[1] F. Luciano,[1] P. De Fabritiis,[1] S. Amadori,[2]
A. Venditti[2]

[1]University Tor Vergata, Ospedale S. Eug, ROME; [2]University Tor Vergata, ROME, Italy

Background. Monitoring of minimal residual disease (MRD) by multiparametric flow cytometry (MPFC) can provide useful prognostic information in adult patients with acute myeloid leukemia (AML), when bone marrow (BM) is used. Recently, it has been reported that using

quantitative PCR, MRD is also detectable and measurable in peripheral blood (PB) of AML patients. *Aims.* Based on these premises, we assessed by MPFC the levels of MRD in PB and BM samples of 55 adult patients with AML to verify the feasibility of MRD detection in PB and its prognostic relevance. *Methods.* A total of 55 adult patients with AML were entered into the EORTC/GIMEMA protocols AML10/AML12 (age <61 yrs) or AML13/AML15 (age>61 yrs), consisting in intensive induction and consolidation cycles, and, for patients aged <61 years, autologous or allogeneic stem cell transplantation. Median age was 47 years (range 21-73), all FAB subtypes were represented with the exception of M3 cases. We studied 55 and 53 pairs of BM and PB at the end of induction and consolidation therapy, respectively. *Results.* Findings in BM e PB were significantly concordant after induction and consolidation therapy. Median value of BM residual leukemic cells (BMRLC) and PB residual leukemic cells (PBRLC) after induction, were 5×10^{-3} (range 1×10^{-4}-1.64×10^{-1}) and 2.3×10^{-3} (range 1×10^{-5}-1.15×10^{-1}), respectively (r=0.84, p<0.001). After consolidation, the median value of BMRLC and PBRLC were 3.9x10-3 (range 2×10^{-5}-6.3×10^{-2}) and 3.4×10^{-3}(range 1×10^{-5}-1.34×10^{-1}), respectively (r=0.85, p<0.001). Using the maximally selected log rank statistics, we found that the cut-off of 1.5×10^{-4} PBRLC correlated with the disease outcome. In fact, 34 of 47 (72%) patients with PBRLC > 1.5×10^{-4} after induction had a relapse, whereas, the 8 patients with <1.5×10^{-4} did not (p<0.001). After consolidation, 42 patients had a level of MRD >1.5×10^{-4} and 32 (76%) had a relapse; 10 out of the remaining 11 patients, whose level of MRD was below 1.5×10^{-4}, are still relapse free (p<0.001). The median duration of relapse free survival (RFS) was not reached among the patients with a PB MRD- status after consolidation, whereas it was 11 months among those with a PB MRD$^+$ status after consolidation (p=0.001); the multivariate analysis confirmed the independent prognostic role of the PB MRD status at the end of consolidation (p=0.019). *Conclusions.* 1) MRD is detectable and measurable in PB of AML patients using MPFC; 2) MRD levels in PB are correlated to those measured in BM; therefore PB may be a complementary source for MRD studies in patients with AML; 3) PB MRD determination after consolidation therapy has a prognostic role; 4) combined BM and PB assessment might allow risk-category stratification to be improved, optimizing MRD monitoring in AML patients

0495

OUTCOME AND CHARACTERISTICS OF NEWLY DIAGNOSED PATIENTS WITH ACUTE MYELOID LEUKAEMIA. A COMPARISON OF MRC AML15 PATIENTS WITH ELIGIBLE NON-TRIAL PATIENTS IN A SINGLE CENTRE

J. Stevens, F. MacDougall, M. Jenner, H. Oakervee, J. Cavenagh, T.A. Lister

Barts and the London School of Medicine, LONDON, United Kingdom

Background. St Bartholomew's Hospital is a major centre for the treatment of acute myeloid leukaemia (AML) and since June 2003 has been participating in the MRC AML15 trial. To date AML15 has recruited 2340 patients from 154 centres; St Bartholomew's is in the top ten centres for recruitment. Aims This analysis has been undertaken to determine what proportion of newly diagnosed patients who are eligible for the trial are actually entered, and to compare the presenting features and outcomes of those entered with those not. Results Since June 2003, 82 patients who were eligible for AML15 presented to our centre (age 17-60 years, median age 46.8 years, male:female ratio 1.3:1) Forty-nine patients (60%) were consented to the trial. The median age of trial patients was 50 years, median age non-trial patients 44.8 years. Twenty-nine (61%) of the male patients were randomised into the trial and 20 (57%) of the female patients. Sixty-five (79%) of the patients presenting were white Caucasian; 6 were African, 4 were African-Caribbean, 3 of South Asian origin and 4 were from other ethnic groups. Forty-one of 65 (63%) of the white Caucasians entered AML15, compared with 8/17 (47%) of the patients from the ethnic minorities. This trend was not statistically significant (p=<0.2). The trial and non-trial groups were matched for the cytogenetic risk status, except for patients with t(15;17). Fifteen of the eligible patients had t(15;17) at presentation, but only 6 (40%) were randomised into AML15. We also analysed the day of the week on which patients first presented to the hospital; only one of four patients who presented at the weekend (Saturday or Sunday), entered AML15, otherwise day of the week of presentation did not influence trial entry. Only 9/82 (11%) of patients were not invited to participate in the trial. One of these presented on the weekend; other reasons documented for not entering the trial included *too unwell to consent* (4 patients) cognitive impairment (3 patients), and communication difficulties (1 patient).Nineteen of the 73 patients invited to participate in the trial were not randomised. Fifteen (20%) patients declined.; 4 patients expressed uncertainty about consenting and 2 of these were judged to need urgent therapy and electively treated off trial, Two other patients who expressed uncertainty about randomisation had FAB type M3 and the physician elected therapy off trial. The reason for non-trial entry could not be established retrospectively in 5 patients. Survival of the cohort not entered into the trial is similar to the cohort that was entered. Conclusions A high proportion of eligible patients (89%) are invited to participate in AML15 at St Batholomew's hospital, and of these 60% enter the study. Recruitment is not affected by age, gender or ethnicity. There was a trend towards lower entry into the trial in patients with FAB type M3, due to physician bias. Outcome did not correlate with entry into the trial.

FUNGAL INFECTIONS IN ACUTE MYELOID LEUKEMIA PATIENTS TREATED WITH INDUCTION REGIMENS INCLUDING FLUDARABINE: A RETROSPECTIVE ANALYSIS OF 224 CASES

M. Malagola,[1] A. Peli,[2] D. Damiani,[3] A. Candoni,[3] M. Tiribelli,[3] G. Martinelli,[4] P.P. Piccaluga,[4] S. Paolini,[4] F. Lauria,[2] M. Bocchia,[2] M. Gobbi,[2] I. Pierri,[2] A. Zaccaria,[5] E. Zuffa,[5] P. Mazza,[5] G. Priccolo,[5] L. Gugliotta,[5] A. Bonini,[5] G. Visani,[5] C. Skert,[2] C. Bergonzi,[2] A. Roccaro,[2] C. Filì,[2] E. Capuzzi,[2] R. Fanin,[3] M. Baccarani,[4] D. Russo[2]

[1]Chair of Haematology, Brescia, BRESCIA; [2]Chair of Haematology, UNIVERSITY OF BRESCIA; [3]Clinic of Haematology, UNIVERSITY OF UDINE; [4]Institute of Haematology Seràgnol, UNIVERSITY OF BOLOGNA; [5]Unit of Haematology, RAVENNA, Italy

Infections are the major cause of morbidity and mortality of acute myeloid leukaemia (AML). Invasive Fungal Infections (IFIs) occur in at least 10 to 20% of the patients submitted to induction and consolidation treatments and are responsible for death during induction (DDI) up to the 5% of the cases. Furthermore, they may cause a delay in consolidation and intensification therapy with autologous or allogeneic stem cell transplantation and for these reasons they may contribute to increase the relapse rate. Among the risk factors for IFIs it has been included the use of Fludarabine (Fluda), which can induce severe and prolonged immunosuppression. In this study we retrospectively analyzed the infections occurred in 224 newly diagnosed AML patients, aged at least 60 years, consecutively treated with a Fluda containing induction regimen. One-hundred thirty-five patients were treated with FLAI (fludarabine + cytarabine + idarubicine) and 89 with FLAIE (fludarabine + cytarabine + idarubicine + etoposide). During induction phase, 134/224 (60%) patients experienced a fever of undetermined origin (FUO), the incidence of Gram negative and positive sepsis was 14% (31/224) and 22% (49/224) respectively and 38/224 (17%) patients developed a possible/probable IFI. In 9/224 patients (4%) a proven IFI was found (6 Aspergillosis and 3 Candida). Taking into consideration the long lasting immunosuppressive effect of Fluda, we collected the data of the incidence of infections during the first consolidation course (FLAI: n=70; high dose cytarabine: n=65; idarubicine and high dose cytarabine: n=89). The overall incidence of FUO was 29% (66/224), the number of Gram negative and positive sepsis was 53/224 (24%) and 49/224 (22%), respectively and 4/224 (2%) patients developed a proven IFI (3 Aspergillosis and 1 Candida). In all but one case, the fungal infections diagnosed during consolidation occurred in patients who developed an IFI during the previous induction therapy. These data, even though retrospectively collected, suggest that the use of a Fluda-based induction chemotherapy doesn't cause a high number of IFIs, neither during induction, nor during consolidation. In particular, the incidence of infective complications in our series of AML patients favourably compares to the one reported by other Authors with induction chemotherapy not including Fluda.

This work was supported in part by FIRB (protocol number: RBAU01RLNB005 - 2004; D. Russo), progetto 60% 2005 (D.Russo) and COFIN 60% 2006.

SINGLE AGENT CLORETAZINE (VNP40101M) IN ELDERLY AML PATIENTS WITH UNFAVORABLE CYTOGENETICS: RESULTS FROM A PHASE II MULTI-CENTER STUDY

N. Vey,[1] D. Rizzieri,[2] J. Karp,[3] V. Karsten,[4] A. Cahill,[4] F. Gile[s5]

[1]Paoli-Calmettes, MARSEILLE CEDEX 9, France; [2]Duke University, DURHAM, NC, USA; [3]Johns Hopkins University, BALTIMORE, MD, USA; [4]Vion Pharmaceuticals, NEW HAVEN, CT, USA; [5]UT MD Anderson Dept of Leukemia, HOUSTON, TX, USA

Background. Outcomes for elderly patients with AML are poor, and it has been shown that elderly patients with unfavorable cytogenetics have a particularly poor prognosis. Additionally, a large number of these patients are considered unfit for intensive chemotherapy due to coexisting comorbidities, and are given best supportive care or low-dose AraC. However, no complete remissions are observed with this treatment and median overall survival is approximately 1 month (Burnett *et al.,* Cancer 2007). Patients with unfavorable cytogenetics who do receive cytotoxic induction treatment achieve complete response rates between 23-33% with very low 5-year survival rates (2-4%) (Grimwade et al Blood 2001, Rowe et al Blood 2004, Farag et al Blood 2006, Buechner et al JCO 2006). *Methods.* We present a subset analysis of patients with unfavorable cytogenetics in a Phase II study of Cloretazine® as a single agent (Vion Study CLI-033). Cloretazine® is a new alkylating agent that causes DNA cross-links and cell death. The study was designed for untreated patients with AML or high-risk MDS over the age of 60. Treatment consisted of Cloretazine® (VNP40101M) 600 mg/m^2 administered as a short IV infusion on day 1 (second cycle allowed) and an additional 400 mg/m^2 as consolidation for responders (CR or CRp). The primary endpoint was overall response (CR or CRp). Overall survival and relapse-free survival were also analyzed. *Results.* The study treated 128 patients of age 60 or older. Fifty-eight patients (45%) had unfavorable cytogenetics (-7, del5q, abnl11q, abnl9q, abnl20q, abnl13q, complex (≥ 3 abnormalities)). Of these 58 patients, 28 (48%) had secondary AML, 19 (33%) had *de novo* AML and 11 (19%) had high-risk MDS. Twenty-three (40%) patients in the unfavorable group had a complex karyotype. The response rate in patients with unfavorable cytogenetics was 26% (15/58). Response by diagnosis: 53% in *de novo* AML, 27% in MDS and 7% in secondary AML. Median overall survival in patients with unfavorable cytogenetics was 3 months (range 0.1-28). In patients achieving CR or CRp, median overall survival was 5 months (range 2-28) and relapse-free survival was 3.5 months (range 1-20). In non-responders, overall survival was 2 months (range 0.1-9). Twelve (21%) patients died within 30 days of receiving induction treatment. *Conclusions.* Cloretazine® has the ability to induce remissions in elderly AML patients with unfavorable cytogenetics. Survival in this group is improved compared to that reported for supportive care or low dose AraC. Cloretazine® may provide an important treatment option for poor prognosis patients with AML.

Autologous stem cell transplantation

0498

THE ROLE OF HIGH DOSE CHEMOTHERAPY AND PERIPHERAL BLOOD STEM CELL SUPPORT IN REFRACTORY TROPHOBLASTIC DISEASE AND NON-GESTATIONAL CHORIOCARCINOMA: A REVIEW OF EIGHT PATIENTS

I. Gabriel,[1] A. Chaidos,[1] C. Giles,[1] J. Apperley,[1] M. Seckl,[2] M. Bower,[3] E Kanfer[1]

[1]Hammersmith Hospital NHS Trust, LONDON; [2]Charing Cross Hospital, LONDON; [3]Chelsea and Westminster Hospital, LONDON, United Kingdom

Objective. To evaluate the role of high dose therapy (HDT) with autologous peripheral blood stem cell support (ASCT) refractory advanced trophoblastic disease and non gestational choriocarcinoma. *Methods.* Eight patients (gestational trophoblastic neoplasia n =6, choriocarcinoma post complete hydatidiform mole n=1, possible non-gestational choriocarcinoma n=1 and germ cell tumour with choriocarcinoma differentiation n=1) were treated with HDT with ASCT. Median age was 33 years. All patients received a conditioning regimen of CarboPEC-Taxol (Paclitaxel 75 mg/m^2 on days -7, -5, and -3, Etoposide 450 mg/m^2 days -7, -5, and -3, Carboplatin 10 mg x glomerular filtration rate (GFR) +25 on days -7, -5,and -3, and Cyclophosphamide 60 mg/kg/day days -5, and -3). Four patients received this regimen as a tandem ASCT, receiving 50% dose of the conditioning regimen drugs with stem cell infusion twice, twelve weeks apart, to limit toxicity. All eight patients had multiply relapsed disease and had received more than two different prior treatments (median number of prior therapies was 3.5 range, 2-5) at time of ASCT. Two patients had cerebral metastases. At transplant four patients were in a partial remission (PR) and four had progressive metastatic disease. *Results.* The regimen was well tolerated. Seven patients showed an initial response immediately post ASCT, one patient demonstrated disease progression throughout. Five patients achieved a complete remission (CR) demonstrated by a reduction in serum tumour markers to normal (<4 IU/L), two patients achieved a good partial remission (PR) with a reduction of serum levels of β HCG to below 20 IU/L. Two patients died of transplant related causes (invasive fungal infection and gram negative neutropenic sepsis), a transplant related mortality (TRM) of 25%. All six surviving patients relapsed within three months (median DFS 0.99 months). Five patients died of progressive disease within fifteen months of transplant with a median overall survival of 8.97 months (range 7.29-15.21 months). Cerebral disease did not confer a worse outcome. One patient who relapsed immediately post-transplant with rising serum βHCG levels, remains alive at 41 months with undetectable βHCG levels despite no further treatment. *Conclusions.* Refractory trophoblastic disease has a poor outcome. High dose therapy using CarboPEC-Taxol with autologous stem cell rescue results in a short response, however, most patients experience early relapse. In young women this short period of remission may be of value, affording longer period of time spent with young families. It should be noted that those patients referred for HDT have been refractory to a number of chemotherapeutic regimens and had widespread disease. The question is whether an improved long-term survival might be seen with earlier high dose therapy and ASCT in CR2 or early progressive disease. Although this disease is not primarily of hematopoietic tissue, allogeneic transplant could be considered in this young age group, with a theoretical advantage of a graft versus tumour effect. We can offer no explanation for the patient who relapsed post-transplant entering a sustained remission, other than the development of an immunological anti-tumour response. If this were the case, then allogeneic transplant with donor lymphocyte infusion could have some role in the treatment of this aggressive disease. More information on the role of transplantation in trophoblastic disease is thus required before any conclusions can be drawn and treatment strategies considered.

0499

ENDOTHELIAL CELL MARKERS KINETICS FOLLOWING UMBILICAL CORD BLOOD TRANSPLANTATION IN ADULTS

A. Petropoulou

Hôtel-Dieu, PARIS, France

Background. Alloreactivity is supposed to induce modifications on the vascular endothelium. Complications occurring in the course of allogeneic haematopoietic stem cell transplantation, such as acute or chronic graft-versus-host disease (GVHD), have been related to endothelial cell alterations. Moreover, the incidence of GVHD is significantly different

following allogeneic bone marrow transplantation (BMT), peripheral blood stem cell transplantation (PBSCT) or umbilical cord blood transplantation (UCBT). *Aims.* Considering the different incidence of acute and chronic GVHD according to the transplanted type of haematopoietic stem cells and taking into account the supported xenotransplantation-related vasculopathy, we aimed to further clarify the vascular impact of the three aforementioned sources of haematopoietic stem cells. *Methods.* We studied 21 patients, 13 male and 8 female. Mean age was 42 years old (21-64). The underlying diseases were: 15 patients presenting an acute myeloid leukaemia, 3 patients with acute lymphoblastic leukaemia, 1 patient with multiple myeloma, 1 with bone marrow aplasia and 1 patient with chronic idiopathic myelofibrosis. Seven patients underwent BMT after myeloablative conditioning regimen (cyclophosphamide and busulphan or total body irradiation-TBI at 12Gy), 6 patients PBSCT following non-myeloablative preparative regimen (fludarabine and TBI at 2Gy) and 8 patients underwent UCBT following reduced intensity conditioning regimen (cyclophosphamide , fludarabine and TBI at 2Gy). We assessed the kinetics of plasma levels of 4 endothelial markers: soluble thrombomodulin (sTM), vWF-Ag, FVIII and the vascular endothelial growth factor (VEGF). Measurements were performed before the conditioning regimen, on days 0, 15, 30, 60 and 90, by using commercialised ELISA kits from Asserachrom (Diagnostica Stago, France). We used the Student paired t-test for statistical comparison. Differences were significant if $p<0.05$. *Results.* In BMT and PBSCT we observed a significant increase of sTM on days 30 and 60 respectively, in comparison to day 0 (141±42 ng/mL and 143±13 ng/mL respectively, $p<0.05$). No significant elevation of sTM, compared to pre-conditioning values, was shown in UCBT during the studied period. sTM in UCBT peaked on day 90 (119±54 ng/mL, $p>0.05$). Similarly, vWF-Ag was significantly increased on day 0 in BMT and PBSCT (217±66% and 214±93% respectively, $p<0.05$ compared to pre-conditioning values), whereas in UCBT vWF-Ag plasma levels remained almost unchanged during the studied period. FVIII was significantly elevated on day 15 in PBSCT (200±6%, $p<0.05$ in comparison to baseline values), but we did not observe any significant increase of FVIII, in comparison to pre-conditioning values, in BMT and UCBT. Finally, there was no significant modification of VEGF in the 3 types of transplantation. *Conclusions.* This is the first study investigating the kinetics of different endothelial cell markers following UCBT and comparing them to BMT and PBSCT. A significant difference was observed in the kinetics of endothelial cell markers, according to the source of stem cells. Cord blood cells seem to hardly affect vascular endothelium, as shown by the stability of sTM and vWF-Ag plasma levels in the course of the UCBT. The low impact of UCBT on the vascular endothelium could possibly be correlated to fewer transplant-related complications and less incidence of GVHD in this type of transplantation.

0500

HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS HEMATOPOIETIC PROGENITOR CELL TRANSPLANTATION (AHCT) FOR NON-HODGKIN S LYMPHOMA IN PATIENTS OVER 65 YEARS OF AGE

C. Hosing, C. Hosing, R.M. Saliba, U. Popat, G.J. Okoroji, P. Kebriaei, M. De Lima, D. Couriel, M. Qazilbash, P. Anderlini, S. Giralt, R. Champlin, I. Khouri

M.D. Anderson Cancer Center, HOUSTON, USA

High-dose chemotherapy followed by AHCT is the treatment of choice for patients with relapsed NHL. Often this therapy is not offered to patients who are older than 65 yrs of age because of concerns regarding their ability to tolerate such aggressive therapy . We present a retrospective analysis of 99 consecutive pts who underwent AHCT for NHL at our institution from 6/96-3/06. All patients signed informed consent prior to AHCT. *Results.* Most common histologies were DLCL (55%), MCL (15%), and FL grades 1-3 (15%). Median age at diagnosis was 65 yrs (range, 47-81) and median age at AHCT was 68 yrs (range, 65-83). Seventy percent were males. Median number of chemotherapy regimens administered prior to AHCT were 2 (range 1-6). Median IPI score at the time of AHCT was 1 (range 0-4), 44% of pts had an IPI of > 1. Majority of patients (99%) had an ECOG PS score of < 2 prior to AHCT. Forty-four percent pts were in CR/CRu, 45% were in PR, and 11% had PD/SD. The preparative regimen comprised of BEAM (35%), BEAM/rituximab (53%), and Cy/TBI ± rituximab (10%). Median length of hospital stay was 23 days (range, 6-85) for AHCT with 38% requiring readmission within the first 100 days. Source of progenitor cells was HPC-A in 89%. Median $CD34^+$ cell dose infused/kg was 4.4×10^6 (0.08-32.2). All patients engrafted. Median time to reach an ANC of 500/mm^3 was 10 days (range 7-47). Ten patients never achieved a platelet count of 20,000/mm^3. For the remaining 88 pts the median time to reach platelet count of 20,000/mm^3 was 13 days (range, 6-375). Median number of PRBC units transfused were 4 (range, 0-50) and the median number of platelets transfusions required were 4 (range, 0-35). Grade 3-5 non hematologic RRT toxicity is summarized in Table 1. Cumulative TRM was 8% (95% CI 4-17) at 26 mths and 12% (95% CI 6-22) at 36 mths. At the time of this analysis the median median follow time among survivors was 26 mths (range, 1-115). The 3 yr OS for the entire cohort was 61% (95% CI 49-71). The 3 yr DFS was for 48% (95% CI 33-61), 68% (95% CI 36-87), and 63% (95% CI 22-87) for DLCL, MCL and FL respectively. On univariate analysis IPI > 1, LDH > normal, and having SD/PD at the time of AHCT were predictors of a worse OS. Disease status at transplant and LDH > normal remained significant predictors for OS ($p=0.002$) on multivariate analysis. Age, gender, histology, number of prior chemotherapy regimens, time from diagnosis to AHCT, and type of conditioning regimen were not significant predictors of OS. Most common cause of death was disease progression/relapse in 60% of patients. Eight patients developed sMDS/AML after AHCT. *Conclusions.* Patients over 65 yrs of age can undergo AHCT with acceptable toxicity and should be considered transplant candidates if they have chemosensitive disease and normal LDH at the time of AHCT.

Table 1. Non-Hematologic RRT Grades 3-5.

0501

EFFICACY AND SAFETY OF CYTARABINE-BASED REGIMENS FOR MOBILIZATION OF PERIPHERAL BLOOD STEM CELLS IN MULTIPLE MYELOMA

V. Montefusco,[1] F. Spina,[1] L. Farina,[1] A. Dodero,[1] F. Zallio,[2] R. Milani,[1] P. Corradini[1]

[1]Istituto Nazionale Tumori, MILANO; [2]Ospedale Civile di Asti, ASTI, Italy

Background. Autologous stem cell transplantation (ASCT) represents one of the most effective treatments for multiple myeloma (MM). High dose cyclophosphamide is generally considered a standard choice for peripheral blood stem cells (PBSC) mobilization. Unfortunately, a small but significant proportion of patients can not mobilize an adequate number of PBSC or can not be treated with cyclophosphamide because of co-morbidities. Cytarabine has been shown as an effective mobilization therapy in highly pre-treated lymphoma patients. *Aim.* The aim of this study was to exploit the feasibility of PBSC mobilization with cytarabine-based regimens in MM patients. *Methods.* Twenty-eight patients with MM were treated with a cytarabine-based regimen, either an association of cytarabine 2 gr/sqm bid, cisplatin 50-75 mg/sqm, and dexamethazone 80-160 mg (DHAP) in 20 patients, or cytarabine alone (0.8 gr/sqm bid for 3 days) in 8 cases. For all patients chemotherapy was followed by a daily administration of G-CSF 5 micrograms/kg starting at day +3. Patients had a median age of 59 years (range 41-71), 21 were female, the median number of previous chemotherapy lines was 2 (range 1-5), 6 patients had previously received a melphalan-based chemotherapy, and 4 patients had previously received radiotherapy. Patients received a cytarabine-based regimen if they failed a PBSC mobilization with cyclophosphamide (10 patients) and/or if they had severe co-morbidities (23 patients), in particular cardiovascular disease (16 patients), renal failure (4 patients), previous radiation therapy for cancer (3 patients). *Results.* All patients mobilized PBSC with a median collection of 15×10^6 $CD34^+$/kg (range $0.5\text{-}53\times10^6$ $CD34^+$/kg). Ten patients, failing a previous mobilization with cyclophosphamide, collected 11×10^6 $CD34^+$/kg (range $7\text{-}43\times10^6$ $CD34^+$/kg). All the 6 patients who previous-

ly received melphalan-based chemotherapy collected a median number of 4.4×10^6 $CD34^+$/kg (range $0.5\text{-}19\times10^6$ $CD34^+$/kg). The cytarabine-based regimens were generally well tolerated. According to the NCI CTC version 3 scale, grade 3-5 toxicity was observed in two cases (7%): a patient reactivated Herpes Zoster infection, and a patient affected by a severe form of Churg Strauss vasculitis with kidney and lung involvement, and a long history of immunesuppression, died of septic shock. After PBSC collection, 4 (14%) patients received a single ASCT, 21 (75%) a double ASCT, one (4%) patient three ASCT, and 2 (7%) were not transplanted. All patients engrafted. The median time to neutrophil count $>500\times10^6$/L was 11 days (range 9-12) and to platelet count $>20\times10^9$/L was 10 days (range 0-14). *Conclusions*. Cytarabine-based regimens are a feasible option to collect PBSC in MM patients. Despite one (4%) chemotherapy related death, the treatment was well tolerated. While not active against MM, cytarabine-based regimens allowed the collection of an adequate number of PBSC to support a double ASCT in most patients, with a hematopoietic recovery comparable with other series.

HUMAN UMBILICAL CORD BLOOD CELLS REGENERATE HEPATOCYTES BY FUSION IN A NON-MYELOABLATIVE SETTING

R. Wong,[1] G. Cheng,[1] K. Tsang,[1] D. Lau,[1] N.P. Chan,[1] W.S. Wong,[1] M.H Ng,[1] C. Tong,[1] A. Chan,[2] J. Tang,2 S. Kok,[2] C.H. Chui[2]

[1]The Chinese University of Hong Kong, HONG KONG, Hongkong; [2]Polytechnic University of Hong Kong, HONG KONG, Hongkong, China

Background. Many studies have shown that haematopoietic stem cells can regenerate hepatocytes. Human umbilical cord blood (UCB) is a rich source of hematopoietic stem cells and mesenchymal progenitor cells which might be used for tissue or organ repair. *Aims.* We evaluated the possibility and mechanism of hepatocyte regeneration by administration of human UCB cells following non-myeloablative conditioning after acute liver injury in an immunocompetent mouse model. *Methods.* Female C57Bl6 mice were administered toxic dose of acetaminophen. Six hours later, they were given fludarabine and cyclosporine followed by infusion of human UCB mononuclear cells. Surviving mice were sacrificed at two and four weeks post transplant. Immunohistochemistry, fluorescence in-situ hybridization (FISH) using centromere enumeration probe for human chromosome Y and FITC-labeled mouse pancentromeric probe, and polymerase chain reaction (PCR) analysis of hepatic DNA for α-satellite region of human chromosome 17 were used to confirm the presence of hepatocytes from human origin and the mechanism of regeneration. *Results.* Fifteen out of 24 mice received human UCB cells infusion after non-myeloablative conditioning survived beyond two weeks. Immunohistochemical analysis demonstrated the presence of hepatocytes expressing human hepatocyte antigen and human albumin in the hepatic sections of all but three of the surviving mice. FISH confirmed the presence of human Y chromosome in 0.5-20% of the hepatocytes. PCR analysis showed that 1-20% of the hepatic DNA was of human origin. Fusion of human cell with mouse cell was demonstrated by FISH (Figure 1).

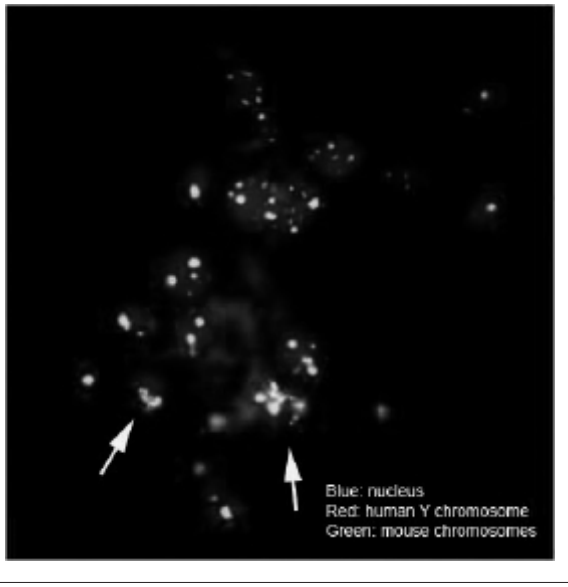

Figure 1. Cell fusion demonstrated by FISH.

Conclusions. Our data suggested that human umbilical cord blood can regenerate functional hepatocytes by fusion after acetaminophen induced acute hepatic injury in a non-myeloablative setting. This may be an effective approach in the management of patients with inherited diseases by using UCB cells for gene therapy.

0503

CLINICAL RESULTS OF A NEW DOSING STRATEGY OF IV BUSULFAN AS PART OF BUMEL HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS STEM CEL TRANSPLANTATION IN CHILDREN WITH HIGH-RISK SOLID TUMORS: REDUCED REGIMEN-RELATED TOXICITY AND VENO-OCCLUSIVE DISEASE

D. Valteau-Couanet,[1] J.C. Gentet,[2] G. Vassal,[1] F. Doz,[3] C. Paillard,[4] N. Corradini,[4] D. Frappaz,[5] O. Hartmann,[1] V. Cadic,[6] H. Zouabi,[6] G. Michel[2]

[1]Institut Gustave Roussy, VILLEJUIF; [2]Hopital La Timone, MARSEILLE; [3]Institut Curie, PARIS; [4]Hopital Hotel Dieu, CLERMONT FERRAND; [5]Centre Leon Berard, LYON; [6]Institut de Recherche Pierre Fabre, BOULOGNE, France

Background. Oral busulfan (Bu) and melphalan (Mel) has been extensively used as a high-dose chemotherapy (HDC) regimen followed by autologous hematopoietic stem cell transplantation (ASCT) in pediatric patients (pts) with high-risk (HR) solid tumors. With the availability of IV Bu, a new dosing strategy based on body weight (BW) has been defined (Nguyen et al BMT 2004). We assessed prospectively this approach. Pharmocokinetic results have been reported in children and adolescents (Vassal et al BMT 2006) and we report here the final clinical results. *Patients and Methods.* 31 children (17 boys/14 girls), median age 4 y (range 0.7 to 14.9 y) and weight 14.5 kg (range 7.2 to 62.5), respectively were enrolled. Pts received IV Bu (Busilvex®) over 2 h at a dose of 1.0 mg/kg or 1.2 mg/kg or 1.1 mg/kg or 0.95 mg/kg or 0.8 mg/kg for <9 kg, 9- to < 16 kg, 16-23 kg, >23-34 kg, and > 34 kg BW, respectively. Mel 140 mg/m^2 was then administered followed by HSCT. Clonazepam was given as seizures prophylaxis. Indications for HSCT were : HR neuroblastoma (NB), n = 27:9 CR1/ CR2, 11 VGPR, 7 PR1/PR2, Ewing sarcoma (EW), n=4:2 CR1, 2 PR1. Regimen-related toxicity (RRT) was graded according to NCI-CTC 2.0. Kaplan-Meier EFS and OS were calculated. *Results.* No adverse effect was observed during IV Bu administration. Pts received 5.8×10^6 $CD34^+$/kg (range 3-34.8) with post transplant G-CSF in 27/31. Neutrophils ($>0.5\times10^9$/L) and platelets ($>50.0\times10^9$/L) recovery occurred at day 11 (range 10-15) and day 34 (range 11-133), respectively. Digestive toxicity (mucositis) was the main RRT: grade I-II and grade III occurred in 24 and 14 pts, respectively. Four pts (13%) had hepatic veno-occlusive disease (VOD) but none was severe. No early or late regimen-related death occurred. 15/31 pts had disease relapse/ progression after a median time of 9 months (2.6-40.4), and 11/31 pts died. With a median follow-up of 41.2 months (range 3.2-52.2) EFS and OS rates were as follows: 42±22% and 57±20%, for HR-NB, respectively; it was 38% and 67% for HR-EW, respectively. *Discussions/Conclusions.* Oral BuMel is currently the standard HDC regimen in pts with HR-NB but its use is limited by the toxicity, especially VOD (up to 40%). The current results suggest that the IVBu has similar impact on efficacy of the BuMel regimen but with reduced toxicity, especially VOD (13%). The IVBu schedule could be an useful alternative in the ongoing prospective randomized trial (HR-NBL-1/SIOPEN).

0504

THREE STRATEGIES OF IMMUNOABLATIVE THERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE SCLEROSIS PATIENTS

Y. Shevchenko,[1] A. Novik,[1] A. Kuznetcov,[1] B. Afanasiev,[2] I Lisukov,[3] O. Rykavicin,[4] A. Myasnikov,[5] T. Ionova,[6] V. Melnichenko,[1] D. Fedorenko,[1] A. Kishtovich,[6] R. Ivanov,[1] G. Gorodokin[7]

[1]Pirogov National Medical Surgical Center, MOSCOW, Russian Federation; [2]Pavlov State Medical University, ST. PETERSBURG, Russian Federation; [3]Institute of Clinical Immunology, NOVOSIBIRSK, Russian Federation; [4]Burdenko Central Military Hospital, MOSCOW, Russian Federation; [5]Republican Hospital, PETROZAVODSK, Russian Federation; [6]Multinational Center of QoL Research, ST. PETERSBURG, Russian Federation; [7]NJ Cent. for QoL and Health Outcome Res., NEW JERSEY, USA

During the last decade immunoablative therapy with ASCT has been used more often as a therapeutic option for MS patients. Among a number of unclear questions are the terms of conducting immunoablative therapy with ASCT. There are 3 strategies of immunoablative therapy with ASCT depending on the terms of disease process: early, conventional and salvage/late. We aimed to study the clinical and patient-reported

outcomes in MS patients after early, conventional and salvage/late transplantation. Forty-three patients with MS (secondary progressive - 22 patients, primary progressive -10, progressive-relapsing - 1, relapsing-remitting - 10) from 6 medical centers were included in this study (mean age - 32.0, range: 17-51; male/female - 18/25). Seven patients underwent early transplantation (EDSS 1.0-3.0), 32 patients -conventional transplantation (EDSS 3.5-6.5) and 5 patients - salvage/late transplantation (EDSS 7.0'8.5). Median EDSS at base-line was 6.0 (range 1.5-8.0). The median follow-up duration was 18 months (range 6-84 months). All of the patients had previously undergone conventional treatment. Neurological and quality of life (QoL) evaluation was provided at baseline, at discharge, at 3, 6, 9, 12 months, and every 6 months thereafter following immunoablative therapy with ASCT. MRI examinations were conducted at baseline, at 6, 12 months, and at the end of follow-up. FACT-BMT and FAMS were used for QoL evaluation. Notably, no transplant-related deaths or unpredictable severe adverse events were observed. All 29 patients (2 patients - early transplantation; 24 - conventional transplantation; 3 - salvage/late transplantation) with the follow-up longer than 1 year experienced a clinical stabilization or improvement. More than half of them improved: 8 patients showed significant improvement in EDSS (by more than 1.0 point), 4 patients improved by 1.0 point, and 4 patients - by 0.5 points on EDSS. Thirteen patients achieved stabilization. Two patients deteriorated to a worse score after 18 months of stabilization; 2 other patients progressed after 12 and 30 months of improvement, respectively. All of the patients with clinical stabilization and improvement had negative MRI scans. Out of 23 patients included in QoL analysis 21 exhibited improved QoL 6 months post-transplantation. In conclusion, immunoablative therapy with ASCT appears to be an effective treatment for MS both in terms of clinical and patient-reported outcomes. The data obtained point to feasibility of early, conventional and salvage/late transplantation in MS patients. Further studies should be done to investigate clinical and QoL response in MS patients receiving early, conventional and salvage/late immunoablative therapy with ASCT to better define treatment success.

0505

COMPARISON OF HIGH DOSE VS. LOW DOSE G-CSF FOR PERIPHERAL BLOOD STEM CELL MOBILIZATION: ANALYSIS OF A CASE CONTROL SERIES

N. D'Cunha,[1] W. Kolb,[2] M. Chriva-Internati,[1] E. Cobos,[1] F. Hardwick[1]

[1]Texas Tech University, Health Sc Ctr, LUBBOCK, TEXAS; [2]Southwest Cancer Center, University Med, LUBBOCK, TEXAS, USA

Objective. PBSC mobilization typically requires administration of multiple daily doses of G-CSF to achieve target collections of $CD34^+$ cells. A decrease in patient visits to the clinic may result in reduced overall costs and improved patient convenience. We report the effect of high-dose G-CSF on $CD34^+$ cell yields, days to myeloid and platelets engraftment and number of aphaeresis collections for autologous stem cell transplants (SCT) as compared with a historical control. *Methods.* Eighty-six patients underwent peripheral stem cell collection for various malignancies for stem cell transplantation during 2001 (n=31) and 2002 to 2006 (n=55). In 2001 G-CSF 10 mcg/kg/day was administered for 5 days followed by aphaeresis beginning on the 6th day. In 2002 to 2006, G-CSF 20mcg/kg/day was administered for 2 days followed by aphaeresis beginning on the 3rd day. The target $CD34^+$ cell count was 5×10^6 cells/kg (Coulter flow method) and no chemotherapy was used for mobilization. *Results.* The mean number of $CD34^+$ cells collected among patients receiving low dose G-CSF 10 mcg/kg/day for 5 days was 5.66×10^6/kg (range 4.17-9.24) compared to 7.61×10^6/kg (range 4.16-25.05) among patients receiving high dose G-CSF 20 mcg/kg/day for 2 days. All patients achieved target $CD34^+$ stem cell yields. The median percentage of $CD34^+$ stem cell on the first day of collection i.e. on day 6 for low dose G-CSF group was 0.40% compared to 0.30% for high dose G-CSF group. The median number of nucleated cells on the first day of collection for low dose G-CSF group was 19.9×10^8 cells/kg compared to 15.4×10^8 cells/kg for high dose G-CSF group. The mean number of aphaeresis per stem cell transplant in patients receiving low dose G-CSF was 3.3 compared to 2.9 in patients receiving high dose G-CSF. There was no difference between the low dose and high dose groups in terms of mean days to myeloid engraftment 11.8 vs.12.1 (p=0.26). However the mean days to platelet engraftment was better in patients receiving high dose G-CSF than those receiving low dose G-CSF, 14.5 vs.22.9 days (one tail p=0.09). Finally no differences in adverse effect were noted between the low dose and high dose groups. *Conclusions.* The results of our trial conclude that 20 mcg/kg/day x 2 days vs. 10mcg/kg/day x 5 days of G-CSF result in improved $CD34^+$ stem cell yield, decreases aphaeresis, equivalent time to myeloid engraftment and much earlier platelets engraftment. This resulted in decreased patient travel and clinic time. Early platelets engraftment will reduce hospital stay and platelets requirement

0506

THYMIC FUNCTION IN PATIENTS CANDIDATES TO AUTOLOGOUS STEM CELL TRANSPLANTATION

C. . Simonelli,[1] C. Pratesi,[2] S. Zanussi,[3] R. Talamini,[2] L. Abbruzzese,[2] V. Gattei,[2] M. Spina,[2] M. Michieli,[2] P. De Paoli,[2] U. Tirelli[2]

[1]National cancer Institute; [2]National Cancer Institute, AVIANO; [3]Narional Cancer Institute, AVIANO, Italy

Background. Signal joint T cell receptor excision circles (sjTRECs) have been reported to be a clinical marker to evaluate the thymic reservoir after immunosuppression treatments. *Aims.* The aim of the study was to evaluate the impact of different features such as: age, type of lymphoma, number of first line chemotherapy (CT) cycles, time from the end of first line CT to the enrolment (TECT), HIV infection and T subpopulations. *Methods.* We studied the sjTRECs levels in a mono-institutional series of a cohort of 26 HIV-positive and 29 HIV-negative patients (pts) with relapsed or refractory lymphomas, candidates to ASCT considering important biological and clinical characteristics and virological and immunological parameters. Peripheral blood samples were collected in ethylene diamine tetraacetic acid, from all pts before the induction CT. PBMCs were isolated by Ficoll/Hypaque density gradient centrifugation and cryopreserved as dry pellet at -80°; a Real Time PCR method was used to measure sjTRECs. *Results.* The overall study subjects showed lower sjTRECs levels than healthy donors (p<0.01), but no differences in the sjTRECs content have been observed between HIV-negative and HIV-positive pts (536 vs 401 TRECs/106PBMCs respectively) as well as in the T cell naïve count. We found a significant correlation between the sjTRECs decay and the increase of age (r=-0.32, p=0.02), CD4 and CD8 naïve cell count and the sjTRECs level; on the contrary we did not observe any significant correlation between CT cycles number TECT, lymphoma type in both subgroups. HIV-positive viremic pts showed significant lower values of sjTRECs level than aviremic pts. *Conclusions.* Our analyses suggest that *de novo* T cell generation is partially maintained in lymphoma pts candidates to ASCT and could contribute to restore the immune function after transplantation. Chemotherapeutic treatments seem to induce a similar influence on thymic output, despite their intensity and surprisingly HIV infection is not a detrimental factor on the thymic reservoir at the time of lymphoma relapse, a good control of HIV replication seems to preserve the thymic reservoir.

0507

IMPACT OF INFUSED LYMPHOCYTE DOSE ON THE OUTCOME OF PATIENTS WITH MULTIPLE MYELOMA UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

A. Symeonidis,[1] S. Ings,[2] N. Rabin,[2] M. Watts,[2] S. D'Sa,[2] D. Linch,[2] K. Yong[2]

[1]University of Patras, Medical School, PATRAS, Greece; [2]Department of Hematology, University College London, London, United Kingdom

Introduction. It has previously been reported that the number of infused lymphocytes influences the outcome of patients with multiple myeloma (MM) undergoing ASCT, with patients receiving a lymphocyte-rich graft experiencing longer relapse free and overall survival. This could be because re-infused lymphocytes play a role in disease control, or because patients with lymphocyte-poor grafts have intrinsically worse disease, and/or have received more prior therapies. We sought to address these issues by carrying out a similar analysis of MM patients undergoing ASCT, and including in our analysis a third group of patients who received CD34-selected grafts. *Patients and Methods.* We analysed 135 patients (52 female, 83 male, median age 57 years, range 38-71) who underwent high dose melphalan and ASCT with unselected peripheral blood stem-cell grafts. The median number of infused lymphocytes was 1.05×10^9/kg of body weight (range 0.05-5.37). Patients were split into two groups, group A (those who received $<0.5\times10^9$ lymphocytes/kg, N=46) and group B (those who received $>0.5\times10^9$ lymphocytes/kg, N=89). We compared transplantation outcome of these patients with a third group C (n=48), of patients who received immunomagnetically selected autologous $CD34^+$ cells. *Results.* Time to neutrophil and platelet engraftment was comparable in all groups, however, group A patients had significantly longer hospitalization period, as compared to both, group B and -C patients (26.4±10.9 vs. 22±5.5 days, p=0.002, vs. 25.3±9.4 days for group C, p=0.0129). Common bacterial and viral infections

were similar among the 3 groups. However, episodes of varicella-zoster and CMV reactivation, as well as other opportunistic infections were more frequently encountered among patients of groups A and C (16/46 and 19/48 respectively), as compared with patients of group B (14/89, ×2: $p<0.001$). After a median follow-up time of 32 months, 17 patients from group A (37%), 53 from group B (59.5%) and 11 from group C (22.9%) are alive. Median relapse-free survival was 12.3 months in group A, 27.5 months in group B ($p=0.016$) and 20.6 months in group C (group A vs C, $p=0.097$, group B vs C, $p=0.711$). Similarly, median survival from SCT was 26.4 months in group A, 52.1 months in group B ($p=0.033$) and 45.3 months in group C (p: not significant for both comparisons). Median overall survival was 38.5 months for group A, 54.5 for group B and 49 months for group C. *Conclusions.* Lower lymphocyte dose in the graft predicts for a poorer outcome in patients with MM undergoing ASCT. This poor outcome is not seen in patients receiving a CD34-selected graft, suggesting that a lower lymphocyte dose is a reflection of patient disease state, and/or previous treatment, and that the lymphocytes infused in the graft play little part in disease control.

0508

COMPARISON OF A COMBINED APPROACH WITH AUTOGRAFTING FOLLOWED BY NON-MYELOABLATIVE ALLOGRAFTING VERSUS TANDEM AUTOGRAFTING IN MULTIPLE MYELOMA PATIENTS

A.M. Carella,[1] M. Spriano,[2] A.G. Congiu,[2] G. Catania,[2] S. Biasco,[2] S. Nati,[2] R. Vimercati,[2] E. Rossi,[2] M. Risso,[2] E. Lerma[2]

[1]S.Martino Hospital, GENOVA; [2]Hematology 1, S. Martino Hospital, GENOVA, Italy

Multiple Myeloma (MM) is an incurable disorder despite the numerous attempts to find new therapy approaches. The better understanding of its molecular pathogenesis has led to the development of effective novel therapeutic agents like thalidomide and the proteasome inhibitor bortezomib. High-dose therapy (HDT) with stem cell transplantation and novel targeted therapies represent two approaches to overcome resistance of multiple myeloma cells to conventional treatments. The novel agents have shown impressive activity in relapsed/refractory MM patients. Autografting (AutoSCT) results have been compromised by high relapse rate while conventional allografting (AlloSCT) by excessive transplant-related mortality (TRM) and toxicity. Reduced intensity conditioning for transplant (RICT) has been shown to achieve remissions in MM patients. High-dose therapy/AutoSCT followed shortly thereafter by RICT allogeneic transplant might improve outcomes in MM as compared to AutoSCT or conventional AlloSCT used alone. As we have previously reported, we compared two retrospective cohort of advanced stage MM patients who underwent tandem AutoSCT (HDT consisted of melphalan 200 mg/m^2) or AutoSCT followed closely by RICT (patients with HLA-matched siblings) (AutoSCT+RICT). The two groups were matched for pre-transplant therapy, disease status at transplant, time from diagnosis to transplant. The median age was 56 years and 51 years in the AutoSCT and AutoSCT+RICT groups, respectively. All patients had received a median of 4 (range, 3-6) prior chemotherapy regimens. The median time from diagnosis to the first transplant was 6 months (range, 5-60) in AutoSCT group and 9 months (range, 7-42) in AutoSCT+RICT group, respectively. In the AutoSCT+RICT group, after a median interval of 80 days from AutoSCT, a dose-reduced regimen consisting of fludarabine (30 mg/m^2) and 2 Gy TBI followed by peripheral blood stem cell allografting from matched related donors was given to the patients in the attempt to induce a graft-versus-myeloma effect. Graft-versus-host-disease prophylaxis consisted of CyA/MTX. We have evaluated toxicity, engraftment, chimerism, GvHD, and response to RICT allograft after cytoreductive autografting. In the AutoSCT+RICT group the complete remission rate was higher (50%) than in AutoSCT group (14%); beside the risk of disease progression was reduced. The complete response in AutoSCT+RICT patients was obtained after achievement of full donor chimerism and the development of GvHD. Since the first clinical signs of response were noted between 70 and 120 days and the maximum response between 160 and 200 days after RICT, those responses should be considered immune-mediated. TRM has been 0% in both groups. The double AutoSCT+RICT protocol provides rapid engraftment with complete donor chimerism, reduces the risk of transplant-related organ toxicity, and induces high remission rates. Our results are encouraging and demonstrate that RICT following an AutoSCT mediates a potentially curative graft-versus-myeloma effect and it delays the incidence of disease progression, even though multicentric studies are required.

0509

CD34+ CELL MOBILISATION WITH INTERMEDIATE-DOSE CYTARABINE (ARA-C) IN PATIENTS WITH LYMPHOMA: AN EFFECTIVE BUT TOXIC REGIMEN

S. Montoto

St Bartholomew's Hospital, LONDON, United Kingdom

Background. Peripheral stem cell mobilisation can be difficult in patients with lymphoma, especially after treatment including purine analogues or in heavily pre-treated patients. Intermediate-dose Ara-C (ID Ara-C) has been shown to be an effective mobilisation regimen in patients with chronic lymphocytic leukaemia (CLL) who have previously received fludarabine and campath (Montillo et al, Leukaemia 2004). *Aims.* To analyse the toxicity and efficacy of ID Ara-C as a mobilisation regimen in patients with lymphoma. *Methods.* Twenty-five patients with lymphoma (median age: 51 years, range: 20-74) were sequentially treated with ID Ara-C. Histological diagnoses were as follows: 10 patients, Hodgkin's lymphoma (HL), 12, follicular lymphoma (FL) and 3 other Non-Hodgkin's lymphoma (NHL). The median number of previous lines of chemotherapy was 1 (range: 1-4) for HL, 3 (range: 2-5) for FL and 2 (range: 2-3) for other NHL. Prior therapy included fludarabine in 5 patients. Five patients had previously failed stem cell harvest with other mobilisation regimens. ID Ara-C comprised Ara-C: 800 mg/sqm bd x 6 followed by G-CSF: 5°g/kg/d to the end of harvesting. *Results.* All patients required hospital admission, for neutropenic fever (18 patients, 5 of whom required second-line antibiotics) or neutropenic surveillance (7 patients), the median hospital stay being 9 days (range: 5-14). Platelet transfusion was required at least once in all patients, with a median of 3 units being transfused per patient. The median number of RBC units transfused was 2. Harvesting was successful in all the patients, with a median CD34$^+$ yield of 11.4×10^6 cells/kg (range: 1.96-112), at a median time of 15 days (range: 14-35) after start of Ara-C. The median CD34+ yield in patients who had received fludarabine was 11.4, whereas it was 3.77 for 11 patients who had received 3 or more previous lines of chemotherapy. *Conclusions.* ID Ara-C is a very effective mobilisation regimen for patients with lymphoma, including heavily pre-treated patients and those who had received purine analogues. However, given its considerable and universal haematological and, therefore, clinical toxicity and the consequent need for hospitalisation with its attendant costs, it should be reserved for patients in whom difficulties in harvesting are predictable in view of their previous treatment.

