[1]Hannover Medical School/ Institute of Cell and Molecular Pathology, HANNOVER; [2]University of Freiburg/ Department of Paediatrics, FREIBURG; [3]University Hospital Schleswig-Holstein/ Department of Paediatrics, Campus Kiel, KIEL; [4]Hannover Medical School/ Institute of Cell and Molecular Pathology, HANNOVER, Germany

Background. The response to initial glucocorticoid (gc) therapy in childhood acute lymphoblastic leukemia (ALL) reliably predicts the response to multi-agent chemotherapy. In a recent study, we identified the valosin-containing protein (VCP), part of the ubiquitin proteasome degradation pathway (UPDP), as a differentially expressed protein in prednisone good (PGR) and poor responder (PPR) patients. *Aims*. The aim of the study was to investigate the association of differential VCP expression and glucocorticoid response in childhood ALL in order to find ways to overcome prednisone resistance. *Methods*. To investigate whether treatment of ALL cells with the proteasome inhibitor bortezomib acts synergistically with glucocorticoid treatment, human B-cell precursor leukemic cell lines MHH cALL 2 (PPR) and MHH cALL 3 (PGR) were treated with prednisone (6.2 µM) and various concentrations of bortezomib (1.5 nM-12 nM) up to 96 hours. Cells were sampled every 24 h for subsequent analyses. To quantify the amount of VCP expression, real-time PCR and Western blot analysis using the mouse monoclonal anti-VCP antibody (MA3-070, Dianova) were performed. Viability was determined by WST-1 analyses and trypan blue stainings. *Results*. Both cell lines showed a similar response to single bortezomib treatment after 96 h, but compared to single prednisone treatment the decrease in viability of the PPR cells was earlier and stronger, e.g. with 7 nM bortezomib as a single treatment, PPR cells showed a 13-fold higher decrease in viability compared to prednisone single treatment. In combined bortezomib and prednisone treatment, the loss of viability was even 21-fold higher than with prednisone alone. The effect of prednisone was potentiated dose-dependently by bortezomib treatment, which caused a significantly higher decrease of viability in the PPR cells within 48 h compared to PGR cells. Untreated PPR cells showed a 1.5-fold higher VCP RNA expression than PGR cells. Within 72 h after prednisone treatment, VCP RNA expression increased to 1.5-fold compared to the initial level in the PPR cell line, whereas, in PGR cells, the VCP amount remained unchanged. However single prednisone treatment decreased viability in PPR cells to 70% only after 72h, but just 10% viable cells were detectable after combined prednisone and 7nM bortezomib treatment. *Conclusions*. The results of this study suggest that VCP, an important member of ubiquitin proteasome degradation pathway, modulates prednisone response in childhood ALL. In addition, proteasome inhibitors like bortezomib seem to be able to sensitize glucocorticoid-resistant childhood ALL cells for prednisone treatment. Therefore, drug targeting the proteasome may be a novel therapeutic option in resistant ALL.

IMATINIB INDUCES AUTOPHAGY THROUGH INCREASING THE EXPRESSION LEVELS OF BECLIN-1 AND ATG-5 GENES IN BOTH PARENTAL SENSITIVE AND IMATINIB-RESISTANT K562 CELLS

Y. Baran,[1] G. Can,[2] H.A. Ekiz,[2] S.G. Genc[3]

[1]Izmir Institute of Technolology, IZMIR; [2]Izmir Institute of Technology, IZMIR; [3]Dokuz Eylul University, Department of Oncology, Balcova, IZMIR, Turkey

Background. Chronic myeloid leukemia (CML) is a hematological malignancy resulting from a translocation between the chromosomes 9 and 22 which generates a strong oncogenic BCR/ABL protein. BCR/ABL regulates cell growth and proliferation, migration, adhesion and differentiation. Imatinib is a chemotherapeutic agent that specifically binds to the ATP-binding pocket of the BCR/ABL protein and inhibits phosphorylation of downstream targets. Autophagy is the biological event in which the components of the cell are degraded through activation of the lysosomal machinery. Autophagy plays important roles in programmed cell-death, maintenance of the homeostasis, resistance to chemical stress and nutrient deprivation. Formation of autophagosomes involves several genes belonging to ATG family. The most known members of this family are ATG6 (Beclin-1) and ATG5 (autophagy related 5 homolog). *Aims*. In this study, we aimed to examine the autophagic effects of imatinib on parental sensitive and 3 µM imatinib-resistant K562 cells and the possible roles of autophagy in imatinib-induced cell death and/or drug resistance. *Methods*. Philadelphia chromosome positive (Ph(+)) K562 cells were cultured in the increasing concentrations of imatinib step by step starting from the initial concentration of 50 nM. The cells that were able to grow in the presence of the drug were selected gradually in the culturing and the final cells which are resistant to 3 µM imatinib (K562-IMA3) were maintained. IC10 values for both sensitive and resistant cells were determined by XTT cell proliferation assay. Drug concentrations were picked according to IC10 concentrations. Total RNA was isolated at the end of 72 hours by using Nucleospin RNA Isolation Kit and reverse-transcriptase PCR was conducted by using beclin-1 and atg5 primers with the internal control of β-actin. Products were then visualized by the agarose gel electrophoresis. *Results*. XTT data was plot in the inhibitory concentration (IC) graph. IC50 values of K562 and K562/IMA-3 0.24 µM and 14,6 µM, respectively. There were 60 times increase in resistance to imatinib in K562/IMA-3 cells comparing to parental cells. According to the XTT data IC10 and smaller concentrations were picked as follows: 0.1- 1- and 10 nM imatinib for parental sensitive cells; and 10- 100- 500 nM imatinib for the resistant cells. mRNA analyses of beclin1 and atg5 genes by reverse transcriptase PCR techniques have shown that there were significant dose-dependent increase in the expression levels of these genes in both sensitive and the resistant cells. *Summary and Conclusions.* In this study, we have shown for the first time that imatinib induces autophagy in CML cells. These data provides an insight into the relationship between autophagy and Ph^+ CML. Dose-dependent increase in expression levels of autophagy related genes is encouraging for our further plans of experiments with more advanced techniques such as real-time PCR, western blotting and GFP-tagging. In this context, the mechanistic role of autophagy will have been elucidated in Ph^+ CML in response to imatinib. It might play a role in either imatinib-induced cell death or the drug resistance. Gaining more information about autophagy might provide novel targets for an effective CML therapy by promoting the autophagy.

DEVELOPMENT OF A PERSONALIZED MEDICINE TEST FOR HAEMATOLOGICAL MALIGNANCIES

T. Bennett,[1] D. Primo,[1] L. Suarez,[1] S. Lago,[1] M. Matoses Osborne,[1] C. Tudela,[1] E. Arroyo,[1] A. Espinosa,[1] W. Jackson,[1] A. Okun,[2] A. Orfao,[3] J. Ballesteros[1]

[1]Vivia Biotech, MÁLAGA, Spain; [2]Etogen Scientific, SAN DIEGO, USA; [3]Universidad de Salamanca, SALAMANCA, Spain

Background. We have developed a cell-based screening platform, called ExviTech, which incorporates both automated sample preparation and automated evaluation by flow cytometry, in conjunction with proprietary analytical software and a database structure geared for rapid data acquisition, analysis and reporting of results. The ExviTech platform has been used to test samples, either peripheral blood or bone marrow, extracted from patients diagnosed with B-cell chronic lymphocytic leukaemia (B-CLL). The patient's biological sample is tested against all drugs approved for the treatment of B-CLL, and results are obtained by assessing the ability of each drug to induce apoptosis in the leukemic cell population. The complete patient sample is diluted and plated, retaining the erythrocyte population and serum proteins. B-CLL is a clinically heterogeneous disease in which the individual prognosis of patients is extremely variable. We propose that screening such targets in their biological context will add valuable data to aid in the prognosis and treatment of this disease. *Methods*. Working in collaboration with four hospitals in Spain, samples are extracted from patients diagnosed with B-CLL, having first obtained informed consent. The experimental assay is setup within 2-6 hours of obtaining the sample. The sample is diluted to achieve a leukemic cell concentration of approximately 4,000 cells/µm, then 45 µL of the suspension are added to each well of 96-well plates that contain the pharmacological agents. Sample extraction from the patients and the experimental setup are all done under sterile conditions. The compound plates are then incubated for 24, 48 or 72 hours at 37oC with 5% CO_2. After incubation, the erythrocytes are lysed and Annexin V-FITC, monoclonal antibodies anti-CD45-APC and anti-CD19-PE, are added to each well. The plates are then transferred to an automated flow cytometry system where the contents of each well is aspirated and analyzed by a CyAn flow cytometer. *Results*. The ability of individual cytotoxic drugs to induce apoptosis in the leukemic cell population varies greatly from patient to patient, even among patients with similar prog-

noses. The maximum level of apoptosis for a compound can range between 20% and almost 100% among the patients. Additionally, the kinetics of the induction of apoptosis can differ between patients for a given cytotoxic drug. *Conclusions*. By testing patient samples directly we are looking at the effectiveness of a given drug *in vitro* to do exactly what it is expected to do *in vivo*. The large level of variability between patients illustrates what is already known, that CLL patients do not always respond well to treatments given according to standard protocols. We are expanding the range of drugs we are testing to include the polypharmacy that is inherent in the treatment of haematological malignancies. Using our automated ExviTech screening platform we are able to screen each patient sample against all drug combinations in the accepted protocols, at concentrations similar to the reported plasma concentrations. Personalized medicine offers the capacity to respond to this disease on a case by case basis, identifying which treatment will be the most effective for each individual.

0572

EFFECTS OF THALIDOMIDE, ROFECOXIB AND CAPTOPRIL ON VASCULAR ENDOTHELIAL GROWTH FACTOR IN EHRLICH ASCITES CARCINOMA

M.F. El-Azab, E. El-Awady, M. Moustafa, S. Abd-El-Hamid

Suez Canal University, ISMAILIA, Egypt

Background. The growth and metastasis of tumors are dependent on their development of a vascular supply. An array of factors that regulate angiogenesis has been isolated, with the most pivotal positive regulator being vascular endothelial growth factor (VEGF). *Aims*. The study was conducted to evaluate the effects of thalidomide, rofecoxib and captopril on the angiogenic marker, VEGF, when used alone or in combination with cisplatin in Ehrlich ascites carcinoma (EAC)-bearing Swiss albino mice. *Methods*. The EAC cells were implanted subcutaneously at 2 sites bilaterally to produce solid tumors on the lower ventral side of Swiss mice. These tumors were used to evaluate the effects of thalidomide (100 mg/kg, i.p.), rofecoxib (20 mg/kg, p.o.) or captopril (50 mg/kg, p.o.) as individual treatments or in combination with cisplatin (2 mg/kg, i.p.) on VEGF. Inhibition of VEGF is proposed as a possible mechanism through which these drugs exert their anti-tumor and anti-angiogenic effects. All treatments were started 24 hours after tumor cells inoculation. VEGF was measured as a time course on days 7, 14 and 21 both in plasma (using ELISA) and tumor tissue (using immunohistochemistry). The tumor weight was evaluated as a criterion for the anti-tumor activity. *Results*. Individual treatments with thalidomide or rofecoxib (not captopril), alone or combined with cisplatin, reduced plasma levels of VEGF on day 7. Comparing the plasma levels of VEGF on days 14 and 21 post inoculation, one-way ANOVA showed a non-significant effect among all groups. EACs in the control group showed a strong expression of VEGF (VEGF-rich tumors). Individual treatments with thalidomide, rofecoxib or captopril could reduce the percentage of VEGF-rich tumors to reach 42.9%, 57.1% and 66.6% of the control, respectively. The combination of cisplatin with thalidomide, rofecoxib or captopril has produced a further reduction in the percentage of VEGF-rich tumors to reach 28.6%, 42.9% and 57.1%, respectively. A significant reduction in tumor weight was observed after individual treatments.

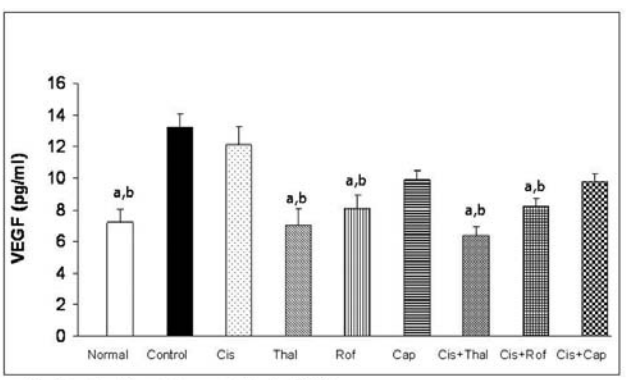

Figure 1. Effect of cisplatin (2 mg/kg, i.p.) alone and in combination with thalidomide (100 mg/kg, i.p.), rofecoxib (20 mg/kg, p.o.) or captopril (50 mg/kg, p.o.) on plasma levels of VEGF on day 7 in EAC-bearing female Swiss albino mice.

Conclusions. The data indicate that EAC is a VEGF-producing tumor and VEGF is essential for initial but not continued *in vivo* growth of EAC cells. Thalidomide and rofecoxib proved to exert their anti-tumor and anti-angiogenic effects through the inhibition of VEGF, while the anti-tumor effect of captopril might be mediated through a different mechanism. The results suggest a beneficial role of anti-angiogenic agents as an adjuvant treatment to chemotherapy.

0573

A VERY SENSITIVE AND RAPID METHOD FOR BCR-ABL T315I MUTATION DETECTION BY PEPTIDE NUCLEIC ACID DIRECTED PCR CLAMPING

E. Bracco, M. Spagna, R. Pedrola, V. Rosso, F. Arruga, M. Lo Iacono, S. Carturan, F. Messa, C. Panuzzo, P. Nicoli, E. Messa, A. Rotolo, A. Morotti, S. Mussino, A. Balbo, D. Cilloni, S.G. Saglio

University of Turin, ORBASSANO (TO), Italy

Background. BCR-ABL kinase domain (KD) mutations are the major cause of resistance to tyrosine kinase inhibitors (TKIs). Among different mutations identified the frequently observed T315I is of particular concern being not effectively targeted by any TKIs so far available. Currently, the recommended method for BCR-ABL mutation detection is the sequencing the KD. This is time consuming, available in few centres and allows to reach a maximum sensitivity of 15-20%. The latter point represents a limit as frequently mutated clones may be present at a lower percentage. The availability of a simple, sensitive and quick assay, allowing a rapid detection for the T315I mutation is therefore crucial, as the detection of this mutation represents an important element in clinical decision making for CML patients. We report a novel method allowing easy, rapid and sensitive detection of the mutation affecting the codon 315 (T315I). *Rationale and Methods.* The innovative strategy we propose is based on a variant of a single tube PNA-PCR clamping. Peptide Nucleic Acid (PNA) is a potent DNA mimic in terms of sequence specific hybridization. PNA/DNA is thermally more stable than DNA/DNA or DNA/RNA duplexes, but PNA sequences cannot be extended by DNA polymerase (5). As consequence, PNA/DNA duplex suppresses DNA amplification. Furthermore, a single base pair mismatch discrimination is greater for PNA/DNA than for the corresponding DNA/DNA duplex. Based on this premise we attempted to develop a novel and sensitive detection assay aimed to quickly and easily identify T315I mutation in CML patients making use of primer exclusion PNA directed PCR clamping. The experimental design forecasts that both PNA and PCR primer target sites overlap, thus leading to a direct competition towards complementary template DNA. When perfect matching occurs PNA-template hybridization is favoured, in comparison to template-primer duplex, and DNA amplification is suppressed. Conversely, a single mismatch destabilizes the PNA-template duplex, favouring the hybridization between template and primer thus allowing template amplification. Competitor PNA sequence was designed to perfectly match wild-type (WT) template sequence. Therefore, when a single base pair mismatch occurs (like in the case of T315I) PNA-template stability is strongly impaired and DNA amplification favoured. *Results and Conclusions.* cDNA synthesized from total RNA isolated from patients harboring either wt or mutated Bcr-Abl alleles have been amplified by nested PCR. During the first step a specific pair of primers designed to discriminate between the kinase domain of c-Abl and Bcr-Abl have been utilized. The second step involves the use of sequence specific 19-mer PNA, matching within the region around the codon 315 (T315I), in a *PNA primer exclusion PCR clamping* reaction. Initially, we aimed to study patients previously analyzed by sequencing in which either the wt or the mutated allele were to be predominant. Encouraging results show amplification in patients harboring the point mutation at position 315 which determine the substitution of a threonine for isoleucine (T315I) indicanting the bona-fide of this novel method. These results were further corroborated by carrying-out a *blind analysis*, in which samples were subsequently sequenced. Afterwards, we tested the sensitivity of the method. Serial dilutions with WT and mutated T315I templates were performed keeping constant the total template amount. Surprisingly, the method displayed a quite high sensitivity, allowing to detect amount of mutated template as low as 0.5%, which are not identified by classical sequencing allowing the identification of T315I mutation even when present at low amount. We suggest that this approach could be extended to few others relevant and frequent BCR-ABL mutations (i.e. P-loop mutations) thus allowing to drive the clinical decisions after imatinib failure on the use of the most appropriate second generation TKIs or directly to switch to stem cell transplantation.

DEVELOPMENT OF A NOVEL METHOD TO EVALUATE THE EFFICACY OF MOLECULAR TARGETED THERAPY IN CHRONIC MYELOGENOUS LEUKEMIA BY BIO-IMAGING SYSTEM

T. Kondo, T. Mizutani, S. Darmanin, M. Tsuda, J. Tanaka, M. Imamura, H.K. Kawaguchi, M.A. Asaka, Y.O. Ohba

Hokkaido University Graduate School of Medicine, SAPPORO, Japan

Background. Imatinib, a potent inhibitor of the oncogenic tyrosine kinase BCR-ABL, has shown significant clinical achievement in treatment of chronic myelogenous leukemia (CML). However, some patients have shown imatinib resistance and several second-generation ABL kinase inhibitors have also been developed to overcome this problem. Thus, an assay system to examine the drug efficacy for each patient is strongly desired. *Aims*. Our purpose is to develop a bio-imaging system to evaluate BCR-ABL kinase activity in living cells. Here we utilized fluorescence resonance energy transfer (FRET)-based biosensing. *Methods and Results.* CrkL is a main substrate of BCR-ABL in CML cells. We first constructed the probe molecule, which consisted of YFP (yellow fluorescent protein), a part of CrkL and CFP (cyan fluorescent protein), named Pickles. When CrkL is phosphorylated at Tyr207, an intramolecular binding of Src-homology 2 (SH2) domain to phosphorylated Tyr207 induced conformational change of CrkL, brought YFP closed to CFP, and yielded a FRET between YFP and CFP. The FRET efficiency within the cells was evaluated by fluorescence microscopy, which enables the evaluation of the cells one by one. When Pickles is co-expressed with BCR-ABL in 293F cells. FRET efficiency was increased by expression of BCR-ABL in dose-dependent manner. This FRET efficiency was decreased in response to imatinib. When imatinib-resistant type of BCR-ABL mutant was expressed, the FRET efficiency was retained. We also expressed Pickles in K562 cells, a CML-derived cell line. FRET efficiency was increased, and this efficiency was inhibited by imatinib. Finally we expressed Pickles in primary mononuclear cells from *de novo* CML patients. Similar to the results of cell lines, we clearly detected increased FRET efficiency in samples from CML patients. This efficiency was not detected in mononuclear cells from healthy volunteers. *Conclusions*. 1) Pickles, a FRET-based biosensor, enables the evaluation of BCR-ABL kinase activity in living cells. 2) The drug efficacy was assessed by the decrease in FRET efficiency compared to that of control cells. 3) This assay would be applied not only for screening to assess the sensitivity of molecular targeted drugs against CML cells but also for detecting drug-resistant cells.

0575

MULTIDRUG RESISTANCE TESTING WITH ABC TRANSPORTER ASSAY

K. Tauber Jakab, J. Marki-Zay, E. Kis, K. Herédi-Szabó, Z. Hollo, P. Krajcsi

Solvo Biotechnology, BUDAÖRS, Hungary

Background. Since the beginning of the 90's several studies have confirmed the role of multidrug transporter proteins in chemoresistance in a variety of hematological malignancies. The studies focused on rapidly progressing acute leukaemia's, with the emphasis being on acute myeloid leukaemia (AML). There are numerous technical approaches to study multidrug resistance, which came into the centre of interest; however correlating results derived from different methods raised serious difficulties. We have developed two major forms of ABC transporter assays to investigate the MDR phenomenon: dye efflux assays using whole cells expressing the transporter of interest and ATPase and vesicular transport (VT) assays using purified membrane vesicles. Both methods could be used to determine whether a compound acts as a transporter substrate (EC50) and/or inhibitor (IC50). *Aims*. Aims of this study were to test the interactions several drugs and ABC efflux transporters and to measure function of these transporters on the cell lines. We have intended to develop a new fluorescent assay, in order to extend it for the measurement of BCRP/ MXR activity as well. *Materials and methods*. In our study we used *in vitro* membrane based methods (ATPase and vesicular transport assay) and cellular assays (Hoechst assay and calcein assay) to show interactions between the three clinically highly relevant transporters (MDR1, MRP1, BCRP) and different chemotherapeutics (e.g. chlorambucil, cisplatin, taxane) and immunosuppressive drugs (e.g.NSAID, DMARD). ATPase and VT assays were performed on membrane preparations from recombinant baculovirus infected Sf9 cells. Dye efflux assays are based on determining fluorescence intensity differences in a flow cytometer after a short *in vitro* incubation of the cell suspension with a fluorescent dye such as the calcein-acetoxymethyl ester (calcein AM) for MDR1 and MRP1 with or without the addition of selective inhibitors of MDR1 and MRP1 and Hoechst 33342. The BCRP arm of the MDQ kit utilizes mitoxanthrone as dye and Ko134 as BCRP-specific inhibitor. *Results*. We have characterised 35 drugs for their interaction with the MDR1, MRP1 and BCRP transporters. In general, good correlations have been found between the methods employed. Some novel, highly transporter specific interactions have been found (e.g. leflunomide and it's active metabolite teriflunomide specifically interacts with BCRP. Data on the new, improved functional assay measuring the multidrug resistance activity of the three, clinically most relevant efflux transporters, such as MDR1, MRP1 and BCRP in clinical specimens will also be presented. *Conclusions*. It's known, that several review focused drug-transporter interactions but this study demonstrates full particulars regarding transporter profile of selected chemotherapeutic drug. These transporter assays have more capabilities and they are useful for the testing of different parameters: (1) new drug-candidates in drug resistant cell lines and prepared membranes (2) multidrug resistance of the cell lines. These assays and results might have potential role in theranostic application.

ABCB1 SINGLE NUCLEOTIDE POLYMORPHISMS IN *DE NOVO* AML WITH NORMAL KARYOTYPE - IMPLICATIONS ON DRUG RESISTANCE AND SURVIVAL

E. Paul,[1] K. Lotfi,[2] I. Jakobsen Falk,[2] R. Rosenquist,[3] C. Paul,[1] H Nahi,[1] H. Green[2]

[1]Karolinska Institutet, HUDDINGE; [2]Linköpings Universitet, LINKÖPING; [3]Uppsala University, UPPSALA, Sweden

Background. Multidrug resistance and expression of the ATP-dependent drug transporting protein ABCB1 is a clinically relevant problem in the treatment of acute myeloid leukaemia. Single nucleotide polymorphisms (SNPs) altering the function and activity of ABCB1 might influence the clinical outcome in AML and predict individual differences in response to therapy with ABCB1 substrates. *Aims*. To investigate the impact of ABCB1 SNPs in exon 11, 12, 21 and 26 on treatment response and survival in AML patients. *Methods*. PCR and Pyrosequencing were used to determine the genotype of the SNPs G1199T/A, C1236T, A1308G, G2677T/A and C3435T in 97 *de novo* acute myeloid leukaemia, patients with normal karyotype treated at Linköping University hospital or Huddinge University Hospital. Almost all patients were treated with one anthracycline and Ara-C during the induction regime. The genetic variants in ABCB1 affect on survival were analysed using Kaplan-Meier Log-rank tests. Patients receiving transplantation were censored at that point in the analysis. A Nordic reference material of 130 healthy volunteers of equal age and sex distribution was also included. *Results*. The survival of the AML patients were significantly correlated to the ABCB1 genotypes G1199T/A (p=0.002), C1236T (p=0.02) and G2677T (p=0.02, A-allele excluded from analysis due to low frequency). Only the wild type of A1308T was found in the material and C3435T did not correlate to survival. Comparison of allele frequencies between AML patients and healthy volunteers showed no significant difference. *Conclusions*. Our findings suggest that ABCB1 SNPs do not affect the development of the disease but the survival after chemotherapy. The correlation between ABCB1 genotype and the overall survival of AML patients might provide useful information for treatment strategies and individualized chemotherapy.

0577

ANALYSIS, PHARMACOKINETICS AND BIODISTRIBUTION OF THE NEW CDK INHIBITOR-CR8

H. Sallam,[1] L. Meijer,[2] M. Hassan[3]

[1]Karolinska Institutet, STOCKHOLM, Sweden; [2]C.N.R.S., Cell Cycle Group, Station Biologique, BRETAGNE, France; [3]Experimental Cancer Medicine, Karolinska Institutet, STOCKHOLM, Sweden

Background. Roscovitine is cyclin-dependent kinase (Cdk) inhibitor that has been shown to be effective against several tumors, and is passing Phase II clinical trials in cancer patients. The drug has limited side effects and toxicity compared to conventional chemotherapy. However, roscovitine was found to have short half life and rapid metabolism, leading to suboptimal exposure in the clinical trials. Recently, CR8 was introduced as the second generation of roscovitine. CR8 was shown to be about 50-fold more potent compared to roscovitine in inducing apoptosis in different tumor cell lines including ALL and CLL.[1] Despite these promising results still the pharmacokinetic profile of CR8 is not investigated prior to clinical investigation. In the present paper we have estab-

lished an analytical method and evaluated the pharmacokinetics of CR8 in mice. *Aims*. 1- To develop and validate analytical method for CR8 in the biological matrix. 2- To study the pharmacokinetics, oral bioavailability and distribution of CR8 to the bone marrow (BM) in female bulb/C mice. *Methods*. We have developed a simple and rapid liquid chromatographic method using UV-detection for the determination of CR8 in plasma. CR8 was administered both orally (75 mg/kg) and I.V. (50mg/kg), animals were killed at 5, 10, 20, 30 min, 1, 2, 3, 4, 6, 8, 12 and 24 hours. Blood was collected and plasma separated, both femurs were flushed using 0.5 mL PBS. The pharmacokinetic parameters e.g. area under the concentration-time curve (AUC), distribution volume, half life, the maximum concentration, clearance and oral bioavailability were calculated using WinNonlin, Version 5.2. *Results*. The retention time of CR8 was 5 minutes. The lower limit of quantification was 0.10 μg/mL and the linearity was within the range 0.10 - 10 μg/mL (r2 > 0.998). The accuracy and precision were more than 86%. The recovery from plasma was more than 90%. CR8 was stable at RT, +4°C and -20°C for 2 months. CR8 pharmacokinetics after IV and oral administration were found to fit a two-compartment open model with biphasic elimination. CR8 was rapidly absorbed. The exposure to CR8 expressed as AUC was about 85-90 μg/mL.hr and the elimination half life was about 2.5hr which is longer than 2 fold compared to roscovitine. CR8 concentrations in the bone marrow were less than 1% of that observed in plasma. The oral bioavailability of CR8 was found to be 100%. *Conclusions*. CR8 has 100% bioavailability and longer half life compared to roscovitine that allow systemic exposure higher than the IC50 for duration of about 10 hours. The low distribution to BM may indicate lower myelosuppressive effect which in turn can benefit patient treatment. CR8 has pharmacokinetics pattern that may allow further *in vivo* studies.

EXPRESSION OF PHOSPHORYLATED HISTONE H2AX AND ITS POTENTIAL TO MODULATE ADRIAMYCIN RESISTANCE IN K562/A02 CELL LINE

F. Zhou, H. Mei, Q. Wu, R. Jin

Huazhong University of Science&Technology, WUHAN, China

Background. Histone H2AX phosphorylation (ser139) (γH2AX) plays an important role in DNA damage repair, however, whether it is involved in drug resistance remained unknown. *Aims*. To investigate the reversal effect of γH2AX on adriamycin resistance of K562/A02 cells and related mechanisms. *Methods*. We cultured K562/A02 cells with adriamycin and (or) LY294002 which could reduce γH2AX and then analyzed the proportion of cells expressing γH2AX by flow cytometry; the sensitization to adriamycin by MTT assay; the level of DNA double strands breaks (DSBs) by Single-cell gel electrophoresis assay and the expression of P-glycoprotein, γH2AX and BRCA1 proteins by Western blot. *Results*. γH2AX expression increased by adriamycin in a concentration dependent manner (p<0.01); and treated with the same concentration, γH2AX expression of K562/A02 was lower than that of K562 cells (p<0.01). After K562/A02 cells treated with LY249002, the γH2AX expression diminished (p<0.01); the IC50 decreased significantly with a high reverse time of 5.98; the level of DSBs which was judged by tail moment and tail DNA% in K562/A02 enhanced significantly (p<0.01) and the expression of P-gp and BRCA1 suppressed. *Conclusions*. It is feasible to use γH2AX to predict the sensitivity of tumor cells to chemotherapy agents. Depressed H2AX phosphorylation by LY294002 has a reversal effect on the adriamycin resistance of K562/A02 cells through reducing repair of DSBs, and down-regulating BRCA1 and P-gp expression.

Anemia, aplastic anemia - PNH

GENETIC ANALYSIS OF THE SHELTERIN COMPLEX COMPONENTS (POT1, RAP1, TPP1, TRF1 AND TRF2) IN DYSKERATOSIS CONGENITA

J. Walne, T. Vulliamy, R. Beswick, M. Kirwan, I. Dokal

Institute of Cell and Molecular Sciences, LONDON, UK

Background. Dyskeratosis congenita (DC) is a multi-system syndrome which displays marked clinical heterogeneity. Patients present with a wide range of haematological and non-haematological features including nail dystrophy, abnormal skin pigmentation, leucoplakia and aplastic anaemia (AA). Six genes have been implicated in DC, all involved in telomere maintenance either by telomere elongation (telomerase) or telomere protection (shelterin). Mutations within these genes account for approximately 50% of cases of DC, with the remainder being genetically uncharacterised. *Aims*. The shelterin complex is comprised of six proteins: telomeric-repeat binding protein 1 (TERF1, TRF1), telomeric-repeat binding protein 2 (TERF2, TRF2), TRF1-interacting nuclear factor 2 (TINF2, TIN2), TERF2-interacting protein (TERF2IP, RAP1), TIN2-interacting protein 1 (ACD, TPP1) and protection of telomeres (POT1, POT1) (gene and protein name abbreviation, respectively). Only TIN2 has been previously screened in DC patients. The aim of this study was to screen the other members of the shelterin complex for any potential mutations that could be associated with DC in a subset of the remaining uncharacterised patients. *Methods*. 47 patients with genetically uncharacterised DC were screened for possible mutations in all the remaining shelterin complex genes. Each gene was analysed by heteroduplex analysis using denaturing high performance liquid chromatography following PCR amplification. Any abnormal elution patterns were sequenced to determine the nucleotide change involved. All coding changes observed were compared to known SNPs on the SNP database at www.ncbi.nlm.nih.gov. *Results*. From all the analyses performed 6 changes were identified that alter the coding sequences of the genes investigated (Table 1). Two of these were novel: POT1c.820G>A p.Gly274Arg and TPP1 c.1383T>G p.Phe461Leu. The POT1 mutation did not segregate with disease and the affected individuals in this family also had mutations in TIN2 (Arg282Cys) There were no additional family members available to perform segregation analysis of the TPP1 mutation. *Conclusions*. The data obtained from this large genetic screen of the remaining proteins of the shelterin complex indicates that there is little involvement of any of these proteins in the pathophysiology of dyskeratosis congenita. This result is surprising as mutations in TIN2 account for approximately 10% of DC. The unclassified variant seen in POT1 is unlikely to be pathogenic due to a lack of segregation within the family whereas it was not possible to draw a conclusion regarding the TPP1 mutation. In conclusion, although TIN2 mutations have been found to play a significant role in the pathophysiology of DC, this does not appear to be case for the other shelterin proteins.

Table 1. Coding changes identified in shelterin complex.

Gene	No. exons	Coding SNPs	Novel coding changes
POT1	15	Gly 404 Val	Gly 274 Arg
RAP1	3	Lys 324 Glu	0
TPP1	12	Val 518 Ala	Phe 461 Leu
TRF1	10	Glu 55 (8-10)	0
TRF2	10	0	0

IMMUNOSUPPRESSIVE THERAPY WITH RABBIT ANTITHYMOCYTE GLOBULIN MIGHT BE COMPARABLE TO HORSE ANTILYMPHOCYTE GLOBULIN IN CHILDHOOD SEVERE APLASTIC ANEMIA WITHOUT HLA-IDENTICAL SIBLING DONOR

D.C. Jeong,[1] B. Cho,[1] N.G. Chung,[1] P.S. Jang,[1] Y.J. Kwon,[2] D.H. Lee,[3] S.Y. Kim,[4] Y.S. Park,[5] H.K. Kim[1]

[1]College of Medicine, The Catholic University of Korea, INCHEON; [2]National Cancer Center, GOYANG; [3]College of Medicine, Hallym University, AHNYANG; [4]College of Medicine, Choonnam National University, DAEJEON; [5]College of Medicine, Kyunghee University, SEOUL, South-Korea

Background. Antilymphocyte globulin or antithymocyte globulin has a major role in immunosuppressive therapy (IST) for children with severe aplastic anemia (SAA), who are not suitable donor for hematopoietic stem cell transplantation. *Aims*. We investigated long-term clinical outcome in in children with SAA, who received IST with horse ALG (H-ALG) or rabbit ATG (R-ATG). *Method*. We retrospectively analyzed 112 children with SAA who were treated with either H-ALG 1mL/kg/day (n=46) or R-ATG 2.5mg/kg/day (n=66), and cyclosporin A. There was no difference in demographic characteristics of both groups, except for the administration of oxymetholone (82.6% in H-ALG vs. 13.6% in R-ATG). *Results*. The overall response rate was higher in H-ALG than R-ATG at post-IST 6 month (p=0.02), and complete response higher in H-ALG than R-ATG at post-IST 6 month (p<0.01). The adverse effects during IST showed similar incidence in both groups. However, relapse rate was higher in H-ALG than in R-ATG (p<0.01), with similar time from response to relapse in both groups. The higher response rate in H-ALG might be contributed by administration of oxymetholone because relapse in H-ALG was developed after stop of androgen. The overall survival (OS) was 69.7%(median: 6 years), and associated with severity at diagnosis, and response on post-IST 6 month (p<0.01). The OS was not different in both groups. The causes of death were mainly infection (66.7%), bleeding (25.9%) and cardiomyopathy due to iron overload (7.4%), and not different between both group. The failure free survival (FFS) was related to response on post-IST 6 month (p<0.01), and similar between H-ALG and R-ATG groups. *Conclusions*. Our results suggest that the front line IST with R-ATG is comparable to H-ALG in childhood SAA. We propose that treatment with R-ATG is accepted as a front line IST for childhood SAA. We need clinical trial for dose modification of R-ATG.

0581

EFFICACY OF THE COMPLEMENT INHIBITOR ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS NEVER TRANSFUSED

A. Risitano,[1] F. Alfinito,[1] E. Seneca,[1] L. Marando,[1] C. Boschetti,[2] S. Bonfigli,[3] S. Fenu,[4] F. Re,[5] G. Gosetti,[6] G. Khursigara,[7] R. Rother,[7] A. Zanella,[2] B. Rotoli[1]

[1]Federico II University of Naples, NAPLES, Italy; [2]IRCCS Ospedale Policlinico Maggiore, MILAN, Italy; [3]University of Sassari, SASSARI, Italy; [4]S. Giovanni-Addolorata Hospital, ROME, Italy; [5]University of Parma, PARMA, Italy; [6]S. Chiara Hospital, TRENTO, Italy; [7]Alexion Pharmaceuticals, CHESHIRE, USA

Background. Hemolysis of paroxysmal nocturnal hemoglobinuria (PNH) is due to the lack of the complement inhibitors CD59 and CD55 from the cell surface, leading to complement-mediated intravascular hemolysis and subsequent anemia. The release of free hemoglobin during hemolysis causes a number of debilitating symptoms, which include hemoglobinuria, sever anemia requiring transfusions, disabling fatigue, abdominal pain crises and dysphagia, as well as life-threatening morbidities, such as thromboembolisms, kidney dysfunction and pulmonary hypertension. The terminal complement inhibitor eculizumab (Ecu) has proven effective for the treatment of hemolysis in PNH patients requiring minimal transfusions. However, many patients with PNH do not require transfusions but continue to demonstrate marked hemolysis and its downstream clinical consequences. *Aims*. We assessed efficacy and safety of eculizumab in a cohort of 9 PNH patients who had received no transfusions before starting the anti-complement therapy and in a subset of patients previously enrolled in clinical trials who had been only minimally transfused. *Methods*. The Italian Early Access Program included untransfused PNH patients with at least one of the following conditions: i. severe anemia due to intravascular hemolysis: ii. frequent paroxysmal crises; iii. severe symptoms due to intravascular hemolysis; iv. life-threatening thromboses. Eculizumab was given at the standard dose: 600 mg weekly for 4 weeks; then 900 mg every two weeks, preceded by anti-meningococcal vaccination. We compared our results to a subset of 21 patients included in three previous eculizumab trials, who had received zero or one transfusions during the year prior to the treatment. *Results.* Six of the 9 untransfused patients had a long disease history, while 3 had been recently diagnosed. Even in the absence of transfusion needs, patients had recurrent hemolytic crises, often associated with severe symptoms of PNH (haemoglobinuria, abdominal pain, dysphagia). All patients had moderate anemia, with the exception of two with Hb ≥10 g/dL who were eligible to receive eculizumab because they had experienced brain and/or abdominal thromboemboli. Following eculizumab treatment (median duration 16 months), all patients showed dramatic reductions of hemolysis measured as LDH level, from a median of 1,500 U/L to 356 U/L (upper normal limit 230 U/L; p=0.008). Overall, there was a significant increase in median Hb level (from 9.0 to 10.7, before and after treatment, respectively, p=0.0003), with a median increase of 2.0 g/dL. Eculizumab treatment prevented any further hemolytic crisis and associated serious morbidities in these patients, resulting in improvement of quality of life. With a cumulative exposure of 127 months, no severe adverse event or thromboembolic event has been observed. These data are in agreement with those relating to the 21 patients minimally transfused and treated by eculizumab in the setting of the registration trials (Table). *Conclusions*. This report indicates that eculizumab provides substantial clinical benefit even to hemolytic PNH patients who are not transfusion dependent because of compensated anemia. Besides the immediate effect of eculizumab treatment in increasing Hb level and abrogating all signs and symptoms of intravascular hemolysis, such a treatment promises to result in reduction of long-term morbidity and mortality.

HOME INFUSION OF ECULIZUMAB: A UNIQUE AND INNOVATIVE MODEL OF DRUG DELIVERY TO REDUCE TREATMENT-ASSOCIATED BURDEN AND ENHANCE QUALITY OF LIFE FOR PATIENTS WITH PNH

L. Arnold,[1] J. Stephenson,[2] R. Kelly,[1] D. Buchanan,[1] A. Hill,[3] F.P. Stichler,[1] J. Bagabag,[1] G. Jones,[2] C. Bilbrough,[1] P. Hillmen[1]

[1]Leeds Teaching Hospitals Trust, LEEDS; [2]Health Care at Home, BURTON UPON TRENT; [3]Bradford Royal Infirmary, BRADFORD, UK

Background. Paroxysmal Nocturnal Haemoglobinuria (PNH) is an acquired clonal stem cell disease, characterised by intravascular haemolysis, bone marrow failure and thrombosis. Symptoms of PNH include haemoglobinuria, fatigue, anaemia, thromboses, recurrent pain, renal impairment, erectile dysfunction and pulmonary hypertension. Patient care is complex and challenging, as many patients experience chronic symptoms with periods of acute exacerbations. Historically the management of PNH included bone marrow transplant, blood transfusion and supportive care, all necessitating frequent hospital visits. Eculizumab is a monoclonal antibody that binds to the C5 complement component inhibiting terminal complement formation and preventing haemolysis. Clinical trials of eculizumab demonstrated the resolution of the majority of symptoms and complications of PNH and resulted in its approval in the UK in June 2007. Eculizumab is administered as a 30 minute intravenous infusion every 14 days, and under the terms of its current EU licence, must be administered by a healthcare professional. Due to the rarity of PNH there are relatively few specialist centres resulting in patients travelling long distances for review and treatment. *Aims*. To develop a unique safe method of drug delivery for patients at home to reduce their frequency of hospital visits whilst enhancing patient qual-

ity of life. *Method*. In the UK, Leeds Teaching Hospitals with Healthcare at Home have developed a home infusion programme that ensures safe administration of eculizumab in the patient's home at a time convenient to them, leading to enhanced treatment-associated convenience for patients and their families. Patients then only attend the PNH centre every 3 months to ensure appropriate monitoring and patient education. *Results*. A recent survey of patients reports a reduction in treatment-associated burden for PNH patients and their families when receiving infusions at home. 46 patients responded to the survey with just over half receiving eculizumab. Of the 21 patients at the time receiving home infusions 19 found this more convenient than the hospital. Home treatment allows flexibility and for some, the return to full-time employment, with the associated financial benefits and improvement in psychological well-being. Of the 21 patients on home care 7 stated there ability to work was transformed with a further 10 having great improvement. Whilst the purpose of the survey was not to address financial burden, the home infusion programme has reduced the financial burden on the patient and their family by eliminating the need for time off work, allowing return to full-time employment, and removing the cost of frequent travel to and from the hospital. No patients reported negative impact, including effect on social life and family relationships, whilst 15 experienced improvement or complete transformation in both areas. The patients reported confidence in the homecare programme, knowing that a very close working relationship existed between the expert hospital and homecare teams. *Summary*. This innovative programme of medication delivery by a dedicated home nursing team allows patients who have previously struggled to cope with their illness to lead a near normal life with an associated enhancement in quality of life. Patients are able to carry on with activities of daily life, including work, recreational activities and holidays, whilst at the same time ensuring compliance with treatment and therefore allowing maximum therapeutic benefit.

0583

USE OF FLAER-BASED ASSAY OF WHITE BLOOD CELLS (MONOCYTES AND GRANULOCYTES) IN THE PRIMARY SCREENING OF PNH CLONES

D.R. Sutherland,[1] M. Keeney,[2] N. Kuek,[1] J. Azcona-Olivera,[3] E. Acton,[1] T. Anderson,[1] D. Barth,[1] M. Reis[1]

[1]Toronto General Hospital, TORONTO; [2]London Health Sciences Centre, LONDON; [3]R&D Systems, MINNEAPOLIS, USA

Background. Paroxysmal Nocturnal Hemoglobinuria (PNH) is an acquired stem cell disorder caused by a somatic mutation in the X-linked PIG-A gene. This leads to a partial/complete loss of all GPI-linked proteins and clinical features of chronic intravascular hemolysis, thrombosis and marrow failure. Diagnosis and follow-up of PNH improved with flow cytometry-based assays that involved the analysis of CD55 and CD59, typically on red cells and neutrophils. However, the ability to accurately detect PNH RBCs is compromised by prior hemolysis and/or the presence of transfused RBCs. Aplastic Anemia (AA) and Myelodysplastic Syndrome (MDS) patients may also show the presence of PNH clones that are not readily detectable by RBC-based flow assays. We recently described a sensitive multi-parameter fluorescent Aerolysin (FLAER)-based flow assay utilizing CD45, CD33 and CD14 that accurately identified PNH monocyte and neutrophil clones in PNH, AA and MDS patients. The assay could detect small PNH clones (0.5-1%) in samples up to 48 hours post-draw and required only 40 minutes from sample receipt to result availability. Analysis could be performed on a wide range of 4-colour instruments and specialised software was not required. The assay also has utility in detecting other (non-PNH) hematologic abnormalities in samples submitted for PNH screening. *Aims*. In this study, we compared the efficiency of detection of PNH monocyte and neutrophil clones using the FLAER assay with a CD59-based assay on RBCs upon samples submitted for PNH screening at our Institution from October 2005 to December 2008. *Results*. Of 536 evaluable samples, PNH clones were detected in 63 (11.75%) with the FLAER assay, while PNH RBCs were detected in only 33 (52.4%) of these PNH clone-containing samples. Of the samples containing PNH clones by both assays, clone size was always larger with the FLAER assay. When PNH clones were detected in samples with the CD59 test only, repeat analysis of both assays demonstrated the RBC-derived data to be in error. The explanation for this discrepancy in bona fide PNH cases is that the FLAER assay is unaffected by hemolysis and/or prior transfusion. In cases of aplastic anemia and myelodyplasia, almost all patients had prior RBC transfusions, further reducing the utility of the RBC assay. We also stabilized a fresh PNH blood sample and showed that the qualitative and quantitative aspects of the FLAER assay were unaffected by the stabilization process and significant differences were not detected up to 12 weeks post stabilization. These data indicate that it will be possible to generate material suitable for Quality Controlling and Proficiency Testing this assay, an important aspect of clinical assay design. *Summary and Conclusions.* Our results suggest that the FLAER assay on WBC's is a much more sensitive and robust primary screening assay for the detection of PNH clones in the clinical flow laboratory than are RBC-based assays. Since the probability of a thrombo-embolic event is directly related to the PNH WBC clone size, this new assay should improve the identification of patients at risk for this life-threatening complication.

0584

EFFECT OF ECULIZIMAB THERAPY ON THROMBOCYTOPENIA IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

I. Weitz, L. Rochanda, H. Liebman

University of Southern California, LOS ANGELES, CALIFORNIA, USA

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired disorder resulting from a mutation in the PIG A gene of the hematopoietic stem cell. This defect results in the loss of the GPI membrane anchored proteins such as CD 59, a membrane inhibitor of reactive lysis. CD59 deficient cells are more susceptible to complement lysis. All hematopoietic bone marrow derived cells, including the megakaryocyte and platelets, are affected. The disorder is characterized by chronic hemolysis, leucopenia, thrombocytopenia, and high incidence of thrombosis. The association with bone marrow failure syndromes such as Aplastic Anemia, is well recognized. Eculizumab, an inhibitor of C5 activation, reduces red cell hemolysis and the risk of thrombosis in patients with PNH. However, no effect on thrombocytopenia or leucopenia has been reported. *Methods*. We recently reported the preliminary results of an ongoing study (Weitz *et al.* Blood 2008; 112: Abst 407) on the effect of Eculizumab therapy on markers of inflammation and thrombin generation in patients with PNH. Patients were treated by the FDA-approved protocol with blood samples obtained prior to treatment on day 1 and prior to each dose on days 8, 15, 22, 29, 43, and 90. In addition to plasma samples for studies of markers of inflammation and thrombin generation, complete blood counts were also obtained. Treatment resulted in sustained and statistically significant reductions in D-Dimer, thrombin-antithrombin complex (TAT) and IL-6 levels were seen and did not correlate with hemolysis as assessed by measurement of LDH. Since thrombin in a potent platelet agonist, we hypothesized that some patients would demonstrate significant increases in platelet count with Eculizumab treatment. *Results*. At the present time 11 patients have been enrolled in this study with treatment follow-up ranging from 2 to 20 months. 7/11 (64%) patients had thrombocytopenia with platelet counts below 100×10^9/L (range: 26 to 88×10^9/L) prior to treatment. Of the 7 patients, 2 patients had aplastic/hypoplastic bone marrows, but large WBC PNH clones; 2 patients had classical paroxysmal PNH and 2 patients had splenomegaly due to a pre-existing Budd Chiari syndrome. A sustained platelet recovery above 100k occurred in 4/7 (57%) patients with Eculizumab therapy. D-Dimer and TAT were elevated in all of the patients with thrombocytopenia prior to treatment, but decreased with Eculizumab therapy. *Summary*. The results of this ongoing prospective study suggest that the improvement in platelet counts may be occur is some patients with PNH due to a reduction in complement-mediated thrombin generation and thrombin-induced platelet activation and aggregation.

0585

EFFICACY OF THE TERMINAL COMPLEMENT INHIBITOR ECULIZUMAB USED CHRONICALLY IN A PATIENT WITH COLD AGGLUTININ DISEASE

A. Röth,[1] A. Hüttmann,[1] C. Hock,[1] R. Rother,[2] U. Dührsen,[1] T. Philipp[1]

[1]University Hospital Essen, ESSEN, Germany; [2]Alexion Pharmaceuticals, CHESHIRE, USA

Background. Previously, we reported initial efficacy data of the terminal complement inhibitor eculizumab in cold agglutinin disease (CAD). Here, we report the chronic use of eculizumab in a patient with CAD refractory to previous treatments. In CAD, IgM autoantibodies can activate the complement system in colder areas of the body (e.g. extremities), resulting in red blood cell hemolysis. Prednisone is typically ineffective and only on rare occasions can chemotherapy suppress autoantibody production. Some cases are mild and self-limited, but others require hospitalization and can be life-threatening. Supportive transfusions of red blood cells may be necessary. Eculizumab, a monoclonal antibody targeting complement factor C5, has shown efficacy in patients

with paroxysmal nocturnal hemoglobinuria (PNH) through inhibition of terminal complement activation. Based on the pathogenesis of CAD, blockade of terminal complement by eculizumab could be a new possible therapeutic approach. *Aims and Methods.* To test for continued efficacy of eculizumab in a transfusion-dependent patient with chronic CAD refractory to extensive previous treatments (including several cycles of rituximab) and experiencing elevated hemolysis for at least 1 year prior to treatment. Eculizumab was dosed as follows: 600 mg IV every 7 days x 4; 900 mg 7 days later; and then 900 mg every 14±2 days. Prior to treatment, the patient was vaccinated against Neisseria meningitidis as eculizumab treated patients are at an increased risk for meningococcal infection. Transfusion requirements as well as clinical and biochemical indicators of hemolysis were monitored. *Results*. Hemolysis, as measured by lactate dehydrogenase (LDH) against time, was significantly reduced 47% from 848±41.2 U/L (mean±SE) to 446 ± 8.3 U/L (12 months pre-treatment vs. 20 months post-treatment). The chronic control of hemolysis resulted in an improvement in anemia (median of 9.9 g/dL 12-months pre-treatment vs. 11.6 g/dL 20-months post-treatment) and reduced transfusion requirements from 18 PRBC units during a 12 month pre-treatment period to 0 during 20 months of treatment. Furthermore, the patient continues to report a sustained improvement in fatigue and quality of life and no longer suffered from angina pectoris at 20 months of treatment. There were no drug-related adverse events and ongoing therapy with eculizumab continues to be safe and well tolerated in this patient. *Conclusions*. Here we present a long-term follow-up of our initial report of eculizumab efficacy in a CAD patient. Importantly, since the initiation of eculizumab treatment, hemolysis has been controlled with no exacerbations of the disease. Chronic treatment with eculizumab remains safe and highly effective for over 20 months. With limited available effective treatment options, this promising result with a well-tolerated antibody provides a strong rationale for a planned clinical trial for the use of eculizumab in patients with CAD.

0586

ANEMIA DURING PEGYLATED INTERFERON-RIBAVIRIN THERAPY RESULTS FROM BOTH INCREASE SUPPRESSION OF ERYTHROID DIFFERENTIATION AND HEMOLYSIS

L. Ronzoni, A. Aghemo, M.G. Rumi, A. Colancecco, S. Monico, P. Grillo, M. Colombo, M.D. Cappellini

Fondazione Policlinico, Mangiagalli, Regina Elena IRCCS, University of Milan, MILAN, Italy

Background. Anemia is a common side effect of Pegylated Interferon (PegIFN) and Ribavirin (RBV) combined therapy in patients with chronic hepatitis C (HCV). Hemolysis as consequence of RBV concentration in erythrocytes is the most accepted underlying mechanism; however, since the degree of treatment related anemia is highly variable, other pathogenic mechanisms could be hypothesized. *Aims*. To evaluate the prevalence of hemolysis in patients treated with the combination of PegIFN and RBV compared to patients on monotherapy with PegIFN and to assess other possible mechanisms underlying anemia. *Methods*. We studied 18 patients with chronic hepatitis C HCV-2 treated with PegIFN-α2a (180 mcg/week) plus RBV (800 mg/day) for 24 weeks and 10 patients with chronic hepatitis B treated with PegIFN-α2a 180 mcg/week monotherapy for 48 weeks. Routine hematologic parameter, reticolocyte count and serum LDH and haptoglobin levels were monitored. The therapy effect on erythropoiesis was evaluated *ex vivo* through peripheral erythroid progenitors cell cultures and gene expression analysis during treatment. Peripheral blood mononuclear cells were plated in methylcellulose-supporting media at a concentration of 2×10^5 cells/mL and colony formation (BFUe and CFU-GEMM) was analyzed after 14 day of culture. Expression of gamma-globin and GATA2 gene was evaluated with quantitative real-time PCR. *Results*. All the patients developed anemia after 24 weeks of treatment, although the mean hemoglobin decrease was higher in HCV patients (2.77 vs 1.82 g/dL at week 24, p=0.03), particularly at week 4 (1.86 vs 0.51 g/dL, p=0.007). Only 3 out of 18 HCV patients (16%) developed hemolytic anemia, documented by a marked increase in reticulocytes (3,4%) and in LDH levels (502 U/L) and by a significant decrease in haptoglobin levels (40,3 mg/dL). These patients showed a sharper and faster decrease of Hb compared to the remaining 15 HCV patients (week 4: 3.40 vs 1.55 g/dL, p=0.01). None of the HBV patients on treatment developed hemolytic anemia. HCV patients with hemolysis had an increase in BFUe number at week 4, whereas patients without signs of hemolysis showed a decrease in colonies formation at week 4 (baseline: 15.5 to 7.5 colony/105 cells). A decrease in BFUe number was also observed in HBV patients along PegIFN treatment period. In all the HCV and HBV patients the reduction in BFUe number was associated with an increase in undifferentiated CFU-GEMM colonies (BFUe: 87 to 76% in HCV, 91 to 64% in HBV; CFU-GEMM: 13 to 24% in HCV, 9 to 36% in HBV) and in primitive erythropoiesis specific genes (gamma-globin and GATA2 genes) expression. *Conclusions*. These observations suggested that the inhibitory effect of PegIFN on erythroid differentiation plays a major role in causing anemia even in combined treatment with RBV. The hemolysis as cause of anemia so far attributed to RBV is apparently restricted to few cases and deserves further investigation.

0587

MODIFICATION OF THE STANDARD ECULIZUMAB DOSE TO SUCCESSFULLY MANAGE INTRAVASCULAR HAEMOLYSIS BREAKTHROUGH IN PATIENTS WITH PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA

R.J. Kelly,[1] L.M. Arnold,[1] S.J. Richards,[1] A. Hill,[2] S. van Bijnen,[3] P. Muus,[3] D. Dorr,[4] R. Brodsky,[4] J. Beauchamp,[5] G. Khursigara,[5] R.P. Rother,[5] P. Hillmen[1]

[1]St James's University Hospital, LEEDS, UK; [2]Bradford Royal Infirmary, BRADFORD, UK; [3]Radbound University, NIJMEGEN, Netherlands; [4]John Hopkins, BALTIMORE, USA; [5]Alexion Pharmaceuticals Inc, GUILDFORD, UK

Background. Paroxysmal nocturnal haemoglobinuria (PNH) is characterised by a lack of CD59 on erythrocytes rendering cells susceptible to intravascular haemolysis. Eculizumab blocks terminal complement resulting in reductions in haemolysis, thrombotic events, renal impairment and transfusion requirement and improvement in quality of life. The standard dosing regimen for eculizumab is 600 milligrams per week for 4 weeks; 900 milligrams one week later; and then 900 milligrams every 14±2 days. This regimen maintains eculizumab levels >35 micrograms per millilitre which consistently blocks complement-mediated haemolysis. 4/195 (2%) patients in PNH clinical trials were not consistently blocked with this regimen and developed breakthrough intravascular haemolysis, with haemoglobinuria, abdominal discomfort and dysphagia, 12-13 days after an eculizumab infusion. *Aims*. An increased dose of 1200 milligrams of eculizumab every 2 weeks was evaluated for effectiveness and safety. *Method*. LDH, pharmacokinetics (PK), and clinical signs of complement breakthrough were monitored.

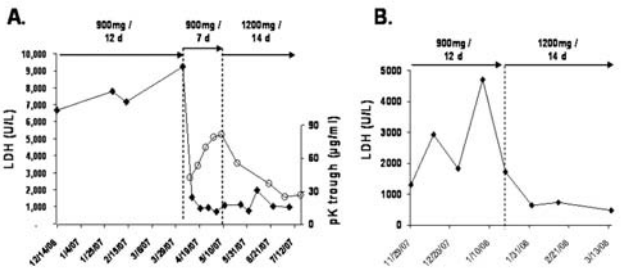

Figure 1. Patient LDH levels in response to 1200 mg dosing.