0510

EFFECTS OF RITUXIMAB ON PERIPHERAL BLOOD STEM CELL MOBILIZATION AND ENGRAFTMENT IN B CELL NON HODGKINS LYMPHOMA

F. Gaudio, A. Guarini, V. Pavone, T. Perrone, D. Pastore, P. Curci, A. Giordano, M. Leo, A. Mestice, G. Specchia, V. Liso

Hematology, BARI, Italy

Treatment with rituximab is widely used for B cell non Hodgkin's lymphomas (B-NHL). However, its effects on peripheral blood stem cell mobilization are not completely known. We retrospectively evaluated 52 consecutive B-NHL (30 follicular and 22 diffuse large cells) patients responding to first-line chemotherapy (CHOP or R-CHOP), but failing to achieve complete remission (CR). In this group we compared the mobilization characteristics and engraftment kinetics of 24 patients receiving and 28 not receiving rituximab six months before PBSC mobilization. Patients mean age was 37 years (range 17-60). 44 patients (84.6%) had stage III-IV disease. 34 patients (65.4%) had bone marrow involvement; systemic B symptoms were present in 30 patients (57.7%). At the time of PBSC mobilization 32 patients (61.5%) were considered to be responsive (complete remission, partial remission or sensitive relapse) and 20 (38.5%) not responsive (refractory relapse or refractory to therapy). Mobilization chemotherapy consisted of a high dose cytarabine containing regimen (DHAP) in all patients. The median $CD34^+$ cells collected was 5.8×10^6/kg in patients receiving rituximab vs 7.2×10^6/kg $CD34^+$ cells (p=n.s.) in the non rituximab treated group. Failure to mobilize, defined as failure to reach a circulating $CD34^+$ cell count of 10/mcl, occurred in 2 patients (8.3%) in the rituximab group and 3 (10.7%) in the non rituximab group. All patients were transplanted using myeloablative chemotherapy conditioning regimen (BEAM); G-CSF was administered subcutaneously from day +3 at a dose of 5 microg/kg body weight/day. Comparison of the two groups showed no statistical significant difference between median days to absolute neutrophil $>0.5\times10^9$/L and platelet $>20\times10^9$/L counts after autologous stem cell transplantation, and no differences in incidence and severity of infections, days of fever or duration of antibiotic treatment between groups. In conclusion, the use of rituximab six months before PBSC does not affect the ability to collect an adequate number of PBSC for autologous stem cell transplantation in B-NHL. Further studies are warranted in larger populations to determine the impact of rituximab on collection, engraftment and survival.

Chronic lymphocytic leukemia and related disorders - Biology II

0511

THE HIGH FREQUENCY OF T REGULATORY CELLS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL) IS DECREASED BY THALIDOMIDE AND FLUDARABINE TREATMENT

K. Giannopoulos,[1] M. Schmitt,[2] P. Wlasiuk,[1] J. Chen,[2] A. Bojarska-Junak,[1] M. Kowal,[1] J. Rolinski,[1] A. Dmoszynska[1]

[1]Medical University of Lublin, LUBLIN, Poland; [2]University of Ulm, ULM, Germany

Background. The control of a rather slowly progressing B-cell chronic lymphocytic leukemia (B-CLL) by the immune system is not yet fully understood. Several mechanisms underlay the immunosuppressive status of CLL patients including the excess of T regulatory lymphocytes (Tregs). The forkhead family transcription factor FOXP-3 is critically important for the development and function of Tregs. *Aims*. In current study we wanted to define the expression of FOXP-3 on $CD4^+CD25^{high}$ T lymphocytes in the peripheral blood mononuclear cells (PBMC). Additionally, we wanted to characterize the influence of Tregs on immune responses against tumor and viral antigens in the complex system of PBMC. We also tried to define the influence of thalidomide (THAL) alone as well as combined with fludarabine (FLU) on Tregs subpopulation of CLL patients. *Methods*. In 60 previously untreated patients with B-CLL the subpopulation of $CD4^+CD25^{high}FOXP3^+$ T cells that phenotypically correspond to Tregs was identified. Immunosuppressive function of Tregs was evaluated in an enzyme-linked immunosorbent spot (ELISpot) assay to estimate T-cell immune responses against HLA-A2 restricted epitopes derived from tumor associated antigens (TAAs) of survivin, fibromodulin and RHAMM as well as viral peptide derived form infuenza matrix protein. *Results.* The frequency of Tregs was significantly higher in B-CLL patients compared to healthy volunteers (HVs) (12.1% vs. 1.9%, p=0.0001). The progressive increase of Tregs percentages were noted in advanced stages of disease, mean: 9.5% in stage A, 13.4% in stage B and 15.4% in stage C according to the Binet classification. Higher frequencies of Tregs correlated with decreased T cell responsiveness against viral and tumor antigens. Significantly lower secretion of IFN-γ was observed in patients with higher percentages of Tregs (more than 11% of the CD4 cells). In 80% CLL patients treated with THAL + FLU regimen significant reduction of circulating Tregs after THAL was observed. The combination with FLU resulted in further decrease of Tregs in 12 of 15 patients. After THAL therapy the mean reduction was higher in the population of Tregs compared to whole lymphocyte population (41.2% vs. 19.9%, p=0.046). Higher frequencies of Tregs were observed in CLL patients with higher levels of TNF-α serum levels (r2=0.45, p=0.001, n=20). *Conclusions*. Tregs presented in high frequencies in B-CLL constitute the crucial immunosuppressive mechanism among the mononuclear cells of the peripheral blood. The strategies combining THAL are very promising, since THAL might target not only the CLL cell population but also Tregs and therefore restore the $CD8^+$ T cell function. Increased TNF level might promote Tregs proliferation. Nontheless, the results of our study suggest that TNF is unable to block suppressive activity of Tregs in B-CLL

0512

B CHRONIC LYMPHOCYTIC LEUKEMIA CELLS EXPRESS THE ORPHAN RECEPTOR TYROSINE KINASE ROR-1

A.H. Danesh Manesh,[1] E. Mikaelsson,[1] M. Jeddi- Tehrani,[2] A.A. Bayat,[2] R. Ghods,[2] M. Ostadkarampour,[2] M. Akhondi,[2] S. Lagercrantz,[3] C. Larsson,[3] A. Österborg,[3] F. Shokri,[4] H. Mellstedt,[3] H. Rabbani[3]

[1]Karolinska Institute, STOCKHOLM, Sweden; [2]Avesina Research Institute, TEHRAN, Iran; [3]Karolinska University Hospital Solna, STOCKHOLM, Sweden; [4]Tehran University of Medical Sciences, TEHRAN, Iran

Background. Ror receptors are cell-surface receptors participating in signal transduction, cell-cell interaction, regulation of cell proliferation, differentiation, cell metabolism and survival. Ror-1 is a member of the RTKs family of orphan receptors related to muscle specific kinase (MUSK) and Trk neutrophin receptors. The human Ror1 is highly expressed in heart, lung, and kidney but to a lesser extent in placenta, pancreas and skeletal muscles. In B-CLL a 43.8 fold increase of the orphan receptor tyrosine kinase (RTK) gene (Ror-1) expression has been observed previously. *Aims.* To study the expression of Ror-1 in B-CLL.

Methods. Several read-out systems were used in this study including RT-PCR, flow cytometry, Western blotting and phosphorylation assay. *Results.* Ror-1 was expressed at the gene and protein levels in leukemic B cells of all B-CLL patients (n=100). Ror1 was not expressed in leukocytes from healthy individuals, enriched B cells, T cells, and granulocytes but weakly in normal tonsil B cells. A strong activation signal (PMA/Ionomycin) induced expression of Ror1 in normal lymphocytes. Five different variants of the Ror1 protein were identified, ranging from 68 to 105 kDa (68, 85, 96, 102, and 105). The 102 and 105 kDa isoforms may represent the native Ror-1 molecules and were differentially expressed in progressive and non-progressive disease. The 68, 85, and 96 kDa isoforms were auto-phosphorylated but not the 102 and 105 kDa variants. *Conclusions.* The ectopic expression of auto-phosphorylated Ror1 in CLL, indicate a potential role of this RTK in the pathobiology of B-CLL.

GENE EXPRESSION COMPARISON BETWEEN B CELLS EXPRESSING HIGH AND LOW LEVEL OF ZAP-70 MRNA REVEALS DISTINCT PROFILES, POTENTIAL THERAPEUTIC TARGETS AND NEW PROGNOSTIC FACTORS FOR CHRONIC LYMPHOCYTIC LEUKEMIA

B. Stamatopoulos, C. Equeter, B. Haibe-Kains, A. Soree, C. Sotiriou, D. Bron, P. Martiat, L. Lagneaux

Bordet Institute, BRUSSELS, Belgium

Background. Chronic Lymphocytic Leukemia (CLL) is a heterogeneous disease characterized by a highly variable clinical course based on the IgVH mutational status currently considered as one of the powerful prognosis factors. Because of the complexity of this analysis, several surrogate genes of this mutational status have been found in the recent years, among them Zap-70 seems to be a reliable prognostic factor. *Methods.* We compared three predictive markers (Zap-70, lipoprotein lipase and CD38 expression) in term of treatment-free (TFS) and overall (OS) survival and finally Zap-70 (zeta-associated protein 70) was chosen because of its strong association with the IgVH status and high prognostic values. We developed a quantitative real time PCR to measure Zap-70 mRNA expression in a cohort of 100 patients and to classify patients with high and low Zap-70 expression. Gene expression profiles of high (Zap-70^{high}, n=7) and low (Zap-70^{low}, n=7) mRNA expression were then compared using Affymetrix U133 plus 2.0 genechips representing more than 47000 transcripts. *Results.* Among genes differently expressed ($p<0.05$), only genes with a fold change upper of 1.5 and with a false discovery rate (FDR) lower than 10% were selected. Zap-70, the first gene of the list, was followed by the phosphodiesterase 8A (PDE8A, $p<0.0001$), integrin α 4 (ITGA4, $p<0.0001$) and some genes of Fc receptor like family (FCRL, $p<0.0001$). These genes were confirmed in an extended patient cohort (n=80) and were able to separate the patients in term of TFS indicating their relevant clinical predictive power. *Conclusions.* CLL cells expressing high and low level of Zap-70 mRNA are characterized by a distinct gene expression profile that reveals new potential therapeutic target, new prognostic factors and genes implicated in cellular activation, adhesion and migration.

0514

A COMPARATIVE ANALYSIS OF PROTEIN EXPRESSION PROFILES IN PERIPHERAL BLOOD CHRONIC LYMPHOCYTIC LEUKEMIA CELLS AT DIAGNOSIS AND UPON DISEASE PROGRESSION

E. Gine,[1] A. Muntañola,[2] M. Crespo,[3] E. Calpe,[3] M.J. Gomes,[3] E. Montserrat,[2] F. Bosch[2]

[1]Hospital Clinic, BARCELONA; [2]Institute of Hematology and Oncology, BARCELONA; [3]IDIBAPS, BARCELONA, Spain

Background. CLL has a heterogeneous clinical course. Half of the patients diagnosed in early stage eventually progress and require treatment. Although some genetic abnormalities such as del(17p) have been associated with disease progression, the mechanisms underlying such a phenomenon are not well-known. *Aims.* To compare protein expression profiles in CLL cells at diagnosis and after disease progression in patients with early, low-risk CLL. *Methods.* We studied 6 patients in early stage and without poor risk cytogenetics (i.e., +12, 11q-, 17p-) for which leukemic cells obtained at diagnosis and after disease progression were available. To make sure that patients had low-risk disease those progressing or receiving therapy within the first 2 years after diagnosis were not eligible for the study. Cell purity of samples at diagnosis and at progression was assessed (mean $CD5^+/CD19^+$ cells 90% and 91%, respectively). Protein expression profile was analyzed by using a Fluorescence 2-D Difference Gel Electrophoresis (DIGE). Image analysis and statistical quantification of relative protein levels were performed using DeCyder V. 5.0 software (GE Healthcare) and the identification of differential spots by MALDI-MS analysis. *Results.* Different protein expression patterns were observed between diagnosis and disease progression both in the whole group of patients (Table 1) and in paired samples. Proteins undergoing significant changes in their expression levels have been involved in the ubiquitin-dependent degradation pathway, carbohydrate metabolism, and RNA cytoplasmic transport. In addition several of the proteins identified, such as EF-2, HNR, annexin A1 and nucleophosmine, have a role in cell proliferation and human oncogenesis. *Conclusions.* This study identified changes on the expression of a group of proteins that are part of important oncogenic pathways in CLL progression. The analysis of the exact role of these proteins in CLL disease progression deserves further investigation.

Table 1.

TELOMERASE AS A NEW PROGNOSTIC FACTOR IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

L. Trentin,[1] L. Terrin,[2] M. Degan,[3] I. Corradini,[2] N. Maschio,[4] E. Rampazzo,[2] E. Boscaro,[4] R. Bertorelle,[2] P. Carli,[4] M. Dal Bo,[3] G. Binotto,[4] V. Gattei,[3] G. Semenzato,[4] A. De Rossi[2]

[1]Università di Padova, PADOVA; [2]IOV-Dept Oncol Surg Sci Padua University, PADOVA; [3]Clin Exp Hematol CRO/IRCCS, AVIANO; [4]Dept Clin Exp Med Hematology Sect., IOV, PADOVA, Italy

Background. Activation of telomerase reverse transcriptase (hTERT), the catalytic rate-limiting component of the telomerase complex, is essential for unlimited cell growth and plays a critical role in tumorigenesis. *Aims.* The aim of the present study was to determine hTERT gene expression in B-cell Chronic Lymphocytic Leukemia (B-CLL) and to evaluate its prognostic value. *Methods.* We investigated hTERT gene expression in B-CLL and evaluated its prognostic value. Because hTERT mRNA undergoes alternative splicing as a regulatory mechanism of hTERT, real-time PCR assays to quantify either all hTERT transcripts (AT) or only the full length (FL) transcript encoding the functional protein were developed. *Results.* hTERT transcripts were quantified in 134 B-CLL cases, and compared them with other prognostic markers including IgVH mutation status, CD38 and ZAP-70 expression. hTERT-AT levels strongly correlated with hTERT-FT levels(r=0.743, p<.0001); both inversely correlated with the percentage of IgVH mutation (p<0.005) and were significantly higher in unmutated IgVH than in mutated B-CLL cases (p=0.004 and p=0.001, respectively). From ROC curve analyses, the hTERT values which best discriminated between the unmutated and mutated IgVH cases were 150 and 40 copies for hTERT-AT and hTERT-FL, respectively. Using these cut-off values, there was a significant difference in the survival of patients with high or low hTERT levels (p<0.0001). Interestingly, hTERT identified different groups of patients with poorer or better prognosis in IgVH mutated and unmutated cases; the unmutated cases with low hTERT level had an overall survival close to the mutated cases with high hTERT level. *Conclusions.* This work identifies hTERT as a new prognostic marker in B-CLL, and it may be used to identify previously unrecognized patient groups with the same IgVH mutation status and different disease outcomes.

0516

CORRELATION BETWEEN CD4+FOXP3+ REGULATORY T CELLS AND ZAP-70 EXPRESSION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S. Kay, Y. Herishanu, S. Baron, E. Naparstek, B. Tartakovsky, A. Polliack, V. Deutsch

Sourasky Medical Center, TEL AVIV, Israel

Background. Although several immune abnormalities are recognized in CLL patients the relationship between the activated T cells and the B -CLL cells is poorly understood. T-regulatory cells (Treg) are a distinct subset of $CD4^+/CD25^{high}/FOXP3^+$ T lymphocytes essential for down-regulating immune responses to self antigens . Tregs also suppress activation of both $CD4^+$ and $CD8^+$cells in an antigen independent manner and their reported increase in numbers have been considered as another mechanism for reducing immunity. The activation of T and B-CLL cells described in CLL patients indicates that both activated T cells and Tregs may be involved in the pathogenesis of CLL. Expression of ZAP-70 in B-CLL cells is regarded as a negative prognostic factor in CLL. This tyrosine kinase mediates TCR signaling and is structurally homologous to Syk, playing a role in BCR signaling. We reported that high ZAP-70 expression in B-CLL cells correlated with high ZAP-70 expression in T cells, implying elevated T-cell activation in these CLL patients. This positive correlation between ZAP-70 expression in B-CLL cells and T-cells in CLL may imply dual activation , involving T-cell/B -CLL cell interaction and may suggest that this crosstalk may affect clinical outcome in these patients (1) Additionally, an increase in the percentage of $CD4^+CD25^+$ Tregs in the blood of CLL patients was recently reported (2). *Aims.* The aim of this study was to determine whether there is a correlation between Tregs and ZAP-70 expression in B-CLL cells and T cells in CLL patients. *Methods.* Blood samples were collected from 32 newly diagnosed untreated CLL patients and healthy individuals. The diagnosis of CLL was based on standard morphologic and immunophenotypic criteria. Quantitative analysis of the intracellular levels of ZAP-70 was performed by flow cytometry MESF (3). CD4, CD25 and the transcription factor FOXP3 in the blood of CLL patients and viability of the lymphocyte populations (7AAD staining) were measured by flow cytometry. *Results.* $CD4^+/FOXP3^+$cells and $CD4^+CD25^{high}/FOXP3^+$ cells display highly significant elevations in CLL patients compared to healthy individuals, similar to the previously reported increase in $CD4^+/CD25^{high}$ cells(2). Both the $CD4^+/FOXP3^+$ cells and $CD4^+CD25^{high}/FOXP^{3+}$ were proportionately higher in ZAP-70+ patients than in ZAP-70- patients (7.1% vs 4.8%, p=<0.05), showing a correlation of Treg increase with ZAP-70 expression. ZAP-70 was also elevated in T cells of patients with high ZAP-70 in the B-CLL population. The percentage of $7AAD^+$ T cells in patients, was the same as that in normal blood (3%-5%). Moreover, no difference was seen in the viability of the Treg populations from $ZAP\text{-}70^+$ or $ZAP\text{-}70^-$ patients, indicating no difference in the viability of T cells in CLL patients. *Conclusions.* The number of $CD4^+CD25^+FOXP3^+$ Tregs is increased in CLL patients. We report for the first time that this is more prevalent in the cells from patients with elevated ZAP-70 levels, showing a correlation between ZAP-70 expression and the numbers of Tregs. These findings indicate that dual T and B-CLL cell activation may involve a simultaneous proliferation of Treg cells in CLL , which could regulate the immune response in these patients.

0517

IL-21 AND IL-15 EXERT OPPOSITE EFFECTS IN CHRONIC LYMPHOCYTIC LEUKEMIA (APOPTOSIS VERSUS SURVIVAL) AND ACTIVATE DIFFERENT SIGNALING PATHWAYS

D. De Totero,[1] R. Meazza,[1] M. Capaia,[1] M. Fabbi,[1] G. Cutrona,[1] E. Balleari,[2] I. Pierri,[2] M. Gobbi,[2] M. Ferrarini,[1] B. Azzarone,[3] S. Ferrini[1]

[1]National Institute for Cancer Research, GENOA, Italy; [2]Hematology and Oncology Dept, GENOA, Italy; [3]U542 INSERM, PARIS, France

Background. Cytokines secreted in the microenviroment may influence natural hystory of B cell chronic lymphocytic leukemia (B-CLL). CLL B cells are prone to undergo apoptosis when cultured *in vitro*, but their survival can be extended when leukemic cells grow in contact with stromal cells present in the cultures. We recently reported that IL-21 induces apoptosis of CLL B cells, in particular after CD40-CD40L interaction which significantly upregulated IL-21R. IL-15, a cytokine with structural homology to IL-21, instead, enhances survival and induces proliferation of CD40-activated CLL B cells. *Aims.* We studied differential activities of IL-21and of IL-15 on CD40-activated CLL B cells. We further tried to identify differential signaling pathways triggered by the two cytokines leading to apoptosis or, on the contrary, to survival. *Methods*. Annexin-V/PI staining and subsequent cytofluorographic analyses were performed to determine the percentage of CD40-activated CLL B cells that undergo apoptosis or, on the contrary, that are rescued from apoptosis following cultures with IL-21 or with IL-15. CLL samples were in parallel studied by Western Blot to detect phosphorylation of JAK and STAT molecules after IL-21 and IL-15 treatments. Activity of IL-15, with or without JAK inhibitor or moAbs against β/γ chains of the IL15R, was also evaluated in proliferative assays. *Results.* IL-15R, the heterotrymeric complex consisting of IL-15R α chain, IL-15/IL-2R β chain (CD122), and the common IL-15R/IL-21R γ chain (CD132), was upregulated on CLL B cells after CD40 activation and, according to higher expression of the receptor, survival and mitogenic effects induced by IL-15 were stronger on activated than on resting cells. When, however, IL-15 and IL-21 were added in combination, IL-21counteracted IL-15 survival effects. In line with the observed opposite effects exerted by the two cytokines, the pathways of signaling induced by IL-15 and IL-21 showed relevant differences. JAK-3 was activated by both IL-21 and IL-15 while JAK-1 activation was evident only after IL-21 treatment. In addition STAT-1 was tyrosine-phosphorylated by IL-21 and not by IL-15, while STAT-5 was preferentially activated by IL-15, and STAT-3 preferentially phospsophorylated by IL-21. Proliferation of CLL B cells, induced by IL-15, was blocked by addition of antibodies against β/γ chains of the IL-15R or of JAK3 inhibitor (AG490). In agreement with proliferative data addition of AG490 and of anti-β/γ chains of the receptor counteracted the IL-15-survival effect on anti-IgM-induced apoptosis of CD40-activated CLL B. *Summary and Conclusions.* IL-15 and IL-21 show antagonistic effects on CD40-activated CLL B cells. Opposite effects of IL-15 and of IL-21 can be related to activation of different signaling molecules such as phosphorylation of JAK-1 and of STAT-1 by IL-21 only. IL-15, which can be present at level of bone marrow (stromal cells) and of germinal center (follicular dendritic cells), can have a role in trafficking and in expansion of the malignant B cell clone. Deeper understanding of the pathways leading to proliferation or, on the contrary, to apoptosis could be helpful in designing novel therapeutic strategies.

0518

SERUM AND CELLULAR EXPRESSION OF THROMBOPOIETIN IN EARLY B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA IN COMPARISON WITH IMMUNOGLOBULIN HEAVY-CHAIN MUTATION STATUS

S. Molica,[1] G. Vitelli,[2] G. Cutrona,[3] K. Todoerti,[4] R. Mirabelli,[1] G. Digiesi,[2] F. Morabito,[5] A. Neri,[6] M. Ferrarini[3]

[1]Azienda Ospedaliera Pugliese-Ciaccio, CATANZARO; [2]Clinical Pathology, IRCCS REgina Elena, ROMA; [3]Medical Oncology C, IST, GENOVA; [4]Dpt Scienze Mediche Università di Milano, MILANO; [5]Department Hematology, Az. Ospedaliera, COSENZA; [6]IRCCS Policlinico, Genetica Molecolare, MILANO, Italy

We analyzed the correlation between well-established clinical (i.e., Rai substages, β2-microglobulin, LDH) or biological parameters of prognostic relevance (i.e, mutational status of the immunoglobulin heavy chain variable region [IgVH], ZAP-70- and CD38-expression) and serum levels of thrombopoietin (TPO) in a series of 71 previously untreated Binet stage A B-cell chronic lymphocytic leukemia [CLL]B-cell CLL patients. Serum levels of TPO did not correlate with peripheral blood lymphocytosis (p=0.928), Rai substages (p=0.516), platelet count (p=0.572), hemoglobin level (p=0.228), LDH (p=0.144) and β2-microglobulin (p=0.520). The same applied when correlation with ZAP-70 (p=0.562), CD38 (p=0.258) or mutational status of IgVH (p=0.0794) were sought. After a median follow-up time of 32 months (range, 2-180 months) 28 (39.4%) out of 71 patients experienced a need for chemotherapy. Kaplan-Meier estimates of time to first treatment [TFT] , plotted after setting a cutoff at the median value for TPO (i.e., 46 pg/mL), failed to demonstrate any statistical difference between two groups [Hazard ratio (HR),1.42; 95% Confidence interval (CI), 0.67-3.15; p=0.342]. Similar results were found for a cut-off corresponding to 25th and 75th percentile, respectively. Gene expression of purified cells from 60 B-CLL patients were profiled using high density oligonucleotide microarrays. Normalized expression values for TPO gene transcipts denoted a very low expression in B-CLL cells. Furthermore, we wondered whether the pattern of distribution was homogeneous among patients with different biological profile. The analysis carried out after stratifying patients according to mutational status of IgVH showed a relatively higher normalized expression values of TPO gene transcript in patients with mutated CLL (p=0.01; Mann-Whitney test). Our results indicate that in early B-cell CLL clinico-biological profile including among other parameters TPO does not provide a useful insight into the complex interrelationship of prognostic variables. As a matter of fact, TPO may not replace the need for the determination of IgVH mutational status, as suggested by MD Anderson group (Blood 2006,108:1001-6). Finally, TPO gene transcipts is low in B-CLL cells although patients with mutated CLL display a relatively increased expression.

0519

THE CLINICAL SIGNIFICANCE OF MEMBRANE CD26 (DIPEDTIDYL PEPTIDASE IV) EXPRESSION IN B-CLL

L. Galligan, M.A. Catherwood, T.C.M. Morris, H.D. Alexander

Belfast City Hospital Trust, BELFAST, Northern Ireland

Background. CD26 (dipeptidyl peptidase IV) is a type II transmembrane glycoprotein with prolyl oligopeptidase activity and diverse biological functions including T-cell activation, chemokine regulation and is a receptor for adenosine deaminase (ADA). The role of CD26 in tumour cell transformation and development appears multi-faceted. Loss of CD26 expression has previously been associated with malignant transformation in melanoma. Conversely, CD26 appears to be differentially expressed in T-cell malignancies and has been associated with reduced survival and shorter complete remissions in T-cell NHL. CD26 is also expressed on normal B-cells. However, the significance of its expression in malignant B-cell disorders has not been elucidated. *Aims.* The aim of this study was to assess the clinical and biological significance of membrane-associated CD26 expression in B-CLL. *Methods.* Two hundred and thirty-two B-CLL patients were recruited for this study. Information on age at diagnosis, Binet clinical stage and time to treatment was available on all patients. Membrane expression of CD26 was assessed by 2-colour flow cytometric analysis of CD19 positive cells using anti-CD26PE. A value of ≥15% positivity was assigned to define a sub-group of patients (high CD26) with a relative increase in surface CD26 expression. IgVH mutational status and gene usage were determined using multiplex BIOMED-2 primers (InVivoScribe Technologies) and protocol and by sequence analysis. Interphase FISH analysis was performed to screen for common cytogenetic aberrations. *Results*. A statistically significant increase in the proportion of males was detected in the high CD26 sub-group (80% versus 58.3% in the low CD26 sub-group, p<0.0001). In addition, increased CD26 expression was associated with advanced stage disease (31.6% versus 19.9%) requiring chemotherapeutic treatment (47.4% versus 29.1%). No association was observed between CD26 membrane expression and age at diagnosis nor with cytogenetic abnormalities commonly observed in B-CLL. However, somatic hypermutation of the IgVH gene was significantly more frequent in the low CD26 sub-group (p<0.0001). Preliminary results also indicate that IgVH 4-34 gene usage is associated with low CD26 membrane expression. In addition, IgVH 3-21 gene usage (n=19) was not detected in the high CD26 sub-group. *Summary/Conclusions* In our B-CLL cohort, increased CD26 B-cell membrane expression was associated with the male gender, un-mutated IgVH gene status and more advanced Binet stage requiring treatment, irrespective of age upon presentation. Interestingly, CD26 expression has previously been associated with unfavorable prognosis in T-cell malignancies and poor response to 2'-deoxycoformycin, an inhibitor of the CD26 ligand ADA. In contrast, CD26-positive hairy cell leukaemia responds favorably to 2'-deoxycoformycin treatment. The significance of CD26 expression in B-cell malignancies remains to be fully elucidated. The possibility that it may be linked to responsiveness to treatment with the ADA inhibitor 2'-deoxycoformycin is intriguing and warrants further investigation.

0520

EXPRESSION OF INHIBITOR OF APOPTOSIS PROTEIN (IAPS) FAMILY AND ITS ANTAGONISTS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS IN RELATION TO THE DISEASE ACTIVITY

O. Grzybowska-Izydorczyk, B. Cebula, A. Linke, T. Robak, P. Smolewski

Medical University of Lodz, LODZ, Poland

Apoptotic mode of the cell death is a major regulatory process in all complex organisms. The slow accumulation of malignant cells in chronic lymphocytic leukemia (CLL) suggests that the disease is caused by a defect in apoptosis regulation. Apoptosis is executed through the activity of caspases, cysteine proteases which are regulated by a number of pro- and anti-apoptotic proteins. One such checkpoint is the control of caspase activation by relatively new family of apoptosis inhibitor of apoptosis proteins (IAPs). IAPs and their antagonists were poorly explored in CLL up to date. Majority of them were not investigated in this disease yet. Therefore, we aimed to perform a complex analysis of their expression in relation to the clinical course of the disease. Fifty six patients with CLL were included to the study. Patients were divided into two groups: with stable (N=31) and progressive disease (N=25). Expression of IAPs (cIAP1, cIAP2, XIAP, and survivin) and their inhibitors (Smac/Diablo and Htra2/omi) in CLL cells were investigated using flow-cytometry, after careful comparative studies by Western blot method. Protein expression was expressed as the mean fluorescence ratio (MFI). Leukemic cells from all patients studied were examined before treatment. Results were compared with several disease-related parameters, such as clinical stage according to Rai, ZAP-70, CD38 or β-2-microglobulin concentration. The secondary end-point of the study is to compare the results with outcome in the examined group. Patients with progressive disease (PD) showed significantly lower expression of two IAP antagonists, Htra2/omi and Smac/Diablo, in comparison to those with stable disease (SD). Median MFI levels for Htra2/omi and Smac/Diablo were 113.4 vs. 156.2 and 97.3 vs. 218.2, respectively (p=0.038 and 0.034, respectively). Lower expression of these pro-apoptotic proteins in the PD group before treatment, may suggest inhibition of CLL cells apoptosis in these patients. Moreover, PD patients showed a distinct trend toward higher expression of anti-apoptotic survivin (median MFI 69.3 vs. 29.8; p>0.05). Consequently, expression of Smac/Diablo correlated negatively with survivin levels (R=-0.44, p=0.0007). Among disease-related parameters Smac/Diablo correlated negatively with clinical stage according to Rai (R=-0.039, p=0.0.003) and ZAP-70 expression (R=-0.32, p=0.042). On the other hand, in patients with SD we found higher level of XIAP and cIAP2. Median MFI for XIAP and cIAP2 in SD vs. PD patients were 71.4 vs. 33.0 and 62.5 vs. 28.3, respectively (p=0.011 and 0.008, respectively). Moreover, cIAP2 correlated positively with β-2-microglobulin concentration (R=-0.42, p=0.015). Actually, the follow up of the study group is ongoing in terms of correlation between examined protein expression and patient fates, including outcome in those required treatment. In conclusion, this is the first comprehensive study on IAPs and their antagonists expression in CLL. The data suggest the connection between expression of these apoptosis-regulating proteins and activity of the disease. However, our results indicate also that these correla-

tion are very complex. Further studies on IAPs/IAP antagonists system in CLL to elucidate these mechanisms and to assess its potential prognostic usefulness seem to be warranted.

THE EFFECT OF THE B-CLL MICROENVIRONMENT ON CD38 EXPRESSION BY THE MALIGNANT CLONE

P.E.M. Patten,[1] A.S.G. Buggins,[1] J. Richards,[1] A. Wotherspoon,[2] J. Salisbury,[1] T. Hamblin,[1] G.J. Mufti,[1] S. Devereux[1]

[1]King's College London, LONDON; [2]Royal Marsden Hospital, LONDON, United Kingdom

In order to determine whether microenvironment derived signals might influence CD38 expression in B-cell chronic lymphocytic leukemia (B-CLL), we compared levels of this molecule in peripheral blood (PB), bone marrow (BM), splenic red pulp (RP) and splenic white pulp (WP). In 35 paired BM and PB samples, significantly higher CD38 expression was observed on BM B-CLL cells compared to PB (27% vs 19%, p=0.009). Five splenic samples infiltrated with B-CLL were examined by confocal immunofluorescence microscopy. In three cases with detectable CD38 expression, a significantly higher percentage of CD38 was found expressed by tumor cells in the WP, an area containing Ki67$^+$ tumor cells and T-cells, compared to RP. We therefore hypothesized that non-malignant cell derived signals within the leukemic microenvironment might be responsible for the level of CD38 expression in B-CLL. To test this theory, we examined the effect of co-culture of B-CLL cells with T lymphocytes using an in-vitro system aimed at mimicking the tumor microenvironment. B-CLL cells were cultured at a 4:1 ratio with CD3/CD28 bead activated autologous T-cells. CD38 expression by B-CLL cells increased significantly in 15/15 cases over the 6-day culture period, an effect most marked with cell to cell contact. Proliferation of tumor cells was also induced and was more marked in cases with higher initial levels of CD38. A parallel reduction in apoptosis was also observed. Immunofluorescence microscopy of B-CLL lymph node showed that Ki67$^+$ tumor cells were significantly more likely to be in close contact with activated CD4$^+$ T-cells than Ki67$^-$ cells (p<0.0001 for all cases assessed). In 8 lymph nodes examined, 6 had detectable CD38 staining and in these cases the Ki67$^+$ tumor cells expressed CD38. We next examined CD31 expression, constitutively expressed on endothelial cells and the only known ligand for CD38. Assessment of the vascularity within infiltrated lymph node showed significantly increased amount of CD31 expressing endothelium on cases with detectable CD38 compared to negative cases (p=0.0078). High power confocal views showed areas containinh Ki67$^+$ tumor cells in close contact with both T-cells and vessels. Strongly CD38$^+$ tumor cells were also detectable in such areas. Our *in vitro* model and other findings show that CD38 expression in B-CLL is dynamic and CD38 levels predict for B-CLL proliferation. Furthermore, the level of CD38 expression may be influenced by both activated T cells and CD31 expressing endothelium. Expression of this molecule in the peripheral blood may therefore serve as a surrogate marker for the extent of proliferation and survival signals provided by non-malignant cells in the leukaemic microenvironment, and give a biological explanation for why CD38 is an independent prognostic factor in the disease.

CLLU1 EXPRESSION DISTINGUISHES B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA FROM OTHER B-CELL LYMPHOPROLIFERATIVE DISORDERS

E. Oppliger Leibundgut,[1] D. Dissler,[2] D. de Beer,[3] D. Marti,[2] J.C. Schuller,[4] J. Duerig,[5] A. Roeth,[5] G.M. Baerlocher[3]

[1]University Hospital Bern, BERN; [2]Molecular Diagnostics, University Hospit, BERN; [3]Hematology, University Hospital, BERN; [4]Swiss Group for Clinical Cancer Researc, BERN, Switzerland

Background. Distinction of B-cell chronic lymphocytic leukemia (B-CLL) from other B-cell lymphoproliferative disorders, especially from leukemic forms of mantle cell or marginal cell lymphoma, can be a challenge, and the correct diagnosis has important prognostic and therapeutic implications. Recently, a novel gene called CLL upregulated gene1 (CLLU1), has been shown to be exclusively upregulated in B-CLL cells. Six transcripts of the CLLU1 gene have been identified, one of which has been shown to be of prognostic significance in B-CLL when overexpressed (Buhl AM, *et al.* Eur J Haematol 2006). Low expression levels of CLLU1 have been detected in single cases of other B-cell lymphoproliferative disorders and in normal blood cells. *Aims.* Our study aimed to assess the specificity and sensitivity of the CLLU1 expression and its utility in distinguishing B-CLL from other leukemic B-cell lymphoproliferative disorders. *Methods.* CLLU1 expression levels were measured by quantitative RT-PCR in a total of 96 patients with lymphoproliferative disorders including B-CLL (n=71), mantle cell lymphoma (n=14), diffuse large B-cell lymphoma (n=5), follicular lymphoma (n=5) and marginal cell lymphoma (n=1). In addition, CLLU1 expression of healthy controls (n=17) was measured and a range for the normal expression was defined. *Results.* Overexpression of CLLU1 was observed in 60/71 cases of B-CLL (85%). 15% of B-CLL cases and 32% of B-cell lymphomas exhibited CLLU1 expression within the normal range. Interestingly, in the majority of the lymphoma patients (17/25), no CLLU1 expression was detectable. Our results demonstrate a specific expression pattern of CLLU1 in B-cell lymphoproliferative disorders: The expression of CLLU1 was high in patients with B-CLL (Median: 185.2, range: 0.08-18879), low in patients with B-cell non-Hodgkin lymphoma (Median: 0.0001, range: <0.0001-8.7) and intermediate in healthy controls (Median: 0.53, range: 0.02-3.18). All three groups differed significantly from each other (p<0.01). CLLU1 overexpression was highly specific for B-CLL (specificity: 0.96, sensitivity: 0.85, positive predictive value: 0.98, negative predictive value: 0.68), whereas absent CLLU1 expression was highly predictive for B-cell non-Hodgkin lymphoma (specificity: 1, sensitivity: 0.68, positive predictive value: 1, negative predictive value: 0.91). Clinically, high CLLU1 expression levels have been shown to identify patients with an unfavorable disease. In our cohort of B-CLL patients, high CLLU1 expression was significantly associated with known bad prognostic markers such as unmutated IgVH (p<0.01), high expression of CD38 and ZAP70, and the unfavorable cytogenetic aberrations del(17p) and del(11q), confirming the prognostic value of this molecular marker. *Conclusions.* CLLU1 overexpression is highly specific for B-cell chronic lymphocytic leukemia, and lack of CLLU1 expression is significantly associated with B-cell non-Hodgkin lymphomas. Thus, analysis of CLLU1 expression by RT-PCR is a simple novel diagnostic tool that enables the distinction of B-CLL from other B-cell lymphoproliferative disorders, especially in cases where known diagnostic parameters fail to establish the diagnosis.

0523

DNA REPAIR INHIBITION IN RESTORING CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES SENSITIVITY TO FLUDARABINE AND RITUXIMAB

T. Sergienko, V. Smolnikova, A. Bakun, I. Taras, A. Svirnovski

Center for Hematology and Transfusiology, MINSK, Rebublic of Belarus

Background. Combined application of cytotoxics and monoclonal antibodies not always enhances therapeutic activity in leukemia cells. Modified DNA repair contributes to resistance development in chronic lymphocytic leukemia (CLL) lymphocytes. Majority of cytotoxic drugs, including fludarabine (Frn), influence DNA synthesis and repair. Rituximab (Rtx) has multiple mechanisms of inducing *in vivo* cytotoxicity and direct apoptotic signaling is one of them. Lack of appropriate response to Frn and Rtx can be associated with enhanced DNA repair in peripheral blood lymphocytes. Usage of DNA-dependent protein kinase (DNA-PK) inhibitor vanillin (Vnl) may contribute to Frn and Rtx resistance overcoming. *Aims.* To investigate CLL cell response *in vitro* to the action of Frn and Rtx under the DNA repair inhibition with vanillin. *Methods.* MTT assay was used to evaluate cell sensitivity to purine nucleoside analog and monoclonal antibody (in concentrations similar to therapeutic), vanillin (in nontoxic concentration to normal lymphocytes) *in vitro*. According to lymphocyte viability, cell samples were divided into groups with different sensitivity to Frn and Rtx: sensitive (cell viability less than 35%), intermediate (35-70% viable cells) and resistant (cell viability more than 70%). *Results.* Vnl not significantly enhanced Frn activity in CLL cells irrespective of lymphocyte response to Frn (shown in table). In cells with high and intermediate sensitivity to Rtx negligible protective effect of Vnl was detected. On the contrary, in Rtx resistant CLL lymphocytes combined action of Vnl and Rtx significantly suppressed cell viability twice as much as a monoclonal antibodies alone. In Frn resistant group strong correlations between cell sensitivity to Vnl and Frn were observed (r=0.83-0.93, p<0,05), whilst no significant correlation was detected between Rtx and Vnl action (p>0.05). Correlation analysis confirmed unidirectionality of CLL cells response to Van and Frn, and lack of interdependence between Van and Rtx action. Cell sensitivity and clinical data dependence was studied. No significant correlations were observed in cell susceptibility to drugs and peripheral blood $CD5^+$ and $CD20^+$ cell number. Apoptosis marker bcl-2 level was also measured. Intrinsic bcl-2 level *ex vivo* didn't correlate with cell sensitivity to Frn, Rtx, and Vnl. Most likely Frn and Rtx don't directly influence bcl-2 pathway. Consequently endogenous bcl-2 lymphocyte level can not be used as strong prognostic factor for cell sensitivity. *Summary and conclusions.* Vanillin is an effective agent to overcome Rtx resistance in CLL lymphocytes, but it doesn't influence Frn activity. DNA repair inhibition is one of the possible pathways that leads to lymphocyte sensitivity restoration to Rtx, where as Frn unreceptiveness overcoming is achieved with DNA-PK inhibitor suggesting another pathways of Frn resistance formation.

Table 1. Viability modification by vanillin in cells with different sensitivity to Frn and Rtx.

Cell sample	Viable cells (%) under the influence of		Cell viability modification under the influence of Vnl	Viable cells (%) under the influence of		Cell viability modification under the influence of Vnl
	Frn	Vnl+Frn		Rtx	Vnl+Rtx	
Sensitive	21.0	13.4	7.6 ↓	9.3	15.5	6.2 ↑
Intermediate	48.7	40.2	8.5 ↓	53.3	59.5	6.2 ↑
Resistant	75.1	70.0	5.1 ↓	86.4	42.5	43.9 ↓↓↓ *

↓ - cell viability decrease; ↑ - cell viability increase; *- difference is significant, p<0.001

EFFICACY OF FLUDARABINE IN A NOVEL NOD/SCID XENOTRANSPLANTATION MODEL OF CHRONIC LYMPHOCYTIC LEUKEMIA

P. Ebeling, F. Grabellus, S. Seeber, U. Duehrsen, T. Moritz, J. Duerig

University of Duisburg-Essen, ESSEN, Germany

Background. Chronic lymphocytic leukemia (CLL) represents the most frequent leukemia in the western world. Although improvements in therapeutic strategies has been achieved in recent years, this desaese still remains incurable. Therefore novel therapeutical stragegies to improve patient outcome need to be established. However, preclinical *in vivo* drug testing, a crucial prerequisite for the developpent of such novel strategies in CLL, so far still is hampered by the lack of a suitable animal model. We have previously reported reliable engraftment of CD19/CD5/CD23/CD45 positive human B-CLL cells in the spleens of NOD/SCID mice (NSS-CLL cells) following i.v. and/or i.p. transplantation of 1×10^8 peripheral blood derived mononuclear cells from CLL patients (PB-CLL). On histology, in the majority of the samples, NSS-CLL cells formed focal aggregates which also contained various amounts (range:0-50%) of human $CD45/CD3^+$ T cells (ASH 2005; #52). *Aims.* We now have further characterized these NSS-CLL cells. Additionally, drug testing experiments were performed to determine if this novel model may be suitable to preclinically investigate therapeutic effects of established treatment strategies in CLL. *Methods.* For further characterization of NSS-CLL cells, a panel of surface and intracellular marker molecules like Ki67, Survivin, CD100, CD10, CD11c, CD127 and CD49d was utilized. Drug testing experiments in this model were performed using fludarabine (Flud), a chemotherapeutical agent with proven activity against CLL. For theses latter experiments 1×10^8 PB-CLL were injected i.v. into the tail vein of NOD/SCID mice. Starting two weeks after transplantation the animals were allocated to receive therapy with either Flud or no therapy, respectively. Flud was given at a dosis of 35mg/kg ip. for 5 consecutive days. Four weeks after transplantation animals were sacrificed and BM and spleens were analyzed for the presence of CLL cells using multicolor flow cytometry. *Results.* Concerning the further characterization of NSS-CLL cells, immunohistological analysis showed positive staining for the proliferation marker Ki67 in 18.5±3.5% of these cells. Further, markers related to proliferation/activation of B-CLL proliferation center cells such as survivin (mean MFI: 5.5±0.8 vs. 2.3±0.2; p=0.028; n=6) and CD100 (semaphorin 4d; mean MFI: 3.3±0.5 vs. 1.1±0.2; p=0.043; n=5) were significantly up-regulated in NSS-CLL vs. PB-CLL cells. In contrast, no expression of human CD10, CD11c, CD127 or CD49d was detected in B-CLL cells derived from either PB- or NSS-CLL cells, while both sources uniformly stained positive for CD40. With regard to 8 individual drug testing experiments a significant lower amount of 2.2±1.2 vs. $11.4\pm2.4\times10^5$ (p=0.003) CLL cells could be recovered from the spleens of treated animals when compared to the control group. Thus, treatment with Flud resulted in a relative reduction of total amount of CLL cells recovered from the murine spleen of 85.5±8.1% (p=0.003). *Summary.* NSS-CLL cells display certain similarities of CLL proliferation centers like expression/upregulation of proliferation/activation markers and therefore this model could serve as a valuable tool to investigate CLL tumour biology. In addition the model allowed for reliable *in vivo* drug testing of a conventional therapeutic agent and thus argues for a preclinical evaluation of this new model also to investigate novel chemotherapeutic strategies.

0525

CD74 IS A NOVEL SURVIVAL RECEPTOR IN CHRONIC LYMPHOCYTIC LEUKEMIA

M.Z.H. Haran,[1] I. Binsky,[2] D. Starlets,[2] N. Harpaz,[3] L. Shvidel,[3] A. Berrebi,[3] I. Shachar[2]

[1]Kaplan Medical Center, REHOVOT; [2]Immunology, Weizmann Institue of science, REHOVOT; [3]Hematology Inst., Kaplan Medical Center, REHOVOT, Israel

Background. Previous studies have shown that chronic lymphocytic leukemia (CLL) lymphocytes express relatively large amounts of CD74 mRNA compared to normal B cells. We have recently demonstrated in a murine model that CD74 stimulation with anti-CD74 antibody leads to an induction of a signaling cascade resulting in NF-κB activation, entry of the stimulated cells into the S phase, elevation of DNA synthesis, cell division, and augmented expression of BCL-XL. These findings therefore demonstrated that surface CD74 functions as a survival receptor. *Aims.* In the current study we aimed to determine whether activation of cell surface CD74 in B-CLL cells leads to induction of a signaling cascade resulting in cell survival.

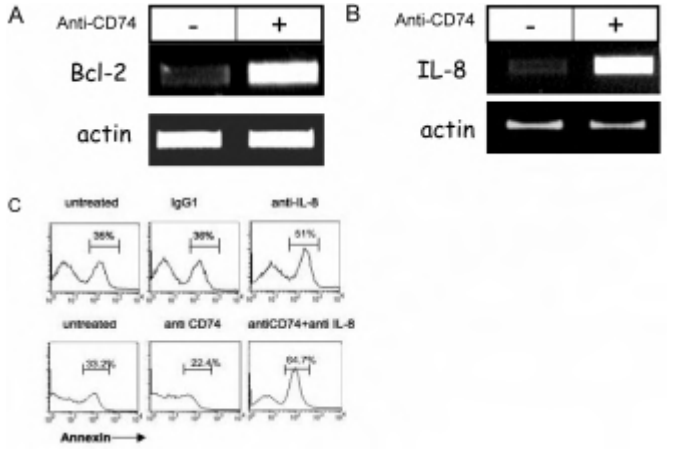

Figure 1. A) CD74 stimulation induces IL-8 and Bcl-2 expression in CLL B cells. Cells were incubated in the presence or absence of anti-CD74 antibody, Id2, a control antibody or MIF for 18 h. RNA was purified and levels of IL-8, Bcl-2 and actin mRNA were analyzed. The results presented are representative of 12 CLL patients. B) The conditioning medium of the cells was collected, and the level of IL-8 was assessed by ELISA. The results are representative of 3 independent experiments. C) IL-8 secreted following CD74 stimulation regulates B-CLL cell survival. CLL cells were incubated in the presence or absence of an agonistic anti-CD74 antibody, anti-IL-8 or a control antibody (c-jun) for 48 h. Cells were stained with annexin V and analyzed by FACS. The results presented are representative of 7 CLL patients.

Materials and Methods. B cells were purified from the peripheral blood of CLL patients in different stages, in accordance with the IRB of our hospital. CD74 stimulation was achieved using an agonistic anti-CD74antibody or MIF (a natural occurring ligand of CD74). IL-8 expression and function was determined by RT-PCR, western blot, ELISA and Annexin V staining. *Results.* In all the cells obtained from CLL patients there was a significantly increased expression of cell surface CD74, as compared to normal B cells. Activation of cell surface CD74 initiated a signaling cascade that resulted in increased expression and secretion of Interleukin 8, as well as over-expression of bcl-2 (see panels A, B in Figure 1). Stimulation of CD74 led to increased cell survival, as seen by annexin staining, whereas blocking of IL-8 led to increased apoptosis (panel C in Figure 1). *Conclusions.* Our data show that over-expression of CD74 in CLL is an important survival mechanism, operational from the very early stages of the disease, and inherent in all further stages. This survival mechanism thus appears to be an early and significant event in the pathogenesis of the disease. Our findings open prospects for novel therapeutic strategies aimed at interruption of this survival pathway.

OVER EXPRESSION OF THE ABC-TRANSPORTER BCRP, MRP1 AND MDR1 IN CML PATIENTS AT DIAGNOSIS, WHO RESPOND AND WITH ACQUIRED RESISTANCE TO IMATINIB MESYLATE

I. Bendit,[1] L. Nardinelli,[2] M. Bendit,[2] M.C. Mello,[2] M.N.Y. Novaes,[2] W.M. Lima,[2] R.R. Giorgi,[2] J.E.B. Neto,[2] D.A.F. Chamone,[2] P. Llacer-Dorliac[2]

[1]University of Sao Paulo, SAO PAULO; [2]Medical School at USP, SAO PAULO, Brazil

IM is widely used for the treatment of CML inhibiting the BCR-ABL tyrosine kinase activity. Although, 90% of the patients respond to IM, resistance to this drug has been seen mainly due mutations in ABL tyrosine kinase domain. Recently, it was reported that IM is a substrate for the ABC-transporters BCRP (breast cancer resistance protein), MRP1 (multidrug resistant protein 1) and MDR1 (P-Glycoprotein). We studied 29 patients (9 CP, 17 AP, and 3 BC) who initiated treatment with IM after 49 mo (±10 mo) from diagnosis and develop resistance 31 mo (± 4mo) after beginning of therapy. To compare the expression of the resistant group, 34 CML patients at diagnosis (23 CP, 5 AP, and 2 BC) and 29 good responders to IM (22 CP, 5 AP, and 2 BC) with a mean time from diagnosis to initiation of IM of 29 mo (±6,6 mo). To detect the expression of those ABC-transporters RNA was extracted and cDNA was synthesized and amplified through real time PCR applying SYBR Green as a dye and reported as the 2- Ct where it is assumed that the amplification efficiency of the target gene (BCRP, MRP1 or MDR1) and the internal control gene (ABL) are the same. Over expression of BCRP was observed in 65.5% of the resistant group (4 CP, 12 AP, and 3 BC) when compared to 11,8% of patients at diagnosis (2 CP, 1 AP, and 1 BC), and to 10,3% of patients that respond to IM (3 CP) (Kruskal-Wallis test, $p<0.05$). MRP1 expression was detected in 51,7% in the resistant group (4 CP, 9 AP, and 2 BC), 10,3% in the responder group (1 CP and 2 AP), and no expression was detected in the group at diagnosis (Kruskal-Wallis test, $p<0.05$). For the MDR1 expression no difference was seen between the 14/29 resistant (4 CP, 9 AP, and 1 BC) patients and the 9/29 responder to IM (6 CP, 2 AP, and 1 BC), but when compared to the 6/34 patients at diagnosis (3 CP and 3 AP) a statistical difference was noted (Kruskal-Wallis test, $p<0.05$). Over expression of BCRP was more frequent in AP of the resistant group and MRP1 expression was not detected at diagnosis. For MDR1 expression no difference was seen among the distinct groups and at different phases. These data confirms that over expression of BCRP and MRP1 may contribute to imatinib resistance leading to a reduction in intracellular concentrations of IM. MDR1 expression could not be considered as a mechanism of resistance to IM in CML.

0527

THE POLYCOMB GROUP BMI-1 GENE IS A MOLECULAR MARKER FOR PREDICTING PROGNOSIS OF CHRONIC MYELOID LEUKAEMIA

M. Mohty, A.S.M. Yong, R.M. Szydlo, J.F. Apperley, J.V. Melo

Imperial College, LONDON, United Kingdom

Background. Despite a consistent molecular abnormality, the BCR-ABL oncogene, CML exhibits marked clinical heterogeneity, and various attempts have been made to determine prognosis for individual patients at the time of diagnosis in chronic phase (CP). The PcG gene BMI-1 plays an essential role for the self-renewal of both hematopoietic and neuronal stem cells, as well as cancer stem cells. Coexpression of Bmi-1 and other proteins from the PcG confers a higher degree of malignancy. *Aims.* Because Bmi-1 regulates the proliferation of both normal and leukemic stem cells, we examined whether Bmi-1 might serve as a biomarker to predict disease aggressiveness and progression from CP to more advanced phases. *Methods.* Two independent cohorts of CML patients were studied: 1) patients in CP whose nucleated cells were collected by leukapheresis before start of treatment, and for whom complete follow-up was available (n=64); 2) patients with cryopreserved cells collected at CP or blast crisis (BC). Expression of BMI-1 and other genes of interest was assessed by Q-RT/PCR using the ABI *Assays-on-demand* TaqManTM probe-and-primer reagents according to the manufacturer's instructions. *Results.* BMI-1 expression levels in $CD34^+$ cells were significantly lower in CP than in more advanced stages (accelerated phase and BC) of CML ($p=0.006$). The same significant difference

held true when BMI-1 expression was compared in unfractionated CML-derived PBMCs (p<0.0001). In order to gain insights into the mechanisms underlying BMI-1 upregulation in CML, we also assessed the expression of E2f-1, a transcription factor that was shown to directly regulate Bmi-1 activity. We found that PBMCs from CML patients (all disease stages) displayed significantly higher levels of E2F-1 as compared to healthy controls (p=0.001). Furthermore, we uncovered a significant difference in BMI-1 levels between patients with an *indolent* (survival for over 7 years prior to the onset of BC), or an *intermediate* (survival between 3 and 7 years without developing BC) clinical pattern as compared to those who had an *aggressive* (development of BC within 3 years of diagnosis) clinical evolution (p=0.01). Patients displaying a low BMI-1 expression level at diagnosis had significantly longer survival than other patients. (p=0.005). When BMI-1 was included in a Cox multivariate survival analysis model (together with the previously established prognostic markers, CD7, ELA-2, PR-3, and other relevant demographic and clinical parameters), the combination of low BMI-1 and high PR-3 expression levels was found to be a strong independent marker associated with significantly longer overall survival (p=0.001; RR=0.20, 95%CI; 0.08-0.54). *Conclusions.* Our observations suggest an important role for BMI-1 in CML pathophysiology and prognosis. Genetic alterations impairing E2F-1, BMI-1 and their downstream targets may render hematopoietic cells refractory to the induction of differentiation. From the clinical standpoint, our findings demonstrate that BMI-1 can serve as a novel biomarker to predict prognosis in CML, particularly in conjunction with the expression level of immune-related proteins such as Pr-3. Therefore, the prospective screening for BMI-1 expression in combination with other molecular markers can help refining CML disease staging and prognosis towards optimizing therapeutic interventions, including perhaps Bmi-1-targeted inhibitors.

EXPRESSION OF PRO-APOPTOTIC BID AND BIK GENES IS DECREASED IN CHRONIC MYELOID LEUKEMIA AND LOW LEVELS OF BIK MRNA ARE ASSOCIATED WITH LACK OF RESPONSE TO IMATINIB TREATMENT

F. Castro,[1] A. Ferreira,[1] M.A. Zanichelli,[2] M.D. Colassantti,[2] P.R. Tobo,[3] L. R. Lopes,[3] N. Hamerschlak,[3] C. A. Moreira-Filho,[4] G.P. Amarante-Mendes,[4] J. F. Jacysyn[4]

[1]FCFRP-USP, RIBEIRÃO PRETO-SP; [2]Hospital Brigadeiro, SÃO PAULO; [3]IIEP-S.B.I.B. Hospital Albert Einstein, SÃO PAULO; [4]Departamento de Imunologia, ICB-USP, SÃO PAULO, Brazil

Background. Chronic myeloid leukemia (CML) is a myeloproliferative disease in which survival of Bcr-Abl leukemic cells is mediated by modulation of pro-apoptotic and anti-apoptotic molecules. Fully understanding the basic apoptotic pathway and its regulation in Bcr-Abl cells might unveil novel targets for manipulation, which may be translated into novel therapies. *Aim and Methods.* The present study investigated the expression of six important pro-apoptotic genes, members of Bcl-2 family, in CML. bax, bad, bak, bid, bik and bimel gene expression was evaluated in 15 healthy controls (8 men, 7 women; median age 49y [range 25-72]), and in 71 CML patients (36 men, 35 women; median age 52y (range 23-73); 20 in chronic phase [CP], 15 in accelerated phase [AP], 9 in blastic phase [BP], 20 in complete cytogenetic remission [CCR], and 7 imatinib-refractory [IR]). Gene expression was assessed in peripheral blood mononuclear cells by quantitative real-time PCR, and results were given as relative expression (amplicon ratio: investigated gene/β-actin housekeeping gene). Kruskall-Wallis post-test followed by the Dunn test for multiple comparisons was used to look for statistical differences in gene expression between controls and CML patients (taken as a single group), between controls and each of the five above-mentioned CML subgroups, and between the different CML subgroups. *Results.* Median bik levels were: 0.46 in controls, 0.14 in the whole CML group, 0.11 in CP, 0.10 in AP, 0.14 in BP, 0.28 in CCR and 0.01 in IR patients. bid expression was 6.7 in controls, 1.6 in the whole CML group, 1.0 in CP, 1.7 in AP, 1.5 in BP, 2.9 in CCR and 1.0 in the IR subgroup. Significant reduction in bik (p<0.001) and bid (p<0.001) mRNA was observed in the CML group (taken as a whole) in comparison to controls. In addition, in subgroup analyses, a significant decrease of bik expression was also found in IR patients when compared to other CML subgroups and to controls (p<0.001 for all comparisons). No significant differences between controls and CML patients (neither taken as a whole nor as subgroups) were verified regarding bax, bad, bak and bimel gene expression (p>0.05 for all comparisons). *Conclusions.* Our data indicate that altered expression of bid and bik is a feature of CML, and encourage further exploration of the role played by these two pro-apoptotic genes in contributing to the apoptosis resistance phenotype observed in CML. Finally, the finding of bik down-regulation specifically in the subgroup of IR-CML patients suggests that bik may be an attractive therapeutic target to be investigated in CML refractory to imatinib.

ASSOCIATION BETWEEN GSTM1, GSTT1 AND GSTP1 GENETIC POLYMORPHISM AND RISK TO CHRONIC MYELOID LEUKEMIA

D. Agrawal,[1] A.K. Tripathi,[2] P. Bajpai[1]

[1]Industrial Toxicology Research Centre, LUCKNOW; [2]King George's Medical University, LUCKNOW, India

Background and Aim of the study. Glutathione S- Transferases (GSTs) are a polymorphic group of enzymes involved in phase II detoxification of wide range of xenobiotics & chemotherapeutic agents. Polymorphisms associated with genes coding for glutathione S-transferase enzymes are known to influence metabolism of different carcinogens and have been associated with incidence of various types of cancer. Humans are polymorphic in their ability to detoxify intermediates, which in theory may explain differences in leukemia risk as a result of exogenous exposure. Allelic variants of these genes may result in less effective or absent enzymatic detoxification and thus increased susceptibility to Chronic Myeloid Leukemia (CML). The aim of our study was to investigate the role of GSTM1 & GSTT1 null genotype & functional Ile 105 Val polymorphism in GSTP1 as genetic risk factor for CML. *Methods.* DNA was isolated by standard proteinase K and phenol-chloroform method. Multiplex PCR was carried out to determine GSTM1 & GSTT1 null genotype. β globin was used as an internal positive control. PCR-(RFLP) was performed to investigate the GSTP1 allelic variants. PCR products were separated using 2% agarose gel. The relationship between GSTM1, GSTT1 and GSTP1 genotypes and risk of CML was assessed by means of chi square test. The odds ratio (OR) with 95% confidence limits was calculated by logistic regression. *Results.* The frequency of GSTM1 and GSTT1 null alleles in the controls was 24.7% (26/105) and 8.5% (9/105), respectively. A higher frequency of these genotypes was reported in CML patients, which was 30% (24/80) and 20% (16/80), respectively. In CML patients the frequency of GSTP1 homozygosity for the Ile105 wild-type allele, heterozygosity (Ile105/Val105), and homozygosity for the Val105 mutant allele is 79% (59/75), 19% (14/75), and 3% (2/75) respectively. Likewise in controls the frequency of GSTP1 homozygosity for the Ile105 wild-type allele, heterozygosity (Ile105/Val105), and homozygosity for the Val105 mutant allele is 86% (67/78), 13% (10/78), and 1% (1/78) respectively. *Conclusions.* The study provides valuable evidence based data from Indian population to the knowledge of GST polymorphism. There was no difference in the frequencies of the GSTM1 null genotype and the combined GSTM1 and GSTT1 null genotypes between patients and controls in the study. A higher frequency of heterozygosity of (Ile105/Val105), and homozygosity for the Val105 mutant allele in CML patients as compared to controls is reported, which was 22% and 14% respectively. Though the frequency for homozygosity for Val 105 mutant allele was not statistically significant but Odds Ratio = 2.27 projects two fold higher risk with CML patients carrying this mutation as compared to controls. However, statistical significance was found with GSTT1 null genotype frequency in CML patients as compared to controls [16/80 (20%) vs 9/105 (8.5%); OR=2.67, 95% CI: 1.03 - 7.01]. It projects a 2.67-fold increased risk for CML in individuals with GSTT1 null genotype as compared to those possessing both alleles of the gene.

CCN3 REDUCES CLONOGENIC CAPACITY OF BCR-ABL+ CELLS

L. McCallum,[1] W. Lu,[1] S. Price,[1] N. Planque,[2] B. Perbal,[2] A.D. Whetton,[3] A.E. Irvine[1]

[1]Queens University Belfast, BELFAST, United Kingdom; [2]Universite Paris 7-D Diderot, PARIS, France; [3]University of Manchester, MANCHESTER, United Kingdom

Background. Chronic Myeloid Leukaemia (CML) is characterized by expression of the constitutively active BCR-ABL tyrosine kinase. Previously, we identified down-regulation of the negative growth regulator, CCN3, as a result of BCR-ABL kinase activity. CCN3 has a reciprocal relationship of expression with BCR-ABL and consequently reduced CCN3 expression is a prominent feature in both primary human CML cells and cell lines (McCallum *et al.*, Blood 2006; 108(5):1716-23). *Aims.* to investigate the functional consequence of expressing CCN3 in BCR-ABL+ cells. *Methods.* Colony formation assays were performed over a

period of 7 days to investigate CCN3 growth regulation. K562 cells were transfected with vector alone, vector containing CCN3 construct or with treated with Imatinib (1 micromolar) for 24h prior to plating in methyl cellulose. Primary human CML CD34+ cells were isolated from peripheral blood and treated with CCN3 (1 nanomolar) or imatinib (1 micromolar) for 24h before plating into culture. *Results.* K562 cells that had been transfected with vector alone or vector containing full-length CCN3 were compared to cells treated with Imatinib. Increased CCN3 expression significantly reduced colony formation by 65.4%±18.8 when compared to cells transfected with vector alone (p=0.027, n=3). Treatment with Imatinib also reduced colony formation (75%±8.2; p=0.001, n=3) compared to untreated cells. Full-length CCN3 comprises 5 domains. To further characterise the functional component within CCN3, partial length constructs encoding domains 2-5 (NH25), 3-5 (NH35) and 4-5 (NH45) were transfected into K562 cells using nucleofector™ technology. Expression of NH25 and NH35 significantly reduced colony formation capacity by 20% (p=0.001) and 25% (p=0.036) respectively, whilst expression of the NH45 construct did not alter colony formation. We next assessed the clonogenic effects of CCN3 and Imatinib on primary human CD34+ progenitor cells derived from CML peripheral blood samples at diagnosis (n=3). Cells pre-treated with exogenous addition of full-length CCN3 protein for 24h prior to plating in methyl cellulose cultures reduced clonogenic capacity by 25.5±3.9% (p=0.011). Pre- treatment with Imatinib reduced colony formation by 37.9%±19.9 (p=0.010). *Conclusions.* This study demonstrates that CCN3 expression regulates the colony formation capacity of BCR-ABL+ cells. Domains 2 and 3 comprising an insulin-like growth factor binding and Von Willebrand type C domain appear to be significant contributory components in mediating negative growth regulation. Loss of CCN3 expression mediated by BCR-ABL disrupts cell growth regulation confering growth advantage to CML cells.

TRAIL MEDIATED ANTI-LEUKEMIC EFFECTS OF INTERFERON-ALPHA COMBINED WITH G-CSF ON CHRONIC MYELOGENOUS LEUKEMIA DURING IMATINIB THERAPY

S. Ota,[1] M. Musashi,[1] N. Toyoshima,[1] J. Tanaka,[1] M. Kasai,[2] M. Imamura,[1] M. Asaka[1]

[1]Hokkaido University, SAPPORO; [2]Sapporo Hokuyu Hospital, SAPPORO, Japan

Aims. In the treatment of patients with chronic myelogenous leukemia (CML), a major goal of therapy is the eradication of BCR-ABL-positive leukemic clone. Simultaneous exposure of BCR-ABL-positive leukemia cells to imatinib and interferon-α (IFN) produced synergistic anti-proliferative effects. As G-CSF augments IFN-induced release of soluble TNF-related apoptosis- inducing ligand (sTRAIL) from leukocytes, if G-CSF has a proliferative effect on normal clone but not malignant clone, a combination therapy of imatinib, IFN, and G-CSF is expected to eradicate malignant clone. In this *in vitro* study using bone marrow and peripheral blood mononuclear cells (BMC, PMC) from patients with CML and healthy volunteer donors (HVD), we evaluated whether imatinib in combination with IFN and G-CSF enhanced the anti-leukemic effects via TRAIL/TRAIL receptor (DR4 & DR5) system. *Methods.* Colony assay was performed by a methylcellulose method. Patient's BMC and leukemic cell lines were incubated with imatinib, IFN, G-CSF or recombinant human sTRAIL (rhsTRAIL). Ratio of BCR-ABL- positive cells to -negative cells in pooled colonies was evaluated by RT-PCR with BCR-ABL mRNA. To evaluate indirect cytotoxic effects of IFN-stimulated BMC, PMC, and neutrophils from HVD, their co-culture with K562 was performed using transwell chamber. Apoptosis was detected by Annexin V staining. Concentration of sTRAIL was measured by ELISA. Expression of DR4 and DR5 on leukemic cell lines was examined by FACScan. *Results.* Sequential colony assay of the patients showed that the colony formation decreased paralleled with reduction of Ph clone after imatinib administration, and recovered after achieving a cytogenetic remission. In untreated cases, colonies were effectively suppressed by an addition of imatinib to cultures, while that were more strongly suppressed by IFN than imatinib in patients undergoing imatinib. Although there were no significant differences in BCR-ABL mRNA ratio of pooled colonies between mono-agent treatment and the combinations, IFN with or without G-CSF suppressed BCR-ABL mRNA expression level compared to the control. IFN increased sTRAIL concentration in culture of BMC from patients with CML, also induced sTRAIL from BMC, PMC, or neutrophils obtained from HVD, in a cell number-dependent manner. To clarify the effects of sTRAIL minutely, we examined sTRAIL-induced apoptosis in leukemic cell lines. DR4 and DR5 were highly expressed on K562, KU812, and HL60. rhsTRAIL induced dose- and time-dependent apoptosis in the cell lines, and the effect was completely abolished by anti-TRAIL antibody. Apoptosis of K562 was not induced by a co-culture with IFN, but was induced by IFN-stimulated BMC, PMC, or neutrophils from HVD in the membrane-separated transwell chamber. There were no significant differences in incidence of apoptosis between IFN alone and IFN plus G-CSF treatment. *Conclusions.* We suggest that IFN, adding to its direct effects, induces sTRAIL from BMC, PBC, and neutrophils, which may contribute to reduce leukemic progenitor cells in patients with CML. G-CSF dose not abrogate the cytotoxic effects of IFN, but increases sTRAIL release from blood cells. From these observations, we suggest that G-CSF can enhance anti-leukemic effect of IFN on BCR-ABL-expressing cells via sTRAIL during imatinib therapy.

THE LEVEL OF CIRCULATING T REGULATORY CELLS CORRELATES WITH THE DISEASE BURDEN IN CHRONIC MYELOID LEUKAEMIA

J.-M. Rojas, S. Owen, L.H. Wang, K. Knight, R.E. Clark

University of Liverpool, LIVERPOOL, United Kingdom

Chronic myeloid Leukaemia (CML) is characterised by the BCR-ABL gene recombination. We and others have demonstrated that T cells capable of recognising BCR-ABL junctional peptides are present in the circulation of CML patients. We also demonstrated an inverse correlation between the level of these BCR-ABL-specific T cells and the disease burden, as assessed by the BCR-ABL/ABL transcript ratio. However, in spite of the presence of these BCR-ABL-specific T cells, the CML cells persist in the patients. The CD4+ CD25+ naturally-occurring T regulatory cell (Treg) population has immunosuppressive activity involved in limiting immune responses. Studies have also shown that Treg cells can inhibit antitumour immune responses. Thus, we hypothesised that Treg cells may be involved in limiting anti-CML immune responses. In the present study, we carried out an analysis of the amount of Treg cells detected in the peripheral blood of 22 CML patients at multiple time points. All patients were in first chronic phase and currently receiving or having recently received imatinib 400-600 mg daily. The Treg cell numbers were evaluated using flow cytometry for the Treg cell markers CD25 and FOXP3. We correlated these data with BCR-ABL/ABL transcript ratios measured by real-time RT-PCR for each time point. We observed that the Treg population was consistently elevated in patients with high BCR-ABL/ABL transcript ratio (ratio>10%) as compared to patients with low BCR-ABL/ABL transcript ratio (ratio<10%). The median CD4+CD25+ population detected in patients with high BCR-ABL/ABL transcript ratio was 2.29% of all gated lymphocytes whereas this median was 1.29% in patients with low BCR-ABL/ABL transcript ratio (p<0.01 Mann-Whitney two-tailed test). Similarly, the CD4+ FOXP3+ population was consistently elevated in patients with high BCR-ABL/ABL transcript ratio (median of 3.02% for high transcript ratio versus a median of 1.35% for low transcript ratio, p<0.05 Mann-Whitney two-tailed test). We were able to isolate the Treg cell population using CD25-coupled magnetic beads, and are currently investigating the function of these cells in immunity in CML. These data suggest that Treg cells may be involved in limiting anti-CML immunity.

SURVIVIN EXPRESSION REDUCES IMATINIB EFFICACY IN CHRONIC MYELOID LEUKEMIA

F. Stagno,[1] S. Stella,[2] S. Berretta,[1] E. Tirrò,[2] E. Conte,[2] F. Di Raimondo,[1] A. Messina,[2] R. Giustolisi,[1] P. Vigneri[2]

[1]Hematology Section, CATANIA; [2]Pathology Section, CATANIA, Italy

Background and Aims. Imatinib Mesylate (IM) is a semi-specific inhibitor of the BCR-ABL tyrosine kinase and currently represents the treatment of choice for patients diagnosed with Chronic Myeloid Leukemia (CML). Survivin (SVV) is undetectable in normal tissues but highly expressed in most forms of human cancer and functions as both a cell death inhibitor and a mitotic regulator (Altieri, Nat. Rev Cancer 2003;3:46). Previous evidence suggests that SVV is overexpressed in CML cells and that a significant correlation exists between BCR-ABL levels and SVV expression (Conte *et al.* Cancer Lett 2005;225:105). Moreover, our recent findings show that BCR-ABL kinase activity induces SVV expression in both murine and human models of CML (Conte *et al.* submitted). *Patients and Methods.* We investigated the interplay between SVV levels and the clinical response to IM in 20 consecutive patients (pts) with typical BCR-ABL-positive CML (10 males and 10 females; median age 55 yrs, 18 pts in Chronic Phase, 2 pts in Accelerated Phase; 100%

Ph+ cells in the bone marrow). We also evaluated the possible influence of SVV levels on the clinical outcome (time to progression, response to therapy and overall survival) of the pts. All CML pts underwent IM therapy at 400 mg/die and their SVV levels were assessed by quantitative RT-PCR prior to the first IM treatment. Complete hematologic response (CHR), cytogenetic response (Cy-R) and molecular response (MolR) were scored as previously described (Baccarani *et al.* Blood 2006;108:1809). *Results and Conclusions*. All CML pts expressed the SVV transcript (median SVV=727 units). Nineteen out of 20 CML pts (95%) reached a CHR at 3 months; 10/20 pts (50%) obtained a Cy-R (complete + partial) at 12 months; 7/20 pts (35%) achieved a MolR (complete + major) at 12 months. Four pts (20%) displayed a failure to treatment within 12 months. In our analysis, SVV transcripts produced a median time to progression and survival of 31 (p=0.04) and 53 months (p=0.6), respectively. These findings indicate that increased SVV expression reduces IM therapeutic efficacy, in agreement with our previous *in vitro* observation that high SVV levels significantly reduce cell death in CML cells. Thus, our data suggest that strategies aimed at lowering SVV expression may improve the efficacy of IM, therefore representing a possible therapeutic option for both IM-sensitive and IM-resistant CML patients.

DETECTION OF SINGLE NUCLEOTIDE POLYMORPHISMS IN THE ABL KINASE DOMAIN OF CML PATIENTS

T. Ernst, M.C. Müller, P. Erben, N. Härtel, C. Walz, R. Hehlmann, A. Hochhaus

Universitätsklinikum Mannheim, MANNHEIM, Germany

Background. BCR-ABL kinase domain mutations constitute the leading cause of resistance in CML patients treated with imatinib. Detection of BCR-ABL mutations prior to and during the course of imatinib therapy may aid in risk stratification as well as in determining optimal individual therapeutic strategies. More than 50 different point mutations have been described so far. The K247R change has been identified as a rare gene polymorphism occurring also in normal control patients and other cell types. Despite its position near to the P-loop, biochemical and cellular assays of imatinib and dasatinib sensitivity showed no alteration compared to wild-type ABL. *Aims.* Since gene polymorphisms do not automatically necessitate a change in the therapeutic strategy we sought to investigate if other BCR-ABL mutations are rather polymorphisms than mutations associated with resistance to tyrosine kinase inhibitors. *Methods.* In comparison to real BCR-ABL kinase domain mutations, single nucleotide polymorphisms (SNPs) also have to occur on the normal, untranslocated ABL allele. Therefore, we designed an allele-specific PCR for amplification of the normal ABL allele following mutation analysis by denaturing high-performance liquid chromatography (D-HPLC) and subsequent sequencing. A multiplex PCR was performed to ensure that both Ib and Ia ABL splice variants were amplified. Ninety-one imatinib-resistant CML patients (chronic phase, n=88; accelerated phase, n=1; blast crisis, n=2) with 65 different BCR-ABL kinase domain mutations leading to 50 different amino acid changes were investigated in our study. 39 of 65 different mutations were evaluable in two different patients and 26 different mutations in one patient, respectively. *Results.* Amplification of the normal ABL allele succeeded in all cases. The D-HPLC analysis indicated a mutation in the normal ABL allele in eight cases. The nucleotide exchanges were confirmed by direct sequencing in both directions. In all cases the same mutation of the BCR-ABL allele was confirmed in the normal ABL allele (mutated ABL (%)/ mutated BCR-ABL (%)): T240T (50/100), F311V (50/100), T315T (40/100), Y320C (90/30), K247R (100/20; 40/100) and E499E (100/100; 40/100). In three cases the SNP did not lead to an amino acid change (silent mutation). Five patients had a wild-type as well as a mutated ABL allele leading to 50% mutated ABL allele. In these patients the SNP including ABL allele seems to be translocated to BCR-ABL thus containing 100% mutated BCR-ABL. Another patient harbouring the F311V mutation at the BCR-ABL allele did not show the mutation at the normal ABL allele. *Conclusions.* In addition to the previously described polymorphism K247R we uncovered five new polymorphisms, two of these led to amino acid changes. SNPs should be taken into consideration for design of mutation-specific PCRs, particularly the T315T polymorphism for T315X amplifications. Newly identified mutations should be confirmed by amplifying the normal ABL allele to exclude polymorphisms. Clinicians should be aware that polymorphisms do not reflect mutations that automatically demand a change in therapeutic strategy, unless there are other signs of inadequate response to treatment.

0535

MAPK-ACTIVATION IN RESPONSE TO BCR-ABL INHIBITION IS CYTOKINE-DEPENDENT AND CAN BE OVERCOME BY DASATINIB

P. La Rosée, N. Härtel, T. Klag, R. Hehlmann, A. Hochhaus

University of Heidelberg, MANNHEIM, Germany

Background. Inhibition of BCR-ABL by imatinib mesylate is current standard treatment for patients with chronic myelogenous leukaemia (CML). Despite favourable response rates, imatinib fails to eradicate minimal residual disease in the majority of patients, which is believed to be caused by stem-cell resistance. A proposed mechanism of human CML stem-cell survival is growth-factor- (GF) dependent activation (phosphorylation) of the MAPK Erk1/2 in response to imatinib (Chu *et al.,* Blood 2004). *Aims.* We used IL3-dependent murine haematopoietic cell lines and their IL3-independent BCR-ABL-expressing progenies to study MAPK-signalling in response to imatinib and the high affinity BCR-ABL inhibitor dasatinib. Primary CD34+ enriched human CML cells were used, to validate cell-line results in a clinically relevant cellular context. *Methods.* Murine Baf3 and 32D cells transformed by p210Bcr-Abl were grown in the presence of 5 µM imatinib with and without WEHI-conditioned media as source of IL3. Cytotoxicity was determined by trypan blue viability count. Cells were harvested after 3h, 6h, and 24h and lysed for Western blot analysis. Human CML mononuclear cells derived from 5 patients with first chronic-phase CML prior to treatment were enriched by magnetic separation for CD34+. MAPK-signalling after treatment with BCR-ABL-inhibitors for 16h was studied in serum-free media in the presence of standard GF-mix. *Results.* Baf3p210 and 32Dp210 cells treated with 5 µM imatinib for 24h were rescued by IL3 as determined by trypan blue viability count. Western blot analysis after 3h, 6h, and 24h of treatment demonstrated time-dependent significant activation of Erk1/Erk2 with peak phosphorylation after 6h in the presence of IL3. In the absence of IL3, Erk1/Erk2 phosphorylation was abolished at any time. Simultaneous detection of phosphotyrosine (pTyr) and BCR-ABL demonstrated complete inhibition of BCR-ABL with and without IL3. Similar results were obtained in both cell lines. Exposure of Baf3p210 cells with 60nM dasatinib induced marked MAPK-inhibition independent of IL3 as early as 3h after start of treatment. Treatment of CD34+ enriched CML cells confirmed imatinib-induced MAPK-activation. Exposure of patient (n=5) cells with dasatinib (12 nM, 62 nM) in contrast showed significant (p<0.05) Erk1/2 inhibition consistent with cell-line data. *Conclusions.* GF-dependent MAPK-activation in response to imatinib initially reported in primary CML cells can be simulated in murine haematopoietic cell lines expressing BCR-ABL. This model allows further mechanistic studies and effective screening of alternative BCR-ABL-inhibitors for MAPK-modulation. The multikinase inhibitor dasatinib potently inhibits MAPK in cell lines (± IL3) and primary CML cells and may thus be more effective than imatinib in eradication of CML progenitor cells.

GENETIC POLYMORPHISMS IN THE METHYLENETETRAHYDROFOLATE REDUCTASE GENE ASSOCIATED WITH CHRONIC MYELOID LEUKEMIA

A. Gnani,[1] S. Soverini,[1] S. Colarossi,[1] E. Turrini,[2] I. Iacobucci,[1] F. Castagnetti,[1] M. Baccarani,[1] P. Hrelia,[2] G. Martinelli,[1] S. Angelini[2]

[1]Dept. of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Department of Pharmacology, BOLOGNA, Italy

Background and Aims. Folate metabolism plays an important role in carcinogenesis through DNA methylation and nucleotide synthesis, thus affecting gene expression and DNA instability. Methylenetetrahydrofolate reductase (MTHFR) is a key enzyme regulating intracellular folate metabolism. Two common MTHFR single nucleotide polymorphisms (SNPs) - one located in exon 4, C677T, and one located in exon 7, A1298C - have been reported to be associated with reduced enzymatic activity. Perturbation of folate metabolism as a consequence of reduced MTHFR activity has been shown to result in DNA hypomethylation and to promote DNA damage through uracil misincorporation into DNA during replication, leading to an increased risk of DNA double-strand breaks during DNA excision repair and subsequent genetic instability. So far, conflicting results have been reported on the possible role of MTHFR polymorphisms and leukemogenesis and few studies have addressed this issue in chronic myeloid leukemia (CML). In the present study a group of 109 patients with CML and a group of 270 racially matched healthy controls were genotyped for the two common MTHFR SNPs and overall frequencies were compared. *Methods.* DNA was extracted from bone marrow or peripheral blood samples. PCR-RFLP assays were

used to assess the two common polymorphisms in the MTHFR gene. *Results.* MTHFR 677T genotype frequencies in CML and controls were 25.29% and 13.76%, respectively. MTHFR 1298C genotype frequencies in CML and controls were 11.76% and 7.84%, respectively. The MTHFR 677T genotype frequency in CML patients was significantly different from controls [p=0.03]. MTHFR 1298C genotype frequency was only marginally lower in cases compared to controls [p =0.05]. *Conclusions.* On the basis of the present results it is suggested that decreased MTHFR activity associated with the presence of the 677T genotype, may result in increased stability of DNA leading to a protective effect against CML. Also the effect of the 1298C genotype, even less prominent, on DNA stability cannot be excluded. Understanding genetic susceptibility to CML, with particular respect to folate metabolism, will allow the identification of novel therapeutic strategies. Further studies are ongoing in a larger population of CML patients, also in relation to potential susceptibility to ABL kinase domain mutations development and subsequent resistance to therapy with tyrosine kinase inhibitors. Results will be presented.

IMPACT OF CYTOGENETIC ABERRATIONS IN PHILADELPHIA CHROMOSOME NEGATIVE HEMATOPOIESIS ON EVENT-FREE SURVIVAL OF CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH IMATINIB MESYLATE

F. Maloisel,[1] S. Struski,[2] C. Gervais,[2] A. Zamfir,[3] A.C. Voegeli,[4] B. Lioure,[3] M.P. Gaub[4]

[1]Hôpitaux Universitaires, STRASBOURG; [2]Laboratory Hematology blood coagulatio, STRASBOURG; [3]Department of Hematology & Oncology, STRASBOURG; [4]Laboratory of Molecular Biology, STRASBOURG, France

Background. Clonal aberrations (CA) of Philadelphia (Ph) negative metaphases have been described after treatment with interferon α or imatinib (IM) in a minority of patients (pts) with cytogenetic response. Conflicting data suggest selection of pre-existing clones versus induction of aneuploidy by tyrosine kinase inhibitors. The prognostic impact of aberrations in the Ph negative hematopoiesis for the individual pts remains to be determined. *Aims.* To evaluate the incidence and prognostic impact of CA occurring during imatinib therapy, we retrospectively analysed the outcome of our pts with chronic (CP) or accelerated phase (AP) of CML who obtained at least a major cytogenetic response during the first year of IM treatment. *Material and Methods.* between april 2000 and December 2006, 127 pts received IM and 90 obtained a partial cytogenetic response (PCR) or complete cytogenetic response (CCR) during the first year of treatment. Cytogenetic analysis was performed every 3 months during the first year and every 6 months after. CA was defined as abnormalities seen in 2 or more metaphases. Two groups were defined according with the presence or not of CA. Characteristics of each population (age, sex, prior therapies, sokal index, disease phase, response, bcr-abl kinetic) were analysed. During the follow-up, relapse, progression of the disease or death was noted. *Results.* with a median time of follow-up of 41 months, 32 pts developed CA (35%). The median time from the start of IM to appearance of CA was 278 days (range 82-1495 d). In 15 pts these events have been transient and disappeared after a median of 4 months (range, 3-9 months). CA were: -7/del 7 (6 pts); -Y (6 pts), +8 (5 pts), mar (3 pts), der 12p (2 pts), and -1, +6, der 9p, del 10q, der 11p, +15, der 17q, -18, t(3;11), and t(12;14). Characteristic of two groups (CA- vs CA+) were analysed: no significant difference was seen according to age, sex, prior treatment, Sokal index and cytogenetic response. However, the kinetic of bcr-abl transcript decrease was significantly faster in the group of pts without CA. Furthermore, hematologic or cytogenetic relapse and blast crisis occurred in 13/32 pts (41%) and 11/58 pts (19%) in CA^+ and CA^- groups, respectively (p<0.05). The median time of EFS was 55 months for the CA+ group and was not reached in the CA- group. The logrank test showed a significant difference between the two curves (p=0.0335). Mutation analysis showed 8 cases of abl mutation (33%). No significant difference was noted between the 2 groups. Mutations were : P-loop (4 cases); T315I, F317L, E292K and F311I (1 case each). *Conclusions.* Cytogenetic aberration occurring in Ph-negative hematopoiesis during IM therapy defined a group of patient who show an increase risk of IM resistance. CA should be a marker of genetic instability and inadequate control by IM. The present data argues to perform regular cytogenetic analysis even in complete cytogenetic response. In case of CA, abl mutation should be performed and pt requires a more stringent monitoring.

0538

NUCLEAR IMPORT OF NORMAL C-ABL PROTEIN IN RESPONSE TO M-TOR INHIBITOR RAD001 (EVEROLIMUS) DRIVES APOPTOTIC DEATH OF CHRONIC MYELOID LEUKEMIA PROGENITORS

M. Mancini,[1] E. Zuffa,[2] E. Pagnotta,[3] G. Brusa,[2] P. Corrado,[1] V. Corradi,[4] E. Barbieri,[2] M.A. Santucci,[1] M.A. Santucci[1]

[1]Istituto di Ematologia Seràgnoli, BOLOGNA; [2]Dipartimento di Scienze Radiologiche, BOLOGNA; [3]Dipartimanto di Biochimica G. Moruzzi, BOLOGNA; [4]Dipartimento Farmaco-Chimico-Tecnologico, SIENA, Italy

Nuclear accumulation of c-Abl protein in response to genotoxic damage addresses apoptotic cell death. The process, driven by the disruption of its binding to 14-3-3 scaffolding proteins, is independent from c-Abl catalytic state and conditional upon 14-3-3 phosphorylation by the c-jun N-terminal kinase (JNK) (Yoshida *et al.* Nat Cell Biol 7,278,2005). Our work moved from the observation that c-Abl nuclear import in response to gamma irradiation is precluded by the constitutive activation of Abl tyrosine kinase (TK) in p210 Bcr-Abl fusion protein, supporting a role of residual c-Abl protein *loss of function* in the apoptosis-resistant phenotype of Chronic Myeloid Leukemia (CML). In 32D cell clones transducing a temperature-conditional Bcr-Abl mutant, p210 TK inhibition in response to 24 hour exposure to 1 microM Imatinib mesylate (IM) is followed by c-Abl nuclear import and cell commitment to apoptotic death. The two last events are further enhanced by complementary inhibition of the 14-3-3 binding site by R18 peptide, supporting that the negative impact of p210 TK on pro-apoptotic function of residual normal c-Abl arises, at least in part, from the fusion protein effects on 14-3-3sigma. Previous studies proved that the activation of p38 MAP kinase contributes to IM effects in CML (Parmar *et al.*, J Biol Chem 279,25345,2004). Interestingly, p38 MAP kinase is involved in tuberous sclerosis 2 gene protein (TSC2, also known as tuberin) phosphorylation and enhanced binding to 14-3-3 possibly promoting the activation of IM-compensatory signals including m-Tor (Li *et al.*, J Biol Chem 278,13663,2003). Accordingly, in Bcr-Abl-transduced 32D cell clones the enhanced c-Abl nuclear import in response to combined inhibition of p210 TK by IM and m-Tor by RAD001 (everolimus; kindly provided by Novartis Pharma AG) was associated with p38 MAP kinase inactivating dephosphorylation, JNK phosphorylation and 14-3-3 phosphorylation at serine residues critical for client protein binding (including the apoptotic death effectors Bad, Bax and Ask1). C-Abl nuclear shuttling and apoptosis enhancement in response to *in vitro* exposure to IM and RAD001 were confirmed in early ($CD34^+$) myeloid progenitors from CML patients at clinical diagnosis. Our results support the advantage of p210 TK and m-Tor inhibitor association to overcome IM-compensatory pathways that may promote the outcome of a drug-resistant phenotype in CML.

MICRORNAS AS THE TARGET OF DELETIONS ON DER(9) IN CHRONIC MYELOID LEUKEMIA

F. Albano,[1] L. Anelli,[1] A. Zagaria,[1] A. Pannunzio,[1] A. Russo Rossi,[1] F. Manodoro,[1] V. Liso1 M. Rocchi,[2] G. Specchia[1]

[1]Hematology- University of Bari, BARI; [2]DIGEMI, University of Bari, BARI, Italy

Background. Deletions on der(9) are associated with chronic myeloid leukemia(CML) in 15-18% of cases. To date, the biological significance of this genomic loss in the pathogenesis of CML is unknown. The most plausible hypothesis is that the loss of a tumor suppressor gene may confer a proliferative advantage to the Philadelphia-positive clone. On the other hand, it has now become evident that microRNAs (miRNAs) play an important regulatory role in some hematological malignancies. Aims. To investigate the presence of miRNAs within the genomic regions lost on der(9) we analyzed 60 CML patients with der(9) deletions. Methods. Genomic characterization of the deleted sequences was performed by fluorescence *in situ* hybridization (FISH) using a contig of DNA clones; the miRBase (http://microrna.sanger.ac.uk/) was queried to assess the presence of miRNAs in the der(9) deleted genomic regions. *Results.* FISH experiments showed that the genomic loss on der(9) of the 9 (centromeric to ABL) and 22 (telomeric to BCR) chromosome sequences ranged from 260 Kb to 54 Mb and from 230 Kb to 12.9 Mb, respectively. Consultation of the miRBase revealed that in 16 (27%) patients there was loss of miRNAs mapping on chromosome 9 whereas no known miRNAs were mapped on the deleted genomic sequences belonging to chromosome 22. Moreover, 4 cases with a complex t(9;22) rearrangement and der(9) deletions showed loss of the miRNAs sequence also on the third

derivative chromosome (4p16, 7p14, 13q14, and 11q13, respectively); among them, only in one case the loss of miRNAs on the third derivative was not associated with the miRNAs deletion mapped on chromosome 9. The most recurrent miRNAs deleted on der(9) were mir-219-2 (deleted in 100% of cases) and mir-199-b (lost in 67% of cases). It is noteworthy that mir-219-2 neighbors and overlaps CpG-islands, suggesting a potential role of this miRNA in CpG-island methylation. *Conclusions.* Experimental studies indicate that miRNAs can function as tumor suppressor genes or as oncogenes. In fact, in chronic lymphocytic leukemia associated with del(13)(q14) it has been demonstrated that the miRNAs loss can induce downregulation of the antiapoptotic BCL-2 protein. The novel evidence that deletions on der(9) in CML are associated with miRNAs loss may shed new light on the significance of genomic sequences loss. Further studies are needed since it is known that some microRNAs may have as many as a few thousand targets, so prediction algorithms and strategies allowing large-scale screening of multiple target genes are required.

0540

SEMEN ANALYSIS DURING IMATINIB THERAPY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

F. Maloisel,[1] A. Zamfir,[2] K Bennada,[2] A. Clavert[3]

[1]Hôpitaux Universitaires, STRASBOURG; [2]Department of Hematology & Oncology, STRASBOURG; [3]CECOS, STRASBOURG, France

Background. Imatinib is the main treatment of chronic myeloid leukaemia and induces high rate of cytogenetic response and major molecular response. The 5 years survival from IRIS trial is 87% and the annual risk of relapse for responder patients is about 1% by year. Imatinib is a strong inhibitor of bcr-abl, c-kit and PDGF-R, and could explain sides effects related to the drug. C-kit is involved during spermatogenesis and influenced the spermatogonies maturation. Imatinib induces qualitative and quantitative deteriorations of spermograms in rats. Data about qualitative and quantitative characteristics of spermograms from patients treated with imatinib are lacking and sperm cryopreservation before treatment is recommanded. *Methods.* Semen cryopreservation was performed at diagnosis before treatment to every patient under 50 years of age. After information and fully consenting, patients aged >17 and <50 years old had serial spermograms analysis during treatment with imatinib for chronic myeloid leukaemia to determine any change in sperm volume, sperm number, mobility and morphology of sperm. *Results.* Ten male patients participated to the present study. All patients had no prior treatment before imatinib. All patients received 400 mg of imatinib. The mean age was 35 years (range 24 to 49 years). Spermogram was performed at 6, 12, 18 and 24 months after imatinib start. At the inclusion all patients had a normal sperm with ejaculate volume 3.87±0.25 mL, sperm concentration 92±25.5×10^6/mL, mobility 86±5% and untipycal spermatozoid 23±%. Serial semen analysis showed a reduction of number of spermatozoid: 68±22×10^6/mL at 6 months, 65±25 at 12 months, 43±29 at 18 months and 37±32 at 24 months. No alteration was seen in ejaculate volume, mobility or% of untypical spermatozoid at any time. At 24 months, 1 over 4 patients analysed was oligosperm. Imatinib induces a significant reduction of sperm concentration of: 26%, 29%, 47%, and 60% at 6, 12, 18 and 24 months respectively, without mobility abnormalities and increased of untypical forms. Such deteriorations of sperm characteristics do not induce reduction of fertility. Despites recommendation for contraception, one pregnancy occurred leading to a normal birth. *Conclusions.* these preliminary data show a significant reduction of 35±5% of sperm concentration during imatinib therapy but with limit impact on fertility. However, the duration of imatinib therapy in CML argues to prolong the study with a largest cohort of patients. Lack of sufficient data requires to proposal semen cryopreservation before treatment.

IDENTIFICATION OF BREAKPOINT HOTSPOTS IN PHILADELPHIA NEGATIVE BCR/ABL POSITIVE CML

A. Virgili,[1] D. Brazma,[1] C. Grace,[1] A. Reid,[2] J. Apperley,[2] E.P. Nacheva[1]

[1]Royal Free and UCL Medical School, LONDON; [2]Dept of Haematology, Imperial College, LONDON, United Kingdom

Background. Chronic myeloid leukaemia (CML) is a pluripotent stem cell malignancy, characterized by the presence of the Philadelphia chromosome (Ph). The Ph, usually due to t(9;22)(q34;q11) or its variants, results in the formation of the BCR/ABL fusion gene which is a constitutively activated tyrosine kinase. Less than 2% of CML patients appear to be Ph negative by G-banding, but carry a cryptic BCR/ABL fusion that can be located by FISH either at 22q11, 9q34 or in a third chromosome. There are two models to explain the formation of BCR/ABL fusion gene in those patients: direct insertion or two consecutive translocations. In the first model, an insertion either of 9q34 material into BCR region at 22q11 or of 22q11 material into ABL region at 9q34 is postulated. The second model suggests a classical t(9;22)(q34;q11) followed by a second rearrangement between the Ph and the der(9) or a third chromosome, which results in restoring the *normal* chromosome morphology. *Aims.* In order to assess which of the two mechanisms is more plausible, we undertook comprehensive molecular cytogenetics investigations of 4 patients and 1 cell line (CML-T1) with Ph negative BCR/ABL positive CML disease. *Methods.* FISH using a range of DNA probes and high resolution array CGH analysis (Agilent) were used to assess the rearrangements of the region that flanks ABL and BCR breakpoints. *Results.* In all patients the fusion gene was found on chromosome 22. In 3 out of the 4 cases studied, a common fragment from 9q was found inserted into 22q at the telomeric site of BCR breakpoint. The fragment is less than 1 Mbp in length and its proximal boundary coincides with the ABL breakpoint, while the distal boundary falls within a common region of 300 Kbp, flanked by the BAC clones RP11-643E14 and RP11-326N3. In CML-T1 the fusion gene was also found on chromosome 22. CML-T1 cells also showed duplication of the masked Ph and loss of the normal 22. The inserted 9q segment was found to be larger than the one seen in the previous 3 patients and the distal breakpoint falls within RP11-92B21. This BAC includes the 3' end of RXRA gene, which is disrupted as a result of the insertion. Similarly, in the fourth patient the size of the 9q segment was estimated to be nearly 6 Mbp. Surprisingly the breakpoint at 22q remains constant within BCR breakpoint in all cases studied so far, with no material from 22q detected within the structure of the der(9). *Summary.* Our findings show that while the 9q fragment inserted into 22q varies in size, there is no evidence of secondary rearrangements within the region distal to the BCR breakpoint. This leads to the conclusion that the most likely mechanism of formation of the Ph negative BCR/ABL positive rearrangement is an insertion rather than sequential translocations. Ongoing mapping aims to resolve the involvement of the genes housed by the distal breakpoint region, of which RAP-GEF1 is the most plausible candidate.

0542

APOPTOSIS-RELATED GENE EXPRESSION IN T-CELLS FROM IMATINIB TREATED CHRONIC MYELOGENOUS LEUKEMIA PATIENTS

Y. Wei,[1] S. Jönsson,[2] B. Olsson,[2] D. Stockelberg,[2] A. Ricksten,[3] H. Wadenvik[2]

[1]Qilu Hospital JINAN, P.R. of China; [2]Hematology Section, Sahlgrenska Academy, GOTHENBURG, Sweden; [3]Clinical Chemistry, Sahlgrenska Hospital, GOTHENBURG, Sweden

Background. Imatinib mesylate (Glivec®, Gleevec™) is the first-line treatment for patients with chronic phase CML. Recently several 'off-target' effects have been reported, e.g. immunomodulatory effect, altered serum phosphate levels and effects on cardiomyocytes in animal models. It has been demonstrated that imatinib inhibits T-cell activation and proliferation *in vitro*. However, little is known about the T-cell function in imatinib treated patients. *Aims.* To obtain more information regarding the effect of imatinib on apoptosis pathways in T-cells, an important regulator of the immune response. *Methods.* Eleven imatinib treated (400 mg q.d.) chronic phase CML patients (mean age 57±12 (SD)) and 11 age and sex matched healthy individuals were included in this study. At time of blood sampling, all patients were in complete cytogenetic remission (CCgR) and the median imatinib treatment duration was 48 (range 14-72) months; peripheral blood interphase-FISH for the bcr-abl fusion gene was also *negative* in all patients. Mononuclear cells (PBMCs) were isolated from peripheral blood using Ficoll™ density gradient centrifugation. $CD3^+$ T-cells were separated from PBMCs by immunomagnetic cell sorting (MACS™). Total RNA was extracted from 2-4 millions purified $CD3^+$ T-cells and subject to complementary DNA synthesis. Apoptosis-related gene expression was determined by the Taqman® low density array (LDA) apoptosis panel (Applied Biosystems), which included 94 apoptosis-related genes and two reference genes. On every LDA card, cDNA from one patient and his age and sex matched healthy individual was loaded. The difference in target gene expression (ΔΔCt: patient (Cttarget-Ctreference)- healthy individual (Cttarget- Ctreference)) was calculated for every gene and patient-control pair. If the 95% confidence interval for the mean ΔΔCt did not include zero, the difference in gene expression was considered statistically significant. *Results.* Out of 94 apoptosis-related genes, 16 genes had significantly different expression levels

in CD3+ T-cells obtained from imatinib treated CML patients and healthy individuals. These results are given in the attached Figure 1. *Conclusions.* Most likely the observed difference in gene expression of apoptosis-related genes can be linked to the imatinib treatment, since: (i) all patients were in CCgR and (ii) all had a negative interphase FISH for the bcr-abl fusion gene. Fifteen of 94 studied apoptosis related genes were downregulated in T-cells from imatinib treated patients and only one gene was upregulated. Functional assays are needed to explain how these alterations affect the T-cell function, e.g. proliferation and activation induced cell death (AICD) - an important regulator of the immune response.

BCR-ABL KINASE MUTATIONS IN RESPONSE TO DASATINIB

J. Sorouri Khorashad, P. Mehta, D. Milojkovic, D.C. Marin, J.S. Kaeda, B. Swale, D. Stevens, J.M. Goldman, J.F. Apperley

Imperial College of London, LONDON, United Kingdom

Background. Dasatinib is a novel Src-Abl kinase inhibitor with efficacy in patients with CML resistant to imatinib. *In vitro* studies show that dasatinib is active against nearly all the known BCR-ABL kinase mutations except T315I. *Aims.* Analysis of the kinetics of BCR-ABL kinase mutations in patients treated with dasatinib. *Methods.* Karyotyping for evaluation of cytogenetic response, RT-PCR for measurement of BCR-ABL transcript levels, direct sequencing and pyrosequencing for detection and quantification of the mutations in serial samples of patients with a suboptimal response to dasatinib. *Results.* 47 imatinib-resistant CML patients received dasatinib. Patients were followed for 3-23 months. 12 patients had mutations in the BCR-ABL kinase domain, prior to treatment with dasatinib. Of these 12, 10 (82%) achieved MCyR with dasatinib usually within three months of starting therapy. 22% later lost their MCyR. Kinetic analysis of the mutant clones revealed 3 patterns of response. Group 1 (n=6): patients initially responded to dasatinib with a 1-3 log reduction in BCR-ABL/ABL ratio, but this was not maintained. A new mutation was noted either in isolation or in addition to pre-existing mutations. Group 2 (n=4): patients achieved a MCyR with dasatinib, which was accompanied by disappearance of the mutant clone (E453V, H396R, F359V). Group 3 (n=2): patients achieved a MCyR with dasatinib. However, the mutant clone persisted with fluctuating levels after more than 18 months follow up. Nearly all the patients with mutations known to be sensitive to dasatinib in cellular studies achieved MCyR with dasatinib. This response was accompanied with decline or disappearance of the mutant clone (group 2), or a fluctuating level of the mutant clone (group3). The only exception was one patient with L248V (group1), in whom L248V remained dominant during the follow-up with a transient MCyR. Group 1 included patients who had an initial response, but subsequently lost this as demonstrated by an increase in the mutant BCR-ABL positive clone. In two patients in this group, a pre-existing mutant clone disappeared along with > 2 log reduction in BCR-ABL/ABL ratio. This response was later lost following the re-appearance of the previously detected mutation along with T315I, Quantitative analysis showed that these mutations co-existed in the same clone. In a further 3 patients in Group 1 there was an initial reduction in the BCR-ABL/ABL ratio but this was lost with the emergence of a new mutation, F317L. The appearance of F317L coincided with disappearance of the pre-existing mutant clones, M244V, M351T and H396R. The F317L induces a 9 to 13.5-fold increase of dasatinib IC_{50} in comparison to wild-type BCR-ABL in cellular assays. These results show the emergence of new mutations under dasatinib and document their different kinetics of mutation.