Results. Patient 1 was managed for 6 months with 900 milligrams every 12 days before experiencing complement breakthrough (Figure, panel A). LDH levels (closed diamonds) reached 9234 U/L (ULN, 430-450 U/L) and breakthrough symptoms occurred 2 days prior to the next dose. The patient was re-induced with 900 mg eculizumab every 7 days for 5 weeks followed by 1200 milligrams every 14 days. Trough levels of eculizumab increased (open circles) each week during the induction phase (42.7 - 81.8 µg/mL) resulting in an immediate reduction in LDH to near normal levels. A maintenance dose of 1200 mg every 14 days resulted in sustained complement blockade with normal LDH levels for 1 year before further breakthroughs occurred. A further 1200 milligrams dose in between the 14 day dosing interval every 4-5 doses provides complement blockade. Patient 2 experienced breakthrough haemolysis after 19 months of standard dosing. Complement breakthrough occurred during a post-cholecystectomy infective endocarditis. An adjustment to 900 mg every 12 days did not control complement breakthrough (Figure 1, panel B) and the dose was changed to 1200 mg every 14 days. Further episodes of haemoglobinuria and other symptoms of haemolysis were not observed. Patients 2 and 3 experienced breakthrough haemolysis after 4 and 19 months of standard dosing respectively and were changed to 1200 milligrams every 14 days without re-induction. No further episodes of breakthrough haemolysis have occured. Patient 4 received

900 milligrams every 12 days for 58 months after breakthrough before changing to 1200 milligrams every 2 weeks for convenience. *Summary*. It is important to recognise the phenomenon of breakthrough from complement blockade as these patients can be effectively managed with a higher dose of eculizumab. We demonstrate good correlation between eculizumab and LDH levels, suggesting that complement breakthrough can be monitored by LDH levels near the end of the dosing interval. It appears that using the standard dosing regime that approximately 2% of patients will break-through and this appears to occur within the first 12 months of eculizumab therapy.

0588

DIAGNOSING IRON DEFICIENCY ANEMIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

E.C. van Dongen-Lases, A.M. Linssen, F. de Vegt, P.L.C.M. van Riel, D.W. Swinkels, A.E. van Ede

UMC St. Radboud, NIJMEGEN, Netherlands

Background. Iron deficiency anemia (IDA) in patients with rheumatoid arthritis is difficult to diagnose with certainty. *Aims*. The aim of our study was to explore the value of hepcidin, reticulocyte hemoglobin equivalent (Ret-He), erythrocyte hemoglobin equivalent (RBC-He) and delta hemoglobin equivalent (Delta-He) in diagnosing iron deficiency anemia (IDA) among patients with rheumatoid arthritis in comparison to the conventional diagnostic parameters mean cell volume, ferritin and transferrin saturation. *Methods*. One-hundred-and-six patients with rheumatoid arthritis participated in this explorative cross-sectional study. Fresh EDTA-anticoagulated blood samples of all patients were analyzed for Ret-He, RBC-He and Delta-He on a Sysmex XE-5000 automated hematology analyzer. Serum hepcidin levels were measured by weak cation exchange chromatography followed by mass spectrometry. The presence and type of anemia (IDA, anemia of chronic disease or both) was determined by conventional laboratory tests. *Results*. Receiver operator characteristic analysis showed that hepcidin had the highest discriminating power in the diagnosis of IDA (either with or without anemia of chronic disease), with an area under the curve (AUC) of 0.85 (95% confidence interval = 0.71-1.00). RBC-He had only a slightly lower performance, with an AUC of 0.83 (0.67-0.95). Also Ret-He turned out to be useful for this diagnostic purpose (AUC = 0.77; 0.59-0.99), but Delta-He did not lead to a better identification of IDA as coincidence would do. The percentage total agreement between the conventional classification and the classifications based on hepcidin or RBC-He measurement alone was 75% and 72%, respectively. *Summary and Conclusions*. Our results show that both hepcidin and RBC-He are useful for the differentiation between the different types of anemia in patients with rheumatoid arthritis.

0589

IN VITRO EFFECT OF RIBAVIRIN AND PEGYLATED INTERFERON ON ERYTHROPOIESIS

L. Ronzoni, A. Colancecco, A. Cattaneo, A. Aghemo, M.G. Rumi, M. Colombo, M.D. Cappellini

Fondazione Policlinico, Mangiagalli, Regina Elena IRCCS, University of Milan, MILAN, Italy

Background. The antiviral drug ribavirin (RBV) is widely used in combination with pegylated interferon (PegIFN) for the treatment of hepatitis C virus (HCV) infection. A major side effect of RBV is a reversible anemia. The mechanism underlying anemia in RBV treated patients remains speculative although hemolysis was suggested. *Aims*. To obtain more insights on this issue, we evaluated *in vitro* the effect of RBV and PegIFN on pheripheral CD34 proliferation and erythroid differentiation. *Methods*. After informed consent, the mononuclear cells derived from pheripheral blood of healthy volunteers were enriched for $CD34^+$ cells by positive selection using anti-CD34-tagged magnetic beads. $CD34^+$ cells were cultured for 14 days with a specific medium containing erythropoietin to induce erythroid differentiation. RBV (0.5 mM and 0.1 mM) and PegIFN (100U and 1000U) were added alone or in combination at different days of culture: precisely at day 0 corresponding to CD34 stage and at day 7 corresponding to proerythroblast stage. Cells growth and viability were evaluated by tripan blue exclusion; erythroid differentiation was investigated by cytofluorimetric analysis of Glicophorin A (GPA) expression, by morphological analysis on benzidine-May-Grunwald-Giemsa stained smears and by erythroid specific (gamma-globin and GATA2) gene expression analysis with real-time PCR. *Results*. RBV inhibited cell growth and differentiation with reduction of GPA^+ cells in a time and dose dependent manner; drug added at day 0 of culture had a stronger inhibitory effect than addition at day 7 as well as RBV 0.5mM versus RBV 0.1 mM (Addition at day 0: RBV 0.1 mM: 8.5 and 1.6-fold reduction in cells growth and GPA+ cells respectively vs untreated cells; RBV 0.5 mM: 12 and 30-fold reduction in cells growth and GPA^+ cells vs untreated cells. Addition at day 7: RBV 0.1 mM: 2.4 and 0.7-fold reduction in cells growth and GPA+ cells respectively vs untreated cells; RBV 0.5 mM: 3.6 and 2.3-fold reduction in cells growth and GPA^+ cells vs untreated cells). Addition of PegIFN both at day 0 and day 7 of culture delayed erythroid differentiation with reduction of GPA^+ cells and orthocromatic erythroblasts and increase of more undifferentiated polychromatophilic erythroblasts and primitive erythropoietic genes expression (GPA^+ cells: 61% untreated cells, 50% PegIFN100U and 47% PegIFN1000U; orthocromatic e.: 55% untreated cells, 56% PegIFN100U and 23% PegIFN1000U; polychromatophilic e.: 17% untreated cells, 37% PegIFN100U and 57% PegIFN1000U; gamma gene expression: 1 untreated cells, 1.75 PegIFN100U and 2.39 PegIFN1000U). The combination of PegIFN and RBV both at day 0 and day 7 of culture affected cell growth and erythroid differentiation less than RBV alone; however cells treated with the combination of PegIFN and RBV were more undifferentiated than cells treated with PegIFN alone. *Conclusions*. All these data confirmed the inhibitory effect of PegIFN on erythroid differentiation and strongly suggested an inhibitory action of RBV on cell growth, particularly on undifferentiated stem cells. These observations provide possible explanation for the pathophysiology of anemia observed with ribavirin treatment.

ANTI CD 20 (RITUXIMAB) IN PEDIATRIC AUTOIMMUNE HAEMOLYTIC ANAEMIAS. LONG FOLLOW UP IN A SINGLE CENTRE

A. Catala, S. Rives, T. Toll, M. Camos, R. Berrueco, N. Conde, A. Quintero, J. Estella

Hospital Sant Joan de Deu, BARCELONA, Spain

Introduction. Pediatric autoimmune haemolytic anaemia (AIHA) usually responds to steroids therapy. However, in some cases, especially in infants and adolescents, it can be resistant. In these patients failure of second and third line treatments is frequent. In the past years the chimeric monoclonal antibody that targets CD 20, expressed in B lymphocytes surface, has been used in the management of autoimmune diseases. Recently it has been implemented in pediatric autoimmune anaemia. *Aims*. To communicate a single centre experience with rituximab as a salvage treatment of pediatric autoimmune haemolytic anaemia. *Methods*. Children and infants with refractory or steroid-dependent AIHA were included in this series. Rituximab was administered as a third-line treatment (375 mg/m^2/week, 4 doses). Prophylactic iv immunoglobulins and cotrimoxazole were administered to all patients. *Results*. Table 1.

Table 1.

n	age	DAT	Δ FLT-RTX	days to normal Hb	relapse (n)	2 nd RTX (t)	BL recovery	follow up
1	11mo	IgG warm	3.5mo	26	no	no	3mo	52mo
2	3mo	IgG warm	1.5mo	39	no	no	5mo	46mo
3	13yrs	IgG warm	2.5mo	26	yes	yes (8mo)	no	36mo
4	18mo	IgG/C3 warm	11mo	45	no	no	3mo	18mo
5	4yrs	IgG warm	4.5mo	60	yes	yes (8mo)	4mo	16mo
6	5yrs	IgG warm	8mo	pr	no	no	no	4mo

FLT: first line treatment; RTX: rituximab; BL: B-lymphocytes; pr: partial response; FLT-RTX: interval between FLT and RTX; (t) time from first dose of previous course.

Conclusions. In this series, children and infants with AIHA achieving successful results with rituximab are described. All of them were treated with steroids and immunoglobulins as a first line therapy. No serious side effects or opportunistic infections were observed in a long follow up

period with a median of 27 month (range 4-52 mo). Rituximab was effective in controlling refractory disease in all patients but two, who achieved partial response. Responders took 4-8 weeks to attain normal haemoglobin values. Disease may recur but it can be responsive to a second course of rituximab. The immunosuppression and potential life-threatening opportunistic infections reported in other series with rituximab have to be balanced against the harmful complications of prolonged corticosteroid use and other immunosuppressant agents in this young population.

0591

LONG-TERM OUTCOME OF ACQUIRED APLASTIC ANEMIA: COMPARATION BETWEEN IMMUNOSUPPRESSIVE THERAPY AND BONE MARROW TRANSPLANTATION

Lj. Tukic, D. Stamatovic, O. Tarabar, M. Elez, Z. Tatomirovic, O. Radic-Tasic, B. Balint, N. Kuljic-Kapulica

Military Medical Academy, BELGRADE, Serbia

Background. Both immunosuppressive therapy (IST) and bone marrow transplantation (BMT) are accepted treatments for patients with aplastic anemia (AA). Choosing one of these therapies depends not only on donor availability but also on such factors as patient age. The aim of this study was to compare survival rates and long-term complications after IST or BMT in patients with AA and to identify prognostic factors associated with improved survival. *Patients and Methods*. between 2/1986 and 2/2009 48 patients with newly diagnosed AA were treated either with allogeneic BMT (18 patients) or with IST (32 patients). The median time from diagnosis to therapy was 2 months (range 1-9) in IST and 3 months (range 1-16) in BMT group. There was no statistical difference between 2 treatment groups in sex, severity of AA, disease duration, previous transfusion support, except age (patients in BMT group were younger). Eighteen allogeneic BMT were performed in 16 patients. All donors were HLA-identical sibling (1 donor was identical twin). Source of stem cells was bone marrow in 15 (2 with second transplants) and peripheral stem cell in 3 BMTs. Conditioning regimens were based on cyclophosphamide (CY) with antithymocyte (ATG) in 15 and Flud with CY and ATG in 3 BMTs. Nineteen patients received combined IST with ATG or ALG (antilymphocyte globuline), cyclosporine A and steroids and 13 patients ATG with steroids (from which 5 were splenectomized). *Results*. engraftment was documented (median time 16 days) in 15 transplanted patients (93.8%). In the first 100 days died 3 (18.8%) transplanted patients: one without engraftment (6.3%) on +23 days with gram-negative sepsis, the other developed steroid-refractory aGvHD grade 3-4 with invasive fungal infection and died on 78 days and the third died on 60 days with pneumonitis interstitialis (CMV+). Two patients (12.5%) who rejected allograft after 6.5 months, were retransplanted: 1 successfully, the other died 8 days following the second BMT. One female patient (8.3%) developed cGvHD. In IST group responded 25 patients (78.1%) and 6 of them (24%) had two cycles IST. Five patients (15.6%) from IST group died, major causes of death were infection and hemorrhage. Aplasia recurred in 6 patients (24%) with partial response following IST in 24 months. Long-term complications of IST were: an evolution in MDS/AML after 76 months at 2 patients (8%), avascular necrosis of hip at 5 patients (20%) and Ca prostate gland (after 150 months) at 1 patient (4%). Between groups did not difference in probability 12-years overall survival: 65% in BMT and 71% in IST group. Difference in survival was found in patients with/without very severe neutropenia (p<0.05) and with/without response/engraftment (p<0.001). An improvement of peripheral blood counts was faster following BMT (median 16 days) related to IST (median 4 months) (p<0.001). *Conclusions*. This study indicates that over 65% of patients with AA can be successfully treated with either BMT or IST. Long-term overall survival does not differ in the two treatment groups.

0592

THALASSEMIA INTERMEDIA: AN EGYPTIAN EXPERIENCE

G. Mokhtar, A. A.G.Tantawy, A. A.Abdel Moneim, M. Waheed

Faculty of Medicine, Ain Shams University, CAIRO, Egypt

Background. Thalassemia Intermedia (TI) includes a wide clinical spectrum of varying severity.A number of clinical complications commonly associated with thalassemia major (TM) are rarely seen in (TI). There are no clear guidelines for initiating and maintaining transfusions in TI for prevention of complications. *Aims.* To assess the phenotypic variability of Egyptian children, adolescents and young adults with TI, their clinical characteristics as well as frequency of complications in comparison to age and sex matched β TM patients. The clinical and haematological response to various therapeutic modalities in TI patients were assessed. *Study Design*. Sixty TI patients (aged 4-25 years, mean 12.48± 5.43 years) were compared to forty β-TM patients (aged 4-25 years, mean 13.22±5.97 years). All patients were subjected to full history taking and clinical examination stressing on transfusion protocol, chelation therapy and presence of complications. Investigations included complete blood count, haemoglobin electrophoresis,serum ferritin, as well as abdominal ultrasound, two dimensional M- mode echocardiography, with Echo-Doppler, and Dual Energy X-ray Absorptiometry for measurement of bone mineral density(BMD).TI patients were subdivided into 3 groups according to therapy: group A(n=20) received hydroxyurea (mean dose of 20.7±3.58 mg/kg/day),group B(n=20) received hydroxyurea (mean dose of 18±5.2 mg/kg/day)with L-carnitine (mean dose of 45±10.2 mg/kg/day),and group C (n=20) received L-carnitine (mean dose of 50±4 mg/kg/day). All patients were prospectively followed up for 12 months for clinical and haematological response. *Results*. Compared to TM patients, TI patients had higher incidence of left atrial dilatation (p=0.008),right ventricular dilatation (p<0.001)and pulmonary hypertension (p=0.001). However, TM patients had higher incidence of left ventricular dilatation (p=0.001), restrictive left ventricular filling pattern (p=0.03), and impaired left ventricular contractility (p=0.01), with an overall higher incidence of heart disease compared to TI patients (45% versus 17.5%, p=0.001). Higher incidence of osteoporosis was present in TM compared to TI patients (40% versus 15%, p=0.006).TI patients had higher incidence of fractures compared to TM patients (5% versus 2.5%, p=0.03).Compared to TM, TI patients had lower prevalence of hepatitis B viral infection (p=0.04),diabetes mellitus (p=0.03),delayed puberty (p=0.01) and short stature(p=0.005). However TI patients had higher incidence of cholelithiasis and thrombocytosis compared to TM patients although did not reach statistical significance. Therapy with hydroxyurea alone in TI was associated with significant decrease in transfusion index, increase in mean haemoglobin and mean haemoglobin F values (p<0.001),with improvement in quality of life. L-carnitine therapy used alone or when added to patients already on hydroxyurea treatment did not have significant effect on transfusion frequency or haemoglobin F (p>0.05). *Conclusions.*TI patients differ from TM in the frequency and distribution of complications.The use of hydroxyurea in paediatric TI patients to minimize or even eliminate the need for blood transfusion is recommended. L-carnitine therapy should be individualized according to the patient response.

0593

SUCCESSFUL TREATMENT OF COMPLEMENT MEDIATED REFRACTORY HAEMOLYSIS ASSOCIATED WITH COLD AND WARM AUTOANTIBODIES USING ECULIZUMAB

M. Bommer,[1] B. Höchsmann,[2] W.A. Flegel,[2] H. Doehner,[3] H. Schrezenmeier[2]

[1]University of Ulm, ULM; [2]Institute for Clinical Transfusion Medicine and Immunogenetics,University of Ulm, ULM; [3]Department of Internal Medicine III, University of Ulm, ULM, Germany

Background. In about 10% of patients, chronic lymphocytic leukemia (B-CLL) is complicated by autoimmune haemolysis. Approximately 80% of cases are caused by autoantibodies of the IgG type (warm autoantibodies) while about 20% of cases are mediated by autoantibodies of the IgM type (cold autoantibodies). Destruction of RBCs by cold autoantibodies is mediated by complement activation and subsequent formation of the membrane attack complex on the cell surface. Eculizumab blocks the cleavage of complement protein C5 and is a potent inhibitor of terminal complement activation. Eculizumab is approved for the treatment of paroxysmal nocturnal haemoglobinuria (PNH). *Aims*. We describe a case of autoimmune haemolytic anemia due to both cold and warm autoantibodies that was successfully treated with eculizumab. *Case report.* A 50 year old male with chronic lymphocytic leukemia (B-CLL) and chronic hepatitis B presented with severe autoimmune mediated haemolytic anemia. Laboratory tests were as follows: haemoglobin 7.2 g/dL, reticulocytes 342×10^9/L, LDH 372U/L, haptoglobin undetectable, and total bilirubin 101 µmol/L. Serologic testing revealed cold and warm autoantibodies as well as erythocyte allo-antibodies type anti-Cw and anti-Lua. The patient was also direct antiglobulin test (DAT) positive with polyspecific antiglobulin serum, monospecific anti-IgG, anti-IgA, anti-C3c and anti-C3d antibodies. Serum levels for complement factors were low: C3c 0.51g/L (normal range 0.90-1.80) and C4 <0.01g/L (0.10-0.40). He required up to 8 PRBC transfusions/week. Various therapeutic approaches failed: 1) prednisolone (beginning with 2 mg/kg/day over a period of 4 months), 2) polyvalent human immunoglobulins (2 g/kg), 3) rituximab (4 cycles of 375 mg/m^2) and cyclophosphamide (500

mg), and 4) alemtuzumab (90 mg/week s.c.) and rituximab (375 mg/m^2/week i.v.) for 8 weeks. Thus we decided to use the complement inhibitor eculizumab off label. The patient gave informed written consent. One month after ending the alemtuzumab/rituximab-combination therapy, eculizumab was given 4 infusions of 600 mg/week followed by 900 mg every 2 weeks. Meningococcal vaccination was given as per label. DAT became negative for anti-IgA and anti-C3c during treatment. Indirect antiglobulin test showed a decrease of free autoantibody in the serum from a titer of 1: 32 to 1:4 during therapy. No change in the titers of erythocyte allo-antibodies type anti-Cw and anti-Lua was observed. The number of PRBC units transfused has dropped from 131 during the 7 months before eculizumab therapy to 12 during 7 months of eculizumab treatment and haemoglobin levels have remained stable. The patient has been transfusion independent for the last 4 months and continues on eculizumab. *Conclusions*. We report a case of severe refractory autoimmune haemolytic anemia due to both cold and warm autoantibodies that was successfully treated by the complement inhibitor eculizumab. We conclude that eculizumab could be an effective treatment for complement mediated autoimmune haemolysis. Clinical trials confirming our results are warranted.

0594

EFFECT OF DIHYDROARTEMISININ ON HUMAN ERYTHROID CELL DIFFERENTIATION: IMPLICATIONS FOR MALARIA TREATMENT IN PREGNANCY

S. Finaurini,[1] L. Ronzoni,[2] A. Colancecco,[2] M.D. Cappellini,[2] D. Taramelli[1]

[1]*University of Milan, MILAN;* [2]*Fondazione Policlinico, Mangiagalli, Regina Elena, IRCCS, University of Milan, MILAN, Italy*

Background. Severe malaria in pregnancy causes anemia, low birth weight and increased mortality of both mother and infants. WHO recommends few antimalarials due to safety problem; artemisinin combination therapy is the first line treatment; however artemisinin derivatives showed animal embryotoxicity with a reduction of embryonic erythrocytes when treatment is performed on certain days of gestation. *Aims*. To investigate the effect of dihydroartemisinin (DHA), the metabolite of artemisinin, on an *in vitro* model reproducing human erythropoiesis and to characterize the target erythroid stage, in order to predict the window of susceptibility to DHA in human pregnancy. *Methods*. The mononuclear cells derived from pheripheral blood of healthy volunteers were enriched for CD34$^+$ cells by positive selection using anti-CD34-tagged magnetic beads. CD34$^+$ cells were cultured for 14 days with a specific medium containing erythropoietin to induce erythroid differentiation. DHA at 0,5 or 2 µM, according to the dosages of previous animal experiments, was added for the first time at day 0 (on isolated stem cell), at day 2 (on early erythroid progenitors), at day 4 (in presence of both early progenitors and pro-erythroblasts), at day 7 (on basophilic erythroblasts) or at day 11 (polychromatic erythroblasts) and then continuously every 3 days up to 14 days, because of its short half life. Cells growth and viability were evaluated by tripan blue exclusion; erythroid differentiation was investigated by cytofluorimetric analysis of Glicophorin A (GPA) expression, by morphological analysis on benzidine-May-Grunwald-Giemsa stained smears and by erythroid specific globin gene expression analysis with real-time PCR. *Results*. DHA added on stem cells or early erythroid progenitors (day 0 and 2 of culture) caused a transient inhibition of both cell growth and erythroid differentiation (p<0.05) up to day 7, but then the treated cells started growing and completed their erythroid differentiation at day 14 of culture. When DHA was added on more differentiated basophilic erythroblasts (day 4 and 7 of culture) a significant and long lasting decrease in proliferation as well as a delay in erythroid differentiation was observed up to day 14. With DHA added on mature stages (polychromatic erythroblasts, day 11 of culture), only a small reduction of cell growth has been observed without any consequence for erythroid cell differentiation. *Conclusions*. These data suggest that DHA's specific target is the basophilic erythroblast since DHA added at this stage causes a significant inhibition of erythroid differentiation. Based on these *in vitro* results, we hypothesize that DHA could affect human primitive erythropoiesis, which occurs during the late phase of human secondary yolk sac erythropoiesis (weeks 4-8 of gestation), when foetal blood is formed of only primitive erythroblasts. This means that if the treatment with DHA or artemisinin derivatives is performed during the first trimester of human pregnancy, toxic effects on embryo could be expected.

0595

OSTEOPROTEGERIN AND RECEPTOR ACTIVATOR OF THE NF-KB LIGAND (RANKL) IN EGYPTIAN PATIENTS WITH THALASSEMIA-INDUCED OSTEOPOROSIS

A.E.D.S. Abd El Hamid, M. Attia, A. Saad, M. El Nesr, M. Hassan Saleh

Faculty of Medicine, Suez Canal University, ISMAILIA, Egypt

Background and Objectives. Osteoporosis represents an important cause of morbidity in thalassemic patients, many etiologic factors were accused. The aim of the study was: to characterize the possible role of the osteoprotegerin (OPG) and receptor activator of the NF-κB ligand (RANKL) system & Viral hepatitis-C infection (HCV) in Egyptian thalassemic patients with evident bone loss. *Individuals and Methods*. The study group: the study included 35 thalassemic patients (19 males and 16 females), mean age 17.3 years ± 5.57; range(9-25) year old; The control group: included 35 healthy age and sex matched individuals. *Methods*. medical history, clinical examination, abdominal ultrsonography were carried out to all individual included in the study. Complete blood count, serum ferretin, calcium, phospshorus, alkaline phosphatase measurements; HCV antibodies by Elisa and RT-HCV PCR followed by serum concentrations of OPG and RANKL, were carried out. In addition to lumbar spine bone mineral density (BMD) by DEXA. *Results*. Thalassemic patients had significantly lower levels of OPG compared with healthy controls (1.41±0.74 vs. 3.31±1.95, respectively; p<0.05) and higher not statistically significantly, serum levels of s-RANKL (2.11±0.75 vs. 1.96±0.97, respectively; p<0.05) with a consequent significantly lower OPG/RANKL ratio (0.75±0.23 vs. 2.37±1.93, respectively; p<0.05). Also, thalassemic patients displayed a lower bone mineral density values (detected by DEXA) than the healthy controls group. HCV infection was detected in62.1% of the thalassemic patients; the incidence of osteoporosis was numerically increased in thalassemic patients infected with HCV (27.8% vs. 9.1% with HCV negative patients; p value > 0.05). Differences between HCV infected thalassemic patients and HCV non infected thalassemic patients regarding OPG, RANKL and OPG/RANKL ratio were statistically significant (p>0.05). ROC curve analysis showed that an OPG value ≤1.5 can be used to detect osteopenia/osteoporosis among thalassemic patients with 67% sensitivity (95% CI=44.7-84.3) and 76% specificity (95% CI=58.8-89.2) and an OPG/RANKL ratio ≤0.95 can be used to detect the presence of osteopenia/osteoporosis with 80% sensitivity (95% CI=57.8-92.8) and 65% specificity (95% CI=46.5-80.2). *Conclusions*. Our data suggest that, in thalassemic patients, an altered modulation of the OPG/RANKL system resulting in the decrease of OPG could contribute to the enhanced osteoclastic bone resorption and bone loss characteristic of thalassemic patients. HCV infection could be considered as a potential osteoporotic aggravating factor in these group of patients.

0596

A CHILD WITH DYSKERATOSIS CONGENITA AND RECENTLY DESCRIBED TINF2 MUTATION

N. Sarper, E. Zengin

Kocaeli University, KOCAELI, Turkey

Introduction. Dyskeratosis congenita (DC) is a multisystem bone marrow failure syndrome characterized by a triad of mucocutaneous abnormalities (skin pigmentation, nail dystrophy, leucoplakia) and a predisposition to cancer. The genetic basis of DC remains unknown in more than 60% of patients. Mutations have been identified in components of the telomerase complex (dyskerin, TERC, TERT, NOP10, and NHP2), and recently in one component of the shelterin complex TIN2 (gene TINF2). *Case report*. A 26 month-old boy had gum bleed during an upper respiratory infection and his complete blood count showed anemia and thrombocytopenia. He was the second child of the family. There was no consanguineous marriage and parents and brother were healthy. Patient born at term and had good features except dystrophic nails. There was no abnormal skin pigmentation. Complete blood count showed a Hb 9.4 g/dL, MCV 95.5 fl, WBC 8050/mm^3, ANC 1000/mm^3, PLT 50700/mm^3 and reticulocyte count 29000/mm^3. Bone marrow aspiration and biopsy were hypocelular. Hb electrophoresis showed increased HbF (17%). There was no increase in chromosomal breakage with DEB and nitrogen mustard. Cytogenetic study showed a normal karyotype (46 XY). Viral serologic study of hepatitis A, hepatitis B, hepatitis C, EBV, CMV and parvovirus showed no acute viral infection. Informed consent of the parents was obtained for the genetic study of DC. A mutation analysis showed TINF2 mutation c.845 G>A amino

acid substitution:p.Arg 282His. This gene encoding a component of the sheltrin complex has been screened by a combination of denaturing HPLC and direct sequence analysis. The patient was heterozygous for the mutation. Mother did not carry the mutation. The patient could not undergo a hemotopoietic stem cell transplantation due to unavailability of a donor. He is in the 40th month of the follow-up and on androgen (1-2 mg/kg/day) and metil prednisolon (0.25 mg/kg/day) therapy. He is followed as outpatient without any severe infection so far but packed red cells are infrequently transfused. He also had epiphora in the last months due to stenosis of lacrimal canal which is an associated finding in DC. *Discussion*. TINF2 mutations account for approximately 11% of all DC cases. Mutations affect amino acid 282, changing arginine to histidine or cysteine. Telomere lengths in patients with TINF2 mutations were the shortest compared with other DC subtypes, but TERC levels were normal. Patients with TINF2 mutations have severe disease, with most developing aplastic anemia by the age of 10 years. TINF2 is generally a *de novo* mutation. Physical anomalies of the patients with aplastic anemia must be carefully evaluated. Dystrophic nails must not be overlooked. Patients with DC may not have typical skin findings. Useless treatments as immunotherapy must not be tried in patients with congenital bone marrow failure syndromes. *Acknowledgement*. Thanks to Tom Vulliamy, Inderjeet Dokal and coworkers from Center for Paediatrics, Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry for performing the mutation analysis of the patient.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN ADOLESCENTS AND ADULTS. UNDERESTIMATED PROBLEM?

W. Jedrzejczak, M. Jablonska, E. Dwilewicz-Trojaczek, G. Ziarkiewicz-Wroblewska, J. Dzieciatkowski, P. Boguradzki, R. Charlinski, M. Wiater, J. Witkowska, T. Waszczuk-Gajda, W. Hensler, M. Tormanowska

Medical University of Warsaw, WARSAW, Poland

Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening syndrome very rarely described in adults and usually not even mentioned in manuals of internal medicine. Its initial presentation may resemble sepsis and patients are initially admitted to infectious diseases departments and then unsuccessfully treated for this condition. After the first such patient was referred to our Department because of pancytopenia, within 4 years we identified additional seven who have met the diagnostic criteria for HLH. Description of their clinical characteristics, treatment and outcome constitutes this report. *Materials and methods*. Eight patients, age between 15 and 41 years, 5 of them male and 3 female are included. They have been evaluated for HLH symptoms using the Histiocyte Society Criteria excluding sCD25 and cytotoxicity assays for NK cells that were not available. All of them meet at least 5 out of 6 remaining criteria. *Results*. All patients presented with fever, splenomegaly, hyperferritinemia (8514-76315 ng/mL), hypertriglyceridemia, all except one had also hypofibrinogenemia. All had cytopenias of normal cells, including 3 who had very severe pancytopenia. In all hemophagocytosis could be demonstrated, 3 in the bone marrow aspirate, 3 in trephine biopsy, and in one only in a lymph node biopsy. Other abnormalities included hepatomegaly in all patients, skin changes (3 patients panniculitis, 4 patients maculopapular rash, 1 patient without skin involvement), in 7 patients fluid in either peritoneum, pleura or pericardium, coagulopathy with very high D-dimer level (16600-58700 ng/mL), and 3 patients with both a very prolonged prothrombin and APTT time, highly elevated CRP, LDH, β2-microglobulin (serum), moderately elevated transaminases, and decreased albumin level. One had concomitant blastic phase of chronic myelocytic leukemia as initial presentation associated with pruritus. One patient had a history of moderate lupus erythematodes, and one had clearly EBV-associated HLH (2910 EBV DNA copies in the peripheral blood). In the remaining patients there was no obvious trigger for the syndrome, but all had elevated levels of some anti-EBV antibodies (VCA, EA, EBNA) without clear and uniform pattern. EBV PCR was positive only in 1 of remaining 4 tested patients. In the patient with lupus erythematodes, EBV was detected in the excised lymph node by EBV-LPM staining. Three patients, transferred to our hospital in grave condition, died without specific treatment within few days of admission and were diagnosed postmortem. Five patients started treatment according to the HLH-2004 protocol (etoposide, cyclosporine A, corticosteroids) and one died day 18 of Enterococcus sepsis with ferritin level already decreased 10-fold. Of the remaining four, three achieved complete remission that has been maintained between 10 and 18 months, and one is in partial remission maintained on cyclosporine A. *Conclusions*. Treatment with etoposide, cyclosporine A and corticosteroid s has allowed for control of the syndrome for all four patients who survived long enough to achieve remission. Identification of eight cases in relatively short time in a single department may suggest that this syndrome may occur more frequently in adults than usually anticipated.

0598

TAFI (THROMBIN ACTIVATABLE FIBRINOLYSIS INHIBITOR) AS A MARKER OF HEMOSTATIC ALTERATION IN PATIENTS WITH β-THALASSEMIA

R.M. Matter, G.M. Mokhtar, M.M. Abdel Aziz, H.S. Mortagi

Ain Shams University, CAIRO, Egypt

Background. Profound hemostatic changes have been observed among thalassemic patients. Thrombin activatable fibrinolysis inhibitor (TAFI) is newly discovered protein which potentially attenuate fibrinolysis. *Aims*. We aimed to investigate plasma level of TAFI in splenectomized and non-splenectomized β-thalassemia patients and to correlate its level with clinical severity and hemostatic alteration. *Methods*. 51 patients (mean age 10.79±5.59 years)(21 splenectomized thalasemia major patients, 18 non splenctomized thalassemia major patients, 12 non-splenectomized thalassemia intermedia) were recruited from Pediatric Hematology Clinic, Ain Shams University, Cairo, in addition to 32 healthy age and sex matched controls(mean age 10.31±5.58 years)were included. In addition to clinical assessment, laboratory investigations included complete blood count, prothrombin time, activated partial thromboplastin time, liver function tests, viral hepatitis markers, serum ferritin and plasma TAFI levels. *Results*. Our study shows significant increase in prothrombin time and activated partial thromboplastin time in thalassemic patients compared to controls. Significant reduction in TAFI levels was shown in thalassemic patients compared to controls ($p<0.0001$), in splenectomized compared to nonsplenectomized thalassemia group ($p<0.0001$) and in thalassemia major compared to intermedia group ($p<0.0001$). Negative correlation was present between TAFI levels and liver enzymes and serum ferritin levels ($p<0.05$).Thalassemic patients suffering from bleeding showed lowest mean TAFI levels. *Conclusions*. Marked alteration in TAFI levels was observed in thalassemic patients with splenectomy, altered liver functions and poor chelation who therefore might be at a higher risk for altered hemostasis.

NAMPT IS ESSENTIAL FOR THE G-CSF-INDUCED MYELOID DIFFERENTIATION

D. Lan

Hannover Medical School, HANNOVER, Germany

Nicotinamide phosphoribosyltransferase (NAMPT) is the rate-limiting protein in NAD+ biosynthesis by converting nicotinamide to nicotinamide mononucleotide, which is further converted into nicotinamide adenine dinucleotide (NAD+). NAMPT also known as pre-B cell colony enhancing factor (PBEF), was originally identified as a gene product expressed in activated peripheral human lymphocytes and was found to be implicated in the maturation of B cell precursors. We identified that NAMPT is an essential enzyme, which mediate granulocyte colony-stimulating factor (G-CSF)-triggered granulopoiesis in healthy individuals and in individuals with severe congenital neutropenia (CN) (Skokowa *et al.*, Nature Medicine, 2009). CN is a hematopoietic disorder characterized by a *maturation arrest* of granulopoiesis in bone marrow at the promyelocyte stage, by absence of neutrophilic granulocytes in peripheral blood and by severe bacterial infections. G-CSF treatment increases blood neutrophil numbers in more than 90% of individuals with CN. A definitive mechanism for this G-CSF-induced differentiation remains unknown. We found that intracellular NAMPT and NAD+ amounts in myeloid cells, as well as plasma NAMPT and NAD+ levels, were increased by G-CSF treatment of both healthy volunteers and CN patients. Additionally, exogenously added NAMPT or lentivirally transduced NAMPT complementary DNA induced myeloid differentiation in progenitor cells with concomitant increased expression of NAD+. The activity of NAMPT was dependent on signaling through G-CSF receptor (G-CSFR), and inhibition of NAMPT with the specific inhibitor FK866 substantially abrogated G-CSF-induced myeloid differentiation. We postulate that NAMPT induces a G-CSF autoregulatory loop via the following sequential mechanism. First, G-CSF promotes increased extra- and intracellular NAMPT expression. Second, high levels of NAMPT lead to increased NAD+ production and activation of the granulocyte specific transcription factors C/EBPα and C/EBPβ. Last, these transcription factors bind the promoters of the genes encoding G-CSF and G-CSFR and activate their expression, leading to a positive feedback regulation of G-CSF as well as NAMPT synthesis and activity. Further we administered oral vitamin B3 (nicotinamide), a substrate of NAMPT, to six healthy individuals (10-20 mg per kg per day) for 1 week. In all subjects who received vitamin B3, we found a significant increase in neutrophil count over a seven-day period, with a decline to physiologic levels after vitamin B3 discontinuation. Vitamin B3 treatment was associated with increased amounts of NAD+ and elevated C/EBPα and C/EBPβ RNA levels in bone marrow progenitors. Based on our data, we conclude that NAMPT and its product NAD+ are essential factors in neutrophil granulopoiesis. Moreover, our findings present new perspectives in clinical and experimental medicine, supporting the therapeutic application of vitamin B3 for the treatment of clinical syndromes associated with chronic or acute neutropenia.

REGULATION OF GRANULOPOIESIS BY NAMPT/NAD+/SIRT1 DEPENDENT ACTIVATION OF C/EBP, IN PATIENTS SUFFERING FROM SEVERE CONGENITAL NEUTROPENIA

B.K. Thakur, D. Lan, K. Gupta, Y. Lippka, J. Skokowa, K. Welte

Hannover Medical School, HANNOVER, Germany

Granulopoiesis is a tightly regulated process and C/EBP transcription factors plays important role in the regulation of granulopoiesis *in vitro* and *in vivo*. C/EBPα is considered to be the master regulator of *steady state* granulopoiesis via upregulation of several myeloid genes (e.g. ELA2, CSFR3, etc.). Recently, C/EBPβ has been shown to be essential for cytokine induced emergency granulopoiesis *in vivo* in absence of C/EBPα (Hirai H *et al.*, Nature Immunology, 2006). We were able to show that in patients with congenital neutropenia (CN) harbouring HAX-1 or ELA2 mutations C/EBPα is severely abrogated secondary to defective expression of LEF-1 transcription factor (Skokowa J *et al.*, Nature Medicine, 2006). Therefore, we were interested, whether other transcription factors are capable of substituting C/EBPα, since these patients respond to G-CSF with slight increase in neutrophils from less than 200/uL to above 1500/uL depending on the dose of G-CSF. Indeed we found that C/EBPβ mRNA was upregulated 2.8-fold in $CD33^+$ myeloid cells from CN patients by G-CSF treatment, as compared to healthy individuals. It was associated with upregulation of G-CSFR mRNA and protein expression as well as ligand binding to G-CSFR in myeloid cells, and elevated levels of biologically active G-CSF in serum from CN patients. Recently we found that levels of NAMPT, a protein involved in biosynthesis of NAD+, were significantly higher in myeloid cells and in plasma of CN patients treated with G-CSF, as compared to healthy individuals (Skokowa *et al.*, Nature Medicine, 2009). We also measured elevated levels of NAD+ in myeloid cells and plasma of CN patients, that correlated with induction of SIRT1. SIRT1 is an enzyme involved in deacetylation of several histone and non- histone proteins by utilising NAD+. We asked if induced SIRT1 can positively regulate C/EBPβ to induce granulopoesis in CN patients having abrogated levels of C/EBPα. Indeed, we observed that ectopically expressed SIRT1 protein interacts with both C/EBPα and C/EBPβ proteins. Moreover, endogenous SIRT1 interacts with endogenous C/EBPβ in HL-60 cells. We clearly demonstrated the activation of the promoters of the genes encoding G-CSF and G-CSFR containing C/EBP binding sites in presence of NAD+ or after transfection with SIRT1. In presence of specific siRNA against SIRT1, neither NAMPT nor NAD+ significantly activated these gene promoters. Further we demonstrated that the promoters of the genes encoding G-CSF and G-CSFR harbouring mutations in C/EBP binding sites also do not get significantly activated in presence of NAMPT or NAD+. These results suggest that G-CSF induced NAMPT regulates G-CSF and G-CSFR expression through SIRT1- dependent activation of C/EBPα and C/EBPβ in a NAD+ dependent manner. Based on this we conclude that since in CN patients C/EBPα is not available for binding to SIRT1 and the steady-state granulopoiesis is abrogated, SIRT1 dependent activation of C/EBPβ mediates emergency granulopoiesis leading to sufficient numbers of neutrophils in these patients.

IS THE RISK OF DEVELOPING AML OR MDS INCREASED IN X-LINKED NEUTROPENIA

K. Beel,[1] K. Beel,[2] M. Cotter,[3] J. Blatny,[3] C. Chatelain,[3] A. Uyttebroeck,[4] B. De Moerloose,[5] N. Van Roy,[6] G. Verhoef,[7] H. Demuynck,[8] P. Vandenberghe[2]

[1]KU/UZ Leuven, LEUVEN, Belgium; [2]Centre for Human genetics, University Hospital Leuven, LEUVEN, Belgium; [3]Department of Haematology/Oncology, Our Lady's Children's Hospital, Crumlin, DUBLIN, Ireland; [4]Department of Paediatric Haematology, University Hospital Leuven, LEUVEN, Belgium; [5]Department of Paediatric Haematology, University Ghent, GHENT, Belgium; [6]Centre for Medical Genetics, University Ghent, GHENT, Belgium; [7]Department of Haematology, University Hospital Leuven, LEUVEN, Belgium; [8]Department of Haematology, H.Hart Hospital, ROESELARE, Belgium

Background. In 2001, we described X-linked neutropenia (XLN) as a novel subtype of severe chronic neutropenia (SCN) with an L270P gain-of-function mutation in the Wiskott-Aldrich Syndrome protein (WASP). Since then, two other cases have been described. *Aims*. to discover new XLN cases and to investigate the association of XLN with myeloid leukemia. *Methods*. PCR and dHPLC were used for WAS mutation screening. Exon 17 of CSF3R was sequenced to detect truncating CSF3R mutations in leukaemic samples of XLN patients. *Results*. We discovered 3 more XLN families. The first family is a large kindred with an activating I294T WASP mutation, in which we described additional features of the phenotype: a variable degree of neutropenia, not correlating with the severity of infections, low-normal IgA levels and low NK cells. The second new XLN family had an L270P mutation, and is probably related to our originally described XLN family. The third case was discovered with an L270P mutation when screening 16 Irish ELA2 negative XLN patients. The risk of transformation to MDS/AML in XLN remains unclear. One of two cases reported by Ancliff *et al*. reportedly presented as MDS and two out of five L270P male cases of the original family developed MDS/AML, with (-7), after a prolonged disease course and under G-CSF. Acquired truncating CSF3R mutations were found in leukaemic samples. We screened exons 7-10, encoding the GTP-ase binding domain (GBD) of WASP in 253 patients with MDS (23%) or AML (77%), including 25% with (-7). No relevant mutations were observed in the GBD of WAS in 253 paediatric and adult MDS/AML cases. *Conclusions*. two cases of MDS/AML have been observed in the L270P XLN family, but no malignancies were documented in a large kindred with I294T XLN. The cases in the L270P XLN might be related to more liberal use of G-CSF. This is further supported by the presence of CSF3R mutations in the leukaemic phase. Our findings indicate that the risk of

progression to leukaemia might be increased in XLN, like in other SCN syndromes, most likely via a final common pathway involving CSF3R and (-7). In contrast, we found no cases initially presenting as MDS or AML.

STUDY OF THE QUANTITATIVE AND FUNCTIONAL CHARACTERISTICS OF T REGULATORY CELLS IN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

A. Antoniou, P. Verginis, M. Kavousanaki, H. Koutala, S. Mastrodimou, I. Mavroudi, K. Pyrovolaki, M. Psyllaki, C. Kalpadakis, H.A. Papadaki

University of Crete School of Medicine, HERAKLION, Greece

Background. Functional and/or quantitative changes of T-regulatory (T-reg) cells have been implicated in the pathophysiology of autoimmune diseases. CIN is a disorder of granulopoiesis characterized by increased apoptosis of bone marrow (BM) granulocytic progenitor cells due to the presence of activated T-lymphocytes. The role of T-regs in CIN has not been studied. *Aims*. To investigate the frequency and function of T-regs in CIN patients and probe the underlying mechanisms implicated in their abnormalities, if any. *Methods*. We studied 50 patients fulfilling the previously defined diagnostic criteria for CIN and 20 age- and sex-matched healthy controls after informed consent. We evaluated the proportion of FOXP3$^+$ cells within the CD4$^+$/CD25^{high} (T-reg) cell fraction in the peripheral blood (PB) and BM using flow-cytometry and we also assessed the FOXP3 mRNA levels of immunomagnetically sorted patient and normal CD4$^+$/CD25$^+$ T-cells by means of real-time PCR. For the evaluation of T-reg cell function, we performed suppression assays using anti-CD3 activated normal CD4$^+$/CD25$^-$ effector cells labeled with the fluorescence dye CFSE, in the presence of patient or normal CD4$^+$/CD25$^+$ T-cells. Fluorescence intensity was measured by flow-cytometry. Because the pro-inflammatory Th17 cells display opposite functions with T-regs and interleukin(IL)-17 levels reflect Th17 numbers, we evaluated cytokine levels in serum and long-term BM culture (LTBMC) supernates of patients and controls using an enzyme-linked immunosorbent assay (ELISA). *Results*. In keeping with our previously reported data, CIN patients displayed statistically significant lower number of total lymphocytes (1632±493) and CD4$^+$ T-cells (765±281) compared to healthy controls (2575±559 and 1096±308 respectively) (p<0.001 and p<0.001, respectively). The percentage of FOXP3$^+$ cells within the CD4+/CD25high T-cell fraction was significantly lower in CIN patients (57.77±15.77%) compared to controls (72.95%±12.23%, p<0.01). In accordance with flow-cytometry data were the real-time PCR results; the FOXP3 mRNA levels of patient CD4$^+$/CD25$^+$ cells were significantly lower compared to healthy subjects (p=0.0293). The parallel measurement of T-reg proportion in PB and BM of CIN patients showed a statistically significant increased percentage of FOX3$^+$ cells within the CD4$^+$/CD25high T-cells of BM (68.51±11.88%) compared to PB (52.20±12.77%, p=0.0005) suggesting a possible accumulation of T-regs in the BM. Patient CD4/CD25$^+$ T-regs sufficiently suppressed CFSE-labeled CD4$^+$/CD25$^-$ effector T-cells as was demonstrated by the CFSE fluorescence in day-3 and day-5 of co-culture. Serum IL-17 levels did not differ significantly between CIN patients (5.41±7.98 ng/mL) and healthy controls (5.99±9.40 ng/mL, p=0.8788). IL-17 levels, however, in LTBMC supernatants were significantly increased in patients (4.09±6.20 ng/mL) compared to controls (0.69±1.82 ng/mL, p=0.0268). *Summary and Conclusions*. CIN patients display decreased number of T-regs in the PB as was demonstrated by the low expression of FOXP3 within the CD4$^+$/CD25$^+$ cell fraction. Compared to healthy subjects, CIN patients display increased levels of IL-17 in the BM indicating increased number of Th17 cells. The increased number of T-regs in patients' BM compared to PB indicates probably an accumulation of these cells in the BM in an attempt to suppress the local immune reactions mediated by activated T- cells and pro-inflammatory Th17 cells.

0603

ABNORMALITIES OF SERUM IMMUNOGLOBULIN LEVELS IN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA: RESULTS FROM A COHORT OF 295 PATIENTS

I. Mavroudi, V. Papadaki, K. Pyrovolaki, M. Velegraki, M. Spanoudakis, M. Kaparou, P. Kanellou, G. Gvazava, G.D. Eliopoulos, H.A. Papadaki

University of Crete School of Medicine, HERAKLION, Greece

Background. Activated oligoclonal T-lymphocytes with immunosuppressive properties have been implicated in the pathophysiology of chronic idiopathic neutropenia (CIN) through overproduction of pro-inflammatory cytokines and pro-apoptotic mediators that induce the apoptotic death of the granulocytic progenitor cells. *Aims*. Because immunoglubulin production by B-cells is under the surveillance of the T-cell system either through interactions of CD40/CD40-Ligand (CD40L) or through the production of a variety of cytokines that may affect the immunoglobulin class/subclass switching, we sought to evaluate the immunoglobulin levels in CIN patients and probe the mechanisms associated with the underlying abnormalities, if any. *Methods*. We studied 295 patients fulfilling the previously defined diagnostic criteria for CIN and 82 healthy subjects after informed consent. Patients neutophil counts were lower than 1800/μL (mean 1484±314, range 288-1799). We evaluated (a) the levels of serum IgM, IgA, IgG1, IgG2, IgG3, IgG4 by means of nephelometry, (b) the expression of CD40 on CD19$^+$ cells by quantifying both the proportion of CD19$^+$/CD40$^+$ cells and the mean fluorescence intensity by flow-cytometry, (c) the induction of surface CD40L on T-cells by flow-cytometry following incubation of cells with PMA (10ng/mL) and Ionomycin (500ng/mL), (d) serum levels of transforming growth factor (TGF)-β1 by means of an enzyme-linked immunosorbent assay (ELISA). *Results*. Patients with CIN displayed statistically significant increased serum levels of IgM (160.4±90.7 mg/dL) compared to healthy subjects (103.4±30.9 mg/dL; p<0.001). In contrast, serum levels of IgG3 and IgG4 were significantly decreased in the patients (40±19 mg/dL and 46.4±22.8 mg/dL, respectively) compared to controls (55±21 mg/dL and 75.1±31.2 mg/dL, respectively; p<0.001 and p<0.001 respectively). Serum IgG1, IgG2, and IgA levels did not differ significantly between CIN patients and controls. Interestingly, an inverse correlation was observed between the levels of IgM and the number of neutrophils (r=-0.2363, p<0.001) and the levels of IgG3 (r=-0.3968, p<0.001) and IgG4 (r=-0.3546 p<0.001). CD40 antigen was normally expressed on patient B-cells. This was demonstrated by both the proportion of CD40$^+$ cells within the CD19$^+$ cell fraction (93.37±11.49 in patients versus 94.06±3.81 in controls; p=0.2447) and the mean fluorescence intensity of CD40 expression (9.60±3.06 in patients versus 9.49±3.11 in controls; p=0.7004). CD40L induction on patient T-cells following activation (42.46±40.07%) did not differ significantly from the controls (46.09±38.81%; p=0.558). The above data suggest that the CD40/CD40L system seems unlikely to have a pathogenetic role in the abnormal immunoglobulin levels of CIN patients. Because a number of cytokines, including TGF-,1, have been implicated in the immunoglobulin class/subclass switching we evaluated serum cytokine levels in the patients. TGF-β1 levels were significantly higher in CIN patients (56.68±31.18 ng/mL) compared to controls (19.21±10.69 ng/mL; respectively; p<0.001) and correlated positively with serum IgM (r=0.3610, p<0.001) and inversely with serum IgG3 (r=-0.2544, p=0.008) and IgG4 (r=-0.3664, p<0.001) levels. *Summary and Conclusions.* CIN patients display increased serum IgM and decreased IgG3 and IgG4 levels compared to healthy subjects. These abnormalities have a major clinical significance because they correlate with the severity of neutropenia. Increased serum TGF-β1 levels may have a pathogenetic role for these abnormalities, at least in part.

0604

NOVEL G6PC3 MUTATIONS IDENTIFIED IN AUTOSOMAL RECESSIVE SCN PATIENTS WITH AND WITHOUT CONGENITAL ABNORMALITIES

N. Smith,[1] B. Hayee,[2] C. Evans,[1] P. Ancliff,[3] G. Hall,[4] A. Segal,[2] D. Linch,[1] R. Gale[5]

[1]UCL Cancer Institute, University College London, LONDON; [2]Department of Medicine, University College London, LONDON; [3]Great Ormond Street Hospital, LONDON; [4]Oxford Children's Hospital, OXFORD; [5]Cancer Institute, University College London, LONDON, UK

Over the past decade there has been considerable progress in elucidating the underlying genetic defects thought to be causative of severe con-

genital neutropenia (SCN). Patients with autosomal dominant (AD) or sporadic disease predominantly have mutations in the ELA2 gene encoding neutrophil elastase, and rare AD cases are attributed to mutations in the transcriptional repressor Gfi1. A few cases of X-linked SCN have mutations in the Wiskott-Aldrich syndrome gene. In autosomal recessive (AR) disease, homozygous mutations in the HAX1 gene have been identified in patients of Middle-Eastern and Jewish origin, as well as the original Kostmann family and two British cases with unrelated parents. More recently, a homozygous missense mutation was identified in the G6PC3 gene encoding glucose-6-phosphatase, catalytic subunit 3 of two consanguineous SCN families of Aramean ethnicity (Boztug *et al.*, NEJM, 360:32-43, 2009). Subsequently, the same group found other biallelic missense and nonsense mutations in unrelated SCN patients. Of note, the G6PC3 mutations were associated not only with neutropenia but also other distinct features such as structural heart defects and urogenital abnormalities. We used denaturing HPLC analysis to determine the frequency of G6PC3 mutations in our cohort of SCN patients, who were negative for ELA2, HAX1 and WAS mutations. All six G6PC3 exons and splice junctions were screened in samples from 36 patients with known or probable AR inheritance using mixtures of patient and control PCR products to detect homozygous mutations. The hotspots in exons 1 and 6 were screened in a further 60 patients with sporadic inheritance. Novel exon 1 mutations were detected in two AR kindreds. Two affected sibs from a consanguineous family of Pakistani origin had a homozygous 21bp deletion (c.190_210del) resulting in an in-frame deletion of seven amino acids (p.Thr64_Ile70del). The parents were heterozygous for the mutation and clinically normal. The index case possessed a complex phenotype characterized by severe neutropenia, an atrial septal defect, splenomegaly, digital clubbing, short stature, growth retardation, granulomatous inflammatory bowel disease and an abnormally low respiratory burst. He has also had intermittent presentations with perianal abcesses, recurrent oral ulceration and bacterial pneumonia in which he responded to standard bacterial therapy and intermittent G-CSF. These features are consistent with those reported for G6PC3-mutated patients. Another male patient of unrelated Pakistani parents had an atypical SCN picture. He presented at 13yrs of age with intermittent mouth ulcers and a neutrophil count of 0.4×10^6cells/mL, was negative for auto-antibodies, and has remained well over the past 5 years with no bacterial infections and no complicated symptoms, receiving only intermittent G-CSF on recurrence of ulcers. He harboured a homozygous missense variant (c.130C>T) resulting in an amino acid change in exon 1 (p.P44S). His mutation may reflect a rare polymorphism but it does cluster with two published exon 1 mutations in more severely affected patients. No mutations have been identified, to date, in sporadic patients. Our results indicate that biallelic G6PC3 mutations are relatively uncommon in our cohort (6% of presumed AR patients) and may be associated with an SCN phenotype without additional congenital abnormalities.

DIFERENTIAL STIMULATION OF MONOCYTIC CELLS RESULTS IN DISTINCT POPULATIONS OF MICROPARTICLES

M.P. Bernimoulin,[1] E.K. Waters,[2] M. Foy,[3] B.M. Steele,[3] M. Sullivan,[3] H. Falet,[4] M.T. Walsh,[2] N. Barteneva,[2] J.-G. Geng,[5] J.H. Hartwig,[4] P.B. Maguire,[3] D.D. Wagner[2]

[1]Hopital Necker, PARIS, France; [2]Immune Disease Institute, BOSTON, USA; [3]UCD Conway Institute, DUBLIN, Ireland; [4]Brigham and Women's Hospital, BOSTON, USA; [5]Vascular Biology Center, MINNEAPOLIS, USA

Background. Microparticles (MPs) are small vesicles (0.05-1.00 um), shed from the plasma membrane of cells in response to stress, which permit cross talk between cells within a particular environment. Their composition is thought to reflect their cell of origin and differs when MPs are produced by stimulation versus apoptosis. Whether or not MP properties vary according to the stimulus is not currently known. Monocyte-derived MPs are hereby of particular interest, as they are known to promote inflammation and to be highly procoagulant. *Aims*. The present study addresses the hypothesis that different activating stimuli produce MPs that vary in composition and biological function, even when they originate from the same parent cell. *Methods*. We studied the characteristics of MPs, produced from monocytic THP-1 cells upon stimulation with: two pathophysiologic stimuli: (1) lipopolysaccharide and (2) soluble P-selectin chimera (P-sel-Ig) and with: their controls: (3) PBS (to study spontaneously generated MPs) and (4) IgG control, using proteomics, flow cytometry, western blotting, and electron microscopy. *Results*. Utilizing a novel criterion of calcein-AM staining to define MPs, we compared the properties of the four MP populations. We found that MP populations were similar with respect to size, presence and organization of cytoskeleton, expression of certain antigens such as adhesion molecules: as $\beta2$ and αL integrins or presence of tetraspanins: as CD81 and to procoagulant activity. We found that MPs also have distinct characteristics depending on stimuli. These include: (1) differences in outer plasma membrane lipid bilayer composition as assessed by phosphatidylserine (PS) expression, with less PS-positive MPs produced upon P-sel-Ig stimulation, (2) expression of proteins from specific subcellular locations such as the mitochondria, which was much increased in MPs generated through LPS and (3) of presence of unique antigens such as leukocyte-associated immunoglobin-like-receptor (LAIR)-1 which was found only upon stimulation with the soluble P-selectin chimera. *Conclusions*. We found that the properties of MPs depend on the stimulus that produced them. This supports the concept that monocytic MPs differentially modulate thrombosis, inflammation and immune regulation according to stimulus.

LEUKOPENIA AND WAS GENE MUTATION IN AN INFANT. A CASE REPORT

A. Catala,[1] S. Rives,[1] T. Toll,[1] M. Camos,[1] R. Berrueco,[1] N. Conde,[1] A. Quintero,[1] J.I. Arostegui,[2] J. Estella[1]

[1]Hospital Sant Joan de Deu, BARCELONA; [2]Hospital Clinic, BARCELONA, Spain

Background. Wiskott-Aldrich syndrome is a primary immunodeficiency with a characteristic clinical picture of thrombocytopenia with small platelets, eczema and recurrent infections. X linked neutropenia (XLN) is a rare syndrome of severe congenital neutropenia described in 2001 and with very few cases reported in the literature. The Wiskott-Aldrich syndrome protein (WASP), encoded by the WAS gene, is an important regulator of the actin cytoskeleton polymerization. Mutations in WAS gene causing a reduced WASP activity are responsible for the Wiskott-Aldrich syndrome (WAS) and X linked thrombocytopenia. XLN is caused by gain-of-function type mutations of the WAS gene resulting in a loss of autoinhibition of WASP. *Aims*. To present a peculiar case with severe leukopenia and a novel WAS gene mutation. *Case*. A 6 month old boy was referred to our institution to study severe leukopenia (1.6 leucocytes $\times10^9$/L: 0.3 neutrophils $\times10^9$/L, 0.5 lymphocytes $\times10^9$/L, 0.1 monocytes $\times10^9$/L) demonstrated in a blood count at 5 month old during a febrile episode. Except for a mild eczema his physical examination was normal with no growth impairment. The bone marrow aspirate showed a normal maturation of the myeloid compartment, no dysplasia signs neither other abnormal features. Cytogenetic analyses were consistently normal. Metabolic disorders, viral infections and autoimmune neutropenia were ruled out. ELA 2 and HAX1 gene mutations were negative but interestingly we found a novel mutation in exon 7 of WAS gene (p.R211Q). Immunologic analysis revealed low natural Killer cells (4%), normal CD4/CD8 ratio, normal phytohemaglutinin response test and normal response to vaccination (rubella and measles). He has presented 4 mild infections during all the follow up time. Platelet counts have always been in the normal range and size. He is now 2 years old and maintains normal white blood counts during the last six months. Familiar genetic analysis revealed that his mother is a sane carrier of WAS mutation. She has normal blood cell counts. *Discussion*. A novel mutation in WAS gene is described. This mutation region has been described as a mutational hot spot for Wiscott-Aldrich syndrome with high scores disease. However our patient has a normal phenotype with normal platelet number and size. Surprisingly the patient has recovered completely from his leukopenia. More studies must be done to determinate how WASP is affected in this individual. Meanwhile a diagnosis of mild WAS vs XLN has been done.