0544

WHEN IS A DOUBLE PHILADELPHIA NOT A DOUBLE PHILADELPHIA

D. Brazma,[1] C. Grace,[1] A. Virgili,[1] J. Howard,[1] A. Chanalaris,[1] J.V. Melo,[2] J.F. Apperley,[2] E.P. Nacheva[1]

[1]Royal Free and UCL Medical School, LONDON; [2]Imperial College&Hammersmith Hospital, LONDON, United Kingdom

Background. Chronic myeloid leukaemia (CML) is a pluripotent haematopoietic stem cell disorder defined by expression of the BCR-ABL fusion gene, a constitutively activated tyrosine kinase. The fusion gene commonly results from formation of the Philadelphia chromosome (Ph) after a t(9;22)(q34;q11) or related variant rearrangement. We studied 48 samples and 12 cell lines from CML patients at various stages of the disease by arrayCGH using a 1 mbase BAC array (Spectral Genomics, Houston, USA), 44k 60 mer oligo arrays (Agilent) and by molecular cytogenetics techniques. Gains in 9q34.1-qter distal to the ABL breakpoint along with gains of 22pter-c-22q11.2 were detected in 1/22 CP, in 3/26 BC samples and in 6 cell lines. This is in keeping with the presence of a second Ph chromosome as confirmed by both G banding, chromosome painting and D-FISH. Contrary to expectations, 5 of these samples (50%) did not display the aCGH profile corresponding to the presence of extra Ph markers instead, various gains were identified from the 9q34.1-9qter segment that (a) failed to cover the whole 9q material of the Ph marker and (b) disagreed with the G banding data. *Aim.* In the absence of BAC array coverage of the ABL breakpoint region, a more precise assessment of the 9q34 imbalances was sought using a high resolution oligo based aCGH analysis of three BC patients and two cell line samples. *Results.* The oligo's aCGH profile confirmed the presence of gains from the 9q34.12 sub-band and delineated a common amplicon with an estimated size of 330 Kbp. Three genes - ABL, LAMC3, NUP214 are located in this amplicon. We constructed a dual colour FISH probe from clones RP11-83J21 (containing ABL from the 5' end to exon 1), RP11-143H20 (covering LAMC3) and RP11-544A12 (partially LAMC3 & NUP214 genes), and applied it to the mitotic figures of bone marrow from 15 CML patient's samples in accelerated phase/blast crisis and with 10 CML cell lines. Extra copies of the region covered by the probe were detected as follows: a) High copy number gains were seen as 'tandem duplications' within similar acrocentric marker chromosomes in 2 cell lines, K562 and KU812; b) Duplication of the ABL-NUP14 region within the Ph chromosome with an apparently normal G-banding morphology in (3/15) patient's samples; similar changes were found in the cell lines MC3, MEG-01, EM-2 and KYO while affecting one of the two copies of the Ph chromosome that were indistinguishable by G-banding; c) The ABL-NUP214 region was found inserted within one of the apparently morphologically *normal* chromosome 22 homologues at the 22q11.2 sub-band in two instances. *Conclusions.* These findings clearly demonstrate that the Philadelphia chromosome is an unstable structure and prone to rearrangements that commonly involve sequences downstream of the ABL breakpoint, specifically the ABL-NUP214 region.

0545

STABILIZED BONE MARROW IS NOT SUPERIOR TO PERIPHERAL BLOOD FOR MOLECULAR ANALYSIS OF CML PATIENTS WITH RESISTANCE TO TYROSINE KINASE INHIBITORS

T. Ernst, M.C. Müller, P. Erben, N. Härtel, C. Walz, R. Hehlmann, A. Hochhaus

Universitätsklinikum Mannheim, MANNHEIM, Germany

Background. Recommendations for treatment surveillance of CML patients on tyrosine kinase inhibitors include systematic molecular monitoring by accurate quantification of BCR-ABL transcripts. Emergence of BCR-ABL kinase domain mutations is considered the major cause of resistance. Inadequate response or loss of response to therapy requires an early and accurate measurement of BCR-ABL transcripts and BCR-ABL kinase mutations indicating the need to change the therapeutic strategy. The sensitivity of the respective assays clearly depends on quality and quantity of RNA derived from peripheral blood (PB) and bone marrow (BM) leukocytes. Bedside RNA preservation systems (e.g. PAXgene) have been developed in order to maintain RNA stability during shipment of the sample from the clinical site to the laboratory. *Aims.* RNA stabilization systems have been tested for PB but not BM cells in previous studies. Therefore, we sought to investigate the applicability of stabilization systems for BM samples and to compare the performance of the system for quantification of BCR-ABL transcripts and detection of BCR-ABL kinase domain mutations in both tissues. *Methods.* Simultaneously stabilized PB and BM samples (PAXgene system, 2.5 mL each) were obtained from n=49 imatinib resistant CML patients in chronic phase to compare RNA yield and purity, quantitative results for housekeeping genes (total ABL and β-glucuronidase, GUS) by RT-PCR, ratios BCR-ABL/ABL and BCR-ABL/GUS, and BCR-ABL mutations analyzed by sensitive denaturing high-performance liquid chromatography (D-HLPC) and by direct sequencing. *Results.* RNA yield was significantly higher in BM (median 9.9 µg RNA/mL BM) than in PB (median 3.8 µg RNA/mL blood, p=0.0013). Using 10 µg RNA for the generation of 40 µL cDNA by reverse transcription, the number of housekeeping gene transcripts indicating sample quality and sensitivity of RT-PCR was comparable between PB and BM (median ABL copies/2 µL cDNA 13,750 vs 26,230, p=0.52; median GUS copies/2 µL cDNA 38,830 vs 59,560, p=0.22, respectively). Further, ratios BCR-ABL/ABL (PB vs BM, median 47% vs 57%, p=0.07) and ratios BCR-ABL/GUS (PB vs BM, median 27% vs 23%, p=0.33) were not significantly different. BCR-ABL kinase domain mutations were detected in 26 of 49 (53%) patients, and in 27 of 49 (55%) patients using PB or BM, respectively. In one patient the D276G mutation was only detectable in PB (20% mutated alleles) but not in BM cells. However, in three patients mutations were only found in BM but not in PB: Mutation H396R (n=1, 20% mutation fraction) and the silent mutation E499E (n=2, mutation fraction 30% and 40%, respectively). In general, the relative fraction of the mutated clone was significantly higher in PB than in BM samples (median 70% vs 50%, p=0.0023). *Summary and conclusions.* Optimum sample quality is a crucial requirement for molecular monitoring of CML patients on therapy. Sensitivities of the assays depend on a sufficient amount of non-degraded RNA in the sample after transit to the laboratory. We conclude that BM is suitable for stabilization with RNA preservation systems but is not superior to PB for quantification of BCR-ABL transcripts and mutation analysis in CML patients.

Chronic myeloid leukemia - Clinical

0546

PLEURAL AND PULMONARY EVENTS IN PATIENTS TREATED WITH DASATINIB FOR CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

PH. Rousselot,[1] A. Bergeron,[2] D. Réa,[2] V. Levy,[2] C. Picard,[2] V. Meignin,[2] J. Tamburini,[2] H. Bruzzoni,[2] F. Calvo,2 A. Tazi,[2] P. Rousselot[1]

[1]Hôpital de Versailles, LE CHESNAY; [2]Hôpital Saint-Louis, PARIS, France

Background. Dasatinib is a novel multi-targeted kinase inhibitor of BCR-ABL and SRC family kinases indicated for patients with chronic myeloid leukemia (CML) or Ph+ acute lymphoblastic leukemia resistant to or intolerant of imatinib. *Aims.* To describe the characteristics and management of pleural and pulmonary events observed in association with dasatinib 70 mg b.i.d therapy. *Methods.* This was a single-center case series of 40 patients with chronic-phase (CP) CML resistant to or intolerant of imatinib, who received treatment with dasatinib in clinical trials. *Results.* Nine of these 40 patients (22.5%) developed pleural effusions and/or pulmonary manifestations. Clinical symptoms included dyspnea, cough, and chest pain; extra-thoracic symptoms (fever, myalgia, arthralgia, or paresthesiae) were present in 3 cases. High-resolution CT scans identified pleural effusions in 6 patients, and lung abnormalities were present in 8. All pleural effusions were exudative and contained lymphocytes. Three patients underwent pleural biopsy: no abnormalities were identified in one patient, while a lymphocytic infiltration and a myelocytic infiltration were observed in the other 2 cases. BAL revealed lymphocytic alveolitis in 4 patients with lung abnormalities and neutrophilic alveolitis in a further case. Treatment with dasatinib was interrupted in all but one case (this patient was administered steroid therapy instead) and 2 patients received antibiotics empirically; diuretics were not routinely given. Resolution of these lung manifestations was evident for all 9 patients. Re-introduction of dasatinib at a reduced 40-mg b.i.d. dose was successfully achieved in 3 of 4 patients without any recurrence; the fourth patient developed a pleural effusion. *Summary and conclusions.* Pleural effusions and pleuro-pulmonary manifestations observed in association with dasatinib 70 mg b.i.d therapy resolve upon treatment interruption. Dose reduction appears to allow resumption of dasatinib therapy.

0547

A COMBINATION OF DAUNORUBICIN, CYTARABINE AND IMATINIB MESYLATE FOR PATIENTS WITH *DE NOVO* PHILADELPHIA POSITIVE ACUTE MYELOBLASTIC LEUKEMIA AND MYELOID BLAST CRISIS CML : RESULTS OF THE AFR01 DOSE ESCALATING STUDY

PH. Rousselot,[1] B. Deau,[1] F. Nicolini,[2] J. Guilhot,[3] F. Huguet,[4] B. Rio,[5] A. Guerci,[6] L. Legros,[7] C. Pautas,[8] D. Réa,[9] E. Raffoux,[9] C. Berthou,[10] D. Guyotat,[11] P. Cony-Makhoul,[12] M. Gardembas,[13] S. Castaigne,[1] M. Michallet,[2] F.X. Mahon,[14] F. Guilhot,[3] P. Rousselot[1]

[1]Hôpital de Versailles, LE CHESNAY; [2]CHU Lyon, LYON; [3]CHU La Miléterie, POITIERS; [4]CHU Purpan, TOULOUSE; [5]Hôpital Hôtel-Dieu, PARIS; [6]CHU Nancy, NANCY; 7CHU Nice, NICE; [8]Hôpital Mondor, CRÉTEIL; [9]Hôpital Saint-Louis, PARIS; [10]Hôpital Morvan, BREST; [11]Hôpital Nord, SAINT ETIENNE; [12]Hôpital d'Annecy, ANNECY; [13]CHU Angers, ANGERS; [14]Hôpital Haut-Lévêque, BORDEAUX, France

Background. Only 15% of patients (pts) with chronic myelogenous leukaemia in myeloid blast crisis (MBC CML) and treated with imatinib mesylate (IM) achieve a complete haematological remission (CHR) and 28% return to chronic phase (CP). For pts in CHR, the median duration of response is only 10 months and overall survival is around 7 months. We conducted a dose escalating study to assess the safety and the efficacy of IM associated with chemotherapy. *Patients and methods*. Pts ≥ 18 years with MBC CML and *de novo* Philadelphia positive AML not previously treated with tyrosine kinase inhibitors (TKI) were eligible. In the first part of the study a fixed dose of IM (600 mg/d) was administered combined with increasing dosages of daunorubicin (cohort 1: no daunorubicin, cohorts 2, 3 : 15 and 30 mg/m^2/day of daunorubicin IV day 1 to day 3 respectively) and cytarabine (Ara-C) 100 mg/m^2/d for 7 days. G-CSF was administered from day 9 until recovery. Responding pts received a second identical course. Hematopoietic stem cell transplantation (HSCT) was then offered to all eligible pts. Intermediate dose Ara-C and IM maintenance was proposed for the others. Pts included in the second part of the study were treated with IM 600 mg/d in combination

with a classical 3+7 chemotherapy (daunorubicin 30 to 45 mg/m^2, Ara-C 100 mg/m^2) (validation cohort). *Results.* 45 pts (38 MBC CML and 7 Ph+ AML) were included[(median age 53 years, (22-74); sex ratio 67%] from 2001 to 2006 with a median follow-up of 3.9 years. 7 pts were treated in cohort 1, 6 in cohort 2, 6+8 in cohort 3 and 18 in the validation cohort. Haematological responses were observed in 31 pts (68.9%) including 26 patients in CR (57.8%) and 5 patients in CP (chronic phase). The rate of CR and CP was significantly higher in pts treated in cohorts 3 and in the validation cohort (21 CR, 2 CP, 8 failures) compared to cohorts 1 and 2 (3 CR, 3 CP, 7 failures) (p=0,013) indicating a benefit of combining standart chemotherapy and IM. After induction, a complete cytogenetic response was observed in 13 pts (42%) including 4 of them with a major molecular response. 5 pts (11%) died early during induction due to disease progression (n=3), septicaemia (n=1) and following splenectomy for haematoma (n=1). All responding pts had a neutrophil recovery before day 45 (median 22 days). The median duration of grade 3-4 thrombocytopenia was 25.5 days. For pts with MBC CML (n=38), response rate (CP and CR) was 63.1%. However, median survival and DFS were 9.8 and 14.4 months respectively. Only pts who received allogeneic stem cell transplantation (n=11) experienced a prolonged DFS (not reached versus 10.9 months, p=0,01) and a trend in survival (65.9% at 3 year). For pts with Ph+ AML (n=7), the CHR rate is 100% and median survival and DFS were not reached. At 3 year, estimated survival and DFS were 85.7%. 4 out of 7 Ph+ AML received allogeneic HSCT. Their survival was +4.2, +6.5, +19.3 and+23.1 months compared to +43.6, +17.9 and 4 months for non allografted patients. *Conclusion.* IM combined with the classical 3+7 induction protocol produce 63.1% of haematological remission in pts with MBC CML without significant toxicity but only pts who received allogeneic HSCT experienced prolonged DFS and survival. All our 7 pts with Ph+ AML obtained a CR and long survivors were observed either after allogeneic HSCT or maintenance with IM and chemotherapy.

0548

ALTERED BONE AND MINERAL METABOLISM IN CHRONIC PHASE CML PATIENTS TREATED WITH IMATINIB

S. Jönsson,[1] Y.W. Wei,[2] B.O. Olsson,[1] D.M. Mellström,[1] H.W. Wadenvik1

[1]Sahlgrenska Academy of Göteborg Univ., GOTHENBURG, Sweden; [2]Shandong University, Qilu Hospital, JINAN, P.R. of China

Background. Imatinib mesylate (Glivec®, Gleevec™) is the drug of choice for most patients with chronic phase CML. It was recently suggested that hypophosphatemia develops in imatinib treated patients as a consequence of suppression of bone turnover and renal phosphate wasting. *Aims.* To gain more information regarding the imatinib-associated hypophosphatemia we analyzed bone and mineral metabolism in imatinib treated CML patients and age and sex matched healthy individuals. *Material.* Eighteen imatinib treated CML patients (11 males/7 females; mean age 60±11 (SD) years) and 19 helthy volunteers (11 males/8 females; mean age 58±12 (SD) years) were included. All CML patients were treated in first chronic phase, targeting an imatinib dose of 400 mg q.d. At time of study, all patients were in complete cytogenetic remission and the mean imatinib treatment duration was 48±21 (SD) months.

Table 1.

	CML (n=18)	Controls (n=19)	P-value
S-Potassium (mmol/L)	4.1±0.3	4.2±0.2	<0.05
S-ionized Calcium (mmol/L)	1.21±0.02	1.24±0.03	<0.001
S-Phosphate (mmol/L)	0.89±0.17	1.06±0.16	<0.01
S-Magnesium (mmol/L	0.79±0.05	0.84±0.05	<0.01
S-Creatinine (µmol/L)	93±25	79±10	<0.05
tU-Calcium (mmol/24 hours)	3.19±1.79	5.25±1.86	<0.01
tU-Phosphate (mmol/24 hours)	28±11	31±8	ns

S-25-OH-vitamin D (ng/L)	24.6±6.8	28.1±7.6	ns
S-1,25 $(OH)_2$ vitamin D (ng/L)	42.5±10.4	49.2±9.2	<0.05
S-Osteocalcin (µg/L)	7.2±2.7	10.1±3.7	0.01

Blood was collected in the morning, between 8-10 am, after a light breakfast. All serum and plasma samples were stored frozen at -80°C until analysis. Twenty-four hours urine collections, for determination of Calcium and Phosphate excretion, were also obtained from all patients and controls. *Results.* The results from the biochemical evaluation are given the attached table. Results from bone density measurements (DEXA and pQCT) are pending. *Conclusions.* The imatinib treated patients had lower levels of 1,25-(OH)2 vitamin D, lower ionized Calcium, lower S-Phosphate, lower S-Osteocalcin and increased S-Parathyroid hormone; the changes were small but still statistically significant. These alterations in mineral metabolism resemble those seen in hereditary, vitamin D-dependent rickets type 1, i.e. a dysfunctional renal 1-OHase enzyme. It is still unknown if the altered mineral metabolism has any clinically relevant effect on the bone mineralization. Results from our DEXA and pQCT measurements will be presented.

IMATINIB 400 MG IN LOW SOKAL RISK CML PATIENTS IN EARLY CHRONIC PHASE: RESULTS OF AN OBSERVATIONAL, MULTICENTRIC PROSPECTIVE TRIAL OF THE GIMEMA CML WP

F. Castagnetti,[1] I Iacobucci,[1] F. Palandri,[1] G Marzocchi,[1] P Giannoulia,[1] M. Amabile,[1] T. Intermesoli,[2] M. Breccia,[3] F. Radaelli,[4] E Usala,[5] E Abruzzese,[6] F Pane,[7] G Saglio,[8] G. Martinelli,[1] M Baccarani,[1] G Rosti[1]

[1]Institute of Hematology Seràgnoli, BOLOGNA; [2]Ospedali Riuniti, BERGAMO; [3]Chair of Hematology, Università La Sap, ROMA; [4]Chair of Hematology, Università di Mila, MILANO; [5]Hematology Unit, Ospedale Businco, CAGLIARI; [6]Hematology Unit, Ospedale S. Eugenio, ROMA; [7]CEINGE - Università di Napoli, NAPOLI; [8]Patologia Medica, Orbassano, TORINO, Italy

Background. Imatinib 400 mg (SD) is the established first line treatment of chronic myeloid leukemia (CML) in chronic phase. The efficacy of imatinib in early chronic phase has been demonstrated by phase 2 and 3 controlled trials like the IRIS study (Druker BJ et al NEJM 355:23, 2006). Large multicentric studies aimed to evaluate the impact of imatinib 400 mg/daily outside strictly monitored frameworks are not yet available. AIMS The GIMEMA (Gruppo Italiano Malattie Ematologiche dellAdulto) CML Working Party opened in January, 2004, an observational study (serial n. CML/023) to investigate the efficacy of imatinib SD in newly diagnosed CML patients in chronic phase. Since response to treatment is risk related and reporting on the cumulative response rate irrespective of risk is confusing, we report the results obtained in low (Sokal) risk patients. This allows a more suitable comparison with other published series. METHODS Clinical and anagraphical data were collected through a web-based system. Peripheral blood samples for quantitative molecular analysis (RT-Q-PCR, Bcr-Abl/Abl x 100 - Taqman) were centralized in Bologna. RESULTS Overall, between Jan 2004 and Jan 2006, 55 italian centers enrolled 217 low Sokal risk newly diagnosed CML pts . Median age was 50 yrs (range 18-84), 136 (63%) males and 81 (37%) females. 217 patients were evaluable for response at 3 months, 181 at 6 months and 118 at 12 months. Median observation time is 12 months. At 6 months, 86% of evaluable cases obtained a complete cytogenetic response (100% Ph-neg, CCgR). A major molecular response (MMolR) defined as a Bcr-Abl/Abl x 100 ratio < 0.05%, was shown in 54% of CCgR pts. At 12 months, the CCgR rate was 88% and the MMolR rate in CCgR pts was 60%. With this short observation period, only 4 pts (1,8%) progressed to accelerated/blastic phase.CONCLUSIONS 201 low Sokal risk pts were enrolled in the IRIS trial: at 12 months CCgR and MMolR (reduction of Bcr-Abl/Bcr ratio level > 3 logs) rates were 76% and 66%, respectively (T. Hughes *et al.,* NEJM 349:15, 2003). Our multicentric study confirms and reinforce the results of the IRIS trial in the same Sokal risk category, showing that imatinib is highly effective and manageable outside of academical structures as well as in strictly monitored trials. ACKNOWLEDGMENTS COFIN 2003, FIRB 2001, AIRC, Fondazione del Monte di Bologna e Ravenna, European Leukemia Net, BolognaAIL. *Background.* Imatinib 400 mg (SD) is the established first line treatment of chronic myeloid leukemia (CML) in chronic phase. Background. Imatinib has become the treatment of choice for CML. The standard dose (SD) for chronic phase (CP) CML is 400 mg daily: results are less favourable in pts at high or intermediate Sokal risk vs low Sokal risk ones. In intermediate Sokal risk patients, the IRIS trial (Hughes et al NEJM 349:15, 2003) reported at 12 mos a complete cytogenetic response (CCgR- 0% Ph-pos) rate of 67% and a major molecular response (MMolR) rate of 45%. Pre-clinical and clinical data suggest that high doses (HD - 800 mg daily) of imatinib may be more effective. AIMS The GIMEMA CML Working party is conducting a phase II, multi-istitutional prospective study (serial n. CML/021) to investigate the effects of imatinib HD in intermediate Sokal risk. Between Jan , 2004 and May, 2005, 25 centers enrolled 78 pts ; median age 56 yrs (26-79) (24% were aged 65 years or more at enrollment). The median observation time is 18 mos. RESULTS At 6 mos, 81% obtained a CCgR and 54% of CCgR pts a MMolR (Bcr-Abl/Abl x 100 ratio < 0.05%). At 12 mos, the CCgR rate was 88% and the MMolR rate was 56%. Two patients progressed to accelerated/blastic phase. The compliance to HD treatment was good: at 3, 6 and 12 mos 56%, 53% and 54% of the pts received a median daily dose of imatinib equal or superior to 600 mg . Non hematopoietic AEs accounted for the great majority of dose reductions. CONCLUSIONS The results of this trial further indicate that imatinib HD induces higher and more rapid responses in intermediate Sokal risk CML pts in early chronic phase, being superior to the results obtained with SD (IRIS) and in the range of the MD Anderson results (Kantarjian et al Blood 2004 103:2873). MULTIPLE ANALYSES AFFIRM THE INDEPENDENT ADVERSE INFLUENCE OF ABL/BCR BREAKPOINT SPANNING DELETIONS ON SURIVAL IN CHRONIC MYELOID LEUKEMIA

M. Pfirrmann,[1] S. Kreil,2 C. Haferlach,[3] K. Wagdorn,[2] A. Chase,[2]
R. Hehlmann,[4] A. Reiter,[4] A. Hochhaus,[4] N.C.P. Cross[2]

[1]University of Munich, MUNICH, Germany; [2]University of Southampton, SALISBURY, United Kingdom; [3]MLL Münchner Leukämielabor, MUNICH, Germany; [4]Med. Fakultät MA, Universität Heidelberg, MANNHEIM, Germany

Background. Deletions at or encompassing the ABL/BCR junction on the derivative chromosome 9 [(der(9)] are seen in 10-15% of patients with chronic myeloid leukemia (CML). However whether deletions are genuinely associated with an adverse prognosis on survival remains controversial. We investigated the prognostic significance of der(9) deletions in 339 patients enrolled in three randomized German CML trials and allocated to receive interferon-α (IFN). Initial univariate analysis showed no significant survival difference between 59 deleted and 280 non-deleted patients. Only the 21 patients with breakpoint-spanning deletions had a significantly poorer survival compared to patients without deletions. *Aims.* We sought to investigate whether der(9) deletion status (no deletion vs. one-sided deletions vs. deletions spanning the ABL/BCR breakpoint) provided independent prognostic information with regard to survival when additional factors (age, spleen enlargement, white blood cell count hemoglobin, and the proportions of blasts, eosinophils, and basophils in peripheral blood) were also considered. *Methods.* Deletions were defined using a novel DNA-based deletion screen based on multiplex ligation-dependent probe amplification. Associations between the candidate variables and survival were assessed with multiple Cox regression. In order to attribute survival probabilities to IFN treatment, survival times were censored at the start of imatinib therapy or the date of an allogeneic stem cell transplantation for patients still in chronic phase. *Results.* Firstly, we examined the prognostic value of deletion status in a common Cox model with the Hasford score (Hasford et al., JNCI 1998; 90:850-858) which was developed and validated to differentiate three prognostic groups with regard to survival after start of IFN treatment. Of 338 patients with deletion status and score available, 131 had died. Patients without deletions (n=279, 83%) had a median survival of 6.8 years. Whilst the 21 cases (6%) with deletions at the whole breakpoint showed a median survival of 6.1 years, the 38 patients (11%) with one-sided deletions (whether ABL or BCR was concerned made no difference in survival) had a six-year survival probability of 0.74. Of the 12 patients observed beyond that time, nobody died. The Hasford low-risk group contained 132 patients (39%, median survival: 8.6 years), intermediate-risk group 166 (49%, median survival: 6.8 years), and the high-risk group 40 patients (12%, median survival: 5.6 years). For both Hasford score and deletions status, the logrank test indicated a statistically significant discrimination of survival probabilities. As prognostic factors in a common model, deletion status and Hasford score kept their statistical significance (p=0.007 and p=0.011). In a second approach, all candidate variables were entered into the model. Backward elimination yielded a final model with three independent variables: deletion status (p=0.007), age (p=0.018), and spleen enlargement (p<0.001). In both models, compared to baseline category *no deletion*, one-sided deletions were associated with a significant beneficial effect and deletions at the whole breakpoint with significantly worse survival. *Conclusions.* Our results indicate that deletion status at diagnosis provides independent, statistically significant prognostic information. In particular, the unfavorable influence of ABL/BCR breakpoint spanning deletions on survival was affirmed, in conjunction with the Hasford score or with age and spleen size.

GRADE 3/4 ADVERSE EVENTS IN IMATINIB RESISTANT/INTOLERANT CHRONIC PHASE CML (CML-CP) PATIENTS TREATED WITH NILOTINIB AND DASATINIB

J. Stephens, K.T. Carpiuc, S.J. Snedecor, M.F. Botteman

Pharmerit North America LLC, BETHESDA, USA

Background. Toxicities of new treatments for CML may impact ability to maintain the treatment regimen and increase the care and resources required to manage patients. *Aims.* The objective of this study was to compare the incidence rates of Grade 3/4 AEs reported for nilotinib and dasatinib, the second generation tyrosine kinase inhibitors (TKIs), in imatinib resistant/intolerant CML-CP pts in preparation for an economic analysis. *Methods.* A systematic search was conducted to identify published articles, registration documents, or abstracts of clinical trials in CML-CP for nilotinib 400 mg BID and dasatinib 70 mg BID. The base case incidence rates were selected from the most rigorous sources, specifically data from the dasatinib product label and the 120-day update of the nilotinib phase II trial. The AEs selected for the comparison were based on frequency (>5%) and/or high likelihood of incurring incremental costs for medical treatment/monitoring. The full ranges for the incidence of AEs (if available) were summarized from publication to provide ranges for sensitivity analyses in future economic analyses. The nilotinib median duration of exposure was 8.1 months while the median treatment duration of dasatinib was 5.6 months. *Results.* The Grade 3/4 hematologic AEs are the most common AEs (table below) and are approximately twice as high for dasatinib compared to nilotinib. Common Grade 3/4 biochemistry abnormalities include hyperglycemia in

11% and lipase elevations in 15% of nilotinib pts (1 patient developed Grade 1/2 pancreatitis; no Grade 3/4 pancreatitis), while dasatinib abnormalities are hypophosphatemia in 11% and hypocalcemia in 22%. Rates of Grade 3/4 non-hematologic AEs such as pleural effusion, GI bleeding, arrhythmia, and pneumonia/infection are >2-7 times higher for dasatinib than nilotinib. *Summary and Conclusions.* The toxicity profiles of the second generation TKIs for imatinib resistant/intolerant CML-CP appear to be different and favor nilotinib with its reduced rates of Grade 3/4 AEs even with longer median duration of drug exposure compared to dasatinib. Further analysis is required to understand the cost impact to health care payers of the differences in safety profiles among the new TKIs.

Table 1.

	Base AE Occurrence Rate % (Range)	
Grade 3/4 Adverse Event	**Nilotinib**	**Dasatinib**
Anemia	7.9 (5.3-9.9)	18.0 (9.0-20.0)
Neutropenia	28.3 (13.1-33.1)	49.0 (36.4-58.0)
Thrombocytopenia	28.5 (19.9-32.9)	48.0 (35.0-54.0)

Despite its remarkable efficacy in chronic myelogenous leukemia (CML) resistance to imatinib mesylate (IM) may arise, and the onset of BCR-ABL point mutations remains the main cause identified, being responsible for resistance. Among these mutations, some located in the ATP binding loop (P-loop: residues 248-255) or at residue 315 seem particularly critical by disturbing IM binding or by altering the flexibility of the ABL kinase domain. The poor clinical prognosis of these mutations is generally accepted but still debatable. Among the P-loop group, biochemistry and cellular assays suggest that there is some heterogeneity in impairing the response to IM and mutations located at residues 253 and 255 are responsible for particularly high IC_{50} values *in vitro*. In a vast retrospective study from 5 different French centers, we analysed and compared the features and clinical outcomes of 75 CML patients treated with IM and presenting either clinical, cytological, cytogenetical resistance or molecular progression. Progression has been defined as a loss of any previous response, progression to a more advanced phase and a ≥2-fold increase in BCR-ABL/ABL ratio confirmed on 2 assessments 3 months apart. Fourty-six patients (32M/14F, median age 52) harboured 49 P-loop mutations [Group 1 (G1)] and 29 patients (19M/10F, median age 52) harboured 37 mutations with at least a T315I mutation (± other) [Group 2 (G2)], as detected by direct sequencing. At mutation discovery 24 patients (52%) were in chronic phase (CP), 12 (26%) in accelerated phase (AP), 10 (22%) in blast crisis (BC) in G1 and 12 (41%), 4 (14%), 13 (45%) in G2 respectively. The median duration of IM was 16 months (1.3-65.6) for G1 and 19 (0-57.6) for G2 (p=ns). In patients who had received IFN prior to IM, duration of IFN was similar between the 2 groups (5 months (0-89) for G1 vs 9 months (0-131) for G2, p=ns). The median interval between diagnosis and day 1 of IM was 16 months (0-61.5) for G1 and 13 months (0-49.5) (p=ns) for G2. Univariate analysis for gender, age, sokal, prior treatment with IFN, initial dose of IM, intervals between diagnosis-IM start, diagnosis-mutation detection, IM-mutation detection and major cytogenetic response with IM, did not show any significant impact of these variables. Multivariate analysis demonstrated a significantly worse PFS since IM start for E255K/V+Y253H mutants vs other P-loop mutants (p=0.016, HR:2.96, 95%CI: 1.22-7.16). IFN treatment prior to IM was associated with better survival rates (p=0.00013, HR:0.12, 95%CI: 0.04-0.35). Progression free survival (PFS) Kaplan Meier curves for all phases, since IM start showed a significant better survival for other P-loop mutations than Y253H, E255K/V and T315I groups (p=0.03) (See Figure 1). In conclusion, our results confirm that P-loop and T315I mutations are associated with poor prognosis, but they show that Y253H and E255K mutations are of particularly severe prognosis within the P-loop group as suggested by *in vitro* data. Those mutations would require early therapeutic intervention in order to improve survival

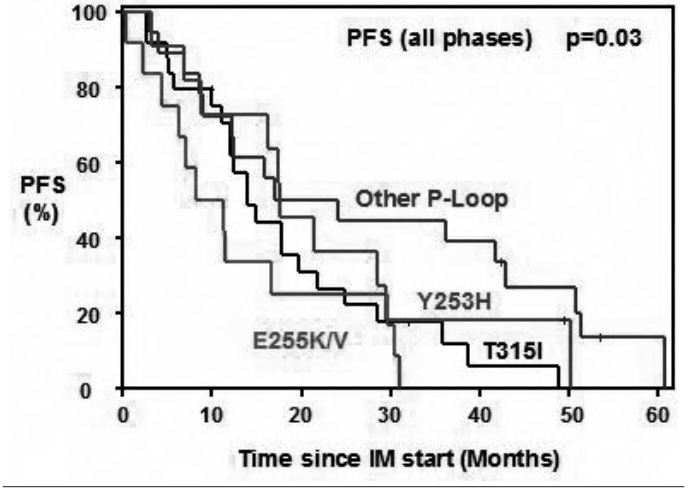

Figure 1. PFS, CML all phases according to mutation status.

0554

NILOTINIB THERAPY AFTER DASATINIB FAILURE IN PATIENTS WITH IMATINIB-RESISTANT OR-INTOLERANT CHRONIC PHASE AND ACCELERATED PHASE PHILADELPHIA-POSITIVE CHRONIC MYELOGENOUS LEUKEMIA

F. Giles,[1] P. Le Coutre,[2] K. Bhalla,[3] G. Rosti,[4] G. Ossenkoppele,[5] G. Alimena,[6] A. Weitzman,[7] A. Haque,[7] Y. Shou,[7] H. Kantarjian[1]

[1]MD Anderson Cancer Center, HOUSTON, USA; [2]Campus Virchow Klinikum, Charite, BERLIN, Germany; [3]University of South Florida, TAMPA, USA, [4]Institute of Hematology and Oncology, BOLOGNA, Italy; [5]Department of Pathology, Free University, AMSTERDAM, Netherlands; [6]University La Sapienza, ROME, Italy; [7]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA

Background. Nilotinib is a potent, highly selective, aminopyrimidine inhibitor which is 30-fold more potent *in vitro* than imatinib and active against 32/33 imatinib-resistant cell lines with Bcr-Abl mutations. *Aims.* These results are from an ongoing phase II study evaluating the efficacy and safety, as defined by hematologic and cytogenetic response rates (HR/CyR), of nilotinib administered at a daily dose of 400 mg BID to patients (pts) with Philadelphia-positive (Ph^+) chronic myelogenous leukemia (CML) in chronic phase (CP), accelerated phase (AP), and blast crisis (BC) who were resistant or intolerant to imatinib and dasatinib. *Methods.* All pts signed an informed consent and received nilotinib for an unapproved indication. *Results.* Data from 42 pts are available. Included were 16 CP, 9 AP, and 17 BC; 13 myeloid; 4 lymphoid) pts were included. Median age 58 (19 -78) years; median time since first diagnosis of CML was 18 (0.1-166) mos. Of the 42 pts, 10 (24%) had extramedullary involvement. Median exposure was 81 (4-420) days with

median dose intensity being 800 (216-1195) mg/day. 13 (31%) pts have ongoing treatments and 29 (69%) pts discontinued treatment (16 disease progression, 6 adverse event, 5 other reasons, and 2 deaths). The primary endpoint for CP pts was CyR, while the primary endpoint for AP pts was HR. 13/16 CP pts had no baseline complete hematologic response (CHR). 4/13 (31%) pts had major cytogenetic response (MCyR); 2 (15%) complete and 2 (15%) partial cytogenetic response: 1 minor, 2 minimal, 3 none, 1 not assessable, and 2 disease progression. 5/13 had CHR. Of the 9 AP pts, 2 (22%) returned to CP, 6 (67%) were not available and there was 1 (11%) death. Of the 17 BC pts, 3 (18%) had CHR 1 (6%) returned to chronic phase, 5 (29%) had stable disease, 4 (24%) were not available, and 4 (24%) had progressive disease. Overall, thrombocytopenia (33%), pyrexia (29%), anemia (24%), and neutropenia (24%) were the most common adverse events including all grades. The most common grade 3/4 adverse events were thrombocytopenia (26%), neutropenia (24%), and anemia (7%). Any hematologic and/or cytogenetic responses were observed in 4/8 CP and 3/7 AP patients with baseline mutations vs. 6/7 CP and 2/3 AP patients without baseline mutations. *Summary and Conclusions.* Nilotinib has clinical activity in CML-CP, -AP, and -BC pts who were resistant or intolerant to imatinib and have also previously failed dasatinib therapy. In these heavily pre-treated pts, nilotinib administration has acceptable safety and tolerability similar to that previously profiled. Updated information will be presented at the meeting.

0555

A PHASE II STUDY OF NILOTINIB, A NOVEL TYROSINE KINASE INHIBITOR ADMINISTERED TO IMATINIB-RESISTANT AND -INTOLERANT PATIENTS WITH PHILADELPHIA-POSITIVE CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE

G. Martinelli,[1] G. Rosti,[1] P. Le Coutre,[2] K. Bhalla,[3] F. Giles,[4] G. Ossenkoppele,[5] A. Hochhaus,[6] N. Gatterman,[7] A. Haque,[8] D. Resta,[8] A. Weitzman,[8] M. Baccarani,[1] H. Kantarjian[4]

[1]Institute of Hematology and Oncology, BOLOGNA, Italy; [2]Campus Virchow Klinikum, Charite, BERLIN, Germany; [3]University of South Florida, TAMPA, USA; [4]MD Anderson Cancer Center, HOUSTON, USA; [5]Department of Pathology, Free University, AMSTERDAM, Netherlands; [6]III Medizinische Klinik, MANNHEIM, Germany; [7]University of Dusseldorf, DUSSELDORF, Germany; [8]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA

Background. Nilotinib is a potent, highly selective, aminopyrimidine inhibitor that *in vitro* is 30-fold more potent than imatinib and active against 32/33 imatinib-resistant BCR-ABL mutations. *Aims.* This open-label study was designed to evaluate the safety and efficacy of nilotinib, as defined by hematologic/cytogenetic response rates (HR/CyR), administered at a daily dose of 400 mg BID to patients (pts) with imatinib-resistant or -intolerant Philadelphia-positive (Ph^+) chronic myelogenous leukemia (CML) in chronic phase (CP). *Methods.* Nilotinib could be escalated to 600 mg BID for pts who did not adequately respond to treatment. All pts signed an informed consent and received nilotinib for an unapproved indication. *Results.* 318 pts were enrolled including 223 (70.1%) with imatinib resistance and 95 (29.9%) with imatinib intolerance. Median age was 58 (21-85) years and the median time since CML diagnosis was 57.3 mos. 50.6% were men. Treatment with nilotinib is ongoing for 221 (69.5%) pts. A total of 97 (30.5%) pts have discontinued treatment. The median duration of nilotinib exposure was 245 (1-502) days. The median average dose intensity for all pts was 796.6 (151-1111.5) mg/day. The nilotinib dose was escalated for 41 (12.9%) pts. Efficacy data are available for 280 pts with ″6 months of follow-up. Major CyR (MCyR) was observed in 145 (51.8%) pts, of which 96 (34.3%) were complete and 49 (17.5%) partial. 10 (3.6%) pts had disease progression. The median time to MCyR was 2.8 (0.9-11.1) months. 95 (33.9%) had a CHR at baseline and 185 (66.1%) did not. 137 (74.1%) of the 185 pts without baseline CHR achieved CHR. The median time to CHR was 1 (0.9-8.3) mo. Of 101 pts with baseline mutation analysis performed, 45 (44.6%) had BCR-ABL mutations. Of the 318 pts included in the safety analysis, overall the most frequent grade 3/4 adverse events included thrombocytopenia (n=70, 22%), neutropenia (n=49, 15.4%), anemia (n=22, 6.9%), and elevated serum lipase (n=22, 6.9%). 3 (0.9) pts experienced QTcF >500 msec. Overall, there were 4 deaths (1 myocardial infarction and ventricular rupture, 1 coronary artery disease and sudden death, 2 sepsis). *Summary and conclusions.* Nilotinib has demonstrated significant clinical activity as defined by 51.8% MCyR rate and 74.1% CHR rate, and an acceptable safety and tolerability profile in pts with imatinib-resistant or -intolerant CML-CP.

0556

NILOTINIB MONOTHERAPY IN PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT PH+ CHRONIC MYELOGENOUS LEUKEMIA IN BLAST CRISIS OR RELAPSED/ REFRACTORY PH^+ ACUTE LYMPHOBLASTIC LEUKEMIA

O. Ottmann,[1] R. Larson,[2] H. Kantarjian,[3] P. Le Coutre,[4] M. Baccarani,[5] A. Weitzman,[6] F. Giles[3]

[1]University of Frankfurt, FRANKFURT, Germany; [2]University of Chicago Hospital, CHICAGO, USA; 3MD Anderson Cancer Center, HOUSTON, USA; [4]Campus Virchow Klinikum, BERLIN, Germany; [5]Institute of Hematology and Oncology, BOLOGNA, Italy; [6]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA

Background. Nilotinib is a potent, highly selective, aminopyrimidine inhibitor of BCR-ABL that *in vitro* is 30-fold more potent than imatinib. It is active against 32/33 imatinib-resistant BCR-ABL mutations. *Aims.* This open-label phase II study was designed to evaluate the safety and efficacy of nilotinib at a dose of 400 mg BID in adult patients (pts) with imatinib-resistant or -intolerant CML-BC or in pts with relapsed/refractory Ph+ALL. The primary endpoints were investigator assessments of best hematologic response (HR) and complete remission, respectively. *Methods.* Daily doses of nilotinib could be escalated to 600 mg BID for pts who did not adequately respond to treatment, and in the absence of safety concerns. All pts signed an informed consent and received nilotinib for an unapproved indication. *Results.* Safety and efficacy data are reported for 120 BC (87 myeloid, 27 lymphoid, 6 unknown) and 41 Ph^+ ALL pts (37 active disease, 4 residual disease; 38 relapsed, 3 refractory). 60% of pts had >35% Ph^+ metaphases for BC and 31% for Ph^+ ALL. Median ages were 54 yrs for BC and 46 yrs for Ph^+ALL pts. Chromosomal abnormalities other than Ph^+ were noted in 64 (53%) BC and 12 (29%) Ph^+ ALL pts. Extramedullary involvement was present in 44 (37%) BC and 3 (7%) Ph^+ ALL pts. Median treatment duration was 53 (1-441) and 72 (3-363) days for BC and Ph^+ ALL, respectively. Median dose intensity was 800 mg/day for both pt groups. Treatment is ongoing for 21 (18%) BC and 4 (10%) Ph^+ ALL pts. Most discontinuations were due to disease progression (61 [51%] in BC; 26 [63%] in Ph^+ ALL). Hematologic responses (HR) were observed in 42 (35%) BC pts. Of the 120 BC pts, complete HR was reported in 25 (21%) pts, marrow responses (no evidence of leukemia) in 7 (6%) pts, and return to chronic phase in 10 (8%) pts. Complete remission was reported in 10 (24%) Ph^+ ALL pts, of which 1 pt had minimal residual disease. The most common grade 3/4 AEs were thrombocytopenia (41%), neutropenia (28%), pneumonia (11%), and anemia (27%) in BC and thrombocytopenia (24%) in Ph^+ ALL pts. During the study period, death occurred in 9 (8%) BC and 3 (7%) Ph^+ ALL pts. No Ph^+ ALL pt developed CNS disease while on therapy. *Summary and conclusions.* Nilotinib monotherapy has significant clinical activity and is well tolerated in pts with imatinib-resistant or -intolerant BC and pts with relapsed/refractory Ph+ ALL. Nilotinib represents an important new treatment option for these pts, in which there remains a high unmet medical need. Given the safety and efficacy of nilotinib monotherapy, the combination of nilotinib with systemic chemotherapy warrants investigation in Ph^+ CML-BC or ALL. Updated data will be presented at the meeting.

0557

A PHASE II STUDY OF NILOTINIB, A NOVEL TYROSINE KINASE INHIBITOR ADMINISTERED TO IMATINIB-RESISTANT OR -INTOLERANT PATIENTS WITH PHILADELPHIA-POSITIVE CHRONIC MYELOGENOUS LEUKEMIA IN ACCELERATED PHASE

P. Le Coutre,[1] R. Larson,[2] H. Kantarjian,[3] N. Gattermann,[4] A. Hochhaus,[5] A. Haque,[6] D. Resta,[6] A. Weitzman,[6] F. Giles,[3] S. O' Brien[7]

[1]Campus Virchow Klinikum, BERLIN, Germany; [2]University of Chicago Hospital, CHICAGO, USA; [3]MD Anderson Cancer Center, HOUSTON, USA; [4]University of Dusseldorf, DUSSELDORF, Germany; [5]III Medizinische Klinik, MANNHEIM, Germany; [6]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA; [7]University of Newcastle, TYNE, United Kingdom

Background. Nilotinib is a potent, highly selective, aminopyrimidine inhibitor of BCR-ABL that *in vitro* is 30-fold more potent than imatinib. It is active against 32/33 imatinib-resistant BCR-ABL mutations. *Aims.* This open-label study was designed to evaluate the safety and efficacy of nilotinib, as defined by hematologic/cytogenetic response (HR/CyR) rates, at a dose of 400 mg BID in patients (pts) with Philadelphia-positive (Ph^+) imatinib-resistant or -intolerant chronic myelogenous leukemia (CML) in accelerated phase (AP). *Methods.* Nilotinib could be escalated to 600 mg BID for pts who did not adequately respond to treatment. All

pts signed an informed consent and received nilotinib for an unapproved indication. *Results.* Data are available on the 120 enrolled pts, of whom 97 (80.8%) pts were resistant and 22 (18.3%) were intolerant to imatinib. 67 (55.8%) were male. The median age was 58 (22-79) years and the median time since first diagnosis of CML was 71.3 (2.2-298.2) mos. The median duration of nilotinib exposure was 137.5 (2-503) days and median average dose intensity for all pts was 796.6 (145.4-1149) mg/day. Nilotinib dose was escalated for 26 (21.7%) pts. Treatment is ongoing for 64 (53.3%) patients, and 56 (46.7%) have discontinued (25 [20.8%] for disease progression, 14 [11.7%] for adverse events). Baseline mutation data are available for 46 of the 64 pts. Of the 96 pts who had ≥6 months of follow-up, confirmed hematologic response (HR) occurred in 43 (44.8%) patients. 18 (18.8%) pts had complete HR, 9 (9.4%) had marrow responses (no evidence of leukemia), and 16 (16.7%) returned to chronic phase. Time to confirmed HR was 1 (0.8-3) month. Major CyR occurred in 29 (30.2%) pts, of whom 15 (15.6%) had complete CyR and 14 (14.6%) had partial CyR. 12 (12.5%) pts had minor CyR, and 20 (20.8%) had minimal CyR. The rate of MCyR for resistant and intolerant AP patients was 30.4% and 29.4%, respectively. Of the 120 patients included in the safety analysis, overall the most frequent grade 3/4 adverse events included thrombocytopenia (n=41, 34.2%), neutropenia (n=24, 20%), anemia (n=16, 13.3%), and elevated serum lipase (n=11, 9.2%). No pts experienced QTcF intervals >500 msec. Overall, there were 9 deaths including 4 for disease progression, 2 due to other malignancies, 1 related to progressive disease complicated by a cerebral hemorrhage, 1 cardiac failure, and 1 due to sepsis. *Summary and Conclusions.* These data demonstrated that nilotinib is clinically active and has an acceptable safety and tolerability profile when administered to pts with imatinib-resistant or -intolerant Ph^+ CML-AP.

0558

REDUCED INTENSITY CONDITIONING OF ALLO-SCT IN CML PATIENTS IS SUPERIOR OVER MYELOABLATIVE CONDITIONING AND RESULTS WITH 60% OF LONG TERM SURVIVAL

A. Lange,[1,2] M. Sedzimirska,[2] K. Suchnicki,[1] D. Duda,[2] E. Nowak,[2] S. Madej,[2] J. Lange[2]

[1]L.Hirszfeld Inst. of Immunol. Exp. Ther., WROCLAW; [2]Lower Silesian Center for Cellular Trans, WROCLAW, Poland

Background. In the era of Imatinib a number of allo SCT in CML patients has been considerably reduced. However, in some patients we come to the decision of allo SCT while toxicity or progression to more advanced stages of the disease become clinically apparent. There are rather rare events but still this problem may be relevant up to 20% of patients especially during the first three years of treatment. An optional proposal to proceed with allo SCT should have a rational basis behind. *Methods.* In this study we present the data of allo SCT performed in one center in two cohorts composed of patients receiving myeloablative (cohort 1: Busulfan 16 mg/kg b.w., Cyclophosphamide 120 mg/kg b.w. + anti-thymocyte globulin - ATG 20 mg/kg b.w. in alternative donors transplantation) and non myeloablative (cohort 2: Bu 8 mg/kg b.w., Flu 120 mg/kg, ATG usually 10 mg/kg b.w.) preparative regimens. Patients characteristics in cohort 1 and cohort 2 are as follow: n=40 (n=58), 1st CP: 31 (49), > 1st CP: 2 (9), ACCP or BC: 7 (0), sib/alternative donors: 30/10 (23/35), marrow/PBPC: 35/5 (14/44), years of transplant: 1989-2000 (1999-2006). The results of the transplant procedure when compared cohort 1 vs cohort 2 differed with respect to the incidence of transplant related toxicity ≥ III grade (10/40 vs 1/58, p<0,001), but not with respect to aGvHD (19/40 vs 18/58, p=0.098), extensive cGvHD (11/40 vs 15/58, p=0.857) and relapses incidence (5/40 vs 9/58, p=0,675). Overall survival of RIC patients (cohort 2) was significantly better than myeloablative patients (cohort 1) (Log-rank test, p=0.029). From an univariate analysis it became apparent that the results of the procedure was affected by: time from diagnosis to transplantation (p<0.025), years of transplant (p<0.007), stage of the disease (p<0.031) and intensity of conditioning (p<0.030). There are several bias behind the latter comparisons: myeloablative and RIC transplantations were performed in two different time periods what may affect the outcome due to the improvement in supportive care, on the other hand cohort 2 patients received more frequently VUD then sibling transplantation. Therefore, a multivariate analysis was performed which documented that only time from the diagnosis to allo SCT (p<0.012) and intensity of conditioning (p<0.011) independently affected the outcome. In conclusion patients transplanted under RIC with a low dose of ATG enjoy in 60% long term survival affected by 25% incidence of extensive cGvHD independent whether they received sibling or MUD transplant providing high resolution typing.

0559

IMATINIB 400 MG IN LATE CHRONIC PHASE CML PATIENTS: LONG TERM EVALUATION OF RESPONSES AND SURVIVAL OF A PHASE II STUDY OF THE GIMEMA CML WP

F. Palandri,[1] I. Iacobucci,[1] F. Castagnetti,[1] N. Testoni,[1] M. Amabile,[1] S. Bassi,[2] S. Soverini,[3] G. Saglio,[4] F. Pane,[5] M. Breccia,[6] R. Bassan,[7] B. Martino,[8] S. Merante,[9] P. Giannoulia,[3] G. Martinelli,[3] G. Rosti,[3] M. Baccarani[3]

[1]Dept of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Department of Oncology/Hematology, MILANO; [3]Dept of Hermatology/Oncology Seràgnoli, BOLOGNA; [4]Dept of Clinical and Biological Sciences, (ORBASSANO) TURIN; [5]CEINGE, NAPLES; [6]Dept of Human Biotechnology and Hematol., ROME; [7]Division of Hematology, BERGAMO; [8]Hematology Unit, REGGIO CALABRIA; [9]Istituto di Ematologia, PAVIA, Italy

Background. Imatinib is the drug of choice for the treatment of Ph+ CML, where a complete cytogenetic response (CCgR) is achieved in more than 80% of early chronic phase (ECP) patients. In patients who start imatinib in late chronic phase (LCP) the cytogenetic response rate is lower (40-50%) and the long term effect on survival is not yet determined. *Aims.* The GIMEMA (Gruppo Italiano Malattie Ematologiche dell'Adulto) CML Working Party is conducting a phase II, multi-istitutional prospective study (CML/002) to investigate the long-term effects of imatinib in LCP patients, treated with imatinib 400 mg daily after failure of Interferon-γ. 295 patients were enrolled; median age was 52 yrs (range: 19-82). The median duration of chronic phase prior to imatinib treatment was 38 months (range: 1-202). We monitored the hematologic, cytogenetic and molecular response to imatinib in this cohort, with focus on the rate of major molecular response and on progression-free survival and overall survival of complete cytogenetic responders. The median observation time is 62 months (range, 6-72). *Methods.* Patients were monitored for cytogenetic and molecular response every 6 months. Cytogenetics was performed with conventional methods. Molecular response was assessed in Bologna on peripheral blood samples by quantitative PCR (RQ-PCR) using TaqMan methodology and expressed as a ratio of BCR-ABL to ABL%. Major molecular response (MMR) was defined as BCR-ABL/ABL% below 0.05, whereas a complete molecular response (CMR) was defined as undetectable BCR-ABL transcript levels (below 0,001%) by RQ-PCR confirmed by nested PCR. *Results.* 158 patients (53%) achieved a CCgR at a median time of 6 months from start of imatinib and 124 of them (78%) are still in continuous CCgR at 60 months. 34 patients (22%) lost the CCgR: 23 (67%) within 24 months from the date of its first achievement and 11 at a later timepoint (5 between 25 and 36 months, 6 after 37 months). For patients who obtained a CCgR, the 5-year progression free survival is 92% and overall survival is 91,5% (versus 60% e 73,5% for those without a CCgR, p=0.00001). 115/124 patients with stable CCgR were evaluable for molecular response. Considering all timepoints, the median number of evaluable samples was 100 (range: 73-115). The frequency of MMR increased during follow-up (38%, 46%, 53% at 6, 12 and 24 months) up to 70% at 36 and 60 months. During the course of treatment, 44 patients (38%) had a stable MMR; 27 (23%) fluctuated between MMR and undetectable levels of BCR-ABL (BCR-ABL/ABL% below 0,001, nested PCR positive) and one patient maintained a stable RT-PCR negativity. 24 patients (21%) never achieved a MMR, although in stable CCgR. Four patients (3%), achieved a CMR, which was unstable during follow-up. *Conclusions.* For complete cytogenetic responders progression-free and overall survival are likely to be as good as for ECP patients, suggesting that the achievement of CCgR represents a main prognostic factor for CML patients. Moreover, even in late chronic phase CML patients, imatinib determines a high and early frequency of MMR, which increases over time.

0560

A RETROSPECTIVE COMPARISON OF THE SAFETY PROFILES OF HIGH-DOSE IMATINIB AND DASATINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS

E. Moyneur,[1] L. Pinheiro,[1] V. Barghout,[2] D. Williams,[2] A. Salvado,[2] M.S. Duh[1]

[1]Analysis Group, Inc., BOSTON; [2]Novartis Pharmaceuticals Corporation, FLORHAM PARK, USA

Background. Patients with chronic myeloid leukemia (CML) treated with kinase inhibitors may experience undesirable side effects. *Aims.* This study aims to compare the safety profiles of high-dose (HD) imatinib and dasatinib in chronic phase (CP) CML patients who have been previously treated with standard dose 400 mg daily imatinib using data

from pivotal clinical trials. *Methods.* Adverse event (AE) data were extracted for patients who had at least two occurrences of daily imatinib dose escalated from 400 mg to 600 or 800 mg from the 5-year IRIS study in newly diagnosed CP-CML patients (N=158) and, for those receiving dasatinib 70 mg twice daily for imatinib-resistant or intolerant CP-CML, from the FDA's publicly-available Sprycel Drug Approval Package (N=186 to 214). AEs were selected based on their frequency, clinical significance and availability. Conservative approaches to systematically favor dasatinib were employed throughout the analysis. Incidence rates were reported as number of patients with the AE per 100 patient-years of observation, and incidence rate ratios were used to compare both drugs using Poisson distribution. The imatinib group's observation period was constructed based on time periods of imatinib treatment beginning from the date of dose escalation to > 400 mg, and ending at the earliest of the last imatinib treatment date or the AE end date, thus assuming AE occurrence even during treatment gaps. For the dasatinib group, in the absence of specific patient-level data, it was conservatively assumed that all AEs occurred only at the latest treatment end date (279th day) for the group, artificially increasing the denominator for the incidence rate calculation which in turn underestimated the AE incidence for the dasatinib group. All AEs (drug-related or not) were considered for imatinib, whereas only those judged by the investigator as drug-related were included for dasatinib. Sensitivity analyses based on the subset of HD imatinib patients receiving ≥ 800 mg or the HD imatinib patients receiving interferon-alfa plus cytarabine before crossing over to standard imatinib dose were also conducted. *Results.* At baseline, relative to HD imatinib, the dasatinib group was older (mean age; 56.5 vs. 49.5 years, $p<0.05$), had more males (53.8% vs 33.5%, $p<0.05$), and had comparable ECOG performance scores (mean; 0.280 vs 0.284, $p=0.96$). The median daily dose during observation was 667.1 mg in the HD imatinib group, and 114 mg in the dasatinib group. The dasatinib group presented statistically significantly ($p<0.05$) higher incidences for all studied AEs than the HD imatinib group (Table 1). Sensitivity analyses confirmed the statistically significantly different AE incidences between the two groups. *Summary and conclusions.* CP-CML patients receiving dasatinib may be at greater risk for a variety of clinically important AEs than those treated with HD imatinib following treatment with standard dose imatinib, as suggested by the significantly higher incidence rates observed for dasatinib despite an overwhelmingly conservative analytical approach in favor of dasatinib and despite a lower median daily dose of dasatinib than prescribed (140 mg). Further analysis addressing the limitations stemming from lack of randomization is warranted.

Table 1. Comparison of AE incidence rates between HD Imatinib and Dasatinib patients.

0561

IMATINIB 400 MG AND PEGYLATED RECOMBINANT INTERFERON-ALPHA IN EARLY CHRONIC PHASE CML: HIGH FREQUENCY OF COMPLETE CYTOGENETIC AND MAJOR MOLECULAR RESPONSES IN THE LONG TERM

F. Palandri,[1] A. Poerio,[1] I. Iacobucci,[1] F. Castagnetti,[1] N. Testoni,[1] M. Amabile,[1] E. Trabacchi,[2] G. Saglio,[3] F. Pane,[4] T. Intermesoli,[5] F. Iuliano,[6] M. Gobbi,[6] E. Pungolino,[6] F. Pampineschi,[6] M. Tiribelli,[6] G. Martinelli,[1] G. Rosti,[1] M. Baccarani[1]

[1]Dept of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Divisione di Ematologia, PIACENZA; [3]Dept of Clinical and Biological Sciences, (ORBASSANO) TURIN; [4]CEINGE, NAPLES; [5]Division of Hematology, BERGAMO; 6Hematology, CATANZARO, Italy

Background. Imatinib 400 mg is the established first line treatment of chronic myeloid leukemia (CML) in chronic phase. *Aims.* Between July and December 2001, 76 patients were enrolled in a phase II study of the Italian Cooperative Study Group on CML (serial n. CML/011) to investigate the efficacy of imatinib 400 mg daily and a variable pegylated IFN-α dose (50, 100 and 150 microg/wk) in early chronic phase (ECP) CML patients. *Methods.* Patients were monitored for conventional cytogenetic and molecular response every 6 months. Peripheral blood samples for quantitative molecular analysis (RT-Q-PCR, Bcr-Abl/Abl x 100 - Taqman) were centralized in Bologna. Major molecular response (MMR) was defined as BCR-ABL/ABL% less than 0.05. *Results.* 76 ECP CML patients were monitored, with a median observation time of 54 months (range: 12-65). Median age at diagnosis was 47 yrs (range 18-68). According to Sokal scale, 45% were low, 31% intermediate and 24% high risk. 75 patients discontinued IFN-α after a median time of 10 months (range: 1-49) because of side effects (96%) or unsatisfactory therapeutic effect (4%). Imatinib have been discontinued in 10 (12%) patients at a median time of 21 months (range: 4-56) because of: unsatisfactory therapeutic effect (4), submission to allogeneic SCT while in CCgR (1), CCgR loss (3), progression to AP (1), consent withdrawal (1). The mean daily imatinib dose was 348 mg. 66 (87%) patients obtained a CCgR (specifically 72%, 96% and 88% of high, intermediate and high risk patients, respectively). 56 patients (78%) are still in continuous CCgR at 60 months. 59 patients (90%) achieved the CCgR within 12 months of therapy, 2 patients between 13 and 24 months and 5 (6,5%) after 25 months. 3 patients (2 low and 1 intermediate Sokal risk) lost the CCgR, after 9, 31 and 24 months from its first achievement, respectively. 6 patients underwent allogeneic SCT. 3 patients died: 1 after allogeneic SCT and 2 from a cause unrelated to CML. The 5-year overall progression free survival (PFS) is 82% and overall survival (OS) is 97%. Analyzing patients by Sokal risk, no difference in PFS and OS resulted statistically significant among the 3 groups. 60/63 patients with stable CCgR were evaluable for molecular response. Considering all timepoints, the median number of evaluable samples was 56 (range: 55-60). The frequency of MMR was very high at 6 months (60%) and increased over time (72%, 80%, 86%, 89% and 80% at 12, 24, 36, 48 and 60 months). During follow-up, 27 patients (45%) had a stable MMR; 25 (42%) fluctuated between MMR and undetectable levels of BCR-ABL (BCR-ABL/ABL% below 0,001, nested PCR positive) and one patient maintained a stable RT-PCR negativity. Only 1 patients (1,5%) never achieved a MMR. *Conclusions.* Our study shows that imatinib is highly effective and manageable in ECP CML patients, reinforcing the results of the IRIS trial.

0562

LONG-TERM MOLECULAR RESPONSES TO IMATINIB IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA: COMPARISON BETWEEN PATIENTS TREATED IN EARLY AND IN LATE CHRONIC PHASE

F. Palandri,[1] I. Iacobucci,[1] A. Poerio,[1] F. Castagnetti,[1] N. Testoni,[1] M. Amabile,[1] S. Bassi,[2] P. Giannoulia,[3] G. Saglio,[4] F. Pane,[5] T. Barbui,[6] F. Iuliano,[7] M. Gobbi,[7] E. Pungolino,[2] A. Cappucci,[8] R. Fanin,[8] G. Martinelli,[3] G. Rosti,[3] M. Baccarani[3]

[1]Dept of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Department of Oncology/Hematology, MILANO; [3]Dept of Hermatology/Oncology Seràgnoli, BOLOGNA; [4]Dept of Clinical and Biological Sciences, (ORBASSANO) TURIN; [5]CEINGE, NAPLES; [6]Ospedali Riuniti Hematology Dept, BERGAMO; [7]Hematology, CATANZARO; [8]Hematology Dept, PERUGIA, Italy

Background. Imatinib is the drug of choice for the treatment of Ph+ CML, with very high cytogenetic response rates both in patients treated in early (ECP) and in late (LCP) chronic phase. As the rates of cytogenetic remission improves, monitoring minimal residual disease by PCR has become more important. *Aims.* We evaluated the pattern and the clinical significance of molecular response to imatinib by comparing patients treated in ECP and in LCP. We analyzed the results of quantitative PCR (RQ-PCR) in 187 patients with CML who achieved a stable CCgR with imatinib 400 mg daily (124 treated after failure of IFN-α and 63 previously untreated). The patients on study have been enrolled in two different phase II, multi-istitutional prospective study of the Italian Cooperative Study Group (serial no.: CML/002 and CML/011). Median observation time for both groups is 60 months (range, 6-72). *Methods.* Patients were monitored for conventional cytogenetic and molecular response every 6 months. Molecular response was centralized in Bologna, assessed on peripheral blood samples by quantitative PCR (RQ-PCR) using TaqMan methodology and expressed as a ratio of BCR-ABL to ABL%. Major molecular response (MMR) was defined as BCR-ABL/ABL% below 0.05. Complete molecular response (CMR) was defined as undetectable BCR-ABL transcript levels (below 0,001%) by RQ-PCR confirmed by nested PCR. *Results.* 295 patients were treated with imatinib after failure of Interferon-α (administered for a median time of 38 months, range: 1-202). 158 patients achieved a CCgR: 124 (78%) are still in continuous CCgR and 115/124 are evaluable for molecular response at 60 months (median number of evaluable samples: 100, range: 73-115). 76 ECP CML patients were treated with imatinib and a variable pegylated IFN-α dose (50, 100 and 150 microg/wk), which has been discontinued by 75/76 patients after a median time of 10 months (range: 1-49). 66/76 patients obtained a CCgR (specifically 72%, 96% and 88% of high, intermediate and low risk patients). 63 (83%) patients are still in continuous CCgR and 60/63 are evaluable for molecular response at 60 months (median number of evaluable samples: 56, range: 55-60). The frequency of MMR increased during follow in both early and late CP patients, but the rapidity of achievement and the quality of the molecular response was higher in ECP patients. Specifically, the proportion of patients treated in ECP achieving a MMR was 60%, 72%, 80%, 86%, 89% and 80% at 6, 12, 24, 36, 48 and 60 months (versus 38%, 46%, 53%, 70%, 68%, 68% of LCP patients at the same time-points). Even the rate of RQ-PCR negativity was higher in ECP (22%) than LCP patients (7%) at 5 years. During follow-up, MMR was stable in 88% and in 78% of early and late CP patients, respectively. *Conclusions.* Our long-term results shows that Imatinib induces a very high rate, which increases over time, of MMR both in early and late CP patients. Notably, ECP patients, maybe even thanks to the association of IFN-α in the first year of treatment, obtained earlier, higher and more durable molecular responses.

0563

HIGH SENSITIVITY TESTING IDENTIFIES ADDITIONAL LOW LEVEL BCR-ABL KINASE DOMAIN MUTATIONS IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA AND RESISTANCE TO IMATINIB

O. Pelz-Ackermann,[1] M. Deininger,[2] M. Cross,[3] K. Wildenberger,[3] C. Günther,[3] S.Y. Wang,[3] H.K. Al-Ali,[3] D. Niederwieser,[3] T. Lange[3]

[1]University Leipzig, Medical clinic II, LEIPZIG, Germany; [2]Health & Science University Cancer Inst., PORTLAND, USA; [3]University of Leipzig, Hematology, LEIPZIG, Germany

Background and Aims. Mutations of the BCR-ABL kinase domain (KD) are the most frequent cause of acquired resistance to imatinib (IM) in patients with chronic myeloid leukaemia (CML), most likely due to selection of mutant clones on IM treatment. As new BCR-ABL inhibitors become available, precise quantification of low level mutation will be required to monitor response. Here we report our results for 5 key mutations (G250E, Y252H, E255K, T315I, F359V) in both IM resistant and newly-diagnosed CML patients using a sensitive and quantitative Ligation-PCR (L-PCR) assay in comparison to direct sequencing. *Patients and Methods.* Forty three CML patients on IM (24 male, 19 female) with a median age of 60 (range 20 to 75) years in blast crisis (n=11), accelerated phase (n=20) or chronic phase (n=12) and IM failure were analysed using both approaches. Sequencing of the ABL KD was performed using forward and reverse primers of the ABL exons 4 to 7, while the L-PCR analysis focused on the G250E, Y253H, E255K, F359V and T315I mutations. Briefly, pairs of probes specific for either wild type (wt) or mutant BCR-ABL were added to the RT-PCR amplified BCR-ABL KD, and then ligated under conditions optimized for specificity. Ligated probe pairs were then amplified in a quantitative PCR using universal primers. Values were expressed as% BCR-ABLmut/BCR-ABLwt based on ct values. In our hands, this assay can detect 0.05-0.1% mutant allele in a BCR-ABLwt *Background.* Results were scored positive only if two independent runs showed amplification exceeding the lowest controls. *Results.* Patients were treated with a median IM dose of 600 (range 500-800) mg for a median of 15.5 (range 1 to 75) months. Dose reductions due to toxicity were necessary in 18 (42%) patients. Overall, one (n=16) or two (n=2) mutations of the BCR-ABL KD were detected by direct sequencing (42%). In contrast, L-PCR for G250E, Y253H, E255K, F359V T315I detected 40 (one n=16, two n=7, three n=2, four n=1) mutations in 26 (60%) patients with a median of 0.25% (range 0,07-100) BCR-ABLmut in BCR-ABLwt. Direct sequencing identified mutations in only 9 (21%) of the 26 patients (p=0.002). On median follow-up of 7 (range 1-53) month in 11 patients, one progression from 0.1 to 23% BCR-ABLE255K in BCR-ABLwt within 30 days was observed; all other mutated clones remained stable at low levels. No mutations were detected in 14 newly diagnosed CML patients either by direct sequencing or L-PCR. *Conclusions.* (1) L-PCR detects low levels of mutant clones in a high proportion of patients on IM who remain negative by direct sequencing. (2) The failure of L-PCR to detect mutations in newly diagnosed patients is consistent with selection on IM therapy. (3) Limited follow-up data suggest that some mutant clones may remain stable at low level over prolonged periods of time. Their prognostic significance remains to be determined.

RATIONAL USE OF THE REAL-TIME QUANTITATIVE PCR PROTOCOL TO MEASURE TELOMERE LENGTH IN BLOOD SPECIMENS

J. Ohyashiki

Tokyo Medical University, TOKYO, Japan

Background and Aims. It has been presumed that the measurement of telomere length is troublesome and time-consuming, despite the fact that telomere attrition is closely linked to bone marrow failure syndrome as well as leukemia and lymphoma. We present here an automated telomere measurement system that combines magnetic filtration and real-time PCR. *Methods.* Genomic DNA was extracted from 100 µL of whole blood by an automated magnetic bead system, then quantitative PCR was done in a closed tube using a carefully designed pair of oligonucleotide primers as reported by Cawthon *et al.* (Nucleic Acid Res 2002, 30: e47). In this assay, the quantity of telomere repeat in each experiment sample was measured as the level of an arbitrarily chosen reference sample, then the telomere signal was normalized to the signal from a single copy gene to generate a relative ratio (T/S). *Results.* In 107 peripheral blood specimens obtained from healthy volunteers (aged 8 to 84) and 6 leukemia cell lines, the T/S ratio was significantly associated with the mean telomere restriction fragment (TRF) measured by traditional Southern blot analysis [y=TRF, x=T/S, y=6.55x±2.39, R2=0.564]. The relative telomere ratio in blood specimens obtained from healthy volunteers was 1.06±0.21 (mean ± S.D). In 87 peripheral blood specimens obtained from various hematologic diseases, the relative telomere ratio was as follows: chronic myeloproliferative disorders (n=34), T/S=0.93±0.41, acute leukemia (n=31), T/S=0.77±0.75, myelodysplastic syndrome (n=23), T/S=0.39±0.34. Of note is that the T/S ratio in myelodisplastic syndrome was more closely linked to the length of the G-tail rather than TRF, which included the subtelomeric region. *Conclusions.* Our results suggest automated telomere measurement is suitable for high throughput of samples. The resolution of this assay should be adequate for many genetic and epigenetic studies. This assay will facilitate investigations of the biology of telomeres and their roles in hemopoetic stem cell biology as well as bone marrow failure syndrome.

COOPERATING MUTATIONS OF RECEPTOR TYROSINE KINASE/RAS PATHWAY IN ADULT CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA: DIFFERENT PATTERNS BETWEEN AML1-ETO AND CBFB-MYH11

L.Y. Shih, C.F. Huang, C.L. Lai, T.H. Lin, J.H. Wu, M.C. Kuo, T.L. Lin

Chang Gung Memorial Hospital, TAIPEI, Taiwan

Background. Two-hit model of leukemogenesis has been proposed for AML; class I mutations that drive proliferation and survival, and class II mutations that block differentiation. *Aims.* We sought (1) to determine the cooperating mutations of class I including receptor tyrosine kinase (RTK)/Ras signaling pathway in adult AML patients with core-binding factor (CBF) translocations which are class II mutations, and (2) to determine the difference in the patterns of cooperating mutations between AML with AML1-ETO and AML with CBFβ-MYH11. *Patients and Methods.* By RT-PCR analysis, 123 adult patients were identified to have CBF AML, 93 with AML1-ETO and 30 with CBFβ-MYH11. Bone marrow samples at diagnosis were analyzed for FLT3-ITD, FLT3-TKD, N-ras, K-ras, c-KIT and c-FMS mutations. Mutational analysis was performed by DNA-PCR followed by GeneScan analysis for FLT3/ITD, and by PCR-RFLP followed by direct sequencing for FLT3-TKD, by DNA/cDNA PCR followed by direct sequencing of all PCR products for N-ras, K-ras, c-KIT and c-FMS. *Results.* Forty-six of 93 patients (49.5%) with AML1-ETO had RTK/Ras mutations compared with 21 of 30 patients (70%) with CBFβ-MYH11 (p=0.059). The frequencies of RTK/Ras mutations in 93 AML1-ETO AML were 5.4% (n=5) for FLT3/ITD, 7.5% (n=7) for FLT3/TKD, 1.1% (n=1) for N-ras, 3.2% (n=3) for K-ras, 33.3% (n=31) for c-KIT, and 1.1% (n=1) for c-FMS mutation (A273V). The frequencies of RTK/Ras mutations in 30 CBFβ-MYH11 AML were 3.3% (n=1) for FLT3/ITD, 26.7% (n=8) for FLT3/TKD, 20% (n=6) for N-ras, 20% (n=6) for c-KIT, and none for K-ras and c-FMS mutations. All RTK/Ras mutations were mutually exclusive except two, one of them had both N-ras and K-ras mutations, the other harbored FLT3/TKD and c-KIT mutations. Patients with CBFβ-MYH11 had a significantly higher frequency of FLT3/TKD and N-ras mutations than patients with AML1-ETO (p=0.010 for FLT3/TKD, and p=0.001 for N-ras). Taken together, c-KIT mutations accounted for 30% in CBF AML, and there was no difference in the frequency between AML1-ETO and CBFβ-MYH11 groups. Of the 31 patients with AML1-ETO and c-KIT mutations, 23 had mutations located at kinase domain (exon 17), 3 in exon 8, 1 in exon 9, and 4 in exon 11. Of the 6 patients with CBFβ-MYH11 and c-KIT mutations, two each had mutations in exons 8, 11 and 17. Patients with AML1-ETO were more frequently associated with c-KIT mutations in exon 17 as compared with patients with CBFβ-MYH11 (p=0.073). *Conclusions.* Our results showed that occurrence of cooperating mutations of RTK/Ras pathway are common in adult patients with CBF AML. The patterns of mutations were different between AML1-ETO and CBFβ-MYH11 groups.

0566

COOPERATING MUTATIONS IN CHILDHOOD ACUTE MYELOID LEUKEMIA

D.C. Liang,[1] L.Y. Shih,[2] C.F Huang,[2] Y.T Chang,[1] C.L Lai,[2] H.C Liu,[1] C.P Yang[3]

[1]Mackay Memorial Hospital, TAIPEI; [2]Chang Gung Memorial hospital, TAIPEI; 3Chang Gung Children's Hospital, LINKOU, Taiwan

Background. There have been rare reports on the cooperating mutations of class I mutations which drive proliferation of acute myeloid leukemia (AML) blasts and class II mutations which block differentiation of blasts in childhood AML. *Aims.* We sought to systematically study the cooperating mutations in a large series of childhood AML. *Patients and Methods.* By cytogenetics and RT-PCR analysis,166 children with newly diagnosed AML were divided into t(8;21) (N=31), inv(16) (N=14), MLL rearrangement (N=21), t(15;17) (N=14), Down syndrome (N=6), unfavorable group (N=15) which included -7 or 7q-, complex karyotype and t(6;9), and intermediate group for all other patients (N=65). Bone marrow samples at diagnosis were examined for mutations of FLT3-ITD, FLT3-TKD, N-Ras, K-Ras, c-KIT, c-FMS, CEBPα, and NPM1. Mutational analysis was performed by PCR followed by GeneScan analysis for FLT3-ITD, by PCR-RFLP followed by direct sequencing for FLT3-TKD, and by PCR followed by direct sequencing for other genes. *Results.* c-KIT mutations were more prevalent in t(8;21) than others (p<0.0001), and in inv(16) than others (p<0.0001). The frequencies of c-KIT mutations between t(8;21) and inv(16) were not statistically different (p=1.0). FLT3-ITD was more frequently present in the intermediate group (22/65) than others (p<0.0001). In 28 patients with FLT3-ITD mutations, 4 had allelic ratio of mutant to wild type >2.

Table 1. Gene mutations in childhood AML.

The frequencies of FLT3-TKD between the intermediate group and others were not statistically different (p=1.0). N-Ras mutations were more prevalent in patients with inv(16) than others (3/14 vs 2/61, p=0.042), and in the intermediate group than others (9/65 vs 2/61, p=0.055). The frequency of K-Ras mutations in patients with MLL rearrangement was not statistically different from those of others (3/21 vs 3/75, p=0.117) or the intermediate group (6/65) (p=0.682). The frequency of CEBPα mutations in the intermediate group (8/53) was higher than others (2/94) (p=0.005). Similarly, the frequency of NPM1 mutations in the intermediate group (6/57) was higher than others (0/94) (p=0.002). In patients with recurrent chromosomal translocations, two

cooperating mutations were only found in 2 patients: FLT3-TKD + K-Ras in one with t(11;19) and c-KIT + N-Ras in another with inv(16) , all others with two cooperating mutations occurred in the intermediate group: FLT3-ITD + NPM1 in 5, FLT3-ITD + CEBPα in 4, FLT3-TKD + K-Ras, FLT3-TKD + CEBPα, and N-Ras + K-Ras in one each. *Conclusions.* In childhood AML, the core-binding factor leukemias are more frequently associated with c-KIT mutations. AML with inv(16) has more N-Ras mutations. Patients with intermediate cytogenetic risk group have more FLT3-ITD, CEBPα, and NPM1 mutations.

DETECTION OF PATIENT-SPECIFIC BCR-ABL GENOMIC DNA IN CML PATIENTS WITH NO DETECTABLE BCR-ABL BY QUANTITATIVE REVERSE TRANSCRIPTASE PCR

D. Ross,[1] P.A. Bartley,[2] A.A. Morley,[2] J.F. Seymour,[3] S. Branford,[1] T.P. Hughes[1]

[1]IMVS, ADELAIDE; [2]Flinders University & Medical Centre, ADELAIDE; [3]Australasian Leukaemia & Lymphoma Group, MELBOURNE, Australia

Background. With prolonged imatinib therapy for CML an increasing proportion of patients have persistently undetectable BCR-ABL using real-time reverse transcriptase quantitative PCR (RQ-PCR), referred to as *complete molecular remission* (CMR). However, most patients in CMR have residual disease, and imatinib withdrawal may result in early relapse. More sensitive molecular methods are required to identify patients at higher risk of relapse and to quantify residual disease so that the efficacy of therapy given after attaining CMR can be assessed. *Aims.* To determine if a patient-specific DNA PCR assay can detect residual disease below the level of CMR as measured by RQ-PCR. *Methods.* The patient-specific DNA PCR assay was developed after determining the genomic BCR-ABL breakpoint in each patient. DNA was extracted from cells frozen at presentation. The BCR-ABL breakpoint was identified using long template PCR with a forward primer in BCR and reverse primer in ABL. The sequence flanking the breakpoint was amplified and characterised. A sensitive DNA PCR assay with patient-specific primers and probe was then used for detection of BCR-ABL in follow-up samples. First, the breakpoint region was amplified using TaqGold DNA polymerase, then the breakpoint amplicon was detected in real-time PCR using nested primers and a TaqMan probe spanning the breakpoint. Each PCR was performed in two independent experiments. There were two negative controls in each assay; no template, and DNA from another CML patient. DNA PCR results were compared with prior RQ-PCR *Results.* RNA was reverse transcribed with random hexamer primers and Superscript II. BCR-ABL cDNA was quantified using RQ-PCR with TaqMan probes on the ABI Prism 7000. *Results.* We report on two DNA PCR assays developed for the first patients enrolled in the Australasian Leukaemia and Lymphoma Group study of imatinib withdrawal in patients with CMR for ≥2 years. To assess specificity each DNA assay was tested on 5 other CML patients. No non-specific amplification was detected. The limit of detection for serial dilutions of the breakpoint amplicon from presentation samples was similar for both patients suggesting comparable sensitivity. Both patients had received imatinib treatment for ≥3 years with no detectable BCR-ABL by RQ-PCR for 2 years prior to cessation of imatinib (baseline). Patient #1 had molecular relapse by RQ-PCR 3 months after imatinib cessation. Retrospective analysis by DNA PCR detected BCR-ABL in this patient's samples collected immediately prior to imatinib cessation and 6 months earlier. In contrast, for patient #2 the available DNA samples at baseline and 14 months earlier were negative by DNA PCR. This patient remains in CMR 6+ months after imatinib cessation. *Conclusions.* A major limitation of sensitive RQ-PCR is the potential for BCR-ABL contamination from other patient samples. Patient-specific DNA detection should overcome this problem. This DNA PCR assay for BCR-ABL is more sensitive than RQ-PCR in the two patients analysed to date. In these cases DNA PCR results correlated with remission/ relapse status after cessation of imatinib therapy. We aim to develop a quantitative DNA PCR assay which might enable more precise enumeration of residual CML cells.

SENSITIVE DETECTION OF C-KIT POINT MUTATIONS BY D-HPLC AND QUANTITATIVE PCR IN PERIPHERAL BLOOD AND BONE MARROW SAMPLES FROM PATIENTS WITH SYSTEMIC MASTOCYTOSIS

P. Erben, S. Lauber, T. Ernst, M.C. Mueller, T. Schenk, J. Kruth, G. Metzgeroth, P. Paschka, R. Hehlmann, A. Reiter, A. Hochhaus

Universitätsklinikum Mannheim, MANNHEIM, Germany

The majority of patients (pts) with systemic mastocytosis (SM) is characterized by the presence of the transforming mutation D816V of the c-kit gene, resulting in a factor-independent activation of the receptor tyrosine kinase KIT. The mutation is regarded the causative event for the pathogenesis and a potential target for therapeutic intervention with novel tyrosine kinase inhibitors like dasatinib, nilotinib (AMN107) and midostaurin (PKC412). However, the sensitivity of screening procedures for mutations are compromised by a minor proportion of malignant cells in the bone marrow (BM) sample. We therefore established and compared sensitive strategies for the detection of c-kit mutations in BM and peripheral blood (PB) samples on mRNA level: (i) D-HPLC (denaturing-high performance liquid chromatography) combined with direct sequencing in case of a positive D-HPLC signal and (ii) a LightCyclerTM based quantitative PCR assay for the D816V mutation amplifying the c-kit wildtype (wt) and the mutated allelen. Levels of the D816V mutation are expressed as ratios D816V C-KIT/wt C-KIT. The different techniques have been established using serial dilutions of c-kit D816V positive HMC-1 cells in a background of NB4 cells harboring wildtype c-kit and pts mRNA in control mRNA. D-HPLC and the quantitative PCR were optimized for the detection of the D816V mutation down to 0.1-0.5% fraction of the mutated clone (cell line and RNA dilution). No false positive results were observed in 20 different control samples obtained from healthy donors PB samples. In comparison, the detection limit for D816V mutations by conventional sequencing was 10 to 15%. These techniques were applied to BM (n=122) and PB (n=65) samples from 102 pts (55 m, 47 f) meeting the WHO criteria for SM. Median age was 51 yrs (range, 23-81). At diagnosis, D-HPLC was positive in 89% of the BM samples (110/123) and the quantitative PCR in 89% of the BM samples (59/66) whereas conventional sequencing revealed the D816V mutation in 73% of the BM samples (90/123). Two patients showed the D816H and one patient the D816L mutation. The analysis of PB samples revealed D-HPLC positivity in 48% of the samples (31/65) with a consecutive detection of the D816V mutation by direct sequencing alone in 40% of pts (26/65). D816V mutation was detected by quantitative PCR in 58% of pts (14/24). The mutant proportion of the D816V mutation analysed in the positive samples by quantitative PCR in BM samples was in median 22% (range, 0.5-67%) and in PB samples 22% (range, 2.8-91%). In conclusion, i. D-HPLC is a reliable and sensitive method for the screening of c-kit mutations in SM which is superior to conventional direct sequencing. ii. The quantitative PCR assay for the most common mutation D816V offers easy handling but overlooks rare mutations and is suitable for the surveillance of pts with SM during therapy with novel tyrosine kinase inhibitors. iii. Employing these sensitive techniques, the D816V mutation could be detected in BM as well as in PB samples, but the reliability for a positive result of the mutation was higher in BM.

0569

A NOVEL DENATURING-HIGH PERFORMANCE LIQUID CHROMATOGRAPHY (D-HPLC)-BASED METHOD FOR KIT MUTATION SCREENING OF PATIENTS WITH SYSTEMIC MASTOCYTOSIS

S. Colarossi,[1] S. Soverini,[1] A. Gnani,[1] M. Rondoni,[1] S. Gatto,[2] S. Merante,[2] E. Gottardi,[3] D. CIlloni,[3] P. Musto,[2] M. Tiribelli,[2] R. Zanotti,[2] G. Martinelli,[1] M. Baccarani[1]

[1]Dept. of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Hematology, ALESSANDRIA; [3]Dept of Clinical and Biological Science, ORBASSANO (TURIN), Italy

Background. Systemic mastocytosis (SM) is a clonal disorder characterized by anormal growth and accumulation of mast cells (MC) in various tissues. Kit is a tyrosine kinase transmembrane receptor on the surface of MC. The presence of an enzimatic site (ES) mutation (e.g., D816V) renders Kit resistant to inhibition by imatinib, whereas Kit with juxtamembrane (JM) mutations (e.g., V560G) remains sensitive to imatinib. Sensitive methods are required to assure appropriate therapeutic management of SM patients as the proportion of malignant cells in the available tissues which carry the mutation is small. *Aims*. Our aims were:

to set up and optimize a D-HPLC-based screening method for mutations in critical regions of Kit; to assess the sensitivity and reliability of our D-HPLC assay as compared to RFLP analysis; to characterize additional mutations. *Methods.* Kit mutation analysis was performed on 77 bone marrow and/or peripheral blood samples obtained from 51 patients. For each sample a PCR product of 287 bp, spanning codons 763-858 corresponding to the catalytic loop and to the activation loop, was screened in parallel by D-HPLC assay and by RFLP assay. In case of a positive D-HPLC signal, direct sequencing was performed to confirm the presence of a mutation. The PCR product was digested with the restriction enzime HinfI to detect a GAC-to-GTC nucleotide change at codon 816, leading to a Asp-to-Val amino acid substitution (D816V). For each sample scored as wild-type by D-HPLC and by RFLP analysis, a PCR product of 350 bp, spanning codons 510-626 corresponding to the transmembrane domain and to the juxtamembrane domain, was screened by D-HPLC combined with direct sequencing. *Results.* By RFLP analysis 34/51 pts were positive for the D816V. By D-HPLC analysis, an abnormal eluition profile was seen in 36/51 pts - all the 34 RFLP-positive cases as well as two additional pts. Direct sequencing confirmed the presence of the D816V in all the 34 RFLP-positive cases and showed that in two of these cases a I798I polymorphism was also present. The two pts scored positive by D-HPLC but negative by RFLP were found to have the I798I polymorphism. The 15 pts who did not harbour ES type mutations were further investigated by D-HPLC analysis of a RT-PCR product spanning the transmembrane and juxtamembrane domains. D-HPLC showed an abnormal elution profile in 5 pts. By direct sequencing one patient showed the K546K mutation and 4 pts showed the M541L mutation in the TM domain. *Conclusions.* Our D-HPLC'based assay proved a straightforward, reliable and sensitive method for Kit mutation analysis. Furthermore our D-HPLC-based screening method highlighted the importance of screening for mutations other than the D816V, mainly because the function of Kit regions, such as TM domain, is still unclear.

PREPARING FOR JAK2 V617F TARGETED THERAPY: DEVELOPMENT OF A HIGHLY SENSITIVE AND SIMPLE REAL-TIME RT-PCR METHOD FOR JAK2 V617F TRANSCRIPT QUANTIFICATION

B. Maes, R. Smets, G. Bries, V. Madoe, V. Peeters, J.L. Rummens

Virga Jesse Hospital, HASSELT, Belgium

Background. The identification of the JAK2 V617F mutation, occurring in almost all cases of polycythemia vera (PV) as well as in approximately 60% of cases of essential thrombocythemia (ET), has strongly simplified the diagnosis and classification of these diseases. Recently, it has been suggested that the JAK2 V617F burden may have prognostic significance. In addition, new promising JAK2 V617F targeted drugs are under development. *Aims.* We developed a novel real-time RT-PCR method for quantification of JAK2 V617F transcripts that would allow determination of JAK2 V617F burden at diagnosis as well as the evaluation of the response to newly developed therapeutic agents. *Methods.* RT-PCR reactions were performed on a Rotor-Gene 3000 (Westburg) in single tubes with 1 set of primers and two differently labelled, allele-specific TaqMan probes, directed to respectively wild-type (WT) and mutant (Mut) JAK2 sequences (1 mismatch). Probes were adapted by Locked Nucleic Acid (LNA) modification for increased hybridization specificity and enhanced allelic discrimination. Standard curves were constructed with JAK2 V617F WT and Mut plasmids. Results are expressed as percentage of JAK2 V617F of total JAK2. Whole peripheral blood or bone marrow samples of a total of 54 JAK2 V617F positive cases, including 23 untreated and 7 conventionally treated PV cases and 19 untreated and 5 conventionally treated ET cases, were analysed. In addition, also 30 peripheral blood samples of normal individuals were analysed. *Results.* Reaction efficiencies of this single tube assay for JAK2 Mut and JAK2 WT were equal (97%). Quantities down to 10 copies of JAK2 Mut plasmid amongst WT cDNA and patient JAK2 V617F cDNA diluted down to 0,09% into WT cDNA could be reliably detected. Low intra- and inter-assay variabilities ensure good reproducibility of the assay. None of the negative control samples showed any increase of the fluorescent signal derived from the Mut probe, demonstrating the high specificity of the assay and no requirement for defining a cut-off value. For PV patient samples, the assay showed mean JAK2 V617F quantities of 82% for untreated cases versus 56% for treated cases. Untreated ET cases showed a significantly lower mean JAK2 V617F% compared to untreated PV cases (55% versus 82%). *Conclusions.* We have developed a robust and simple method for quantification of JAK2 V617F transcripts that is more sensitive than all previously described methods. It provides the potential to evaluate the prognostic significance of the JAK2 V617F burden at diagnosis as well as the response to JAK2 V617F targeted therapy that will become available in the near future.

0571

THE VALUE OF CLOSE MONITORING OF WT1 EXPRESSION LEVEL DURING THERAPY AND POST-THERAPY FOLLOW-UP OF ACUTE MYELOID LEUKEMIA: AN INDEPENDENT PROGNOSTIC FACTOR AND A VALUABLE PREDICTOR OF RELAPSE

H.B. Ommen,[1] C.G. Nyvold,[1] K. Brændstrup,[1] B.L. Andersen,[1] H. Hasle,[2] P. Hokland,[1] M. Østergaard[1]

[1]Laboratory of Immunohaematology, ÅRHUS C; [2]Department of Paediatrics, AARHUS, Denmark

Background. The Wilms' tumour gene 1 (WT1) is expressed during normal fetal development, but only to a low extent in adult tissues. However, since it is highly expressed in virtually all AML patients, it has been suggested as a tool for minimal residual disease (MRD) detection and for individualized therapy decisions.[1-2] *Aims.* a) To determine whether high residual WT1 expression in first complete remission (CR1), established by morphology and immunophenotyping, is an adverse prognostic factor, and b) to evaluate the value of WT1 expression levels in peripheral blood (PB) and bone marrow (BM) for prediction of disease relapse. *Methods.* WT1 levels were quantified using real-time quantitative RT-PCR by normalization to the control genes β2M and ABL, and in follow-up samples expressed as a fraction of the BM diagnostic level. (described in detail in (1)) Normal BM and PB WT1 levels were defined as described in.[1] 185 patients (160 adults, 25 children) treated at the Departments of Haematology and Paediatrics, Aarhus University Hospital, were analyzed at diagnosis. A cohort of 89 patients (73 adults, 16 children) were selected for follow-up based on high WT1 expression and lack of fusions transcripts. These patients were sampled at every visit during therapy and follow-up (median number of WT1 determinations per patient: 11, range 2-38). Prognostic difference between groups was determined using the Cox Proportional Hazards statistical model including age, sex, cytogenetics, *de novo* secondary leukemia and FLT3-ITD. When comparing the predictive value of rising WT1 expression levels in PB and BM Wilcoxon's ranksum test was employed. *Results.* When we analyzed the WT1 expression of patients achieving CR1 we found that the disease free survival (DFS) in the group with BM WT1 expression above normal levels at CR1 was significantly shorter than in the BM WT1-normal group (Hazard ratio (HR) = 6,88 (95% Confdence interval (CI) 2,07-22,9), p=0,002). Similarly, the DFS was significantly shorter in the PB WT1 high group vs. the PB WT1 normal group (HR=8,60, CI 1,76-41,9, p=0,008). Of even greater importance, we were able to address relapse kinetics in 29/32 relapses observed in the 89 patient cohort. We were able to detect WT1 above normal levels in 100% of the BM samples that available 3 months before relapse. (Range 1-8, median 4 months). 33% of PB samples were positive 3 months before relapse (Range 0-8, median 1 month). (p=0,0086) *Conclusions.* CR1 WT1 expression levels in both BM and PB are independent prognostic factors in AML. Relapse was seen significantly earlier in BM than PB, but WT1 levels above normal can still be seen in PB in 33% of patients 3 months prior to relapse.

A MOLECULAR CYTOGENETICS STUDY OF THE ROLE OF CHROMOSOME 9P IN CML CELL LINES AND CMPD PATIENT SAMPLES

R. Vaughan, D. Brazma, C. Grace, J.D. Howard, E.P. Nacheva

Royal Free Hospital, LONDON, United Kingdom

Chronic Myeloproiferative Disorders (CMPDs) are a spectrum of haematological malignancies of which the molecular pathogenesis remains unknown. Chronic Myeloid Leukaemia (CML) being the only disorder with a recognisable pathogenomic abnormality, the Ph chromosome. Recent published data has supported the role of tyrosine kinases

in the disease pathogenesis, in particular the role of a cytoplasmic tyrosine kinase JAK2. It has been shown that >80% of Polycythaemia Vera (PV) patients and 30% of Essential Thrombocythaemia (ET) patients demonstrate a clonal and recurrent mutation V617F in the JH2 pseudokinase domain of JAK2 located on 9p24.1. Array CGH investigations of cell lines, established from lymphoid and myeloid blast phase samples revealed a complex pattern of imbalances affecting the short arm of chromosome 9: on the background of 2-3-fold amplification, a loss of the 9p24.1 region, which harbours the JAK 2 along with a number of other kinases, was repeatedly observed. The aim of this investigation was to clarify the aCGH observations using BAC DNA probes from the 9p24.2 and 9p23 region. FISH mapping was carried out to map the JAK2 gene and the flanking sequences. Results so far indicate the presence of both imbalances (amplifications & deletions) and rearrangements involving the JAK2 region in 5 cell lines. This work is now being extended to include BAC clones telomeric and centromeric to JAK2. An on going FISH study of CMPD patients (CML, PV, ET and MF) with normal and abnormal karyotypes has revealed 9p24 imbalances in 18% (5 out of 28). The pathegenomic significance of aberrations found in the region surrounding JAK2 has yet to be defined and our study demonstrates the importance of molecular cytogenetics in exploring the importance of 9p in the CMPD disease model.

ANALYSIS OF 482 PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) FOR THE IDENTIFICATION OF MUTATIONS IN THE PROMOTER REGION AND THE CODING SEQUENCE OF THE CEBPA GENE BY CAPILLARY ELECTROPHORESIS

C. Juhl-Christensen,[1] M. Bomberg,[1] D. Melsvik,[1] M. Oestergaard,[1] H. Hasle,[2] P. Hokland,[1] C. Nyvold[1]

[1]Laboratory of Immunohematology, AARHUS; [2]Department of Pediatrics, AARHUS, Denmark

Background. The CEBPA gene encodes a transcription factor, CCAAT/enhancer binding protein (C/EBP)α. The wildtype (WT) protein is essential for the lineage specific differentiation of myelocytic haematopoietic precursors into mature neutrophils. Approximately 9% of all AML patients harbour one or more mutations in this gene, while the frequency in the cytogenetically negative group of patients is reported to comprise up to 15%. Until recently, the mutational status of the gene has been determined using cloning and sequencing. *Aims.* We designed a fragment analysis using capillary electrophoresis that enabled us to discriminate as little as a single base pair insertion or deletion accounting for about 90% of all CEBPA mutations. *Methods.* Diagnostic bone marrow (BM), or when not available peripheral blood (PB), from 444 adults and 38 children diagnosed with AML at a single centre from 1980 to date and from whom bio banked material was available were assessed for mutations employing fragment analysis. Mononuclear cells were isolated, cryopreserved, and stored until use at -80°. Genomic DNA was extracted from approximately 1 million mononuclear cells and eluted in a volume of 100 µL using MagNa-Pure LC Robot (Roche Diagnostics, Basel CH). Four overlapping and tailed primer pairs were designed to cover the entire coding sequence and the region upstream the intronless gene using Oligo (Primer Analysis Software, version 6.83, Molecular Biology Insights, CO, USA) and purchased from Applied Biosystems (Foster City, CA, USA). PCR was performed for each primer pair and subsequently the PCR products for each patient were pooled and transferred to capillary electrophoresis on a 3130 Genetic Analyzer (Applied Biosystems). The T-Cell line 8402 was included as a wildtype control. The results were analysed using GeneMapper software version 3.7 (Applied Biosystems). Samples harbouring insertions or deletions were identified and sequenced directly on both forward and reverse strand. *Results.* We analyzed 482 patients hereof 38 children. In total, we identified 45 abnormal PCR fragments in the CEBPA gene in 37/444 (8,3%) and 1/38 (2,6%) adult and childhood AML patients respectively. Using the method described above we were able to distinguish between N- and C- terminal mutations and reached the same mutational frequency as described in the literature. *Conclusions.* We conclude that fragment analysis by capillary electrophoresis can be used as an easy and high throughput diagnostic procedure for the mutational status in the CEBPA gene.

0574

GENE POLYMORPHISMS OF METHYLENTETRAHYDROFOLATREDUCTASE IN MALIGNANT DISEASE

R. Simanek, R. Vormittag, P. Bencur, C. Ay, G. Alguel, C. Zielinski, U. Jaeger, I. Pabinger, C. Mannhalter

Medical University of Vienna, VIENNA, Austria

Background. Methylentetrahydrofolatreductase (MTHFR) plays a role in the human folate metabolic pathway. The MTHFR 677 C>T polymorphism is associated with a reduced enzyme activity, which leads to a reduced probability of DNA double-strand breakage. A number of studies focused on the polymorphism's influence as a risk factor for different malignancies, however, data are conflicting. *Aims.* It was the aim of our study to analyse the prevalence of mutations in patients with malignant disease and healthy controls. *Methods.* Between October 2003 and July 2006, 427 patients with solid malignant tumours (225 female/202 male; mean age=62y) of the breast, lung, stomach, colon and prostate and 80 patients with haematological malignancy (32 female/48 male; mean age=56y) including Hodgkin's lymphoma, non-Hodgkin's lymphoma and multiple myeloma were enrolled. Seventy-four healthy controls were matched for age and sex (36 female/38 male, mean age=61y). MTHFR genotype was analysed with MS-PCR. *Results.* Genotype distribution was in Hardy-Weinberg equilibrium and 41% CC, 45% CT and 13% TT in patients with solid tumours, 38% CC, 54% CT and 9% TT in those with haematological malignancies and 31% CC, 51% CT and 18% TT in healthy controls (p-values for pair-wise comparisons not significant). TT genotype was not associated with a significantly reduced risk for malignancy in univariate analyses (solid tumours: OR=0.6 [95% CI=0.3-1.2], p=0.14, haematological malignancies: OR=0.4 [0.1-1.2], p=0.10, respectively). In a subgroup analysis for colorectal carcinoma (n=97, 46% CC, 44% CT and 9% TT) MTHFR 677 TT was associated with a significantly lower risk in univariate (OR= 0.35 [0.13-0.95], p=0.039) and bivariate analyses corrected for age (OR=0.37 [0.137-0.997], p=0.049). Summary/*Conclusions.* MTHFR 677 C>T polymorphism seems to modulate the risk for selected malignancies, but it does not seem to influence the risk for developing cancer in general.