0607

GLUCOCORTICOIDS REVERT THE DASATINIB-MEDIATED ENHANCEMENT OF HISTAMINE RELEASE IN IGE-R CROSS-LINKED BASOPHILS

H. Herrmann, K. Blatt, M. Klauser, M. Kneidinger, K. Marth, R. Valenta, P. Valent

Medical University of Vienna, VIENNA, Austria

Background. Dasatinib is a novel multi-kinase targeting drug that blocks several tyrosine kinases including BCR/ABL. Apart from its well-known anti-leukemic activity, the drug produces several side effects including edema formation and pleural effusion. We have recently

shown that low doses of dasatinib (<0.1 μM) promote IgE-dependent secretion of histamine in human blood basophils, especially in allergic individuals, whereas at 1 μM, dasatinib potently blocks IgE-mediated histamine secretion. *Aims*. In the present study, we examined the effects of 3 different glucocorticosteroids (dexamethasone, prednisolone, and hydrocortisone) on histamine release provoked by IgE receptor cross-linking in blood basophils in the absence or presence of low dose dasatinib. *Methods*. Normal blood basophils (n=5) or basophils derived from allergic donors sensitized against Bet v 1 and/or Phl p 5 (n=5) were preincubated with glucocorticosteroids for 24 hours and then exposed to an anti-IgE antibody (0.001-10 μg/mL) or allergen (Bet v 1 or Phl p 5; dose range: 0.0001-1 μg/mL) with or without low dose dasatinib (0.025 μM). After incubation, basophils were examined for histamine release and/or expression of CD63 and CD203c by multicolor flow cytometry. *Results*. All three glucocorticosteroids were found to counteract histamine release provoked by anti-IgE or allergen in the presence or absence of low dose dasatinib in non-allergic or allergic individuals. Even in patients with maximum histamine release, glucocorticoids were found to counteract the dasatinib-induced enhancement of IgE-dependent histamine release in basophils. The inhibitory effects of glucocorticosteroids on basophil histamine release were dose-dependent. In addition, all three glucocorticoids were found to decrease anti-IgE-induced upregulation of CD63 and CD203c in the presence or absence of low dose dasatinib. *Summary*. The addition of glucocorticosteroids may be an effective therapeutic maneuver to counteract the co-inflammatory effects of low dose dasatinib in IgE-receptor cross-linked basophils.

0608

CLINICAL CHARACTERISTICS AND TREATMENT OUTCOME OF LANGERHANS CELL HISTIOCYTOSIS: LARGE STUDY OF SINGLE INSTITUTE

H.J. Kang, J.W. Lee, H. Kim, H.Y. Shin, H.S. Ahn

Seoul National University College of Medicine, SEOUL, South-Korea

Background. Langerhans cell histiocytosis (LCH) is a disease with unknown etiology which is characterized by abnormal proliferation and accumulation of antigen presenting dendritic cells in various tissues. Large studies of a single institute were rare because of the rarity of the disease and the diversity of clinical manifestations. *Aims*. In this study, we analyzed the clinical manifestations and prognostic factors of LCH and evaluated the outcome. *Methods*. We retrospectively analyzed the medical records of patients who were diagnosed as LCH in our institute for 22 years from January, 1986 to December, 2007. *Results*. A total of 167 patients were evaluated. There were 99 (59.3%) male and 68 (40.7%) female patients. The median age at diagnosis was 2.7 years (range 0-13.6 years). Sites of involvement at the time of diagnosis are bone in 152 (91.0%), skin in 33 (19.8%), lymph nodes in 26 (15.6%), liver in 24 (14.4%), bone marrow in 20 (12.0%), soft tissue in 18 (10.8%), spleen in 17 (10.2%), pituitary gland in 11 (6.6%) and lung in 7 (4.2%) patients. In 58 (34.7%) patients, more than two organs were involved. Risk organ (bone marrow, liver, spleen and lung) involvements were observed in 31 (18.6%) patients. Patients with single bone lesion received indomethacin for 6-12 months. Other patients received induction regimen (vinblastine, prednisolone, cyclophosphamide and methotrexate) for 12 weeks, and then maintenance therapy (6-mercaptopurine, methotrexate and cyclophasphamide). Thirty patients (18.0%) had relapse or disease progression during treatment. Overall survival and event free survival were 96.5% and 76.2% with median follow-up time of 6.3 years. Event-free survivals were significantly lower in patients younger than 3 years of age, patients with risk organ involvement, and patients with multiple organ involvement (p=0.003, 0.000, 0.000). Endocrine sequelae were observed in 13 patients, and diabetes insipidus was most common. *Conclusions*. LCH showed high survival rate despite of the frequent relapses. Age, numbers of involved organ, and involvement of risk organ were evaluated to be prognostic factors.

NK-LIKE HOMEODOMAIN PROTEINS ACTIVATE NOTCH3-SIGNALING IN LEUKEMIC T-CELLS

S. Nagel,[1] L. Venturini,[2] G.K. Przybylski,[3] P. Grabarczyk,[4] C. Meyer,[1] M. Kaufmann,[1] K. Battmer,[2] C.A. Schmidt,[4] H.G. Drexler,[1] M. Scherr,[2] R.A.F. MacLeod[1]

[1]DSMZ, BRAUNSCHWEIG, Germany; [2]Medical School Hannover, HANNOVER, Germany; [3]Polish Academy of Sciences, POZNAN, Poland; [4]University of Greifswald, GREIFSWALD, Germany

Background. Three NK-like homeobox genes (NKLs), TLX1/HOX11, TLX3/HOX11L2 and NKX2-5/CSX, are ectopically activated via chromosomal aberrations in subsets of T-cell acute lymphoblastic leukemia (T-ALL). Their close relation suggests shared activities which are involved in leukemogenesis, however, remaining largely unknown. *Aims*. Here we screened additional NKLs in 24 T-ALL cell lines by RT-PCR and identified common expression of MSX2. Analysis of this homeobox gene may contribute to the understanding of the function of its oncogenic relatives. *Results*. Quantification of MSX2 mRNA in primary hematopoietic cells demonstrated higher levels in $CD34^+$ stem cells as compared to peripheral blood cells and mature $CD3^+$ T-cells, suggesting downregulation during T-cell development. Subsequent analysis of MSX2 expression levels in T-ALL cell lines after treatment with core thymic factors confirmed their involvement in regulation. These results indicated that MSX2 represents a physiological NKL family member in T-cells. For functional analysis T-cell-derived JURKAT cells were lentivirally transduced, overexpressing either MSX2 or oncogenic TLX1 and NKX2-5, respectively. These cells displayed transcriptional activation of NOTCH3-signaling, including NOTCH3 and HEY1 as analyzed by gene expression profiling and quantitative RT-PCR, and consistently decreased sensitivity for gamma-secretase inhibitor as analyzed by MTT-assays. Furthermore, in addition to MSX2, both TLX1 and NKX2-5 proteins interacted with NOTCH-pathway repressors, SPEN/MINT/SHARP and TLE1/GRG1, representing a potential mechanism of (de)regulation. In T-ALL cell lines containing the t(5;14)(q35;q32) which activates expression of TLX3 or NKX2-5, respectively, we detected chromosomal deletion of MSX2 (at 5q35), resulting in functional exchange between MSX2 and oncogenic NKLs. Finally, corresponding to the cell line data, elevated expression of NOTCH3 and HEY1 was detected in primary TLX1/3 positive T-ALL cells. *Conclusions*. Identification and functional analysis of MSX2 in hematopoietic cells implicated a modulating role via NOTCH3-signaling in T-cell differentiation and in leukemogenesis if supplemented by oncogenic NKLs.

PROGNOSTIC SUBGROUPS DEFINED IN A NOD/SCID/HUALL XENOGRAFT MODEL FOR PAEDIATRIC B CELL PRECURSOR ALL ARE CHARACTERISED BY A GENE SIGNATURE INVOLVING SURVIVAL PATHWAYS AND IDENTIFY POTENTIAL NEW THERAPEUTIC TARGETS

H. Meyer,[1] S.M. Eckhoff,[1] M. Queudeville,[1] A. Zangrando,[2] E. Vendramini,[2] A. Moericke,[3] M. Zimmermann,[4] A. Schrauder,[3] G. Lahr,[1] K. Holzmann,[1] M. Schrappe,[3] G. Basso,[2] K. Stahnke,[1] G. te Kronnie,[2] K.-M. Debatin[1]

[1]University of Ulm, ULM, Germany; [2]University of Padova, PADOVA, Italy; [3]University Hospital Schleswig Holstein, KIEL, Germany; [4]Medical School Hannover, HANNOVER, Germany

Despite increasingly successful treatment of children with acute lymphoblastic leukaemia (ALL), the poor outcome of particularly early relapsed patients remains a challenge to identify factors which reflect characteristics of leukaemia biology and provide therapeutic targets. In a recent study we transplanted primary paediatric B cell precursor (BCP) ALL samples (N=50) into NOD/SCID mice and demonstrated a clearly inferior survival for patients whose cells led to manifestation of leukaemia in the recipients within 10 weeks (TTLshort) in contrast to patient samples with prolonged *in vivo* growth (TTLlong). Short TTL was strongly associated with high risk for early relapse providing a new independent prognostic factor for outcome in paediatric BCP- ALL. In this study we further characterised the biological properties of the two phenotypes TTLshort and TTLlong to identify novel parameters which ideally reflect the functional biology of the disease and identify therapeutic targets. Gene expression profiles were analyzed in NOD/SCID/huALL xenograft

leukaemia samples (N= 14) using a human whole genome array approach (Affymetrix U133 Plus 2.0). 108 probe sets (102 genes) were found to be differentially regulated between TTLshort and TTLlong. Application of this signature (108 probe sets, derived from xenograft samples) on expression profiles obtained from patients (N= 197) who have been treated according to a BFM-based protocol (AIEOP-LLA-2000) resulted in separation into 2 groups of which patients clustering in the TTLlong signature group showed a superior relapse free survival. When applying Significance Analysis of Microarrays (SAM) on the profiles of the 14 xenografts, 2 of the differentially regulated genes identified by T-test were also identified by SAM to be highly discriminatory: DNA-damage-inducible-transcript-4-like (DDTI4L, a negative regulator of the mTOR pathway) and phosphodiesterase-4A (PDE4A, involved in cAMP-mediated apoptosis signalling). These 2 genes also separated the cohort of 197 patients into 2 groups with TTLlong signature patients showing a superior relapse free survival. TTLshort is characterized by DDIT4L^{low}/PDE4A^{high} and TTLlong involves DDIT4L^{high} and PDE4A^{low}. Our findings have important therapeutic implications since both pathways identified provide immediate targets for therapeutic intervention. The lacking mTOR inhibition in TTL^{short}/DDIT4L^{low} leukaemia could be overcome by rapamycin leading to growth inhibition of TTLshort leukaemia. Growth inhibition of TTLshort leukaemia could be also achieved inhibiting PDE4A activity using compounds like rolipram resulting in increased apoptosis sensitivity. In fact, *ex vivo* treatment of primary xenograft leukaemia cells with inhibitors of both pathways, rapamycin and rolipram, showed clearly increased cell death in TTL^{short} (DDIT4L^{low}/PDE4A^{high}) but not in TTLlong (DDIT4L^{high}/PDE4A^{low}) samples. Taken together, the importance of our observations in the xenotransplant model could be translated into an independent group of patients and led to identification of pathways involved in regulation of cell growth and apoptosis which can be targeted by well known drugs such as the mTOR inhibitor rapamycin. Therefore, our model provides a powerful tool to identify prognostic factors in paediatric acute leukaemia leading to rational targets for directed therapy.

APOPTOSIS DEFICIENCY DEFINES PROGNOSTIC SUBGROUPS AND THERAPY RESISTANCE IN A XENOGRAFT MODEL OF PEDIATRIC BCP- ALL

M. Queudeville, S.M. Eckhoff, K.-M. Debatin, L.H. Meyer

University of Ulm, ULM, Germany

Deficient activation of apoptosis signaling pathways is known to play a role in leukemogenesis as well as in drug resistance and treatment failure. In two previous retrospective studies we described the importance of intact apoptosis signaling for treatment response in pediatric ALL and AML. A correlation of 2 key apoptogenic events, caspase-3 activation and cytochrome c release, reflecting the functional integrity of this molecular mechanism, was only found in patients with good outcome. Using a NOD/SCID xenotransplantation model for primary pediatric B-cell precursor (BCP)-ALL, we found that rapid engraftment in the mouse (short time to leukemia, TTLshort) determines poor patient outcome while delayed manifestation of leukemia in the recipient (TTLlong) indicates a good prognosis for the patient. In this study, we analyzed the importance of deficient apoptosis signaling for leukemia engraftment and therapy resistance in this xenotransplantation model. 17 BCP-ALL xenograft leukemia samples (5 TTLshort and 12 TTLlong) were analyzed. Correlation of cytochrome c release and activation of caspase-3, indicating proficient apoptosis signaling, was only found in the TTLlong group, whereas it was absent in TTLshort. Likewise, intact connection of both parameters was exclusively found in xenograft leukemia samples of patients with favorable prognostic factors (e.g. absence of hyperleucocytosis at diagnosis, presence of TEL/AML1, no or late relapse). In addition, a significant positive correlation of time from transplantation of the leukemia and clinically ouvert leukemia in the mouse (time to leukemia, TTL) and cytochrome c release (Spearman's, p=0.022) indicated prolonged leukemia engraftment to be due to efficient apoptosis signaling. Mice transplanted with different leukemias (5 TTLshort and 4 TTLlong, all standard and medium risk groups, no prednisone poor responders) were treated according to induction therapy regimens used in pediatric ALL-patients (including vincristine, dexamethasone and asparaginase) for 21 days and the time to reoccurrence (TTR) of leukemia was estimated. Recipients carrying a TTLshort leukemia showed an inferior survival after treatment compared to those transplanted with a TTLlong leukemia (log rank, p<0.001). Furthermore, a significant positive correlation of post-treatment time to reoccurrence (TTR) of leukemia in the mice and cytochrome c release (Spearman's, p=0.001) was found, indicating that proficient apoptosis signaling is necessary for effective therapy. These results demonstrate that deficient apoptosis signaling is an important feature determining not only leukemia growth but most importantly also therapy resistance in the NOD/SCID/huALL model *in vivo*, and accordingly poor prognosis of the patient. The propensity to undergo apoptosis not only serves as a biomarker for prognosis but also as an indicator of treatment response. Thus, the apoptotic machinery represents a promising therapeutic target. In fact, preliminary *in vitro* toxicity experiments with XIAP-antagonists/Smac-mimetics confirm this assumption and will eventually translate into new clinical applications.

0612

METHADONE IMPROVES THERAPEUTIC SUCCESS IN LEUKEMIA CELLS *IN VITRO* AND *EX VIVO*

C. Friesen,[1] M. Roscher,[1] I. Hormann,[1] M. Queudeville,[2] L.-H. Meyer,[2] K.-M. Debatin,[2] E. Miltner[1]

[1]Institute for Legal Medicine, University Ulm, ULM; [2]Childrens'Hospital, University Ulm, ULM, Germany

Background. Chemoresistance and radioresistance is one of the primary causes for therapeutic failure in radiotherapy and chemotherapy of cancer. Therefore new options are needed to improve therapeutic success in the treatment of leukemias and solid tumors. The therapeutic opioid drug methadone (D,L-methadone), a long-acting μ-opioid receptor agonist, is a highly effective and safe medication for the opioid dependence of outpatients. It suppresses opioid withdrawal, and provides blockade to the effect of illicit opioids. In addition, to treatment of opioid withdrawal, methadone is of significant utility as a long-acting analgesic, particulary for neuropathic pain syndromes. *Aims*. In our studies we analyzed the effect of methadone and methadone in addition of doxorubicin on different B cell precursor (BCP)-ALL cells *in vitro* and *ex vivo*. *Methods*. BCP-ALL cell lines (Nalm6, Reh, Tanoue) and primary BCP-ALL cells isolated from xenografted/transplanted NOD/SCID mice were treated with different therapeutic concentrations of D,L-methadone alone or in addition to therapeutic concentrations of doxorubicin. After different time points, cell death was measured by flowcytometry analyses and activation of apoptosis pathways was analyzed by Western Blot analyses. *Results*. We found that methadone is a potent inducer of cell death and apoptosis in leukemia cells. A strong increase of cell death from 15% up to 90% was measured at low therapeutic concentrations of methadone in addition to doxorubicin in leukemia cell lines *in vitro*. In addition, a high cell kill were also observed on primary BCP-ALL cells *ex vivo*. This indicates that methadone improves therapeutic success of doxorubicin in treatment of leukemia cells. At higher concentrations of methadone leukemia cells were killed without doxorubicin treatment. Methadone alone or in combination with doxorubicin inhibited proliferation in leukemia cells and induced cell death through apoptosis induction. Activation of apoptosis pathways through activation of caspase-9, caspase-2 and caspase-3, downregulation of Bcl-xL and XIAP, and cleavage of poly(ADP-ribose)polymerase were found after treatment with methadone alone or in combination of methadone and doxorubicin in leukemia cells. In addition, methadone reversed deficient induction of cell death by doxorubicin in doxorubicin-resistant and apoptosis-resistant leukemia cells. *Summary and Conclusions*. We found that methadone improves therapeutic success of doxorubicin in treatment of BCP-ALL leukemia cells *in vitro* and *ex vivo* and breaks doxorubicin-resistance. These results demonstrate that methadone provides the foundation for new strategies using methadone as additional anticancer drug in leukemia therapy to improve therapeutic success especially when conventional therapies are less effective.

PERIPHERAL BLOOD INVOLVEMENT PROVIDES AN IMPORTANT PROGNOSTIC INFORMATION DURING EARLY TIME POINTS OF CHILDHOOD ALL TREATMENT

J. Volejnikova,[1] E. Fronkova,[1] E. Mejstrikova,[1] K. Muzikova,[1] L. Reznickova,[1] D. Pospisilova,[2] V. Mihal,[2] J. Sterba,[2] Y. Jabali,[3] D. Prochazkova,[4] B. Blazek,[2] J. Hak,[2] Z. Cerna,[2] J. Stary,[1] J. Trka[1]

[1]2nd Medical School, Charles University Prague, PRAGUE; [2]University Hospital, OLOMOUC; [3]Hospital, CESKE BUDEJOVICE; [4]Masaryk Hospital, USTI NAD LABEM, Czech Republic

Background. In the most progressive pediatric acute lymphoblastic leukemia (ALL) treatment protocols, minimal residual disease (MRD) testing is essential for the risk group stratification procedure and is an

important predictor of outcome. While routinely performed on bone marrow (BM) samples, MRD in peripheral blood (PB) is not usually examined although PB sampling could cause less discomfort especially in children. Some studies have shown a good correlation of MRD levels in PB and BM in T-ALL; the data concerning B-cell precursor (BCP)-ALL remain controversial, with most studies lacking sufficient number of samples with quantifiable MRD in both compartments taken during the early phase of treatment. *Aim and Methods.* To simultaneously evaluate MRD in BM and PB using patient-specific immunoglobulin and T-cell receptor gene-based RQ-PCR. *Results*. 221 paired samples from 47 children with BCP-ALL treated according to the Berlin-Frankfurt-Muenster (BFM) ALL IC-BFM 2002 protocol were taken at diagnosis (dg, n=47), day 8 (d8, n=39), day 15 (d15, n=44), day 33 (d33, n=34), week 12 (w12, n=31) and at the end of maintenance therapy (post-MT, n=26). Informed consent was obtained from patients or their guardians. In 125 paired samples MRD was detected in both tissues, in 18 pairs in BM only and in 5 pairs in PB only. MRD levels in PB varied greatly and were a mean of 149-fold lower than in BM (range 0.04-8293). Like in the BM at d15, patients with lower MRD in PB at d15 were more likely to achieve MRD negativity in BM at d33 in the univariate analysis (p=0.01, Mann Whitney). Patients younger than 10 yrs had lower MRD in PB at d8 and at d15 than other patients (p=0.03 and p=0.01, respectively). Unlike in BM, patients with hyperdiploidy had lower MRD in PB at d15 than other patients excluding TEL/AML1 cases (p=0.05). There were no significant associations with diagnostic white blood cell count (WBC), sex, immunophenotype (cALL/prae-B ALL) or presence of TEL/AML1 fusion at any time point. Patients with MRD<1E-04 in PB at d15 had a 5-year relapse-free survival (RFS) of 100% vs. 62.5±9.9% for those with a higher MRD (p=0.0089). No such threshold could be set for dg, d8 and d33 PB MRD level. Low numbers of MRD-positive results at w12 and post-MT samples precluded statistical analysis. We next examined the prognostic impact of BM/PB MRD ratio. Patients having MRD levels in PB similar to those in BM (BM/PB MRD<10) at d8 and d15 were more likely to relapse (d8: RFS 88.1±6.4% vs. 61.5±13.5%, p=0.04; d15: RFS 89.5±5.7% vs. 54.5±15%, p=0.01). No such relationship was observed for dg or d33. *Summary*. Our data show that in childhood BCP-ALL, MRD in PB is not simply proportional to the BM level and provides additional prognostic information. A higher relapse rate in patients with PB MRD level similar to that in BM suggests that leukemic blasts with the propensity for massive escape from BM to PB during the induction treatment have a great potential for giving rise to relapse.

AID EXPRESSION IN BCR/ABL POSITIVE ALL IS ASSOCIATED WITH A PECULIAR GENE EXPRESSION PROFILE AND DEREGULATION OF DNA REPAIR AND REPLICATION GENES

M. Messina,[1] S. Chiaretti,[1] I. Iacobucci,[2] S. Tavolaro,[1] A. Vitale,[1] I. Della Starza,[1] A. Lonetti,[2] C. Papayannidis,[2] A.D. Negulici,[1] S. Soverini,[2] D. Cilloni,[3] A. Guarini,[1] G. Martinelli,[2] R. Foà[1]

[1]Sapienza University, ROME; [2]Institute of Hematology and Medical Oncology "L. and A. Seràgnoli", BOLOGNA; [3]Department of Clinical and Biological Science, University of Turin at Orbassano, TURIN, Italy

Background. Activation-induced cytidine deaminase (AID) initiates somatic hypermutation and class switch recombination of immunoglobulin (Ig) genes by deaminating deoxycytidine residues in mature germinal center B cells. AID can also induce mutations in non-Ig genes. In addition to the full-length isoform, five splice variants have been reported in normal B cells and in mature B-cell disorders. Furthermore, aberrant expression of AID has been detected in B-lineage acute lymphoblastic leukemia (B-ALL) and a strong correlation between AID expression and BCR/ABL-positivity has been found; intriguingly, BCR/ABL$^+$ ALL, the most frequent genetically-defined ALL in adults, is characterized by a high genetic instability. *Aims*. To deepen the role of AID in BCR/ABL$^+$ ALL, AID expression was studied in these patients and then its association with gene expression profiling was evaluated. *Methods*. We analyzed 16 adult BCR/ABL$^+$ ALL patients at the onset of disease for AID expression: after cDNA amplification, PCR products were loaded on the ABI Prism 3730 DNA Analyzer for automated capillary gel electrophoresis and the results were plotted with the AbiPrism GeneMapper v3.5 software (Applied Biosystems). Subsequently, gene expression profiling experiments were performed on the same set of patients using the HGU133 Plus 2.0 arrays (Affymetrix); statistical analysis was carried out using the dChip software. Unsupervised and supervised analyses (Analysis of Variance, ANOVA) were used to evaluate the presence of potential subsets and to compare the BCR/ABL$^+$ ALL subgroup based on AID results. *Results*. AID mRNA was detected in 7 patients: 4 expressed only the full-lenght isoform, 2 displayed the splice variant that retains exons 1, 2 and 5, while 1 patient co-expressed the full-lenght isoform and two splice variants. The remaining cases proved negative for AID expression. By unsupervised clustering, gene expression profiling data analysis revealed that AID-full-lenght and AID-splice variants patients display a similar profile. This finding was confirmed by supervised analysis: in fact, comparison on the 3 AID subsets (i.e. AID-full-lenght, AID-splice variants and AID-negative) grouped AID-full-lenght and AID-splice variants in the same cluster, as opposed to AID-negative cases. Among the 1151 differentially expressed genes, 328 resulted specifically and homogeneously upregulated in AID-full-lenght patients. Of interest, this group of patients was characterized by the overexpression of a large set of genes involved in i) DNA repair (PCNA, RPA3, RAD50, XRCC4, TP53), ii) DNA replication (ORC5L, MCM10, CETN3, ANAPC7), iii) cell cycle regulation (CDK6, MKI67, MYC), iv) nucleotide metabolism (NT5C3, PPAT, PRPS2). Functional annotation analysis, performed using the DAVID software, corroborated these findings. *Conclusions*. These results indicate that AID-full-lenght and splice variants exert a similar genomic profile, distinct from AID-negative patients, suggesting that gene expression profiling is mainly affected by AID positivity or negativity, rather than by the presence of AID-splice variants. Furthermore, AID positive patients are characterized by a peculiar signature in which genes involved in DNA repair and replication are overrepresented, indicating a possible deregulation of these mechanisms: it is intriguing to speculate that this phenomenon might be implicated in the genetic instability observed in these patients. Functional studies are ongoing to confirm this hypothesis.

0615

THE IMMUNOMODULATORY AGENT FTY720 INDUCES APOPTOSIS AND INHIBITS GROWTH OF BCR-ABL POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA CELLS AND OVERCOMES IMATINIB RESISTANCE *IN VITRO*

A. Schmidt-Tanguy, S. Badura, B.A. Nijmeijer, S. Wystub, A. Romanski, O.G. Ottmann

University, FRANKFURT, Germany

Background. Imatinib is highly effective initial therapy for *de novo* Philadelphia chromosome-positive ALL (Ph$^+$ ALL) but resistance to this tyrosine kinase inhibitor (TKI) eventually develops in the majority of patients. Approximately 80% of patients with acquired imatinib resistance harbour mutations in the tyrosine kinase domain (TKD) of Bcr-Abl, whereas primary resistance appears to be largely independent of TKD mutations but the mechanisms have not been elucidated. FTY720 (fingolimod) is a synthetic compound produced by modification of a natural immunosuppressor. This immunomodulator is noted to interfere with T-cell trafficking and is used in organ transplantation. Recent studies indicate that FTY720 induces apoptosis through activation of the serine/threonine phosphatase PP2A in a variety of B-cell malignancies independently of Bcl-2 expression, but precise mechanisms of action are incompletely elucidated. *Aims.*We examined the potential effect of FTY720 in a Ph$^+$ ALL cell line displaying non-mutational imatinib-resistance and in long-term cultured primary human Bcr-Abl positive and negative ALL cells. *Methods.* As a model of imatinib resistance we employed the SupB15RT cell line which was derived from the previously well characterized Bcr-Abl positive B-precursor SupB15W cell line by gradually increasing the exposure to imatinib. SupB15RT cells are cross-resistant to the second generation Abl kinase inhibitors with no evidence of commonly implicated mechanisms of imatinib resistance, e.g. Bcr-Abl gene amplification, point mutations in the TKD mutations, or Bcr-Abl overexpression. In addition we used long-term cultured primary human ALL cells obtained from patients with Bcr-Abl positive (n=2) and Bcr-Abl negative cells (n=3). Cells were treated with 1 to 10 µM FTY720 from a period of 7 days. Cell viability was determined by trypan cell counting. Apoptosis was measured using the Annexin V-FITC apoptosis kit. Abl phosphorylation was analyzed by western blot. *Results.* FTY720 induced apoptosis in a dose-dependant manner in all cases of Bcr-Abl positive ALL cells (n=4) and in none of the three Bcr-Abl negative cells (n=3). The maximum apoptotic effect was observed after 48 hours. In SupB15W, FTY720 has dramatic effect with 75% of apoptosis with principally late apoptosis (53%) after 48 hours and suppresses growth already with low concentration (as of 2.5 µM). In imatinib-resistant SupB15RT, we show the apoptotic and antiproliferative effects after 48 hours. However the apoptotic effect is different with less apoptosis (39%) but mostly early apoptosis (27%).The potential effect of FTY720 on phosphorylation of Bcr-Abl, a known substrate of PP2A, was examined by Western blotting, demonstrating that in SupB15W and in SupB15RT cells, the level of Abl phosphorylation is not modified by FTY720. *Conclusions*. The immunomodulator FTY720 is a

potent inducer of apoptosis and an antiproliferative agent in Ph+ ALL but not in Ph negative ALL cells. It partially abrogates mutational-independent imatinib resistance and may be of potential use as a therapeutic agent in Ph+ ALL. The mechanism by which FTY720 induces cell death appears to differ between imatinib-sensitive and imatinib-resistant Ph+ ALL cells, and is currently being elucidated.

0616

PROGNOSTIC INTEREST OF BIPARAMETRIC CD45-DNA ANALYSIS OF MEDULLAR LYMPHOBLASTS AT DIAGNOSIS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

P. Rachieru-Sourisseau,[1] E. De Carli,[1] L. Baranger,[1] F. Génèvieve,[1] J. Rakotonjanahary,[1] S. Proust,[1] F. Mechinaud,[2] N. Robillard,[2] O. Minckes,[3] V. Salaun,[3] A. Robert,[4] N. Dastugue,[4] F. Millot,[4] F. Brizard,[4] A. Chassevent[5]

[1]C.H.U. Angers, ANGERS; [2]C.H.U.Nantes, NANTES; [3]C.H.U.Caen, CAEN; [4]C.H.U., TOULOUSE; [5]CRLCC Paul Papin, ANGERS, France

Background. The increase of survival in childhood acute lymphoblastic leukaemia (ALL) during the last fifty years was induced by the amelioration of antileukemic treatments and by their early adaptation depending on clinical and biological risk factors at diagnosis and on chemotherapy response. DNA index (DI), which expresses the blast cells DNA content measured by flow cytometry (FCM), is a prognostic factor in childhood ALL. When the leukemic clone does not show pejorative structural abnormalities, a better survival is associated with a hyperdiploidy (DI>1.16) and a poor prognosis is induced by a severe hypodiploidy (DI<0.8). Single DNA staining provides accurate DI, but the percentage of blastic S-phase cells (%S), (which can predict chemotherapy sensibility and prognosis) is difficult to determine accurately in DNA-diploid and near-diploid cases, as it reflects the mean of all cells in a bone marrow aspirate. *Aims*. In order to ascertain the prognostic value of specific blast cell DI, CD45-FI and %S, a CD45-DNA double staining was realized in childhood ALL samples and the FCM parameters were studied according to clinical, biological and therapeutic characteristics. *Methods*. One hundred and eighty-five patients younger than 18 years with newly ALL, treated between 1987 and 2006 (CHU Angers, Caen, Nantes, Poitiers and Toulouse), were included in this retrospective study. Patients were treated in different treatment schedules, according to the period of diagnosis (EORTC 58881, 58951, FRALLE 2000-A, FRALLE 2000-BT and INTERFANT). Main characteristics were noted at diagnosis: clinical such as sex, age, extramedullar localization and: biological ones, such as leucocytosis, immunophenotypic, cytogenetic and molecular characteristics. During follow-up, were noted: the steroids sensitivity at day 8 and cytological or molecular remission at day 42, the treatment schedule, the relapse and/or death events. One hundred thirty-nine frozen and 46 fresh diagnostic samples were analyzed by a CD45-DNA double staining and the DI, CD45-FI and %S were determined for all detected subclones. *Results*. The DI and CD45-FI were correlated with validated risk factors and survival. The hyperdiploidy was associated to a longer event-free survival (EFS) (p<10-4, 5-year EFS rate=89.8%). A high CD45-FI was strongly correlated to poor prognostic factors (younger than 1 year, extra-medullar localization, T phenotype, hypodiploidy, (9;22) translocation, and associated to shorter EFS (p=0.017, 5-year rate=61.7%) and OS (p=0.02, 5-year rate=69.3%). The S-phase percentage value was not identified as a prognostic parameter in our study. Supplementary clones were detected by FCM, including 3 severe hypodiploid cases (DI: 0.56, 0.73 and 0.77) and 8 cytogenetic failure cases. *Conclusions*. The accurate, rapid and cheap determination of heterogeneous blastic populations by biparametric CD45-DNA analysis, associated to the prognostic value of DI and CD45-FI, justify the interest of this technique at diagnosis and can be added to monitor residual disease in childhood ALL.

0617

ECTOPIC CDX2 EXPRESSION IS A FREQUENT AND PROGNOSTICALLY RELEVANT EVENT IN HUMAN ACUTE LYMPHOBLASTIC LEUKEMIA

S. Thöne,[1] V.P.S. Rawat,[1] B. Heilmeier,[2] E. Hoster,[2] K. Metzeler,[2] T. Herold,[2] W. Hiddemann,[2] N. Gökbuget,[3] D. Hoelzer,[3] S. Bohlander,[2] M. Feuring-Buske,[2] Ch. Buske[2]

[1]Helmholtz Zentrum München, MÜNCHEN; [2]Klinikum Gro,hadern, MÜNCHEN; [3]Johann Wolfgang Goethe Universität, FRANKFURT/ MAIN, Germany

We previously could show that the homeobox gene CDX2 is aberrantly expressed in 79% of acute myeloid leukemia (AML) patients with especially high expression levels in patients with normal karyotypes (median ΔCT 7.58). In AML, expression levels of CDX2 were highly correlated with deregulated expression of HOX genes. To test if an aberrant expression of CDX2 could be also observed in acute lymphoblastic leukemia (ALL), we analyzed the expression of CDX2 in 57 adult patients with ALL by TaqMan real-time qRT-PCR. Of these patients, the majority of 81% was positive for CDX2 expression. With highest median expression in pre-T ALL (ΔCT 4.1, n=7) followed by cALL (ΔCT 5.4, n=10) and pro-B ALL (ΔCT 5.78, n=9) those groups showed higher expression of CDX2 than AML patients with normal karyotype. The proportion of patients ectopically expressing CDX2 differed between ALL subtypes with 100% positivity in patients with pro-B ALL, c-ALL and Ph+ ALL versus 40% positivity in B-ALL/Burkitt lymphoma, 70% in thymic T-ALL and 71% in pre-T ALL. In contrast to AML, where CDX2 expression correlated with HOX gene deregulation, in ALL we could not detect any correlation between CDX2 and HOXA7 or HOXA9, respectively, and only a weak correlation between CDX2 and HOXB6 (p=0.048, Mann-Whitney U-test). As these results suggest that in ALL CDX2 is exerting its leukemogenic effect not by deregulation of HOX genes, we tested by TaqMan LDA for differential regulation of genes involved in lymphopoiesis. Hereby we found that CDX2 is able to significantly upregulate lymphoid genes such as Lef1 (3.9-fold, p=0.001), Tcf3 (13.3-fold, p=0.0004), and Id3 (10.2-fold, p=0.0001). Promoter hypomethylation could be excluded as a possible cause for the aberrant CDX2 expression as we did not detect any methylation differences between CDX2 positive and negative ALL patients in a methylation region surrounding the transcription start site of CDX2 (n=9). Expression of CDX2 was highest in high risk and very high risk patients. Despite the small number of only 30 patients included in statistical analysis, CDX2 turned out to significantly correlate to poor overall survival (p=0.019, log rank test), and remained a significant risk factor also after adjusting for the other risk factors age or presence of molecular markers by bivariate analysis. Here we show that CDX2 does not perturb HOX expression in the same extent as in AML, but is able to upregulate also lymphopoietic genes. Furthermore, we could demonstrate for the first time that aberrant CDX2 expression is a frequent event in adult ALL, that high expression levels of this protooncogene predict poor treatment outcome in these patients and CDX2 expression therefore has prognostic impact in adult patients with ALL.

MIRNA EXPRESSION PROFILE OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA EXPRESSING OR NOT CD56

H.L. Gimenes Teixeira,[1] G.A. Dos Santos,[1] P.S. Scheucher,[2] D.L. Zanette,[3] L.F. Dalmazzo,[2] A.G. Araújo,[2] W.A. Silva-Jr,[3] R.P. Falcão[2]

[1]FMRP, RIBEIRAO PRETO; [2]Medical School of Ribeirão Preto, RIBEIRÃO PRETO; [3]National Institute of Science and Technology in Stem Cell and Cell Therapy, RIBEIRÃO PRETO, Brazil

The expression profiles of miRNAs in tumour samples have been used to provide specific phenotypic signatures with better discrimination than mRNA expression profiles. Recently our group has demonstrated that the expression of CD56, a marker of natural killer (NK) cells, in T cell acute lymphoblastic leukaemia (T-ALL) is an independent adverse prognostic factor for disease free survival (DFS) in multivariate analysis (855 vs 2095 days, p=0.002). Also patients tended to be older and to present normal platelet counts in the T-LLA/CD56+ group. Therefore, better characterization of these two subgroups of T-ALL is necessary to understand its diversity as disease entities. Our aim was to determine the miRNA expression profile of T-ALL with or without CD56 expression as well as normal mature T and NK cells. We used 48 T-ALL samples (36 T-ALL/CD56- and 12 T-ALL/CD56+) with more than 80% of blasts from peripheral blood or bone marrow of patients diagnosed at Hospital das Clinicas de Ribeirão Preto - January 2000 to December 2006. Normal CD3+/CD56- and CD3-/CD56+ cells were isolated from peripheral blood of four healthy subjects by immunomagnetic labeling. Total RNA (1ug from each sample) was pooled according to groups described above. We used the Taqman MicroRNA Assay Human Panel (Applied Biosystems) to perform a screening of 164 knowledge mature miRNA sequences. Total RNA (2.5 ng/reaction) from pools was reverse transcribed with specific looped RT primers for each miRNA. In the real-time PCR step, specific primers and probes for each miRNA were used according to manufacturer instructions. Total RNA input was normalized based on the geometric means of Ct values obtained for the endogenous RNAs: RNU6B, RNU19, RNU38B and RNU66. All reactions were run in duplicate and a coefficient of variation greater than 5% was used as an exclusion factor (seven miRNAs were excluded). The fold

change was calculated using comparative 2-ΔΔCt method. We defined a strength cutoff for differential expression as 10 times for upregulation and 0.1 for downregulation. With this strategy we identified nine miRNAs for further validation using real time PCR of the individual 56 samples (Figure). MiR-29b is upregulated in leukemia compared to normal samples (A). This is a new finding in disagree with previous work that described it as a tumor suppressor gene downregulated in tumors of aggressive behavior. It is possible that miR-29b be specifically involved in initial phases of T-cell maturation. MiR-181a (E) and miR-181b (F) are upregulated in T-ALL when compared to normal T cells. Indeed the increase of miR181a was previously described involved with antigenic stimulation in normal T cells. Finally, in the comparison between T-ALL/CD56$^+$ and T-ALL/CD56$^-$ we observed that miR-221 is up regulated in the T-ALL/CD56$^+$ group (G). Indeed, miR-221 is commonly upregulated in aggressive tumors as glioblastoma and melanoma. Interestingly, in a previous work of Lawrie and colleagues, miR-221 was upregulated in the aggressive activated vs the more indolent germinal center form of diffuse large B cell lymphoma. Our findings implicate miR-221 as a marker of T-ALL expressing CD56 and possible as a target for future therapy.

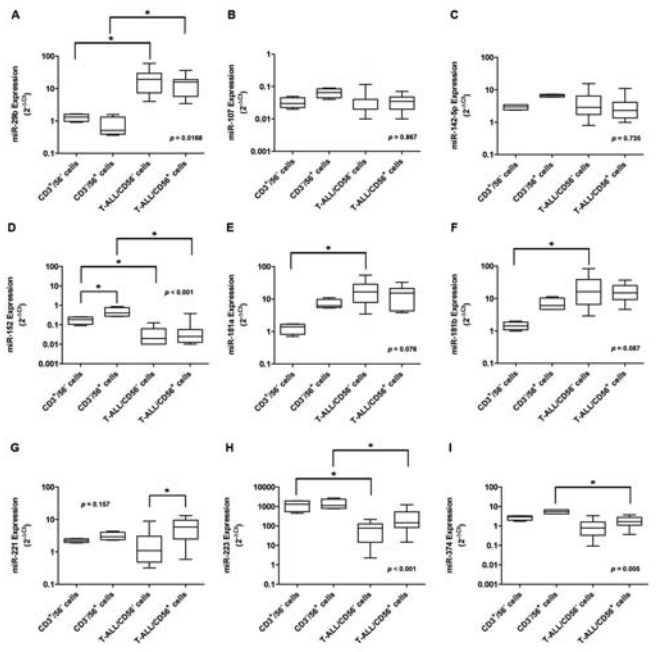

Figure. Quantitative analysis of miR-29b (A), miR-107 (B), miR-142-5p (C), miR-152 (D), miR-181a (E), mir-181b (F), miR-221 (G), miR-223 (H) and miR-374 (I) expression. Leukemic samples from 48 T-ALL patients were obtained from cell bank, and normal cells were isolated from peripheral blood of four healthy subjects. Expression of miRNAs was quantified by quantitative real-time PCR. The horizontal bars represent the mean and 95% confidance interval of miRNAs relative expression calculated by $2^{\Delta CT}$. T-ALL samples were subdivided according to presence or not of CD56 cell marker: 12 samples were positive (T-ALL/CD56$^+$), whereas 36 were negative for CD56 (T-ALL/CD56$^-$). Normal samples represent the population of T (CD3$^+$/56$^-$) and NK (CD$^-$/56$^+$) cells. Asterisks indicate significant difference in comparison with the other group. Non-parametric one-way ANOVA analysis of variance and Fisher's multiple comparison test were performed using the software Minitab 14.

METHYLENETETRAHYDROFOLATE REDUCTASE GENE 677C/T POLYMORPHISM AND GEOGRAPHIC ORIGIN IN ITALIAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

E. Parodi,[1] S. Vallero,[1] E. Rivetti,[1] P. Giordano,[2] N. Santoro,[2] V. Cecinati,[2] R. Calabrese,[1] E. Barisone,[1] N. Bertorello,[1] C. Alliaudi,[1] P. Saracco[1]

[1]University of Turin, TORINO; [2]Univerisity of Bari, BARI, Italy

Background. Several factors have been proposed and identified in the past years as prognostic indexes in the treatment of acute lymphoblastic leukaemia (ALL) in childhood. Folate pathway enzymes play a peculiar function in DNA synthesis and methylation. Role of polymorphism 677C/T of Methylenetetrahydrofolate reductase (MTHFR) in paediatric ALL has been investigated with conflicting results. *Aims*. to evaluate the role of MTHFR 677C/T polymorphism and other covariates in determining relapse risk in our Italian population of childhood ALL. *Material and Methods*. we genotyped MTHFR 677C/T (DNA extraction, PCR amplification, digestion by restriction enzymes and agarose gel electrophoresis) in 107 Italian children enrolled in ALL-AIEOP 2000 trial. The allelic frequency obtained was compared with that expected in the Italian population (Bauduer, Mol Genet Metab, 2005). We collected information on age at diagnosis, gender, WBC count at diagnosis, immunophenotype, steroid type used in induction phase (prednisone or dexamethasone), protocol risk class (standard, intermediate, high). We assigned each patient to a geographic origin group (northern, central or southern Italy) on the basis of their parents' birthplace. Time-to-event analysis (single and multiple Cox regression) was performed to model the risk of relapse given by MTHFR 677C/T polymorphism and other covariates. Univariate and multivariate analysis was performed. *Results*. Genotype frequencies: 677 C/C 43% (46/107); C/T 37% (40/107); T/T 20% (21/107). Allele T frequency in ALL (38%) was not different from general population (p<0.05). 20 relapses were registered (median relapse time 62 months from diagnosis, range 5-211; median follow-up time 170 months from diagnosis, range 5-251). None of the variables on univariate analysis resulted to be significantly associated with relapse risk. On multivariate analysis, only geographic origin was significantly related with relapse risk. In particular, relapse risk is 4.5 times higher in patients of southern origin compared to patients of northern origin (p=0.016). *Conclusions*. Our data do not confirm the role of 677C/T MTHFR polymorphism in conferring a higher relapse risk in ALL patients. Interestingly, multivariate analysis shows a higher relapse risk in patient of southern Italian origins, independently from the medical centre in which they were treated. Our results rise questions about the presence of unknown genetic factors that predispose southern Italian patients to a higher relapse risk. Anamnestic data about patients' families should be taken into consideration in wider retrospective or prospective studies on childhood ALL, especially in series from Italy and Southern Europe, in order to clarify the role of geographic origin in ALL relapse risk.

VALIDATION OF MX1 (MXA) AS A GENETIC MARKER FOR GLUCOCORTICOID-INDUCED APOPTOSIS IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS?

S. Junk,[1] G. Cario,[2] M. Lauten,[3] N. Wittner,[4] M. Schrappe,[2] B. Schlegelberger,[4] N. von Neuhoff[4]

[1]Hannover Medical School/ Institute of Cell and Molecular Pathology, HANNOVER; [2]University Hospital Schleswig-Holstein/ Department of Paediatrics, Campus Kiel, KIEL: [3]University of Freiburg/ Department of Paediatrics, FREIBURG; [4]Hannover Medical School/ Institute of Cell and Molecular Pathology, HANNOVER, Germany

Background. The response to initial glucocorticoid therapy in childhood acute lymphoblastic leukemia (ALL) reliably predicts the response to multi-agent chemotherapy. Patients resistant to glucocorticoids (prednisone poor responders (PPR)) have a poorer event-free survival compared to glucocorticoid-sensitive patients (prednisone good responders (PGR)). In an expression profiling study to investigate differential gene expression in leukaemic blasts from childhood ALL patients at time of diagnosis, the Mx1 myxovirus (influenza virus) resistance 1 gene was identified as one of the highly expressed genes in standard-risk patients (Cario *et al.* 2005), whereas the expression in the high-risk patient group was decreased 2-fold. *Aims*. The aim of our study was to investigate whether the expression of Mx1 on the transcriptome and on the proteome level differs between prednisone good and prednisone poor responders, respectively, particularly after prednisone treatment. *Methods*. The human B-cell precursor leukemic cell lines with known gc sensitivity, i.e. MHH cALL 2 (PPR) and MHH cALL 3 (PGR), and further ALL cell lines, e.g. REH, SD-1 and SUP-B15, were studied after 24, 48, 72 and 96 hours, untreated and after induction with prednisone (3 µg/mL Solu-DecortinH®) or the proteasome inhibitor bortezomib, respectively. Real-time PCR were performed to quantify the MX1 expression. Western blot analyses were performed on whole cell lysates using a rabbit polyclonal Mx1 (MxA) antibody (sc-50509, Santa Cruz). To quantify viable cells, WST-1 assays were performed. *Results*. The level of Mx1 RNA was 2.4-fold higher in untreated PGR cells compared to the untreated PPR cells. After prednisone induction, the MX1 RNA expression in PGR cells increased 18-fold in comparison to the initial level, whereas it decreased slightly in PPR cells and in the SD1 cell line, whereas it remained unaffected in REH and in SUP-B15 cell lines. In agreement with these findings, Mx1 protein was detectable at low levels in untreated PGR cells, but undetectable in PPR cells. Prednisone treatment led to

a 30-fold rise in Mx1 protein expression in the PGR cell line, but caused no significant changes in the PPR cells, 72 and 96 hours after induction. In contrast, the protein levels of Mx1 decreased in SD-1 and SUB-P15 following prednisone treatment. Bortezomib, particularly in combination with prednisone, alleviated the increase in MX1 RNA expression the PGR cell line, but did not affect Mx1 protein expression. In the PPR cell line, bortezomib treatment caused no significant changes. All pre-B-ALL cell lines, that showed an unaltered viability under treatment with 6.2 µM prednisone, also had an unaltered or slightly decreased MX1 RNA expression. In contrast, the only pre-B ALL cell line with a significant prednisone response, showed an immediate and persistent increase of MX1 RNA expression. *Summary and Conclusions*. These *in vitro* results show that MX1 expression is increased and further induced after prednisone treatment in PGR cells. They are in agreement with previous gene expression profiling data, reporting an increased MX1 gene expression in standard-risk childhood ALL patients. MX1, a GTP-binding interferone-induced gene, is involved in the induction of apoptosis, again linking apoptosis defects with prednisone resistance in childhood ALL.

0621

THE MAMMALIAN TARGET OF RAPAMYCIN INHIBITOR RAD001 INHIBTS PROLIFERATION OF T- AND B-LYMPHOBLASTIC CELLS VIA CELL CYCLE ARREST

C. Schult,[1] F. Amoroso,[1] M. Dahlhaus,[1] S. Ruck,[1] S. Lange,[1] F. Buljubasic,[1] M. Freund,[1] L. Neri,[2] C. Junghanss[1]

[1]*University of Rostock, ROSTOCK, Germany;* [2]*University of Ferrara, FERRARA, Italy*

Background. The protein kinase mammalian target of rapamycin (mTOR) regulates cell growth, survival and cell proliferation. Activation of mTOR leads to phosphorylation of downstream targets S6 kinase and 4E-BP thereby influencing translational control. RAD001 is a specific mTOR inhibitor which has been shown to inhibit cell growth of solid tumor cells as well as low grade lymphoma cells. It's efficacy in those diseases is currently investigated in clinical trials. Effects of mTOR inhibition on proliferation and cell function of acute lymphoblastic leukemia (ALL) are unknown. *Aims*. Investigation of the effects of mTOR pathway inhibition on ALL cells using RAD001, in particular in regards to the cell proliferation, apoptosis, necrosis and its influence on the PI3K/Akt pathway. *Methods*. Acute lymphoblastic leukemia cell lines with different cytogenetics and phenotypes were used (SEM, RS4;11, Jurkat and MOLT4). Cells were incubated with different concentrations of RAD001 (1 nM, 10 nM and 100 nM). Cell count, apoptosis, necrosis, cell cycle analysis and metabolic activity were determined at 24 h, 48 h, 72 h and 96 h using microscopy, flow cytometry and WST-1, respectively. Phosphorylationstatus of Akt (Ser473, Thr308) and FoxO3A (Thr32) were determined by western blot. *Results*. Treatment with RAD001 inhibited proliferation in a dose and time dependent manner in all investigated ALL cell lines. Changes in apoptosis and necrosis rates were not detected. Metabolic activity decreased significantly in Jurkat and MOLT4 cells (both T-ALL) using 10 nM and 100 nM RAD001 and decreased not significantly in SEM and RS4;11 (both B-ALL) cell lines. RAD001 induced cell cycle arrest in G0/G1 phase after 48 h and 72 h. In Jurkat cells means of G0/G1 phase were 57% in control cells compared to 68% in treated cells. Similar results were obtained in MOLT4 cells: in control cells means in G0/G1 phase were 65% compared to 74% in treated cells. Western blot results were inconsistent. It seemed that Akt phosphorylation (Ser473 und Thr308) was not influenced early after treatment (0.5-4 h), but subsequently increased after 24-96 h in RAD001 treated cells. In line with this data phosphorylation of FoxO3A (Thr32) seemed to increase in RAD001 treated cells. *Conclusions*. Inhibition of mTOR reduces cell proliferation by cell cycle arrest and reduces metabolic activity in ALL cells with more pronounced effects in the T-ALL cells compared to B-ALL cells. Combination of RAD001 with conventional cytostatic drugs might induce synergistic effects and warrant further investigation.

0622

IMMUNOPHENOTYPIC MODULATION IN ACUTE LYMPHOBLASTIC LEUKEMIA WITH POSTIVE MRD AFTER INDUCTION TREATMENT

P. Barba,[1] A. Aventin,[1] J. Úbeda,[1] M. Carricondo,[1] R. Martino,[1] I. Badell,[1] A. Parente,[2] E. Bussaglia,[1] C. Estivill,[1] J. Sierra,[1] J. Nomdedéu[1]

[1]*Hospital de la Santa Creu i Sant Pau, BARCELONA;* [2]*Hematology. Hospital Sant pau, BARCELONA, Spain*

Background. Antigen modulation has been demonstrated in viable acute lymphoblastic leukaemia (ALL) cells resistant to the induction therapy. Up-regulation of CD20 and down-regulation of CD10 have been the phenotypic changes most frequently described. The study of antigen modulation in specific scenarios (such as BCR-ABL1 positive patients or ALL adult patients) requires further investigation. *Aims*. The primary objective of the study was to describe phenotypic, genetic and molecular characteristics of ALL with positive MRD after induction treatment. Secondary objectives were to investigate antigen modulation and to identify common immunophenotypic modulation patterns among molecular and age groups. *Methods*. We studied 45 bone marrow samples from adult (n=32) and pediatric (n=13) patients diagnosed with ALL with MRD >0.1% at day +14 or +35 of induction therapy. Patients were treated according to adult and pediatric standard protocols with induction regimens including daunorubicin, vincristine and prednisone. Multiparapetric flow cytometric analysis was performed at diagnosis, day +14 and day + 35. Mean fluorescence intensity (MFI) was measured for CD10, CD19, CD20 and CD34. Over and underexpression of antigens were considered with a difference greater than 100 MFI units. Cytogenetic and molecular data were also included in the analysis. Pearson correlation coefficient was used to compare MFI values between time points. The Wilcoxon signed-rank test (2-tailed) was used to asses the significance of observed differences between cohorts. *Results*. Median age at diagnosis was 29 years (range 2-79). Positivity for CD10, CD 19, CD 20 and CD 34 was 80%, 96%, 62% and 91% respectively. Thirty and 23 patients had positive MRD at day +14 and at day +35, respectively, and were included in the analysis. Most frequent aberrant phenotypes at diagnosis were underexpression of CD45 (n=13), crosslinage of CD33 (n=11), and overexpression of CD 34 (n=10). Most frequent cytogenetics were t (9;22) (n=8), normal cariotype (n=6) and anomalies involving MLL (n=3). Ten patients (22%) had BCR/ABL1 rearrangement and one patient had TEL/AML1 rearrangement. For the whole group, we observed a significant decrease of CD10 and an increase of CD 19 expressions at day +14 compared to the diagnosis (mean MFI CD10, 140 vs 129 [p=0.02], mean MFI CD19, 145 vs 216 [p=0.04]). Differences persisted at day +35 for CD10 (140 vs 48 [p=0.007]) but not for CD 19. We did not identified differences regarding expression of CD20 and CD34 between diagnosis and time points. In the subgroup analysis, BCR-ABL1 negative patients had an overexpression of CD20 and CD19 at day +14 as compared to underexpression in BCR-ABL1 positive patients (p=0.006 for CD19 and p=0.03 for CD20). We did not find any difference in antigen modulation between pediatric and adult patients, high vs low levels of MRD (more or less than 5%) at day +14, or in normal vs abnormal caryotipe. *Conclusions*. Antigen modulations in ALL occur during induction therapy with down-regulation of CD10 being the most consistent pattern throughout the induction treatment. BCR-ABL1 positive patients seem to have a specific pattern of antigen modulation throughout induction.

0623

ONCOGENIC PIK3CA MUTATIONS ARE ABSENT IN BCR-ABL POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH+ ALL)

S. Wystub,[1] H. Pfeifer,[1] S. Badura,[1] B. Nijmeijer,[2] O.G. Ottmann[1]

[1]*University of Frankfurt, FRANKFURT, Germany;* [2]*Department of Hematology, Leiden University Medical Center, LEIDEN, Netherlands*

Background. Phosphatidylinositol 3-kinase (PI3K) is a lipid kinase. It regulates cellular growth and proliferation. It is an important downstream mediator of BCR-ABL signalling, implicated in leukemogenesis and in clinical resistance to ABL kinase inhibitors such as imatinib. Somatic mutations in the gene encoding the PI3K catalytic subunit p110α (PIK3CA) have been reported in various cancers. These somatic missense mutations were predominantly located at specific *hot spots* at residues E542K and E545K (exon 9) in the helical and H1047R (exon 20) in the kinase domains. Further studies in murine cells have confirmed the leukemogenic potential of these three mutations leading to an elevated activity of the PI3-kinase and the constitutive phosphorylation of the downstream targets. *Aims*. To investigate the possible involvement of the PIK3CA gene in leukemogenesis, we analysed 33 genomic DNA samples from 26 patients with BCR-ABL positive ALL, 2 chronic myeloid leukemia patients with blast crisis and 5 long-term cultured primary human BCR-ABL positive ALL cells for the presence of activating helical and kinase domains mutations. Additionally, AKT1 cDNA from the patients and primary Ph+ ALL long term cultures was analyzed for the shortly described transforming mutation E17K. *Methods*. Bone marrow or peripheral blood samples from newly diagnosed and imatinib naive patients (n=8) and patients after first (n=16) or second (n=4) relapse on imatinib were examined. Genomic *touch down* PCR amplifications of

exons 1,2,6,7,9,14 and 20 of the PIK3CA gene were performed. The PCR products were directly sequenced. The cDNA from these samples was examined for BCR-ABL kinase mutations and the AKT1 mutation E17K by dHPLC and sequencing. *Results*. A single nucleotide alteration in the PIK3CA gene located in exon 6 (A1173G) was detected in 4 of 28 (14%) patient samples and in 2 of the 5 (40%) analysed Ph+ ALL long-term cultures. A search of the SNP database revealed that A1173G is an annotated SNP (rs2230461). None of the 33 analysed samples harboured the known activating mutations in the PIK3CA gene. Mutations of the ABL kinase domain were not detected in newly diagnosed ALL but in 12 of 20 patients (38%) after first or second relapse on imatinib. In three of these patients the SNP in the PIK3CA gene was found. Furthermore, we failed to identify the transforming AKT1 mutation E17K in the Ph+ ALL patients and long-term cultures. *Summary and Conclusions*. The absence of mutations in the PIK3CA gene in a sizeable number of patients with advanced Ph+ALL suggest that such mutations are at best rare events. In conjunction with the absence of activating AKT mutations in this patient samples and long-term cultured primary human Ph+ALL cells, these data suggest that mutations of these members of the PI3K/AKT pathway do not play a significant causal role in resistance or disease progression of BCR-ABL positive ALL. Our data indicate that mechanisms other than mutations are involved in deregulation of PI3K/AKT signalling in BCR-ABL positive ALL, but do not exclude the possibility of functionally relevant mutations of other subclasses of PI3-kinases or other catalytic subunits (e.g. 110δ and 110γ).