0575

A HIGHLY SENSITIVE METHOD FOR DETECTION OF HAEMOPOIETIC CHIMERISM IN ALLOGENEIC HAEMOPOIETIC STEM CELL TRANSPLANT RECIPIENTS

A. Abdallah,[1] L. Pearce,[2] A. Mijovic,[3] G. Mufti,[2] K. Tobal[2]

[1]National Blood Bank Service, King's College Hospital LONDON; [2]King's College London, Rayne Institute, LONDON; [3]National Blood Bank Service, LONDON, United Kingdom

Background. The ability to detect donor cell engraftment in reduced intensity conditioning allogeneic hematopoietic stem cell transplant recipients with high sensitivity would enable early detection of patients at high risk of relapse. *Methods.* Sixteen specific biallelic polymorphic markers were selected to identify informative markers for analysis of chimerism in transplant donor/recipient pairs. Four informative markers were then used in SYBR green Q-PCR to quantify post-transplantation chimerism in serial samples from these patients. The percentage of donor cells was calculated using a standard curve, constructed using artificially mixed donor/recipient chimeric DNA in 8 serial dilutions (0.01-100%). A linear correlation with r higher than 0.98 and a sensitivity of 0.1% proved reproducible. DNA from 9 donor/recipient pairs was retrospectively screened for informative markers and 38 post-transplant samples were monitored for chimerism using the SYBR green Q-PCR method. *Results.* We were able to find at least 4 different informative markers for 7 donor/recipient pairs, 2 markers for 1 donor/recipient pair and 1 marker for 1 donor/recipient pair. These results were compared to the existing method using PowerePlex 16 microsatellite STR analysis kit (Promega). The detection limit of the Q-PCR method was 0.1%, which is significantly higher than that achieved with STR methodology (5%). This high sensitivity enabled us to predict relapses up to 4 months earlier than the STR method. *Conclusions.* this assay is highly sensitive and provides an accurate quantitative assessment of mixed chimerism that can be useful in evaluating patients' response to transplantation and distinguishing those at high risk of relapse at an early stage to enable implementation of additional treatments. Detailed analysis of data from large cohort of transplant patients will be presented.

0576

WESTERN BLOT IDENTIFICATION OF NPM1 LEUKEMIC MUTANTS IN CYTOLOGICAL AML SAMPLES: A POWERFUL DIAGNOSTIC TECHNIQUE

M.P. Martelli, N. Manes, A Liso, B Verducci Galletti, V. Pettirossi, M.T. Pallotta, N. Bolli, R. Pacini, A. Tabarrini, F. Di Raimondo, F. Fabbiano, G. Specchia, M.F. Martelli, B. Falini

Hematology, BARI, Italy

Nucleophosmin (NPM1) mutations occur in 50-60% of adult acute myeloid leukemia (AML) patients with normal karyotype and are predictors of favourable prognosis. For these reasons, analysis of NPM1 mutations has recently become a major new step in the diagnosis and prognostic stratification of AML patients. About 40 different molecular NPM1 mutation variants have been so far identified, with about 90% represented by mutation A (about 80%) and B (about 10%), other NPM1 mutations being extremely rare. Mutations of the NPM1 gene can be reliably identified by molecular biology techniques or by immunohistochemistry through detection of aberrant cytoplasmic NPM positivity (NPMc+). Mutational analysis is carried out only in specialized laboratories; immunohistochemistry overcome this problem but it is only applicable to paraffin sections from bone marrow biopsies. Hereby, we describe a highly sensitive and specific Western blot method that allows the easy identification of NPM1 leukemic mutants in cytological samples from AML patients. Rabbit polyclonal antibodies were generated against the altered C-terminal portion of the most common NPM mutant protein (type A). Western blot analysis of a selected number of AML samples proved that these antibodies reacted specifically with the NPM mutant but not with the wild-type NPM protein. These findings prompted us to use this method to analyze systematically cytological leukemic samples and to compare blindly the results obtained by Western Blot with those derived from immunohistochemical studies and, when available, from NPM1 mutational analysis. A total of 114 AML patients classified by immunohistochemistry into $NPMc^+$ (cytoplasmic-positive; n=57) and NPMc- (cytoplasmic-negative; n=57) were enclosed in the study. Western Blot analysis was performed retrospectively in 83 AML cases and prospectively in 32 cases. We investigated a total of 174 cytological preparations (82 from $NPMc^+$ and 92 from NPMc- AMLs) of various types, including frozen dry cell pellets of Ficoll-isolated leukemic cells; 1 to 2 drops of fresh whole bone marrow or peripheral blood; or even cells obtained scraping the surface of leukemic cytospins or smears. Western Blot analysis was performed according to standard procedures. Seventy-two out of 82 (88%) $NPMc^+$ AML samples resulted positive at Western Blot analysis. Results obtained in cytological material of different types were comparable, indicating the high flexibility of the method. However, retrospective Western Blot analysis of badly preserved leukemic smears sometimes gave negative *Results.* In addition to NPM mutant A, the specific anti-NPM mutant antibodies recognized NPM mutant proteins of type B, D, E, and L. For patients studied prospectively, Western Blot analysis predicted NPM1 mutation in all (16 out of 16) $NPMc^+$ AML patients investigated. Importantly, no false-positive results were registered. In conclusion, Western Blot analysis represents a new highly sensitive, specific and low cost assay for detecting the most common NPM1 mutations in AML cytological samples processed in different ways. This also represents the first example of employment of Western Blot for identification of a specific genetic lesion in AML, that should turn out to be very useful not only for leukemia diagnosis but also for research purposes.

HLA AND IMMUNOGENIC MARKERS IN PATIENTS WITH LGL-CD3+ PHENOTYPE

P. Garrido,[1] J. Almeida,[2] J. Canton,[1] M.A. Lopez-Nevot,[1] Y. Sandberg,[3] A. Langerak,[3] F. Garrido,[1] A. Orfao,[2] F. Ruiz-Cabello[1]

[1]Hospital Virgen de las Nieves, GRANADA, Spain; [2]Cancer Investigation Center (CSIC-USAL), SALAMANCA, Spain; [3]Erasmus Medical Center, ROTTERDAM, Netherlands

Background. T - Large granular lymphocyte lymphocytosis (LGL) represents a clonal expansion of both $CD3^+$ cells and natural killer (NK) cells. The most common phenotype typical for this condition is T α/β $CD3^+$, $CD8^+$, $CD57^+$. Autoimmune diseases (arthritis, erithroblastopenia) are frequently associated with LGL, although, these conditions frequently have a benign course. Recent studies support an idea that a subtype of LGL, TCR α-β+/$CD4^+$ T-large granular lymphocyte (LGL) lymphocytosis, represents a clonal expansion with a CDR3 sequence homology in TCR and a common HLA DRB1*0701 genotype, and has an antigen-driven mechanism underlying its origin (Garrido et al. Blood. 2007. February. PMID: 17303697). Considering that HLA DRB1*0701 is a frequent allele in the Caucasian population, a possible defect in the immune regulation could be relevant in the development of this clonal expansion. OBJECTIVES: To analyse the possible implications of functional polymorphisms in IFN- γ, CTLA - 4, IL10, IL4, TNF-α, FAS, FASL, and MICA genes in association with autoimmune diseases and persistent viral infections predisposing development of LGL $CD4^+$, $CD8^+$. *Methods.* In 41 cases with LGL - T- $CD3^+$, $CD8^+$ and in 40 cases with LGL- $CD4^{++}$, CD8+ we performed a single nucleotide polymorphism (SNPs) genotyping using a Taqman 5´ allelic discrimination assay. PCR reactions were carried out in a total reaction volume of 5 microlitres with the following amplification protocol: denaturation at 92°C for 15 seconds, followed by an annealing and extension at 58ªC for 1 min. Post-PCR, the genotype of each sample was assigned automatically by measuring the allele -specific fluorescence on the ABI FAST 7500 Sequence Detection Systems using the SDS 1.3.1 software for allelic discrimination (Applied Biosystems, Foster City, CA, USA). The results were compared with 170 DNA samples from a healthy population obtained from a blood bank. *Results.* the frequencies of the studied allelic polymorphisms in the LGL $CD4^+$, $CD8^+$ population were similar to that found in control group. *Conclusions.* The results obtained suggest that the analyzed polymorphisms do not seem to play a major role in the LGLs susceptibility.

GvHD - GvL - graft rejection

LUNG TRANSPLANTATION AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Dodds,[1] V. Potter,[1] K. Bradstock,[2] T. O'Brien,[3] A. Glanville[1]

[1]St Vincents Hospital, SYDNEY; [2]Westmead Hospital, SYDNEY, Australia; [3]Sydney Children's Hospital, SYDNEY, Australia

Background and Aim. Pulmonary complications cause significant morbidity and mortality after haematopoietic allogeneic stem cell transplant (HSCT). We describe our experience with bilateral lung transplantation as a therapeutic option in HSCT patients with end-stage lung disease. *Methods.* Cases were identified via search of database information from St Vincent's Hospital and personal contact with lung transplant units in Australia. Information from medical records of identified cases was analysed. Pathology specimens of the end stage lung were reviewed. *Results.* Five cases have been identified. All received HLA matched allogeneic transplants from related donors (four sibling, one maternal) for haematological disease (three CML, one AML, one aplastic anaemia). Conditioning was with Cy/Bu in four patients and Cy/TBI in one. Graft versus Host Disease (GVHD) prophylaxis was with CsA/MTX. Acute GVHD (grades II-III) occurred in two patients. Chronic GVHD other than lung occurred in three. Pathology review confirmed the diagnosis of bronchiolitis obliterans (BO) in three patients, interstitial fibrosis in a fourth, and a mixed process in the fifth. Time from HSCT to lung transplant ranged from 23 to 125 months. Four of five patients are alive after lung transplant with no evidence of relapse of haematological malignancy (range +8 to+74 months). One patient died three years after lung transplant from Post-Transplant Lymphoproliferative Disorder. The remaining patients maintain normal pulmonary function. Morbidity in the living patients includes gastro-oesopharangeal reflux disease, osteoporosis, hypertension, mild renal impairment, and opportunistic infections (CMV, aspergillus colonization, MAC reactivation, herpes zoster and simplex). Marrow function is normal and performance status ECOG 0-1 in the surviving patients. *Conclusions.* Lung transplantation is a viable therapeutic option for patients with prior HSCT and end-stage lung disease. Interesting questions requiring further research include those related to causative processes, HLA matching, stem cell dose, prevention and therapy of end stage lung disease. Ongoing immunosuppression does not appear to affect recipient bone marrow function or contribute to relapse.

0579

THE GRAFT CONTENT OF DONOR T-CELLS EXPRESSING γ/δ TCR+ AND CD4+FOXP3+ PREDICTS THE RISK OF ACUTE GRAFT VERSUS HOST DISEASE AFTER TRANSPLANTATION OF ALLOGENEIC PERIPHERAL BLOOD STEM CELLS FROM UNRELATED DONORS

U. Platzbecker, C. Pabst, G. Ehninger, M. Bornhauser

Universitätsklinikum Carl Gustav Carus, DRESDEN, Germany

Purpose. Recently, high numbers of regulatory T-cells within the stem cell graft were described to be associated with less graft versus host disease (GVHD) after related peripheral blood stem cell transplantation (PBSCT). Studies in mice also suggest a distinct role of γ/δ TCR+ T-cells in mediating GVHD. Therefore, the aim of this study was to define the yet unknown role of regulatory and gamma/delta TCR+ T-cells in human PBSCT from unrelated donors. *Experimental design.* The frequency of both T-cell subsets within the graft was analyzed in 63 patients receiving unrelated allogeneic PBSCT. The respective amounts were quantified by flowcytometry and PCR and further correlated with clinical outcome. *Results.* The grafts contained a median of 11.2×10^6/kg $CD4^+foxp3^+$ and 9.8×10^6/kg γ/delta TCR^+ T-cells, respectively. Patients receiving more $CD4^+foxp3^+$ cells had a lower cumulative incidence of acute GVHD II-IV (44% vs. 65%, p=0.03). Interestingly, in patients who received higher concentrations of donor γ/delta TCR^+ T-cells acute GVHD II-IV was more frequent (66% vs. 40%, p=0.02). In multivariate analysis only the graft concentration of γ/δ TCR^+ T-cells (p=0.002) and a positive CMV-status of the recipient (p=0.03) were significantly associated with the occurrence of acute GVHD II-IV. *Conclusions.* Graft composition of T-cell subsets seems to affect the outcome of patients receiving allogeneic PBSCT from unrelated donors. Therefore, selective manipulation or add-back of particular subsets might be a promising strategy to reduce the incidence of GVHD.

TREATMENT OF STEROID REFRACTORY GRAFT VS. HOST DISEASE BY INTRA-ARTERIAL INFUSION

M.Y. Shapira, A.I. Bloom, R. Or, I.B. Resnick, M. Aker, M. Bitan, S. Slavin, A. Verstandig

Hadassah Hebrew University Medical Cen, JERUSALEM, Israel

Introduction. Graft versus host disease (GVHD) still is the major draw-back of allogeneic stem cell transplantation (SCT). In its resistant form, it carries high morbidity and mortality. The mainstay of GVHD therapy is preventive and once it is developed the first line therapy is systematically high dose steroids, and cyclosporine or tacrolimus. It has been shown by us and other groups, that intra-arterial targeted steroid therapy may be useful even in steroid refractory GVHD. *Methods.* A total 35 patients with 37 cases of steroid resistant/dependent gastrointestinal (GI) (n=16), hepatic (n=15) or combined (n=6) GVHD, were included and given intra-arterial treatment, for one or more of the following arteries - the hepatic, gastro-duodenal, superior mesenteric, inferior mesenteric, internal iliacs. We defined GI partial response and complete response as the day that symptoms decrease or resolved, respectively. Hepatic partial response and complete response were defined as the day that bilirubin level began to decrease or decreased below 30% of initial level, respectively. *Results.* The procedure was safe with no major complications. We found that Intra-arterial catheter guided steroid therapy was associated with partial and complete remission among patients with steroid resistant or dependent GI or Hepatic GVHD. Hepatic partial response was observed in 14 (66.6%) patients among whom 7 (33.3%) reached complete response. GI partial response was observed in 19 (86.4%) patients among whom 12 (54.4%) reached complete response. An early administration of the local therapy, female gender, myeloid basic disease, and a non-active status of the basic disease at the day of transplantation were found related for predicting a better response for the intra-arterial treatment. *Conclusions.* Intra-arterial catheter guided steroid therapy is safe and effective in steroid resistant or dependent GVHD. A further research is warranted characterizing the patients benefit most.

0581

TREATMENT OF CHRONIC EXTENSIVE GRAFT VERSUS HOST DISEASE WITH ALEFACEPT

M.Y. Shapira, I.B. Resnick, P. Tsirigotis, M. Aker, M. Bitan, B. Gesundheit, S. Slavin, R. Or

Hadassah Hebrew University Medical Cen, JERUSALEM, Israel

Introduction. Alefacept (AMEVIVE®) is an immunosuppressive dimeric fusion protein that consists of the extracellular CD2-binding portion of the human leukocyte function antigen-3 (LFA-3) linked to the Fc (hinge, CH2 and CH3 domains) portion of human IgG1. We have recently shown its effect in acute, steroid resistant/dependent GVHD. In this study, we describe the effect of alefacept treatment on chronic extensive graft versus host disease (cGVHD). *Patients and Methods.* A total of 12 patients (13 cGVHD episodes) were included in this study, 7 males and 5 females with median age 27 years (range 3-60 years).

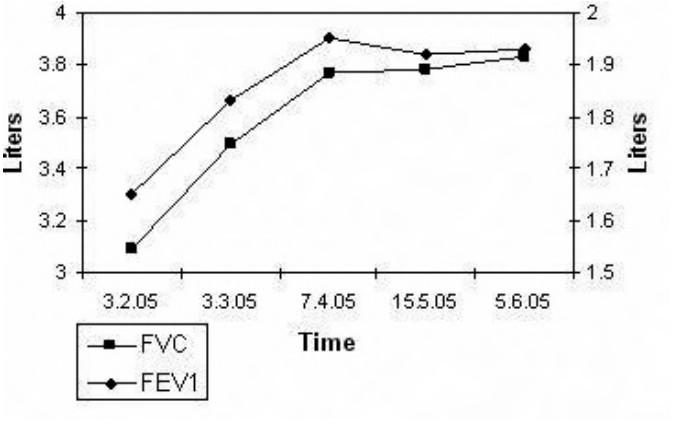

Figure 1. Pulmonary function test.

Basic disease was AML (n=5), ALL (n=3), NHL (n=1), hemophagocytosis (n=1) and malignant melanoma (n=1). Seven patients were transplanted from HLA-A, B, C and high resolution DR fully matched family members (siblings=6, father=1); 2 patients received stem cell graft from fully matched unrelated donor (MUD) non-reactive in mixed lymphocyte culture; 2 from mismatched family members and 1 from a matched unrelated cord blood unit. All patients had an extensive cGVHD.Alefacept dose for children was 15 mg given intramuscularly (IM) once weekly. The dose for adults was 30 mg IM once weekly. *Results.* a median of 9 (range 1-25 injections were given to the patients. Eight out of 12 patients (9/13 episodes) showed response. The median time to initial response was 2.25 weeks (range 1-8). The response was either marked (n=3), moderate (n=2) or minimal (n=4). One patient with pulmonary GVHD had a consistent improvement (Figure 1). In 2 responding patients, the response was only temporary. Treatment complications included infection (n=3), pericarditis (n=1) and squamous cell carcinoma of the lip (n=1). All these events may be related to other drugs given simultaneously. Currently, 7/12 patients are alive all with stable or improved cGVHD. Five patients died due to GVHD progression. Conclusions. Alefacept is effective for the treatment of cGVHD, dose and treatment's time intervals should be explored.

0582

EPIGENETIC REGULATION OF ADHESION IN HEMATOPOIETIC AND LEUKEMIC STEM CELLS

U. Mahlknecht, U. Mahlknecht, Ch. Schönbein

University of Heidelberg, HEIDELBERG, Germany

The $\alpha 4 \beta 1$ integrin very late activation antigen-4 (VLA-4) plays a key role in the adhesion of both hematopoietic progenitor cells and leukemic blast cells to bone marrow stromal cells expressing the vascular cell adhesion molecule-1 (VCAM-1). VLA-4 is an a4 (CD49d)/b1 (CD29) heterodimer and its expression on leukemic cells has been associated with bone-marrow minimal residual disease (MRD). Conversely, the absence of VLA-4 reduces bone marrow retention of both hematopoietic progenitor and leukemic blast cells. In this study, we have demonstrated a downregulation of VLA-4/CD49d on various AML cells lines, on primary cells from AML patients and on hematopoietic stem cells and peripheral blood mononuclear cells from healthy donors upon treatment with the histone deacetylase inhibitors suberoylanilide hydroxamic acid (SAHA) and valproic acid (VPA). This was also functionally associated with decreased adhesion to mesenchymal stromal cells. These findings suggest that HDAC-inhibitor treatment might impair homing of both normal and leukemic progenitors to the bone marrow. On the other hand it might also facilitate the mobilization of hematopoietic progenitors.

0583

CLINICAL BENEFIT OF TREATMENT WITH SYNTHETIC PGI-2 IN PATIENTS SUFFERING FROM RESISTANT SCLERODERMIC CHRONIC GVHD AFTER ALLOGENEIC HEMOPOIETIC STEM CELL TRANSPLANTATION

M. Sorio, A. Andreini, D. De Sabata, R. Di Bella, S. Ledro, G. Ruggeri, C. Tecchio, M. Tinelli, F. Benedetti

BMT unit, VERONA, Italy

Background. Scleroderma is a late manifestation of cGVHD, presenting as progressive tightness of the skin and hampering patients' quality of life. In recent times Iloprost, a synthetic PGI-2, has been proving effective in the therapy of idiopathic systemic sclerosis, which has a similar pathogenesis to sclerodermic cGVHD. *Patients and Methods.* From 2001 to 2006 we observed 9 pts. affected by diffuse or limited sclerodermic cGVHD. The patients (8 affected by acute leukemia, 1 by NHL) were transplanted with classical conditioning regimen (FTBI 1200 cGy plus Cytoxan 120 mg/Kg) from their sibling donors. The source of stem cells was bone marrow in 3/9 cases and peripheral blood in 6/9 cases. Chronic GVHD was observed at a median of 20 months from HSCT (range 11-36), presenting as diffuse skin changes (tightness and thickening of the face, neck, hands, thorax and abdomen), cutaneous dyschromia, digital pitting scars and functional joint impairment. In two patients these alterations were linked with itching and pain. In all cases cGVHD severely affected quality of life. It was limited to the skin in 8/9 cases, and involved internal organs in the other one (liver and lungs); in two cases diffuse scleroderma was associated with severe discomfort in tendons or muscles. In seven cases it presented as *de novo* cGVHD. All pts had already been treated with various regimens including CSA, azathioprine, mofetil mycophenilate, steroids, repeated cycles of PUVA with little or no effect on the skin. Iloprost, 50 microgram a day over 8 hours IV continuous infusion for 5 days every month, was started after a median of 8 months from the appearance of cGVHD (range 1-64). *Results.* The drug was well-tolerated with little or no severe side effects: the most frequent side effect was mild hypotension. No other major side effects were observed. In 8/9 cases we saw a significant clinical benefit after a median of 5 cycles (range 3-12). Further improvement was observed over the subsequent courses. Iloprost courses were given in Outpatient Department for at least 8-10 courses every month until a satisfactory clinical response that was obtained after a median of 5 courses. In all cases the patients received a maintenance therapy with 3-4 treatments a year. At present, one patient has died because of relapse of acute leukaemia, 7 out of the 8 remaining pts are alive and well, with satisfactory improvement of quality of life. One patient, poor responder, is still on Iloprost, with stable severe skin Scleroderma after 14 cycles. *Conclusions.* In our study Iloprost seems to be one of the most effective drugs in reverting sclerodermic diffuse cGVHD and in reducing the extension of the skin lesions. Skin tenderness and disappearance of pain were reached after less than 6 months from the beginning of symptoms. The quality of life has improved dramatically in all but one case.

0584

ANALYSIS OF BONE MARROW-RESIDING CD4+CD25+FOXP3+ T REGULATORY CELLS IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH ALLOGENEIC STEM CELL TRANSPLANTATION

D. Atanackovic, Y. Cao, T. Luetkens, C. Faltz, K. Bartels, C. Wolschke, A.R. Zander, C. Bokemeyer, N. Kröger

University Medical Center Hamburg, HAMBURG, Germany

Introduction. Peripheral tolerance is largely maintained by immunosuppressive regulatory T cells (Treg), such as $CD4^+CD25^+$ T cells co-expressing transcription factor forkhead box P3 (FOXP3) and it has been suggested that Treg contribute to the prevention of graft-versus-host disease (GVHD) following allogeneic stem cell transplantation (alloSCT). Unfortunately, Treg also represent a main obstacle of an effective anti-tumor T cell response and depletion of $CD4^+CD25^+FOXP3^+$ Treg seems to enhance anti-tumor immunity. It is unclear, however, whether a reduced number or function of Treg might play a role in the induction of graft-versus-myeloma (GVM) effects in multiple myeloma (MM) patients post alloSCT and very little is known about Treg residing in the bone marrow (BM) of these patients. *Aims and Methods.* We performed the first systematic analysis of Treg numbers and function in the BM and in the peripheral blood (PB) of MM patients treated with alloSCT (N=40), newly diagnosed MM patients (N=17), and healthy BM donors (N=20) using flow cytometry and functional assays. Mechanisms which might serve as potential mediators of the immunosuppressive function of BM Treg were investigated using real-time PCR. *Results.* Following alloSCT, donor-derived $CD4^+CD25^+FOXP3^+$ Treg expanded faster than conventional $CD4^+$ T cells, leading to an accumulation of Treg in the BM of transplanted patients. Since patients post alloSCT are devoid of a relevant thymic function, Treg reconstitution was most likely based on peripheral expansion. This idea was supported by the fact that reconstituted BM $CD4^+CD25^+FOXP3^+$ Treg of MM patients post alloSCT consisted preferably of CD45RA-CCR7- memory T cells. BM-residing Treg of newly diagnosed and MM patients post alloSCT showed a strong inhibitory function and transforming growth factor (TGF)-β1 seemed to represent an important mediator of Treg function in the BM of MM patients post alloSCT and might also be involved in the expansion of BM-residing $CD4^+CD25^+FOXP3^+$ Treg. *Conclusions.* Our study demonstrates for the first time that BM-residing Treg expand outside the thymus and accumulate in the BM of MM patients post alloSCT. These Treg, which are donor-derived and lead to an efficient replenishment of Treg in the periphery, might be necessary for the prevention of GVHD. However, BM Treg might also contribute to the failure of an effective GVM effect in these patients.

0585

IS THERE A DIFFERENCE IN OUTCOME AND INCIDENCE OF ACUTE/CHRONIC GVHD IN PEDIATRIC PATIENTS UNDERGOING UNMANIPULATED MUD-PBSCT VS MUD-BMT? SINGLE LARGE CENTER EXPERIENCE

K. Kalwak, E. Gorczynska, M. Ussowicz, J. Owoc-Lempach, D. Wójcik, M. Slociak, A. Dyla, A. Chybicka

Wroclaw Medical University, WROCLAW, Poland

There is an unresolved question whether unmanipulated matched

unrelated donor (MUD) PBSCT leads to a worse overall outcome and higher incidence of severe GvHD in both adults or children in comparison with well established MUD-BMT. It is well known that PBSC grafts contain ca 1 log more mature T cells, which may result in higher rate of severe often fatal acute/chronic GvHD after MUD-PBSCT. The aim of our study was to compare the results of MUD-PBSCT vs MUD-BMT in a large pediatric patient population. We analysed the records of 157 pediatric pts (ALL n=57, AML n=25, CML n=28, MDS/JMML n=14, NHL/HD n=6 and nonmalignant disorders n=27), who underwent MUD-BMT (39 pts) or MUD-PBSCT (118 pts) between 1999 and 2006 in our institution. Probability of overall survival for all pts after MUD-PBSCT was 0.53 and after MUD-BMT was 0.45, whereas pDFS after MUD-PBSCT was 0.53 and after MUD-BMT - almost significantly worse 0.39 (p=0.07). Median follow up of surviving 90 pts (57%) was 2 years and of dead 67 pts was 4 months. Probability of DFS for pts after MUD-BMT was for ALL 0.4, for AML 0.17 and for CML 0.67, respectively, whereas it was much higher for pts after MUD-PBSCT for AML 0.69 (p=0.01 log-rank) and not lower for pts with ALL 0.38 and CML 0.56, respectively. Furthermore, there was no difference between the incidence of both acute GvHD grade III-IV between the recipients of MUD-PBSCT (19.5%) or MUD-BMT (20.5%) and extensive chronic GvHD (19.6%for MUD-PBSCT recipients and 15.4% for MUD-BMT recipients), respectively. In conclusion the results of MUD-PBSCT in a large prospective pediatric cohort of pts are similar if not better that the results of MUD-BMT. There seems to be no increased risk of severe GvHD after MUD-PBSCT. MUD-PBSCT seems to offer a better disease control in patients with malignancies, especially with AML due to more pronounced T-cell mediated GvL effect.

STUDIES IN C3 DEFICIENT MICE REVEAL BENEFICIAL ROLE OF COMPLEMENT IN AMELIORATING CONSEQUENCES OF GRAFT-VERSUS-HOST DISEASE AFTER HEMATOPOIETIC ALLOTRANSPLANTATION

O. Wiecha,[1] E. Lesko,[1] W. Miezynski,[1] L. Wojakowski,[2] M.Z. Ratajczak,[2] M. Majka[1]

[1]Jagiellonian University Medical College, KRAKOW, Poland; [2]University of Louisville, LOUISVILLE, USA

Graft-versus-host disease (GvHD) is the main complication after allogeneic hematopoietic stem cell transplantation. Immunosuppressive regimen used in its prevention and treatment is only partially effective making research focusing on new possibilities for control of GvHD necessary. While activation of complement during GvHD has been observed there are no published data concerning its significance for GvHD pathophysiology. The aim of the study was to evaluate the role of complement in pathogenesis of GvHD by employment of C3 knock-out animals. $C3^{+/+}$ (n=90) and $C3^{-/-}$ (n=74) mice from the C57/BL6 background were transplanted with 5×10^6 BM cells and 4×10^6 or 10×10^6 splenocytes isolated from allogeneic H2 and sex mismatched C3H mice or from C57/BL6 syngeneic animals(21 $C3^{+/+}$, 22 $C3^{-/-}$) one day after ablative TBI. Mice were weighted and physically examined by looking for changes in skin, posture, physical activity and chimerism in transplanted animals was confirmed by detection of sry gene with real-time PCR. Peripheral blood morphology assessment and fluorocytometric analysis of peripheral blood lymphocytes were performed for some animals on days +17, +31 and +45. Histopathological examination was performed in randomly chosen animals on day +8 and +16 and furthermore on most of mice which died during the experiment. Evident physical (weight loss, skin desquamation, hunching) and histopathological (involvement of liver, skin, spleen and gut) symptoms of GvHD were observed in all mice transplanted with allogeneic cells but not in mice transplanted with syngeneic cells. Analysis of peripheral blood of allotransplanted animals revealed severe lymphopenia affecting B and T cells, strongly increased expression of CD69 activation antigen on $CD4^+$ and $CD8^+$ cells and lower values of RBC, Hb, Hct and MCV as compared to syngeneic controls. The most important difference between $C3^{-/-}$ and $C3^{+/+}$ allogeneic graft recipient populations was significantly worse survival of C3 deficient animals (median: 50 vs. 63, mean: 112 vs. 158 days, hazard rate=1.62, p=0.028; Figure 1). Characteristic pattern of weight loss was observed consisting of a fall to ca 86% of initial body weight on day +7 followed by return to the initial weight on days +14 to +17 and another decrease in weight leading either to the death of the animal or to a long time plateau. The average weight of $C3^{-/-}$ animals was significantly lower on day +10 as compared to $C3^{+/+}$ mice (90,1% vs. 93,7%, p=0.002). Interestingly, the body weight on day +10 was strongly correlated with overall survival (p=0.001). Blood examinations revealed higher WBC count in C3-/- knock-out mice on day +45 (19 vs. 11×10^3/uL, p=0.024). Skin changes tended to be less severe in wild type animals but observed differences were not statistically significant. This study showed for the first time the beneficial role of the complement cascade in ameliorating consequences of GvHD in mice. The positive influence of the cascade on the overall survival is particularly interesting because of its potential clinical implications. In the light of our data, assessment of the role of complement in the course of GvHD in transplanted patients could be interesting in the future.

Figure 1. Kaplan-Meier survival curves for populations of $C3^{-/-}$ (ko) and $C3^{+/+}$ (wt) mice transplanted with allogeneic (allo) and syngeneic (syn) cells.

A COMPARISON OF THE CYTOTOXIC EFFECTS OF 4 COMMERCIALLY AVAILABLE PREPARATIONS OF ANTI-T CELL GLOBULINS IN VARIOUS HEMATOLOGICAL MALIGNANCIES

A. Ayuk, N. Maywald, S. Hannemann, U. Larsen, A.R. Zander, K. Nicolaus

University Medical Center Hamburg, HAMBURG, Germany

Background. Polyclonal anti-T-cell globulins (antithymocyte globulins), ATGs are widely used in allogeneic stem cell transplantation mainly due to their anti-T cell activity. ATGs however contain a wide range of antibodies targeting antigens expressed on various hematopoetic cells. Lymphoglobulin® and Atgam® are produced by immunizing horses with human thymocytes. Thymoglobulin® is produced by immunizing rabbits with human thymocytes, while ATG-Fresenius® is produced by immunizing rabbits with the jurkat cell line. We have previously reported potent ant-myeloma activity of ATG-Fresenius®. Similar data were later reported for Thymoglobulin®. Various ATG preparations have been shown to induce apoptosis in malignant B cell lines. Future conditioning regimens may therefore take advantage of the direct effects of ATGs against hematological malignancies. *Aims and Methods.* We sought to compare the cytotoxic activity of 4 commercially available ATG preparations in myeloma cell lines and myeloma patient samples, B-NHL cell lines and CLL patient samples, myeloid leukemia cell lines as well as primary T cell samples. Viability was assessed by staining with 7AAD and subsequent flow cytometry. *Results.* In all, Atgam® showed significantly lower anti-T cell activity compared to the other 3 ATG preparations. Atgam® also showed significantly lower anti-leukemia activity compared to the other 3 ATG preparations. The anti-CLL effect of Thymoglobulin® was twice as strong as that of ATG-Fresenius®. Thymoglobulin®, ATG-Fresenius® and Lymphoglobulin® had similar anti-myeloma activity. Thymoglobulin®, ATG-Fresenius® and Lymphoglobulin® showed potent complement-mediated cytotoxicity against myeloid leukemia cell lines but no significant complement independent cytotoxicity could be observed against myeloid leukemia cell lines. *Conclusions.* Our data show that Thymoglobulin®, ATG-Fresenius® and Lymphoglobulin® have potent cytotoxic effects against myeloma, CLL and other B cell lymphomas, but limited activity against myeloid leukemia. These findings would be helpful in choosing the ATG preparation and dose when targeting hematological malignancies.

EXTRACORPOREAL PHOTOPHORESIS FOR TREATMENT OF ACUTE GVHD IN PAEDIATRIC PATIENTS

L. Rivabella, G. Tripodi, L. Scarso, M. Risso, G. Morreale, E. Lanino, M. Faraci

Gaslini Children Institute, GENOVA, Italy

Background. Extracorporeal photophoresis (ECP) represent a possible and efficacious treatment in management of acute or chronic Graft versus Host Disease (aGvHD/cGvHD) resistant to first line treatment consisted in steroid therapy given to low (2 mg/Kg/day) or high dose (5mg/Kg/day). *Methods.* In our department ECP was used to treat drug resistant acute and chronic GvHD, to reduce the early and late steroid toxicity and to increase the immunological reconstitution until to decrease the incidence of opportunistic infections. ECP (1,5 TBV utilizing COBE Spectra Auto PBSC6.1) was administered according to a schedule consisted in 2 cycles/week for the first month, 2 cycles/every 15 days for the second month and 2 cycles/month for the following 4 months. *Results.* During the period between 2000-04, we enrolled 14 children (median age 9.3 yrs) affected by aGvHD after an allogeneic haematopoietic stem cell transplantation. ECP was administered to cure aGvHD (global grade 1 = 8 pts, grade 2 = 3 pts; grade 4=1 pt) treated with steroid therapy (2 mg/Kg/day in 8pts, 5 mg/Kg/day in 6pts) or to maintained a CR obtained with steroid (2 pts). Steroids were associated to other immunosuppressive therapies in 3 pts (anti CD25 in 2 pts and anti-TNF in 1). We evaluated the response to ECP at the end of first, second and six months of treatment. After the 1st month of ECP, 7/14 pts improved, 4/14 pts not responded, while 3/14 pts worsened. At the end of 2nd month of ECP, 12/14 pts raised CR of aGvHD (3 pts received other immunosuppressive therapies), 1 pt showed a grade 1, and 1 a grade 2 of aGvHD. The cGvHD evaluated at the end of ECP schedule (after 6 months) was absent in 11/14 pts, it was limited in 1/14 pts and extensive in 2/14 pts. After 6 months, 6 pts received ECP for relapse of cGvHD (4/6) or for a consolidation of CR obtained after a first treatment (1/6) or to reduce the immunosuppressive therapy (remaining 1). Five pts died :2 for cGvHD, 2 for sepsis and 1 for relapse of underlying disease. 6 pts without a relapse of cGvHD are alive and they are in CR, 2 of pts who not relapsed of cGvHD died for haematological relapse. *Conclusions.* We confirm that ECP represent an efficacious treatment of aGvHD also in paediatric patients. No events adverse were observed in our populations. In our experience the major response was obtained after the first 2 months of therapy, when ECP was administered more frequently, in particular the patients who obtained a CR during this first period rarely developed a cGvHD. Patients who relapsed after a complete treatment of ECP and who were treated with a new ECP treatment not obtained a improved of cGvHD (2 of them died for cGvHD). We suggested that probably ECP cycles should be increase in the first months of treatment until to obtained a better and prolonged response.

INFLUENCE OF NON-HLA GENETIC POLYMORPHISMS ON THE INCIDENCE OF GRAFT-VERSUS-HOST DISEASE AND MORTALITY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

G. Reddiconto,[1] P. Chiusolo,[2] A. Fiorini,[2] G. Farina,[2] S. Marietti,[2] S. Bellesi,[2] S. Giammarco,[2] D. De Ritiis,[2] L. Laurenti,[2] A. Catalano,[2] G. Leone,[2] S. Sica[2]

[1]Università Cattolica del Sacro Cuore, ROME; [2]Università Cattolica S. Cuore Hematology, ROME, Italy

Hematopoietic stem cell transplantation (HSCT) may be associated with a variety of complications such as graft-versus-host disease (GVHD) and major non infectious transplant-related complications. Although HLA compatibility has a central role in selecting donors and determining transplant outcome, the sequencing of human genome has revealed numerous non HLA single nucleotide polymorphisms (SNPs), whose significance in allogeneic HSCT could be relevant. Due to these polymorphisms, patients may be predisposed to releasing high levels of certain cytokines pre and post trasplant during the *cytokine storm* and therefore may be more predisposed and/or protected from GVHD and mortality. In our study we examined the association of SNPs at position 677 and 1298 in the MTHFR gene, at -308 in the TNF α gene and -252 in the TNF β gene, at -1082 and -592 in the IL10 gene, at -238 in the IL10 receptor gene and at 908, 702, 1007 in the NOD2/CARD15 gene, on incidence of GVHD (grade II-IV) and mortality in a group of 42 patients submitted to allogeneic HSCT in our Institute from 2004 and in their donors respectively. Variant genotypes were determined using PCR/restriction fragment length polymorphisms, except for variant 1007 and 702 determined using allele-specific PCR. Table 1 presents patients' characteristics. Kaplan Meyer incidence curves, with differences compared by the Log-Rank test, were used to assess the association between polymorphisms and clinical covariates (age, disease status, regimen conditioning, gender compatibility, HLA mismatch) and GVHD development and mortality. The level of significance was performed to $p<0.05$. Our results showed that global incidence of GVHD (grade III-IV) was 21.4%. In univariate analysis we found an association statistically significant between development of GVHD and TNF β homozygous variant recipient (p: 0.002) and TNF α homozygous variant donor ($p=0.002$). We did not observe significant correlation of genotypic variants and clinical characteristics with acute GVHD. Regarding mortality we found a higher incidence in patients with TNF α homozygous variant ($p=0.004$); in addition we observed that patients with advanced status disease had a lower survival ($p=0.001$) . These data suggest that the determination of functional genotypes in relevant cytokine pathways may have clinical utility for risk assessment, counseling and treatment planning before transplantation.

Table 1. Patients' characteristics (n=42).

PERSISTENCE OF RECIPIENT LANGERHANS CELLS FOLLOWING ALLOGENEIC HAEMOPOIETIC STEM CELL TRANSPLANTS WITH REDUCED INTENSITY CONDITIONING

J. Richards,[1] L. Pearce,[2] P.E.M. Patten,[1] A.Y. Ho,[2] A. Pagliuca,[2] G.J. Mufti,[1] S. Devereux[2]

[1]King's College London, LONDON; [2]King's College Hospital, LONDON, United Kingdom

Langerhans cells (LCs) are members of the dendritic cell family found predominantly within the suprabasal area of the epidermis where they form the first immunological barrier against the external environment. They are thought to originate from bone marrow precursors although studies in mice suggest they have the ability to renew *in situ* and are only replaced by precursors from the bone marrow after inflammatory changes. Murine models have also shown that recipient LCs are required for development of acute graft versus host disease (GVHD) following allogeneic haemopoietic stem cell transplantation (allo-HSCT). Engraftment of LCs following human allo-HSCT has previously been assessed using migration from isolated epidermal sheets, which may be inaccurate because of differential migration capacity of donor and recipient cells. We therefore studied LC engraftment using fluorescence immunophenotyping and simultaneous *in situ* hybridisation for X/Y chromosomes in sex mismatched transplants. Skin biopsies were performed at days 28, 56 and 100, 6 months and 1 year post transplant on 9 patients receiving alemtuzumab based RIC allo-HSCT regimens. Ten micron cryosections were taken, LCs labelled with anti-CD1a and X/Y chromosomes detected with the CEP X/Y probe kit. Slides were examined on a Zeiss LSM510 Meta confocal microscope and Z-stack images were collected to cover a volume of 100 microns cubed. Chimerism of purified $CD15^+$ and $CD3^+$ peripheral blood cells was determined in parallel. Results are tabulated below and show that compared to $CD15^+$ myeloid blood cells, donor LC engraftment is markedly delayed (day 28, 56 and 100 paired t-tests give $p<0.0001$, $p=0.0006$ and $p=0.0207$ respectively). Of the 9 patients studied, 3 developed biopsy proven

GVHD and in all cases, recipient LCs were still present. These results show that LC engraftment after RIC-allo-HSCT is markedly delayed with persistence of recipient cells at up to 1 year.

Table 1.

Cell Type	Day 28	Day 56	Day 100	6 Months	1 Year
LC	21.4 (n=9)	72.85 (n=8)	90.5 (n=8)	93.85 (n=7)	96.6 (n=3)
$CD3^+$ PB	98 (n=9)	85 (n=7)	73 (n=7)	82 (n=5)	100 (n=3)
$CD15^+$ PB	100 (n=9)	100 (n=7)	100 (n=7)	100 (n=5)	100 (n=2)

Median % donor chimerism at specific time points Post allo-HSCT

0591

DECREASED CHRONIC GVHD RATE AFTER REDUCED INTENSITY CONDITIONING WITH LOW DOSE ATG IN ALLOGENEIC HEMATOPOIETIC SCT

S. Langner, P. Staber, D. Strunk, W. Linkesch

Medical University Graz, GRAZ, Austria

Background. Reduced intensity conditioning (RIC) regimens have been established to diminish toxicity in patients not eligible for standard myeloablative allogeneic hematopoietic stem cell transplantation (SCT). RIC is associated with higher rates of morbidity and mortality from graft versus host disease (GvHD). Anti-thymocyte globulin (ATG), in addition to its dominant action as a T cell depleting agent, has been implicated to beneficially influence GvHD by depleting host antigen presenting cells. *Aims.* We studied the effect of low dose rabbit ATG (4×5 mg/kg) on the morbidity and mortality due to GvHD. *Methods.* Forty-eight patients (23AML, 2ALL, 4CML, 7CLL, 3NHL, 9MM), not eligible for myeloablative SCT, either by age (median 52 years, range 21-72) or co-morbidities, underwent RIC-SCT. Seven patients had PD, 26 were in PR, 3 in CR2 and 12 in CR1. Eighteen patients (38%) had matched unrelated, 26 (54%) matched related and 4 (8%) mismatched unrelated donors. As a conditioning regimen they received fludarabine 3-5×30 mg/m^2 (with additional cyclophosphamide 3×300 mg/m^2 for NHL or melphalan 100 mg/m^2 for Myeloma) and TBI 2-4 Gy. GvHD prophylaxis consisted of cyclosporine A (2x1.5mg/kg starting at day +1) and mycophenolate mofetil (2x15 mg/kg starting 6h after SCT). In particular patients with an unrelated donor (n=21) received rabbit ATG (5 mg/kg at days -4 to -1; Fresenius, Germany). *Results.* After a median follow up of 708 days 28 of 48 patients (58%) were alive. The 1 year overall survival as well as the transplant related mortality after 1 year was not different between the study groups. The incidence of acute GvHD grade II-IV was 38% with ATG compared to 33% without ATG (p=ns). The occurrence of overall chronic GvHD was 52% in controls and 14% in the ATG arm (p=0.03). In addition the groups also differed in chronic GvHD grading (p=0.04) with extensive chronic GvHD of 7% versus 19%. GvHD related deaths occurred in one ATG treated patient and two controls. There was no statistical significant difference in developing a positive CMV-PCR (38% vs 31%) between the groups within one year. *Conclusions.* RIC including low dose (4×5 mg/kg) rabbit ATG resulted in a considerably low incidence of chronic GvHD. Prospective randomized studies are warranted to corroborate these *Results.*

0592

CHIMERISM OF DENDRITIC AND REGULATORY T-CELLS AFTER CHEMOTHERAPY BASED CONDITIONING IN GVHD MOUSE MODEL

B. Sadeghi,[1] Z. Hassan,[1] M. Abedi Valugerdi,[2] M. Hassan[1]

[1]Karolinska Institute, STOCKHOLM; [2]Stockholm University, STOCKHOLM, Sweden

Background. Hematopoietic stem-cell transplantation (HSCT) remains an important curative therapy for many malignant and non-malignant diseases. However, transplantation related complications such as veno-occlusive disease and graft-versus-host disease (GVHD) are still the major causes of mortality and morbidity following allogeneic HSCT. Dendritic cells (DCs) as the most potent antigen-presenting cells (APCs) play a central role in the development of acute and chronic graft-versus-host disease. Regulatory T (Treg) cells and host APCs have been implicated in GVHD, but their relative contributions remain unclear. *Aims.* To evaluate the time course and pattern of chimera of DCs and Treg cells after allogeneic HSCT in a mice model of GVHD. *Methods.* Female BALB/c were transplanted with male C57BL/6 mice in the allogeneic settings (group I and II) while female BALB/c were transplanted using female BALB/c in the syngeneic setting (group III and IV). Group I and III were treated with busulfan (Bu) 20 mg/kg/ day for four days while group II and IV received 25 mg/kg/day for four days. Cyclophosphamide (Cy) was given as 100 mg/kg/day for two days in all groups. The conditioning started at day -7 days and both Bu and Cy were administrated IP. GVHD was studied by histological analysis of skin, intestine and liver. The chimerism and engraftment were surveyed by FACS analysis in spleen. The plasma levels of cytokine were measured by Multiplex Antibody Bead kits. *Results.* Symptoms of acute GVHD started at day 5 post transplantation mainly in group II. Full donor chimerism achieved faster (day+7) and was durable in group II compared to group I. Percent of DCs in spleen increased at day 7 in group I and II compared to the syngeneic transplanted mice (group III and IV). The percent of DCs in group II was higher than group I at day+7. The number of DCs normalized from day14 in both groups. Full donor chimerism was persistent in group II compared to group I. T regulatory cell population in both allogeneic transplanted groups was higher at day +7 compared to syngeneic settings. Treg population in group I decreased by the time and followed total chimerism pattern whereas in group II it decreased even less than normal level in spite of full donor chimerism, which probably due to the development of GVHD. *Conclusions.* Short term engraftment of both DCs and T regulatory cells may not predict the level of chimerism or the development of GVHD. Moreover, the allogeneic transplantation settings have more pronounced effect on DCs and T regulatory cells chimerism compared to syngeneic settings, which may play an important role in initiation of GVHD.

0593

EXPANSION OF NATURAL KILLER CELLS WITH LYTIC ACTIVITY AGAINST ACUTE MYELOID LEUKEMIA BLASTS UNDER GOOD MANUFACTURING PRACTICE CONDITIONS. A POSSIBLE NEW STRATEGY FOR ALLOGRAFTED PATIENTS?

G.F. Torelli

University La Sapienza, ROMA, Italy

Background. Natural killer (NK) cells are known to play a key role in the context of haploidentical KYR mismatch stem cell transplantion (SCT), that is when a donor-versus-recipient NK cell alloreactivity is present. We recently demonstrated the possibility of expanding and activating NK cells both from normal donors and from leukemic patients; moreover, we verified the capacity of this population of expanded effectors to recognize and kill allogeneic and autologous primary myeloid and lymphoid leukemia blasts. This population of effector cells has been also demonstrated capable of controlling the leukemic expansion in experimental models. These observations open the way to possible future clinical trials for the management of minimal residual disease (MRD), also in the setting of an HLA-compatible or haplotype-mismatch allogeneic SCT, regardless of the KYR epytope matching. *Aims.* In order to translate these pre-clinical data into a potential clinical trial, the aim of this work was to verify whether NK cells can be expanded from the peripheral blood of normal donors under Good Manufacturing Practice (GMP) conditions and whether these expanded effectors may potentially exercise anti-leukemic activity. *Methods.* We investigated the peripheral blood of 17 adult donors. Ficoll density gradient separated peripheral blood lymphocytes (PBL) underwent NK cell enrichment by negative depletion after adherence to plastic and were co-cultured with allogeneic or autologous irradiated mononuclear feeder cells in addition to different concentrations of IL-2, IL-15 and phytohemagglutinin-M (PHA). Expanded NK cells were then engaged in cytotoxic tests against fresh primary acute myeloid leukemia (AML) blasts, by means of the annexin-V flow cytometry technique. *Results.* Enriched NK cells co-cultured for 14 days at 37 °C with irradiated autologous lymphocytes (lymphocyte : NK cell ratio =2.5:1) plus IL-2 500 U/mL and IL-15 50 ng/mL (n=5) presented an expansion capacity (mean fold increase 37.2±14.9) comparable to the expansion obtained in the presence of an allogeneic feeder and PHA. $CD3^-/CD56^+$ NK cells represented 97.1%±2.0 of this expanded population, the remaining cells being $CD3^+$. Preliminary data also show that by adding to the culture medium IL-2 500 U/mL + IL-15 50 ng/mL during the last 24 hours of the expansion period, NK cells

acquire a cytolytic capacity against leukemia cell lines and against allogeneic primary AML blasts. *Summary and conclusions.* These results confirm that NK cells can be significantly expanded under GMP conditions and indicate that from 100 mL of donor peripheral blood it is possible to obtain 1-5×10^8 NK cells, which means the opportunity of infusing into a recipient of 70 kg 1.5-7×10^8 NK cells/kg of body weight. Taken together, these findings indicate a possible new strategy for the expansion of cytolytic effectors that may be considered for the management of AML patients with evidence of disease persistence or recurrence after an allogeneic SCT. Clinical protocols appear feasible, particularly considering that the infusion of NK cells should induce very limited toxicity and no or very low risk of graft-versus-host disease, thus avoiding the potential complications associated to donor T-lymphocyte infusions.

0594

PLASMA CHANGES OF ENDOTHELIAL INJURY MARKERS IN PATIENTS TREATED WITH DIFFERENT CONDITIONING REGIMENS FOLLOWED BY HAEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Czyz, A. Blazejczak, A. Lojko, E. Hanszke, L. Gil, D. Dytfeld, K. Zawilska, M. Komarnicki

University of Medical Sciences, POZNAN, Poland

Background. The endothelial injury caused by conditioning regimen is thought to play a central role in the non-infectious complications in patients undergoing haematopoietic stem cell transplantation. The aim of the study was to evaluate the plasma changes of endothelial injury markers in patients treated with different type of preparative regimens and to investigate whether these changes are associated with toxicity of conditioning schedule. *Patients and Methods.* Plasma levels of von Willebrand factor antigen (vWF Ag), trombomodulin (TM) and vascular endothelial growth factor (VEGF) were measured by immunoassay tests in 21 patients (pts), median age 30 (19-67) years, transplanted with allogeneic (18 pts) or autologous (3 pts) haematopoietic stem cells after BuCy2 (busulfan 16 mg/kg, cyclophosphamide 120 mg/kg) - 5 pts, TBI/Cy (total body irradiation 12 Gy, cyclophosphamide 120 mg/kg)- 5 pts, Treo/Cy (treosulfan 14 mg/m^2, cyclophosphamide 120 mg/kg)- 6 pts or fludarabine-based reduced-intensity regimen- 4 pts for AML (10 pts), ALL (5 pts), CML (4 pts) and AA (1 patient). For the statistical analysis patients were divided into the subgroups according to the type of conditioning schedule: 1.BuCy2 2.TBI/Cy 3.myeloablative regimens (BuCy2, TBI/CY) and 4.reduced-toxicity regimens (fludarabine-based regimen, Treo/CY). Endothelial injury markers were measured before conditioning regimen (day -10), and on the day of stem cells infusion, 48 hours after finishing preparative schedule, but before stem cells infusion (day 0). *Results.* After conditioning regimen vWF Ag concentration increased significantly on the day 0 in comparison to the day -10 ($p<0.05$) in the whole study group. wWF Ag concentration did not differ significantly between subgroups on the day 0. In the subgroup treated with TBI based regimen (5 pts) VEGF level increased on the day 0 in comparison to the day -10 ($p<0.05$). Plasma level of TM did not change significantly either in the whole study group or in the subgroups. *Conclusions.* vWF Ag is a sensitive endothelial injury marker, but not specific enough to determine toxicity of different conditioning regimens. Further studies with a larger group of patients are necessary to evaluate the role of VEGF as a marker of chemotherapy induced endothelial injury and a predictor of non- infectious complications.