0624

PROLIFERATIVE EFFECT OF HUMAN HEMOKININ-1 ON HUMAN PRE-B LYMPHOCYTE CELL LINE REH

S. Grassin Delyle,[1] E. Naline,[1] A. Buenestado,[1] L. Vallat,[2] F. Remy,[2] O.A. Bernard,[3] P. Debré,[4] C. Advenier,[1] P. Devillier,[1] H. Merle Béral[2]

[1]UPRES EA220, SURESNES; [2]Service d'Hématologie Biologique, Hôpital de la Pitié-Salpêtrière, PARIS; [3]INSERM EO210, Hôpital Necker, PARIS; [4]INSERM U543, Hôpital de la Pitié-Salpêtrière, PARIS, France

Background. Hemokinin-1 (HK-1), such as previously known substance P (SP), neurokinin A and neurokinin B, is a member of the tachykinin family. This peptide is encoded by the gene TAC4 which has been identified in lymphoid B hematopoietic cells of mouse bone marrow, where HK-1 promotes survival and expansion of B cell lineage. *Aims.* The aim of our study was to investigate the effects of HK-1 on differentiation, apoptosis and proliferation of the human pre-B lymphocyte cell line REH, in comparison to those of SP. *Methods*. REH cells were cultured in RPMI medium and stimulated by either SP or human HK-1 (1 nM to 100 µM) with or without LPS (5 ng/mL) in the presence of the peptidase inhibitor phosphoramidon (0.1 µM). After 12, 24 or 48 hrs, differentiation was assessed by extensive immunophenotyping, apoptosis quantified with annexin V and propidium iodure staining and proliferation measured with [3H]-thymidine incorporation. mRNA expression was evaluated with custom designed qRT-PCR assay. *Results.* Hemokinin-1 increased REH cell proliferation in a dose-dependent manner after 48 hrs of stimulation. This effect was potentiated in presence of LPS and phosphoramidon (maximal effect for HK-1 (1 µM): 7870 ± 2086 cpm versus 1723±841 cpm for control, n=3, $p<0.01$). Under these conditions, substance P had no effect. TAC4 mRNA was detected in REH cells. NK1 receptor and neutral endopeptidase mRNA were also abundantly expressed, whereas a low expression of TAC3 was observed. Expression of these mRNA was not affected by a 24 hrs stimulation with LPS (5 ng/mL). Effects of HK-1 (1 µM) on proliferation were however not abolished by a mixture of NK receptor antagonists (SR140333, SR48968 and SR142801 0.1 µM). TAC1 (coding for substance P), NK2 receptor and NK3 receptor mRNA were not found. Finally, under our experimental conditions, pre-B cells REH did not differentiate to B stage after stimulation with either hemokinin-1 or substance P. Apoptosis was not affected. *Conclusions*. Our results demonstrate that hemokinin-1 induces proliferation of human leukemic pre-B lymphocytes. TAC4 mRNA was detected in these cells concomitantly with a high expression of NK1 receptor mRNA. However, this receptor does not seem involved in the response to HK-1. In accordance with mouse studies in literature, substance P had no effect in this model. These data, together with previous biochip studies (Campo Dell'Orto *et al.*, 2007) showing TAC4 expression in 22 acute lymphoblastic leukemias, suggest a role for hemokinin-1 in physiological or pathological hematopoiesis.

Chronic myeloid leukemia - Clinical

Background. Preliminary observations indicate that elderly CML patients are treated with imatinib less frequently and at lower dosage. *Aims*. To verify these observations a subanalysis of the German CML Study IV, a randomised 5 arm study to optimize imatinib therapy by combination, dose escalation and transplantation, has been performed. *Methods*. Patients older and younger than 65 years were compared with regard to time to hematologic, cytogenetic and molecular remissions, imatinib dose and adverse events (AEs). *Results*. From July 2002 to February 2009 1273 patients with Ph+ or BCR-ABL+ CML in chronic phase were randomized, 302 patients for treatment with imatinib 400mg. Of the latter group 223 patients were evaluable, 58 aged ≥65 (26%) and 165 aged <65 years (74%). Median age was 69 and 49 years, respectively; the median daily dose in both groups was 400mg with ranges between 291 to 671mg and 231 to 720mg, respectively. In the older group 7 patients (12%) discontinued the randomized therapy and 5 (8.6%) died.

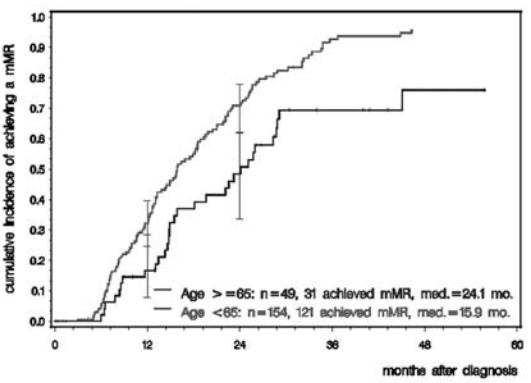

Figure 1. Time to major molecular remission.

In the younger group 7 patients (8.4%) discontinued the randomised therapy, 4 (2.4%) died and 4 (2.4%) received an allogeneic stem cell transplant. Euro risk score was in the elderly low in 13.8%, intermediate in 75.9% and high in 10.3% as compared to 44.2%, 40.6% and 13.3% in younger patients. 223 patients (58 and 165, respectively) were evaluable for hematologic, 198 (48 and 150, respectively) for cytogenetic and 203 (49 and 154, respectively) for molecular responses. Older patients achieved complete cytogenetic and major molecular responses later than younger patients. Median time to complete cytogenetic remission (CCyR) in the older group was 12.3 months versus 10.7 months in the younger group. Median time to major molecular remission (MMR)

was 24.1 months versus 15.9 months, respectively (image 1_102392). Some differences were observed in type, frequency and severity of AEs. 193 patients (50 and 143, respectively) were evaluated on common toxicity criteria (WHO). Hematologic AEs grade III/IV were documented slightly more often in the older than in the younger patients (leukopenia <2000/µL 4.2% vs. 2.8%; thrombocytopenia <50.000/µL: 4.2% vs. 2.8%, respectively). Non hematologic AEs were mainly gastrointestinal symptoms (29% vs. 28%) and myalgia (17% vs. 16%). Edema (17% vs. 23%) and neurologic symptoms (6% vs. 14%) were observed more often in younger patients, dermatologic AEs were seen more often in the elderly (17% vs. 13%). There was no evidence that non hematologic AEs grade III/IV were more frequent in older patients. *Conclusions*. These data show that imatinib 400mg is well tolerated also in the elderly (≥65 years) at similar dosages as in the younger patients, but the responses seem to be achieved later compared to younger patients.

0626

SOKAL SCORE AND RESPONSE TO IMATINIB IN EARLY CHRONIC PHASE CML: THE GIMEMA CML WORKING PARTY EXPERIENCE ON 559 PATIENTS

Background. Imatinib (IM) 400 mg daily is the standard treatment for chronic myeloid leukemia in early chronic phase (ECP): the results of the IRIS trial have shown for the IM 400 mg arm a 12-months probability of complete cytogenetic response (CCgR) of 69% but CCgR rates were different according to Sokal risk, being 76%, 67% and 49% in low, intermediate and high Sokal risk categories, respectively (Hughes *et al.*, NEJM 2003). At 84 months, overall survival was 86%, EFS and PFS (no ABP) 81% and 93%, respectively. The outcome was significantly influenced by the Sokal score: at 5 years, the estimated probability of progression to ABP was 17%, 8% and 3% for low, intermediate and high risk Sokal. However, the risk of progression to ABP was not significantly influenced by the Sokal risk in pts who obtained a CCgR (Druker *et al.*, NEJM 2006). *Aims*. To evaluate the long-term outcome, overall and by Sokal risk, of 559 IM treated, early chronic phase patients, treated according to 3 investigator sponsored trials of the GIMEMA CML Working Party.

Table.

	Low	Int	High	Total	P value
Patients, n (%)	219 (39)	216 (39)	124 (22)	559	/
Age, median (range)	44 (18-69)	61 (18-84)	52 (21-79)	52 (18-84)	/
CCgR 12M, %	85	83	65	80	<0.01
MMR 12M, %	62	58	44	56	<0.01
CCgR overall, %	95	94	79	91	0.11
CCgR overall, %	95		79	91	0.04
MMR overall, %	92	89	72	87	<0.01
EFS, %	79	74	50	71	<0.01
FFS, %	89	83	56	81	<0.01
PFS, %	95	89	85	90	0.02
OS, %	96	91	79	91	0.01

Methods. The 559 patients were enrolled in 3 simultaneously running trials of the GIMEMA CML WP: CML/022 (Clin Trials Gov. NCT00510926), phase III, IM 400 vs 800 mg in high Sokal risk; CML/021 (Clin Trials Gov. NCT00514488), phase II, IM 800 mg in intermediate Sokal risk; CML/023, observational, IM 400 mg. Response monitoring was based on conventional cytogenetic examination of bone marrow cells every 6 months and quantitative molecular (Q-PCR) evaluations (PB) after 3, 6 and 12 months on IM (every 6 months thereafter). Definitions: Major Molecular Response (MMR): BCR-ABL/ABL ratio < 0,1%IS. Failures (ELN criteria): no CHR at 6 months, no CgR at 6 months, no PCgR at 1 year, no CCgR at 18 months, loss CHR, loss CCgR, progression to accelerated/blastic phase and death. Events: failures, off-treatment for toxicity, refusal and lost to follow-up. *Results*. (Table): 559 patients were treated with IM 400mg daily (76%) or 800 mg daily (24%). Currently the median follow-up is 42 (1-64) months. Responses and outcome are significantly different by Sokal group; the overall CCgR rate was not different but comparing low and intermediate risk vs high the P resulted significant. The PFS of CCgR patients only, stratified by Sokal risk, is not significantly different but high risk CCgR patients have a significantly greater probability to fail treatment (ELN criteria) vs low and intermediate CCgR ones. *Conclusions*. These data confirms that the Sokal risk influences significantly responses and outcome. Moreover, high risk patients achieving a CCgR still has a significantly greater probability of failing IM with respect to non high risk ones.

Lee Moffit Cancer Center University of South Florida, TAMPA, USA; [5]University of Chicago, CHICAGO, USA; [6]Heinrich-Heine-University, DÜSSELDORF, Germany; [7]Medizinische Klinik III, FRANKFURT, Germany; [8]Novartis Pharmaceutical Corporation, FLORHAM PARK, USA; [9]Novartis Pharma AG, BASEL, Switzerland; [10]University of Bologna, BOLOGNA, Italy; [11]University of Medicine of Berlin, BERLIN, Germany

Background. Nilotinib is a potent and highly selective BCR-ABL inhibitor approved for treatment of Ph^+ CML patients in CP or accelerated phase who are resistant or intolerant to prior therapy including imatinib. *Aims*. This study evaluated the efficacy and safety of nilotinib in CML-CP patients resistant or intolerant to imatinib. *Methods*. Intolerant patients must not have had a major cytogenetic response (MCyR) at study entry, since only these patients could be appropriately assessed for the primary study endpoint. Primary endpoint was MCyR. Secondary endpoints included complete cytogenetic response (CCyR), complete hematological response (CHR), MCyR duration, overall survival (OS) and safety. In this analysis, we evaluated the kinetics and duration of CCyR, along with other parameters described below. *Results*. CML-CP patients (n=321) with a minimum follow-up of 19 months were evaluated. Overall, 70% of patients were imatinib-resistant and 30% were imatinib-intolerant. Patients were heavily pretreated, with 72% having received ≥600 mg/day imatinib prior to enrollment. Median duration of CML was 58 (range 5-275) months, and prior imatinib treatment was 32 (range 1-94) months. Median dose intensity of nilotinib was 790 (range 151-1110) mg/day, closely approximating the planned dose of 800 mg/day. Nilotinib led to rapid and durable hematologic and cytogenetic responses. CHR was achieved or maintained in 94% of patients, with 75% of patients with no baseline CHR achieving a new CHR, at a median of 1 month following initiation of nilotinib therapy. MCyR was achieved in 59% of patients at a median of 2.8 months following initiation of nilotinib therapy. In patients with a baseline CHR, 73% achieved MCyR. Overall, 44% of patients achieved a CCyR with a median time to first CCyR of 3.3 (range 0.9-23.5) months. Responses were durable, with 78% of patients maintaining MCyR, and 83% maintaining CCyR at 24 months. Overall, major molecular response (MMR) was achieved in 25% of patients. Estimated time to discontinuation of study drug was 578 (range 1-958) days. Estimated OS rate was 88% at 24 months. Nilotinib was generally well-tolerated and no new safety issues emerged with 24 months of follow-up. The most frequent grade 3/4 biochemical laboratory abnormalities were elevated lipase (17%), hypophosphataemia (16%), hyperglycemia (12%), and total bilirubin (8%). All biochemical abnormalities were transient and clinically asymptomatic. Grade 3/4 non-hematologic adverse events were infrequent,

with rash, headache, and diarrhea occurring in 2% of patients. The most common grade 3/4 hematological laboratory abnormalities were neutropenia (31%), thrombocytopenia (31%), and anemia (10%). Brief dose interruptions were successful in managing most adverse events. Pleural or pericardial effusions occurred in 2% of patients (all grades), and grade 3/4 were uncommon (<1%). *Conclusions*. These results demonstrate that nilotinib was highly effective, inducing rapid and durable cytogenetic responses in CML-CP patients failing prior imatinib therapy due to resistance or intolerance. Nilotinib was well tolerated with a favorable risk/benefit profile in this study. The estimated 88% OS rate at 24 months in this heavily pretreated patient population suggests that nilotinib is effective and can provide favorable long-term outcomes for patients.

SUBOPTIMAL RESPONSE TO IMATINIB 400 MG DAILY FOR CHRONIC MYELOID LEUKEMIA IN EARLY CHRONIC PHASE: A GIMEMA CML WP ANALYSIS OF 423 CONSECUTIVE PATIENTS

F. Castagnetti,[1] G. Gugliotta,[2] M. Breccia,[3] D. Sartor,[4] F. Cavazzini,[5] S. Rupoli,[6] P. Pregno,[7] M. Bruno,[8] F. Palandri,[1] M. Amabile,[1] N. Testoni,[1] G. Marzocchi,[1] A. Poerio,[1] I. Iacobucci,[1] G. Martinelli,[1] G. Saglio,[9] F. Pane,[10] M. Baccarani,[1] G. Rosti[1]

[1]Dept. of Hematology and Oncological Sciences, BOLOGNA; [2]University of Bologna, BOLOGNA; [3]University La Sapienza, ROME; [4]Hematology Unit, Ca' Foncello Hospital, TREVISO; [5]Chair of Hematology, University of Ferrara, FERRARA; [6]Chair of Hematology, Ospedale Regionale di Torrette, ANCONA; [7]Service of Hematology, Ospedale Maggiore di San Giovanni Battista, TORINO; [8]Division of Hematology, Ospedali Riuniti, REGGIO CALABRIA; [9]Medical Pathology, Ospedale Luigi Gonzaga, ORBASSANO; [10]Dept. of Biochemistry and Medical Biotechnology, University Federico II, NAPOLI, Italy

Background. Imatinib (IM) 400 mg daily is the standard treatment for Chronic Myeloid Leukemia (CML) in early chronic phase (ECP). The European LeukemiaNet (ELN) recommendations suggest, at given timepoints, when the treatment strategy should be changed ("failure" patients), or alert physicians "that the long-term outcome of the treatment would not likely be as favourable" ("suboptimal responders"). Marin *et al*. recently analyzed a single center experience based on 224 patients, reporting that suboptimal responders at 6 and 12 months may have a significantly poorer PFS and lower probability of Complete Cytogenetic Response (CCgR) (in this analysis, the 18-months suboptimal response was less useful). *Aims*. To investigate the outcome of suboptimal responders in a multicentric, nationwide experience. *Methods*. We performed an analysis within 2 simultaneously running trials of the GIMEMA CML WP: CML/022 (Clin Trials Gov. NCT00510926), phase III- imatinib 400 vs 800 mg in high Sokal risk; CML/023, observational - imatinib 400 mg. Response monitoring was based on conventional cytogenetic examination of bone marrow cells every 6 months and quantitative molecular (Q-PCR) evaluations (PB) after 3/6/12 months on imatinib (every 6 months thereafter). Definitions: suboptimal response at 6 months: Ph^+ >35%, in absence of failure; suboptimal response at 12 months: Ph^+ ≥1%, in absence of failure. Major Molecular Response (MMR): BCR-ABL/ABL <0,1%IS. Events: no PCgR at 1 year (for suboptimal responders at 6 months), no CCgR at 18 months, loss of CHR, loss of CCgR, progression, death for any reason. *Results*. 423 consecutive CML patients in ECP were treated with imatinib 400mg daily. Sokal score was low/intermediate/high in 52%/32%/16%, respectively. Median follow-up: 41 (1-64) months. 26 patients went off study within the first 6 months: 361 of the remaining 397 patients were evaluable for CgR at 6 months. 45 patients went off study within the first 12 months: 354 of the remaining 378 patients were evaluable for CgR at 12 months. At 6 and 12 months suboptimal responders were 20/361 (6%) and 31/354 (9%), respectively. At 6 months, the probability of CCgR, MMR and EFS for suboptimal/optimal responders was 60/98%, 50/93% and 60/90%, respectively. At 12 months the probability of CCgR, MMR and EFS for suboptimal/optimal responders was 81/100%, 68/96% and 68%/94%, respectively (all the differences observed were statistically significant). We have observed no difference in PFS and OS. This may be due to the still short period of observation and/or to the efficacy of second generation TKIs in this setting of patients. Finally, we observed no differences between 18-months suboptimal/optimal responders in terms of CCgR, MMR and EFS. *Conclusions*. The suboptimal responders within 12 months represent a minority of all the IM-treated patients (6%/9% at 6/12 months, respectively): responses and outcome are significantly worse with respect to the optimal ones. Our results confirm the predictive value on outcome of ELN recommendations, strengthening the need of an early intervention in this setting of patients to flatten the higher rate of negative events observed beyond 12 months on treatment. *Acknowledgements*. European LeukemiaNet, COFIN, University of Bologna and BolognAIL.

THE ORALLY ACTIVE AURORA KINASE A INHIBITOR MLN8237 HAS POTENT ACTIVITY IN PRECLINICAL MODELS OF RESISTANT CHRONIC MYELOID LEUKEMIA AND SIGNIFICANTLY INCREASES THE EFFICACY OF NILOTINIB

R. Kelly,[1] R. Swords,[1] S. Nawrocki,[1] D. Mahalingam,[1] E. Medina,[1] S. Smith,[1] S. Padmanabhan,[1] J. Ecsedy,[2] F. Giles,[1] J. Carew[1]

[1]Institute for Drug Development, SAN ANTONIO; [2]Millennium Pharmaceuticals, CAMBRIDGE, USA

Background. Novel therapies are urgently needed to prevent and treat tyrosine kinase inhibitor resistance in chronic myeloid leukemia (CML) particularly in cases expressing the gatekeeper T315I BCR-ABL mutation. Aurora A is a serine/threonine kinase that plays a key role in mitosis and is frequently overexpressed in leukemia. MLN8237 is a novel, orally available inhibitor of Aurora A currently under investigation in Phase I and II studies in solid tumors, lymphomas and myeloma. *Aims*. To evaluate the efficacy of MLN8237 alone and in combination with Nilotinib in preclinical models of CML. *Methods*. Ba/F3 cells expressing wild type (p210) with and without stable shRNA p53 knockdown and T315I BCR-ABL, Lama84 and K562 cells and primary human cells from CML patients were used. Apoptosis was evaluated by PI/FACS and cell viability was assessed by MTT assay. The prolonged *in vitro* effects of MLN8237 were assessed by MethoCult colony formation assays. Effects of MLN8237 on Aurora A activity, BCR-ABL activity and caspase activation and were measured by western blot analysis. An *in vivo* model of AML was generated by injecting K562 cells into the flanks of immunodeficient mice. *Results*. Nanomolar concentrations of MLN8237 potently inhibited the *in vitro* growth and survival of K562 and Lama84 cell lines and disrupted cell cycle kinetics as evidenced by the accumulation of G2/M and aneuploid cells prior to the onset of apoptosis. MLN8237 possessed equipotent *in vitro* and *in vivo* anticancer activity against Ba/F3 cells expressing wildtype (p210) and the mutant T315I form of BCR-ABL. Impairment of p53 function did not significantly affect the anticancer activity of MLN8237. MLN8237 equally inhibited survival of primary human CML cells from patients with unmutated and T315I-mutated BCR-ABL. Co-treatment with MLN8237 and nilotinib in K562 and Lama84 cell lines resulted in significantly greater apoptosis and more effective inhibition of clonogenic survival than treatment with either single agent. Similarly, co-administration of MLN8237 and nilotinib to immunodeficient mice bearing K562 xenografts was well-tolerated and resulted in significantly greater tumor growth inhibition than what was achieved by either agent alone. MLN8237 and nilotinib cooperated to reduce BCR-ABL activity as evidenced by a reduction of BCR-ABL autophosphorylation and its downstream target CrkL. The processing of caspases-9 and -3 to active forms was also potentiated by the combination. *Conclusions*. The combination of MLN8237 and nilotinib is very effective and well tolerated in preclinical models of CML and represents a novel therapeutic strategy for refractory CML, that is available orally and has the potential to suppress the emergence of T315I mutated clones. Based on this promising preclinical data, a clinical investigation of the efficacy of this combination in patients with refractory CML is warranted.

FINAL SAFETY ANALYSIS OF 1,793 CML PATIENTS FROM ENACT (EXPANDING NILOTINIB ACCESS IN CLINICAL TRIALS) STUDY IN ADULT PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA

F.E. Nicolini,[1] G. Alimena,[2] H.K. Al-Ali,[3] A.T. Turkina,[4] Z. Shen,[4] S. Jootar,[5] G. Smith,[6] C. De Souza,[7] J. Wang,[8] M. Berton,[9] T. Szczudlo,[8] D.A. Rizzieri[10]

[1]Hôpital Edouard Herriot, LYON, France; [2]University La Sapienza, ROME, Italy; [3]Universitat Leipzig, LEIPZIG, Germany; [4]Hematological Scientific Center, MOSCOW, Russian Federation; [5]Mahidol University, SALAYA, Thailand; [6]Leeds Teaching Hospital, LEEDS, UK; [7]University of Campinas, SÃO PAULO, Brazil; [8]Novartis Pharmaceutical Corportation, EAST HANOVER, USA; [9]Novartis Pharma AG, BASEL, Switzerland; [10]Duke University Medical Center, DURHAM, USA

Background. Nilotinib, a potent and highly selective BCR-ABL kinase

inhibitor, approved for the treatment of Ph+ chronic myeloid leukemia (CML) patients (pts) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy, including imatinib. *Aims*. The ENACT study, which is a Phase IIIb, open label, multicenter study, was initiated to obtain additional safety information in pts with imatinib-resistant or -intolerant CML in chronic, accelerated, or blast crisis (BC) phase in a clinical practice setting outside of a registration study. *Methods*. Pts received nilotinib 400 mg twice daily (BID). Dose escalation was not permitted. Pts who required dose reduction to 400 mg once daily due to toxicity were allowed to have a dose re-escalation to 400 mg BID after resolution of the adverse events (AEs), lack of response, or persistent disease at the investigator's discretion. Efficacy was provided by investigator assessment. Patients who failed dasatinib were also eligible. *Results*. A total of 1,793 pts enrolled in the ENACT study between Jan. 2006 and Oct. 2008, including 1,422 CP pts (79%), 181 AP pts (10%) and 190 BC pts (11%), from 293 study sites worldwide. The median age of all pts was 52 years and 69.2% of patients received prior imatinib ≥600mg/d. At study completion, 941 (53%) pts were continuing on nilotinib. Median (range) duration of nilotinib exposure was 266 (1-807) days for CP pts, 160 (6-736) days for AP pts, and 78 (1-642) days for BC pts; median average dose intensity was 783, 779 and 773 mg/day, respectively. The main reasons for treatment discontinuation were inadequate responses (22%) and AEs (14%). The majority of grade 3/4 AEs were hematologic and the most common hematologic toxicities were thrombocytopenia (24%) and neutropenia (17%). Non-hematologic AEs were mostly grade 1/2. Grade 3/4 non-hematologic AE's were infrequent and included headache, rash and nausea. Death on study was reported for 54 (3%) pts and occurred most frequently among those with BC (n=27; 14%). A low incidence of QT prolongation (defined as absolute QTcF > 500 msec; n=6, 0.3%) was observed overall. Grade 3/4 lipase elevation was observed in 115 patients (6.4%), but only 5 patients (0.3%) had lipase elevation associated with treatment discontinuation. Pancreatitis, including acute, occurred in 27 patients (1.5%) and was associated with discontinuation in 4 patients (0.2%). Only one patient (0.1%) had hyperglycemia associated with treatment discontinuation. Overall major cytogenetic response (MCyR) rates were consistent with those observed in earlier phase II trial at 45.1% in CP (34.2% CCyR,) 19.3% in AP and 19.5% in BC pts. Likewise, complete hematologic response (CHR) rates were 43% in CP, 22.1% in AP and 8.4% in BC pts. *Conclusions*. This final safety analysis of a large expanded access study further demonstrates that nilotinib is generally well tolerated in heavily pretreated pts in all phases of CML with safety profile reported in ENACT being similar to that observed in the pivotal phase II registration study.

NILOTINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS IN ACCELERATED PHASE (CML-AP) WITH IMATINIB RESISTANCE OR INTOLERANCE: 24-MONTH FOLLOW-UP RESULTS OF A PHASE 2 STUDY

A. Hochhaus,[1] F. Giles,[2] J. Apperely,[3] G. Ossenkoppele,[4] J. Wang,[5] N.J. Gallagher,[6] M. Baccarani,[7] J. Cortes,[8] H. Kantarjian,[8] P.D. Le Coutre[9]

[1]Med. Fakultät Mannheim der Universität Heidelberg, MANNHEIM, Germany; [2]San Antonio's Cancer Therapy & Research Center's Institute for Drug Development, SAN ANTONIO, USA; [3]Imperial College School of Medicine, LONDON, UK; [4]VU University Medical Center, AMESTERDAM, Netherlands; [5]Novartis Pharmaceutical Corporation, FLORHAM PARK, USA; [6]Novartis Pharma AG, BASEL, Switzerland; [7]University of Bologna, BOLOGNA, Italy; [8]MD Anderson Cancer Center, HOUSTON, USA; [9]University of Medicine of Berlin, BERLIN, Germany

Background. Nilotinib is a potent and highly selective BCR-ABL inhibitor approved for the treatment of Ph+ CML patients in chronic phase (CP) or AP who are resistant or intolerant to prior therapy including imatinib. *Aims*. This study evaluated the efficacy and safety of nilotinib (400 mg bid) in CML-AP patients resistant or intolerant to imatinib. *Methods*. Intolerant patients must not have had a major cytogenetic response (MCyR) at study entry. Primary endpoint was confirmed hematologic response (HR). Secondary endpoints included MCyR, time to progression (TTP), overall survival (OS), and safety. In this analysis, we also evaluated the kinetics and duration of response, as well as response by subgroup analysis based on peripheral blood basophil (< 20% vs. >20%), blast (>15% to <30% vs other values), and platelet count (>100×10^9/L vs. <100×10^9/L) at study entry. Patients with additional chromosomal abnormalities alone were not eligible. *Results*. CML-AP patients (n=137) with a minimum follow-up of 11 months were evaluated. Overall, 80% of patients were imatinib-resistant and 20% were imatinib-intolerant. Patients were heavily pretreated, with 79% having received ≥600 mg/day, and 45% receiving ≥800 mg/day imatinib prior to enrollment. Overall, 62% of patients exhibited BCR-ABL kinase domain mutations, and 31% of all patients exhibited other chromosomal abnormalities. Overall, 62% of patients exhibited BCR-ABL kinase domain mutations at study entry. Median dose intensity of nilotinib was 775 (range 150-1149) mg/day, closely approximating the planned dose of 800 mg/day. Nilotinib led to HR in 56% of patients, with 31% of patients achieving a CHR at a median of 1 month following start of therapy. MCyR was achieved in 32% of patients at a median of 2.8 months; CCyR was reached in 20% of patients and over 70% of these patients remained in CCyR at 24 months. Overall, no significant differences were found in responses based on pre-treatment basophil, blast, and platelet counts, respectively (Table 1). Estimated OS rate was 67% at 24 months. Overall, 6 (4%) patients received stem cell transplant after discontinuation of study drug. The safety profile of nilotinib did not change with longer follow-up, with 9% of patients discontinuing due to adverse events. The most frequent grade 3/4 laboratory abnormalities were neutropenia (42%), thrombocytopenia (41%), anemia (25%), elevated serum lipase (18%), and hypophosphatemia (14%). All biochemical abnormalities were transient and clinically asymptomatic. Grade 3/4 myelosuppression was predictable, and easily managed with a median onset of 14 to 29 days and a median duration of 8 to 26 days. Grade 3/4 non-hematologic adverse events were rare (<1%) and included nausea, fatigue, and diarrhea. *Conclusions*. These results demonstrate that nilotinib was highly effective, inducing rapid and durable hematologic and cytogenetic responses in CML-AP patients failing prior therapy. Nilotinib was well tolerated with a favorable risk/benefit profile in this study. The estimated 67% OS rate at 24 months in this heavily pretreated patient population with advanced disease suggests that nilotinib therapy is effective and can provide favorable long-term outcomes for patients.

Table 1. Response by subgroups.

	HR n (%)	CHR n (%)	MCyR n (%)
Basophil count			
< 20% (n = 116)	62 (53)	34 (29)	35 (30)

Businco, CAGLIARI; [9]Division of Hematology, Ospedale Luigi Gonzaga, ORBASSANO; [10]Dept. of Biochemistry and Medical Biotechnology, University Federico II, NAPOLI, Italy

Background. Age was a consistent poor prognostic factor in chronic myeloid leukaemia (CML) before the introduction of imatinib (IM). The efficacy and tolerability of IM reduced significantly the impact of age on outcome in late chronic phase (CP) patients and in early CP ones. However, as far as early CP, available data are based on limited number of patients and still the allocation to IM of older CML patients is not a

widely accepted practice. *Aim.* To asses the effects on the responses and outcome of IM in early CP, older patients. *Methods*. We performed an analysis by age groups of 3 concurrent clinical trials of the GIMEMA CML Working Party (Clin Trials Gov. NCT00514488, NCT00510926 and the observational trial CML/023). Overall, 559 patients have been enrolled between April 2004 and April 2007 and treated with IM 400 mg or 800 mg daily ((76% and 24%, respectively); the median age was 52 (extr.18 - 84) years, the median follow-up is currently 42 (extr.1-64) months. WHO has set at 65 years the older age: at diagnosis, 444 patients (79%, median age 46 years) were <65 years (group A) and 115 patients (21%, median age 71 years) ≥65 years (group B). The same proportion in both groups (23% and 25%, respectively) received 800 mg daily IM front-line. The Sokal risk distribution, as expected, was different in the 2 groups A and B: low in 47%/9%, intermediate in 30%/72%, high in 23%/19%. *Results*. In group A and B, the cumulative Complete Cytogenetic Response (CCgR) rate and the cumulative rate of Major Molecular Response (MMR) were 88%/84% and 82% / 81%, respectively. Failures (no CHR at 6 months, no CgR at 6 months, no PCgR at 1 year, no CCgR at 18 months, loss CHR, loss CCgR, progression to accelerated/blastic phase and death) were 68/444 (15%) and 23/115 (20%) for group A and B, respectively. Events (failures, off-treatment for toxicity, refusal and lost to follow-up) were 99/444 (22%) and 34/115 (31%) for group A and B, respectively. The rates of progression to accelerated/blastic phase were the same (5%) in both groups. The OS was 95% and 88% (all causes of death) and 97% and 96% (CML related deaths) for group A and B, respectively. All the differences were not statistically significant. *Conclusions*. Our analysis confirms, based on a large patients population and a proper period of observation, that age per se is not a negative prognostic indicator in early CP CML patients IM treated. Not the patient's age, but the presence of relevant comorbidities suggesting in advance a negative cost-to-benefit balance of IM, should be used as treatment choice advise.

Background. Patients with Ph+ CML who are resistant or intolerant to both imatinib and dasatinib have limited treatment options. One option is nilotinib, a potent and highly selective BCR-ABL inhibitor approved for the treatment of pts with Ph+ CML in chronic phase (CP) or accelerated phase (AP) who are resistant or intolerant to prior therapy. *Aims*. The ENACT study evaluated the safety and efficacy of nilotinib in patients with CML-CP, -AP, or -blast crisis (BC) who were either resistant or intolerant to both imatinib and dasatinib. *Methods*. Pts received nilotinib 400 mg BID. Dose escalation was not permitted. Pts requiring dose reduction to 400 mg once daily due to toxicity were allowed to dose re-escalate to 400 mg BID after resolution of the adverse events (AEs), lack of response, or persistent disease at the investigator's discretion. Efficacy was provided by investigator assessment. *Results*. A total of 292 pts with CML-CP (n=218; 75%), -AP (n=34; 12%) and -BC (n=40; 14%) were included in the analysis (16.2% of the entire study). Median time since first diagnosis of CML was 80, 75 and 59 months, respectively. Median duration of prior imatinib therapy was 35 months for CP, 27 months for AP and 23 months for BC pts, and the majority (61%, 80% and 73%) were imatinib-resistant with 71.6% of patients receiving prior imatinib ≥600mg/d. Median duration of prior dasatinib therapy was approximately 9.2 months for CP, 7.9 months for AP and 5.1 months for BC pts. Prior best major cytogenetic response (MCyR) was 14.2% CP, 5.8% AP and 10% BC pts. The median (range) duration of nilotinib exposure was 226 (4-758) days for CP, 111 (7-563) days for AP and 59 (3-553) days for BC pts, with 64%, 27% and 18% remaining on nilotinib at study completion, respectively. In total, 26 (12%) CP, 5 (15%) AP and 2 (5%) BC pts discontinued nilotinib due to AEs; 35 (16%) CP, 16 (47%) AP and 17 (43%) BC pts discontinued due to unsatisfactory therapeutic effect. Complete hematologic response (CHR) was achieved with nilotinib treatment in 40% CP, 10% AP and 3% BC pts. MCyR was achieved in 41% CP (CCyR 27.8%), 7% AP and 14% BC pts. These responses are similar to those observed in the total study cohort. A total of 285 pts (98%) experienced AEs and 196 pts (67%) experienced grade 3/4 AEs. The majority of grade 3/4 AEs were hematologic and the most common of these were thrombocytopenia (25%) and neutropenia (21%). On study, myelosuppression was not increased in pts treated with 2 prior TKI's. Non-hematologic AEs were mostly grade 1/2 and included rash, headache, and nausea. A total of 9 (3%) and 1 (0.3%) pts experienced pleural and pericardial effusion, respectively, of which 2 (1%) pleural effusions were grade 3/4. *Conclusions*. Nilotinib is highly active in Ph+ CML pts who have failed both prior imatinib and dasatinib therapy. These results support the significant efficacy and favorable tolerability of nilotinib in the treatment of CML even after 2 prior TKIs.

RELEASE OF INTRACELLULAR CALCIUM PRIMES CHRONIC MYELOID LEUKAEMIA CELLS FOR TYROSINE KINASE INHIBITOR -INDUCED APOPTOSIS

S.L. Forchap,[1] M. Pirmohamed,[2] R.E. Clark[1]

[1]Royal Liverpool University Hospital, LIVERPOOL; [2]The University of Liverpool, Department of Pharmacology, LIVERPOOL, UK

Background and Aims. The tyrosine kinase inhibitor (TKI) imatinib has become the standard of care in chronic myeloid leukaemia (CML). More recently, second generation TKI have become available, which are effective in imatinib refractory / intolerant patients, and there is considerable current interest in their use in newly diagnosed patients. Each TKI has slightly different activity and toxicity profiles, suggesting that combinations of TKI are worthy of investigation. Currently there are no clinical and very little *in vitro* data on TKI combinations. In initial experiments in CML cell lines, we showed that any pairing of dasatinib, nilotinib and imatinib leads to potentiation of the anti-proliferative and pro-apoptotic effects of TKI. The original aim of the present work was to investigate the mechanism of potentiation between different TKI, with particular reference to whether one TKI affects the cellular transport of another. In the light of our findings, this evolved into an investigation of the effect of TKI on intracellular $Ca2^+$. *Methods and Results*. Imatinib though not dasatinib and nilotinib is transported into cells by the influx transporter hOCT1, and amantadine and prazosin are widely used as blockers of hOCT1 function. In experiments on LAMA84 and 3 other CML cell lines using amantadine to block hOCT1, it was found that pre-treatment with amantadine 500 uM or prazosin 20 uM significantly reduced cell proliferation in response to 0.5 uM imatinib or 0.05 uM nilotinib or 0.02 uM dasatinib, concentrations which are ineffective when used alone (p<0.01 in each case). Similar significant effects on cell viability were also seen. However, this effect was not seen in 3 BCR-ABL negative leukaemia cell lines or in normal blood mononuclear cells. Amantadine alone significantly attenuated CrKL phosphorylation to 64% (p=0.003), suggesting a priming effect. BCR-ABL expressing cells are known to have decreased free releasable $Ca2^+$ in the endoplasmic reticulum (ER). In experiments with the $Ca2^+$ chelator EGTA and the ER $Ca2^+$ releasing agent thapsigargin, here it was found that amantadine caused an increase in intracellular $Ca2^+$, mediated by a combination of release from the ER and increase in capacitative $Ca2^+$ uptake. Addition of TKI to amantadine-primed cells further increased the intracellular $Ca2^+$ concentration. Furthermore, the effect of amantadine priming of TKI apoptosis was attenuated by both BAPTA (a membrane permeable $Ca2^+$ chelator) and Z-VAD-FMK (pan caspase inhibitor). *Summary and Conclusions.* These data suggest that release of free $Ca2^+$ in the cytosol may be an important mechanism of TKI-induced apoptosis. Taken with existing data, our findings suggest that, unlike normal and other leukaemic cells, BCR-ABL+ cells may be particularly vulnerable to rises in intracellular $Ca2^+$, and that $Ca2^+$ mobilisation may be an important component of TKI action. Further study of agents that alter intracellular $Ca2^+$ is warranted in CML.

A SHORT (12M) IFNA/IMATINIB COMBINED THERAPY CAN SECURE LONG TERM MAINTENANCE OF IMATINIB INDUCED CYTOGENETIC REMISSION AFTER DISCONTINUATION OF IMATINIB IN CML PATIENTS WITHOUT MOLECULAR REMISSION

I. Hardan,[1] S.M. Stemmer,[2] N. Amariglio,[1] M. Koren-Michowitz,[1] I. Levi,[3] A. Shimoni,[1] Y. Binenbaum,[1] D. Ben-Yehuda,[4] M. Bennett,[5] G. Rechavi,[1] A. Nagler[1]

Background. Imatinib Mesylate (IMA) is a gold standard of therapy in CML, however it is a crucial question whether this therapy can cure CML, as its discontinuation usually results in an early disease progression. Cessation of IMA therapy is feasible in about half of the patients that achieve complete molecular remission (CMR, the minority of CML patients), mainly those that were also previously exposed to IFN. IFN is active in CML. Responding patients can maintain long term complete cytogenetic remission (CCyR) off therapy, probably due to the effect of IFN on the early/dormant leukemic progenitor stem cells. Recently it was shown that IFN activates dormant haematopoietic stem cells to be exposed to therapy. *Aims*. To facilitate discontinuation of IMA therapy in patients with CML and complete cytogenetic, but not molecular, remission, by the addition of a short course of IFN to the therapy. *Methods*. CML patients with IMA induced CCyR (without molecular remission) of more than 12 month duration were randomized to either continue with IMA therapy and no cessation of therapy, or to add a weekly injection of IFN to the IMA therapy followed by cessation of therapy (study group). The study group patients received Peg- IFN (Pegasys, Roche pharmaceutics) for 52 weeks and stopped IMA therapy after 39 weeks of IFN therapy. *Results*. 12 eligible patients (9M,3F, median age 49y) were enrolled in the study group since January 2006. One patient stopped therapy after two weeks dew to intolerability, and 11 patients completed 52 weeks of Peg-IFN therapy (median dose/w/pt 135ug), stopped IMA therapy after 39 weeks of IFN therapy and are eligible for evaluation > 12 month off all therapy. The median time from diagnosis to enrolment for the 11 patients was 55 month (range 18-84 month). Five of the eleven patients were exposed to IFN at diagnosis, one had a previous allogeneic and one an autologous BMT. After a median follow up of 18 month (range 12-25) from discontinuation of IFN therapy (21 month from cessation of IMA therapy), six of the 11 patients (*responders*) are in a maintained CCyR of a median duration of 24 month (four patients > 24 month, one patient 18 month and one patient 12 month). Five patients (*non responders*) progressed (at 6-7 month after cessation of therapy in the five pt's) and regain complete remission following reintroduction of IMA therapy. The Sokal score of the responders is higher than in the non responders.The degree of molecular response was similar or responders and non responders. Five of the six patients that were exposed to IFN at diagnosis responded compared with two of five patients that were not exposed. *Summary*. The addition of a short (12 month) course of IFN to Imatinib can facilitate discontinuation of Imatinib therapy and secure a long term maintenance of Imatinib induced cytogenetic remission off all therapy in patients with CML and complete cytogenetic, without a molecular, remission. Exposure to IFN at diagnosis may be a positive predictor of success by this strategy.

0636

RESPONSE TO NILOTINIB IS SIMILAR IN IMATINIB-RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS IN ACCELERATED PHASE (CML-AP) WITH AND WITHOUT BCR-ABL MUTATIONS EXCEPT E255K/V, Y253H, AND F359C/V

Fakultät Mannheim der Uni, MANNHEIM, Germany

Background. CML-AP is an aggressive form of CML characterized by the presence of the Philadelphia chromosome (Ph^+), combined with hematologic progression and often additional cytogenetic abnormalities. Together, these factors contribute to lower response to therapy, an increased likelihood of imatinib resistance and BCR-ABL mutations, and poorer overall survival, than patients with chronic phase (CP) CML. Nilotinib is a selective, and potent BCR-ABL inhibitor, developed through structure-based drug design, with *in vitro* activity against most BCR-ABL mutants (excluding T315I), indicated for the treatment of CML-CP and -AP patients resistant or intolerant to prior therapy including imatinib. In a previous analysis of nilotinib in CML-CP patients with BCR-ABL mutations at baseline, mutations occurring at 3 specific amino acid residues (E255K/V, Y253H, or F359C/V) were shown to be associated with less favorable response to nilotinib. *Aims*. Imatinib resistant CML-AP patients were subdivided into groups who had *no mutation*, *all other mutations* excluding those occurring at these 3 residues, or the *E255K/V, Y253H,* or *F359C/V* mutations. *Methods*. Patients were analyzed for response to nilotinib, as well as time to disease progression (TTP) and overall survival (OS), by mutation group. *Results*. Overall, 62% (54/87) of patients had baseline mutations, including 31 (36%) patients with *all other mutations* and 17 (20%) patients with E255K/V, Y253H, or F359C/V mutations. Patients with T315I mutations (6/87, 7%) were excluded from this analysis. Response and outcomes to nilotinib by mutation type are summarized in Table 1. Hematologic response (HR), major (MCyR), and complete cytogenetic response (CCyR) were achieved within 12 months of therapy in 55%, 30%, and 18% of patients without mutations, 58%, 29%, and 6% of patients with all other mutations, and 24%, 6%, and 0% of patients with E255K/V, Y253H, or F359C/V mutations, respectively. Median time to MCyR was 3.3 months (range, 1.0-13.1) for patients without mutations and 2.5 months (range, 0.9-27.6) for patients with all other mutations. At 24 months, MCyR was maintained in 73% of patients without mutations and in 70% of patients with all other mutations. Median TTP was 9.9 months (range, 0.8 - 29.4) for patients without mutations, 19.5 months (range, 1.5-28.7) for patients with all other mutations, and 3.3 months (range, 0.4-12.2) for patients with E255K/V, Y253H, or F359C/V mutations. Estimated OS rate at 24 months was 50% for patients with no mutations, 70% for patients with all other mutations, and 42% for patients with E255K/V, Y253H, or F359C/V mutations.

Table 1. Nilotinib efficacy by mutation.

	HR n (%)	MCyR n (%)	CCyR n (%)	TTP (months) median (range)	Estimated OS at 24 months, %
No mutation (n=33)	18 (55)	10 (30)	6 (18)	9.9 (0.8-29.4)	50
All other mutations (n=31)	18 (58)	9 (29)	8 (26)	19.5 (1.5-28.7)	70
E255K/V, Y253H, or F359C/V mutations (n=17)	4 (24)	1 (6)	0 (0)	3.3 (0.4-12.2)	42

Conclusions. For CML-AP patients with BCR-ABL mutations (excluding E255K/V, Y253H, or F359C/V) following imatinib therapy, nilotinib

treatment resulted in rapid responses, and estimated TTP and OS, mirroring that of patients with no BCR-ABL mutations. Excluding T315I patients, patients with E255K/V, Y253H, or F359C/V mutations had poorer responses and outcomes than patients with other mutations. Alternative therapies such as transplant or clinical trials may need to be considered for these patients. The results of mutation analysis need to be considered in the clinical context of each individual patient when deciding the best treatment strategy to use.

0637

A STUDY OF PLASMA LEVELS OF IMATINIB AND ITS BIOACTIVE METABOLITE CGP-74588 REVEALS NO CORRELATION WITH SUBSEQUENT CLINICAL OUTCOME IN IMATINIB-TREATED CHRONIC MYELOID LEUKAEMIA

A. Davies,[1] A.K. Hayes,[1] A. Giannoudis,[1] C.M. Lucas,[1] K. Knight,[1] S.J. Watmough,[1] M. Pirmohamed,[2] R.E. Clark[1]

[1]Royal Liverpool University Hospital, LIVERPOOL; [2]Department of Pharmacology and Therapeutics, University of Liverpool, LIVERPOOL, UK

Background. In patients with chronic myeloid leukaemia (CML) receiving treatment with imatinib, 2 papers have reported that trough (24±3 hours post dose) plasma levels after either 29 days or 12 months of treatment are predictive of the clinical response. If verified in a general CML population, this could be clinically useful for identifying patients who might benefit from an early switch to alternative therapy. However, the value of serial plasma levels in predicting outcome has not been reported, and the interpretation of levels measured at time points earlier than trough has not been investigated. *Aims*. The aim of this work was to investigate whether plasma levels of either imatinib or its main bioactive metabolite CGP-74588 were predictive of subsequent cytogenetic and molecular response. *Methods*. All 60 unselected patients aged 16 or over with chronic phase CML diagnosed between July 2000 and September 2007 receiving 400 mg imatinib daily at our institution were included in the study. Twenty-two were currently excluded from the analysis, pending analysis of an earlier vaccination protocol, and incomplete follow-up data are currently available on a further 8 cases; leaving 30 patients used for this analysis. All gave informed consent. Samples were taken at routine clinic visits in the mornings, together with information on concurrent medications and timing of dose. Steady state plasma levels of imatinib and CGP-74588 were assessed by a novel UV-HPLC technique, that in quality control testing gives high concordance with results from mass spectrometry techniques. Individual patient 24 hour trough plasma levels were estimated from a sparse sampling data set consisting of 155 serial samples collected from May 2006. Responses were monitored at 12, 18 and 24 months by BCR-ABL transcript level using standard real-time quantitative PCR; a major molecular response (MMR) was defined as a BCR-ABL/ABL transcript ratio level below 0.1%. Complete cytogenetic response (CCR) was measured either by conventional cytogenetics or defined as a transcript ratio below 1%. *Results*. Overall, the median 24 hour trough plasma level for imatinib was 875ng/mL (range, 147-1542); and for CGP-74588 was 274ng/mL (range, 61-619). No significant difference was seen between the plasma imatinib levels of patients who did and did not achieve CCR, at either 12, 18 or 24 months of therapy. Similarly, no significant difference of imatinib levels was seen between patients who did and did not achieve MMR, at either 12, 18 or 24 months. Furthermore, no difference in plasma CGP-74588 levels was seen between cytogenetic or molecular responders versus non-responders. Exclusion of patients whose 24 hour levels were estimated from sparse sampling did not alter these findings. Analysis of serial samples taken at the same time of day from the same patient revealed a high degree of variation in the plasma imatinib and CGP 74588 concentrations. *Conclusions*. The present data do not confirm earlier reports of the predictive value of plasma imatinib concentrations. Further work is required to investigate how additional factors such as concomitant medications and diet modify plasma levels, before recommending its routine use in the clinic.

Background. Dasatinib is a 2nd generation tyrosine-kinase inhibitor active in CML patients resistant or intolerant to Imatinib; at present there is no data on its toxicity and efficacy in elderly patients. *Aims*. To highlight this issue, 83 patients treated with Dasatinib when aged > 60 years were retrospectively evaluated. Patients There were 50 males and 33 females, median age at Dasatinib start was 69.9 years (IR 65.5 - 73.9), Sokal Risk at diagnosis was low in 19 patients, intermediate in 33, high in 13 and not valuable in 18. Thirty-four patients (40.9%) were primarily resistant, 11 (13.3%) were intolerant and 38 (45.8%) had secondary resistance to Imatinib; all patients were in CP when Dasatinib was started. Median time from diagnosis to Dasatinib treatment was 87.8 months (IR 49.9 - 118.1); 44/83 patients (53.0%) had been pretreated with IFN ± Ara-C before Imatinib, all patients received Imatinib at standard dose (400 mg/day) followed in 48/83 (57.8%) by increased dose (600 - 800 mg/day) with an overall median period of Imatinib treatment of 50.5 months (IR 29.5-66.7). In addition, 21/83 patients (25.3%) received other 2nd line treatment (9 Nilotinib, 7 HU, 2 Imatinib + HU and 3 other drugs) before Dasatinib. *Results*. Starting dose of Dasatinib was 140 mg/day in 38 patients, 100 mg/day in 40 patients and ≥50 mg/day in 5 patients, respectively. After a median period of treatment of 14.3 months (IR 8.6-19.7) all patients were evaluable for toxicity; among 38 patients receiving 140 mg, grade 3 - 4 haematological and extra-haematological toxicities were reported in 19 (50.0%) and 13 (34.2%) patients, respectively; among 40 patients receiving 100 mg, grade 3 - 4 haematological and extra-haematological toxicities were reported in 9 (22.5%) and 7 (17.5%) patients, respectively. Pleuro-pericardial effusions (grade 3-4) occurred in 8 patients (21.0%) treated with 140 mg and in 5 patients (12.5%) treated with 100 mg. Overall, 8/83 patients (5 treated with 140 mg) permanently discontinued Dasatinib due to toxicity; a dose reduction was needed in 53/83 patients [37/38 (97.3%) treated with 140 mg and 13/40 (32.5%) with 100 mg]. As to response, 79 patients were considered evaluable (≥3 months of treatment) and 4 were considered as too early; eight patients (10.2%) did not have any response (including 4 patients with early Dasatinib discontinuation for toxicity), 24 (30.3%) achieved a Haematological Response only,. 26 (32.9%) achieved a Cytogenetic Response (CyR) (Major CyR in 11, Complete CyR in 15) and the remaining 21 (26.6%) also achieved a Molecular Response (MolR) (Major MolR in 11, Complete MolR in 10). *Conclusions*. Present analysis shows that Dasatinib, when employed at the current recommended dose of 100 mg/day, is effective and has a favourable safety profile also in heavily pretreated elderly subjects.

EFFICACY OF NILOTINIB AFTER IMATINIB FAILURE IN PH-POSITIVE CHRONIC MYELOID LEUKEMIA: IMPACT OF ADDITIONAL CHROMOSOMAL ABERRATIONS AND FREQUENCY OF BCR-ABL POINT MUTATIONS

T.D.K. Kim, S. Türkmen, M. Schwarz, P. Daniel, B. Dörken, P. Le Coutre

Charité - Universitätsmedizin Berlin, BERLIN, Germany

Background. Additional chromosomal aberrations (ACA) in Philadelphia chromosome-positive (Ph-positive) chronic myeloid leukemia (CML) are nonrandom and strongly associated with disease progression, but their prognostic impact and influence on treatment response is not clear. Point mutations of the BCR-ABL kinase domain are the clinically most relevant mechanisms of imatinib resistance. Nilotinib is a second-generation tyrosine kinase inhibitor with significant clinical activity in imatinib-resistant or -intolerant Ph-positive CML. However, resistance to nilotinib is a major reason for treatment failure and can be attributed to various mechanisms. *Aims*. We retrospectively investigated the influence of ACA on the clinical efficacy of nilotinib. *Methods*. Patients with Ph-positive CML and imatinib-resistance or -intolerance received nilotinib 400 mg bid. Dose was reduced if necessary. Bone marrow samples were analysed for cytogenetic aberrations before initiation of treatment and during follow-up. Sequencing of Abl was performed in a subset of patients. *Results*. 52 patients (median age 62 years, range 25 - 85) with a median follow-up of 16 months (range 1-50) were included in the present study. 37, 5 and 10 patients were in chronic phase (CP), accelerated phase (AP) and blast crisis (BC), respectively. Median duration of previous treatment with imatinib was 31.5 months (range 1-107). 85% had received hydroxyurea and 40% interferon. Median duration of nilotinib was 13.5 months (2-50). Overall, ACA were identified in 21 of 52 patients with 1 -3 aberrations per patient. More than half (62%) were so-called major route aberrations (+8, +Ph, i(17q), +19, -Y, +21, +17, -7). Whereas ACA were found in 24% of patients in CP, patients in AP or BC had ACA in 80% (p=0.001). 16 of 32 patients (50%) had point mutations in the abl kinase domain with no significant differences between patients with or without ACA. 8 of 13 patients carried both point mutations and ACA. There were no significant differences with respect to age, disease duration, duration of imatinib or nilotinib treatment between patients with or without ACA. Best response as assessed by cytogenetics was comparable with a major cytogenetic response in 62 and 68%, respectively. However, more patients with ACA failed nilotinib (38%) than patients without ACA (6%, p<0.005) and survival was significantly worse for patients with ACA. Overall survival at 36 months was 53 and 93% (p<0.005) for the whole cohort and 62 and 100% (p<0.005) for patients in CP, respectively. *Conclusions*. ACA impact negatively on the efficacy of nilotinib in patients with Ph-positive CML. Whether the decreased efficacy reflects instrinsic aggressiveness of the disease or rather specific mechanisms of resistance remains to be determined.

0640

THE ONCOGENIC KINASE BCR-ABL DIRECTLY REGULATES SPLICING EVENTS OF BCLX THROUGH A QUATERNARY COMPLEX COORDINATED BY NCK-BETA AND SAM-68 ADAPTER PROTEINS

E. Bracco,[1] V. Rosso,[1] S. Mussino,[1] F. Arruga,[1] S. Carturan,[1] F. Messa,[1] C. Panuzzo,[1] M. Lo Iacono,[1] P. Nicoli,[1] E. Messa,[1] A. Rotolo,[1] M. Spagna,[1] A. Morotti,[1] A. Balbo,[1] I.I. Iacobucci I.,[2] M.G. Martinelli,[2] D. Cilloni,[1] S.G. Saglio[1]

[1]*University of Turin, ORBASSANO (TO);* [2]*University of Bologna, Seragnoli Institute of Haematology, BOLOGNA, Italy*

Background. Philadelphia positive (Ph+) disorders, such as Chronic Myelogenous Leukemia (CML) are characterized by the presence of abnormal chromosome rising from translocation between chromosome 9 and 22 thus giving birth to a chimeric oncogenic protein named Bcr-Abl. This oncogenic kinase displays constitutive tyrosine kinase activity which leads to tyrosine residues autophosphorylation, in turn recruiting SH2 and/or PTB containing proteins. In the last decade Bcr-Abl targeted therapy has been successfully employed and, among currently available drugs inhibiting Bcr-Abl activity, Imatinb mesylate represents the most efficient. Despite the huge amount of data reporting the effects of Imatinib on signal transduction pathways (for example ERK1/2 and PI3K activation, CrkL phosphorylation etc[3DOTS]) in Ph+ leukemic cells rather few experimental evidences are available on the effects of Imatinib on adapter molecules. Therefore we are currently attempting to investigate such field. *Aims and Methods*. The significance of interactions occurring between Bcr-Abl and adapter molecules is still matter of debate. Most of the interactions so far described (CrkL, Grb2, PI3K p85 regulatory subunit etc[3DOTS]) appear to play a role in coordinating and integrating a plethora of signals which in turn lead to proliferation, cell survival and/or cytoskeletal organization. In the last years few, but very interestingly, data supporting the hypothesis that adapter molecules might also act as c-Abl catalytic regulators have been presented. By means of an interactomic approach, based on proteomic strategy using GST-Pull Down assay with an array of SH2 containing proteins, we attempted to gain insight into the role played by adapter molecules and Bcr-Abl interactions. *Results and Conclusions*. The data herein presented aims to demonstrate the presence of quaternary complex involving the SH2-SH3 containing adapter protein Nck-β, the oncogenic tyrosine kinase Bcr-Abl, the RNA binding protein Sam68 and the spliceosome ribonucleprotein hnRNPA1. The experimental evidences we have collected support the hypothesis of an Imatinib-dependent interaction occurring between Nck-β and Bcr-Abl. Furthermore, Pull Down experiments indicate an intermolecular interaction between Nck-β, Sam68, and hnRNPA1 supporting the idea of a novel complex Bcr-Abl/Nck-β/Sam68/hnRNPA1. Biochemical analysis carried-out by Pull-Down experiments has been further corroborated by immunofluorescence staining. RNA Pull Down assay suggest that the quaternary complex Nck-β/Sam68/hnRNPA1/Bcr-Abl might modulates splicing process of a gene encoding for a protein capable of regulating apoptosis events, such as Bcl-X whose function has been recently described as crucial in myeloproliferative disorders. Astoningshly, the data collected so far indicates that other mRNAs can be sequestered by the complex and among them Bcr-Abl mRNA itself. Taken together these results represent the first experimental evidences showing an interaction between the oncogene Bcr-Abl and Sam-68 leading to speculate a novel putative role played by Bcr-Abl in the intriguing and complex mRNA splicing scenario.

COMPARATIVE *IN VITRO* CELLULAR DATA ALONE IS INSUFFICIENT TO GUIDE CHOICE OF BCR-ABL INHIBITOR TO TREAT IMATINIB-RESISTANT CHRONIC MYELOID LEUKEMIA

P. Laneuville,[1] C. DiLea,[2] J. Mestan,[3] O. Yin,[2] P.W. Manley[4]

[1]*McGill University, QUEBEC, Canada;* [2]*Novartis Pharmaceuticals Corporation, FLORHAM PARK, USA;* [3]*Novartis Pharma AG, BASEL, Switzerland;* [4]*Novartis Institutes for BioMedical Research, BASEL, Switzerland*

Background. Following the paradigm of imatinib as a BCR-Abl kinase inhibitor for the treatment of chronic myeloid leukemia (CML) and an understanding of the molecular mechanisms that can lead to drug resistance, new targeted therapies have been developed to treat relapsed patients. Relapse is often caused by the emergence of clones that express mutant forms of BCR-Abl having single amino-acid substitutions in the kinase domain, which interfere with imatinib binding and reduce the sensitivity of the enzyme to inhibition by the drug. *Aims*. The potency of kinase inhibitors against wild-type and mutant forms of BCR-Abl is assessed by *in vitro* assays to quantify their effects on BCR-Abl-mediated protein phosphorylation and/or cell proliferation in murine haematopoietic cells expressing the BCR-Abl oncoprotein. It has been proposed (J Clin Oncol 2009) that such *in vitro* data could serve as a tool to help clinicians in their choice of drug to combat particular BCR-Abl mutants in CML patients. However, because this approach neglects other important variables, caution should be exerted when attempting to predict comparative clinical efficacies from *in vitro* data. To translate *in vitro* potency into *in vivo* efficacy, a drug must be delivered at adequate concentrations to its target in the relevant tissue compartment which, in the case of CML is the BCR-Abl kinase in the cytoplasm of leukemic cells located within the patient's bone marrow and/or peripheral blood. This process requires satisfactory absorption, metabolism, distribution and excretion properties, which are independent variables directly related to molecular structure. The purpose of this analysis was to understand these dynamics for nilotinib and dasatinib. *Methods*. A comparison of nilotinib and dasatinib was performed by analyzing *in vitro* and pharmacokinetic data. *Results*. In Ba/F3 cells, transfected to express 210 kDa wild-type, M315T or E255K BCR-Abl, nilotinib and dasatinib have been shown to have anti-proliferative mean GI50 values of 25 / 38 / 548 and 6.4 / 8 / 83 nM, respectively (Biochim Biophys Acta 2005). In patients, steady-state peak and trough plasma levels of nilotinib following oral administration of 400 mg q12h are 3600 and 1700 nM (NEJM 2006). For comparative purposes, following an oral 70 mg q12h regimen of dasatinib, day 8 peak and trough plasma levels are approximately 90 and 10 nM (J Clin Pharmacol

2008). Consequently at peak levels, nilotinib is present at concentrations 144-, 94- and 6.5-fold greater than its GI50 value for the inhibition of wild-type, M351T and E255K respectively, compared to ratios of 14-, 11- and 1.1-fold for dasatinib. At trough levels, the drug-concentration: GI50 ratios for nilotinib are also greater than those for dasatinib for all three forms of BCR-Abl (Table 1). *Conclusions*. Although dasatinib is more potent *in vitro*, under current dosing regimens nilotinib delivers higher plasma drug concentrations to CML cells, predicting it would be more effective against any of the three forms of BCR-Abl considered. Although this analysis does not account for parameters such as protein binding and cell influx/efflux, it illustrates the inadequate predictability of *in vitro* data alone as a tool for choosing second generation agents.

Table 1. Plasma levels and GI50 values.

BCR-Abl	Proliferation GI_{50} nM		Peak level:GI_{50} ratio		Trough level:GI_{50} ratio	
	Nilotinib	Dasatinib	Nilotinib	Dasatinib	Nilotinib	Dasatinib
p210 *wt*	25	6.4	144	14	68	1.6
M315T	38	8.0	94	11	44	1.3
E255K	548	83	6.5	1.1	3.1	0.12

Background. Nilotinib is a selective and potent BCR-ABL inhibitor, developed through structure-based drug design, with *in vitro* activity against most BCR-ABL mutants (excluding T315I) indicated for the treatment of Philadelphia chromosome positive (Ph^+) CML patients in CP or accelerated phase (AP) resistant or intolerant to prior therapy including imatinib. In a previous analysis of nilotinib in patients with BCR-ABL mutations, mutations occurring at 3 specific amino acid residues (E255K/V, Y253H, and F359C/V) were shown to be associated with less favorable response to nilotinib. *Aims*. Imatinib resistant patients were subdivided into groups who had "no mutation", "all other mutations" excluding those occurring at these 3 residues, or the "E255K/V, Y253H, or F359C/V" mutations, at baseline. Patients with T315I mutations were excluded from this analysis. *Methods*. Patient groups were analyzed for kinetics and durability of cytogenetic and molecular response to nilotinib, as well as time to disease progression (TTP) and overall survival (OS). *Results*. In patients with no mutation, all other mutations, or E255K/V, Y253H, F359C/V mutations, complete cytogenetic response (CCyR) was achieved in 24% (22/91), 17% (13/79), and 0% (0/27) of patients by 3 months, 31% (28/91), 32% (25/79), and 0% (0/27) by 6 months, 34% (31/91), 42% (33/79), and 0% (0/27) by 9 months, and 40% (36/91), 43% (34/79), and 0% (0/27) by 12 months, respectively. Median time to CCyR was 3.2 months (range, 1.0-23.5) for patients with no mutations, and 5.5 months (range, 0.9-22.1) for patients with all other mutations. No patients with E255K/V, Y253H, or F359C/V mutations achieved CCyR with a median follow-up of 6.5 months. At 24 months, CCyR was maintained in 73% of patients with no mutation and in 88% of patients with all other mutations. Major molecular response (MMR) was achieved within 12 months of treatment in 28% (23/82) of patients with no mutation, 28% (19/69) of patients with all other mutations, and 4% (1/25) of patients with E255K/V, Y253H, or F359C/V mutations. The dynamics of BCR-ABL transcript level reductions for each group are shown in Table 1. Median TTP was not reached for patients with no mutations, was 28.6 months (range, 0.3-29.9) for patients with all other mutations, and 7.6 months (range, 0.5 -29.9) for patients with E255K/V, Y253H, or F359C/V mutations. Estimated OS rate at 24 months was 88% for patients with no mutations, 83% for patients with all other mutations, and 92% for patients with E255K/V, Y253H, or F359C/V mutations. *Conclusions*. For patients with BCR-ABL mutations (excluding E255K/V, Y253H, or F359C/V) resistant to imatinib therapy, nilotinib treatment resulted in rapid and durable cytogenetic responses, and estimated TTP and OS, mirroring that of patients with no mutations. Patients with E255K/V, Y253H, or F359C/V mutations had lower and less durable responses, and shorter TTP (but comparable OS) than patients with other mutations. Alternative therapies may be considered for patients with these uncommon mutations. However, the results of mutational screening should only be considered within the greater clinical context for each patient when deciding the best treatment strategy to use.

LONG-TERM SURVIVAL OF PATIENTS WITH LATE CHRONIC PHASE PH-POSITIVE CHRONIC MYELOID LEUKEMIA RECEIVING TYROSINE KINASE INHIBITOR THERAPY AFTER INTERFERON FAILURE

A.G. Turkina, O.V. Stakhina, G.A. Gusarova, E.S. Zakharova, E.Yu. Chelysheva, O.Yu. Vinogradova, T.I. Kolosheinova, C.R. Goryacheva, L.Yu. Kolosova, E.V. Domracheva, A.V. Zakharova, E.M. Abakumov, S.M. Kulikov, N.D. Khoroshko

Hematology Research Center, RAMS, MOSCOW, Russian Federation

Background. Imatinib, a potent selective bcr-abl inhibitor, introduced into clinical practice in 2001, provides an effective treatment for chronic myelogenous leukemia (CML). Data from three-years follow-up of patients receiving imatinib after interferon (IFN) failure, demonstrated that Major Cytogenetic Response (MCyR) and Complete Cytogenetic Response (CCyR) were the most important prognostic factors for survival. The aim of this study was to evaluate long-term survival and stability of hematological response (HR) and MCyR in chronic phase (CP) CML patients treated with imatinib after IFN-α failure with 7-years follow-up in one-center (Hematology Research Center, Moscow, Russia). *Patients and treatment*. This non-randomized, open-label trial recruited patients from July 2000 through September 2001. In total, 79 patients with CP CML resistant/intolerant to IFN-α were enrolled. Median age was 39 (15-64) years old, male:female ratio 41:38. Median time from diagnosis to treatment was 36,1 (3-160) months: <1 year - 10 patients (12,8%), 1-5 years - 51 patients (64,5%), >5 years - 18 patients (22,7%). Initial imatinib dose was 400 mg/day. Median duration of imatinib treatment at the time of analysis (June 2008) is 58,1 (2-87) months. Patients characteristics are listed in Table 1. *Results*. 62 of 79 patients (78,4%) were alive on June 2008. Complete hematological response (CHR) was achieved in 74 (93%) patients with a median time to response of 3 (1-21) months. Failure to achieve HR after 3 moths of therapy was determined to be a strong negative prognostic factor associated with CML progression ($p<0.05$). MCyR was achieved in 51 (65%) pts, including Complete Cytogenetic Response (CCyR) in 44 (56%) pts. Minor CyR was achieved in 3 (4%), minimal in 10 (12%) pts and 15 patients failed to achieve CyR. Median time to CCyR was 9 (5-53) months. Of 74 CHR patients 32 (43%) lost CHR. In those patients median duration of response was 38 (2-82) months. Thus, primary and secondary hemato-

logical resistance was diagnosed in 7% and 43% of patients, with primary and secondary cytogenetic resistance in 35% and 31%, respectively. Clonal evolution in Ph^+ clones was observed in 8% of patients and found to have no prognostic importance for survival. Imatinib therapy was discontinued in 44 (56%) and continuing in 35 (44%) patients with stable CCyR (21 patients on dose 400 mg/day, 9 on 600 mg/day, and 3 on 800 mg/day; 2 on 300mg/day). 27 (34%) patients were switched to second line tyrosine kinase inhibitors (TKI) (10 patients to nilotinib with median duration of treatment 10 months, 12 patients to dasatinib with median duration of treatment 26 months, 2 patients to bosutinib); 2 patients were subsequently switched to third line TKIs. In total, 17 patients died (15 patients with progression to Accelerated Phase/Blast Crisis, 1 patient with brain hemorrhage, 1 patient with hepatocellular carcinoma). It is noteworthy that only one patients died after second line TKIs initiation. In June 2008 median duration of the disease from diagnosis was 105,4 (14-231) months; 22 patients are alive for more than 10 years after diagnosis. Estimated 8-year survival of patients receiving TKIs after IFN-αH failure is 78%. *Conclusions*. Imatinib resulted in significant improvement of survival in CML patients resistant or intolerant to IFN. In majority of patients achieving MCyR on imatinib therapy it was sustained longterm with stable MCyR and CCyR associated with significantly increased survival. Second line of TKIs will further improve prognosis of CML patients. Long-term follow-up of CML patients receiving TKI therapy demonstrated preservation of residual clones of Ph-negative cells and a capacity of normal hematopoesis recovery on TKI treatment.

PREGNANCY AMONG THE PATIENTS WITH CHRONIC MYELOID LEUKEMIA ON IMATINIB THERAPY

E.Y. Chelysheva,[1] A.G. Turkina,[1] G.A. Gusarova,[1] T.I. Kolosheinova,[1] M.A. Sokolova,[1] N.D. Khoroshko,[1] V.M. Pepelyaeva,[2] L.V. Gavrilova[3]

[1]Hematology Research Center, Moscow, Russia, MOSCOW; [2]Regional Clinical Hospital, PERM; [3]Hematology Department of Clinical Hospital SARANSK, Russian Federation

Background. The imatinib therapy has improved a survival rate and a quality of life for the majority of CML patients. Therefore the ability to become parents is one of the crucial issues for the patients of childbearing potential. Current view is to avoid pregnancy because of a possible fetus injury. Furthermore, imatinib discontinuation at pregnancy period can be critical for possible disease relapse. Clinicians are forced to find individual decisions for the patients wishing to maintain pregnancy despite of all the risks. We report about the 6 cases of successful pregnancy of the females and the 6 cases of pregnancy in the partners of the males on imatinib therapy. *Results*. We observed 6 females with CML, 5 in chronic phase (CP), 1 in accelerated phase (AP) at diagnosis, age 27-36 years (median 31.8), disease duration 30-112 months (median 86.6), imatinib treatment period 25.7-84.2 months (median 44.4). Imatinib dose was 400 mg for 3 of 6, 600 mg for 2 of 6 and 1 of 6 had a temporal 3 weeks treatment interruption at the impregnation. 5 of 6 females had been exposed to imatinib for the first 4-8 weeks of pregnancy (except 1 of 6 mentioned above). After pregnancy identifying the patients expressed their strong wish to keep the pregnancy and the imatinib treatment was stopped. At that moment their CML status was the following: complete molecular response (CMR) -3 of 6, major molecular response (MMR)- 1 of 6, only partial cytogenetic response (PCyR) - 2 of 6. During the pregnancy period 2 patients remained in CMR but after the delivery both of them had only MMR. 1 patient lost CMR and kept the complete hematologic remission (CHR), cytogenetic examination wasn't done during the pregnancy. 1 patient lost MMR and had a cytogenetic relapse (CyR) (Ph^+ cells 59%). 2 patients lost PyCR and 1 of them had a partial hematologic response (PHR). For those 3 patients with CyR and PHR a maintenance treatment by interferon α 3 ME daily was applied during pregnancy. All 6 females delivered healthy infants at term, restarted imatinib immediately after delivery and didn't breastfeed. At present time the infants are from 3 months to 2.7 years old with no abnormalities in their development. There were also 6 pregnancy cases in the partners of the CML CP males receiving imatinib therapy. The patients age was 26-36 years (median 31.5), disease duration 21-93 months (median 42.8), imatinib treatment period 13-78 months (median 26.2). Imatinib dose was 400 mg for 4 of 6 patients, 600 mg for 2 of 6 at impregnation moment. In all 6 cases the healthy infants were born at term, now the children are from 6 months to 5.5 years old with no abnormalities in their development. *Summary*. We demonstrated that despite of all risks the successful outcomes of pregnancy in CML patients are possible. Pregnancy management is still an individual decision for every patient. An experience exchange and careful study of every case is significant for developing the further strategy for this actual issue.

Myeloproliferative disorders - Clinical

INCREASED RISK OF LYMPHOID MALIGNANCIES IN PATIENTS WITH PHILADELPHIA CHROMOSOME-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Antonioli,[1] M.C. Susini,[1] G. Masala,[2] P. Guglielmelli,[1] L. Pieri,[1] S. Caini,[2] D. Palli,[2] C. Bogani,[1] A. Pancrazzi,[1] G. Longo,[1] A. Bosi,[1] A.M. Vannucchi[1]

[1]University of Florence, FLORENCE; [2]ISPO Cancer Res Prevent Institute, FLORENCE, Italy

Backgroud. Relatives of patients with myeloproliferative neoplasms (MPN) have a 5- to 7-fold increased risk of developing polycythemia vera (PV), essential thrombocythemia (ET) and MPN-NOS (Landgren, Blood 2008), suggesting susceptibility predisposing genes. Cases of association of MPN with lymphoproliferative disorder (LPD) have been reported. *Aims*. The aim of this study was to assess whether presence of a MPN also carried an increased risk of developing a LPD. *Methods*. Clinical records of 820 MPN patients referred to the Hematology Department of Florence from 1980 to 2008 were examined. Diagnosis was reviewed according to WHO criteria for both MPN and LPD. For each subject, the period at risk was calculated since date of diagnosis of MPN to diagnosis of LPD, death, or last follow-up. Expected numbers of LPD incident cases were calculated based on 5-year age groups, gender and calendar time specific cancer incidence rates in the general population of the same area, provided by the Tuscany Cancer Registry covering an area of approx 1,160,000 inhabitants. Standardized Incidence Ratios (SIR), i.e. the ratio of Observed to Expected cases in MPN, were computed to estimate the relative risk of developing LPD compared to the general population. Analyses were carried out for the whole series and then separately for ET and PV, gender and JAK2V617F genotype. *Results*. We considered 353 patients with PV and 467 with ET, median age at diagnosis 59 yrs. Median follow-up was 3.3 yrs, corresponding to 4,421 person years (PY), 1,882 and 2,539 in PV and ET, respectively. JAK2V617F mutation was found in 70%. We identified 37 patients who developed a LPD (4.5%), 12 with ET (1.4%) and 25 with PV (3.0%). Twenty-six patients had a MGUS, but they were not analyzed because of wide occurrence of this abnormality in the general population. Of the 11 LPD considered there were 4 CLL, 5 NHL and 2 plasma cell disorders (PCD); 7 cases occurred in PV and 4 in ET patients. The median interval time from diagnosis of MPN to LPD was 68 months. A LPD was more common in PV than ET (2% vs <1%, p=0.02). A three-fold increased risk of LPD emerged in the whole series (SIR 3.44; 95% CI 1.90-6.20), ranging from 2.86 (95% CI, 0.72-11.43) for PCD to 12.42 (95% CI 4.66-33.09) for CLL. The risk of developing LPD was increased five-fold among JAK2V617F mutated patients (5.46, 95%CI 2.45-12.15) while there was only one case among wild-type patients (SYR 2.60, 95% CI 0.37-18.43). According to gender, males had significantly increased risk (4.52, 95%CI 2.26-9.03). Sorted $CD19^+/CD20^+/CD23^+$ cells from one CLL patient harbored JAK2V617F mutation with allelic burden comparable to granulocytes; similarly, the V617F allele was found in cells of one mediastinal lymphoma unlike one case of ileal lymphoma where cancer cells were JAK2 wild-type. *Conclusions*. These data indicate that risk of developing a LPD is significantly increased in PV and ET patients compared to the general population, which might be ascribed to the genetic instability that characterizes MPN hematopoietic cells, particularly in association with JAK2V617F mutation.

0646

THE LONG-TERM DURABILITY OF MOLECULAR RESPONSES IN PATIENTS WITH FIP1L1-PDGFRA CHRONIC HEOSINOPHILIC LEUKEMIA TREATED WITH IMATINIB: THE ITALIAN HES0203 EXPERIENCE AFTER A 4-YEAR FOLLOW-UP

M. Rondoni,[1] D. Cilloni,[2] S. Paolini,[3] E. Ottaviani,[3] F. Messa,[4] P.P. Piccaluga,[5] S. Merante,[6] F. Buccisano,[7] M. Titibelli,[8] E. Vigna,[9] A. Spadea,[10] E. Messa,[11] F. Pane,[12] G. Saglio,[13] F. Lauria,[14] M. Baccarani,[15] G. Martinelli[16]

Background. Imatinib mesylate is the first line treatment for hypereosinophilic syndrome with FIP1L1-PDGFRα (F/P) fusion gene. The use of imatinib modified the natural history of the disease, independently from the organ damage present at diagnosis time or from the type of transcript detected with molecular sequencing. However, few clinical and molecular data on the outcome of these patients based on prospective and controlled trials are available. *Aims*. to evaluate the long term follow up of patients with FIP1L1-PDGFRA positive CEL treated with imatinib. *Design and Methods*. A prospective phase 2 multicenter study of the use of imatinib 400 mg/daily in patients with hypereosinophilic syndrome, irrespectably of F/P status was established in 2001. Hypereosinophilic syndrome was defined according to Chusid criteria. The presence of F/P transcript was investigated on bone marrow cells using a nested reverse transcriptase polymerase chain reaction (RT-PCR). Patients at diagnosis were systematically screened for organ damage with instrumental evaluation (chest radiography, echocardiogram, abdomen ultrasonography) and for the presence of symptoms. 72 patients were treated with IM 100 to 400 mg daily; the 33 F/P positive patients (F/P+) were monitored every three months for two years then every six months using nested RT-PCR. The observation period of F/P^+ patients ranges between 23 and 85 months (median 48 months). *Results*. There were 32 males and one female patients. Organ involvement was recorded in 42% of F/P^+. After imatinib therapy all patients achieved a complete hematologic response (CHR) in less than one month, and PCR negativity in a median time of 3 months (range 1-9). They became negative for organ localizations and free of symptoms. All patients who continue imatinib therapy remain in CHR and RT-PCR negative, with a dose of 100-400 mg daily. From September 2007 all patients except one (late responder) were treated with 100 mg daily. In six patients IM treatment was discontinued for variable period for different reasons, and in 5 cases the fusion transcript became rapidly detectable. CHR was maintained, other than in one case. The transcript was again undetectable upon treatment resumption, other than in one case. All samples were valuable for molecular analysis. Fusion gene sequencing demonstrate an extreme variability of FIP1L1-PDGFRA junction sequences, but no evidence of correlation was noted with kinetic of molecular response or with the presence at diagnosis of peculiar organ involvement. More complexity of transcript is noted in patients with longer history of disease prior to imatinib therapy. Transcript of the only female patient is the same of one of the males. *Interpretation and conclusions*. With this large series of patients we can confirm the extremely sensitivity of F/P^+ CEL to imatinib therapy, without any significant toxicity after protracted therapy and without acquisition of resistance. The complexity and variability in FIP1L1-PDGFRα transcripts seems to no correlate with phenotype of disease, even though different kinetic of response have been observed. Prolonged clinical and molecular follow-up of these patient is essential to understand the CEL disease.

0647

REDUCED SURVIVAL IN PATIENTS WITH PRIMARY MYELOFIBROSIS IS PREDICTED BY A LOW BURDEN OF JAK2V617 MUTATED ALLELE

P. Guglielmelli,[1] G. Barosi,[2] G. Specchia,[3] A. Rambaldi,[4] F. Lo-Coco,[5] E. Antonioli,[1] L. Pieri,[1] A. Pancrazzi,[1] V. Ponziani,[1] F. Delaini,[4] E. Ammatuna,[5] V. Liso,[3] A. Bosi,[1] T. Barbui,[4] A.M. Vannucchi[1]

[1]Univeristy of Florence, FLORENCE; [2]IRCCS Pol. San Matteo, PAVIA; [3]Hematology, University, BARI; [4]Hematology, Osp. Riuniti, BERGAMO; [5]Hematology, University Tor Vergata, ROMA, Italy

Backgroud. Sixty-percent of patients with primary myelofibrosis (PMF) harbor a JAK2V617F mutation. A mutated genotype has been variably associated with hematological and clinical characteristics, including reduced overall survival (OS) (Campbell P; Blood 2005) and increased risk of leukemia (Barosi G, Blood 2007). Recently, an inferior survival was found in mutated patients with low burden of mutated JAK2 allele (Tefferi A, Leukemia 2008). *Aims*. The aim of the study was to evaluate the impact of V617F allele burden on disease progression and outcome in patients with PMF. *Methods*. Presence and burden of JAK2V617F allele was evaluated by real-time quantitative PCR in DNA obtained from gradient-purified granulocytes of 186 PMF patients who were evaluated at the time of diagnosis, in the absence of any treatment. Mutational status and mutated allele burden were correlated with baseline hematological and clinical characteristics and with variables associated with disease progression, including time to development of anemia, leukocytosis or leukopenia, thrombocytopenia, massive splenomegaly, transformation to acute leukemia and OS. *Results*. JAK2V617F mutation was found in 68.2% of the patients; median allele burden was 54% (range 5-100%). Frequency of patient according to V617F burden was 13.3% in the first quartile, 33.8% in the second, 24.4% in the third, and 28.3% in the fourth. JAK2V617F-mutated patients had significantly higher leukocyte (p=0.009) or platelet (p=0.02) count and hemoglobin level (p<0.0001) compared to wild-type; anemic patients (hemoglobin <10g/dL) were significantly less among JAK2V617-mutated (12% versus 26%, p<0.007). JAK2V617F mutated patients were preferentially found in the Dupriez low risk category (p=0.017), likely as a result of mutated status association with higher hemoglobin level, while there was no difference according to risk categories of Cervantes score. Time to anemia and leukopenia was significantly longer in JAK2V617F-mutated patients compared to wild-type. Converesely, time to both anemia and leukopenia was significantly shorter in mutated patients belonging to the lower quartile as compared to patients in upper quartiles (p<0.01) as well as to wild-type patients (p<0.01). After a median follow-up of 17.2 months, 23 patients (12.3%) had died, 15 of whom because of leukemia. A JAK2V617F mutated genotype did not impact on leukemia transformation or OS. In multivariate analysis OS was predicted only by age (p<0.0001) and leukocytosis (p=0.001). However, OS was significantly reduced in patients in the lower V617F quartile as compared to either mutated patients with >25% allele or wild-type ones. In multivariate analysis that included patient stratification according to V617F allele burden, factors significantly associated with reduced survival were age (p=0.002), leukocytosis (p=0.02), a blast count >1% (p=0.003) and a JAK2V617F burden <25% (p=0.002). Causes of death in the 1-25% quartile were represented by thrombosis, infections and multi-organ failure, and no case of leukemia was recorded. Conversely, leukemia transformation occurred at similar rate in mutated patients with >25% allele and wild-type ones. *Conclusions*. These data indicate that a low JAK2V617F allele burden in PMF is associated with a mainly myelodepletive rather than myeloproliferative hematological phenotype and represents an independent factor associated with shorter survival due to causes other than leukemia.

POMALIDOMIDE IN MYELOFIBROSIS: RESULTS OF A PHASE-1 DOSE-SEEKING TRIAL

R.A. Mesa,[1] A. Pardanani,[1] K. Hussein,[1] R. Gale,[2] S. Schwager,[1] M.R. Litzow,[1] W. Hogan,[1] A. Tefferi[1]

[1]Mayo Clinic, ROCHESTER; [2]Celgene, SUMMIT, NJ, USA

Backgroud. Pomalidomide (POM) is an immune-modulatory drug (IMiD) recently tested in persons with myelofibrosis (MF). POM appears safer and more effective than other IMiDs in MF including thalidomide (Br J Haematol 2002;117:288) and lenalidomide (Blood 2006;108:1158). An adaptive phase-2 trial of POM (0.5 mg or 2.0 mg/d for 28 d (with or without prednisone; Blood 2008; 112[11]:a663) showed efficacy in MF-associated anemia with no dose- limiting toxicities (DLTs). We performed a subsequent dose-escalation trial to determine whether higher doses of POM can be given safely. *Methods.* A classic phase-I 3 x 3 trial was done in persons with symptomatic MF (anemia and/or symptomatic splenomegaly). The starting dose was 2.5 mg/d d 1-21 every 28 d. Dose-escalation at increments of 0.5 mg/d was done if no subject had a DLT (≥grade-4 hematologic toxicity, ≥grade-3 febrile neutropenia or ≥grade-3 non-hematologic toxicity) in cycle-1. Subsequent cohorts were treated until the maximum tolerated dose (MTD) was reached (dose level before that resulting in DLT in >1 of 6 subjects). *Results*. Subjects: 12 subjects with MF were enrolled 06/08-12/08. 8 had primary MF, 3, post-polycythemia vera MF and 1, post-essential thrombocythemia MF. Median age was 67 years (range, 51-83), 7 were female. 9 had a JAK2-V617F mutation. 11 were RBC-transfusion-dependent and 1 had a hemoglobin <10 g/dL. Median WBC was 4.5×10^9/L (range, $2\text{-}64\times10^9$/L). Median platelets were 111×10^9/L (range, $52\text{-}538\times10^9$/L). 10 subjects had splenomegaly, median size of 12 cm below the LCM (range, 4-26 cm). MTD: 3 subjects were enrolled in each of the 2.5, 3.0, and 3.5 mg dose cohorts. DLTs were observed at the 3.5 mg level: 2 of 3 subjects had grade-4 neutropenia and 1, grade-3 thrombocytopenia. 3 more subjects were enrolled at the 3.0 mg level cohort confirmed this dose as the MTD. 4 of 9 subjects receiving ≥3.0 mg/d had grade-3 neutropenia and 1 had grade-3 thrombocytopenia. Other toxicities were <grade-3 including fatigue, dyspnea, rash, lymphadenopathy and headaches. Efficacy: Subjects received a median of 3 cycles (range, 2-6 cycles). 8 subjects remain on-study; reasons for discontinuation were progression (N=2) and no response (N=2). There is a decrease in RBC-transfusion levels in 2 subjects. *Conclusions*. POM, 0.5-2 mg/d for 28 d (with or without prednisone) reverses anemia in persons with MF. Our data indicate the dose of POM can be increased to 3.0 mg/d for 21 d of a 28 d cycle. The DLT at higher doses is neutropenia. It is unclear as yet whether higher doses alter the anemia response rate seen at lower doses. An expanded phase-2 trial of 3.0 mg/d is ongoing; results will be presented.

0649

PRIMARY AND SECONDARY RESISTANCE TO IMATINIB IS VERY RARE IN CHRONIC AND BLAST PHASE OF MYELOPROLIFERATIVE NEOPLASMS WITH REARRANGEMENTS OF PDGFRA AND PDGFRB

G. Metzgeroth,[1] P. Erben,[1] C. Walz,[2] D. Gosenca,[1] J. Mix,[1] C. Haferlach,[3] S. Schnittger,[3] N. C. P. Cross,[4] A. Hochhaus,[1] A. Reiter[1]

[1]III. Medizinische Klinik, MANNHEIM, Germany; [2]Molecular Oncology Research Institute, Tufs Medical Center, BOSTON, USA; [3]MLL Münchner Leukämie Labor, MÜNCHEN, Germany; [4]Wessex Regional Genetics Laboratory, University of Southampton, SALISBURY, UK

Constitutively activated fusion genes with involvement of the receptor tyrosine kinases (TK) PDGFRA and PDGFRB play a central role in the pathogenesis of eosinophilia-associated myeloproliferative neoplasms (Eos-MPN). The diverse fusion genes fully retain the TK domain which is either activated by dimerization through the partner gene or loss of the TK autoinhibitory domain. Similar to chronic myeloid leukemia (CML), Eos-MPN may can evolve from chronic phase (CP) to blast phase (BP). While primary response rates to imatinib are even higher than those seen in CML, data on secondary resistance are still limited. Here, we report the follow-up of 48 imatinib-treated patients (100-400 mg/d) with a FIP1L1-PDGFRA fusion gene (CP, n=29; BP, n=9) or diverse PDGFRB fusion genes (CP, n=9; BP, n=1). Median age was 51 years (range 20-67) with a remarkable male predominance (46/48, 96%). Overall, all but one patient are currently still on imatinib for a median of 43 months (range 14-76). Complete molecular remissions (CMR) were seen after 6, 12 and 24 months in 55% (16/29), 76% (22/29) and 96% (26/27) of FIP1L1-PDGFRA positive patients in CP. Molecular relapse was only seen intermittently in one patient after imatinib was stopped but CMR was rapidly reinduced. The kinetics of responses was similar in Eos-MPN in CP with PDGFRB fusion genes. Rapid complete hematologic remission (CHR) in all patients and complete cytogenetic remissions in every tested patient within 6 (n=2), 12 (n=4) and 24 (n=6) months. CMR was reached in three of seven patients (43%). No relapse has yet been observed. In patients with diagnosis of BP (n=10), imatinib was used as monotherapy (n=7) or after intensive chemotherapy (n=3). All patients achieved rapid CHR and all nine FIP1L1-PDGFRA positive patients also achieved CMR. One FIP1L1-PDGFRA positive patient died while in ongoing CMR 24 months after diagnosis due to a cerebral bleeding. The median duration of CMR is 24 months (range 8-53) and no relapse has yet occurred in median 47 months (range 19-70) after diagnosis of BP. Hematological toxicity grade III-IV only occurred in one patient with

thrombocytopenia below 30/nL which was successfully managed by temporary discontinuation of imatinib. In summary, the clinical course and the sensitivity to imatinib of Eos-MPN with rearrangements of PDGFRA and PDGFRB clearly resemble CML. However, the high response rates are usually achieved with lower doses which are associated with less toxicity. In addition, primary and secondary resistance seem to be very rare irrespective of disease stage.

THE EVALUATION OF XAGRID EFFICACY AND LONG-TERM SAFETY STUDY: MONITORING SAFETY OUTCOMES IN AT-RISK ESSENTIAL THROMBOCYTHAEMIA PATIENTS TREATED WITH ANAGRELIDE VS OTHER CYTOREDUCTIVE THERAPIES

G. Birgegård,[1] C. Besses,[2] R. Coll,[3] C. Freitag,[3] M. Griesshammer,[4] L. Gugliotta,[5] C. Harrison,[6] J.-J. Kiladjian[7]

[1]*Uppsala University Hospital, UPPSALA, Sweden*

[2]*Hospital del Mar, BARCELONA, Spain;* [3]*Shire Pharmaceuticals Group Ltd, BASINGSTOKE, UK;* [4]*Johannes Wesling Teaching Hospital, MINDEN, Germany;* [5]*Arcispedale S. Maria Nuova, REGGIO EMILIA, Italy;* [6]*Guy's and St Thomas' NHS Foundation Trust, LONDON, UK;* [7]*Hôpitaux de Paris, BOBIGNY, France*

Background. Long-term follow-up studies of cytoreductive treatments in essential thrombocythemia (ET) are needed. The EXELS study is a large-scale, observational safety study that will enrol >3000 at-risk patients with ET. *Aims*. To continuously monitor safety and pregnancy outcomes in at-risk ET patients treated with anagrelide compared with other cytoreductive therapies. Assessments of efficacy (platelet reduction, incidence of thrombohaemorrhagic events) and drug utilisation are secondary objectives. *Methods*. At-risk ET patients (with at least one of the following: aged ≥60 years, platelet count >1000×10^9/L or previous thrombohaemorrhagic events) receiving cytoreductive treatment have been recruited since 2005. Patients are managed according to local practices and are recorded in the anagrelide group or 'other cytoreductive treatment' group at registration. Data on predefined events and suspected serious adverse reactions are collected every 6 months over the 5-year follow-up period. Predefined events include thromboembolic and major haemorrhagic events, disease transformation, heart failure, pulmonary hypertension, mucocutaneous lesions, or non-haematologic malignancy, pregnancy and death. *Results*. Approximately 140 sites across Europe are participating in the study. Of the 2602 patients registered in September 2008, >50% had been diagnosed for >2 years before entry, and about 10% for >10 years. Of the total cohort, 93% received either hydroxyurea (HU) or anagrelide treatment: 592 patients (22.8%) were receiving anagrelide, 1922 were receiving other cytoreductive treatments (HU in 1832 patients [70.4%], interferon-α in 129 patients [5.0%] and pipobroman in 102 patients [3.9%]), and 88 patients were receiving combination therapy. Subjects receiving anagrelide were generally younger than those receiving other cytoreductive therapies (55.3 years vs 67.2 years, respectively): 852 patients were aged <60 years, and 349 of these (41.0%) were receiving anagrelide. Of the 1750 patients aged >60 years, 243 (13.9%) were receiving anagrelide. In the anagrelide group, 11.7% of patients have stopped or changed therapy, compared with 7.4% in the HU group. Overall, 1725 patients (66.3%) were receiving concomitant anti-aggregation therapy (54% in the anagrelide group, 70% in the other treatment group). By September 2008, over 1200 patients had completed 12 months in the study. The change in haemoglobin level at 12 months was -0.1 g/dL in the anagrelide group (n=15) and -0.2 g/dL in the HU group (n= 184). Major thromboembolic and haemorrhagic events were still too few for statistical evaluation (n=67). As of September 2008, 183 subjects have reported 234 predefined events, with the most frequent being 'other cardiovascular symptoms' (n=37). *Conclusions*. Platelet reduction treatment patterns in Europe seem to be concordant with existing guidelines, with HU being the most frequently used agent, followed by anagrelide. In patients aged <50 years, anagrelide was used as often as HU. No new safety concerns have emerged. This large study is expected to provide useful efficacy data for the main ET treatments, with regard to thromboembolic events, platelet control and transformation. For the first time, a fairly large cohort of patients with combination therapy will be followed. Recruitment will end in April 2009, with >3000 patients in the total cohort and >800 patients in the anagrelide group. For this presentation, data will be updated from September 2008 to March 2009.

0652

LIVING WITH ESSENTIAL THROMBOCYTHEMIA IN FRANCE: PROSPECTIVE SURVEY ASSESSING DAILY LIFE DISEASE IMPACT IN 245 PATIENTS

J. Rey,[1] T. De Revel,[2] P. Lenain,[3] E. Raffoux,[4] J.-J. Kiladjian[5]

[1]*Paoli-Calmettes, MARSEILLE;* [2]*Hôpital des Armées Percy, CLAMART;* [3]*CLCC Henri Becquerel, ROUEN;* [4]*Institut d'Hématologie Hôpital Saint Louis, PARIS;* [5]*Hôpital Avicenne, BOBIGNY, France*

Background. Essential thrombocythemia (ET) is the chronic myeloproliferative disease (MPD) with the better prognosis and life expectancy. Morbidity is based on the risk of thrombotic complications and possibility of evolution to myelofibrosis and acute leukaemia. ET more frequently affects patients around 60 years old or younger. Its impact on personal, social and professional life has not been fully studied, and until now, only one US internet-based study evaluated the burden of MPD on quality of life from the patient's perspective. *Aims*. We report a survey in France that evaluated the impact of ET on daily life from patient's perspective compared with data collected from their haematologists. *Methods*. Multi-centre, retrospective and prospective study. Each physician had to include 3 ET patients types (T): T1, <60 years old not receiving cytoreductive (CR) drugs; T2, <60 years old receiving CR drugs; T3, ≥60 years' old receiving CR drugs. Retrospective data about demographics, key diagnosis, treatment and complications were collected from haematologist's patient's files. Prospective data were obtained by the completion of an auto questionnaire by the patients, regarding items about feelings on their disease and their treatment, life style changes, potential complications and quality of information they received about their disease and their expectations. *Results*. 85 French haematologists included 245 patients (T1 (19%), T2 (38%), and T3 (43%)). The characteristics of patients were: median age at diagnosis (53 years), 61% of female, 69% of patients diagnosed on routine blood counts, 16% of patients experienced vascular complications since diagnosis. Although only 30% of patients felt *sick*, 60% considered ET as a *serious* disease. 23% of patients were asymptomatic. Fatigue was the most frequently reported symptom (58% of patients) largely contrasting with fatigue frequency reported by their haematologists (17%). Although the majority of the patients (96%) believed that taking drugs for ET was essential, 32% had *no or little motivation* to do so. The first criterion for treatment efficacy from patient's perspective was diminution of platelet count (89%), when it was primary goal of therapy for only 47% of haematologists. The Majority of patients (85%) didn't feel constrained or felt only slightly constrained by the treatment. Negative impact of ET on professional life was reported by 37%, on hobbies by 24%, on *emotional life* by 24% of patients. ET affected the *mood* in 74% of patients. Although the majority of the patients were aware of ET symptoms, like *burning of hands and feet* or *vascular occlusions*, 17% of patients felt *not informed at all* about their disease, possible disease evolution being the main topic of concern (87%). Doctors remained the major information source for patients (86%), then the internet (40%). *Conclusions*. This survey showed that ET had an important impact globally on patient's life. Discrepancies between patient's and doctor's consideration of symptoms and consequences of ET were highlighted, suggesting that efforts should be made to educate physicians about a global management of ET patients, in particular on patient's information.

0653

APLIDIN IMPROVES MEGAKARYOCYTOPOIESIS AND HALTS NEO-ANGIOGENESIS IN THE GATA1(LOW) MURINE MODEL OF MYELOFIBROSIS

M. Verrucci,[1] A. Pancrazzi,[2] M. Paz,[3] F. Martelli,[1] P. Guglielmelli,[2] M. Aracil,[3] M. Zingariello,[4] E. D'Amore,[1] J. Jimeno,[3] A.M. Vannucchi,[2] A.R. Migliaccio[5]

[1]Istituto Superiore di Sanità, ROME, Italy; [2]University of Florence, FLORENCE, Italy; [3]Pharma mar, COLMENAR VIEJO, MADRID, Spain; [4]University of Chieti G. D'Annunzio, CHIETI, Italy; [5]Mount Sinai School of Medicine, NEW YORK (NY), USA

Background. Primary myelofibrosis (PMF) is a myeloproliferative disorder associated with abnormalities of megakaryocytic (MK) proliferation and maturation ascribed to reduced levels of GATA1 expression. By releasing high levels of cytokines(VEGF and TGF-β) in the marrow, the high numbers of immature MK are considered to be responsible for fibrosis, increased angiogenesis and bone formation observed in PMF. Mice carrying the hypomorphic Gata1(low) mutation express MK abnormalities similar to those observed in PMF patients and develop myelofibrosis, a phenotype resembling PMF and are considered an animal model for the disease. *Aims*. To perform a pre-clinical assessment for the use of Aplidin, a marine-derived depsipeptide currently in several phase II clinical trials that inhibits angiogenesis in *in vivo* and *in vitro* experimental model, as targeted therapeutic agent for myelofibrosis in Gata1(low) mice. *Methods*. Gata1(low) mice (9-months age; n= 18) received Aplidin ip at 60 μg/kg/daily/9 days for two cycles 38 days a part; a second group (aged >12 months; n= 18) received only one course of treatment while a third group (9-months age; n= 36) received four cycles 21 days apart of 100 μg /kg/daily per 5 days. Equivalent numbers of age-matched Gata1(low) mice received saline only and were used as control. At sequential time points, blood was drawn and mice sacrificed for immunohistochemistry, PCR and FACS analyses of bone marrow, spleen and liver. *Results*. A significant increase of platelet count from $<200\times10^6$ to $>600\times10^6$/μL ($p<0.05$) was observed in Gata1(low) mice at day 16 after the first treatment. The increment was sustained for all the duration of the treatment and was associated with increased levels of Gata1 expression (16.6±3.3 vs 34.2±2.6 pixel unit/MK, before and after treatment, $p<0.01$) and reduced numbers of MK (636±37 vs 440±47 MK/mm^2, before and after treatment $p<0.05$) in the marrow. In addition Aplidin normalized all the parameters of the bone marrow under study: the femur cellularity increased from a median of 6×10^6 in untreated Gata1(low) mice to normal values (15×10^6) 53 days after Aplidin treatment, fibrosis was minimal (6.5±2 vs. 3.2±1 reticulin fibers/mm^2 before and after treatment, $p<0.05$), microvessel density (8±1.5 vs 2.6±1.6 pixel/mm^2, $p<0.01$) and bone formation (56.5±8.9 vs. 21.4±7.4 pixel/mm^2, $p<0.05$) greatly reduced. Moreover, mRNA levels for both TGF-β and VEGF were significantly reduced in the marrow of Aplidin-treated mice ($p<0.01$ for both). Of note, Aplidin-treated Gata1(low) mice did not develop extramedullary hematopoiesis in liver, as detectable by CD45-immunostaining or FACS analyses for CD61 and Ter119 expression, in spite of the great numbers of colony forming cells detected in this organ (10^3 and 0.6×10^3 vs 25 colonies/liver in Aplidin-treated and untreated Gata1(low) mice and wild-type controls). *Summary and conclusions*. Aplidin treatment improves most of the myelofibrotic trait expressed by Gata1(low) mice, including thrombocytopenia, decreased marrow cellularity, fibrosis, increased angiogenesis, bone deposition and, most importantly, prevents development of extramedullary hematopoiesis. These data strongly suggest a beneficial effect of Aplidin in the treatment of a murine model of PMF. Based on these results, Aplidin merits to be tested clinically in symptomatic patients with PMF.

0654

EFFICACY OF LENALIDOMIDE IN PATIENTS WITH MYELOFIBROSIS: SPANISH COMPASSIONATE USE PROGRAM. PRELIMINARY ANALYSIS

I. Castillo,[1] A.M. Ojeda,[2] C. Boqué,[3] A. Asensio,[4] M. Hermosilla,[5] M. Blanes,[1] J. Busto,[6] V. Carrasco,[7] I. Cuesta,[8] A. Echeveste,[9] C. Fernández-Miñano,[10] P. García-Sánchez,[11] J. Gil,[12] F. Hernández,[13] A. Ibañez,[14] A. Lemes,[15] A. Ramírez,[16] D. Silvana,[17] N. Somolinos,[18] M.D. Monteagudo,[19] C. Ulibarrena,[20] D. Borrego[1]

[1]General Hospital of Elda, ELDA - ALICANTE; [2]Hospital de Leon, LEON; [3]Instituto Catalán de Oncología, BELLVITGE; [4]Hospital San Jorge, HUESCA; [5]Hospital Universitario Josep Trueta, GERONA; [6]Hospital Virgen de la Luz, CUENCA; [7]Hospital Royo de Vilanova, ZARAGOZA; [8]Hospital Obispo Polanco, TERUEL; [9]Hospital de Donosti, SAN SEBASTIÁN; [10]Hospital Vega Baja, ORIHUELA; [11]Hospital de Torrevieja, ALICANTE; [12]Hospital Príncipe de Asturias, ALCALÁ DE HENARES; [13]Hospital Santa Ana, MOTRIL; [14]Complejo Universitario de Albacete, ALBACETE; [15]Complejo Hospitalario de Albacete, ALBACETE; [16]Hospital Central de Asturias, OVIEDO; [17]Hospital La Fe, VALENCIA; [18]Hospital de Getafe, MADRID; [19]Hospital de Móstoles, MADRID; [20]Complejo Hospitalario de Orense, ORENSE, Spain

Aims. To describe clinical and epidemiological characteristics and preliminary efficacy and safety of patients with myelofibrosis treated with Lenalidomide (LEN). *Patients and Methods*. We designed a transverse and retrospective, multicenter descriptive analysis of cases from which compassionate use was requested. Treatment decision was previous and independent from the decision to conduct the present analysis and depended only on the clinical criterion of the responsible doctors. At least, one response assessment was needed for efficacy analysis. *Results*. From July to December 2008 33 patients have been included of which 26 were eligible for efficacy. Median age was 68.5 years (49-82) and 18 (69.2%) were males. Median interval from diagnosis was 24 months (4-134). Eighteen (72.0%) patients had primary myelofibrosis and 7 (28.0%) secondary. Eleven patients (42.3%) had intermediate Dupriez score at inclusion, 9 (34.6%) high and 6 (26.1%) low. Nine (42.9%) patients had cytogenetic abnormalities and JAK2 mutation was present in 12 (54.5%). Prior median lines of therapy were 3 (0-6). Most patients received blood transfusion [22 (84.6%)], 13 (54.2%) hidroxyurea; 1 (4.2%) interferon; 10 (40.0%) androgens; 14 (56.0%) erythropoyetin; 14 (53.8%) corticosteroids; 6 (25.0%) G-CSF; 6 (24.0%) thalidomide; 1 (4.2%); radiotherapy; 1 (4.2%) splenectomy and 9 (39.1%) "Others". Median LEN dose was 10 mg (5-10) per day. Fourteen (53.8%) patients received the standard dose and schedule (10 mg daily for 3 weeks every 4 weeks) and 12 (46.2%) received less dose and/or different schedule. Median duration of treatment was 3 months (0-17). Dose interruption or reduction was needed in 17 (65.4%) patients. Objective response was obtained in 16 (61.5%) patients. Most of them had moderate (7) or minor response (5) and 2 had complete response. Median Time to progression was 4.0 months (2.2-5.8). At the time of performing this analysis, 14 (53.8%) patients were still on LEN therapy and 21 (80.8%) were alive. Most frequent grade III-IV toxicity were anemia [10 (31.3%)], neutropenia [10 (31.3%)] and thrombocytopenia [7 (21.9%)]. Other important adverse effects (GIII/IV) were asthenia [6 (18.8%)], dyspnoea/hypoxia [2 (6.3%)]; venous thromboembolic disease (VTD) [1 (3.1%)]. The patients with VTD were on low dose aspirin prophylaxis. VTD prophylaxis was done in 26 (81.3%) patients, most of them received low dose aspirin 15 (46.9%), 10 (31.3%) low weight molecular heparin, and 1 oral anticoagulation. *Conclusions*. Compassionate use of Lenalidomide was prescribed for a heavily pre-treated myelofibrosis population. Our results suggest that LEN can be an effective and safe treatment for these patients. Toxicity, mainly myelosuppression was predictable and manageable with dose adjustments. These results should be confirmed in further control clinical trials.

0655

JAK2 V617F-POSITIVE CHRONIC EOSINOPHILIC LEUKEMIA: CLINICAL, LABORATORY AND MOLECULAR DEFINITION OF A DISTINCT DISEASE SUBTYPE

K. Zoi,[1] I.J. Dahabreh,[1] C. Zoi,[1] G. Helbig,[2] S. Krzemien,[2] V. Gota,[1] M. Speletas,[3] S. Giannouli,[4] A. Palliou,[1] K. Stefanoudaki,[5] N. Harhalakis,[6] G. Vassilopoulos,[1] M. Kotsopoulou,[7] P. Tsirigotis,[80] H.M. Moutsopoulos,[4] D. Loukopoulos,[1] M. Voulgarelis[4]

[1]Biomedical Research Foundation, Academy of Athens, ATHENS, Greece; [2]Dept of Haematology and Bone Marrow Transplantation, Silesian Medical University, KATOWICE, Poland; [3]Immunology and Histocompatibility Dept, University of Thessaly, Medical School, LARISSA, Greece; [4]Department of Pathophysiology, Medical School, National University of Athens, ATHENS, Greece; [5]Department of Hematology, Amalia Fleming General Hospital, Melissia, ATHENS, Greece; [6]Hematology and Lymphomas Dept, BMT Unit, Evangelismos General Hospital, ATHENS, Greece; [7]Department of Hematology, Metaxa Cancer Hospital, PIRAEUS, Greece; [8]Haematology Unit, 2nd Dept of Internal Medicine, Attikon Universit y Hospital, ATHENS, Greece

Hypereosinophilic syndrome (HES) and chronic eosinophilic leukemia (CEL) comprise a spectrum of indolent to aggressive diseases characterized by persistent eosinophilia and target-organ damage. The discovery of the FIP1L1-PDGFRA fusion gene in imatinib-responsive patients, who would otherwise have met the diagnostic criteria for HES has provided substantial insight into the pathogenesis of eosinophilic disorders. The JAK2 V617F point mutation, a molecular hallmark of the typical myeloproliferative neoplasms (MPNs), can be occasionally detected in other myeloid hematological malignancies, such as atypical MPNs and HES. In this study, we assembled a cohort of patients positive for the JAK2 V617F mutation with eosinophilia and signs and symptoms consistent with a diagnosis of HES. We provide evidence that JAK2 V617F positive eosinophilia is associated with myocardial involvement, with clinical and laboratory features that distinguish it from other primary eosinophilias.We conducted a retrospective multicenter study of patients with primary eosinophilia followed-up by the hematology units of six tertiary referral hospitals in Greece and seven in Poland. Patient diagnosis was based on the WHO 2001 criteria. For each patient, clinical files were reviewed and the following data were retrieved using a standardized data collection form: demographic information, clinical examination findings, imaging and biopsy results, and results of laboratory evaluations, target-organ involvement, treatment and response information. Patient management, including treatment and follow-up was based on physician and patient preference and was mandated by local institution policies. The JAK2 V617F mutation was detected using a tetra-primer amplification refractory mutation system (ARMS) polymerase chain reaction (PCR) assay with a sensitivity of 1% and the allele burden was estimated with a semi-quantitative method. Of 230 patients evaluated for moerate to severe eosinophilia, 7 (6 female/1 male; mean age 62.1 years) were positive for the JAK2 V617F mutation, fulfilling WHO criteria for CEL. JAK2 V617F-positive patients were compared to a cohort of FIP1L1-PDGFRA (n=18) and HES (n=61) patients. JAK2 V617F-positive CEL appears to be a relatively homogeneous clinicobiological entity characterized by female preponderance, peripheral eosinophilia, leukocytosis, normal hemoglobin, bone marrow infiltration by dysplastic eosinophils and eosinophil-induced tissue damage, predominantly of the heart. Compared to FIP1L1-PDGFRA-positive patients, JAK2 V617F-positive patients were older (p=0.06) showed a female preponderance (p=0.001), had lower white blood cell (p=0.007) and eosinophil counts (p=0.002), and similar hemoglobin values (p>0.9). JAK2 V617F-positivity was associated with cardiac involvement in multivariable analysis (p=0.002). Five JAK2 V617F patients were treated with a combination of steroids and hydroxyurea; four achieved a complete clinical and hematologic response; one patient evolved into acute myeloid leukemia (AML M6). In conclusion, JAK2 V617F-positive eosinophilia (6.2% of those with primary eosinophilia) is a rare but distinct myeloproliferative neoplasm characterized by eosinophilic marrow infiltration, target-organ damage and the potential of evolution to AML.

UK SYSTEMIC MASTOCYTOSIS REGISTRY: ANALYSIS OF DATA ON 71 CASES

B. Myers,[1] S. Marks,[2] J. Thomson,[3] C. Poynton,[4] P. Shepherd,[5] J. Cullis,[6] D. Radia[7]

[1]NHS, NOTTINGHAM; [2]St. Mary's Hospital, LONDON; [3]St. Thomas Hospital, LONDON; [4]University Hospital of Wales, CARDIFF; [5]Werstern general hospital, EDINBURGH; [6]Salisbury NHS foundation trust, SALISBURY; [7]St. Thomas' Hospital, LONDON, UK

Background. Systemic mastocytosis (SM) is a rare, multisystem disorder, characterised by clonal expansion of mutated mast cells. It may be indolent or more rarely aggressive. Diagnostic criteria include multifocal infiltrates (major), and one of the minor criteria: >25% abnormal mast cells, D816V(c-kit) mutation, CD2/CD25 positivity and serum tryptase > 20ng/mL. Symptoms are due to mediator-release or mast-cell infiltration. *Aim and Methods*. To improve UK epidemiological data for this condition. Anonymous data was collected noting: age at diagnosis, gender, serum tryptase level, clinical & mediator findings, and treatment. In this study those with cutaneous disease only are excluded. *Results*. We present results on 71 patients. There was an even sex distribution (33F; 31M; 6 unknown) and a wide age-range (17-82), with the majority being middle-aged, mean 51.6 years. Symptoms at diagnosis varied from none in 4 cases to ≥3 in 54%; they included skin involvement, bone pain, gastrointestinal, vascular instability and headache. The full blood-count at diagnosis was normal in 52% (37 cases); and showed pancytopenia (4), thrombocytopenia (4), thrombocytosis (2), eosinophilia (12) and anaemia in 13 cases. Serum tryptase was >20 in 92% cases, range 6 - >200. Most centres did not quantify above this level. WHO criteria were fulfilled in all cases; interestingly one diagnosis was made after splenectomy and one at post-mortem, following missed splenic rupture. 48 had indolent SM (ISM), 19 aggressive disease and 4, SM with associated non-mast cell haematological disorder (ANMHD). There were no mast-cell leukaemia cases. The serum tryptase was >200 in 42% patients with aggressive disease; in the others there was a complete range of tryptase results from 10.5-169 (mean 83). The associated non-mast cell disorders were - myeloproliferative disorder in 3 cases and myelodysplasia (transformed to acute myeloid leukaemia) in one case. *Treatments*. In 18 patients, no treatments were necessary; in a further 26 patients with indolent disease, mediator-release medications and mast-cell stabilisers were given. Two patients with borderline aggressive disease, were treated with hydroxycarbamide Of the remaining 21 patients with aggressive disease, 10 received one treatment regime, 9 had two, and two had tried 3 treatment options. A total of 13 patients received α-interferon. This was generally effective but frequently poorly tolerated. Cladribine was given to four patients. This produced temporary response in three. Six patients had tyrosine-kinase inhibitors: imatinib (3) with partial responses; nilotinib (2) with no response, and dasatinib (1) with good response. One patient had a splenectomy as a third line treatment without response, and is now awaiting allo-BMT. PKC-412 (novartis) was given to six patients with very aggressive disease with good responses in three, and too early to assess in one patient. *Conclusions*. As expected, the majority of cases have ISM (67%). Aggressive disease, (29%) however, may be over-represented in our registry, as being more 'worthy' of reporting. A range of treatments appear to have at least partial response in aggressive disease, and PKC-412 shows particular promise. Patients with'indolent' disease were very heterogeneous in symptomology, with some having none while others suffered multiple symptoms, including severe fatigue.