0595

ACTIVATING KILLER IMMUNOGLOBULIN-LIKE RECEPTOR (KIR) COMPATIBILITY IS ASSOCIATED WITH IMPROVED SURVIVAL AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANATION

S. Giebel,[1] I. Nowak,[2] T. Czerw,[1] T. Kruzel,[1] J. Wojnar,[1] J. Dziaczkowska,[1] M. Krawczyk-Kulis,[1] M. Markiewicz,[1] I. Wylezol,[1] A. Karolczyk,[1] A. Holowiecka-Goral,[1] P. Kusnierczyk,[2] J. Holowiecki[1]

[1]Silesian Medical University, KATOWICE; [2]Institute of Immunology and Experimental, WROCLAW, Poland

Killer immunoglobulin-like receptors (KIRs) regulate function of NK cells and a subset of T cells. KIR genotype is highly polymorphic and includes 14 genes for activating and inhibitory receptors. Two groups of haplotypes may be distinguished: haplotype A including KIR2DS4 as the only activating KIR and haplotype B with varying number of activating KIRs. The goal of this prospective study was to evaluate prognostic value of donor and recipient KIR genotype in a setting of allogeneic hematopoietic cell transplantation (alloHCT). Presence of particular genes in donors and recipients as well as incompatibility of the whole genotype and in particular loci were analyzed. Mismatches in graft-vs.-host (GVH) direction were considered if gene was present in the recipient and absent in the donor. Incompatibility in HVG direction was recognized in opposite situation. Seventy consecutive patients with hematological malignancies, aged 32.5 (18-58)y, given transplant from HLA-matched related (MRD) (n=28) or matched unrelated donor (MUD) (n=42) were included. The conditioning regimen was myeloablative and based on chemotherapy alone (76%) or TBI (24%). GVHD prophylaxis consisted of cyclosporin, methotrexate, and, in case of MUD-HCT, pretransplant ATG. KIR genotype mismatch was established in 68% of MRD-HCT and 90% of MUD-HCT. At two years the OS rate was 100% for KIR-matched and 70% for KIR-mismatched transplants (p=0.04). The difference resulted mainly from incompatibility regarding activating KIRs (100% vs. 67%, $p=0.01$). In a multivariate analysis including other potential risk factors, increasing number of activating KIR mismatches in HVG direction (analyzed as continues variable) was associated with decreased DFS (RR=3.45; $p=0.008$), increased NRM (RR=1.43, $p=0.02$), and the incidence of grade II-IV acute GVHD (RR=1.35; $p=0.03$). Presence of at least one activating KIR incompatibility in HVG direction was associated with higher peripheral blood $CD8^+/CD4^+$ ratio up to 100 days after alloHCT. Number of mismatched loci correlated positively with this ratio on days +28, +56 and +100. Increasing number of activating KIR disparities in GVH direction resulted in higher risk of relapse (RR=4.43; $p=0.046$) and CMV infection (RR=1.59; $p=0.02$). *Conclusions.* Disparity regarding activating KIR genotype is an independent adverse prognostic factor for patients undergoing HLA-matched alloHCT. Activating KIR mismatch seems to enhance donor-recipient alloreactivity and the effect depends on the mismatch direction. Results of this study may contribute to better donor selection and optimization of the alloHCT procedure.

COMPLIANCE WITH HOME TREATMENT USING ENZYME REPLACEMENT THERAPY FOR TYPE 1 GAUCHER DISEASE A UK CENTRES PERSPECTIVE

A. Milligan, R. Bruce, C. Freud, S. Goodwin, D. Hughes, A. Jennings, L. Richfield, D. Webster, A. Mehta

Royal Free Hospital, LONDON, United Kingdom

Background. Gaucher disease is an inherited metabolic disorder in which accumulation of glucocerebroside in the reticulo-endothelial system results in pathology within the bone marrow, liver, spleen and skeleton. In neuronopathic forms (types 2 and 3) there is CNS involvement. Treatment with enzyme replacement therapy (ERT) is currently long-term, possibly life-long. *Objective*. Management of Gaucher disease involves the meeting of therapeutic goals.[1] These are: the establishment and maintenance of specific haematological parameters, reduction in hepato-splenomegaly, avoidance of bone crises and improvement in quality of life. Currently the annual drug cost of treating a 70-kg adult at the recommended dose of 60 iu/kg 2-weekly would be £325,000. UK practice has been to individualise dose according to clinical status, once disease has been debulked - making the average cost approximately £86,000 per patient.[2] Hollak *et al*.[3] have previously demonstrated the efficacy of dose titration on goals and disease biomarkers. In the UK home treatment with ERT for Gaucher was established within 3 years of the available therapy being licensed and has become the standard. More than 50% of patients become self-infusers with support from treating centres and a designated home nursing team. *Methods.* In view of this independence we examined compliance amongst our co-hort of type 1 Gaucher patients receiving treatment with Cerezyme™. We used a patient-led assessment tool and 3 to 6- monthly monitoring with an approved bio-marker (chitotriosidase). We also compared data to a similar study on patients having intravenous immunotherapy in the home. *Results.* Of 35 patients 21 (60%) stated that they had never missed a dose of their treatment. 14 (40%) had missed a dose at some time and the main reason given for this were vacations lasting more than 2 weeks. Patients were asked to score themselves on a scale of 1 to 10 (1 = non-compliant, 10 = totally compliant, receiving every dose of treatment at the recommended 2- week intervals). 32 (91%) of patients scored themselves between 8 and 9 for compliance. 18 patients (51%) had never experienced any problems with home infusions. Where problems did occur - 11 (35%) had found some difficulties with cannulation when they were still learning. 19 (54%) found that home infusion meant that they felt more in control of their treatment and condition. *Summary.* In the UK the treatment of type 1 Gaucher disease with ERT has shown major clinical benefits to patients. Providing delivery of care in the home has been beneficial to patients in terms of quality of life and maintenance of independence. Compliance with unsupervised treatment has not been shown to be major issue - having positive implications for disease management in the long-term.

CAN WRITTEN ADVICE PROVIDE A SAFE AND ACCEPTABLE ALTERNATIVE TO A NEW PATIENT ASSESSMENT FOR SELECTED REFERRALS TO HAEMATOLOGY

P. Ganly,[1] H. Keeman,[2] M. Smith,[1] W.N. Patton,[1] R.L. Spearing,[1] S. Gibbons[1]

[1]Christchurch Hospital, CHRISTCHURCH; [2]Christchurch School of Medicine, CHRISTCHURCH, New Zealand

Background. Traditionally we have seen all patients referred with haematological problems. An alternative approach for selected patients, in which the possibility of significant pathology is low, is to provide written advice to the referrer instead of seeing the patient in person. If this approach is safe and acceptable to patients and referring doctors, it may allow resources to be used more effectively for those other patients who require most attention. *Aims.* We wished to discover what happens to patients referred and given written advice but not seen and compare this with other patients who were referred and seen in person. *Methods.* After obtaining approval from our IRB we reviewed all referrals to the department between 11/03 and 06/06. Those referrals which were managed with written advice (WA) were examined for content of advice and subsequent course. The diagnoses of these patients were compared with those referrals subsequently seen non-urgently as new patients (NUNP). We asked those who referred patients and received written advice, and recent patients who were managed in this way, for their opinions on usefulness and acceptability of this advice. *Results.* We gave immediate written advice to the referring doctors of 714 (37%) of 1907 referrals. All the remaining referrals were seen according to clinical need, such that 438 (37%) were seen non-urgently after a wait of 4 weeks or more (median wait 56 days). All referrals were followed up for a minimum of 8 months. Diagnoses in WA and NUNP were similar with no acute pathology in either group. There was a higher proportion of MGUS, haemochromatosis and haemostasis problems amongst WA and more myeloproliferative and lymphoproliferative disease amongst NUNP. 4% of WA v 9% of NUNP have died. 13% of WA were subsequently re-referred and this led to 52 (7%) attending in person after a median interval of 4 months from first referral. 21 of these remain current patients of whom 13 have required treatment. There were 5 patients who received a diagnosis which had not been predicted at the time of the written advice letter, and all had been re-referred promptly. 223 (74% of all referring doctors) gave their opinion on this process by questionnaire. Most were unsurprised by receiving written advice for their patient(s). 90-98% of respondents believed the process was rapid, helpful, comprehensive and effective and that they could easily re-refer patients if necessary. 90% of additional comments, when made, were favourable. 31 (28% of all patients referred in 2006 whose doctors received WA) gave their opinion, most being aware of their referral and pleased not to be seen in the clinic. Most of additional comments, when made, were favourable. *Summary and Conclusions.* Providing written advice as opposed to arranging a new patient visit does not disadvantage selected patients or miss important pathology. 662 (35% of all referrals) were not seen at all in the course of our review which allowed some reallocation of resources to other patients. Skilled referrers, appropriately supported by written advice overwhelmingly approved of the process.

0598

COST UTILITY ANALYSIS OF DEFERASIROX VERSUS DEFEROXAMINE (DESFERAL) FOR PATIENTS REQUIRING IRON CHELATION THERAPY IN THE UNITED KINGDOM

J. Karnon,[1] R.L. Akehurst,[1] K. Jewitt,[2] D. Ossa[2]

[1]University of Sheffield, SHEFFIELD; [2]Novartis Plc, CAMBERLEY, United Kingdom

Background. Patients suffering from β-thalassemia (β-thal), sickle cell disease (SCD), and myelodysplastic syndrome (MDS) may require life-long blood transfusions and are at risk of iron overload. If they are not treated with iron chelation therapy (ICT), they can suffer serious organ damage and reduced life expectancy. Desferal, infused subcutaneously for 8 to 12 hours per day, 5 to 7 times per week, has been the gold standard of ICT. Exjade is a once daily oral iron chelator, which has been approved in Europe and the US for the treatment of transfusional iron overload. *Aims.* To estimate the incremental cost per quality adjusted life year (QALY) of using Exjade instead of Desferal in patients with β-thal, SCD, or MDS who require iron chelation, from a UK NHS perspective. *Methods.* A cost utility analysis was performed to compare Exjade with Desferal. The results from Study 107, a pivotal, open-label, randomised, controlled study comparing the efficacy of Exjade to Desferal in 586 adults and children with β-thal, demonstrate non-inferiority of Exjade compared to Desferal in patients who received ≥20 mg/kg/day Exjade. The cost-utility analysis is therefore based on a comparison of the health related quality of life associated with the two forms of administration ie oral therapy versus slow subcutaneous infusion, assuming equivalent clinical efficacy. Drug costs were informed by observed use in the equivalence arms of the 107 trial (the ≥20 mg/kg Exjade, and ≥35 mg/kg Desferal arms)with a mean patient weight of 42kg. The annual equipment cost for the administration of Desferal was informed by a primary study of 29 patients (11 β-thal; 14 SCD; 4 MDS; 31% male; mean age 30.6±20.1 years) from four UK treatment centers on the basis of chart reviews and interviews. The model also includes additional costs associated with Exjade treatment for creatinine monitoring and adverse events. A utility study involving 120 UK general population respondents used the time trade-off approach to estimate utility values for clinically

informed vignettes describing health states involving subcutaneous and oral administration of ICT. The mean utility values were 0.66 and 0.84 for sub-cutaneous and oral ICT, respectively. The 95% CI for the utility difference was 0.147-0.212. Utility decrements were applied to account for the minor adverse events associated with Exjade. The model was run over a 1-year period and unit costs from 2004/2005 GBP were applied. *Results.* In the reference case analysis, Exjade dominates Desferal with lower aggregate costs and improved quality of life,as shown in the results Table 1. A range of one- and multi-way sensitivity analyses are also presented. *Conclusions.* Exjade fills a current unmet need for iron chelation via a simple and convenient mode of administration which significantly reduces the patient burden and improves quality of life. The reference case cost-effectiveness results show that Exjade provides more QALYs and costs less than Desferal; in other words, Exjade *dominates* DFO.

Table 1.

Base case	Desferal	Exjade	Difference
Drug costs	£6463	£12580	£6117
Admin costs	£7552	£0	-£7552
Monitor/AE costs	£6	£25	£19
Total costs	£14021	£12605	-£1416
Utility value	0.644	0.808	0.164
Incremental cost per QALY (ICQ)			Exjade dominates

Sensitivity analysis	Δ costs	Δ QALYs	ICQ
Mean weight increased to 62kg	£2061	0.164	£12566
50% patients use pump, 50% balloons	£1315	0.164	£8017
Weight 62kg and 50% pump use	£4321	0.164	£26348
Weight 62kg, 50% pump use, and utility gain reduced by 25%	£4321	0.119	£36311

THE PRICE FOR SURVIVAL ARE ALL PATIENTS EQUAL?

I. Gabriel,[1] M. Schenk,[2] J. Foster,[2] A. Chaidos,[1] E Kanfer,[1] D. Marin,[2] D. Milojkovic,[2] A. Rahemtulla,[2] E. Olavarria,[2] J. Apperley[1]

[1]*Hammersmith Hospital NHS Trust, LONDON;*[2]*Hammersmith Hospital, LONDON, United Kingdom*

Background. In the UK hospitals are currently reimbursed for SCT according to prices negotiated on a regional level and agreed in advance of the next financial year based on the hospital's historical and predicted future activity. By 2008 this arrangement will change to a fixed national tariff, *Payment by results*, based on a national average cost of a SCT. It is currently unclear how this figure will be validated. *Aims.* We undertook a comprehensive costing exercise in our institution. We looked at variability in transplant costs and compared our results to our current charges. METHOD We selected ten transplants from the three main transplant modalities: autologous PBSC (ASCT), HLA-matched sibling, and matched unrelated donor transplants. In each group we selected patients with shortest and longest inpatient stays. The other eight transplants were selected at random to include a selection of disease groups, disease status, patient age, and conditioning regimens. The cost for each patient transplanted was calculated from the decision to imminently transplant, to 6 and 12 months for ASCT and allografts respectively. We reviewed clinical activity from the casenotes and medication charts and derived investigations from our computerised results system. Using these data and costs for overheads and utilities, we produced an accurate cost for each patient. In the case of unrelated allogeneic transplants, donor search and stem cell procurement were also included. *Results.* Both myeloablative and reduced intensity conditioning regimens were included. In all three transplant types, cost varied considerably. The average price for an ASCT was 50,575.12 Euros (range 28,932.54-127,083.15 Euros), for HLA matched sibling SCT, 105,577.39 (range 72,818.26 - 265,038.33 Euros) and for matched unrelated SCT, 154,953.04 Euros (range 56,401.78-265,038.33 Euros). These costs are remarkably similar to those currently reimbursed with the exception of ASCT (36,000). A wide range in costs was seen for all aspects of the SCT procedure including donor search and cell procurement (range 13,807.50 Euros - 35,328.45 Euros), pharmacy costs (range 2,881.5 Euros - 108,580.5 Euros), and post-transplant follow up. SCT are inherently heterogeneous and complications are often unpredictable so the high and wide ranges of costs were not unexpected. Current actual repayments underestimate the costs of ASCT in particular. The earliest suggestion for the national tariff, underestimates the cost of all procedures necessitating further accurate negotiations with our purchasers. Our experience of the Payment by Results consultation process is that centres are calculating cost in a variety of ways, with differing *Results.* We believe that our costs are accurate although we did not take into account capital asset depreciation. Failure to include all costs will falsely underestimate costs and the fixed tariff will result in an imbalance between expenditure and gain. As a result, trusts may have to select patients for SCT in order to adhere to a fixed price and novel transplants will no longer be an option. Whilst we admit that the present situation is not ideal, the speed of introduction of new regulations and the lack of standardisation is likely to have a detrimental effect on the UK transplant experience.

0600

COST-EFFECTIVENESS OF CHOP-LIKE CHEMOTHERAPY PLUS RITUXIMAB VERSUS CHOP-LIKE CHEMOTHERAPY ALONE IN YOUNG PATIENTS WITH GOOD-PROGNOSIS DIFFUSE LARGE-B-CELL LYMPHOMA

F. Ferrara,[1] R. Ravasio,[2]

[1]*Cardarelli Hospital, Napoli, Italy, NAPOLI;* [2]*Wolters Kluwer Health, Adis Internationa, MILANO, Italy*

Background. There has been little research into the treatment costs associated with conventional haematologic drug regimens. Published economic evaluations focused on the impact of Stem Cell Transplantation in this therapeutic area. *Aims.* To estimate the cost-effectiveness of CHOP-like chemotherapy plus rituximab therapy versus CHOP-like chemotherapy alone therapy, in young patients with good-prognosis diffuse large-B-cell lymphoma, based on data from a large international study (MabThera International Trial MInT Group). *Methods.* The present work used a 3 years model in which two cohorts of patients received CHOP-like chemotherapy plus rituximab or CHOP-like chemotherapy alone. On the basis of efficacy data derived form the above mentioned study, the model simulated a complete or non-complete response to the initial treatment at 5 months and at 3 years. In case of lack of efficacy the model assumed a rescue-therapy (debulking phase plus autologous transplant) would be administered to the non-respondent patients. The analysis was conducted from the perspective of the Italian National Health Service. The model provided estimates of overall survival (LYs - Life Years) and direct medical costs (pharmacological treatment, hospitalization, management of rescue therapy, etc.). Overall survival data were calculated based on the results of the international study (MInT Study) and direct medical costs were based on italian treatment patterns and reported in 2006 Euro. Benefits and costs were discounted at 3%. One-way sensitivity analysis on key clinical parameters was performed. *Results.* The overall survival (per patient) with CHOP-like chemotherapy plus rituximab versus CHOP-like chemotherapy alone was respectively 19.69 LYs and 17.78 LYs (giving 1,91 LYs Gained). The expected cost (per patient) was € 23,617.57 with CHOP-like chemotherapy plus rituximab and € 25,370.08 with CHOP-like chemotherapy alone. Therefore it was not necessary to calculate the Incremental Cost Effectiveness Ratio (ICER) of CHOP-like chemotherapy plus rituximab versus CHOP-like chemotherapy alone, since the former was dominant. The study results were sensitive to a 5-months complete response and to a 3-years complete response. Namely, sensitivity analysis simulated the worst case for CHOP-like chemotherapy plus rituximab with reference to such parameters. For a 5-months complete response an ICER was calculated of € 1,273.43 for CHOP-like chemotherapy plus rituximab versus CHOP-like chemotherapy alone. For a 3-years complete response an ICER was calculated of € 661.43 for CHOP-like chemotherapy plus rituximab versus CHOP-like chemotherapy alone. *Conclusions.* This economic evaluation suggests that CHOP-like chemotherapy plus rituximab is a dominant strategy versus CHOP-like chemotherapy alone for treatment of young patients with good-prognosis diffuse large-B-cell lymphoma. The sensitivity analysis showed CHOP-like chemotherapy plus rituximab was a cost-effective approach even in the worst case assumption.

0601

EUROPEAN LEUKEMIANET - INTEGRATION OF THE LEADING NATIONAL LEUKEMIA NETWORKS (CML, AML, ALL, CLL, MDS, CMPD) AND THEIR INTERDISCIPLINARY PARTNER GROUPS IN EUROPE

S. Saussele,[1] K. Adam,[1] M. Baccarani,[2] M.C. Béné,[3] Th. Buechner,[4] A. Burnett,[5] G. Finazzi,[6] C. Fonatsch,[7] E. Gluckman,[8] N. Goekbuget,[9] D.J. Grimwade,[10] T. Haferlach,[11] M. Leukemias serve as a model for a variety of diseases and possess exemplary relevance for basic research and patient care. Leukemia research and therapy have achieved high standards and even a leading position in several European countries. A true European world leadership, however, had not been accomplished due to national fragmentation of leukemia trial groups, diagnostic approaches and research activities and the lack of central information and communication structures. To overcome national fragmentation the European LeukemiaNet (ELN) was started in 2002. It is funded within the 6th EU-Framework Program since 2004. The ELN now integrates 92 leading national leukemia trial groups (CML, AML, ALL, CLL, MDS and CMPD), 86 interdisciplinary partner groups (diagnostics, treatment research, registry, guidelines) and industry partners across Europe to form a cooperative network for advancements in leukemia-related research and health care. The trial groups and their partners which represent several thousand participating centers and ten thousands of study patients treated within the trial groups, form the backbone of the network. The network with its integration and interdisciplinary cooperation brings together 133 participating institutions and approximately 1000 researchers from 24 countries. The network consists of 16 thematically distinct workpackages. Of these, six deal with the various disease entities and represent subnetworks on their own. Seven workpackages represent interdisciplinary platforms, which provide the support and research expertise required for high quality networking and excellence. Three central service workpackages provide central communication, information and management services for the whole network and support integration. Scientific highlights of accomplished work include: 1. Establishment of information, communication and management structures. Communication is mostly accomplished via the information center (ELIC) and by the network management center (NMC) through annual symposia, regular network- and WP-meetings, an ELN website, and biannual newsletters. A European Leukemia Trial Registry (ELTR) was developed in accordance with the guidelines of the International Committee of Medical Journal Editors and the WHO. ELTR will be connected to the WHO Meta-Registry, as soon as the WHO has defined definitive interfaces for data-transfer. 2. European registries have been started for CML, ALL, ET and MDS. 3. Clinical trials on an European level are ongoing. 4. Quality control rounds and consensus recommendations in diagnostics on a European level were achieved e.g. for molecular monitoring in CML, cytogenetic analysis in CLL and morphological diagnosis of leukemias. 5. Several guidelines and management recommendations were completed and in part published, e.g. management recommendations for CML, recommendations for harmonizing methodology for detecting BCR-ABL transcripts and kinase domain mutations, guidelines for microarray analyses, guidelines on definition of transplant-associated microangiopathy (TAM), recommendations for standardizing indications for SCT, guidelines on prophylaxis and empirical antifungal therapy in neutropenic leukemia patients. The main goals for the first three years have been achieved and the ELN is well prepared for further integration advances in research, diagnosis and treatment of leukemia according to its goals.

0602

PRIMARY PROPHYLAXIS WITH PEGFILGRASTIM WAS MORE COST-EFFECTIVE THAN FILGRASTIM IN PATIENTS WITH NON-HODGKINS LYMPHOMA RECEIVING CHOP-21 IN THE UK

R. Pettengell,[1] P. Booth,[2] J. Malin,[3] C. Atchison,[4] Z. Liu,[5] Q. Doan,[5] A. Lalla,[5] R. Dubois[5]

[1]St George's Hospital Medical School, LONDON, United Kingdom; [2]Amgen Ltd, CAMBRIDGE, United Kingdom; [3]Amgen Inc., THOUSAND OAKS, USA; [4]Amgen Europe GmbH, ZUG, Switzerland; 5Cerner LifeSciences, BEVERLY HILLS, USA;

Background. In the 2006 ASCO and EORTC guidelines, primary prophylaxis with granulocyte colony-stimulating factors (G-CSFs) is recommended when the overall risk of febrile neutropenia (FN) from chemotherapy and patient-related factors is equal to or greater than 20%. Without G-CSF, FN incidence among patients receiving CHOP-21 chemotherapy is 17-50%. Although the daily first-generation G-CSF filgrastim and the long-acting second-generation G-CSF pegfilgrastim are both commonly used, in practice filgrastim is often administered for shorter-than-recommended courses, which has been shown to be associated with less clinical benefit. *Aims.* We evaluated the cost-effectiveness of pegfilgrastim vs. filgrastim used for 11 days (as used in the randomised trials demonstrating efficacy) and 6 days (as often used in clinical practice) in patients with aggressive NHL receiving CHOP-21 in the UK. *Methods.* A decision-analytic model was constructed from the National Health Service's perspective. The study time horizon was life-time. Model inputs, including FN risk (varied by days of filgrastim use), FN case-fatality, relative dose intensity (RDI), impact of RDI on survival, and utility scores were from a comprehensive literature review and expert panel validation. Costs were from official price lists or literature and included drugs, drug administration, FN-related hospitalisations, and subsequent medical costs. NHL mortality data were from literature; all-cause mortality data were from official statistics. The model simulated three clinical scenarios: scenario 1 included the impact of prophylaxis with pegfilgrastim or filgrastim on FN risk; scenario 2 included the impact of a difference in FN risk on FN-related mortality; scenario 3 included a differential impact on RDI and long-term survival. Using data from a meta-analysis (pegfilgrastim vs. 11 days of filgrastim) and observational studies (pegfilgrastim vs. 6 days of filgrastim), we estimated the absolute risk of FN in patients receiving pegfilgrastim decreased by 6.5 percentage points (19.6 vs. 13.1%) vs. 11-day filgrastim, and by 12 percentage points (25.1 vs. 13.1%) vs. 6-day filgrastim. Model robustness was tested using sensitivity analyses. Outcomes were measured as incremental cost-effectiveness ratio (ICER) including £ per percentage (absolute) FN risk decreased, £ per FN event avoided, £ per life-year gained (LYG), and £ per quality-adjusted life-year (QALY) saved. *Results.* Pegfilgrastim was cost saving compared with 11-day filgrastim in all scenarios. Compared with 6-day filgrastim, the ICER was £6,675 per FN avoided or £ 67 per 1% decrease in absolute risk of FN in scenario 1. The ICER was £ 29,438/QALY saved in scenario 2. In scenario 3, when all potential benefits of G-CSF were considered, the ICER became £ 7,699/QALY saved (Table 1).

Table 1. Cost-effectiveness of pegfilgrastim vs. 6-day filgrastim.

	Cost	Scenario 1	Scenario 2		Scenario 3	
	(£)	Risk of FN	LY	QALY	LY	QALY
6-day filgrastim	4,091	25.1%	8.542	7.411	7.249	6.261
Pegfilgrastim	4,892	13.1%	8.572	7.439	7.365	6.365
Difference between pegfilgrastim and 6-day filgrastim	801	-12.0%	0.030	0.027	0.116	0.104
ICER	---	£6,675 per FN event avoided	£26,425 /LYG	£29,438 /QALY	£6,903 /LYG	£7,699 /QALY

Results were sensitive to the relative risk of FN for 6-day filgrastim vs. pegfilgrastim and study time horizon. *Summary and conclusions.* In the UK, pegfilgrastim was cost saving compared with 11-day filgrastim use. The cost of pegfilgrastim vs. 6-day filgrastim at £7,699-£29,438/QALY gained was favourable compared with the £30,000/QALY threshold commonly used in the UK. With primary prophylaxis against FN in NHL patients

using CHOP-21 in the UK, pegfilgrastim was cost-effective compared with filgrastim used for the recommended number of days or fewer.

0603

PREFERENCES TOWARDS COAGULATION FACTOR CONCENTRATES USED TO TREAT HEMOPHILIC PATIENTS WITH INHIBITORS: THE PATIENTS, PHYSICIANS' AND PHARMACISTS PERSPECTIVE

F. Borghetti,[1] A. Gringeri,[2] L. Scalone,[3] S. v. Mackensen,[4] L.G. Mantovani[5]

[1]Center of Pharmacoeconomics MILAN; [2]Angelo Bianchi Bonomi Hemophilia and Thr, MILAN; [3]Center of Pharmacoeconomics, Department, MILAN; [4]Institute and Policlinics of Medical Psy, HAMBURG, Germany; [5]CIRF - Center of Pharmacoeconomics, Univ, NAPLES, Italy

Background. the management of hemophilia when patients develop inhibitors is particularly complex and costly. Although the advances of modern technologies, no agreement still exists on how to optimally treat these patients. Treatment of haemophilia is the result of interactions between patients, physicians, pharmacists and budget holders, each carrying their own set of preferences. *Aims.* this study was conducted to evaluate preferences toward possible coagulation factor concentrates used in patients with inhibitors from a sample of patients or their caregivers (if patients aged <17 years), physicians specialist in hemophilia care, pharmacists with experience in storing/delivering coagulation factor concentrates. *Methods.* a Discrete Choice Experiment was conducted, by describing possible products with 7 attributes, selected from a previous pilot study: viral safety, risk of anamnestic response, possibility of undergoing major surgery, frequency of infusions in prophylaxis, number of injections to stop bleeding, time to stop bleeding, time to pain recovery. Cost, expressed as increase of health care taxes, was added to estimate willingness to pay towards these attributes. The respondents were asked to choose among 16 sets having 2 hypothetical products each one. A logistic model was used to analyse the data. *Results.* 23 adult patients, 10 caregivers, 37 physicians, 25 pharmacists were interviewed. All the patients had severe hemophilia A, historical median peak titre = 233 BU/mL (5-16,400). Among all the respondents, the hypothesized direction of preferences was confirmed (e.g. lower risk of infections was preferred than higher risk) and the importance of preferences was statistically significant (p values <0.01) for every attribute. Anyhow, each subgroup expressed different strengths of preferences for some attributes. *Conclusions.* this study revealed patients/caregivers', physicians' and pharmacists' preferences towards the products used to treat hemophilic patients with inhibitors. Understanding the preferences from different perspectives can be useful to optimize the benefits deriving form the decisions on treatments for patients with inhibitors.

0604

EFFICACY AND COST ANALYSIS OF PALONOSETRON AND TROPISETRON USE IN CHEMOINDUCED NAUSEA AND VOMITING (CINV) IN HEMATOLOGY PATIENTS

G. Giordano, G. Farina, G. Sticca, C. Di Falco, S. Storti

UCSC Campobasso, CAMPOBASSO, Italy

Background. CINV is the most frequent side effect of chemotherapy. Its incidence is 60-90% with charboplatinum and high dose cytarabine, 30-60% with ifosfamide and idarubicin and 10-30% with cytarabine (inferior/equal to100 mg) and daunorubicin. 5-HT3 receptors antagonists are the most effective drugs against CINV. Among these, tropisetron and palonosetron have a prolonged efficacy (half-life of 8 and 40 hours respectively) and, indeed, require a reduced number of administration. *Aims.*To evaluate clinical efficacy and pharmacoeconomic impact of palonosetron and tropisetron in patients receiving 5-7 days chemotherapy. *Methods.* We evaluated 25 patients treated with 5-7 days chemotherapy for NHL(15) or AML(10). M/F was 10/15, median age was 65 years (R25-81). NHL patients, receiving ifosfamide (IGEV regimen) or high dose cytarabine and charboplatinum (MICMA regimen), were at high-risk of CINV. Instead AML patients, receiving daunorubicin and standard dose cytarabine, were at low-risk CINV. For each patient antibiotic and opioid administration, anticipatory emesis, early or late emesis, mucositis, gastropathy, esophagitis and diarrohea presence, CINV-related therapy and meal stop were evaluated. A cost analysis was performed considering the median of global antiemetic expense for each patient. Subsequently only the median of CINV-related antiemetic expense was considered. Patients receiving the same chemotherapeutic regimen were randomized in two groups: one receiving palonosetron and the other tropisetron. This is a monocentric, prospective, randomized study. We administred antiemetic therapy 30 minutes before chemotherapy infusion. Palonosetron was given only at first chemotherapy day, while tropisetron was given from one to three times/day, depending to chemotherapy regimen and patient medical history of CINV. *Results.* In tropisetron group M/F was 5/7, median age 67 years (R25-81), AML/NHL was 4/8. Five patients received antibiotic therapy during antiemetic administration. Three patients showed CINV. In palonosetron group M/F was 5/8, median age 63 years (R31-79), AML/NHL was 6/7. Six patients received antibiotic therapyt during antiemetic administration. Two patients showed CINV (one of them with gastritis and anticipatory nausea responding to methoclopramide administration). Only patients treated with MICMA regimen received steroid infusion as part of chemotherapy administred. Fisher exact test (p=0.6), Odds Ratio (1.8, CI 95%:0.3-11) and relative risk (1.6, CI95%:0.3-8) didn't showed significant difference in CINV incidence between palonosetron and tropisetron group. In palonosetron group, median global antiemetic expense for each patient was 107.25euro (R107.25-834.53), while in tropisetron group was 410.5euro (R30-515). Median antiemetic expense only for real CINV, was 107.25euro (R107.25-167) in palonosetron group, while in tropisetron group was 410.5euro (R30-515). *Summary and conclusions.* Palonosetron efficacy is not inferior to tropisetron in CINV prevention in patients receiving multiple days chemotherapy regimens. In pharmacoeconomic analysis the median cost of palonosetron treatment is about 300euro inferior to tropisetron treatment cost. Nevertheless these data need further confirmation on a larger patient cohort.

0605

RITUXIMAB RAPID INFUSION (90 MINUTES) IS FEASIBLE AFTER THE FIRST DOSE IN AN OUT PATIENT SETTING, A SINGLE CENTER PROSPECTIVE STUDY OF 80 COURSES

P. Brice, P. Franchi-rezgui, C. Derni, V. Nocton, I. Hascouet, C. Kadia, M. Allio, M. Genin

Hopital Saint Louis, PARIS CEDEX 10, France

Background. in 2007, Rituximab represent the standard of care for B-cell lymphomas and its use has increased in different settings. The first way to give it was alone with 4 doses weekly, then in combination with chemotherapy and more recently with a maintenance schedule. Due to the risk of cytokine induced toxicity, a premedication is recommended and the first course must be started slowly at 50mg/hour, than 100 mg/h. Aims, with the increasing number of patients treated with rituximab, the administration dropped to outpatient units and the infusion shortened. We, decided to evaluate prospectively a 90 minutes administration after an IV premedication (methylprednisolone 120 mg, paracetamol 1g and Dexchlorpheniramine 4 mg) given 30 minutes before. *Methods.* rituximab (doses of 600 or 700 mg) was begun at 400 mg/h for a total duration of 90 minutes in the absence of adverse reactions. The study was conducted in an outpatient unit including all patients receiving at least the second dose of rituximab from November 2006 to January 2007. Patients who had adverse reactions after the first dose took an oral antihistaminic drug the evening before. Among 100 courses, 20 were not analysed by the nurses due to lack of time to perform the study which consisted of reporting every 30 minutes, blood pressure, fever, pulsations and adverse effects. 80 courses of rituximab were evaluated in 62 patients with a sex ratio M//F of 3.2 and a median age of 59 years [29 to 87 years]. Diagnosis according to the OMS classification of lymphomas were as follows, FCL n = 29, DBCL n = 14, MZL n = 7, B-CLL n = 7, MCL n = 4, NLPHL n = 1. 42 patients were in first line therapy and 20 had relapsed. Results, Rituximab was given alone in 15 patients, or associated with chemotherapy: CHOP n = 21, CVP n = 13, Fludarabine n = 11 others n = 2. Three patients were evaluated 3 times, 15 patients were evaluated 2 times and the remaining had only one evaluation of the rituximab duration. 39 patients were evaluated from the second to the fourth course of rituximab and 41 after the fourth course. The median duration of rituximab perfusion was at 90 minutes with only 10 courses exceeding this time, 2 patients had a transient discontinuation of the perfusion leading to the longest perfusion duration of 170 and 240 minutes related to 2 adverse events (face erythema and throat dysesthesias). At the end, all patients received the total dose of rituximab. No other adverse events were reported, blood pressure and temperatures remained within normal ranges values according to the underlining disease and no patients were hospitalized for the night. Conclusion, rapid perfusion of rituximab after the first dose is safe after IV premedication and can be given in an outpatient setting even in the elderly and represent a less cost effective management of these patients with B-cell malignancies.

Infection and supportive care II

INVASIVE FUNGAL SINUSITIS IN PATIENTS WITH STEM CELL TRANSPLANTS AND HEMATOLOGICAL DISEASE

C.Y. Chen, Y.C. Chen, W. Tsay, W.C. Chou, J.L. Tang, H.F. Tien

National Taiwan University Hospital, TAIPEI, Taiwan

Background. Invasive fungal sinusitis (IFS) causes high morbidity and mortality in patients with stem cell transplants and hematological disease. *Aims.* We compared IFS diagnosis using EORTC / MSG-NIAID consensus criteria with physician-diagnosed IFS to determine the applicability in clinical study. The clinical characteristics and prognostic factors were correlated with invasive fungal sinusitis in patients of stem cell transplants and hematological disease. *Methods*. We searched the terms *sinusitis* and *sinonasal infection* in the discharge summary database of all patients admitted to the Department of Internal Medicine between January 1995 and September 2006. The medical records were reviewed retrospectively. *Results.* Totally, 103 hematological patients were enrolled, including 39 with clinically diagnosed IFS and 64 with sinusitis. Forty patients met the criteria by EORTC / MSG-NIAID consensus, including 15 with proven IFS, 16 with probable IFS, and 9 with possible IFS. Patients with acute myeloid leukemia and absolute neutrophil count <500 mm^3 for >10 days had a higher rate of IFS. Aspergillus flavus was isolated in 12 of 20 (60%) patients, and mucormycosis was found in 4 of 20. Bony erosion and extra-sinus infiltration were found in 15 of 39 patients with clinically diagnosed IFS by CT or MRI. Refractory or relapsed disease status was the most important prognostic factor in hematological disease with IFS. Even with anti-fungal therapy and aggressive surgical debridement, 21 of 39 patients (53.8%) with clinically diagnosed IFS and 22 of 40 patients (55%) with IFS diagnosed by EORTC / MSG-NIAID criteria died. *Summary and Conclusions.* IFS diagnostic criteria by EORTC /MSG-NIAID can be applied in the clinical research. IFS is an ominous sign in the patients with refractory / relapsed hematological malignancy. More effective IFS treatment is needed in patients with stem cell transplants and hematological disease, and such treatment should be developed.

0607

SURVIVAL OF PATIENTS WITH HAEMATOLOGICAL MALIGNANCY ADMITTED TO THE INTENSIVE CARE UNIT: PROGNOSTIC FACTORS AND OUTCOME COMPARED TO UNSELECTED MEDICAL ICU ADMISSIONS

Q. Hill,[1] A. Hill,[1] R. Kelly,[2] C. Patalappa,[2] A.M. Whittle,[1] A.J. Scally,[3] A. Hughes,[4] A.J. Ashcroft[2]

[1]Leeds General Infirmary, LEEDS; [2]Pinderfields Hospital, WAKEFIELD; [3]Bradford University, BRADFORD; [4]Bradford Royal Infirmary, BRADFORD, United Kingdom

Background. Cancer patients have historically had a very poor outcome following ICU admission. Outcome has however improved over the last decade. *Aims.* To identify factors which predict survival for critically ill patients with haematological malignancy and which can be readily identified prior to admission. This would improve selection of patients suitable for ICU admission, which represents a limited resource. We also assessed the ability of the APACHE II score to predict prognosis in these patients. *Methods.* Since the ICU admission case mix will vary between hospitals, one non-surgical admission within ± 1 week of each haematological admission acted as a control group. Factors which might affect outcome were assessed by multivariate regression analysis. Factors included were age, haematological diagnosis (acute or chronic leukemia, myeloma, lymphoma), time from haematological diagnosis to ICU admission (0-6 months, 6-12 months, >12 months), degree of prior treatment (admission prior to diagnosis, during first line therapy, after first line), remission status, prior stem cell transplant, documented infection and length of neutropenia (none, 1-10 days, >10 days). Predicted hospital mortality was calculated from the APACHE II score by the formula of Knaus et al (Critical Care Medicine 1985) for haematology patients. The APACHE scores of haematology patients were compared to controls by a two-sample t test. Predicted and actual mortalities were compared using a one sample test of proportion. The impact of mechanical ventilation (MV) on mortality was assessed by risk ratios. *Results.* We identified 111 patients with haematological malignancy (acute leukemia n=42, chronic leukemia n=11, myeloma n=19 and lymphoma n=39) admitted to ICU in one teaching and three district general hospitals (November 2000 - January 2006). Median age of haematological patients was 59 years (range 17-84) and M:F ratio 1.22:1. Control patients (n=111) were similar with median age 63 years (range 17-86) and M: F ratio 1.09:1. For control patients, overall ICU and hospital survival rates were 70% and 55% respectively while survival for haematology patients was approximately half at 44% and 24% respectively. In multivariate regression analysis, only increasing age (p=0.016) and documented infection (p=0.016) predicted poor outcome. All other variables were not significant. APACHE scores were significantly higher in haematology patients (median 27) compared to controls (median 19) p<0.001. Predicted hospital mortality for haematology patients was 56%, significantly lower than actual mortality (77%) p<0.001. For controls, hospital survival was slightly reduced for MV v's not receiving MV (risk ratio = 1.37; 95% C.I. =0.91, 2.05). Haematology patients hospital survival was significantly worse for MV - 5/55, 9% v's no MV 20/44, 45% (risk ratio = 5.00; 95% CI = 2.04, 12.50). *Conclusions.* Most pre-admission variables assessed did not predict mortality and should not be used for this purpose. Despite high APACHE II scores, predicted hospital mortality underestimated mortality for patients with haematological malignancy. Need for MV still predicts poor outcome in this group but without MV nearly half survive to hospital discharge.

0608

EMERGING OF MULTIRESISTANT PSEUDOMONAS AND VANCOMYCIN-RESISTANT ENTEROCOCCI: RESULTS OF A PROSPECTIVE SURVEILLANCE STUDY

C. Cattaneo, F. Bracchi, L. Signorini, E. Borlenghi, M.A. Capucci, M. Micheletti, A. Re, G. Ravizzola, N. Manca, G. Carosi, G. Rossi

Spedali Civili, BRESCIA, Italy

Background. Infectious diseases are potentially life-threatening complicances in haematological patients, as a result of their intrinsic and drug-related immunodeficiency. Epidemiological surveillance allows to identify emerging bacterial resistance and to improve empirical antibiotic therapy. Aims. To evaluate epidemiological trends among patients admitted at our Haematology Unit. Methods. Microbiologically documented infections consecutively occurred at our Institution during two sixteen month consecutive periods (A: June 2004-September 2005; B: October 2005-January 2007) were evaluated and correlated with type of infection, state of underlying disease, neutropenia, exposure to prophylaxis with fluoroquinolones (Fq), presence of central venous catheter (CVC), resistance to antibiotics and outcome. Neutropenia was defined as a neutrophil count <0.5×10^9/L. During the two periods, prophylaxis with Fq (levofloxacin 500 mg/d) was carried on in patients with an expected neutropenia lasting more than 7 days; β-lactam plus aminoglycoside ± vancomycin was the regimen adopted for empiric antibiotic therapy in neutropenic patients with fever. *Results.* During the periods A and B, 137 and 146 microbiologically documented infections were recorded and 148 and 149 bacteria responsible for infections were identified respectively. A higher incidence of Gram negative (G^-) with respect to Gram positive (G^+) bacteria was observed in both periods (A: 81/148, 55% vs 67/148, 45%; B: 88/149, 59% vs 61/149, 41%). Overall E. coli was the most frequent microrganism isolated and was similarly represented in the two periods (A: 38/81, 47%; B: 41/88, 47%); whereas Pseudomonas spp infections increased in period B (A: 13/81, 16%; B: 24/88, 27%, p=0.09); four cases were multiresistant (all in B period, 17%). Among G^+ bacteria, Stafilococci were more frequent during period A (42/67, 63%; vs 22/61, 36%, p<0.01), particularly S. aureus (23/67, 34% vs 7/61, 11%, p<0.01); Enterococci increased in period B (A: 13/67, 19%; B: 22/61, 36%, p<0.05) with resistance to vancomicin raising from 23% to 36%. Vancomycin-resistant Enterococci (VRE) and multiresistant Pseudomonas were associated with an uncontrolled haematological underlying disease (10/12), neutropenia (9/12) and hospitalization (12/12 nosocomial infections). VRE were responsible for perianal abscesses in five cases and for bacteraemia in three. Multiresistant Pseudomonas were responsible for pneumonia in one case and for bacteraemia in three. Crude mortality of microbiologically documented infections was 9% (12/137) and 8% (12/146) in period A and B respectively. A bacterial infection was responsible for 8/12 cases in period A (all but one were G^+) and for 6/12 cases in the B period (2 G^+ and 4 G). In two of the 6 cases of the B period, a multiresistant pathogen was implicated (1 vancomicin-resistant E. faecium and 1 multiresistant P. aeruginosa). *Summary and conclusions.* These data show that continuous epidemiological surveillance allows the prompt detection of emergent multiresistant pathogens at haematological units. Antibiotic policy should be guided by it. In particular, our data support a limitation in the use of third generation cephalosporins, of glycopeptide and carbapenems in order to contrast the emergence of resistant strains.

0609

SOFT TISSUE COMPLICATIONS IN PEDIATRIC LEUKEMIA PATIENTS WITH AND WITHOUT CATHETERS

F. Demircioglu, S. Yilmaz, H. Oren, G. Irken, A.A. Ozguven

Dokuz Eylul University, IZMIR, Turkey

Background. Skin and soft tissue complications due to invasive procedures for the administration of chemotherapeutic agents, blood sampling and supportive therapy are frequently seen in patients with leukemia. Central venous lines are an essential tool in the management of these patients especially in developed countries. Despite their benefits, catheters are often associated with local or bloodstream infections and a higher rate of infection in developing countries are expected due to low socioeconomic conditions, insufficient training and care. Frequency of skin and soft tissue complications in pediatric leukemia patients with and without catheters have not been compared previously. *Aims.* We wanted to evaluate skin and soft tissue complications secondary to procedures in acute leukemia patients with and without catheters and if the frequency of these complications is less in patients with catheters. *Methods.* Patient records of the children who were diagnosed and treated as acute leukemia between January 1996 and January 2006 in our hematology department were retrospectively evaluated. The following data were collected for each patient: age, gender, insertion of catheter, catheter type, catheter related complication, reason for removal, duration of induction and consolidation treatment, and skin and soft tissue complications in patients without catheters (e.g. sellulitis, abscess, drug extravasation). Patients were treated with ALL BFM 95 or AML BFM 93-98 protocols. *Results.* 87 acute leukemia patients (75 ALL, 12 AML) were included. There were 30 patients with 37 catheter use (6 port, 31 Hickman catheter) and 57 patients without catheter. Median age of all patients was 6 years, in patients with catheters 3.6 years and in patients without catheters 8 years. Median age of patients with catheters were significantly lower than patients without catheter (p=0.004). There was no gender difference between the patients with and without catheters (F/M ratio was 15/15 and 28/29, respectively; p=0.938). 37 catheters were removed for various reasons: 20 (54.1%) end of treatment, 5 (13.5%) infection, 3 (8.1%) unrelated death, 2 (5.4%) thrombosis, 2 (5.4%) tearing, one (2.7%) displacement, and 4 (10.8%) spontaneous removal. In patients with catheters, skin and soft tissue complications were seen in 20 (66%) children. Most frequent complication was cellulitis (n=11, 55%), which was followed by drug extravasation (n=6, 30%), skin ulceration, abscess and hematoma with one patient each. In one patient, coagulase negative Staphylococcus was shown in blood culture. In patients without catheter, skin and soft tissue complications were seen in 37(65%) patients as the following: 14 (37.8%) cellulitis, 14 (37.8%) extravasation, 7 (18.9%) abscess, and 2 (5.5%) skin ulceration. Blood cultures were positive in 6 patients (Klebsiella oxytoca, Staphylococcus aureus, Pseudomonas aureginosa, coagulase negative Staphylococcus, E. coli and E.coli + Pseudomonas aureginosa). When the frequency of skin and soft tissue complications in patients with and without catheters were compared to each other, there was statistically no significant difference (p=0.792). The duration of chemotherapy was significantly longer in patients who developed skin and soft tissue complications with or without catheters when compared to duration of therapy in patients without any skin and soft tissue complications (259.2±36.3 and 218.3±58.3 days, respectively; p<0.0001). *Conclusions.* In pediatric leukemia patients, with or without catheters, skin and soft tissue complications are common and these complications may prolong the duration of chemotherapy. In developing countries, use of catheters does not decrease the frequency of skin and soft tissue complications.

0610

PROGNOSTIC FACTORS OF INTRACRANIAL HEMORRHAGE IN PATIENTS WITH HEMATOLOGICAL MALIGNANCY

C.Y. Chen, P.Y. Chen, W. Tsay, W.C. Chou, J.L. Tang, H.F. Tien

National Taiwan University Hospital, TAIPEI, Taiwan

Background. Intracranial hemorrhage is the second leading cause of mortality in patients with hematological disease. Acute promyelocytic leukemia (APL) with DIC has been well controlled with all trans retinoic acid (ATRA). Most patients underwent the safety threshold of prophylactic platelet transfusion. However, the prognostic factors of Intracranial hemorrhage in patients with hematological disease is still under investigated. *Aims.* Identify the clinical characteristics and prognostic factors of intracranial hemorrhage in patients with hematological disease. *Methods.* We searched the term of *intracranial hemorrhage* in the discharge summary database of all patients admitted to the Department of Internal Medicine between January 1995 and September 2006. The adult patients with active hematological disease and spontaneous intracranial hemorrhage were enrolled in this study. The medical records and image study were reviewed retrospectively. *Results*. There were 50 patients (35 men and 15 women) with ICH, the median age was 51 year-old (range 17-86). The hematological diseases subtypes were 30 acute myeloid leukemia (non-APL), 11 APL, 4 acute lymphoblastic leukemia and 5 myelodysplastic syndrome / severe aplastic anemia. Most patients were in relapsed / refractory status of underlying hematological disease except 7 patients were in remission status. Intracranial hemorrhage mainly located at supratentorium (41), basal ganglion (8), cerebellum (5), and brain stem (4). There were 19 patients had multiple sites hemorrhage in the image study. The types of hemorrhage included intracerebral hemorrhage (35), subarachnoid hemorrhage (15), subdural hemorrhage (13), epidural hemorrhage (1) and 11 patients had hemorrhage rupture into ventricles. Most of the patients received supportive care because bleeding tendency. Only 4 patients received surgical intervention and three patients survived. Thirty-three patients (66%) died of intracranial hemorrhage. The age, gender, underlying hypertension, sepsis, hematological subtypes, remission status, hemogram, and surgical intervention had no impaction on survival. Patients with subdural hemorrhage had better prognosis (p=0.021) than the other type of hemorrhage. The hemorrhage located at the basal ganglion (p=0.039), and subarachnoid hemorrhage (p=0.009) had worse prognosis. *Summary / Conclusons.* Intracranial hemorrhage cause high mortality and occurred mainly in advanced stage of hematological disease. Further novel treatment of hematological malignancies maybe effectively reduce the incidence of Intracranial hemorrhage.