POLYCYTHEMIA VERA AS A PREDISPOSING FACTOR FOR AORTIC STENOSIS: INCIDENCE AND CORRELATION WITH BLOOD CELLS COUNT AND MUTATIONAL STATUS

S. Siragusa,[1] R. Barone,[2] C. Caracciolo,[2] R. Di Maggio,[2] G. Fazio,[2] L. D'Angelo,[2] M. Montana,[2] D. Caramazza,[2] A. Malato,[2] G. Saccullo,[2] G. Pizzo,[2] A. Casuccio,[2] S. Novo,[2] V. Abbadessa[2]

[1]University of Palermo, PALERMO; [2] Dipartimento di Patologia Umana, Università degli Studi di Palermo, PALERMO, Italy

Background. The association between polycythemia vera (PV) and thrombosis is multi-factorial involving the complex interaction between activated leukocytes, platelets and endothelium. Recent reports have postulated that PV patients may over express adhesive molecules on red cell surface, likely by JAK2V617F mutation (Wautier M *et al.* Blood 2007;110:894-901). This process activates endothelium with production of vascular growth factors and other mechanisms leading to atherosclerosis. Aortic Stenosis (AS) is the commonest valvular heart disease in western countries; its pathogenesis is mainly related to a degenerative process sharing many characteristics with atherosclerosis. At the present is not known whether patients with PV are at high risk of developing AS. Objective of the study. We perform a prospective study for evaluating rate of AS and its correlation with blood cells count and mutational status in patients with PV. *Materials and methods*. Incidence rate of AS among PV patients have been compared with control patients matched for age, cardiovascular risk factors (hypertension, hyperlipidemia, diabetes, smoke and alcohol abuse) and coexisting cardiac diseases (i.e. heart failure). Diagnosis of PV has been posted accordingly to PVSG criteria. Diagnosis and severity of AS has been posted by echocardiography: stenosis with a valve area <1.0 cm^2 has been considered severe. *Results*. Over a period of 18 months we recruited 43 PV patients (28 males and 15 females) and 74 controls. No differences were found in regard of the above cited characteristics; mean age was 66.7 among PV patients and 68.2 among controls. The average duration of PV was 5.7 years with an average follow-up of 2.5 years. Most of the PV patients were on antiplatelet/anticoagulant therapy (27/43, 62.7%) and have been treated with cytoreductive therapy. Twelve (27.9%) had a thrombotic event before PV diagnosis; 4 (9.3%) developed thrombosis during the follow-up (median 1.3 years). A moderate/severe AS was found in 11 PV patients (25.6%) in comparison to 4 (5.4%) in control group (p=0.004), thus giving a Relative Risk of 4.7 (CI 95%: 1.61-13.95). Among PV patients, the multivariate analysis did not show any correlation regarding JAK2V617F mutational status, duration of disease, previous thrombosis, cytoreductive therapy and other common cardiovascular factors. A significant trend was demonstrated in favor of patients with elevated haematocrit (>55%) (p=0.001). *Conclusions*. Our study clearly shows that PV patients carry a fourfold risk of developing AS, mainly related to the presence of high haematocrit level. No clear association were found regarding white blood cell or platelets count, effect of cytoreductive therapy or previous thrombosis. Whether high incidence of AS may be related to expression of adhesive molecules on red cells or altered share stress is currently under investigation.

0658

DASATINIB FOR THE TREATMENT OF TREATMENT-REFRACTORY HYPEREOSINOPHILIC SYNDROME AND CHRONIC EOSINOPHILIC LEUKEMIA

I.J. Dahabreh,[1] S. Giannouli,[2] C. Zoi,[1] V. Gota,[1] G. Leondaritis,[1] C. Sambani,[3] D. Loukopoulos,[1] M. Voulgarelis,[2] K. Zoi[1]

[1]Biomedical Research Foundation, Academy of Athens, ATHENS; [2]Department of Pathophysiology, Medical School, National University of Athens, ATHENS; [3]Laboratory of Cytogenetics, National Center for Scientific Research Demokritos, ATHENS, Greece

In the absence of imatinib-responsive markers, chronic eosinophilic leukemia (CEL) and hypereosinophilic syndrome (HES) pose a therapeutic challenge. We hypothesized that dasatinib (BMS-354825, Bristol-Myers Squibb) could be effective for the management of treatment-refractory or intolerant HES/CEL. Four female HES and 2 male CEL patients, all of whom were negative for imatinib responsive markers, were enrolled in this exploratory study. Prior treatment with imatinib and at least one other therapy had failed for 5 of them; one was considered intolerant to previous treatments. All patients had elevated bone marrow eosinophil counts. Patients received dasatinib at 70 mg bid; toxicity and safety were evaluated weekly for 4 weeks, every two weeks for 2 months and monthly thereafter. Bone marrow examination performed at 2 and 6 months after treatment onset. Complete remission (CR) was defined as eosinophils <5% with WBC<10,000 cells/mm^3 and complete disappearance of all reversible signs and symptoms of disease. All other changes were scored as no response. Therapy continued for at least 8 weeks unless patients experienced unmanageable toxicity. Pulmonary toxicities were managed according to a protocol used for CML patients receiving dasatinib. Toxicity was graded according to the National Cancer Institute Common Toxicity Criteria, v 3.0. Western-blot analysis was used to assess response at protein level: phospho-SRC (pSRC), phospho-STAT5 (pSTAT5), STAT5, and phospho-ERK (pERK) were evaluated in pre-treatment and post-treatment specimens. After a mean follow-up of 12.7 months (range: 5-19) after study enrollment, four patients (66%; 95% CI: 0.22-0.96) achieved CR, which was confirmed by BM biopsy (2 male and 2 female). Three of these responded within 2 months, while the fourth achieved CR within 5 months. The mean response duration was 7.3 months (range: 2-12). A CEL patient with a complex cytogenetic abnormality [del(X)(q24), t(2;9)(q12;q32), del(20)(q12)], achieved complete cytogenetic remission in addition to hematological and clinical CR. Four patients developed pleural effusions (grade 3, n=3; grade 2, n=1), which were bilateral in 2 cases. In all patients developing pleural effusions, dasatinib had to be discontinued for 2-4 weeks and diuretics were administered. Treatment was restarted at 100mg daily in three of them; one refused re-treatment. One patient developed new onset hypothyroidism (grade 2 autoimmune reaction). Two patients experienced grade 2 anemia and leucopenia. Responsive patients showed a remarkable reduction in pSRC and pSTAT5 levels in peripheral blood taken one month post-treatment compared to pre-treatment samples. We conclude that dasatinib may be useful for the treatment of treatment-refractory/ intolerant HES/CEL with a severe but manageable toxicity profile. The occurrence of complete cytogenetic response in an imatinib-refractory CEL patient indicates that dasatinib-responsive molecular aberrations are present in a subset of patients with primary eosinophilia.

0659

HIGH RESOLUTION MELTING CURVE ANALYSIS: A SIMPLE, RELIABLE AND SENSITIVE METHOD OF DETECTION OF JAK2 EXON 12 MUTATIONS

T. Lavabre-Bertrand,[1] S. Carillo,[1] L. Henry,[1] E. Lippert,[2] F. Girodon,[3] I. Guiraud,[1] C. Richard,[4] C. Cleyrat,[5] E. Jourdan,[6] R. Kravlovics,[7] S. Hermouet[5]

[1]Université Montpellier I - CHU Nîmes, NIMES, France; [2]Laboratoire d'Hématologie, CHU Boredeaux, BORDEAUX, France; [3]Laboratoire d'Hématologie, CHU Dijon, DIJON, France; [4]Laboratoire d'Hématologie, CHU Clermont-ferrand, CLERMONT-FERRAND, France; [5]Laboratoire d'Hématologie, CHU Nantes, NANTES, France; [6]Laboratoire d'Hématologie et Oncologie médicale, CHU Nîmes, NÎMES, France; [7]Medical University, VIENNA, Austria

Background. The description of an acquired Jak2 V617F mutation represents a major improvement in the understanding and management of myeloproliferative disorders. Investigation of V617F negative polycythemic cases led to the characterization of new mutations in Jak2 exon12. These exon12 mutations are associated with pure erythrocytosis. About 19 different Jak2 exon12 mutants have now been reported spotting a region from AA 536 to 547. SNPs, deletions, insertions and duplications have been described, all respecting the ORF, that means a huge number of predictable mutational types. So, techniques like AS-PCR are inappropriate and sequencing or pyrosequencing lack sensitivity to screen them. There is therefore obviously a need for a rapid and sensitive assay for Jak2 exon12 mutation screening. We test HRM because it can be used by any medical laboratory and requires just a real time thermocycler, opposed to more expensive technologies like DHPLC. *Aims*. 1) confirm the efficiency of HRM for screening Jak2 exon12 screening; 2) characterize positive HRM signals; 3) analyse Jak2 exon12 biological data. *Methods*. Granulocytes DNA samples from 6 Secondary Erythrocytosis, 15 Idiopathic Erythrocytosis (IE) and 34 Polycythemia Vera V617F negative or with low allelic burden (<25%) patients, diagnosed according to 2001 WHO criteria, were collected by 5 centers (Bordeaux, Clermont-Ferrand, Dijon, Nantes and Nîmes). Nested HRM was performed in Nîmes on LightCycler 480 and confirmed on Rotorgene in Clermont-Ferrand. It consists of a first PCR of 496 bp long, diluted 1:100 for HRM reaction (118

bp). Mutations were characterized by sequencing genomic DNA or cloned plasmids, depending of the allelic burden. *Results*. 1) HRM allows detection of exon12 mutations with high reliability and sensitivity. Use of a nested protocol enhances sensitivity by lowering wild type controls HRM signals compared to genomic DNA. Titrating experiments shows a detection treshold ranking from 1 to 3%. It depends on the mutant and is more or less as sensitive as AS-PCR. Running wild type and mutant plasmids, we did not get false negative and only a small false positive (1 over 30 replicates) which is normally discarded in routine triplicates. Nested HRM detects 13 mutants (24%): 2 IE (13.3%), 11 PV (32.3%), no SE. Among 13 V617F positive PV, 3 harbor an exon12 mutation (23%), adding to the only one double mutant already reported. 2) Sequencing identifies mutations in all the 13 cases. We describe 4 new mutations: H538Q K539L, F537I K539I, K539E and I540T. One of the double mutant presents an exon12 allelic burden higher than the V617F one, as opposed to the others, questioning appraisal pattern. 3) Biological data confirm previous reports: pure erythrocytosis associated with low serum EPO, but the 4 double mutants seems to present a specific profile. *Conclusions*. Nested HRM is a rapid and simple technique particularly appropriate to screen Jak2 exon12 mutations. It allowed description of 4 new mutations. Double mutants are not rare. Exon12 mutations should be looked for in in patients with unexplained pure erythrocytosis and low V617F burden.

EXPRESSION OF A SET OF CELL-STROMA INTERACTING GENES IN PATIENTS WITH PRIMARY MYELOFIBROSIS

A.L. Livun,[1] T.M. Manshouri,[1] R.K. Kusec,[2] Y.Z. Zhang,[1] H.M.K. Kantarjian,[1] S.V. Verstovsek[1]

[1]MD Anderson, HOUSTON, USA; [2]Clinical hospital Dubrava, ZAGREB, Croatia

Background. Primary myelofibrosis (PMF) is stem cell derived Philadelphia chromosome-negative chronic myeloproliferative neoplasia characterized by marrow fibrosis, leukoerythroblastosis, extramedullary hematopoiesis and splenomegaly. Etiology is still unknown, but mutations in several genes are found at increased frequency (e.g. JAK2, MPL, TET2, IKAROS) in this disease. The therapy for PMF is unsatisfactory and median survival is poor. Different medications have, therefore, been evaluated in clinical trials, including novel JAK2 inhibitors, and immunomodulatory inhibitory drugs (IMiDs) like thalidomide and lenalidomide. *Aims*. To assess genes that impact PMF, we analyzed expression of genes that are involved in cell-stroma adhesion (SPARC, CXCR4), metabolism (COX-2, HIF1), differentiation and signaling (Pax5 and Socs3) in mononuclear cells (MNC) from bone marrow (BM) or peripheral blood (PB) of 32 PMF patients before and after treatment with the combination of lenalidomide and prednisone. *Methods*. PB and BM aspirate samples from healthy individuals and PMF patients were ficolled and RNA was isolated from MNCs with Trizol reagent.Q-RT-PCR was performed to measure the expression levels of SPARC, COX-2, CXCR4, Pax5, Socs3 and HIF1 transcripts with β-actin as internal control. *Results*. Pre-therapy, SPARC and COX-2 expression were decreased in BM MNC, while CXCR4, Pax5 and HIF1 were increased, compared to controls. At the same time, COX-2, CXCR4 and HIF1 expression were decreased in PB MNC. No correlations between gene expression and JAK2 mutational status or cytogenetic abnormalities were found. Six months after treatment with lenalidomide/prednisone further decrease in SPARC, Socs3 and HIF1 in BM MNC was recorded, and COX-2 and CXCR4 further decreased in PB MNC. No correlation with response was found. *Summary and Conclusions.* Pre-therapy down regulation of SPARC may indicate its defect in tumor suppressing activity in PMF. Interestingly, lenalidomide treatment known for the dramatic up-regulation of SPARC expression in patients with 5q- myelodysplastic syndrome, did not show the same pattern in PMF. Further investigation of the SPARC regulation in stromal and other elements of hematopoietic niche of PMF is underway.

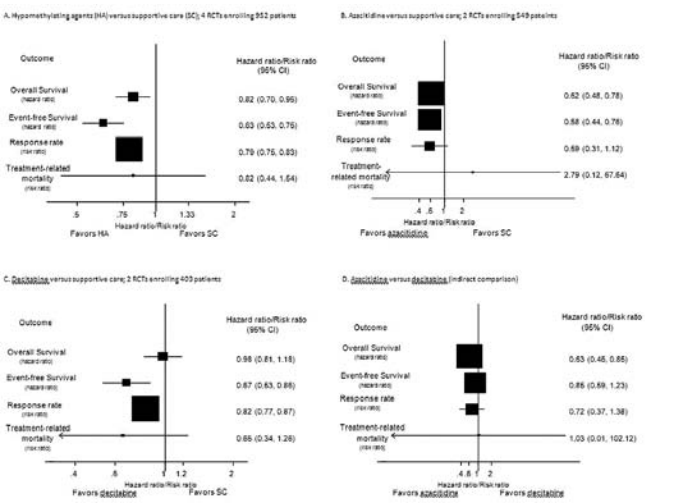
0661

THE IMPACT OF AZACITIDINE AND DECITABINE (HYPOMETHYLATING-AGENTS) IN MYELODYSPLASTIC SYNDROMES: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Kumar,[1] F. List,[1] I. Hozo,[2] B. Djulbegovic[3]

[1]Moffitt Cancer Center, TAMPA; [2]Indiana University Northwest, GARY, IN; [3]University of South Florida, Moffitt Cancer Center, TAMPA, USA

Background. Treatment of patients with myelodysplastic syndrome (MDS) with the hypomethylating agents (HA), 5-azacytidine (AZA-C) and decitabine have been a major focus of clinical research that lead to their FDA approval. Use of these agents has improved hematopoiesis and may impact natural history of disease. However, results for patient oriented outcomes of overall survival (OS), and event-free survival (EFS) have been inconsistent across trials. Furthermore, a direct comparative trial of of AZA-C versus decitabine is lacking. *Aims*. To perform a systematic review of randomized controlled trials (RCTs) to assess the efficacy of AZA-C and decitabine compared to best supportive care (SC) which includes conventional care regimens or SC alone, and AZA-C versus decitabine for the treatment of MDS. *Methods*. A comprehensive literature search of MEDLINE, EMBASE and Cochrane database of RCTs was undertaken to identify all phase III randomized controlled trials (RCT) published until July 2008. Meetings abstracts from ASCO, ASH and European Hematology Association were searched for the years 2006-2008. Data extraction and meta-analysis on benefits and adverse effects of HA for MDS was performed as per the methods recommended by the Cochrane Collaboration. Indirect comparison of AZA-C versus decitabine was conducted according to the methods developed by Bucher, Lumley and Glenny *et al.* and were extended to calculate hazard ratios (HR). We created the following chain of inference: we first pooled RCTs that compared AZA-C with SC, and decitabine versus SC. We then compared the pooled estimates to obtain the unbiased estimate in treatment differences between decitabine and AZA-C.



Figures A through D.

Results. We found 4 RCTs assessing the efficacy of HA for the treatment of MDS. Two RCTs compared AZA-C versus SC, and 2 compared decitabine versus SC. The results have been summarized in Figures A through D. Meta-analysis of RCTs comparing HA versus SC showed significantly better OS, EFS, and response rate in favor of HA without a significant increase in treatment-related mortality (TRM). Comparison of AZA-C versus SC also showed a significant advantage in OS, and EFS favoring AZA-C without significant risk of TRM. The pooled results for the comparison of decitabine versus SC showed significantly better EFS and response rate with decitabine. However, there was no difference in OS and TRM between decitabine and SC. Evaluation of AZA-C versus decitabine showed significantly better OS favoring AZA-C. Nevertheless, EFS, response rate and TRM was similar between AZA-C and decitabine. *Conclusions*. This first systematic review on the efficacy of HA versus SC shows that OS, EFS and RR are significantly better with HA without significant TRM. Use of AZA-C is associated with significantly better OS without a significant increase in TRM compared to decitabine. A RCT comparing AZA-C and decitabine is warranted.

PRESENCE OF JAK2 V617F MUTATION IS A SINGLE STRONG PREDICTOR OF VASCULAR COMPLICATIONS IN PATIENTS WITH MPD

M. Quitt,[1] L. Gedzun,[1] E. Shabad,[1] A. Kotler,[1] O. Valkovsky,[1] M. Ballan,[1] T. Shusterman,[2] E. Mishchenko,[3] N. Lindenfeld,[1] A. Cassel[1]

[1]Carmel Medical Center, HAIFA; [2]Lin Medical Center, HAIFA; [3]Zvulun Medical Center, HAIFA, Israel

Background. Since the discovery of the JAK2 V617F mutation, the clinical and pathological consequences of this acquired defect have been extensively investigated to determine whether its presence characterizes a distinct subgroup of myeloproliferative disorders (MPD). There is increasing clinical evidence to suggest that the mutation may be associated with increased activation of leukocytes and platelets in MPD and may lead to an increased risk of thrombosis. *Aims*. The aim of our study was to investigate the frequency of JAK2 V617F mutation in patients with different subgroups of MPD. Statistical correlation between the presence of JAK2 mutation and clinical and laboratory outcome was performed. *Patients and methods*. We conducted a retrospective study of 233 patients who were referred to our hospital for investigation of JAK2 V617F mutation between January 2006 and July 2008. Only patients with clinically and laboratory confirmed BCR-ABL negative MPD were included. *Results*. There were 99 (42.5%) males and 134 (57.5%) females in our study, with median age of 66 years(21-91). 92/233 (39.5%) patients had polycythemia vera (PV), 107 (45.95%) essential thrombocythemia (ET), 12 (5.2%) idiopathic myelofibrosis (IMF) and 20 (5.2%) unclassified myeloproliferative disorder (CMPD-U). 177/233 (76%) patients were asymptomatic and were referred due to high Hb level, thrombocytosis or leukocytosis. 45/233 (19.3%) patients presented with clinical symptoms, the majority with headache and erythromelalgia. 11/233 (4.72%) patients had a vascular event at the time of diagnosis; 8 presented with an arterial event and 4 with VTE. During the follow up 68/233 (29.2%) patients suffered from arterial or venous thrombotic complications of the underlying MPD; the incidence of arterial or venous thrombosis was similar in PV and ET patients (20/23 and 10/9 respectively). JAK2 V617F mutation was present in 192/233 (83.35%) patients; 82/92 (89.1%) patients with PV, 81/107(74.2%) with ET, 10/12(83.3%) with IMF and 19/20 (95%) with CMPD-U. We found that the majority of thrombotic events- 39/56 arterial and 20/23 venous thromboses- occurred in JAK2 V617F positive patients. Of 80 patients who presented with leukocytosis, 24 suffered from thrombotic complications. They were equally distributed between patients with PV and ET, and 19 of them had positive JAK2 V617F mutation. *Conclusions*. In our retrospective study of 233 patients with MPD we found that our patients with PV had a high incidence of JAK2 V617F mutation (89.1%). Our cohort of patients with ET had a higher incidence of JAK2 V617F mutation than reported in the literature (74.2%). This may be explained by the fact that many of our patients had a well established diagnosis of MPD several years before the test for JAK2 mutation was included in our routine investigations of MPD. We found that 57/79 (72.2%) patients with vascular events were positive for JAK2 V617F mutation. Our findings further confirm the previous reports that presence of JAK2 V617F mutation is a single strong predictor of vascular complications in patients with MPD.

0663

JAK2 V617F MUTATION IN ACUTE MYELOID LEUKEMIA SECONDARY TO PH NEGATIVE CHRONIC MYELOPROLIFERATIVE DISORDERS

C.R. Rinaldi,[1] P. Rinaldi,[1] V. Martinelli,[1] R. Ciancia,[1] A.M. Vannucchi,[2] L. Gugliotta,[3] T. Barbui,[4] B. Rotoli,[1] F. Pane[1]

[1]Federico II University, NAPLES; [2]Unità Funzionale di Ematologia AUO Careggi, FIRENZE; [3]Arcispedale S. Maria Nuova Azienda Ospedaliera di Reggio Emilia, REGGIO EMILIA; [4]Ospedali Riuniti, BERGAMO, Italy

Background. Transformation to acute myeloid leukemia (AML) is a known complication of myeloproliferative disorders (MPDs). Recently, Theocharides *et al.* have published an interesting report about the incidence of JAK2 negative blasts from patients affected by secondary AML derived from JAK2 mutated MPDs. *Methods*. We collected, by cell sorting, blast cells and mature cells from total bone marrow of 17 patients newly diagnosed of secondary AML [9 derived from primary myelofibrosis (PMF); 4 from polycythemia vera (PV) and 4 from essential thrombocythemia (ET)]. All the samples were genotyped for JAK2-V617F mutation by ASO PCR and the measurement of the allele burden was performed in Real Time PCR. At MPD diagnosis, JAK2-V617F was detectable in 9 of 17 patients (4 of 9 PMF; 4 of 4 PV and 1 of 4 ET). All patients had received cytoreductive treatment with HuOH. *Results*. In our cohort of patients we found that JAK2-V617F mutation was still present at the blast transformation in both compartments (blasts and mature cells) in 8 of 9 JAK2 mutated MPDs. Only 1 of 9 patients developed JAK2-V617F negative AML starting from a mutated MPD. Interestingly, the negativity for the mutation was confirmed in blast cells but also in the rest of mature-myeloproliferative bone marrow tissue. Surprisingly we also described a case of JAK2-V617F mutated AML from a wild type MPD but even in this case the positivity occurred in mature and blast compartments. The remaining 7 wild type JAK2 MPDs maintained the same JAK2 status during blast crisis. No differences in the allele burden were found before and after leukemic transformations comparing the two groups of patients. Two JAK2 positive AML from JAK2 positive MPD (1 ET and 1 PV) achieved CR after induction treatment while the others did not respond to the therapy. Discussion. According to our preliminary results, in contrast to the previous study, we conclude that JAK2-V617F positive MPD yields rarely a JAK2-V617F negative AML and at the same frequency of a JAK2-V617F negative MPD transforming in JAK2 mutated AML. Furthermore we wanted to underline how any modifications in the JAK2 integrity or the persistence of the previous status involved the entire bone marrow during leukemic transformation suggesting that the leukemic hit could take place in a common ancestor precursor able to modify entirely the genomic signature of the disease.

0664

STUDY OF THE RELATION BETWEEN THE TIME COURSE OF THE JAK2V617F ALLELE BURDEN AND THE CLINICAL OUTCOME IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPNS); A SINGLE CENTER STUDY

M.S. Sobas,[1] M.M. Perez-Encinas,[2] C. Quinteiro,[3] T. Gonzalez,[3] S. Suarez,[2] D. Vilariño,[2] N. Alonso,[2] J. Diaz,[2] A. Bendaña,[2] S. Gonzalez,[2] J.L. Bello-Lopez[2]

[1]Servicio de Hematologia, Hospital Clinico Universitario, SANTIAGO DE COMPOSTELA; [2]Servicio de Hematologia y Hemoterapia, Hospital Clinico Universitario, SANTIAGO DE COMPOSTELA; [3]Fundación Publica Galega de Medinina Xenomica, SANTIAGO DE COMPOSTELA, Spain

Background. The JAK2V617F is a main molecular marker of MPNs. There are few studies that analyze the time course of the JAK2V617F allele burden. *Aims*. To study the clinical outcome and the time course of the JAK2 allele burden in MPNs. *Methods*. We performed a single centre study on 95 patients: 31 polycythemia vera (PV), 60 essential thrombocythemia (ET) and 4 primary myelofibrosis (PMF), all of them with at least 12 months of follow-up and at least two JAK2 determinations. The JAK2V617F mutation was analyzed in DNA from peripheral blood granulocytes by MutaScreenTMKit (IPSOGEN). *Results*: The median follow-up period was 25 months. As previously reported, none of 26/95 JAK2 negative patients became positive for the mutation. 69/95 patients were positive for JAK2 and in 35/69 (50.7%) JAK2V617F allele burden changed (% last JAK2V617F - % first JAK2V617F > 15%) during the follow-up. The JAK2 allele burden increased in 23/35 patients and interestingly, eight of them (34.8%) presented transformation (Table1).

JAK2V617F allele burden		Clinical outcome (n=69)		
Decrease	12/69 (17.4%)	No progresion (n=57)	Progresion (n=12)	
No change	34/69 (49.3%)	11/12 (91.7%)	1/12 (8.3%)	PV-AML (n=1)*
Increase	23/69 (33.3%)	32/34 (94.1%)	2/34 (5.9%)	ET-PV (n=1) PV-MF (n=1)
Decrease	12/69 (17.4%)	15/23 (65.2%)	8/23 (34.8%)	ET-MF (n=4)*** PMF-AML (n=1)** ET-PV (n=3)

Table 1. Clinical outcome and JAK2V617F allele burden.

Two patients progressed to acute myeloid leukemia (AML): first patient showed decrease (transformation PV to AML)* and second (MFI) presented initial increase with subsequent decrease of the JAK2 allele burden once AML was diagnosed**. 54/69 of JAK2 positive patients were on Hydroxyurea (HDU): 22/54 newly (≤12 months at the time of the first JAK2 study) and 32/54 already treated (>12 months). The JAK2V617F allele burden was stable in 29/54 (53.7%) of patients on HDU (newly and already treated). There were no differences between changes in the JAK2V617F allele burden and a period of HDU administration (>12 vs. ≤12 months). There were 10/69 patients who did not receive cytoreductive treatment and 7/10 showed an increase of JAK2 allele burden. Moreover, an increase in JAK2V617F allele burden was showed in two patients after discontinuation of HDU treatment. Conversion to JAK2V617F negativity (n=1) was observed after allogeneic hematopoietic stem cell transplantation (HSCT)***. *Conclusions*. The JAK2V617F allele burden may change during the follow-up and this can be related to clinical outcome of MPNs. We confirm that, JAK2V617F allele burden decrease with transformation to AML. In case of transformation to PV o MF the JAK2V617F allele burden usually increases or is stable. In the majority of patients on HDU treatment the JAK2V617F allele burden seems to be stable. HDU can change the JAK2V617F allele burden only in individual cases and according to our results, there are no difference between newly and already treated patients. The JAK2V617F allele burden can increase without HDU. HSCT can induce conversion to JAK2V617F negativity, as previously reported. Further prospective studies are needed to conclude whether the follow-up of the JAK2V617F allele burden may be used to predict transformation of MPNs patients or to monitor the response to the treatment.

CRYPTIC 9P24 MICRODELETIONS COVERING HSA-MIR-101-2 ARE RECURRENT IN HEMATOLOGICAL MALIGNANCIES

K. van Roosbroeck,[1] I. Lahortiga,[1] J. Finalet Ferreiro,[1] J. van der Meulen,[2] P. Vandenberghe,[1] J. Cools,[1] F. Speleman,[2] P. Marynen,[1] I. Wlodarska[1]

[1]Catholic University of Leuven, LEUVEN; [2]Ghent University Hospital, GHENT, Belgium

Background. The 9p terminal (9pter) region is recurrently involved in genomic aberrations in hematological malignancies. These aberrations, frequently targeting JAK2 (9p24), include chromosomal translocations, amplifications and mutations. Recently, we have collected a series of leukemia and lymphoma cases with 9p24 deletions. Molecular analysis of these cases is presented. *Aims.* The aim of this study is to identify and molecularly characterize recurrent 9p24 deletions in hematological malignancies. *Methods.* 84 leukemia/lymphoma cases with 9pter aberrations were analyzed by FISH using BAC and fosmid probes. The Agilent oligonucleotide 244k array platform was used to map the identified 9pter deletions. *Results*. FISH analysis with a panel of 9p BACs identified 18 cases with genomic 9pter losses, including 4 cases with cryptic microdeletions. The latter aberrations were mapped by high resolution arrayCGH. The smallest deleted 9p24 region (SDR) established in these cases covers 1.9 Mb and harbours 18 genes including JAK2. The candidate tumor suppressor genes (TSGs) encompassed by SDR include PPAPDC2, CDC37L1 and the microRNA gene, hsa-mir-101-2. The role of hsa-mir-101-2 in tumorigenesis, and particularly in the development/progression of hepatocellular carcinoma has recently been documented. This microRNA targets at least 3 genes, FOS, MCL1 and EZH2. FOS codes for v-fos FBJ murine osteosarcoma viral oncogene homolog, a key component of the activator protein-1 (AP-1) transcription factor and important in regulating the development of cells destined to form and maintain the skeleton. Myeloid cell leukemia sequence 1 (MCL1) is an antiapoptotic member of the BCL2 family, and EZH2 encodes for enhancer of zeste homolog 2, a mammalian histone methyltransferase that contributes to the epigenetic silencing of target genes. It has been shown that deletion of hsa-mir-101-2 in cancer cells correlates with overexpression of EZH2 and results in the increased survival and metastatic properties of cancer cells. In hepatocellular carcinoma, downregulation of has-mir-101 has been observed that may contribute to high expression levels of FOS protein and MCL1. The role of hsa-mir-101-2 in human leukemia and lymphoma has not been documented yet, but Mcl-1 transgenic mice exhibit a high probability of developing B-cell lymphoma. *Conclusions*. The common region of 9pter deletions in hematological neoplasms harbours numerous coding and non-coding genes, including hsa-mir-101-2. Given its postulated role of tumour suppressor, hsa-mir-101-2 is a strong candidate gene affected by the del(9)(p24). Further studies of the candidate TSGs including hsa-mir-101-2 in cases with a del(9)(p24) are ongoing.

NOVEL T(X;14)(P11.4;Q32.33) RESULTING IN UPREGULATION OF GPR34 AND ACTIVATION OF THE NFKB PATHWAY IS RECURRENT IN MALT LYMPHOMAS

M. Wlodarska,[1] T. Tousseyn,[2] L. De Leval,[3] J. Finalet Ferreiro,[4] H. Urbankova,[4] L. Michaux,[4] D. Dierickx,[5] P. Wolter,[6] P. Vandenberghe,[4] P. Marynen,[7] C. De Wolf-Peeters,[2] M. Baens[7]

[1]Catholic University of Leuven, LEUVEN; [2]Dept. of Pathology, Catholic University Leuven, LEUVEN; [3]Department of Pathology, CHU Sart Tilman, LIÈGE; [4]Center for Human Genetics, Catholic University of Leuven, LEUVEN; [5]Department of Hematology, Catholic University Leuven, LEUVEN; [6]Department of Oncology, Catholic University Leuven, LEUVEN; [7]Center for Human Genetics and VIB, Catholic University of Leuven, LEUVEN, Belgium

Background. MALT lymphoma is a low grade B cell neoplasm which commonly develops from a background of chronic inflammatory or auto-immune disorder. Approximately 25% of MALT lymphoma cases is hallmarked by characteristic and mutually exclusive chromosomal translocations including, t(11;18)(q21;q21)/ API2-MALT1, t(1;14)(p22;q32)/IGH-BCL10, t(14;18)(q32;q21)/IGH-MALT1 and t(3;14)(p14;q32)/IGH-FOXP1. The oncogenic products of the first three translocations target the NFkB pathway which plays an important role

in cell survival and proliferation. *Aims*. This study aimed at molecular characterization of a novel t(X;14)(p11;q32) identified in four B-NHL cases. *Methods*. The reported cases were analyzed using FISH, oligo aCGH (Agilent 244K), qRT-PCR, Western blotting and immunohistochemistry. *Results*. Histology, immunophenotype and clinical features of all four cases with t(X;14) were reviewed. MALT type lymphoma was diagnosed in three cases and *de novo* gastric DLBCL in one case. Patients were 3 females and one male with an average age of 75 years (66-82). Two of them had a previous history of Sjögren's syndrome, one of leukocytoclastic vasculitis, and the patient with gastric DLBCL had a chronic gastritis. All patients received an initial therapy and three are alive after 7-86 months from diagnosis. Extensive FISH analysis of t(X;14) showed IGH involvement at 14q32.33 and mapped the Xp11.4 breakpoint in the 3' end of the CASK gene. Of note, this gene houses GPR34 and GPR82 coding for orphan G-protein coupled receptors, located in the intron 5 of CASK. To identify the gene targeted by t(X;14), we performed qRT-PCR analysis of five genes flanking the Xp11.4 breakpoint (tel->USP9X, DDX3X /bkpt/CASK, GPR34, GPR82->cenX) in two available cases. Only one of these genes, GPR34, showed to be highly upregulated (>50 fold) in both analyzed cases. IHC analysis of the GPR34 protein expression is ongoing. So far, involvement of GPR34 in tumorigenesis has not been reported. To examine molecular consequences of an aberrant expression of GPR34 in lymphoma, we analyzed the status of NFkB and MAP kinase pathways by Western blotting with antibodies against phosphorylated Ik-Ba and ERK1. In both analyzed cases a phosphorylated Ik-Ba protein was detected. Further studies to evaluate the NFkB target genes expected to be activated in lymphomas with t(X;14) are ongoing. High resolution aCGH did not identify any recurrent genomic imbalances in these cases. Interphase FISH analysis of 13 MALT lymphomas with unknown cytogenetics showed a normal pattern of the IGH and CASK break apart probes applied in these cases. *Conclusions*. The novel t(X;14)(p11.4;q32.33) is predominantly associated with MALT lymphoma and an underlying autoimmune/inflammatory disorder. The translocation targets GPR34 which is upregulated due to its juxtaposition with strong regulatory elements of IGH. The finding of NFkB activation by t(X;14)/IGH-GPR34 further strengthens the important role of this pathway in the development of MALT lymphoma.

DIFFERENTIAL EXPRESSION OF MICRORNAS IN PRIMARY CENTRAL NERVOUS (CNS) AND NODAL DIFFUSE LARGE B-CELL LYMPHOMAS

L. Fischer,[1] M. Hummel,[2] A. Korfel,[3] D. Lenze,[2] E. Thiel[3]

[1]Charité Campus Benjamin Franklin, BERLIN; [2]Institute of Pathology, Charité C. Benjamin Franklin, BERLIN; [3]Dept. of Hematology & Oncology, Charité C. Benjamin Franklin, BERLIN, Germany

Background. Primary CNS lymphoma (PCNSL) is a rare subtype of diffuse large B-cell lymphoma (DLBCL) confined exclusively to the CNS. Mechanisms leading to lymphoma development in the immunoprivileged CNS are still not fully understood. MicroRNAs play key regulatory roles in eukaryotic gene expression and recently aberrant microRNA expression has been demonstrated in several lymphoma entities. Thus far, no data are available for PCNSL. *Aims*. The aim of the study was to determine the expression pattern of microRNAs in PCNSL and to test whether microRNA profiling can distinguish PCNSL from nodal DLBCL. *Methods*. Total RNA was extracted from formalin-fixed and paraffin-embedded (FFPE) tissue sections of diagnostic biopsy samples derived from newly diagnosed PCNSL and DLBCL. FFPE blocks used had been stored for up to six years. RNA was reverse transcribed using eight predefined primer pools containing up to 48 multiplex RT primers each. Gene expression was measured by quantitative real-time (RT) PCR using commercially available TaqMan low density arrays (TLDA). Each TLDA contained specific primer-probe combinations for 365 microRNA species, three small nuclear RNAs functioning as endogenous controls and two negative controls. Each RT-PCR was run in duplicate. Normalized expression levels were calculated using the 2-dCT method. Mean expression levels in PCNSL and nodal DLBCL of each microRNA were compared using the Mann-Whitney-U test. Biopsy samples were also subtyped immunohistologically into a GCB- and non-GCB type according to the Hans classifier (CD10, BCL6, MUM1). *Results*. Eleven PCNSL and eight nodal DLBCL samples were analyzed: four non-GCB and four GCB nodal DLBCL; and five non-GCB, three GCB, and three non-classifiable PCNSL. Of 365 microRNA species, 40% showed significant expression levels by means of RT-PCR (Ct value of <38). We detected 20 microRNAs with a significantly different expression in PCNSL and nodal DLBCL. Expression of 12 microRNAs was significantly higher in PCNSL, and eight microRNAs showed reduced expression compared to DLBCL (Table). The most significant differences were detected for miR-204, miR-27b, miR-155, miR-214 and miR-432. Expression levels of specific microRNAs differed from 60-fold upregulation to 12-fold downregulation. *Conclusions*. This is the first report demonstrating a differential expression of specific microRNAs in PCNSL and nodal DLBCL. Several of the differentially expressed microRNAs have been implicated in pathways promoting tumor cell survival, such as miR-214 (PTEN/AKT in ovarian cancer), angiogenesis (miR-27b), or regulation of drug metabolizing enzymes or P-glycoprotein expression (miR-27b, miR-415). MiR-204 is highly expressed in acute and chronic B cell leukemias, and miR-155 is known to be associated with NF-kappaB activity and upregulated in non-GCB DLBCL. Thus, some of the differentially expressed microRNAs identified in this study might be involved in the development of PCNSL and warrant further studies.

Table.

microRNA	PCNSL/DLBCL -fold expression	*p*
hsa-miR-204	60,8	0.006

CAL-101, A SPECIFIC INHIBITOR OF THE P110DELTA ISOFORM OF PHOSPHATIDYLINOSITIDE 3-KINASE, FOR THE TREATMENT OF NON-HODGKINS LYMPHOMAS

J. Lannutti, S.A. Meadows, A. Kashishian, B. Steiner, K.D. Puri, N.A. Giese

Calistoga Pharmaceuticals, SEATTLE, USA

Background. Phosphatidylinositide 3-kinases (PI3Ks) are a family of lipid kinases that are involved in signaling events which control a diverse number of cellular processes. The PI3Ks are divided into three classes; I, II, and III. The class I kinases contain four isoforms designated p110alpha, beta, delta, gamma, and are activated by cell surface receptors. Aberrant regulation of the PI3K signaling pathway is frequently observed in human malignancies including those of hematological origin. Giving its role in tumorgenesis, PI3K is an attractive target in cancer therapy. Unlike the other class IA isoforms p110delta expression is largely restricted to hematopoietic cells whereas the α and β isoforms are ubiquitously expressed. CAL-101 is an oral p110delta specific inhibitor which is currently being evaluated in a phase I clinical trial for the treatment of non-Hodgkins lymphomas (NHL) and chronic lymphocytic leukemia (CLL). This compound is a novel potent p110delta inhibitor with an IC50 of 2.5 nM against purified p110delta and EC50 of 65 nM in p110delta-mediated basophil activation in whole blood. CAL-101 demonstrates 300-, 200-, and 40-fold selectivity over the other class I family members (alpha, beta, and, gamma respectively) and no activity against class II and III PI3K family members or other PI3K-related proteins including mTOR and DNA-PK. Furthermore, a kinome-wide

screen failed to detect activity any additional kinases. Previous studies have provided preclinical proof of concept through the analysis of cell lines and primary tumor cells from patients with acute myeloid leukemia, chronic lymphocytic leukemia, acute lymphoblastic leukemia and multiple myeloma. For each of these indications, all cell lines and patient samples expressed a high level of the p110delta isoform and treatment with CAL-101 resulted in PI3K pathway inhibition that correlated with the induction of cellular apoptosis or cell cycle arrest. *Results*. In the present study, we show that treatment of NHL cell lines with CAL-101 resulted in a significant decrease in cellular proliferation. High levels of p110delta were observed in all NHL cell lines while expression levels of the other three isoforms varied. The results showed that cell growth was inhibited in a dose-dependent manner in follicular lymphoma (RL, Karpas-422, WSU-FSCCL, and WSU-NHL), diffuse large B-cell lymphoma (SU-DLH4, SU-DLH5, and HS602) and mantle cell lymphoma (Mino and NCEB) cell lines. Growth suppression observed in both the diffuse large B-cell and follicular lymphoma cell lines correlated with an increase in the percentage of apoptotic cells. Furthermore, CAL-101 induced apoptosis was accompanied by PARP and caspase-3 cleavage. Additional mechanistic studies show that inhibition of p110delta abrogated or reduced the phosphorylation of Akt, GSK-3B, and S6. *Conclusions*. Our results demonstrate that specific inhibition of p110delta and its downstream signaling pathways with CAL-101 inhibits malignant cell growth and survival, thereby providing the preclinical rationale for its clinical testing as a novel therapeutic approach in NHL.

0669

AMPLIFICATION AT 11Q23 TARGETS PROTEIN KINASE SIK2 IN DIFFUSE LARGE B-CELL LYMPHOMA

S. Nagel, C. Meyer, H. Quentmeier, M. Zaborski, M. Kaufmann, H.G. Drexler, R.A.F. MacLeod

DSMZ, BRAUNSCHWEIG, Germany

Background. Subclassification of hematologic malignancies according to chromosomal aberrations and/or gene expression signatures is very important for the judgement and development of therapeutic protocols. This has been done with great success for diffuse large B-cell lymphomas (DLBCLs), identifying three major subtypes: germinal center B-cell-like (GCB), activated B-cell (ABC) and primary mediastinal B-cell lymphoma (PMBL). Nevertheless, in DLBCL several recurrent chromosomal aberrations have been described albeit without knowledge of their effects on gene expressions, including gain/amplification at 11q23-24. *Aims*. Here, we characterized an amplification at 11q23 in the DLBCL-derived cell line KARPAS-422 to identify target genes of this aberration. *Results*. By quantitative genomic PCR and fluorescence *in situ* hybridization analysis we mapped the amplicon to 85-111 Mbp, containing a high peak at 111 Mbp. Quantitative RT-PCR, western blot and immuno-staining identified overexpression of SIK2/SNF1LK2, while neighboring candidates at 111 Mbp were inconspicuously expressed, highlighting this gene as the major target of this amplification. Quantification of SIK2 mRNA in diverse lymphoma cell lines, including anaplastic large cell lymphoma, Hodgkin lymphoma, Burkitt lymphoma and mantle cell lymphoma demonstrated higher average expression levels in DLBCL, indicating a general role of SIK2 in this lymphoma type. SIK2 codes for a protein kinase which has been shown to inhibit cAMP-regulated transcription factor CREB via phosphorylation of its cofactor TORC. Accordingly, siRNA-mediated downregulation of SIK2 expression resulted in elevated expression of the CREB target gene BIM. Functional analysis by treatments of KARPAS-422 cells in comparison to a DLBCL control cell line with SIK2 upstream regulator cAMP or downstream effector 2-deoxy-D-glucose indicated a regulating role for SIK2 in survival and glucose metabolism, respectively. Finally, gene expression profiling of KARPAS-422, analyzing B-cell signature genes suggested that this cell line belongs to the GCB-subtype of DLBCL. *Conclusions*. We have identified SIK2 as a novel potential oncogene in DLBCL which may represent a suitable therapeutic target. The cell line KARPAS-422 may serve as a useful model for further investigations of amp(11)(q23) positive GCB-DLBCLs, overexpressing SIK2.

IMPROVED DIFFERENTIAL DIAGNOSIS BETWEEN WHO-DEFINED MATURE B-CELL MALIGNANCIES USING INTEGRATED 8-COLOR FLOW CYTOMETRY AND NOVEL SOFTWARE FOR MULTIVARIATE ANALYSIS OF IMMUNOPHENOTYPIC DATA

S. Böttcher,[1] A. Rawstron,[2] J. Flores,[3] P. Lucio,[4] R. de Tute,[2] A. Mendonça,[4] Q. Lecrevisse,[3] T. Kalina,[5] M. Kneba,[1] J.J.M. van Dongen,[6] A. Orfao,[3] On behalf of the EuroFlow[7]

[1]University of Schleswig-Holstein, Campus Kiel, KIEL, Germany; [2]Haematology Malignancy Diagnostic Service, St. James's Institute of Oncology, LEEDS, UK; [3]University of Salamanca, Cancer Research Centre and Cytometry Service, SALAMANCA, Spain; [4]Instituto Portugués de Oncologia, Laboratorio de Hemato-Oncologia, LISBON, Portugal; [5]Charles University, Dept. of Paediatric Haematology/Oncology, PRAGUE, Czech Republic; [6]Erasmus MC, Dept. of Immunology, ROTTERDAM, Netherlands; [7]EuroFlow Consortium, C/O ROTTERDAM, Netherlands

Background. Mature B-cell malignancies are currently diagnosed according to the WHO classification using a combination of pathological, cytogenetic, clinical, and immunophenotypic data. With the advent of novel disease specific treatment options reproducible, fast, cost-effective and broadly available methods for these differential diagnoses are becoming increasingly important. *Aims*. We investigated the utility of 8-color flow cytometry to exactly diagnose B-NHL entities. *Methods*. We tested panels that included markers for lineage assignment of malignant B cells in heterogeneous samples (CD19, CD20, CD22, CD37) plus markers for differential diagnosis between WHO disease entities. The differential diagnosis marker set initially included antigens associated with B cell maturation (e.g. bcl-2, CD38, CD81, CD43, CD10), associated with particular B-cell malignancies (e.g. CD5, CD103, CD23), integrins (e.g. CD11a, CD11c), and chemokine receptors (CXCR5). Testing in a total of 144 B-cell malignancies aimed to improve the power for differential diagnosis by adding novel markers for difficult to classify entities and to reduce the number of necessary markers by omitting antigens with redundant information. The final 4 tube 8-color panel version was designed using the INFINICYT software based on those 20 markers that in multivariate analyses contributed the most to differential diagnoses between any combination of two B-cell malignancies. The panel was integrated into a diagnostic work flow for mature B-cell malignancies and therefore contains a tube to orientate towards reactive conditions, and towards mature T/NK malignancies, respectively. The final panel was tested in a total of 42 mature B-cell malignancies with an established diagnosis according to current WHO standard criteria (3 hairy cell leukemia, HCL, 2 follicular lymphoma, FL, 14 typical CLL, 9 mantle cell lymphoma, MCL, 3 lymphoplasmacytic lymphoma, LPL, 5 marginal zone lymphoma, MZL, 1 atypical CLL, 5 Diffuse large B cell lymphoma DLBCL). *Results*. The combination of CD19 and CD20 are necessary and sufficient for lineage assignment in B-cell malignancies, whereas CD22 and CD37 did not additionally contribute. Except for some overlap between FL and DLBCL cases, all the remaining entities could be clearly differentiated in 1 x 1 comparisons using the fluorescence intensities of the 20 markers and multivariate analyses algorithms of INFINICYT software. Furthermore, we developed a diagnostic algorithm that allowed to classify all CLL (14), HCL (3), and MCL (9) cases. With two exceptions (1 MZL, 1 DLBCL) all remaining 14 DLBCL, FL, MZL, atypical CLL and LPL cases formed discrete clusters thus predicting that they will be classifiable based on immunophenotypic information only. Current data therefore predict an overall power of 8-color flow cytometry to diagnose B-NHL entities in 95.2% of cases (40/42). *Summary and Conclusions*: We conclude that our extensively tested 4-tube 8-color panel in combination with INFINICYT software algorithms is likely to greatly improve the diagnostic precision of flow cytometry to classify B-NHL entities solely based on immunophenotype.

ALTERATIONS OF CHEK2 GENE IN NON-HODGKIN LYMPHOMA PATIENTS

O. Havranek,[1] Z. Kleibl,[2] P. Soucek,[3] M. Trneny[1]

[1]Charles University in Prague, First Faculty of Medicine, PRAGUE 2; [2]Institute of Biochemistry and Experimental Oncology,Charles University in Prague, PRAGUE; [3]National Institute of Public Health, Laboratory of Toxicogenomics, PRAGUE, Czech Republic

Background. The risk of non-Hodgkin lymphoma (NHL) development is modified by genetic background. Numerous studies have evaluated the

risk of NHL in carriers of alterations in genes coding for proteins implemented in various cellular functions (e.g. immunomodulation, detoxification, oxidative stress response, DNA repair). Checkpoint kinase 2 (CHK2) participates on regulation of DNA double-strand break (DSB) repair. The CHK2 protein is responsible for activation of several key effector proteins involved in DSB repair, cell cycle arrest, or apoptosis. These processes could be negatively influenced by inactivating mutations in CHK2 gene (CHEK2). Carriers of CHEK2 mutations are at increased risk of several cancer types development (e.g. colorectal, breast, and prostate cancer), but the relation to the NHL remains unclear. *Aims*. We performed mutation analysis in order to evaluate the risk of NHL development in CHEK2 mutation carriers. *Methods*. Mutation analysis of whole coding sequence of CHEK2 gene was performed in 185 patients with NHL, mainly with diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL). Genomic DNA was isolated from peripheral blood of patients that signed approved informed consent prior genetic testing. Individual exons were PCR-amplified and analyzed by denaturing high-performance liquid chromatography (DHPLC; WAVE3500; Transgenomic). Samples with aberrant elution profiles were sequenced from independent amplification (ABI 3100; Applied Biosystems). The large rearrangements of CHEK2 gene were analyzed by multiplex ligation-dependent probe amplification (MLPA) method (MRC Holland). The population frequency of new alterations was estimated in population of non cancer controls. *Results*. The CHEK2 region (exons 2 a 3) coding for highly conservative fork head associated (FHA) domain was shown to contain several gene alterations [c.470T>C (I157T), c.542G>A (R181H), IVS1-5T>A, IVS2+1G>T]. Frequency of alterations in this region was significantly higher in NHL patients (5.95%; 11/185) than in controls (2.78%; 19/683) with OR = 2.2 (95% CI 1.03-4.73; p=0.04). Even more significant result was found in subpopulation of FL patients (8.6%; 5/58; OR = 3.3; 95% CI 1.18-9.18; p=0.02). Frequency of alterations in exon 1 c.122C>T (S41F), c.252A>G (E84E), IVS1+39dupA was the same in control population as in lymphoma cases. Two new alterations were characterized in NHL patients (IVS4-78_-100dup23 and IVS10+28A>G). We have analyzed 160 samples from lymphoma patients by MLPA, but no large rearrangement was found. *Conclusions*. Inherited CHEK2 alterations in FHA-coding region could increase the risk of NHL development, especially of FL. Large genomic rearrangements are rare and, therefore, do not play significant role in NHL pathogenesis. Clinical and pathological characteristics will be correlated with individual genotypes.

DISTINGUISHING OF PRIMARY MEDIASTINAL B-CELL LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA USING REAL-TIME QUANTITATIVE POLYMERASE CHAIN REACTION

H. Votavova,[1] K. Forsterova,[2] V. Campr,[3] J. Stritesky,[4] Z. Velenska,[4] R. Pytlik,[2] K. Kubackova,[5] B. Prochazka,[6] R. Kodet,[3] M. Trneny[2]

[1]General Teaching Hospital, PRAGUE; [2]1st Department of Internal Medicine, General Teaching Hospital, PRAGUE; [3]Department of Pathology, Motol University Hospital, PRAGUE; [4]Department of Pathology, General Teaching Hospital, PRAGUE; [5]Department of Radiation and Oncology, Motol University Hospital, PRAGUE; [6]National Institute of Public Health, PRAGUE, Czech Republic

Background. Primary mediastinal B-cell lymphoma (PMBL) is a subset of diffuse large B-cell lymphoma (DLBCL) with better clinical outcome. These two units can be reliably distinguished only with microarray technology. 24% of patients with clinically expected PMBL diagnosis did not carry the PMBL gene signature when microarrays were used. These patients fell into the DLBCL group and tended to have adverse prognosis. 5% of patients with expected DLBCL were genetically assigned as PMBL ones (Rosenwald, J Exp Med, 2003). *Aims*. Our aim was to help to distinguish PMBL and DLBCL using real-time quantitative polymerase chain reaction (RTqPCR) and routinely available formalin fixed, paraffin embedded material (FFPE). *Methods*. RNA was successfully isolated from 99% (84/85) of originally obtained paraffin blocks. Finally, 82 patients with available clinical data were included in the study. For 39 of them the diagnosis of PMBL was expected (mediastinal bulk > 7cm, histopathology). All the cases were reviewed and the clinical-pathological diagnosis was verified. Based on the published microarray data, CD23, Pdl2 and Blk genes were chosen as potential discriminators between PMBL and DLBCL. Expression of these genes was measured using RTqPCR and ΔΔCT method. *Results*. Testing set included 32 patients. For 11 and 21 of them PMBL and DLBCL diagnosis, respectively, was expected clinical-pathologically. Expression of CD23, Pdl2 and Blk genes was measured and a mathematical formula was established to distinguish both the entities. The formula was verified on a validation set consisting of 50 patients including 28 patients for whom PMBL diagnosis was clinical-pathologically expected. In the validation set, 9 out of 28 of expected PMBL patients were classified as DLBCLs and all 22 expected DLBCLs were confirmed using the formula. When the approach was applied on the whole group of patients the following results were obtained. For 2 out of 43 patients (5%) with clinical-pathologically expected DLBCL the diagnosis was not genetically confirmed. 10 out of 39 patients (26%) with clinical-pathologically expected PMBLs fell into the DLBCL group. Compared to genetically confirmed PMBLs, these discrepant PMBL ones showed some clinical features which were more similar to the DLBCL diagnosis, e.g. more frequent spleen infiltration (p=0.028) and decreased local invasiveness in pericardium (p=0.045). They tended to have worse clinical outcome, more common infradiafragmatic involvement, they had less often tumor sclerosis, fluidothorax, or chest wall involvement and none of them had pleura involvement. *Summary and Conclusions*. A new approach of distinguishing of PMBL and DLBCL patients is presented. It is based on expression of CD23, Pdl2 and Blk genes. Moreover, RTqPCR method and routinely available FFPE material were successfully used.

0673

BIOLOGIC EFFECTS OF P53 ACTIVATION BY NUTLIN-3A IN ALK+ALCL WITH UNMUTATED, MUTATED/PARTIALLY FUNCTIONAL AND MUTATED/NONFUNCTIONAL P53 GENE

G. Rassidakis,[1] E. Drakos,[2] V. Atsaves,[2] J. Li,[2] I. Papanastasi,[2] E. Schlette,[2] L.J. Medeiros[2]

[1]National and Kapodistrian University of Athens, ATHENS, Greece; [2]The University of Texas M.D. Anderson Cancer Center, HOUSTON, USA

Background. p53 is frequently expressed, but infrequently (<10%) in anaplastic kinase-positive (ALK+) anaplastic large cell lymphoma (ALCL) tumors. Nutlin-3a is a recently developed small molecule that targets Mdm2, a critical negative regulator of p53, and disrupts the p53-Mdm2 interaction resulting in p53 stabilization and activation. *Aims.* To investigate the effects of nutlin-3a on p53-dependent apoptosis and the cell cycle in ALK+ ALCL cells with wild-type (wt), mutated / partially functional (mt-pf) or mutated / nonfunctional (mt-nf) p53 gene. *Methods*. The mutation status of the p53 gene was investigated in 4 ALK+ALCL cell lines by direct sequencing of the entire open reading frame of p53 gene following cDNA amplification. ALK+ALCL cell lines carrying wt, mt-pf and mt-nf p53 gene were treated with increasing concentrations of nutlin-3a,TRAIL, CH11, pifithrin-α, pifithrin-μ, and the chemotherapeutic agent doxorubicin. The biologic effects of these treatments were evaluated using standard cell viability, apoptosis and proliferation assays. Western blot analysis was used to assess the levels of apoptosis and cell cycle-regulating proteins before and after nutlin-3a treatment. *Results*. Nutlin-3a activated p53 in ALK+ALCL cells carrying wt or mt-pf p53 gene resulting in p53-dependent cell cycle arrest and apoptosis. Cell cycle arrest was associated with up-regulation of the cyclin-dependent kinase inhibitor p21. Nutlin-3a-induced apoptotic cell death was accompanied by Bax and Puma up-regulation, down-regulation of Bcl-xL and survivin, and caspase-3 cleavage. Nutlin-3a-induced apoptosis was reduced significantly when p53-dependent transactivation activity was inhibited by pifithrin-α, or inhibition of direct p53 targeting of mitochondria by pifithrin-μ was employed. Nutlin-3a sensitized the activation of the extrinsic apoptotic pathway in wt-p53 ALK+ALCL cells, in part through up-regulation of DR-5 and downregulation of cFLIPS/L, and synergized in apoptotic induction with TRAIL. Also, nutlin-3a treatment enhanced the cytotoxicity of doxorubicin against ALK+ALCL cells harboring mt-nf p53 gene, which was associated with upregulation of p73. *Conclusions*. These data suggest that non-genotoxic agents like nutlin-3a offer a novel therapeutic approach for AKL+ALCL patients harboring wt- or mt-p53 gene.

THE HISTONE DEACETYLASE INHIBITOR ITF2357 (GIVINOSTAT) PROMOTES BURKITT'S LYMPHOMA CELL LINE DEATH MODULATING MICRO-RNA AND TISSUE TRANSGLUTAMINASE 2 EXPRESSION

R. Zappasodi,[1] M. Di Nicola,[1] C. Carlo-Stella,[2] F. Baldan,[1] M.V. Iorio,[1] M. Magni,[1] E. Tagliabue,[1] C.M. Croce,[3] A.M. Gianni[1]

[1]Istituto Nazionale Tumori, MILAN, Italy; [2]University of Milan, MILAN, Italy; [3]Ohio State University, COLUMBUS, OH, USA

Background and Aims. The significant toxicities associated to the conventional treatments of Burkitt's lymphoma (BL) are leading to the identification of novel targets for effective but less toxic therapies. While c-myc overexpression and Epstein-Barr virus (EBV) infection are the hallmarks of BL, how they complement one another and what other factors intervene in oncogenic process is yet to be determined. Recent studies support the existence of a c-myc-microRNA (miRNA) interaction within the genesis and the maintenance of the lymphoma phenotype. Furthermore, myc oncoproteins have been found to inhibit the transcription of tumor suppressor genes, including tissue transglutaminase 2 (TG2), a multifunctional protein that promotes apoptosis and differentiation in normal tissues. This can occur by recruiting histone deacetylase (HDAC) 1 proteins to target genes. Therefore, we tested ITF2357 (Givinostat), a new hydroxamate inhibitor of HDAC, on BL cell lines with respect to its effects on cell viability and on c-myc mRNA, miRNAs and TG2 expression modulation. *Methods and Results*. ITF2357 induced late and early apoptosis respectively on Namalwa and Raji BL cell lines, exhibiting an IC50 of 200nM after 48h from drug administration. Accordingly, ITF2357 induced subG1 peak formation in Namalwa and G1 arrest in Raji cells. Notably, c-myc mRNA decreased only in Namalwa cells after treatment. ITF2357 treated Raji cells instead showed a gradual increase of c-myc mRNA, however paralleled by a reduction of c-myc protein. The profound miRNA modulations, particularly evident in treated Raji cells as assessed by array analyses and quantitative real-time PCR, could explain these apparently inconsistent observations. MiR-155 and miR-98, known for their oncogenic activity in myc-associated tumors, were significantly down regulated after treatment. Conversely, ITF2357 induced the expression of Let-7a, which has been shown to negatively affect c-myc at posttranscriptional level. Finally, immunohistochemical analysis revealed an increased cytoplasmatic expression of the tumor suppressor TG2 in ITF2357-treated Raji cells, compared to their untreated counterparts. *Conclusions*. ITF2357 demonstrated potent cytotoxic and growth inhibitory activities on BL cell lines. These effects might be related to the restoration of the expression of different c-myc targets, including oncogenic and tumor-suppressing miRNAs and the tumor suppressor TG2. Accordingly, the reversion of c-myc abnormal expression was achieved in both BL cell lines studied. The potential candidacy of ITF2357 as a therapeutic agent for BL awaits further evidences from ongoing analyses in BL primary tumors and in animal models.

0675

DIFFERENTIAL EXPRESSION OF SIN1 GENE PRODUCT IN NON-HODGKIN AND HODGKIN LYMPHOMA CELL LINES AND TUMORS

G. Rassidakis, P. Tsioli, P. Panayiotidis, T. Vassilakopoulos, E. Patsouris

National and Kapodistrian University of Athens, ATHENS, Greece

Background. The novel mammalian stress activated protein kinase (SAPK) interacting protein 1 (Sin1) gene give rise to multiple isoforms through alternative splicing. Recent studies provide evidence that Sin1 is a key component of the mammalian target of rapamycin (mTOR)-Rictor complex (mTORC2), thus critically regulating the Ser473-phosphorylation / activation of AKT kinase that results in tumor cell survival through multiple downstream targets. Moreover, in the absence of Sin1 gene, mTOR-Raptor (mTORC1) activity is upregulated upon stimulation of the PI3K/AKT/mTOR pathway. Previous studies have shown that the AKT/mTOR oncogenic pathway is activated in many cancers including aggressive non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL). However, the potential role of Sin1 protein in the pathogenesis of NHL and HL is yet unknown. *Aims*. To investigate the expression patterns of Sin1 protein and its isoforms in various NHL and HL cell lines and tumors. *Methods*. The expression of Sin1 gene products was assessed by Western Blot analysis in 13 NHL and HL cell lines and 10 fresh-frozen specimens of NHL of various histologic types. In addition, expression and subcellular localization of Sin1 protein was evaluated using immunohistochemical methods, a tissue microarray (TMA) and duplicate tumor cores from 35 specimens obtained prior to treatment, which included reactive lymph nodes, chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), mantle cell lymphoma (MCL), follicular lymphoma (FL), marginal zone lymphoma (MZL), diffuse large B-cell lymphoma (DLBCL), Burkitt lymphoma (BL), peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS), anaplastic large cell lymphoma (ALCL) and classical HL. The monoclonal antibody used was specific for Sin1 and capable of detecting Sin1 isoforms 80, 76 and 55 kDa. *Results*. Sin1 isoforms 80, 76 and 55 kDa were detected in immunoblots at a variable level in NHL and HL cell lines tested. A reverse correlation between Sin1 protein levels and activation status of downstream targets of the mTORC1, such as phosphorylation of 4EBP1 and rp-S6 as well as total eIF4E was observed with the exception of Granta 519 (MCL) cells. This association was also seen in primary NHL tumor specimens analyzed by Western blot. Immunohistochemical analysis of Sin1 protein revealed that Sin1 was localized in both cytoplasm and nucleus of tumor cells and was expressed at a high level in many NHL types including CLL/SLL, MCL, FL, MZL and a subset of DLBCL. By contrast, A subset of DLBCL, BL and HL expressed relatively lower levels of Sin1 (p=0.007, chi-square test). The expression levels of Sin1 inversely correlated with the levels of 4EBP1 phosphorylation confirming the western blot data. *Conclusions*. Sin1, a critical regulator of mTORC2 integrity and activity, is differentially expressed among NHL and HL tumors and seems to be inversely associated with mTORC1 activation. Additional mechanistic studies are required to shed light on the relative biologic significance of Sin1/ mTORC2 activation in various NHL and HL types, which would provide novel targets for investigational therapies.

0676

SELECTION OF MARKERS FOR IDENTIFICATION OF DISEASE-SPECIFIC PHENOTYPES FOR DIAGNOSIS AND MONITORING OF B-LYMPHOPROLIFERATIVE DISORDERS BY FLOW CYTOMETRY

C. Rawstron,[1] R.M. De Tute,[1] J. Shingles,[1] F.L. Bennett,[1] S. Böttcher,[2] P. Lucio,[3] T. Kalina,[4] E.A. MacIntyre,[5] J.J.M. van Dongen,[6] A. Orfao,[7] A.S. Jack[1]

[1]Leeds Teaching Hospitals, LEEDS, UK; [2]University of Schleswig-Holstein, KIEL, Germany; [3]Portuguese Institute of Oncology, LISBON, Portugal; [4]Charles University 2nd Medical School, PRAGUE, Czech Republic; [5]AP-HP Hôpital Necker-Enfants-Malades, PARIS, France; [6]Erasmus MC, ROTTERDAM, Netherlands; [7]University of Salamanca, SALAMANCA, Spain

Background. The identification of a disease-specific phenotype for CLL has greatly improved the rapidity and simplicity of diagnosis and monitoring. Most other B-lymphoproliferative disorders (B-LPD) do not have a disease-specific phenotype. *Aims*. To perform a comprehensive assessment of the cell surface phenotype in B-LPD and identify suitable markers for each disease category. *Methods*. 66 surface markers were assessed on 12 B-LPD cases. Expression levels were compared using dChip software (http://biosun1.harvard.edu/complab/dchip) and 22 markers with ≤1.5-fold difference between WHO disease categories were excluded from further analysis. The selected markers were then tested on 48 cases and 12 markers were excluded as before, with two (CD43 and CD200) added. The 34 selected markers were further tested on 101 cases and 4 markers were excluded. The remaining 30 antigens were tested on a large series of 1415 cases using 6-colour cytometry. A training set was identified comprising 300 representative cases with a complete diagnosis available from the sample. Three classification approaches were tested: linear discriminant analysis, decision tree analysis, and an algorithm approach, similar to the "CLL score" but based on expression levels derived machine learning vector analyses rather than ± discrimination. Results were defined as an exact match where there was complete concordance between the immunophenotypic classification and WHO classification, a partial match if the phenotype correctly indicated a germinal centre (GC) or non-GC origin of the neoplastic B-cells and a mismatch if GC status was incorrect or if normal B-cells were classified as having a B-LPD phenotype or vice-versa. *Results*. Highly specific and sensitive phenotypes were identified for Burkitt Lymphoma, CLL and Hairy Cell Leukaemia. Differential diagnosis between CLL and Mantle Cell Lymphoma was greatly improved. It was also possible to accurately classify over 70% of Follicular Lymphoma and 60% of Marginal Zone Lymphoma cases with <5% incorrect classification. In addition to standard markers such as CD5, CD10, CD79b and CD103, infrequently used markers such as CD200, LAIR-1, CD31 and CD39 were extremely powerful for classification. Linear discriminant analysis gave an exact match in 80% of cases, and a mismatch in 15%; decision tree analysis an exact match in 79% and a mismatch in 16%; and the algorithm approach an exact match in 66% with a mismatch in 3%of cases. In 204 bone mar-

row samples with no morphological evidence of disease, the B-cell phenotype either confirmed no evidence of infiltration or correctly identified the diagnosis made on subsequent tissue biopsies in 20% of cases using the algorithm, 47% with the decision tree and 65% using linear discriminant analysis. *Summary and Conclusions*. Specific immunophenotypes are identifiable for most B-LPD but this requires ~20 markers and is best suited to 6/8-colour flow cytometry. Statistical approaches to classification are more effective than human-designed algorithms, particularly in samples with low-level infiltration, and ideally should be incorporated within the flow cytometry analysis software. These markers have now been extensively tested by the EuroFlow Consortium using Infinicyt software that incorporates multivariate analysis of data. Such approaches will potentially allow significant improvements in the diagnosis of B-lymphoproliferative disorders.

0677

MUTATION AND SINGLE NUCLEOTID POLYMORPHISM ANALYSIS IN HUMAN HERPESVIRUS 8-ASSOCIATED PRIMARY EFFUSION LYMPHOMA

E. Boulanger,[1] A. Marchio,[2] S.S. Hong,[3] P. Pineau[2]

[1]Oswaldo Cruz Institute (FIOCRUZ), RIO DE JANEIRO, Brazil; [2]Pasteur Institute, PARIS, France; [3]Faculte de Medecine RTH Laennec, LYON, France

Background. Human Herpesvirus 8 (HHV-8)-associated primary effusion lymphoma (PEL) is a rare non-Hodgkin lymphoma often associated with Epstein-Barr virus (EBV) infection. Somatic mutations of tumour suppressor genes and oncogenes are among the most common genetic alterations found in human cancers. Moreover, single nucleotide polymorphisms (SNP) in genes involved in apoptosis or cell cycle regulation have been shown to correlate with an increased risk of cancer development, an accelerated cancer onset, a poor response to treatment or a shorter survival. *Aims*. As mutations of PTEN, PIK3CA, CTNNB1/β-catenin genes, deletion of CDKN2A-ARF (p14ARF-p16INK4a) locus and SNP had never been investigated in primary PEL tumours, we performed an extensive molecular analysis of mutations and SNP in a large series of PEL. *Methods*. Mutations in TP53, PTEN, PIK3CA, CTNNB1/β-catenin genes, deletion of CDKN2A-ARF locus, SNP72 and ins16bp in TP53, SNP309 in MDM2, S31R and 3'UTR (c70t) in CDKN1A/p21Cip1, V109G and 5'UTR (c79t) in CDKN1B/p27Kip1, g870a in CCND1/cyclin D1, A259S in CCND3/cyclin D3, F31I (t91a) in STK15/aurora A, R70C in CDC25C, A655V in CDC2L1 and I441V in CDC6 genes, were investigated in seventeen primary PEL tumours collected from sixteen patients and seven PEL cell lines, using PCR and sequencing. *Results*. TP53 gene mutations were detected in two primary PEL samples (11.8%) and two PEL cell lines (28.6%). BCBL-1 was found to harbor a heterozygous M246I mutation of TP53. BCP-1 contained two missense mutations leading to single nucleotide changes (M246V and D259N) in both alleles of TP53. PTEN gene alterations were identified in two PEL cell lines, associated with a loss of PTEN protein expression in both cases (Figure).

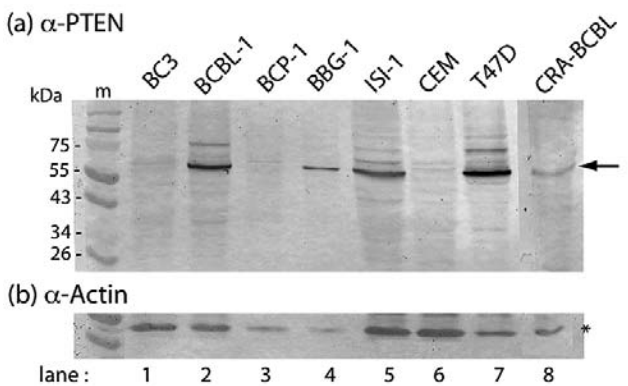

Figure.

BC-3 carried a monoallelic 2 bp-deletion in PTEN exon 7 leading to a non-sense mutation at codon 250. BCP-1 harbored a homozygous deletion of PTEN exons 6 through 9. No mutations were detected in PIK3CA and CTNNB1/β-catenin hotspot sequences. Only BC-3 contained a homozygous deletion of CDKN2A-ARF locus. The mutation rate was found to be significantly higher in EBV-negative PEL (5/12) compared to EBV-positive PEL (0/12, p=0.037). Considering the sixteen patients with PEL, the CDKN1A/p21Cip1 S31R, CDKN1B/p27Kip1 V109G and CDC2L1 A655V polymorphims were found to be significantly associated with an African origin (p=0.033, 0.002 and 0.007, respectively), the CDKN1A/p21Cip1 c70t polymorphism with the presence of a HHV-8-associated multicentric Castleman disease (p=0.015) and the CCND3 A259S polymorphism with Human Immunodeficiency Virus type-1 infection and EBV status of PEL (p=0.001 and 0.015, respectively). No correlation could be found between these SNP, the age of patients at the time of PEL diagnosis and their survival from the date of PEL diagnosis. *Conclusions*. Although detected at a higher frequency in PEL cell lines (3/7) than in primary PEL tumours (2/17), TP53 and/or PTEN gene mutations as well as deletion of CDKN2A-ARF locus are uncommon in PEL, and are found to be restricted to the EBV-negative PEL tumours. No mutations were detected in PIK3CA and CTNNB1/β-catenin hotspot sequences, suggesting that other mechanisms are involved in the pathogenesis of HHV-8-associated PEL.

0678

FOCUSED MICROARRAY FOR LYMPHOMA DIAGNOSTICS

B. Tichy, K. Stano-Kozubik, J. Supikova, A. Janikova, I. Vasova, L. Smardova, J. Mayer, S. Pospisilova

University Hospital Brno and Faculty of medicine Masaryk University, BRNO, Czech Republic

Background. Non-Hodgkin lymphomas (NHL) represent a heterogeneous group of lymphoproliferative disorders with highly variable clinical course and outcome. In some cases, current diagnostic methods based on histopathology and immunohistochemistry may be insufficient for exact tumor classification and subjectively influenced by pathologist's experience, especially in Burkitt's lymphoma. Neither prognostic markers such as the International Prognostic Index (IPI), although highly useful, do not capture all the variability that affects clinical behaviour of lymphomas. The genome-wide transcriptional profiling was reported to accurately define the biological phenotype of the tumor. *Aims*. The aim of the project was to design novel focused oligonucleotide microarray directed at molecular diagnostics and prognostication of lymphoproliferative disorders, particularly non-Hodgkin lymphomas, and to test its reliability on a cohort of newly diagnosed lymphoma samples. *Methods*. We designed custom oligonucleotide microarray (Agilent 8x15K custom array) carrying specific probes for approximately 4000 genes. The genes represented on the microarray were selected on the basis of previously published lymphoma/leukemia gene expression profiling studies. In addition, probes for the genes implicated in crucial cellular processes such as apoptosis or cell cycle control were added. To provide more information, the genes for the majority of CD antigens and'-h*ousekeeping* genes were also included in the microarray design. 67 histologically characterised samples were analysed - 18 Diffuse Large B-cell Lymphomas (DLBCL), 34 Follicular Lymphomas (FL), 3 Burkitt's Lymphomas (BL), 1 MALT Lymphoma, 6 non-malignant lymph-nodes and 3 lymphoma cell lines (SU-DHL-4, WSU-NHL, RAMOS). RNA was obtained either from fresh-frozen lymph-node resections, or from RNAlater preserved needle biopsy samples. *Results*. Cluster analysis revealed following major clusters: a) BL and cell lines, b) DLBCL and c) FL and non-malignant lymph-nodes. The BL branch was clearly distinct and contained only BL and cell line samples, whereas the DLBCL and FL clusters show higher similarity with one another. Statistical analysis of differentially expressed genes among the NHL subtypes revealed tens of significant genes. The indolent subtype (FL) shows higher expression of genes specific for infiltrating cells (e.g. CD3D, CD28, CD7) in comparison to aggressive subtypes (DLBCL and BL). On the other hand, the genes implicated in cell cycle progression and cell proliferation (e.g. cyclins A and E, CDC6, CHEK1) were highly expressed in aggressive subtypes. In the DLBCL sample group, the Activated B-cell like (ABC) and Germinal Centre like (GC) molecular subtypes can be distinguished with our focused microarrays. As the most important finding, we confirmed the characteristic gene expression signature of Burkitt's lymphoma that may help in the diagnosis of histopatologically disputable cases. *Summary*. We demonstrated the benefit of gene expression profiling using novel designed focused microarray for non-Hodgkin lymphoma characterisation. The technology is robust, less expensive compared to whole-genome approach and still capable to retain important information.

DETECTION OF HYPERMETHYLATION OF TUMOR SUPPRESSOR GENES IN OCULAR ADNEXAL LYMPHOMA USING MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA)

E. Coupland,[1] H. Ma,[1] A. Lo,[2] D. Wong,[2] H. Stein,[3] E. Bertil[1]

[1]University of Liverpool, LIVERPOOL, UK; [2]Eye Institute, HONG KONG, Hong Kong; [3]Charite University Hospital Benjamin Franklin, BERLIN, Germany

Background. Ocular adnexal lymphomas (OAL) occur in the orbit, lacrimal drainage system, conjunctiva and eyelid. They comprise 8% of all extranodal non-Hodgkin lymphomas (NHL) with the extranodal marginal zone B-cell lymphoma (EMZL) being the most common, accounting for 2/3 of them. Hypermethylation in CpG sites in promoter regions is an epigenetic change that could lead to silencing of a gene. Hypermethylation in tumor suppressor genes (TSGs) occurs in various tumors, including NHL. *Aims*. We examined the methylation status of multiple TSGs in OAL, comparing EMZL with non-EMZL. *Materials and Methods*. Formalin-fixed paraffin-embedded (FFPE) OAL, including both EMZL and non-EMZL OALs, were examined. DNA was extracted and purified from FFPE, and only those with DNA of sufficient quantity and quality were selected for subsequent analysis using methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA). 33 EMZL and 27 non-EMZL were examined with two MS-MLPA kits, in which methylation status of CpG sites in a total of 35 candidate TSGs were analyzed. Reactive lymphoid hyperplasia cases were used as controls. MLPA PCR products are separated by capillary electrophoresis, and sequencing data were statistically analyzed with specifically designed Excel spreadsheets. CpG hypermethylation in patient samples was determined when statistical significance of standard error > 0.1 as compared to the reference samples. *Results*. From MLPA, specific loci in eight TSGs including CDH13, WT1, MSH6, IGSF4, DAPK1, ESR1, p14-ARF and RAR-β showed hypermethylation in at least 65% of the 33 EMZL OALs, as well as in majority of the non-EMZL OALs. However, hypermethylation status varies among different subtypes of non-EMZLs that includes follicular, diffuse-large-B-cell and Mantle cell lymphomas. Validation of this data is in progress using methylation enriched pyrosequencing. *Conclusions*. Many OALs demonstrated hypermethylation. Correlation of methylation analysis data with clinical presentation and follow-up may reveal epigenetic markers of prognostic value in these tumors.

DETECTION OF PLASMACYTOID (PLASMACYTIC) DIFFERENTIATION IN MARGINAL ZONE B CELL LYMPHOMAS (MZL) BY CD138 EXPRESSION

C. Kalpadakis,[1] G.A. Pangalis,[2] P. Korkolopoulou,[2] T.P. Vassilakopoulos,[2] G. Levidou,[3] M.C. Kyrtsonis,[2] S. Sachanas,[2] X. Yiakoumis,[2] E.M. Dimitriadou,[2] F.N. Kontopidou,[2] M.P. Siakantaris,[2] E. Patsouris,[3] P. Panayiotidis,[2] H. Papadaki,[1] M.K. Angelopoulou[2]

[1]Department of Haematology, University of Crete, ATHENS; [2]Department of Haematology, University of Athens, ATHENS; [3]Department of Pathology, University of Athens, ATHENS, Greece

Background. MZL are usually characterized by a morphological heterogeneous lymphomatous population. The occurrence and frequency of plasmacytoid (plasmacytic) differentiation as well as its clinical impact have not been precisely defined yet. *Aims*. To evaluate the occurrence of plasmacytoid (plasmacytic) differentiation in MZL and to correlate these findings with clinical and laboratory characteristics as well as survival. *Methods*. We analyzed 71 MZL patients diagnosed and followed in our Departments. Among them, 37 were splenic MZL (SMZL), 20 non-gastric mucosa-associated lymphoid tissue (MALT) lymphomas, 7 nodal MZL (NMZL) and 7 primary bone marrow MZL (PBMMZL). The last category is not defined in the WHO classification and included cases with blood involvement and bone marrow infiltration without splenomegaly, lymphadenopathy or other extranodal localization of the disease. Anatomic localization of non-gastric MALT lymphomas were as follows: 5 salivary glands, 5 skin, 3 ocular adnexae, 3 lung, 3 Waldeyer's ring and 1 bladder. Plasmacytoid (plasmacytic) differentiation was defined on the basis of the expression of the plasma cell-related antigen CD138 by immunohistochemistry. *Results*. Tumors were all positive for CD20 and CD79a antigens. Nine out of 71 (13%) MZL cases demonstrated plasmacytoid (plasmacytic) differentiation as this was defined by a >20% CD138 positive lymphoma cells. Analytically plasmacytoid (plasmacytic) differentiation was identified in 2 (5%) of SMZL, in 4 (20%) of non-gastric MALT lymphoma, in 3 (43%) of NMZL, and in none of the PBMMZL patients. Among non-gastric MALT lymphomas only skin and salivary gland localization demonstrated plasmacellular differentiation. Correlation of plasmacellular differentiation with demographics, stage of disease, paraproteinemia, LDH, outcome and survival, on a univariate analysis, disclosed no statistically significant differences. *Summary and Conclusions*. Plasmacytoid (plasmacytic) differentiation in MZL as a whole is not a common finding. However there is significant variation between the different subgroups. NMZL and MALT lymphomas seem to display more commonly features of plasmacytoid (plasmacytic) differentiation. Furthermore in non-gastric MALT lymphomas this differentiation varies according to anatomic site of the disease.

EPSTEIN BARR VIRUS PREDICTS OUTCOME IN PEDIATRIC B-CELL NON HODGKIN LYMPHOMA

P. Chabay, E. De Matteo, J. Lara, M. Lorenzetti, P. Cambra, L. Aversa, M.V. Preciado

Ricardo Gutierrez Children Hospital, BUENOS AIRES, Argentina

Background. In Western countries malignant non-Hodgkin lymphomas (NHLs) represent the fourth most common childhood cancer, accounting for about 6% of pediatric malignancies. The majority of pediatric NHLs derives from B cells (B-NHL) and represents primary high-grade lymphomas. The 3 most prevalent entities are Burkitt lymphoma (43%), B-lymphoblastic lymphoma (7%), and diffuse large B-cell lymphoma (13%). EBV expression as well as some apoptosis markers has been related to prognosis in adult B-NHL, but little is known in pediatric B-NHL. *Aims*. To quantitatively assess EBV, bax, bcl2, Ki67 and activated caspase-3 (casp-3a) expression in B-NHL, and to correlate each one with patients' event free survival. *Methods*. We analyze 40 pediatric B-NHL, 23 Burkitt lymphoma (BL) and 17 diffuse large B-cell lymphoma (DLBCL); age range 1 to 16 yrs, (median: 7 yrs); male: female ratio 5:3. Ki67, casp-3a, bax and bcl2 expression was assessed by immunohistochemistry, and EBV by EBERs *in situ* hybridization in formalin fixed-paraffin embedded lymph node biopsies. Results were expressed as (n° positive cells/field) / (n° total cells/field) - 100, in 10 high-power fields (x1000). *Results*. Ki67, casp-3a, bax and bcl2 were detected in 39/40 (97.5%), 34/40 (85%), 37/40 (92.5%) and 13/40 (32.5%) cases, respectively. Quantification of positive tumor cells for each cellular marker was: Ki67 1 to 97.6% (median 55), casp-3a 0 to 15% (median 1.75), bax 0 to 99.1% (median 9.65) and bcl2 0 to 70.6% (median 0). Significant positive correlation was found only between bax/casp3a (r=0.4504, p=0.0035, Spearman's correlation). The 5-year event-free survival of all patients was 65%. None of the cellular marker was associated with unfavorable outcome according to Kaplan Meier survival analysis, using each median as cut off points. Sixteen out of 40 cases (40%) showed EBERs positive hybridization (8/23 BL, 35%; 8/17 DLBCL, 47%). EBV expression was not statistically associated with Ki67, casp-3a, bax and bcl2 positive staining; however it was significantly associated with a worse event-free survival (EFS) according to Kaplan Meier Survival analysis (p=0.0155, log rank test). *Conclusions*. High expression of Ki 67 and the proapoptotic protein bax together with casp-3a, indicate that high proliferation index could trigger apoptosis, and both are essential on pediatric B-NHL development. EBV expression in pediatric DLBCL is higher than the observed in the adult counterpart. EBV could be a cofactor of both pediatric DLBCL and BL lymphomagenesis. EBV presence was statistically associated with worse EFS, and predicts highly unfavorable prognosis in pediatric B-NHL, thus it could be used as prognosis factor for this pediatric malignancy.

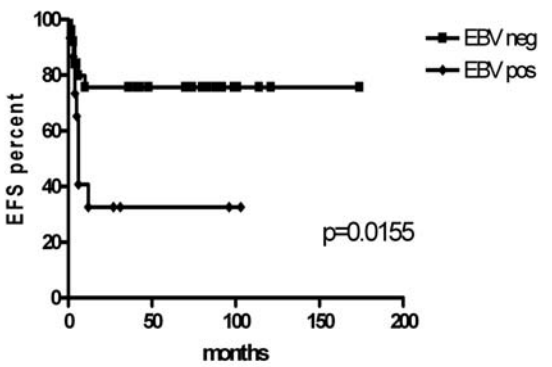

Figure 1. EFS correlated with EBV expression.

0682

EXPRESSION OF CD66ABCE ON TUMOR CELLS IN NON-HODGKIN LYMPHOMAS AND MULTIPLE MYELOMA

H. Mocikova,[1] J. Karban,[2] R. Pytlik,[3] P. Klener,[3] M. Trneny[2]

[1]First Faculty of Medicine and General Teaching Hospital, Charles University, PRAGUE; [2]First Department of Medicine, Charles University General Hospital, PRAGUE; [3]1st Medical Faculty, Charles University, PRAHA 2, Czech Republic

Background. CD66 is expressed on myeloid cells at different stages of maturity in normal hematopoiesis, on epithelial cells, on lymphoid cell lines of T and B cell origin, in childhood acute lymphoblastic leukemias (ALL), chronic myeloid leukemias (CML) and in acute myeloid leukemias (AML). Little is known about the expression of CD66abce in non-Hodgkin lymphomas (NHL) and multiple myeloma (MM). 90 Y-labeled anti-CD66 antibody (clone BW 250/183) is a new radioimmunoconjugate developed for treatment of tumors with positive expression of CD66abce. Aim of this study was flow cytometric analysis of CD66abce expression on tumor cells in newly diagnosed untreated various types of NHL and MM to evaluate the possibility of treatment with 90 Y-labeled anti-CD66 antibody in these malignancies. *Methods*. 227 patients with newly diagnosed untreated hematologic malignancies were examined for expression of CD66abce on tumor cells in bone marrow between January 2007 and December 2008. All patients signed informed consent to participate in this study. The diagnosis of NHL or MM was confirmed histologically including bone marrow involvement in all specimens. Our group consisted of 74 B-chronic lymphocytic leukemias (B CLL), 22 mantle cell lymphomas (MCL), 18 follicular lymphomas (FCL), 15 marginal zone lymphomas (MZL), 13 lymphoplasmacytic lymphomas/M.Waldenstrom (LPL/MW), 13 diffuse large B cell lymphomas (DLBCL), 4 T NHL, 4 hairy cell leukemias (HCL), 3 B NHL not otherwise specified (B NHL NOS), 3 B ALL, and 58 MM. All 227 bone marrow samples were stained with monoclonal antibody CD66abce (clone Kat4C) fluoresceinisothiocyanate (FITC) - conjugated. 115 of 227 bone marrow samples were also stained with monoclonal antibody CD66abce (clone BW 250/183) FITC-conjugated. Expression of anti-CD66 was evaluated separately on unselected population of white blood cells and on malignant clone (positive expression ≥20% malignant cells was used as cut-off). Results are summarized in Table 1.

Table 1. Expression of CD66abce (clone BW 250/183 and clone Kat4C) in hematologic malignancies.

Diagnosis	Expression posit./negat. in bone marrow samples	
	CD66abce (clone BW250/183)	CD66abce (clone Kat 4C)
B CLL	6/30	60/14
MM	8/24	43/15
MCL	3/11	22/0
FCL	3/6	5/13
MZL	4/3	13/2
LPL/MW	2/2	13/0
DLBCL	2/4	11/2
T NHL	1/1	0/4
HCL	0/1	3/1
NHL NOS	0/2	3/0
B ALL	0/2	3/0
Total: posit./negat.	29/86	176/51

Conclusions. Positive expression of CD66abce was most frequently detected on tumor cells of B CLL, multiple myeloma, mantle cell lymphoma and lymphoplasmacytic lymphomas. In these diagnoses, treatment with radiolabelled anti-CD66 antibody would be possible. However, other clones of antiCD66abce than currently used BW 250/183 with better affinity to this antigen might be more beneficial.

SURVIVIN EXPRESSION IN AGGRESSIVE B-CELL LYMPHOMA

M.K. Angelopoulou,[1] P. Korkolopoulou,[1] V. Salpeas,[1] Z. Galani,[1] T.P. Vassilakopoulos,[1] G. Levidou,[1] A. Anastasopoulou,[1] K. Lilakos,[1] S. Sachanas,[1] M.P. Siakantaris,[2] M.-C. Kyrtsonis,[1] P. Panayiotidis,[1] A. Androulaki,[1] T. Papadaki,[3] E. Patsouris,[4] G.A. Pangalis[1]

[1]National and Kapodistrian University of Athens, ATHENS; [2]National & Kapodistrian University of Athens, ATHENS; [3]Evangelismos Hospital, Department of Hematopathology, ATHENS; [4]National and Kapodistrian University of Athens, Department of Pathology, ATHENS, Greece

Background. Survivin, a member of the Inhibitor of Apoptosis Proteins, has recently gained attention as a possible therapeutic target in neoplasia, due to its dual role both as an antiapoptotic protein and a cell cycle regulator. Survivin has been associated with an adverse outcome in several malignancies. However its prognostic significance in diffuse large B-cell lymphoma (DLBCL) is controversial. *Purpose*. To investigate Survivin expression and localization, its correlation with clinical and laboratory characteristics and its prognostic significance in DLBCL and follicular lymphoma grade III (FLGIII). Survivin was studied by immunohistochemistry in formalin-fixed paraffin-embedded tissues from patients treated and followed in our Unit. Positivity for Survivin expression was scored as follows: Nuclear Survivin was expressed as % of neoplastic cells with a positive nuclear staining. Cytoplasmic Survivin was considered positive for any % of positively stained cells in the cytoplasm and negative when all cells showed no cytoplasmic staining. *Results*. Among 66 patients [median age 63 years (17-90)], 62% were males, 39% had elevated LDH and 42% clinical stage III/IV. Histologic subtypes were: DLBCL 72%, primary mediastinal LBCL 6%, FLGIII 17% and transformed low grade lymphoma 4%. The vast majority of patients received R-CHOP. Nuclear expression of Survivin was detected in all patients at a median percentage of 11% of neoplastic cells (2-90%). Cytoplasmic Survivin expression was evident in 38% of the patients. Levels of nuclear Survivin expression were significantly lower in FLGIII compared to other subtypes (p=0.007). Cases with a high percentage of cells with nuclear Survivin expression tended to be cytoplasmic Survivin negative (p=0.11). There was no other significant correlation between nuclear or cytoplasmic Survivin expression and baseline patients' characteristics. 5-year failure free survival was 56% for all patients. Conventional prognostic factors were valid in this patient population. When FLGIII were excluded, higher nuclear survivin expression tended to correlate with inferior FFS at various cut-offs (25-50%), although differences were not statistically significant. Interestingly the presence of any cytoplasmic survivin was associated with superior FFS (5-year rates: 93 vs 50%, p=0.01). *Conclusions*. Our preliminary data show that Survivin is expressed in the nucleus of neoplastic cells in aggressive B-cell lymphomas. Moreover its prognostic significance may vary according to its nuclear or cytoplasmic localization.

0684

BCL-2, BCL-6 AND MYC REARRANGEMENTS AND CLINICAL OUTCOME OF DIFFUSE LARGE B-CELL LYMPHOMA

M.S. Sobas,[1] M. Tojo,[2] M. Tubio,[3] M. Fraga,[2] J.L. Bello,[3] J. Forteza[2]

[1]Servicio de Hematologia, Hospital Clinico Universitario, SANTIAGO DE COMPOSTELA; [2]Servicio de Anatomia Patologica, Hospital Clinico Universitario, SANTIAGO DE COMPOSTELA; [3]Servicio de Hematologia y Hemoterapia, Hospital Clinico Universitario, SANTIAGO DE COMPOSTELA, Spain

Background. Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous group of non-Hodgkin lymphoma (NHL) with clinical, morphological and biological features not well defined. Novel prognostic markers are needed to predict the outcome of patients with DLBCL; in this context, molecular and cytogenetic features may be helpful. The prognostic value of BCL-2, BCL-6 and MYC rearrangements has been investigated in several studies of DLBCL, but the results are still controversial. *Aims*. To study correlation between BCL-2, BCL-6 and MYC rearrangements and the clinical features in 64 patients with DLBCL. *Methods*. We performed a retrospective, single centre study on 64 patients diagnosed of DLBCL: 53 *de novo*, 6 transformed from follicular NHL and 5 transformed from not-specified low grade NHL. All patients were diagnosed and followed-up in our centre in a period 2003-2008. Clinical data were obtained from clinical records. The FISH study was performed in paraffin-embedded tissue and BCL-2, BCL-6 and MYC FISH DNA split-signal probes (Dako, Denmark) were used. *Results*. BCL-

2 rearrangement was found in 13/64 (20.3%), BCL-6 in 15/64 (23.4%) and C-MYC in 5/64 (7.8%) of analyzed patients. BCL-2 rearrangement was present in 6/6(100%) of patients with DLBCL transformed from follicular NHL and in 7/53 (13.2%) DLBCL *de novo*. BCL-2 rearrangement was absent in DLBCL transformed from other type of low grade NHL. BCL-6 rearrangement was found in 13/53 (24.5%) DLBCL *de novo* and in 2/5 (40%) in DLBCL transformed from other type of low grade NHL. There was no case of BCL-6 rearrangements in DLBCL transformed from follicular NHL. MYC was detected in 1/6 (16.7%) in DLBCL transformed from follicular NHL and 4/53 (7.5%) in DLBCL *de novo*. There were two patients with dual rearrangements: one with BCL-2 and MYC and one with BCL-6 and MYC. We observed a significant association (p=0.046) between BCL-2 rearrangement and a higher stage (III and IV) of NHL. No significant correlation was found between presence of BCL-2, MYC and BCL-6 and age, disease presentation, patient ECOG performance status, serum LDH level, response to treatment, overall survival and between BCL-6 or MYC rearrangements and stage of disease. *Conclusions*. According to our results, BCL-2, BCL-6 and MYC rearrangements have no impact on patients' prognosis. However, BCL-2 rearrangement appears to be associated with advanced-stage of disease. This finding and the rarity of BCL2 rearrangement in *de novo* DLBCL, raises the question about the possibility of these lymphomas representing a transformation from previously non-diagnosed follicular NHLs.

RHD GENE POLYMORPHISMS IN ALLOIMMUNIZED D-NEGATIVE INDIVIDUALS WITH HIGH RATE OF RACIAL ADMIXTURE

F. Martin,[1] S. Menezes,[2] A. Chiba,[1] D. Langhi Jr,[2] L. Nardozza,[1] C. Chiattone,[2] J. Bordin[1]

[1]*Universidade Federal de São Paulo, SÃO PAULO;* [2]*Faculdade de Ciências Médicas de São Paulo, SÃO PAULO, Brazil*

Background. The D-negative phenotype is the result of the total RHD gene deletion in almost all Caucasians, but it accounts for only about 20% in Africans and 70% in Asians. In Africans the RHDæ that is an insertion of 37bp in exon 4 is one of the most important causes of the D-negative phenotype. *Aims*. Considering that few studies have investigated the RHD alleles in alloimunized D-negative individuals with high rate of racial admixture (Caucasians, Africans and Asians), in this study we investigated the RHD polymorphisms in D-negative phenotype mixed Brazilians who have developed anti-D alloantibody. *Methods*. Blood samples from 130 individuals previously typed as D-negative were phenotyped again using: (a) two tube reagents (Anti-D blend reagent, Cellular line TH-28, MS-26, DiaMed Latino America, Brazil; and Anti-D polyclonal, Fresenius Kabi, Brazil); (b) one gel test ID-Card for Rh subgroups including Cw and Kell antigens (DiaMed Latino America, Brazil); and (c) ABO/Rh (ID-Card DiaMed Latino America, Brazil) according to manufacturer instructions. The presence of anti-D alloantibody was confirmed by testing patients' sera against two commercial RBC panels (DiaMed Latino America, Brazil; and Fresenius Hemocare, Brazil). All sera were shown to contain anti-D alloantibodies with title ≥64. The method used for RHD screening detected the presence of RHD exon 10 and intron 4. After amplifying exon 10 and intron 4 two PCR reactions were performed to determine the presence of other RHD gene regions. The PCR reproducing exons 2, 3, 5 and 7 of the RHD gene, resulted in 180, 117, 125 and 95bp products, respectively. The exon 2 product was used as internal control of the reaction, as it is found in both RHD and RHCE genes. Sequence analysis was performed on PCR products amplified from genomic DNA for all 10 exons RHD gene. *Results*. We found that 118/130 (90.8%) of D-negative tested individuals had total RHD gene deletion, while 12/130 (9.2%) showed RHD gene polymorphisms. The RHDæ was found in 10 (7.7%) individuals who had the insertion of 37pb between the end of intron 3 and exon 4 and the mutations 609 G>A, 654 G >C, 667 T>G, 674C>T, 807 T>G. One sample (0.77%) hybrid RHD-CE-Ds /RHDψ, and another (0.77%) weak D type 4.2 were characterized due to mutations 186 G>T, 410 C>T, 455 A>C, 1025 T>C / 609 G>A, 654 G >C, 667 T>G, 674C>T, 807 T>G + the insertion of 37pb and 602 C>G, 667 T>G, 957 G>A, 1025 T>C, respectively. *Conclusions*. The presence of the RHD gene in D-negative subjects has been shown to occur in 27.7% of Japanese, in 26.0% of Koreans, and more than 80.0% of Africans. Our results showed that the RHD gene was present in 9.2% of racially mixed Brazilians who produced clinically significant anti-D alloantibodies. Therefore, the data showed that careful attention is necessary for clinicians in applying RhD genotyping to transfusion medicine in populations with high rate of racial admixture. The highly frequent discrepancies between phenotypes and RHD genotypes, specially RHDæ, urge for improvements in imunohematological tests applied for transfused mixed populations.

0686

ACTIVE HEMOVIGILANCE OF PEDIATRIC PATIENTS SUPPORTED WITH PLASMA COMPONENTS PREPARED WITH PHOTOCHEMICAL TREATMENT

J.P. Cazenave,[1] I. Mendel,[1] C. Waller,[1] J.C. Osselaer,[2] M. Jaquet,[3] M. Propst,[3] L. Lin,[3] L. Corash[3]

[1]*EFS Alsace, STRASBOURG, France;* [2]*Blood Transfusion Center, Clin Univ de Mont Godinne, Univ Cath de Louvian, YVOIR, Belgium;* [3]*Cerus Corporation, CONCORD, USA*

Background. Platelet components photochemically pathogen inactivated using the INTERCEPT Blood System™ have been transfused in routine clinical practice to a broad patient population in Europe for 5 years. Transfusion of INTERCEPT platelets to pediatric patients has been shown to be safe and effective (Vox Sang 2006;91(S3):177). The same INTERCEPT Blood System was CE Marked in 2006 for pathogen inactivation of plasma components and has been in clinical use for 2 years. An active hemovigilance program was implemented to gather safety

information on routine transfusion of INTERCEPT plasma components (IPL). *Aims*. This ongoing study evaluated the transfusion safety profile in pediatric patients receiving IPL. Results of 1,029 transfusions in pediatric patients including infants are reported. *Methods*. Centers participating in this study produced IPL (approximately 200 mL per component) in routine practice. Plasma transfusions were ordered by primary care physicians per standard of care. This study assessed the response to all study IPL transfusions within the first 24 hr. The primary endpoint was the incidence of acute transfusion reactions (ATR). An ATR was defined as an adverse event (AE) possibly related, probably related, or related to the plasma transfusion. For each transfusion, patient demographics and primary diagnosis/therapy were recorded regardless of whether an AE was observed. For AEs, the following data were collected: time of event following transfusion, clinical description, objective clinical parameters (vital signs), results from clinical and laboratory tests (radiographs, bacterial cultures), severity (grade 0-4), serious or non-serious nature, and causal relationship (unrelated, probably unrelated, possibly related, probably related, or related). *Results*. To date 1,029 transfusions, comprised of 1,641 IPL, have been administered to 348 pediatric patients (61.8% male, 38.2% female). The mean age was 4.2 years (160 children between 1-18 years, 188 infants <1 year). Of the 348 patients, 109 (31.3%) received IPL transfusion for a hematologic disorder (including 3 with congenital coagulation deficiency, 101 with acquired coagulopathy, and 2 with TTP), 83 (23.9%) for surgery, 156 (44.8%) with another diagnosis as an indication for plasma transfusion. Average number of transfusions (txn) per patient was 3.0 txn (range 1-55, median 2.0). Each patient received a mean of 4.7 IPL (range 1-99, median 2.0). Compared to frequency of transfusions in infants (<1 year), older pediatric patients (1-18 years) received higher numbers of transfusions and plasma components (3.4 txn/7.0 IPL vs. 2.6 txn/2.7 IPL). Patients 1-18 years old with hematology diseases received more transfusions and plasma products (mean 4.7 txn/7.5 IPL) than other diseases. One patient with congenital coagulation deficiency and two patients with TTP received the largest number of transfusions and IPL products (Table 1). In all patients, 153 (44%) patients had previous transfusions, of which 63 (18.1%) patients received INTERCEPT platelets. Among the 1,029 transfusions, no AE, ATR, SAE, deaths or episodes of TRALI due to an IPL transfusion were reported. *Conclusions*. To date no acute transfusion reactions with IPL transfusions were reported in pediatric patients including infants. These results provide additional indication that routine IPL transfusion is safe and well tolerated in this patient population.

Table 1. Transfusion frequency per patient by age group and by diagnosis (Mean txn/mean IPL).

	All (n=348)	Hematology (n=109)	Congenital coagulopathy (n=3)	Acquired coagulopathy (n=101)	TTP (n=2)
1-18 years old	3.4/7.0 (n=160)	4.7/7.5 (n=56)	36.0/37.0 (n=1)	3.3/6.1 (n=51)	28.0/34.0 (n=2)
<1 year old[a]	2.6/2.7 (n=188)	2.7/2.7 (n=53)	1.0/1.0 (n=2)	2.8/2.8 (N=50)	-
Total	3.0/4.7	3.7/5.2	12.7/13.0	3.1/4.5	28.0/34.0

[a] Volume of IPL transfused is based on the body weight of an infant. Any transfusion with a volume up to approximately 200 mL was counted as one IPL.

0687

TRANSFUSION OF PLATELET COMPONENTS PREPARED WITH PHOTOCHEMICAL PATHOGEN INACTIVATION FOR SUPPORT OF SEVERE GLANZMANN THROMBASTHENIA DURING SURGICAL PROCEDURES

J.P. Cazenave,[1] M.L. Wiesel,[1] I. Mendel,[1] A. Faradji,[2] S. Mangin,[2] B. Perricard,[2] D. Kientz[1]

[1]EFS-Alsace, STRASBOURG; [2]Hôpitaux Universitaires de Strasbourg, HAUTEPIERRE, France

Background. Glanzmann thrombasthenia (GT) is a recessive autosomal severe bleeding disorder characterized by defective fibrinogen binding and the absence of platelet aggregation to all physiological agonists. GT is due to the absence (Type 1) or dysfunction (Type 2) of the Gp IIb-IIIa complex. A large consanguineous group of Gypsies, living in Strasbourg, affected by type 1 GT has been studied in our laboratory since 1971. Due to a splice site mutation at the 5' end of Intron 15 of platelet Gp IIb (Gypsy mutation) detectable Gp IIb-IIIa is not expressed on the platelet surface. In the past, female patients from this cohort with severe hemorrhage, such as menorrhagia, have required repeated platelet component (PC) transfusion resulting in alloimmunization against Gp IIb-IIIa. The requirement of GT patients for repeated PC transfusion increases the risk of transfusion-transmitted infection. *Aims*. We evaluated hemostasis of GT patients in response to transfusion with amotosalen and UVA pathogen inactivated (INTERCEPT Blood System™) PC. *Results*. Patient 1 was a 21 year old female, (1.73m / 81kg). During the last 13 years, she received many transfusions: 33 RBCC and 40 non pathogen inactivated apheresis platelet concentrates (APC). Recently, she was diagnosed with an ovarian cyst. Laparoscopy followed by laparotomy was required because of cyst volume. Before surgery, she received 4 buffy coat platelet concentrates (BCPC), 2 more BCPC were transfused during surgery, and 2 more 2 hours after surgery. Then, she received 2 BCPC every 12 hours for 10 days (until the day after staple removal). During surgery, bleeding occurred, and she received 3 red blood cell concentrates (RBCC) and 1 unit of fresh frozen plasma (FFP). No other complications were observed. The total platelet transfusion dose was 192.2×10^{11} platelets. Patient 2 was a 22 year old female, (1.62 m/82kg), with a normal term pregnancy. Presence of antibodies to platelet Gp IIb/IIIa complex was documented since 2004. No anti-HLA antibodies were detected. Before cesarean section she received 1APC, 2 BCPC during surgery, and 2 BCPC 2 hours after surgery. Then, she was transfused with 2 BCPC every 12 hours through day 11 (until the day after staple removal). The cesarean section delivery of a normal male (3 kg) was without bleeding complications; and no complications were observed through day 11. No RBCC or FFP were required during the hospital stay. The total platelet transfusion dose was 186.3×10^{11} platelets. Patient 3 was a 6 year old boy (16.2 kg) requiring avulsion of 2 molar teeth (previously with infected abscess). He received split APC before, after and once a day for 6 days. Because he experienced a moderate urticaria during the third APC transfusion, he received Claritin just before the following transfusions that were uneventful. The total platelet transfusion dose was 12×10^{11} platelets. *Conclusions*. Intensive transfusion with INTERCEPT PC was well tolerated and supported major surgery, without significant bleeding, in 3 Type 1 GT patients. The same total platelet dose was used previously with conventional PC in similar GT patients before implementation of INTERCEPT PC. This report demonstrates effective clinical hemostasis in GT, a severe hereditary platelet disorder, using PC prepared with INTERCEPT pathogen inactivation.

LOSS OF THE RED CELL B ANTIGEN AND BLOOD GROUP CHANGE IS NOT ASSOCIATED WITH METHYLATION OF THE ABO GENE PROMOTER REGION IN A PATIENT WITH 5Q- MYELODYSPLASTIC SYNDROME

A. Martinez, A.M. Kuniyoshi, M.L.L.F. Chauffaille, M. Yamamoto, A.K. Chiba, E.Y.S. Kimura, J.O.B. Bordin

Universidade Federal de São Paulo, SÃO PAULO, Brazil

Background. Blood group change with loss of red cell (RBC) antigen may occur in solid tumors and in hematological diseases, however the mechanisms involved in these changes are uncertain. Aberrant DNA hypermethylation is thought to be involved in myelodysplastic syndromes (MDS), and the methylation of cytosines residues in the dinucleotide CpG may account for the expression patterns of the ABO genes. *Aims*. Using phenotyping and genotyping studies we investigated the possible role of DNA methylation in the ABO promoter gene in a patient with MDS presenting loss of the B antigen. *Methods*. An 80-year-old man was admitted due to acute coronary syndrome with the following laboratory results: Hb=8.2g/dL, MVC=101fl/RBC, WBC=6.1×10^9/L (neutrophils=4.2×10^9/L, lymphocytes=0.6×10^9/L, no myeloblasts), platelets=833×10^9/L. Bone marrow examination showed an increased number of dysplastic megakaryocytes with monolobulated nuclei. Karyotype analysis revealed 46,XY,del(5)(q15q33)[4]/46,XY[16] leading to the diagnosis of 5q- syndrome. The patient became transfusion-dependent, and the immunohematological tests indicated that his RBCs agglutinated with anti-B, while his serum agglutinated type A RBCs. Four months latter no agglutination was seen when his RBCs were tested with anti-A or anti-B, resulting in type O. Since anti-A was still present in his serum the patient was transfused with type O RBCs until he finally died due to heart disease. The B and H antigens expression on the RBCs surface was accessed by flow cytometry, while ABH secreted antigens were investigated in saliva. A PCR-based ABO genotyping using restriction enzyme digestion (Alu and Kpn) followed by agarose gel eletrophoresis was also performed. Methylation of CpG islands was investigated using MSP technique with methylated and unmethylated primer sets for region from -200 to +26 sequence of the ABO gene. *Results*. Flow cytometric analysis with dual staining for H and B antigens showed that the patient's RBCs had a partial positivity with anti-

H/FITC, but negative reaction with anti-B/PE. Genotyping studies showed heterozygosity for the B allele indicating the BO genotype. A macroscopic positive reaction was seen in a tube containing A RBCs, patient's saliva and anti-A, but no agglutination was seen with B RBCs, patient's saliva and anti-B, indicating the presence of the soluble B antigen in patient´s saliva. The presence of a 280bp PCR product in the unmethylated lane associated with the absence of a PCR product in the methylated lane revealed that the evaluated ABO gene promoter region was not associated with DNA methylation. *Conclusion*s. Many patients in the early stages of MDS with symptomatic anemia can be managed supportively with RBC transfusions, therefore the blood group change may augment the risk of serious blood transfusion reactions in such individuals. Using serologic techniques, flow cytometry and ABO genotyping, we demonstrated a blood group change due to loss of the B antigen in a transfusion-dependent patient with 5q- syndrome. These investigations facilitated the transfusion management of the patient who did not experience transfusion reactions. Our data also indicated that the loss of the B antigen was not associated with DNA methylation of the accessed ABO gene promoter region in this particular patient with 5q- MDS.

0689

A 10-YEAR LOOK-BACK ON USE OF CRYOPRECIPITATE IN A TERTIARY CARE HOSPITAL

G. Zakout,[1] M.A. Greiss[2]

[1]Aberdeen Royal Infirmary, ABERDEEN; [2]SNBTS Aberdeen & N/E Scotland Blood transfusion Centre Dept of Transfusion Medic, ABERDEEN, UK

Background. Much of the evidence on use of cryoprecipitate rests on clinical experience and peer-reviewed articles, which defies our current practice of adopting evidence-based medicine. Hence it comes to no surprise that literature to this date shows variable and often inappropriate use of this blood component. *Aims*. To retrospectively assess the pattern of cryoprecipitate use at Aberdeen Royal Infirmary and affiliated hospitals and whether it complies with current practice guidelines *Methods*. A retrospective analysis of use of cryoprecipitate from 01/01/1999 till 12/31/2008 was undertaken. At Aberdeen Royal Infirmary cryoprecipitate is issued under the guidance of a hematologist or transfusion medicine specialist. All cryoprecipitate components issued are documented in the *medical officer* logbook, which includes the entry of each unit of cryoprecipitate being issued to a patient against his/her name, date of birth, unit number, indication and pre-transfusion fibrinogen. The appropriateness of cryoprecipitate transfusions was based on the British Committee for Standards in Hematology, Blood Transfusion Task Force guidelines. These guidelines state that cryoprecipitate transfusion is recommended if patient is bleeding and has a fibrinogen level that is less than 1g/l or dysfibrinogenemia. Any transfusion out with this was deemed inappropriate. There is no evidence that prophylactic transfusions prevent disseminated intravascular coagulopathy or reduce transfusion requirements. Indication was considered as 'not determined' if a pre-transfusion fibrinogen level was not available. *Results*. A total of 6534 units of cryoprecipitate were transfused in 616 events to 531 patients during the study period. Indication for cryoprecipitate transfusion was documented in 82.2% of the events. Both cardiac and non-cardiac surgeries topped the indication list for cryoprecipitate use though cardiac surgical procedures were slightly more common (21% vs.19% respectively). 61% of cryoprecipitate transfusions were deemed appropriate, 27% were inappropriate (33% which represented the highest proportion was from cardiac surgery) and 12% could not be determined. There was no significant difference on analyzing each year separately. *Summary and Conclusions*. Our study revealed results similar to previously published data with variation in the use of cryoprecipitate. In the last decade, despite the availability of specialist guidance, the misuse of this blood component has neither been prevented nor reduced. It is likely that the lack of high-quality trials evaluating the efficacy of this blood component, particularly in the setting of cardiac surgery is a major contributing factor.

THERAPEUTIC PLASMA EXCHANGE (TPE) FOR THROMBOTIC THROMBOCYTOPENIC PURPURA AND HEMOLYTIC UREMIC SYNDROME USING PLASMA PREPARED WITH PHOTOCHEMICAL PATHOGEN INACTIVATION: A ONE YEAR EXPERIENCE IN ROUTINE PRACTICE IN A REGIONAL BLOOD CENTER

D. Kientz,[1] M.L. Wiesel,[1] I. Lanois,[2] T. Krummel,[2] B. Moulin,[2] R. Herbrecht,[2] J.P. Cazenave[1]

[1]EFS-Alace, STRASBOURG; [2]Hopitaux Universitaires de Strasbourg, STRASBOURG, France

Background. INTERCEPT™ Plasma (I-FFP) prepared by photochemical treatment with amotosalen and UVA light to inactivate pathogens in single plasma units was registered by Afssaps in 2007. EFS-Alsace provides blood components for approximately 2 million inhabitants in the Alsace region. EFS-Alsace implemented universal routine production of I-FFP in 2007 in place of quarantine plasma (FFP). TPE is the mainstay therapy for thrombotic microangiopathies (TMA) including thrombotic thrombocytopenic purpura (TTP) and adult hemolytic uremic syndrome (HUS). A prior randomized, controlled clinical trial of TPE for TTP demonstrated I-FFP was comparable to conventional FFP (Transfusion 2006;46: 1693). *Aims*. To further assess the efficacy and safety of I-FFP for TPE of TMA we reviewed our experience during a 1 year period of routine I-FFP use and compared it to a year before where we used quarantine plasma (FFP) for TPE. *Methods*. Patients (pts) with a clinical diagnosis of TTP or HUS received TPE (1.0 to 1.5 blood volumes) with I-FFP per conventional standard of care. The proportion of patients achieving remission (platelet count $\geq 150\times10^9$/ L for 2 consecutive days without neurologic or renal progression) and the global safety profile were assessed. Secondary endpoints were: volume of plasma used and number of TPE. *Results*. 11 pts, mean age of 45 yr, 54% female, received TPE with I-FFP. 90.9% of patients achieved remission. The mean number of TPE was 16 (median 10, range 1 - 71). The mean plasma volume infused per patient was 33.2L (median 17.4, range 1.1 - 153.8). These results are not different from those observed with FFP (see Table 1). No patients had an adverse event associated with I-FFP. There were no deaths and no reports of TRALI. No relapses were observed in treated patients. *Conclusions*. This 1 year experience with routine use of I-FFP for TPE in TMA demonstrated efficacy and safety comparable to prior experience in the treatment of TMA using conventional quarantine FFP. I-FFP was well tolerated.

Table 1. Comparison od TPE using I-FFP vs FFP.