0611

HICKMAN LINE REMOVAL IS SUCCESFULL IN TREATING MOST OF THE SEPTIC EPISODES SECONDARY TO RHODOTURULA FUNGAEMIA IN IMMUNOCOMPROMISED HAEMATO-ONCOLOGY PATIENTS

P. Gallipoli, B. Jones, I.G. McQuaker, A.N. Parker

Glasgow Royal Infirmary, GLASGOW, United Kingdom

Background. Rhodotorula species are saprophytic yeasts belonging to the family Cryptococcaceae. They have been isolated from human skin, environmental sources and seem to have strong affinity for plastics. Rhodotorula species show low virulence but have been reported causing serious infections in immunocompromised patients, particularly in the presence of indwelling catheters. *Aims.* To analyse retrospectively incidence, clinical presentation, risk factors, treatment and outcome of Rhodoturula infections within our 15 bedded haemato-oncology and bone marrow transplant unit between August 2003 and September 2006. *Methods.* All Rhodoturula isolates within our unit during the study period were identified by our Microbiology Department. Case notes from the patients with positive isolates were analysed and information collected on clinical presentation, risk factors, treatment and outcome of the infection. *Results*. 21 positive isolates in 10 different patients were identified. All positive cultures were blood cultures from Hickman lines. 12 infective episodes were documented from case notes giving an incidence of 3.78 episodes/year within our unit. In all cases, patients presented with pyrexia secondary to Rhodoturula fungaemia (defined as at least one positive blood culture) but no evidence of any other organ involvement. 7 episodes were in patients within 6 months of an allogenic bone marrow transplant (all conditioned with MabCampath), 4 in patients who had undergone intensive chemotherapy before the infection, and 1 in a patient who had received immunosuppressive medications during the 6 months before the infection. 6 cases happened in patients who had been neutropenic (Absolute Neutrophil count<1) for a prolonged time (range 10 days to 12 months). In 11 episodes the line was removed when preliminary culture results were available. In one episode the line was not removed but the infection recurred within 60 days requiring line removal. Patients were started on intravenous antifungals in 9 of 12 episodes (7 liposomal amphotericin, 1 conventional amphotericin and 1 caspofungin)and treated with oral azoles (voriconazole, itraconazole and fluconazole) in the remaining 3 episodes. All antifungals were started either empirically for persistent pyrexia or on receiving a positive culture, but before classification of yeast isolates was available. As a result, in 2 cases Rhodotorula proved to be resistant to the chosen agent, but, in both cases, antifungals were not changed as patient conditions had improved. All patients survived the septic episode without clinical consequences. *Conclusons.* Most Rhodotorula infections are of low virulence. Presence of an indwelling catheter and immunosuppression are the main risk factors. Treatment with MabCampath appeared to be a possible risk fac-

tor. In 50% of the episodes, patients had a normal neutrophil count, but they were significantly immunocompromised either because of concomitant treatment or underlying disease, thus confirming that a normal neutrophil count does not provide a significant protection against opportunistic infection in aggressively treated haemato-oncology and post bone marrow transplant patients. Line removal is probably sufficient to treat most of the septic episodes secondary to Rhodoturula, therefore saving the patient unnecessary treatment with a potential toxic drug. However when clinical conditions are not improving, despite line removal, the introduction of antifungals may be needed.

0612

PROSPECTIVE CYTOMEGALOVIRUS MONITORING IN ACUTE MYELOID LEUKAEMIA DURING FIRST LINE THERAPY

S.C. Capria, G. Gentile, S.M. Trisolini, A. Capobianco, L. Cardarelli, G. Natale, A. Belfanti, R. Foà, P. Martino, G. Meloni

La Sapienza University, ROME, Italy

Background. Despite the extensive knowledge about the incidence and clinical impact of CMV infection in acute leukaemia patients receiving stem cell transplantation, very little is known about its role in acute myeloid leukaemia (AML) patients at onset and during first line intensive chemotherapy. *Aims.* Aim of our study was to analyse prospectively the incidence of active CMV infection in AML patients, focusing on the role and therapeutic implications of CMV serial monitoring from diagnosis until transplant procedure. *Methods*. Since 8/2002, 68 AML patients at diagnosis (M/F: 33/35; median age: 45 years, range 24-61) were consecutively evaluated. All patients were scheduled to receive induction therapy including standard-dose (SD) or high-dose (HD) Ara-C, Etoposide and Daunorubicin and consolidation therapy with intermediate-dose (ID) Ara-C and Daunorubicin. Active CMV infection was defined as any positivity of pp65 antigenemia in the peripheral blood, while CMV disease was defined as the detection of CMV in tissue samples. Pp65 antigenemia monitoring was scheduled at diagnosis, post-induction and post-consolidation chemotherapy. CMV pre-emptive treatment consisted of Gancyclovir 5 mg/kg/12h for 12-21 days or Cidofovir 5 mg/kg/week for a total of 4 doses. Recovery was defined as negative antigenemia in two consecutive controls. All patients received Acyclovir prophylaxis for Herpesvirus infections during neutropenia after chemotherapy. *Results.* Among the 68 patients enrolled in the study 58 (85,3%) achieved complete remission (CR) (3 refractory; 7 toxic deaths) and 56 received consolidation (2 early relapses). 54/56 patients are evaluable after consolidation. At diagnosis pp65 antigenemia was negative in all patients evaluated . Overall incidence of positive antigenemia in the whole population was 29% (17/58 patients): in particular 17% after induction (10/58 patients in CR) and 12% (9/54) post consolidation. Among patients positive after consolidation only 2 were positive post induction. None of the patients had CMV disease. Gancyclovir treatment was instituted in 8 patients, Cidofovir in 8, while in 3 patients no treatment was given. Recovery of infection was achieved in all cases. The incidence of CMV infection in patients receiving HD or SD Ara-c was of 46%(11/26) and 18%(6/32) respectively (p<0,05). Median follow up from CR was 24 months (range 1-60). Overall relapse rate of acute leukaemia was 44% (26/58). The median interval from diagnosis to consolidation for patients CMV$^+$ and CMV- after induction was of 87 (51-100) and 64 (44-155) days respectively (p<0,05). Overall projected probability of survival at 70 months is 53% (55% vs 52% for CMV$^+$ and CMV- respectively). *Summary.* CMV active infection has an high incidence (29%) in AML patients during chemotherapy. HD Ara-c is associated with a significant increase in CMV positivity and the time interval between induction and consolidation seems to be delayed in CMV$^+$ patients. Our results show that CMV reactivation is not only a problem of stem cell transplantation, and suggest the importance of CMV monitoring and of therapeutic guidelines since diagnosis, in order to prevent the risk of CMV disease without compromising leukaemia treatment.

0613

SEPSIS IN PATIENTS RECEIVING MYELOABLATIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA: NO ASSOCIATION WITH MANNOSE-BINDING LECTIN GENE (MBL2) POLYMORPHISM

A. Klostergaard,[1] R. Steffensen,[2] J.K. Moller,[1] N.A. Peterslund,[1] C. Juhl-Christensen,[1] I. Molle[1]

[1]Aarhus University Hospital, AARHUS V; [2]Aalborg University Hospital, AALBORG, Denmark

Background. Infections after chemotherapy are a major problem in patients with acute myeloid leukaemia (AML). Mannose-binding lectin (MBL) is part of the innate immune system, and deficiency of MBL occurs in patients with common gene variants (AO/OO) compared with the wild-type gene (AA). In addition, polymorphism in the promoter region influence the concentration of MBL. The promoter variant X is associated with low transcription in contrast to the high-transcription promoter variant Y.[1] Variant MBL2 seems to increase the risk of infections in multiple myeloma patients after high-dose melphalan and autologous stem cell transplantation,[2] in children with malignancy treated with chemotherapy,[3] and in patients admitted to intensive care unit.[4] In contrast, no association between the serum level of MBL and infections in AML patients was seen in a smaller study.[5] *Aims.* To investigate the possible associations between MBL2 polymorphism and sepsis in patients treated with high-dose chemotherapy for AML. *Methods.* Patients were included from a single centre between 1/1-1993 and 1/9-2004. The follow-up period was six month from diagnosis. Prophylactic antibiotics were not used after chemotherapy. We included 191 patients treated with myeloablative chemotherapy for AML. Infections were identified retrospectively using clinical records, and microbiological database extractions. MBL2 genotypes were identified by using real-time polymerase chain reactions (PCR) in stored samples of bone marrow aspirates. *Results.* We identified 603 febrile episodes in 191 patients. In 246 episodes (41%) sepsis was present. Thirty-two patients (17%) either died from sepsis, or sepsis was a major concomitant factor for death. Associations between MBL2 polymorphism and sepsis are shown in the table. No significant association with MBL2 polymorphism and fever, sepsis (p=0.79) or death due to sepsis was seen. Furthermore, no significant association with MBL2 and the type of sepsis (whether gram positive, gram negative, or mixed) was found (p=0.16). *Conclusions.* No association between MBL2 polymorphism and the risk of sepsis in AML patients was seen. This result differs from the previous findings in children with malignancy[3] and multiple myeloma patients,[2] but confirms the previous study in AML patients.[5] The severe and long-lasting neutropenia and mucositis after chemotherapy are probable explanatory factors, why the MBL system seems to offer no protection against sepsis in AML patients. Replacement therapy using recombinant human mannan-binding lectin is possible ,and considerations are made, whether replacement therapy could benefit different patients groups.[6] MBL replacement therapy is not likely to decrease the risk of sepsis in AML patients.

Table 1.

	High-functioning Genotypes (YA/YA; YA/XA)	Intermediate-functioning Genotypes (XA/XA; YA/YO)	Low-functioning Genotypes (YO/YO; XA/YO)	
Culture-positive Sepsis episodes	132	74	40	246
Culture-negative Febrile episodes	188	116	53	357
	320	190	93	603

PREDOMINANCE OF GRAM-NEGATIVE BACTEREMIA IN FEBRILE NEUTROPENIA EPISODES: AN EPIDEMIOLOGIC EVALUATION IN A BRAZILIAN HEMATOLOGIC SERVICE

L.C. Palma, M.I.A. Madeira, L.F. Dalmazzo, M.C. Favarin, C.E.E. Velano, C.H. Kruzich, L.C.O. Oliveira, L.L.P. Figueiredo, G.G. Gaspar, J.F.C. Figueiredo, B.P. Simões, E.M. Rego

HCFMRP-USP, RIBEIRÃO PRETO, Brazil

Background. Some studies have shown a predominance of gram-positive bacteremia in febrile neutropenia patients. Potential reasons include the use of indwelling catheters, local environmental conditions and the administration of specific antibiotic agents, especially prophylaxis. Some reports have shown that weather's characteristics could influence the patterns of infection. Brazilian weather is very heterogeneous varying a lot along its vast territory. Therefore, there is no consistent data about Brazilian febrile neutropenia's epidemiology. *Methods.* We retrospectively analyzed a total of 92 patients, which were divided in two groups: myeloid neoplasia (69 patients) and lymphoid neoplasia (23 patients). *Results.* Between 2000-2006, we analyzed 266 febrile neutropenia episodes. The median age of the patients was 37.5 (16-81) years-old. In 36% of cases, there was at least one organism (bacteria or fungal) isolated in blood culture. Gram-negative bacteremia was identificated in 65% of these cases and the most frequent gram-negative bacterias were Escherichia coli (31%) and Klebsiella pneumoniae (23%). The resistance of these two bacterias to cefepime, which is the standard empirical treatment in our service, was 13% and 81%, respectively. Gram-positive bacterias and fungal were isolated in blood cultures in 31% and 14% of cases, respectively. Staphylococcus epidermidis was the most frequent gram-positive bacteria (9%). In 8% of cases, more than one organism were isolated and gram-negative bacterias predominated in these episodes (81%). There was in 62% of episodes the presence of at least one identifiable site of infection. Pneumonia and skin infection were the most common site of infection (31% and 24%, respectively). There was no difference in the frequency or resistance of the organisms between the myeloid and lymphoid neoplasia groups. 15% of patients died during the febrile neutropenia episode. The most important factors influencing the overall survival in an univariate analysis were diagnosis of a myeloid neoplasia (OR:5.86, p=0.0002), bacteremia by Klebsiella pneumoniae (OR: 4.40, p=0.012), the presence of pneumonia (OR: 4.37, p=0.0001), age ≥ 65 years-old (OR: 3.6, p=0.015), the presence of a gram-negative bacteremia (OR: 2.27, p=0.04), the presence of at least one identifiable site of infection (OR: 2.23, p=0.049). *Conclusions.* These results differ from other ones coming from developed countries (Kanamuru and Tatsumi CID 2004, Ramphal CID 2004), where the gram-positive bacterias are more frequently isolated in blood culture during febrile neutropenia episodes. One explanation for our findings is the fact that we do not usually use ciprofloxacin as a primary prophylaxis. However, recently, some studies showed a shift towards gram-negative bacteremia during febrile neutropenia (Guven Support Care Cancer 2006). Therefore, our results reinforce the concept that antibiotic therapy for febrile neutropenia should be adapted to the local epidemiologic data.

COST-EFFECTIVENESS OF PEGFILGRASTIM VS. FILGRASTIM PRIMARY PROPHYLAXIS IN PATIENTS WITH NON-HODGKINS LYMPHOMA RECEIVING CHOP-21 IN FRANCE

F. Maloisel,[1] O. Bogillot,[2] J. Malin,[3] V. Tochon,[2] Z. Liu,[4] Q. Doan,[4] A. Lalla,[4] R. Dubois[4]

[1]Hospices Civils, STRASBOURG, France; [2]Amgen S.A., PARIS, France; [3]Amgen Inc., THOUSAND OAKS, USA; [4]Cerner LifeSciences, BEVERLY HILLS, USA

Background. Primary prophylaxis (starting in the first chemotherapy cycle and continuing for all subsequent cycles) with granulocyte-colony stimulating factors (G-CSF) is recommended in the 2006 ASCO and EORTC guidelines for patients with a risk of febrile neutropenia (FN) equal to or greater than 20%. Both filgrastim (the first-generation G-CSF, daily injections) and pegfilgrastim (the second-generation, pegylated version of G-CSF, once per cycle) are commonly used. However, data from certain clinical trials suggest that pegfilgrastim was associated with a lower risk of FN compared with filgrastim. Moreover, in clinical practice filgrastim has often been used for shorter-than-recommended courses of administration; this has been shown to be associated with less clinical benefit. *Aims.* We evaluated the cost-effectiveness of pegfilgrastim vs. filgrastim used for 11 days (as used in the randomised trials demonstrating efficacy) and 6 days (as often used in clinical practice) in patients with aggressive NHL receiving CHOP-21 in France. *Methods.* A decision-analytic model was constructed from a healthcare payer's perspective. The study time horizon was life-time. Model inputs, including FN risk (varied by days of filgrastim use), FN case-fatality, relative dose intensity (RDI), and impact of RDI on survival were based on a comprehensive literature review and expert panel validation. Costs were acquired from official price lists or literature and included drugs, drug administration, FN-related hospitalisations, and subsequent medical costs. NHL mortality and all-cause mortality were obtained from official statistics. Using data from a meta-analysis (pegfilgrastim vs. 11 days of filgrastim) and from observational studies (pegfilgrastim vs. 6 days of filgrastim), we estimated that the absolute risk of FN in patients receiving pegfilgrastim decreased by 6.5 percentage points (19.6% vs. 13.1%) vs. 11-day filgrastim, and by 12 percentage points (25.1% vs. 13.1%) vs. 6-day filgrastim. Next, we estimated the impact of a difference in FN risk on FN-related mortality, RDI, and long-term survival. Sensitivity analyses were used to assess the model robustness. Outcomes were measured as incremental cost-effectiveness ratio (ICER) including € per percentage (absolute) FN risk decreased, € per life-year gained (LYG), and € per quality-adjusted life-year (QALY) saved. *Results.* Pegfilgrastim was cost saving compared with 11-day filgrastim (€10,457 vs. €13,081 for pegfilgrastim vs. filgrastim). Compared with 6-day filgrastim, pegfilgrastim was associated with ¢226 per additional 1% decrease in absolute risk of FN. Pegfilgrastim achieved 7.57 LY (6.51 QALY) as compared to 7.45 LY (6.41 QALY) from filgrastim at a moderate cost increase of €2,707 per person, yielding an ICER of €24,387/LYG (€27,214/QALY saved) (Table 1). Results were sensitive to the assumption of RDI impact, relative risk of FN for 6-day filgrastim vs. pegfilgrastim and study time horizon. *Summary and conclusions.* In France, pegfilgrastim was less expensive than 11-day filgrastim. Pegfilgrastim resulted in a gain in life-years with a moderate cost increase compared with filgrastim used for 6 days per CHOP-21 chemotherapy cycle.

Table 1. Cost-effectiveness of pegfilgrastim vs. 6-day filgrastim.

CAPILLARY LEAK SYNDROME IN HEMATOLOGICAL PATIENTS: UNICENTRIC PROTOCOL FOR MANAGEMENT AND TREATMENT

M. Postorino, L. Franceschini, G. De Angelis, L. Pupo, F. Buccisano, D. Renzi, S. Faccia, M. Rizzo, L. Giannì, L. Di Caprio, C. Ditto, M. Cantonetti, W. Arcese

University of Tor Vergata, ROME, Italy

Capillary leak syndrome (CLS) is an uncommon (< 10%) early complication of hematopoietic stem cell transplantation (HSCT) or intensive chemotherapy caused by the injury of the cytokines against the vascular endothelium, with loss of sodium, albumin and fluids into the interstitial space. The clinical features of CLS are: weight gain (>4% in 24h), generalized oedema, hypotension and renal insufficiency of pre-renal origin. The CLS is related to a high risk of mortality due to frequent progression in a multiorgan failure (MOF). In order to evaluate if an early treatment has a prognostic impact, we designed a prospective protocol: all patients undergoing autologous or allogeneic HSCT or intensive chemotherapy for acute leukemia or bulky lymphoma were monitored every 6 hours for weight, arterial pressure and fluid balance from the beginning of chemotherapy until 16 days after the end of chemotherapy or pre-transplant conditioning. In presence of > 2% weight gain and/or 1000 cc positive fluid balance at 6 h, furosemide was given at dose of 0.4 mg/kg. After 1 hour, if patient didn't responde to furosemide (normalization of weight and fluid balance), 100 cc of 18 % mannitolo and after 30 minutes 125 mg of furosemide were administered. In case of a persisting negative response, we began CLS therapy consisting of dopamine (4 ug/kg/min), prednisolone (1 gm/kg) and furosemide (250 mg by continuous infusion) for 24 hours. After 24 hours, if the response to therapy was positive, the pt continued the same therapy until the stabilization of the clinical picture; in the other case we began the continuous hemofiltration until the normalization of clinical parameters. From January 2004 to July 2006, 10 patients met the diagnostic criteria for CLS (2 HSCT: allogeneic n=2, autologous n=3; bulky NHL n= 2; AML: n=3) . The 5 transplanted patients responded to the treatment with dopamine and prednisolone (PDN) with resolution of all symptoms within 24 hours. Two of 3 AML patients not responding to dopamine and PDN underwent hemofiltration within 24 hours with complete resolution of symptoms after a median time of 72 hours (range 48-96 h) . Three patients (2 LNH and 1 AML), not responding to the first line therapy, for clinical and logistic reasons, underwent hemofiltration later than 24 h: all 3 patients progressed in a MOF and died. Altought limited to a small number of cases, from our experience we can draw the preliminary conclusion that our protocol seems to be effective 1) in monitoring patients at risk for developing CLS and 2) in permitting an early diagnosis and treatment of CLS. Furthermore, our study suggests that hemofiltration within 24 hours could be a crucial intervention for patients not responding to the first line therapy.

INFECTIOUS COMPLICATIONS IN REDUCED INTENSITY STEM CELL TRANSPLANTATION PATIENTS

M. Uzunov, S. Wittnebel, E. Chachaty, F. Griscelli, I. Radu, P. Arnaud, N. Itzhar, C. Boccaccio, J.H. Bourhis

Institut Gustave Roussy, VILLEJUIF, France

Background. Infections are a common complication of allogeneic stem cells transplantation (SCT) and contribute significantly to transplant-related morbidity and mortality. It has been hypothesized that transplantation following reduced intensity conditioning (RIC) would result in fewer infections by causing less mucositis, shorter duration of neutropenia and allowing earlier immune reconstitution. *Aims.* We aimed to evaluate the infectious transplant-related mortality in patients which received a RIC in our center. *Methods*. We have retrospectively reviewed the data of 117 consecutive patients (pts) with hematological malignancies or solid tumors that underwent an RIC allogeneic transplantation from November 1999 until November 2006. The conditioning regimen included Fludarabine in 109 pts (93,16 %)+TBI2Gy, Busulfan, ATG, Endoxan, Ida, Ara-C or Melphalan. 81,19% pts received SCT from an identical sibling and 18,8% pts from an MUD. Post transplant immunosuppression consisted in CSA and/or MMF or short course MTX. The patients did not receive antibacterial prophylaxis or systematic oral digestive decontamination. Pneumocystis carinii prophylaxis consisted of trimethoprim/sulfamethoxazole and systemic antifungal prophylaxis by fluconazole. The CMVpp65 antigenemia assay was used to monitor the pts. All patients with a positive antigenemia received pre-emptive therapy (ganciclovir, foscavir or valganciclovir). *Results.* Cytomegalovirus (CMV) infection occurred in 32 pts (36.78% of the 87 pts at risk of reactivation - donor, recipient or both having a positive CMV serology) and CMV pulmonary disease in only 1 pt (1.14%). There is a strong relationship between CMV infection and GVHD. The rate of CMV reactivation was of 50% for the pts at risk that developed a GVHD, and only 27% in the absence of GVHD. First episode of CMV infection occurred at day 39(range 30-180), and 7 pts presented more than one episode. Only one pt died because of CMV pulmonary disease. We noted a trend to a lower lymphocyte count at day 30 and at day 100 in pts reactivating CMV compared to the pts at risk that did not reactivate de CMV. A sustained absolute neutrophil count of >0,5 x 109/l was reached at a median of 18(range 1-37) days. 29(24,8%) patients experienced one or more episodes of bacteriemia - 10 pts (8,5%) during the first 30 days post transplant, 14 pts (12%) from D 30 to D 100, 15 pts (12,8 %) from D100 to one year post transplant, most of them due to coagulase-negative staphylococci (55%). Gram negative bacteraemia accounted for only 21,6% of the events. Pneumocystis carinii pneumonia occured in 3 pts, cerebral toxoplasmosis in 1 pt, and were concomitant with GVHD. Five patients (4,2%) presented new onset invasive aspergillosis in the post transplant period (1 proven, 4 probable). Of note, two other pts that had documented fungal infection before SCT (1 proven pulmonary and intestinal aspergillosis, and 1 probable pulmonary aspergillosis) and received voriconazole prophylaxis did not reactivate the aspergillosis after the transplant. At the time of analysis 50 patients died during the follow-up period and 67 are still alive with a median follow up of 23 months (3-88,5). The majority of deaths (34%) were directly attributed to disease progression or relapse. Only 6 deaths (5.12%) were directly attributed to infection as the principal cause of death. 6 patients died because of uncontrolled GVH and documented infection was a contributively cause of death for 2 patients in the setting of the GVHD. *Conclusion*. Our results suggest that RIC SCT is associated to a low incidence of bacterial, viral and fungal infection. The incidence of documented fungal infections compares favorably with the already published data. In our patients the infectious transplant-related mortality was low. Whether these findings would translate into an improved overall survival needs to be confirmed in further prospective studies.

ADDITION OF CLADRIBINE TO DAUNORUBICIN AND CYTARABINE HAS NO IMPACT ON INFECTIOUS COMPLICATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA. A MULTICENTER, RETROSPECTIVE STUDY BY THE POLISH ADULT LEUKEMIA GROUP

E. Lech-Maranda,[1] M. Seweryn,[2] J. Holowiecki,[2] B. Piatkowska-Jakubas,[3] J. Wegrzyn,[3] A. Skotnicki,[3] M. Kielbinski,[3] K. Kuliczkowski,[3] M. Paluszewska,[4] W.W. Jedrzejczak,[4] M. Dutka,3 A. Hellmann,3 M. Flont,[3] B. Zdziarska,[3] G. Palynyczko,[5] L. Konopka,[5] T. Szpila,[3] K. Warzocha,[3] K. Gawronski,[6] K. Sulek,[6] J. Sokolowski,[3] J. Kloczko,[3] J. Gora-Tybor,[3] T. Robak[3]

[1]Medical University of Lodz, LODZ; [2]Department of Hematology and BMT, SILESIAN MEDICAL UNIVERSITY, KATOWICE; [3]Department of Hematology, JAGIELLONIAN UNIVERSITY, CRACOW; [4]Department of Hematology and Oncology, MEDICAL UNIVERSITY OF WARSAW; [5]Department of Internal Diseases, INSTITUTE OF HEMATOLOGY, WARSAW; [6]Department of Clinical Hematology, MILITARY MEDICAL ACADEMY, WARSAW, Poland

Background. Infectious complications occur in most of the patients with acute myeloid leukemia (AML) receiving the induction therapy. It was reported that addition of cladribine to daunorubicin and cytarabine increases complete remission rate after a single course of induction treatment in AML patients (Leukemia 2004). However, the use of purine analog cladribine may increase the risk of infection due to the prolonged T-lymphocyte depletion produced by this agent. *Aims*. We sought to determine whether the induction therapy with cladribine, daunorubicin and cytarabine (DAC-7 regimen) compared to the standard induction treatment with daunorubicin and cytarabine (DA-7 regimen) had an impact on the incidence and spectrum of infections among a series of untreated adult patients with AML. *Methods.* Three hundred nine AML patients were enrolled into a multicenter, retrospective study. Patients were randomized either to DA-7 (n=157) or DAC-7 (n=152) induction treatment. Differences in the infection rate among treatment arms were tested with the Kruskal-Wallis, Wilcoxon, and chi2 tests. *Results.* A total episodes of 422 infections occurred in 309 patients over the period of the induction treatment. Two hundred eight infections were of grade III/IV according to the WHO classification. There was no difference in over-

all infection rate (p=0.12) as well as grade III/IV infection frequency (p=0.23) among patients treated with DA-7 or DAC-7 regimen. Microbiologically or clinically documented bacterial infections occurred in 127 (41%) patients, including 67 (43%) DA-7 patients and 60 (39%) DAC-7 patients (p=0.5). A total of 71 (23%) episodes of bacteremia were found, including 60% Gram-positive, 30% Gram-negative, and 10% mixed blood cultures. Forty-two (27%) patients in the DA-7 group and 29 (19%) patients in the DAC-7 group had bacteremia (p=0.06). Microbiologically documented fungal infections occurred in 42 (13%) patients, including 16 (10%) DA-7 patients and 26 (17%) DAC-7 patients (p=0.06). A total of 5 (2%) episodes of fungemia were reported and its frequency was similar in both study arms. Viral infections were observed in 35 (11%) patients and it did not occur more often in patients receiving DAC-7 therapy when compared to patients treated with DA-7 regimen (p=0.6). At univariate analysis, AML subtypes according to FAB classification, preceding myelodysplastic syndrome, age, sex, induction treatment arm, response to induction therapy, the presence of Hickman's catheter, and the use of antimicrobial prophylaxis were not significantly associated with the risk of infection. In all, 11 (7%) patients died of infection'related complications in the DA-7 arm compared to 17 (11%) in the DAC-7 arm (p=0.4) *Conclusions.* Addition of cladribine to daunorubicin and cytarabine did not result in significantly more infectious complications than standard treatment with daunorubicin and cytarabine in adult AML patients.

0619

ACICLOVIR PROPHYLAXIS FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION

S. Bacchu,[1] K. Holder,[2] H. Osman,[2] J. Ewing[2]

[1]University Hospitals of Wales, CARDIFF; [2]Birmingham Heartlands Hospital, BIRMINGHAM, United Kingdom

Background. Herpes viruses establish a latent phase following primary infection. Viral reactivation occurs in more than 30% patients following allogeneic stem cell transplant. Most of cases occur between 3-12 months after transplantation. Current evidence suggests that infection rates can be decreased by giving prophylaxis however there is no consensus on the duration of prophylaxis and doses. Our previous audit study (2001 -2003) showed that the administration of prophylaxis until neutrophil engraftment left patients at risk of viral reactivation occurring in 76% of allograft recipients leading to considerable morbidity and healthcare cost. It was shown that these reactivations occurred during the period of time prior to the recovery if CD4 count to a level of >300/mm^3. The audit outcome led to a decision to extend the duration of prophylaxis until CD4>300/mm^3, by doing so we hoped to considerably decrease infection rates. *Aim*. The first aim of the study was to assess compliance in prescribing to our own standard.We also needed to re-audit to assess whether the change in standard resulted in reduction in herpes virus reactivation rates as predicted from our previous study. *Methods.* This was a single centre, retrospective study conducted at Birmingham Heartlands Hospital with a study period between January2004 -January 2006. All patients who survived >100days post-transplant were included. The standard against which we assessed our practice was our own JACIE standard operating protocol for prevention of infection post transplantation (Joint accreditation committee of institute of cellular biology and EBMT). The protocol stated to continue aciclovir prophylaxis at a dose of 200mg bd until CD4 count reaches 300/mm^3.Source data was obtained from the transplant database, case notes, drug charts and confirmatory virology reports.

Figure 1. Shows CD4 and HSV/VZV infection.

Results. In the current study there were twenty eight patients who underwent allogenic transplant during the study period, five were excluded due to transplant related mortality (n=23). Sixteen were Sibling transplant and seven MUD.The median duration for of follow up was 442 days and median duration of prophylaxis was 348 days. During this period there were 6/23 (26%) episodes of HSV/VZV infections (Figure 1). Compliance was seen in 21/23 patients (91%). Non-compliance with prescribing resulted in one episodes each of HSV and VZV infection prior to the target CD4 count being achieved. Four episodes of viral reactivation occurred in patients with CD4>300/mm^3. Of these two patients had disseminated VZV infections resulting in hospitalisation and intravenous aciclovir therapy. Three individuals have since suffered from recurrent episodes of HSV/VZV and are on long term prophylaxis in spite of attaining a CD4>300/mm^3. *Summary and Conclusions*. In our previous study there were sixteen episodes of HSV /VZV reactivation (n=21). In comparison we had only six in our present study. There was also a reduction in recurrent episodes from six (n=21) to four (n=23). We have achieved a significant reduction in morbidity due to re-activation of VZV and HSV infections in allogeneic bone marrow transplant patients by our approach.

0620

HAEMATOLOGICAL FEATURES OF LEISHMANIASIS RESEMBLING BLOOD-RELATED MALIGNANCIES: THE CONCERN OF A DIFFERENTIAL DIAGNOSIS THROUGH THE PRESENTATION OF SIX CASES

M. Palombi,[1] P. Niscola,[1] M.M. Trawinska,[1] S. Fratoni,[2] A.P. Perrotti,[1] S. Amadori,[1] P. de Fabritiis[1]

[1]Tor Vergata University, Sant'Eugenio, ROME; [2]Pathology Department, S.Eugenio Hospital, ROME, Italy

Background. Leishmaniasis is a chronic infectious disease from the group of anthropozoonoses. It is caused by protozoa in the genus leishmania flagellate. Infection is transmitted by insects; Mediterranean countries are one of the major foci of this disease in the world. The course of the disease may be acute, subacute and chronic and several forms are differentiated such as visceral, cutaneous and mucocutaneous. The diagnosis is established by serologic tests; however, parasitological findings in macrophages of the bone marrow (BM) can be observed. Several signs of disease, such as elevated temperature, gastrointestinal disorders, splenomegaly and hepatomegaly, generalized lymphadenomegaly and pancytopenia, may resemble several haematologic malignancies, for which some challenging concerns may arise in the differential diagnosis, as recently observed by us in a series of six cases that is hereby reported. *Case series.* There were 6 patients (3 male) with a median age of 34 (20-60) years. In all patients the symptomatolgy started gradually with uncharacteristic manifestations, such as fatigue, gastrointestinal discomforts, loss of appetite, nausea, and vomiting, accompanied by fever. Temperature increased twice a day and was followed by shuddering and very often by nocturnal sweating. Antibiotics and antipyretics were used without any benefits. Subjective discomforts were increasingly pronounced, so that due to unclear febrile state and in addition to the present pancytopenia for which patients kept under our attention. On the physic examination all presented splenomegaly and three presented lymphadenopathies. The laboratory findings pointed to pancytopenia with lymphocytosis and monocytosis; moreover, important polyclonal hypergammaglobulinemia ranging from 2 to 6 gr (median 4 gr.) was found. BM aspirates and trephine biopsies were performed in all patients. Hypocellularity was found in all cases; moreover, in three patients the examination of BM smears revealed 15% to 25% polyclonal lymphocytes infiltrating the BM. Lastly, both intra- and extracellular protozoa resembling leishmaniasis were detectable in three cases. In the remaining cases, no intramacrophagic or extracellular protozoa were found for which the diagnosis was suspected and then confirmed by serologic tests after the evaluation of all other diagnostic tests in order to exclude an hematologic malignancy that were into normal values. After the establishment of diagnosis, patients received causal therapy with liposomal amphotericin B and rapidly recovered; the decrease of splenomegaly as well the reduction of hypergammaglobulinemia and the improvement in haematological findings were observed. *Conclusions.* Hematologic findings which are characteristic for leishmaniasis may resemble some of those associated with haematologic malignancy, such as lymphomas and acute leukemias; however, in the presence of polyclonal hypergammaglobulinemia, fever, splenomegaly and pancytopenia, this infectious disease should be suspected and specific serologic tests should be done together a BM examination.

0621

ACICLOVIR-INDUCED NEUROTOXICITY IN HEMATOLOGICAL PATIENTS. MEASUREMENT OF THE ACICLOVIR MAIN METABOLITE CMMG MAY DIFFERENTIATE BETWEEN ADVERSE DRUG REACTIONS AND HERPES INFECTIONS

A. Helldén, O. Odar-Cederlof

Dept of Laboratory Medicine, STOCKHOLM, Sweden

Background. The antiviral drug aciclovir and its prodrug valaciclovir is commonly used to treat herpes virus infections in hematological patients. Both drugs have in general low toxicity with GI-disturbances and headache as common side-effects. However, CNS-symptoms such as tremor, confusion, hallucinosis and coma have been reported, mainly in patients with chronic or acute renal failure (ARF). The CNS side-effects may confuse the clinical picture and make it difficult to distinguish between adverse drug reactions (ADRs) and viral infection. It may result in increased doses of aciclovir instead of withdrawal of the drug. Other drugs used in hematology patients may also interact on aciclovir excretion in the kidneys and increase the risk for high aciclovir concentrations, resulting in acute renal failure, followed by CNS-symptoms. We have previously shown that the aciclovir main metabolite 9-carboxymethoxymethylguanine (CMMG) is consistently increased in serum and CSF in patients with aciclovir-related CNS-symptoms and that CMMG might have importance as a marker of aciclovir-induced neurotoxicity. *Aims.* To increase the knowledge on aciclovir-induced toxicity in hematological patients. *Methods.* We present 3 haematological patients, one with myeloma, one with a mantel cell lymphoma and one bone marrow transplanted (BMT) patient with chronic myeloid leukaemia which developed severe aciclovir-related CNS-toxicity despite doses according to the Swedish Physicians Desk Reference. Aciclovir and CMMG concentrations were measured in two of the patients. *Results.* The BMT patient developed acute renal failure, nightmares and depression after institution of valaciclovir 500 mg b.i.d. Aciclovir and CMMG concentrations 16 hrs after last dose were 39 and 29 μmol/L, respectively (normally <10 μmol/L and <6 μmol/L 8 hrs after dose). One myeloma patient on hemodialysis developed confusion, agitation, slurred speech, somnolence and myoclonus on oral aciclovir 200 mg q.i.d. No concentrations was analysed in this patient. The patient with mantel cell lymphoma was treated with IV aciclovir 250 mg b.i.d. and developed ARF, confusion, disorientation, psychosis and somnolence. The aciclovir and CMMG concentrations 72 hrs after last dose were 6.0 and 6.0 μmol/L, respectively, indicating high concentrations 8 hours after last dose. One patient improved after a hemodialysis session, one developed multiorgan failure and died of AMI a few days after the aciclovir-intoxication despite hemodialysis and the last patient improved three days after withdrawal of aciclovir. *Summary and Conclusions.* Aciclovir- or valaciclovir-induced CNS-symptoms and ARF are important ADRs in hematological patients and may be more frequent than previously recognized. Measurement of CMMG seems to be a useful marker of aciclovir toxicity and might function as a diagnostic tool to discriminate between aciclovir-induced ADRs and herpes virus infections.

MINI EPIDEMICS OF SYSTEMIC TRICHOSPORON MUCOIDES INFECTION IN NEUTROPENIC PATIENTS WITH LEUKEMIA

D. Nemet,[1] D. Sertic,[2] N. Durakovic,[2] V. Plecko,[2] M. Jandrlic,[2] R. Stern Padovan,[2] D. Mrsic,[2] R Serventi Seiwerth,[2] I. Radman,[2] I. Aurer,[2] S. Zupancic Salek,[2] B. Labar[2]

[1]Clinical Hospital Center Zagreb, ZAGREB; [2]CHC, ZAGREB, Croatia

Background. Disseminated infection caused by Trichosporon spp. is one of the emerging mycoses in neutropenic patients. Several case reports so far describe individual cases of systemic Trichosporon spp. infections. Generally this infection carries a poor prognosis. Here we reported five consecutive cases of systemic Trichosporon mucoides infection in a short period of time in neutropenic patients. At our knowledge this is the first report of epidemic appearance of systemic Trichosporon infections. Patients: During the 4 month period Trichosporon mucoides were isolated from blood cultures in 5 patients at the same ward. There were 3 males and 2 females, 42-57 years old. Four patients were diagnosed with AML, and one had CML in transformation. All patients received induction chemotherapy and were severely neutropenic with ANC $<0.1\times10^9$/L. All but one patient received antifungal prophylaxis with 300 mg fluconazole orally. Patients presented with general symptoms of severe infection that was not responding to standard antibiotic therapy three of them with severe leg pain. Four patients had characteristic papulous skin lesions with central necrosis. Biopsy of lesions yielded granulomatous inflammation with marked central necrosis and microbiology was positive for T. mucoides in all patients. Four out of five patients had pulmonary infiltrates, and two of them had pleural effusions. Three patients had liver focal lesions, the largest measuring up to 1.8 cm, accompanied with elevated liver enzymes; two of them had also spleen infiltrates. Liver biopsy, done in one patient showed only inflammatory mononuclear infiltration, microbiology remained negative. In all patients initial therapy consisted of Amphotericin B, one patient responded favorably. In other four patients signs of infections or blood cultures remained positive despite Ampho B or Caspofungin therapy in one patient. According to data on *in vitro* susceptibility of T. mucoides voriconazole (6mg/kg loading dose, 4 mg/kg continuing) was introduced. Four to 12 days later patients became afebrile with the regression of pulmonary infiltrates and pleural effusion. The recovery of neutrophil count correlate with regression if infection. Patients continue to receive voriconazole orally until discharge. All patients survived. They all received further intensive chemotherapy, one of them allergenic stem cell transplant without developing Trichosporon infection with the secondary prophylactic use of voriconazole therapy. Although the source of the epidemic at the hematology ward remained obscure, it seems that water or sewage system could be responsible because Trichosporon mucoides were revealed in almost all washstands in reverse isolation rooms were patients were maintained. The department was closed and cleaned after that no cases of systemic Trichosporon infections appeared. *Conclusions.* This report indicates possibility of epidemic appearance of systemic Trichosporon spp. infections and illustrates that voriconazole is efficient in the treatment of disseminated Trichosporon mucoides infections in neutropenic patients as well as in secondary prophylaxis in these patients.

MDS PATIENTS WITH ANTI ERYTHROBLAST AUTOIMMUNITY: EFFECT OF BM CULTURE SUPERNATANTS ON CLONOGENIC ACTIVITY OF NORMAL BONE MARROW

F. Imperiali, A. Zaninoni, M Colombi, A. Zanella, W. Barcellini

Fondazione IRCCS Ospedale Maggiore, MILAN, Italy

Background. Myelodysplatic syndromes (MDS) are characterised by ineffective and dysplastic hematopoiesis, bone marrow hypercellularity and, paradoxically, progressive peripheral blood cytopenias. Autoimmune phenomena, mainly directed against RBC, are thought to play a role in bone marrow failure of early MDS, i.e. refractory anemia (RA) and RA with ringed sideroblasts (RARS). We showed an autoimmune reactivity against erythroblasts in roughly half patients with RA and RARS by a method named mitogen-stimulated-direct antiglobulin test (MS-DAT). The same patients displayed increased erythroblast counts together with peripheral signs of hemolysis. *Aims.* To study the effect of BM culture supernatants from MDS patients with anti erythroblast autoimmunity on clonogenic activity of normal BM *Methods.* MS-DAT was performed by stimulating BM cells with PMA and PHA and antibodies were detected in supernatants by competitive solid phase ELISA. Culture supernatants from BM MS-DAT positive and negative patients were tested on the growth of normal BM progenitors on methylcellulose medium. Colony forming units (CFU) count and morphological evaluation were performed after 14 days of culture. Smears were obtained from CFU and differential counts performed. *Results.* The morphology and the number of colony forming units granulocyte-monocyte (CFU-GM) and burst forming units erythroid (BFU-E) were comparable in cultures performed with or without BM MS-DAT positive supernatants. Likewise, control experiments with BM MS-DAT negative supernatants gave negligible effect on the number of CFU-GM and BFU-E colonies. Addition of BM MS-DAT positive supernatants increased the overall CFU smears cellularity along with the appearance of diserythropoietic signs (nuclear atypia i.e. multiple nuclei, nuclear inclusions, and intercellular bridges). At variance BM MS-DAT negative supernatants had no effect on CFU smears. Regarding the differential BM counts (percentage of myeloid and erythroid precursors) we did not observe major differences in the presence or absence of various supernatants. *Conclusions.* BM culture supernatants from MDS patients with an autoimmune reactivity against erythroblasts induced normal BM progenitors to an hyperplastic and diserythropoietic growth *in vitro*, without a preferential destruction of a cell subset or a blockade in red cell hematopoietic maturation.

Introduction. Despite the value of the overall number of CD34$^+$ cells in the bone marrow (BM) of patients with myelodysplastic syndromes (MDS), currently information about the distribution and behaviour of the different compartments of CD34$^+$ cells in MDS patients remains limited. *Aims.* The aim of the present study is to analyze the relative distribution of different compartments of immature, myeloid and lymphoid CD34$^+$ cell precursors in the BM of patients with MDS and correlate it with the different diagnostic and prognostic subtypes of the disease. METHODS. Overall, 73 BM samples were analyzed corresponding to 23 normal BM samples (NBM), and 50 from patients with newly diagnosed MDS classified according to WHO and IPSS criteria into: refractory anemia (RA) (n=11), refractory cytopenia with multilineage dysplasia (RCMD) (n=9), RA with excess of blasts (RAEB)-1 (n=13), RAEB-2 (n=10), unclassifiable MDS (UNC) (n=2) and myelodysplastic/myeloproliferative disorders (MDS/MPD) (n=5). Low risk (LOW) (n=12), intermediate risk (INT)-1 (n=14), INT-2 (n=9), and high risk (HIGH) (n=4). Analysis of CD34$^+$ cells was performed using a standard 4-color flow cytometry approach for the discrimination of immature precursors (ImP), neutrophil lineage committed CD34$^+$ cells (NP), and B-lymphoid precursors (BCP) within CD34$^+$ BM cells, based on their different light scatter characteristics and expression of CD45, CD34, and cytoplasmatic Myeloperoxidase (cyMPO). In addition, CD34$^+$ precursors phenotypically committed to other less represented cell lineages were also identified using a large panel of monoclonal antibodies: CD34$^+$ plasmacytoid dendritic cell (pDCP), monocytic, basophyl, erythroid and mast cell precursors. *Results.* Overall, the three major compartments of CD34$^+$ cells were identified in every NBM sample analyzed, whereas ImP and NP were detected in 59% and 100% of low grade MDS and in 15% and 85% of high grade MDS, respectively. As compared to NBM, an increased percentage of ImP and a significant decreased number of BCP was detected in RAEB-1 (p=0.003 and p<0.001, respectively), RAEB-2 (p=0.009 and p<0.001, respectively), INT-1 (p=0.02 y p=0.004), INT-2 (p=0.004 y p<0.001) and HIGH risk (p=0.02 y p=0.002) categories of MDS. In addition, the percentage of NP was also significantly decreased among AREB-1(p=0.01) patients. In turn, CD34$^+$ plasmacytoid dendritic cell precursors were significantly decreased in all MDS subgroups and lower percentages of CD34$^+$ monocytic, basophyl and erythroid lineage precursors were also detected in advanced MDS. *Conclusions.* In summary, our results show the existence of significant abnormalities in the distribution of the different major and minor compartments of CD34$^+$ cells in the BM of MDS patients. The decreased frequency of CD34$^+$ precursors committed into different hematopoietic cell lineages among advanced MDS patients points to the occurrence of a more pronounced maturation blockade of CD34+ cells in the BM of these patients.

ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME AND AML AFTER MDS (SAML): SUPERIOR RESULTS WITH REDUCED INTENSITY VERSUS STANDARD CONDITIONING

S. Buchholz, E. Dammann, C. Dobbelstein, M. Stadler, C. Koenecke, E.M. Weissinger, B. Hertenstein, J. Krauter, M. Eder, A. Ganser

Hannover Medical School, HANNOVER, Germany

Background. Myelodysplastic syndromes (MDS) represent a heterogeneous group of clonal stem cell disorders characterized by peripheral cytopenias which can progress into secondary acute myelogenous leukemia (sAML). Allogeneic stem cell transplantation (SCT) is considered the most effective treatment for patients with MDS and sAML, but regimen-related toxicities and comorbidities of these generally elderly patients have limited conventional conditioning regimens to selected patients. This limitation has partially been overcome by the development of reduced-intensity conditioning. *Aims.* Here we retrospectively evaluated efficacy and toxicity of SCT after standard myeloablative (S) or FLAMSA-reduced intensity conditioning (F-RIC) for MDS and sAML. F-RIC was chosen as a reduced, but still myeloablative regimen. *Patients and Methods.* Between 1986 and 2006, 66 patients with MDS (n=21) or sAML (n=45) were transplanted at our institution. 32 patients received standard conditioning (Bu/Cy+/-other or TBI/Cy+/-other) whereas 34 patients were treated according to the FLAMSA protocol combining chemotherapy with reduced intensity conditioning (Schmid et al.; J Clin Oncol 2005;23:5675-5687). 7 MDS patients had an IPSS score of intermediate-2 or high, and 7 had secondary MDS mostly with unfavorable cytogenetics. Of the 45 sAML patients, 17 were transplanted in 1st or higher CR, 19 patients were refractory (relapse or induction failure) and 9 patients untreated. *Results.* The F-RIC group included patients with a higher risk profile according to age (S: median 43, range 21-61; F-RIC: 57, 30-71), refractory status of sAML prior to SCT (S 9%; F-RIC 47%), unrelated donors (S 25%; F-RIC 79%) and mismatch donors (S 6%, F-RIC 26%). Median follow-up in the S group was 14 months, range 0,1-236 and in the F-RIC group 10 months, range 0,6-27. At 1 year, overall survival (OS) was 69% and 54% in the F-RIC and S group, respectively. Also it seems after this short follow-up that in the F-RIC group OS was superior after HLA-identical sibling SCT (100%) than after MUD-SCT (60%), however, both groups were heterogeneous with regard to risk factors. Treatment related mortality was higher after standard therapy (S 56%; F-RIC 3%) but relapse rates were similar for both regimens so far (S 16%; F-RIC 18%). Since both groups differed according to the percentage of unrelated donors, all relapses which occurred in the standard group were in HLA-identical sibling SCTs vs. no relapse in the F-RIC group. In addition, engraftment in F-RIC was 100%, whereas in standard group early death (n=4) or engraftment failure (n=3) was seen in 22%. With the limited follow-up, F-RIC also compared favorably to standard conditioning for aGvHD (44% vs. 53%) and severity of aGvHD grade III-IV (7% vs. 53%). *Conclusions.* F-RIC for allogeneic SCT apparently has acceptable toxicity and a sufficient antileukemic efficacy for high risk pts. with MDS and sAML. Longer follow-up and prospective trials are needed to define its therapeutic benefit and the optimal timing for MDS and sAML patients.

FLT3 EXPRESSION AS A MARKER OF PROGRESSION AND RESPONSE TO TREATMENT IN MYELODYSPLASTIC SYNDROMES

P. Bernasconi,[1] S. Calatroni,[1] B. Rocca,[2] M. Boni,[1] P.M. Cavigliano,[3] I. Giardini,[1] R. Zappatore,[2] I. Dambruoso,[1] M. Caresana,[2] C. Astori,[2] C. Castagnola,[2] M. Lazzarino[1]

[1]Fondazione IRCCS Policlinico San Matteo; [2]Fondazione IRCCS Policlinico san Matteo, PAVIA; [3]Fondazione IRCSS Policlinico San Matteo, PAVIA, Italy

Upon acute myeloid leukemia (AML) progression one third of MDS patients acquire an internal tandem duplication (ITD) or a point mutation of the fms-like tyrosine kinase 3 (FLT3) gene and both these mutations determine an increase of FLT3 expression. Based on this data, the present study is aimed at determining any correlation betyween FLT3 expression and clinical parameters and at estimating the influence of FLT3 expression on the risk of MDS/AML progression and on the probability of achieving any response after intensive chemotherapy. The 22 patients entered in the study were 9 females and 13 males with a median age of 61 years (range 18-76). According to FAB classification five patients were classified as RARS, eleven as RA, six as RAEB. When WHO classification was applied, four patients were diagnosed as RARS, four as RA, two as 5q- syndrome, six as RCMD-RCMDS, two as RAEB-1 and four as RAEB-2. According to IPSS score, eleven patients were classified as low-risk, six as intermediate-1 risk, three as intermediate-2 risk and two as high-risk. Eleven patients (2 RA, 3 CRMD, 2 RAEB-1 and 4 RAEB-2) progressed into AML after a median follow-up time of 21 months (range 8-43). Cytogenetic analyses and real-time PCR were performed on clinical diagnosis and during the follow-up. Chromosome analyses revealed a normal karyotype in sixteen patients, del(5q) in two, del(20q) in three and del(12p) in one. The PCR for FLT3 relative quantification employed SybrGreen I as DNA-binding fluorescent dye. Standard curve for real-time quantification was obtained by serial dilution of total RNA isolated from mononuclear cells collected from an AML patient, exhibiting FLT3 ITD and an increased expression of FLT3 mRNA. Gene expression was calculated by the delta-deltaCt method. FLT3 levels were normalised to ABL and calibrated on a normal sample. On clinical diagnosis the expression levels of the FLT3 gene were similar to that of normal sample in seventeen patients and were two-four times higher than that of the normal sample in four patients (one RAEB-1 and three RAEB-2). When AML progression occurred, a total of eight patients (72.7%) presented an increase of FLT3 expression which was two-seventeen times higher than that of the normal sample. So, four patients developed high FLT3 expression just on AML evolution. Five of these eight patients were submitted to intensive chemotherapy which was able to induce a complete remission (CR) in three patients. In these last FLT3 expression reverted to normal values, whereas in non responsive patients it remained constantly elevated. All the three CR patients relapsed after twenty, eighteen and eight months respectively and again showed a quick rise in FLT3 expression which was six-eight times higher than that of the normal sample. In conclusion, i) 13.6% of our patients presented high FLT3 expression on clinical diagnosis; ii) high FLT3 expression was associated with no peculiar clinical finding; iii) a quick increase of FLT3 expression occurred in 72.7% patients in AML progression; iv) CR achievement was correlated with a normal FLT3 expression which increased upon relapse.