	FFP period (n=5)		I-FFP period (n=11)	
	Number of plasma exchanges/pt	Total plasma infusion Volume/pt (L)	Number of plasma exchanges/pt	Total plasma infusion Volume/pt (L)

UNDERSTANDING TRANSFUSION OUTCOMES THROUGH CLINICAL REGISTRIES: VALIDATION OF A LINKAGE TECHNIQUE

L. Phillips

Monash University, MELBOURNE, Australia

Background. There is evidence of substantial variation in transfusion practice, but little understanding of how this variation affects patient outcomes. While information regarding blood products transfused is required to be retained, these data have not been correlated with clinical outcomes. However, several registries gather clinical outcomes data without transfusion information. An opportunity exists to use these two sources to explore the effect of transfusion on clinical outcomes. *Methods*. Collection of transfusion data by record review or expansion of registry datasets has practical drawbacks. These data are captured by transfusion laboratory information systems (LIS). However, the validity of LIS data has not been confirmed. Prospective validation of LIS data against individual patient records was undertaken at two major clinical centres in Victoria, Australia. Data regarding all transfusion episodes were compared over seven 24 hour periods at each centre. All clinical areas, all fresh blood product types, and each day of the week were included. *Results.*Data regarding 478 units were captured; 218 centre 1 (46%), 260 centre 2 (54%), comprising 315 red cells, 71 platelets, 67 plasma and 25

cryoprecipitate units. 176 (37%) units were issued to inpatient wards including 80 (46%) to haematology/oncology; 126 (26%) to intensive care units; 73 (15%) to outpatient units including 38 (52%) to haematology/oncology day wards; 46 (10%) to operating theatres; and 25 (5%) to emergency departments. The location of transfusion was unrecorded for 32 (7%) units. 360 transfusions (75%) occurred on weekdays, and 118 on weekends (25%). Time of issue was stratified according to nursing shift: 216 day (45%), 173 evening (36%), 89 night (19). All products recorded as issued by the LIS were transfused to the expected patient. Transfusion commenced within the recommended timeframe in 77% of cases for red cells, 68% platelets, 94% plasma and 88% cryoprecipitate. Type of blood product, time of day and time of the week all influenced the length of time between issue and initiation of transfusion. *Conclusions.* Across a range of blood product types and destinations, at two different institutions, comparison of LIS data with clinical records demonstrated concordance. The difference between LIS timing data and patient clinical records reflects the expected time to transport, check and prepare transfusion but does not affect the validity of linkage for most research purposes. Linkage of clinical registries with LIS data can therefore provide robust information regarding individual patient transfusion. This enables electronic analysis of joint data sets, either periodically or continuously, to determine the impact of transfusion on clinical outcomes in particular patient populations.

PLASMA EXCHANGE IN PATIENTS WITH TTP/HUS IN A BLOOD TRANSFUSION CENTRE: RETROSPECTIVE STUDY OF 46 CASES

T.-M. Alemayehu, S. Theodoridou, T. Karafoulidou, P. Papadopoulou, S. Kiritsi, B. Duka, E. Ambatzoglou, G. Papaioannou

Hippokration Hospital, THESSALONIKI, Greece

Background and Method. Plasma exchange (PEX) is effective in TTP because it removes anti-ADAMTS13 autoantibodies and replenishes the missing vWF cleaving protease. Today high clinical suspicion and less stringent diagnostic criteria are used to avoid delay in the implementation of PEX. The aim of this study is to present our experience in the treatment of TTP/HUS with PEX from 1992 to 2008. Fourty six patients, 29 females and 17 males, are included, with the median age of 42 years (range17 to 79 years). Fluctuating neurological manifestations were common, while coma and convulsions were seen in 8 patients. A patient was inadvertently transfused with platelets and latter became comatose. Two of our patients had classical adult HUS, with hemorrhagic diarrhea and anuria. ADAMTS13 levels or anti-ADAMTS13 autoantibodies were not measured in any of our patients. Contraceptives, ticlopidine and hormonal therapy for IVF were confirmed. TTP/HUS associated with pregnancy, post-partum and caesarian section, SLE, APS, surgery and AMI were encountered. There was one intrauterine death and another patient had relapsed after IVF and caesarian section, 20 years after the first episode. PEX was administered within the first 24 hours in almost all patients. Two types of apheresis machines, mainly Cobe Spectra and Hemonetics V50 were used. Microaggregate filters were used to give the replacement plasma (FFP, cryosupernatant (CSP) and liquid plasma). Despite the severity of the disease, CSP was preferred whenever available. We tried to exchange 1.5 the plasma volume for the first 3-5 sessions. PEX was continued daily until complete remission (plt >150K/μL, Ht ~30%, LDH <300u/dL) and discontinued after 3-5 additional sessions. Adjuvant therapy included corticosteroids, antiplatelet drugs, vincristine, ivIg and lately anti-CD20 monoclonal antibody, Rituximab. *Results*. Eighty percent had complete remission (CR), while there were nine deaths. All patients in deep coma died of the disease. Two patients died of severe sepsis, including a 17 yrs male with refractory disease, a history of splenectomy at age 5 for ITP, and corticosteroid and retuximab therapy for the TTP. One patient with frequent relapses who refused PEX had CR with corticosteroids and FFP infusion. We are aware of six patients who relapsed after 1 1/2 to 10 years; three patients after surgery. The number of PEX sessions ranged from 5 to 32. Complications during apheresis were hypotension, allergic reactions (one severe), catheter-associated infection, hemopneumothorax, hematoma, and arrhythmias (atrial fibrillation, bradycardia) and hypocalcemic manifestations and machine dysfunction. Circulatory overload was the main problem whenever plasma infusion was used due to delay in PEX, patient instability or machine dysfunction. Low fibrinogen levels were common whenever CSP was used. *Discussion and Conclusions*. Plasma exchange remains the treatment of choice for TTP. Coma, delay in hospital admission and initiation of PEX, and platelet transfusion are most probably adverse prognostic factors. Surgery and pregnancy are predisposing factors for primary disease and relapse. Microaggregate filters may help in minimizing severe side effects to plasma. High dose plasma infusion is not practical for the treatment of TTP, due to circulatory overload. Mechanical irritation of the heart by the tip of the catheter and infusion of Calcium-poor plasma to the vicinity of the sinus node should be kept in mind.

0693

ALLOIMMUNIZATION TO ERYTHROCYTE ANTIGENS IN TRANSFUSION-DEPENDENT PATIENTS WITH HAEMOGLOBINOPATHIES: AN EXPERIENCE FROM A GREEK BLOOD TRANSFUSION SERVICE

V. Kyriazi, L. Evliati, P. Koutsogianni, D. Kalantzis, E. Gerovaggeli, S. Saridakis, A. Megalou, M. Parara

Evaggelismos Hospital, ATHENS, Greece

Background. Alloimmunization to red cells (RBCs) antigens is a frequent complication among immunocompetent transfusion-dependent patients. This retrospective study analyses the incidence and the clinical significance of the presence of RBCs alloantibody in hospitalized adult patients with inherited disorders in globin synthesis. *Methods*. Data on transfusion history, alloimmunization and transfusion reactions were retrieved from blood bank records, from 2000 to 2008. The routine laboratory procedure for this cohort of blood recipients consisted of: 1/serologic detection of RBCs antigens (ABO, Rh CcDEe, Kell, Kidd, Duffy, MNS, Lewis, Lutheran, P1), 2/antibody screening using indirect antiglobulin test (IAT), 3/antibody identification with a panel of eleven different group O cells, 4/direct Coombs test (DAT). None of the patients receive extended antigen matched RBCs. Leukocyte-reduced and/or washed RBCs were given according to preceding transfusion reactions. *Results*. Among 197 adult patients, RBCs alloantibodies were detected in 29 males (15%) and 38 females (19%), with a reduced incidence the last two years (26%). The median age was 36 (range 20-77) years and the distribution of ABO, Rh D blood group is similar to this of general population. Based on underlying disease the incidence of alloimmunization was: 39% for sickle cell-B-thalassaemia, 33% for sickle cell disease, 25% for thalassaemia major and 38% for thalassaemia intermedia. The most common alloantibodies were directed against antigens of Rh system [anti-D: 8%, anti-C: 9%, anti-c: 23%, anti-E: 24%, anti-e: 1%], Kell system 31%, Duffy system 13% and Kidd system 12%. Multiple blood group alloantibodies were formed in 30 and autoantibodies in four patients. The incidence of positive direct Coombs test did not differ among patients with or without alloimmunization (52% vs 51%). Delayed hemolytic reactions were occurred in nine patients, with clinical evidence of haemolysis in four and with isolated serologic evidence in five, beside the administration of RBCs compatible with their existing antibodies. *Conclusions*. In multiply transfused patients with haemoglobinopathies the estimated prevalence of alloimmunization was 34% and the lowest incidence was observed in thalassaemia major patients. More than three quarters of alloimmunized patients would have not developed RBCs alloantibody, if they had been transfused with limited phenotype matching RBCs (ABO, Rh CcDEe, Kell). Pretransfusion matching for Kidd and Duffy antigens could enhance the reduction of alloimmunization effectively. A limited number of delayed hemolytic reactions were not prevented by extended antigen matching, probably due to a multifactorial process.

0694

PLATELET TRANSFUSION THRESHOLD FOR CENTRAL VENOUS CATHETER INSERTION IN ACUTE LEUKEMIAS

K. Arn,[1] K. Zeidler,[2] O. Senn,[1] U. Schanz,[1] G. Stussi[1]

[1]University Hospital Zurich, ZÜRICH; [2]Kantonsspital Münsterlingen, MÜNSTERLINGEN, Switzerland

Background. Central venous catheters (CVC) are prerequisite for patients receiving high-dose chemotherapy for hematological malignancies. These patients often have hemorrhagic diathesis and many centers mandate a platelet transfusion limit of 50 G/L. However, the bleeding incidence after CVC insertion in this patient setting has never been formally analyzed and there is no appropriate threshold for platelet transfusions. *Aims*. To assess the safety of a more restrictive thrombocyte tranfusion policy regarding the incidence of CVC insertion related bleeding complications. *Patients and methods*. We performed a retrospective single center analysis of all CVC insertions from 2001-2007 in patients with acute leukemia, autologous or allogeneic hematopoietic stem cell transplantations (HSCT). 596 CVC were placed in 191 patients (median age 49 years, range 18-78) for the treatment of AML (82%), APL (6%) or ALL (12%). 507 (85%) received subclavian and 89 (15%) jugular

catheters. Patients were categorized in 4 groups according to their platelet counts [I <20 (n=92), II 20-49 (n=142), III 50-99 (n=93), and IV > 100 G/L (n=261)]. *Results*. The overall bleeding rate was 186/596 (31%). 184 events were mild; only 2 patients experienced a prolonged bleeding. The hemoglobin levels 24 and 48 hours after insertion and the number of transfused RBC did not differ among patients with and without bleeding after CVC insertion. Crude event rates were similar across the platelet groups, although there was a trend toward higher bleeding rate in the lowest platelet group. In multiple logistic regression, there was a significant positive linear association between platelet count and bleeding rate when controlling for additional bleeding risk factors (concomitant heparin and NSAR therapy, DIC, fibrinogen, gender and age, diagnosis, site of CVC insertion, C-reactive protein and fibrinogen levels, and platelet transfusions). As compared to platelet counts > 100 G/L (group IV), the odds ratio for bleeding events in the lowest platelet group was significantly higher (I: OR 3.8, 95%-CI 1.4-10.6, p=0.01), whereas there was no difference in the other groups (II: 1.8, 95%-CI 0.9-3.4, p=0.08, III: 1.8, 95%-CI 1.0-3.2, p=0.06). In total 144 platelet transfusions were administered before CVC insertion, 61 (42%) of which were given in patients with platelet counts > 20 G/L. *Conclusions*. Based on these retrospective data, we recommend a platelet transfusion threshold of <20 G/L before CVC insertion. Strict adherence to this transfusion trigger is not associated with higher bleeding risk and may save more than 40% of platelet transfusions.

Table 1: Bleeding rate according to platelet count.

Platelets (G/L)	Number	Bleeding rate – N (%)	Platelet transfusion rate – N (%)
I (<20)	92	37 (41)	83 (91)
II (20-49)	142	39 (29)	54 (38)
III (50-99)	93	36 (39)	7 (7)
IV (>100)	162	71 (28)	0

0695

RED CELL ALLOIMMUNIZATION IN MULTITRANSFUSED CANCER PATIENTS

A. Bilalis, E. Papadaki, E. Papoulia, L. Matou

Saint Savvas Oncology Hospital, ATHENS, Greece

Background. early detection of red blood cell (RBC) alloimmunization, through pretransfusion serological testing, is of great importance, in order to avoid alloimmune hemolytic reactions. *Aims*. the purpose of this retrospective study is to estimate the frequency of allloimmunization in multitransfused adult patients with malignant diseases. *Methods*. 572 cancer patients (354 males, 218 females) who received multiple transfusions in our Hospital, during 2008, are included in the study. Only patients who received at least 5 RBC units were considered multitransfused, whereas patients who received up to four units because of active bleeding were excluded. Pretransfusion serum samples of all patients were tested against a set of three unpooled commercial antibody-screening reagent RBCs (Ortho Biovue, Surgiscreen) both by the Indirect Antiglobulin Technique (IAT) and by direct centrifugation at room temperature, using the glass beads centrifugation method (Ortho Biovue).All positive samples were further studied for antibody identification using an expanded panel of reagent RBCs (Ortho Biovue Resolve Panel C). Enzyme treated RBCs were used as indicated whereas Direct Antiglobulin Test (DAT) of patient's red cells was performed in all positive cases. All transfused units were ABO and Rh matched and screened for the corresponding antigen in alloimmunized patients. *Results*. The median number of RBC transfusions was 17 (5-111) in our study group. Alloantibodies were identified in 65/572 patients (11.3%). 12 patients had multiple (up to 3) alloantibodies. Anti-Kell alloantibody was the most frequent (26%), followed by anti-E (17%), anti-Lewis b (11%), anti-D (8%), anti-c (9%), anti-M (7.5%), anti-P1 (2.5%), anti-Lewis a (3%), anti-Jka (3.5%), anti-Jkb (2.5%) and five other alloantibodies of lower frequency. In four cases identification of alloantibody specificity was not possible through routine techniques as described. No case of alloimmune hemolytic reaction was reported. *Conclusions*. The incidence of RBC alloimmunization in multitransfused patients is 11.3% in this study. Universal pretransfusion antibody detecting tests in addition to standard crossmatching should guarantee prevention of most alloimmune hemolytic transfusion reactions.

0696

CORD BLOOD BANKING: THE CONTRIBUTE OF BLOOD GROUP MOLECULAR GENOTYPING IN UNITS' VALIDATION

P. Bergamaschi,[1] I. Sbarsi,[2] P. Isernia,[3] A. Pasi,[2] A. Marchesi,[4] C. Badulli,[2] B. Romano,[4] V. Genovese,[4] F. Garlaschelli,[2] M. Guarene,[2] C. Pizzochero,[2] C. Monti,[2] A. Livraghi,[3] M. Martinetti,[2] C. Perotti,[4] L. Salvaneschi[4]

[1]Fondazione IRCCS Policlinico San Matteo, PAVIA; [2]HLA Laboratory, Transfusion Medicine Dept., Fondazione IRCCS Pol. San Matteo, PAVIA; [3]Blood Bank, Transfusion Medicine Dept., Fondazione IRCCS Policlinico San Matteo, PAVIA; [4]Pavia CBB, Transfusion Medicine Dept, Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy

Large employ of umbilical cord blood (CB) for unrelated stem cell transplantation is constantly encouraged by CB banks (CBBs) spreading worldwide. Only fully characterized CBUs can be validated, included in the inventory and managed for stem cell donor search and procurement in the CBBs network. Complete CBUs characterization includes blood group typing. In fact, according to FACT-Netcord international standards, a sample must be taken from each CBU to perform ABO group and Rh type. Traditionally serologic blood group techniques are used on fresh CBUs samples but cannot be accurately performed after thawing due to haemolysis. In case serologic blood group phenotype is not carried out on a fresh sample, this testing remains unavailable; all the more so because the blood group of the neonate cannot be acceptable as a surrogate. As blood group testing represents a requirement for validation, CBUs missing this data are considered nonconforming and excluded from the inventory causing waste of money and human resources. Molecular testing methods were introduced to the transfusion medicine community more than a decade ago. Actually, the molecular basis for almost all blood group polymorphisms has been determined, making possible to predict blood group phenotypes with a reasonable degree of accuracy. Moreover, in several situations (multiply transfused recipients, prevention of anti-D alloimmunization caused by very weak RhD variants in blood donors, foetal typing from amniocytes or cell-free foetal DNA present in maternal plasma), molecular genotyping showed to be a superior, or the only, strategy. The availability of consistent amount of cord's DNA suggested our CBB to extend the use of molecular blood group genotyping techniques to CBUs lacking blood group typing with the aim of evaluating the feasibility and advantages of this approach. We reviewed our CBB data; 7 out of 3395 CBUs were identified to be potentially suitable for validation except for missing blood group testing. ABO and Rh CDE molecular blood group was determined for all 7 cases by PCR-SSP technique using commercial kit READY-GENE AB0 and READY-GENE CDE (INNO-TRAIN Diagnostik GmbH, Kronberg/Taunus, Germany). For this purpose, genomic DNA was obtained from various sources as shown in the Table 1.

Table 1. Results of molecular blood group genotyping:7 CBUs.

Sample #	ABO molecular genotype	Rh molecular genotype	Age of CB unit (years)	Source of DNA
1	O^1A	CcD-ee	12	attached segments
2	O^1O^1	CcD-ee	1	frozen DNA from the original CB collection
3	O^1B	CcD-Ee	3	chorionic villi
4	O^1O^1	CcD-ee	3	chorionic villi
5	O^1A^2	ccddee	8	frozen DNA from the original CB collection
6	O^1B	ccddee	12	chorionic villi
7	AB	CcDΩee	12	frozen DNA from the original CB collection

We succeeded in determining the molecular blood group for all the CBUs examined, the results of ABO and Rh genotypes being detailed in the table. Despite the time of storage, which in 3 cases reaches 12 years, and DNA coming from disparate origin, molecular blood group genotyp-

ing demonstrated to be feasible on CB. Furthermore, with a tiny increase of initial costs, this molecular tool offers economical and organizational advantages by making eligible for validation CBUs otherwise unsuitable and by recovering costs of their characterization and maintenance. In our opinion molecular blood group genotyping could be reasonably implemented in CB banking.

0697

HAEMOLYTIC DISEASE OF THE FETUS/NEWBORN SECONDARY TO ANTI-N/'N'

W.C. Gordon, R.L. Soutar, K. Douglas, D. Frame, R. Green

Scottish National Blood Transfusion Service, GLASGOW, UK

A 32yr female West African patient in her 1st pregnancy had an alloantibody detected by IAT at booking at 12/40 weeks gestation. The antibody was strongly positive with all screening cells at 18 and 37 degrees by IAT. It was destroyed by enzyme. The antibody was identified as IgG Anti-N/'N'. All panel cells including M+N- cells which have no N on Glycophorin A but carry 'N' on Glycophorin B were strongly incompatible. M+N-U- and M-N+U- cells which lack GPB related 'N' but carry N on GPA were also strongly incompatible excluding the presence of anti-U. The only compatible cells were MkMk cells which lack all GPA and GPB antigens. (Only two compatible donors registered in UK). The mother was referred to the regional specialist centre (RHSC) for foetal monitoring. Foetal anaemia was detected by Doppler MCA ultrasound. An intrauterine transfusion at 27/40 weeks was proposed. One Frozen red cell unit was obtained from IBGRL Bristol, but unfortunately these proved to also be strongly incompatible with maternal serum. One autologous red cell unit was obtained from the mother by an emergency isovolaemic venesection, washed and split into two packs. One was frozen, the other resuspended and transfused. Baby's cells were DAGT-ve. However, an eluate contained weak anti-N by IAT. The baby typed as M+N-S-s+U+ (Probable MNS genotype MM/sSu). Therefore the one copy of 'N' on GPBs was responsible for the maternal-foetal incompatibility. There was no further evidence of foetal anaemia by serial MCA Doppler. Red cells compatible with maternal and baby's serum were obtained courtesy of the American Red Cross. The baby was delivered by elective C-section at 37/40 weeks. The baby was DAGT-ve and was not anaemic or jaundiced. Anti-N/'N' has only rarely been implicated in HDFN. To our knowledge this is the first reported case to require intrauterine transfusion.

0698

TREATMENT OF ORBISAC DERIVED BUFFY COAT PLATELETS WITH THE MIRASOL® PATHOGEN REDUCTION TECHNOLOGY AND STORAGE IN ADDITIVE SOLUTION

H. Reikvam,[1] T. Hervig,[2] S. Marschner,[3] R. Goodrich[3]

[1]Institute of Internal Medicine, University of Bergen, BERGEN, Norway; [2]City Hematological Center, BERGEN, Norway; [3]CaridianBCT Biotechnologies, L.L.C., LAKEWOOD, CO, USA

Background. The Mirasol Pathogen Reduction Technology (PRT) system for Platelets and Plasma uses riboflavin and UV light to introduce irreparable lesions to nucleic acids thereby inhibiting pathogen and WBC replication and reducing the pathogen load in donated blood products. To further reduce adverse transfusion reactions storage of platelets in additive solution (PAS) has become an attractive alternative to storage in plasma. *Aims*. The aim of this study was to evaluate low plasma buffy coat units obtained from the Orbisac System (CaridianBCT) and to examine the effects of the Mirasol PRT treatment (CaridianBCT Biotechnologies) on platelet (PLT) storage lesion development during storage in SSP+. *Methods*. Low plasma buffy coat platelet concentrates (BCPC) were generated by pooling 5 buffy coat units using the OrbiSac System (CaridianBCT). Riboflavin was added during the final pooling step. The BCPC product was transferred into an illumination/storage bag, placed in the Mirasol Illuminator and exposed to UV light. The bag was removed after the target energy of 6.24 J/mL was delivered and 150 mL of SSP+ (MacoPharma) was added prior to storage. Platelet function was assessed by pH, swirl, CD62P expression, lactate production and glucose consumption rates over 7 days of storage. *Results*. BCPC generated contained on average $3.45x10^{11}$ platelets in 116±8 mL of plasma prior to illumination and 150 mL SSP+ addition. *In vitro* cell quality parameters of treated units are summarized in the Table 1. *Summary and conclusions*. Orbisac derived BCPC treated with the Mirasol PRT system can be stored in SSP+ for 7 days without compromising cell quality. Elevated CD62P expression, lactate production and glucose consumption rates after PRT treatment are due to cellular activation and increased metabolism of the cells. First clinical evaluation of PRT treated platelets in thrombocytopenic patients showed that patients receiving treated platelets had comparable hemostasis and support requirements.

Table 1.

Parameter	Day 5	Day 7
pH (22°C)	7.13 +/-0.005	7.13 +/- 0.005
Swirl	2.2 +/- 0.5	1.3 +/- 0.5
Glucose consumtion rate (mmol/10^{12} plts/hr)	0.041 +/- 0.007	0.035 +/- 0.006
Lactate production rate (mmol/10^{12} plts/hr)	0.098 +/- 0.019	0.083 +/- 0.024
CD62P (%)	77 +/- 4	84 +/- 3

INTRAUTERINE TRANSFUSION RESULTS IN PRENATAL ANEMIA

C Sanchez Ramos,[1] A. Montoya,[2] M. Jurado,[1] S. Oyonarte,[2] F. Molina[1]

[1]Hospital Universitario Virgen de las Nieves, GRANADA; [2]Centro Regional de Transfusion Sanguinea Granada-Almeria, GRANADA, Spain

Background. The treatment of intrauterine prenatal anemia is safer and more profitable thanks to the developmnet of image techniques making the protocolisation of the proceedings possible. *Aims*. To describe the cases that have appearded in the Regional Centre for Blood Transfusion in Granada-Almeria, Spain. *Methods*. Assessment during the time period 2000-2008, of 174 pregnancies analisying the predictive value of the doppler ultrasonography of middle cerebral artery (MCA) and antibody titers in relation to the degree of anemia. *Results*. In the last 8 years 174 pregnancies have been studied, all of who have been subject to the Intrauterine Transfusion (IUT) 73:1 was treated for erythrocytic enzymopathy, 5 Hydrops nonimmun, 3 Twin-Twin Transfuion Syndrome, 2 neonatal autoimmune thrombocytopenia (anti HPA 1a) and, 62 alloimmunization erythrocytic: 55 for anti-D antibody, (37 anti-D; 18: anti-D+C, anti-D+E, anti-D+C+E, anti-D+Jka, anti-D+Lea and anti-D+Jka), 1 anti-c and, 6 anti-K. They only needed assessment with Peak Systolic Velocity of MCA doppler ultrasonography (PSV-MCA), without having the criteria for IUT, 101 pregnancies were alloimmunized (55 anti-D, 18 anti-D and others, 12 anti-K, 15 antibodies from different antigens and 1 thrombopenia autoimmune). More interventions were not needed during these pregnancies. There were only a total of 14 hydrops fetalis (8 anti-D, 1 anti-K, 5 nonimmunes), which were given a protocol of gradual elevation of the inicial hemoglobin concentration (HC) (around 1,6 -7,6gr/dL, who were previously given a intrauterine exchange transfusion to avoid volume overload in the fetus, arriving at the end of the pregnancy without aftereffects. Of the 110 anti-D alloimmunized pregnancies, 63 have presented anti-D antibody titers superior to 15UL/mL (titer >1:128). According to our own experiences, the IUT should be used, taking into account the aessement for PSV-MCAdoppler. In the 2 cases where the pregnant women have had high titers of anti-D at the expense exclusively of IgG3 antibodies (1:1024 and 1:2048), the fetuses presented very moderate anemia (HC: 11,4 and 10,2gr/dL, in preliminary cordocentesis, so that the presence of IgG3 antibodies, in our experience, does not condition a worst prognosis. Of the 18 anti-K (15 anti-K and 3 anti-K+E), 6 were subject to IUT in the 17-31 weeks of gestation (WG), with HC between 6.1-12,4gr/dL. 1 case suffered from hydrops fetalis in the 31 (WG), with a titers of 1:128 only of IgG1 antibodies and 7.6gr/dL of hemoglobin, which makes us suspect that the sensibilization/alloimmunization for anti-K antiboby and the precocious intervention can condition hydrops with levels of hemoglobin relatively higher that the ones presented in the alloimmunization for anti-D. *Conclusions*. The IUT programme has meant an important advance in the treatment of badly affected fetuses. 322 cordocenteses have been carried out, 259 were followed by IUT, all of them without complications. 72 pregnancies completed the IUT programme. There were 2 failures due to fetal death, both in the interval between the IUT. We have not had serious complications

associated to the procedure. The global fetal survival has been 97.3% and the hydropic fetuses treated according to our protocol have survived.

PREDEPOSIT AUTOLOGOUS DONATION IN RADICAL PROSTATECTOMY: APHERESIS VS WHOLE BLOOD

J.A. García-Erce,[1] A. Borque,[1] A. García-Jalón,[1] B. Soria,[1] M. Guillén,[1] M.J. Gil,[1] P. Gil,[1] D. Rubio,[1] M. Muñoz[2]

[1]SALUD, ZARAGOZA; [2]GIEMSA. Medicina Transfusional. Universidad Málaga, MÁLAGA, Spain

Background. At our institution, 27.8% patients undergoing radical prostatectomy (RP) used to receive allogeneic blood transfusion (ABT). To reduce ABT rates and ABT related risks, a preoperative autologous donation (PAD) program for RP patients was implemented in 2003. We present data of the first 501 RP managed with PAD (2003-2008) and analyze a possible new protocol involving erythropheresis donation and IV iron administration. *Patients and Methods*. Two to three blood units were requested and donated on preoperative weeks 4, 3 and 2. Dereferral rate, autologous unit drawn and transfused, type of donation (standard or aphaeresis), ABT transfusion rate and volume, age, weight, complete blood cell counts, iron metabolism, B12 vitamin and folic acid, EPO and iron treatment were analyzed. *Results*. 482 (96%) RP patients (64±6 y old, 80±12 kg bw) were admitted to the PAD program and donated at least one autologous uint. Blood donation: A mean of 2.6±0.7 U/patient were collected (25.8% by apheresis, double unit); 23% received at least a 200 mg of IV iron; and 24 (4.9%) at least one EPO dose (11: beta 30.000 IU; and 13: α 40.000 IU). Blood Transfusion: 63.8% patients were transfused, but only 5.8% received at least one ABT unit. Patients that donated two units received less PAD units (0.92 vs. 1.39) and total units (1.02 U/pte vs 1.54U/pte) than those with three donations. Patients treated with IV iron showed lower ABT rate (3.7% vs. 6.5%) and index (0.06 U/pte vs 0.6 U/pte). In apheresis donations, those treated with 200 mg IV iron also showed lower ABT rate (4% vs. 15%; p: 0.036) and index (0.06 U/pte vs 0.46 U/pte; *p*:0.036). Adjuvant treatment with EPO did not further decrease ABT transfusion rates. However, 41 % of PAD units were discarded. *Conclusions*. At our institution, PAD seems to be an effective alternative to reduce allogeneic blood transfusion requirements in RP patients. Apheresis donation of only two units plus IV iron, and EPO if anaemia, seems to be a very interesting approach to further reduce ABT requirements and PAD units discarding rate.

CONTRIBUTION OF HAEMATOTHERAPY TO THE TREATMENT OF MICROCIRCULATORY DISORDERS

M. Blaha,[1] E. Rencova,[2] V. Blaha,[3] R. Maly,[4] M. Blazek,[1] R. Prochazkova,[1] C. Andrys,[5] R. Zimova,[1] H. Langrova[2]

[1]IInd Internal Clinic, Charles University, HRADEC KRALOVE; [2]Department of Ophthalmology, Medical Faculty, Charles University, HRADEC KRALOVE; [3]Department of Gerontol. and Metabolic Care, Medical Faculty, Charles University, HRADEC KRALOVE; [4]Ist Dpt. of Medicine, Medical Faculty, Charles University, HRADEC KRALOVE; [5]Institut of Immunology and allergology, Medical faculty, Charles University, HRADEC KRALOVE, Czech Republic

Background. Transfusion medicine and haematology contributed to the therapy of some serious microcirculatory disorders in the last years. Haemorheopheresis was specifically designed to treat microcirculatory disorders. The single rheopheresis treatment simultaneously eliminates an exactly defined spectrum of high-molecular weight rheologically relevant plasma proteins (i.e. α2-macroglobulin, fibrinogen, LDL-cholesterol, lipoprotein(a), von Willebrand factor (vWF), immunoglobulin M (IgM), fibronectin, and putatively multimeric vitronectin). This results in the immediate pulsed reduction of plasma viscosity as well whole blood viscosity, which with a series of treatments can lead to sustained microcirculatory recovery, and change significantly the natural course of a chronic disease. *Aims*. We describe the experience of our Hemapheresis Centre. *Methods and patients*. In the prospective trial presented here, 41 patients were treated - severe familiar hypercholesterolemia (FH): 5 pts; non-healing lesions caused by severe ischemic diabetic foot syndrome (IDFS): 6 pts; age related macular degeneration (AMD): 20 pts; acute sensorineural hearing loss (ASHL): 5 pts; thyreoid orbital endocrinopathy (TAO): 5 pts. Our own modification of rheopheresis was used: Plasma, free from cellular elements is obtained by blood cell separator (Cobe-Spectra, Denver, USA) in high-speed centrifugation. Then it is run through the *second stage* - a rheofilter (Evaflux 4A, Kuraray) with ethylene-vinyl-alcohol hollow fibres with holes of 0,03 micrometer. Plasma flow is continuous, anticoagulation done with heparin. Basic amount of processed plasma (calculated by Cobe computer) is 1,5 of body volume. The size of holes in the filter enables to retain the above mentioned high-molecular elements. Haematological, biochemical and haemorheological parameters were measured before and after procedures and after the finishing of therapeutic series (AMD 8 procedures, IDFS 10, ASHL 3, TAO 10). *Results*. Rheological procedures were very effective and resulted in significant decreases of pathologically effective substances: alfa2-macroglobulin 57,6%, fibrinogen 68,6%, IgM 61,5%, LDL-cholesterol 75,0%, apolipoprotein B 76,0%, lipoprotein(a) 63,2%. It resulted in blood and plasma viscosity decrease (14,13/12,5%). Diabetic foot ulcers were healed in 4 of 6 pts. No progression from dry to wet form of AMD has been observed during 2 years. 6,3% of side effects were observed; they were not severe, transient and easily controlled. *Conclusions*. Hemorheopheresis appears to be a method suitable adjunct therapy for diseases involving severe disturbance of microcirculation, especially when previous therapeutic options were not sufficiently effective or invasive procedures cannot be applied.

ROLE OF RITUXIMAB FOR TREATING PATIENTS WITH IDIOPATHIC TTP/HUS WITH OR WITHOUT ADAMTS-13 ANTIBODIES

C. Caramazza, S. Siragusa, I. Abbene, L. Lo Coco, R. Di Trapani, G. Mazzola, S. Rizzo, R. Palazzolo, R. Barone, A. Malato, P. Ragonese, P. Aridon, V. Abbadessa, G. Quintini

Policlinico Universitario di Palermo, PALERMO, Italy

Background. Idiopathic TTP/HUS (Thrombotic Thrombocytopenic Purpura-Hemolytic Uremic Syndrome) namely defined as absence of congenital deficiency of ADAMTS-13 is a rare disease usually responsive to plasma exchange (PE). Because of the high rate of relapses, a useful strategy is that to select high-risk patients such as those with low level of ADAMTS-13 activity for alternative therapy. Conventional immunosuppressive therapy (cyclophosphamide, cyclosporine, azathioprine and intravenous immunoglobulins) have been shown to successfully treat patients with relapsed/refractory TTP/HUS; few evidences are currently available about therapy with Rituximab®. *Aims*. We tested the role of anti-CD 20 drug for treating patients with relapsed/refractory TTP/HUS. *Methods*. Rituximab® was administered to 4 patients with relapse/refractory idiopathic TTP/HUS, with or without deficient

ADAMTS-13 activity. Characteristics of patients are reported in the Table 1. Complete remission was defined if presence of PLT >100×10⁹/L and normal laboratory values (LDH, serum bilirubin, creatinine, hemoglobin). Three cases were due to ADAMTS13 deficiency antibody-mediated; among them, one relapsed 39 months after complete remission, obtained by PE, while the remaining 2 patients were refractory to PE. The fourth patient did not have ADAMTS13 deficiency and he was refractory to PE. All 4 patients received Rituximab® at the dose of 375mg/m2, one shot a week for one month; no other therapy were given except steroids low dose tapering. *Results.* Complete remission was achieved in all patients just after the first two infusions of Rituximab®. In patients with ADAMTS-13 antibodies, these were not longer detectable after all courses of Rituximab therapy. Remission was maintained for a median period of 6 months (range 2 to 10 months). *Conclusions.* The role of Rituximab® in patients with idiopathic refractory/relapsed TTP/HUS is still unclear in patients with or without ADAMTS-13 antibodies. In our experience, Rituximab® has been proven to be effective in producing a durable complete remission; this happened in 3 patients with deficient ADAMTS-13 activity and in the fourth patient with refractory TTP/HUS without deficient ADAMTS-13 activity. Properly designed studies are required to confirm safety and efficacy of such approach.

Table 1. Patients' characteristics.

Patient N	Age (years)	Sex	ADAMTS-13 Activity (IgG Anti-ADAMTS-13)	Diagnosis	Therapy before rituximab application	Therapy during rituximab application	Rituximab doses	Serious rituximab side effects	Follow-up (months)

THE EFFICACY AND EFFICIENCY PLATELET TRANSFUSION IN BUFFY COAT PLATELET COMPONENTS TREATED OR NOT BY INTERCEPT BLOOD SYSTEM

M.I. Belkaid,[1] N. Bakiri,[1] M. Tsaramaro,[1] G. Brochier,[2] E. Chirpaz,[1] F. Schooneman,[2] T. Henni[1]

[1]CHR Nord Reunion, SAINT DENIS; [2]EFS Reunion, SAINT DENIS, Reunion

Since the epidemic of chikungunya in Reunion island, all platlet components (PC) are treated by the Intercept technology (Cerus corporation). The principle of this new technic is based on a photochemical treatment of the PC (PCT PC) by a chemical substance, the amotosalen, and the UVA so allowing the inactivation of a large number of viruses, bacteria, parasites as well as the residual leukocytes. We compared the efficiency platelet transfusion of 413 PC treated by IBS and 276 untreated PC transfusion for patients (Pts) followed in our department. The Pts presenting a febril syndrom, disseminated intravascular coagulation or a splenomegaly were excluded. The average quantity of transfused platelets was respectively 3.82 (± 0.90) and 4.04 (± 1.03) ×10⁹/L for the PCT PC and untreated PC. The corrected count increment (CCI) were respectively 450 (± 556) and 898 (± 680) for PCT PC and untreated PC; by taking the CCI, the transfusion was ineffective in respectively 30,3 and 5,7% for PCT PC and untreated PC. Clinical effectiveness, i.e. post transfusionnal rate of platelets higher than 20×10⁹/L, is respectively 74,3 and 45% for the PCT PC and untreated PC. This comparative retrospective study showed, that the efficiency of platelets transfusion as well as the CCI are clearly decreased after treatment of the CP, for viral inactivation, by Intercept technology.

DATA REVIEW FROM THE PAVIA CORD BLOOD BANK: CORRELATION BETWEEN CORD BLOOD NUCLEATED AND HAEMATOPOIETIC STEM CELL COUNT AND BIRTHWEIGHT

P. Bergamaschi,[1] C. Capittini,[2] M.P. Mercati,[3] A. Marchesi,[4] G. Viarengo,[1] C. Del Fante,[1] B. Romano,[4] V. Genovese,[4] A. Pasi,[2] M. Guarene,[2] C. Monti,[2] C. Badulli,[2] I. Sbarsi,[2] F. Garlaschelli,[2] C. Pizzochero,[2] M. Cuccia,[5] M. Martinetti,[2] C. Perotti,[4] L. Salvaneschi[4]

[1]Fondazione IRCCS Policlinico San Matteo, PAVIA; [2]HLA Laboratory, Transfusion Medicine Dept., Fondazione IRCCS Pol. San Matteo, PAVIA; [3]Faculty of Medicine, University of Pavia, PAVIA; [4]Pavia CBB, Transfusion Medicine Dept, Fondazione IRCCS Policlinico San Matteo, PAVIA; [5]Genetics and Microbiology Dept., Interdip. Gender Studies Center, Pavia Univ., PAVIA, Italy

Umbilical cord blood (UCB) is a source of hematopoietic stem cells (HSCs) which offers substantial logistic and clinical advantages for allogeneic HSC transplantation to patients otherwise not eligible for this curative approach. A cord blood bank (CBB) consists of a repository of cryopreserved UCB units from healthy newborns. For each unit/baby enrolled for HSC donation, the CBB records HLA profile, cellular characteristics and physiological parameters into databases for subsequent transplantation requests. Thus, beyond immunogenetic data, a huge amount of information regarding cord blood volume, levels of total nucleated cells (TNCs) and CD34⁺ cells are available. Here we examined the relation between birthweight and UCB concentrations of TNCs and CD34⁺ stem cells in 1037 infants/UCB units. Healthy Caucasian mothers were recruited to participate voluntarily in the cord blood banking program of the Pavia Cord Blood Bank, all giving written informed consent. Preterm (<34 gestational weeks) and pathological pregnancies were excluded from UCB donation. Cord blood was collected from umbilical cord vessels by in utero technique immediately after birth. Only the units with net volumes ≥50 mL and containing ≥800 - 10(6) TNCs were banked. All the 1037 babies were classified into 6 centiles according to birthweight, sex and gestational age. A non-parametric statistical analysis was made using Spearman test, and considering $p<0.05$ as statistically significant. As expected by the selective criteria of the CBB, an inverse relation between birthweight and TNC concentration (graphic 1 top, $\rho = -0.07$; $p=0.02$) was found.

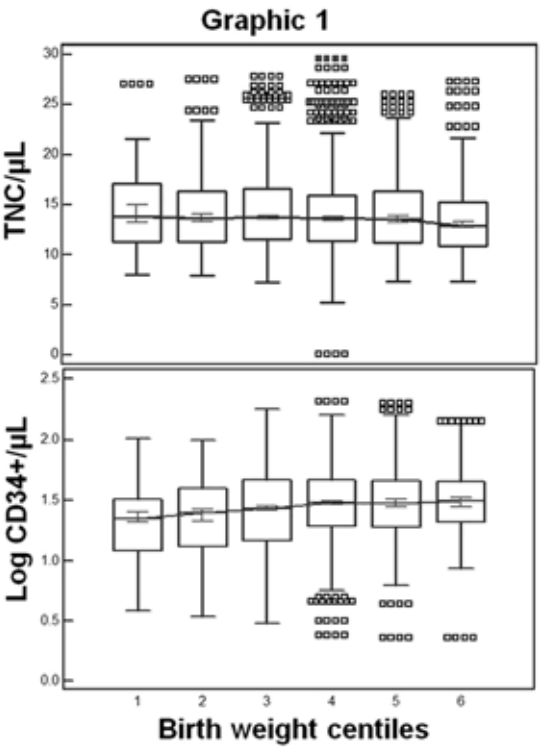

Figure 1. CD34⁺ and TNC count in the 6 birthweight centiles.

In fact, the low-weighted babies had a smaller volume than the big ones, but as they fit the ≥800 - 10(6) TNC total count cut-off, they must

have a higher TNC concentration. On the contrary, CD34+ cell count did not follow the TNC concentration trend. In fact, the heavy-weighted babies showed a higher concentration of early multipotent progenitor cells with respect to the small ones (graphic 1 bottom; ρ=0.11; *p*=0.0003). As expected by excluding preterm and pathological pregnancies, which are known to be characterized by high CD34+ cell levels due to environmental stress in utero, the low concentration of CD34+ cells in small UCB donors supports their healthiness during intrauterine life. Moreover, the amount of organ resident stem cell pools is reflected in the size of organs and consequently in birthweight. Cord blood CD34+ cell count is a good surrogate of the body overall stem cell content, including organ resident stem cells, therefore their highest concentration was found to correlate with the biggest birthweight centiles.

0705

HIGHER IRON SUCROSE DOSE IN A AMBULATORY ANAEMIA TREATMENT PROGRAM

J.A. García-Erce,[1] B. Soria,[1] J. Cuenca,[1] A. Borque,[1] M. Guillén,[1] P. Mayayo,[1] A. García-Jalón,[1] D. Rubio,[1] M. Muñoz[2]

[1]SALUD, ZARAGOZA; [2]GIEMSA. Medicina Transfusional. Universidad Málaga, MÁLAGA, Spain

Background. Recently we have shown feasibility and safety of iron sucrose administration in anaemic out-patients awaiting for surgery.[1] At Spain iron sucrose maximum dose is 200 mg per session, but not in Europe. *Aim*s. We decided to treat with higher dose (300-500 mg, with 7 mg/kg/day dose limit) to those patients with higher needs, worse venous access or chronic bleeding. *Methods*. Since January 2004 we have recollected analytical and clinical data of 57 patients (40 females, 17 males). They were sent by ferropenic or mixed anaemia or symptomatic ferropenia resistant to oral iron. Most of them were scheduled for surgery, but 6 after surgery. Total iron dose was calculated with the classical formula [DTH: (14 - Hb) x 2.41 x weight + 500]. Since January 2007 we have included haematological, heart failure and chronic digestive bleeding (angiodisplasia) under anticoagulant or antiagregant treatment. And we begin to administer under 'compassionate use'/"off label" indication dose of 300 mg/day. *Results*. In the moment of this review at least 27 patients had received at least one 300 mg session and two at least 500 mg. Medium session was 4.2 (1-10) and 884 mg of iron sucrose (200-2900). Only 6 patients had been transfused, due their chronic blood loss. *Conclusions*. Higher dose of intravenous iron administration to anaemic ambulatory patients awaiting for major surgery or affected of chronic ferropenic anaemia seems to be safe, feasible and effective for correcting anaemia and reducing blood transfusion requirements. Further studies to confirm these promising results are warranted.

TARGETED INTRAVENOUS BUSULFAN IN CHILDREN PRIOR STEM CELL TRANSPLANTATION FOR THALASSEMIA: PHARMACOKINETICS, TOXICITY AND TRANSPLANT OUTCOMES

J. Gaziev,[1] L. Spitaleri,[1] G. Lucarelli,[1] A.F. Mozzi,[2] L. Nguyen,[3] C. Puozzo,[3] M.P. Donnorso,[2] P. Sodani,[1] M. Andreani,[1] P. Polchi,[1] A. Isgrò,[1] M. Marziali,[1] M.D. Simone[1]

[1]Mediterranean Institute of Hematology, ROME, Italy; [2]Laboratorio Analisi. Policlinico TorVergata, ROME, Italy; [3]Institut de Recherche Pierre Fabre, CASTRES, France

Background. Busulfan (BU) is the mainstay of conditioning regimen for non-malignant diseases. Younger children have significantly high BU clearance than older children or adults which results in under-or over-exposure when standard doses are used. Intravenous BU (IVBU) is noted to have higher intrapatient pharmacokinetic (PK) consistency as compared to oral BU. No data are available on IVBU safety and PK in a large group of patients with thalassemia to date. *Aims*. Assessment of the IVBU PK in relation to patient and disease- related variables and the relationship of BU exposure to toxicities and transplant outcomes in children given SCT for thalassemia from HLA-matched related donors. *Methods*. 57 children and young adults with median age of 9 years (range, 1.6-24) were given IVBU (Busilvex, Pierre Fabre Medicament, France) as a part of conditioning regimen between 2006 and 2008. BU doses were based on actual body weight: <9-16= 1.2 mg/kg (n=10); 16-23= 1.1 mg/kg (n=13); 23-34= 0.95 mg/kg (n=23) and >34=0.8 mg/kg (n=11) and were given every 6 hours for 4 days. Anticonvulsant prophylaxis consisted of Valproic acid (Depakin). Most patients had liver disease and moderate to severe iron overload. Class 1 and class 2 patients (n=24) received IVBU in combination with CY200 ± thiotepa as conditioning regimen. Class 3 patients (n=33) before conditioning with IVBU/CY160 ± thiotepa were given hydroxyurea, azathioprine and fludarabine. Four blood samples were drawn after the 1st, 5th, 9th, and 13th doses for PK assessment by HPLC-MS. Dose adjustment (DA) was made at the 3rd dose as needed, to target an AUC range of 900- 1350 μmol/min. The influence of patient and disease-related variables on IVBU PK was investigated by a population PK-based approach using the NONMEM program. *Results*. Busulfan PK data are summarized in Table 1. In 58% of patients AUC was within, 37% below and 5% above the target range following the 1st dose of IVBU. Seventeen patients required dose elevations of 5-54% and 19 patents dose reductions of 5-34%. Following DA 79% of patients after the 5th and 9th doses and 91% after the 13th dose reached the target range. The inter-patient variability in IV BU clearance was moderate (CV=19%) and the intra-patient variability was low (CV=7%). We found that only weight or body surface area significantly explained the PK variability. Fifty three patients (93%) had sustained engraftment, 4 (7%) had graft failure. One patient had moderate hepatic VOD resolved with supportive care. Seventeen patients developed grade 2-4 acute GVHD. None of patients had seizure within 30 days post-transplant. Grade 1 or 2 ALT/AST increases or stomatitis/diarrhoea were observed in 19% and 44% or in 47% and 19% of patients respectively. Five patients died. No relationship was found between BU exposure and toxicities, engraftment time, chimerism, rejection, GVHD and survival. *Conclusions*. body weight based dosing of IVBU in children with thalassemia who have disease and treatment related important organ damage is well tolerated with no increase in organ system toxicity. Busulfan exposure did not predict rejection, GVHD, liver VOD or death.

ADEQUATE MOBILIZATION OF CD34 IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS RECEIVING LENALIDOMIDE INDUCTION THERAPY

A. Palumbo,[1] D. Ben Yehuda,[2] F. Cavallo,[1] S. Bringhen,[1] C. Di Bello,[1] F. Di Raimondo,[3] I. Hardan,[4] M.T. Petrucci,[5] A. Siniscalchi,[3] F. Rossini,[3] V. Montefusco,[3] N. Pescosta,[3] J. Peccatori,[3] P. Tacchetti,[3] A. Baraldi,[3] F. Patriarca,[3] G. Benevolo,[3] C. Crippa,[3] A.M. Carella,[3] M. Boccadoro[1]

[1]A.O.U. San Giovanni Battista, TORINO, Italy; [2]Hadassah Medical Center, JERUSALEM, Israel; [3]Italian Multiple Myeloma Network, GIMEMA, Italy; [4]Sheba Medical Center, TEL-HASHOMER, Israel; [5]Dipartimento di Biotecnologie Cellulari ed Ematologia, Università La Sapienza, ROMA, Italy

Background. New drugs have been introduced as induction regimens before ASCT. Lenalidomide has raised concerns regarding its potential impact on the ability to collect stem cells. The use of Cyclophosphamide to mobilize stem cells may overcome these concerns. *Aims.* In the prospective randomized trial RV-MM-PI-209, Lenalidomide and Dexamethasone (RD) were used as induction and Cyclophosphamide (CY) was used to mobilize stem cells. The effectiveness of this approach was determined and compared with an historical control of patients treated at diagnosis with Vincristine-Doxorubicin-Dexamethasone (VAD) and mobilized with the same CY+G-CSF schema. *Methods*. Fifty newly diagnosed myeloma patients received Lenalidomide (25 mg/d for 21 days followed by a 7 days rest period) 28-days cycles in combination with Dexamethasone (40 mg days 1, 8, 15 and 22). Stem cells were mobilized with CY 4 g/m^2 /day, i.v. on day 1 and G-CSF 10 ug/kg/day from day 5 until the end of stem cell collection. Patients who failed to collect a minimum of 4×10^6/kg CD 34$^+$ cells received a second CY+G-CSF mobilization course. The historical control included 134 patients who received VAD induction and were mobilized with the same CY+G-CSF schema used in the RD protocol. The inclusion criteria for patients entering the RD or VAD trial were identical. *Results*. Baseline patients characteristics were similar in the 2 groups. Median time from CY to leukapheresis was 12 days (range 8-23) in the RD group and 11 days (range 7-15) in the DAV group (p=0.0003). The median days of leukapheresis was slighty superior in the RD patients, 3 (range 1-5) versus 2 days (range 1-3). A second mobilization was performed in 15% of patients in both RD and VAD groups. After the first mobilization course the number of patients who did not collect at least 2×10^6/kg CD34 was 4/50 (8%) in the RD and 22/134 (15%) in the VAD group. At the completion of the mobilization phase only 1 patient (2%) in the RD group and 10 patients (7%) in the VAD group did not collect a minimum of 4×10^6/kg CD34 and therefore could not receive the planned autologous stem cell transplant. The median yield of CD34$^+$ cells collected was lower in the RD group (RD: median 10×10^6/kg, range 0-25; VAD: median 14×10^6/kg, range 0-54, p=0.0005). *Conclusions*. RD as part of induction regimen allowed to collect an adequate number of stem cells to support autologous transplantation in 98% of patients, while VAD in 93%. The median number of CD34$^+$ cells harvested was 10×10^6/kg after RD and 14×10^6/kg after VAD. An update of the the first 100 patients enrolled in the RD trial will be presented at the meeting.

STEM CELL TRANSPLANTATION IN DIAMOND-BLACKFAN ANEMIA: A RETROSPECTIVE ANALYSIS

M. Kartal,[1] J.J. Meerpohl,[1] B. Strahm,[1] M.E. Bernardo,[2] P. Lang,[1] S. Matthes-Martin,[3] A. Schulz,[4] M. Schmugge,[1] A. Fischer,[1] F. Locatelli,[2] C.M. Niemeyer[1]

[1]University Children's Hospital, FREIBURG, Germany; [2]Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy; [3]St. Anna Children's Hospital, VIENNA, Austria; [4]University Hospital, ULM, Germany

Objective. We retrospectively analyzed the characteristics and outcome of patients (pts) who received hematopoietic stem cell transplantation (HSCT) for Diamond-Blackfan Anemia (DBA) in Germany, Italy, Austria and Switzerland between 1987 and 2007. Engraftment, complications and survival were analyzed separately for patients transplanted from either a matched sibling donor (MSD) or an unrelated donor (UD). *Patients and Methods*. Thirty-seven pts (24 males and 13 females) were transplanted between 1987 and 2007 in Germany (23), Italy (12), Switzerland (1) and Austria (1). All pts received regular red blood cell (RBC) transfusions, and 19 pts were given iron chelation therapy for secondary hemosiderosis. Median age at HSCT was 5.8 years (range 1.2-15.1 years). Twenty-six pts were transplanted from a MSD, while 11 pts were grafted from a matched or 1 Ag mismatched UD. The majority of patients (24) received a conventional preparative regimen including busulfan (BU), cyclophosphamide (CY) ± thiotepa (TT). Ten pts were conditioned with BU, TT and fludarabine (FLU) and 2 pts received a reduced intensity regimen with TT and FLU. Stem cell source was bone marrow, peripheral blood and cord blood in 28, 4 and 3 pts, respectively. Two pts received grafts from combined stem cell sources. In 22 pts GvHD prophylaxis consisted of cyclosporine A, methotrexate ± antithymocyte globuline, while the other patients received various different prophylactic regimens. *Results*. Engraftment was achieved in all pts, the median time to neutrophil engraftment being 16 days (range 9-44). One pt grafted from an UD experienced secondary graft failure and subsequently died. One pt each developed acute GvHD grade > III and extensive chronic GvHD. Four pts, including two grafted from a MSD, experienced transplantation-related mortality. There was no veno-occlusive disease (VOD). With a median follow-up of 4.1 years (range 0.2-15.1) the probability of overall survival (OS) for patients transplanted from either a MSD or an UD is 0.92 (0.81-1.00) and 0.72 (0.44-1.00), respectively. *Conclusions*. HSCT offers an excellent survival for pts with DBA transplanted from a MSD. Results for patients receiving an allograft from an UD are encouraging and compare favourably with published experiences. Despite pre-existing hemosiderosis VOD does not seem to be a common complication.

0709

HLA-E UP-REGULATION ON IFN-G-ACTIVATED AML BLASTS IMPAIRED CD94/NKG2A-DEPENDENT NK CYTOLYSIS FOLLOWING HAPLO-IDENTICAL HAEMATOPOIETIC STEM-CELL TRANSPLANTATION (SCT)

S. Nguyen,[1] V. Beziat,[1] N. Dhedin,[1] M. Kuentz,[2] P. Sujobert,[1] M. Uzunov,[1] J.P. Vernant,[1] P. Debré,[1] V. Vieillard[1]

[1]Hopital Pitie-Salpetriere, PARIS; [2]Hopital Henri Mondor, CRETEIL, France

Background. We previously reported that NK-cell generated after haplo-SCT in high risk AML patients are characterized, during the first 6 months post-SCT, by specific phenotypic features and impaired functioning having potential impact for transplantation outcome (Nguyen *et al.*, Blood 2005). *Aims*. In the present study, we examined the impact of INF-γ on the impaired recognition of AML blasts by NK cells after haplo-SCT. *Methods*. We studied NK cells at 1 to 6 months (M1-M6; n=21patients) or at 24 months (M24; n=3 patients) post -SCT. Patients received CD34$^+$ haplo-transplant after a myeloablative conditionning regimen for high risk hematological diseases. *Results*. As previously observed,the subset of CD56brightCD94/NKG2A+ NK cells was increased and NK lysis of AML blasts was poor, suggesting an immature status of NK cells post transplant. However, at M24, CD56brightCD94/NKG2A+ NK subset and lytic functions restored and returned to donors levels. Blocking, *ex vivo*, the inhibitory CD94/NKG2A receptor on NK cells restored the lysis at M3 but not at M24. Higher level of intra-cellular IFN-g production was detected by FACS in CD94/NKG2A+NK at M1-M6 as compared to the donors and at M24, after incubation with IL-12+IL-18 (70% vs 14%). IFN-g treatment led to higher surface expression of HLA-E on AML blasts, resulting in decreased killing by NK cells from healthy donors. Actually, adjonction of IFN-g on AML blasts inhibited the lysis by healthy donor NK cells (12% specific lysis with INF-γ, vs. 37% without INF-γ). Blocking CD94/NKG2A restored the lysis previously inhibited by INF-γ. Neutralization of INF-γ during the interaction of NK cells post-SCT with mismatched AML blasts restored the lysis (16% lysis without INF-γ neutralization versus 44% after IFN-γ neutralization at M1). This effect was no more observed at M24 or in healthy donors. *Conclusions*. Increased secretion of INF-γ by immature NK cells generated after haplo-SCT upregulates the cell surface expression of HLA-E on AML blasts. Increased HLA-E expression protects AML targets from NK-mediated lysis through the inhibitory CD94/NKG2A receptor which is overexpressed on NK cells during the early period post-SCT. This suggests that HLA-E could be a component of an immune escape strategy against NK attack on AML blasts currently observed after haplo-SCT. By contrast, at 2 years post-SCT and in donors, mature NK cells were functionally, which is encouraging to develop clinical trials using adoptive transfer of healthy donor alloreactive NK cells.

0710

PLERIXAFOR CAN PREDICTABLY MOBILIZE HEMATOPOIETIC STEM CELLS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA PREVIOUSLY TREATED WITH FLUDARABINE AND UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

J.R. Schriber,[1] J. McCarty,[2] J. McGuirk,[3] G. Spitzer,[4] J.P. Uberti,[5] G. Calandra[6]

[1]Banner Good Samaritan Medical Center, PHOENIX, AZ; [2]Virginia Commonwealth University, RICHMOND, VA; [3]The University of Kansas Medical Center, KANSAS CITY; [4]Cancer Centers Of The Carolina, GREENVILLE, SC; [5]Karmanos Cancer Institute, DETROIT, MI; [6]Genzyme Corporation, CAMBRIDGE, MA, USA

Background. Purine analogues such as fludarabine are increasingly being utilized for patients with non-Hodgkin's lymphoma (NHL) and have been associated with unsuccessful mobilization of hematopoietic stem cells (HSC). This poses a challenge to pursue autologous stem cell transplantation (ASCT), a potentially curative procedure, in this patient population. *Aims*. The aim of this retrospective subgroup analysis is to examine the efficacy of mobilization with plerixafor + G-CSF among NHL patients previously treated with fludarabine. *Methods*. Patients with NHL who participated in the compassionate use program (CUP) who received plerixafor + G-CSF and had complete data on the number of cycles of fludarabine and total $CD34^+$ cells collected were analyzed. The methodology of the CUP has been described previously (Calandra BMT 2007). Briefly, patients in CUP received plerixafor + G-CSF as a HSC remobilization strategy after failing other mobilization regimens. Patients received G-CSF at a dose of 10µg/kg subcutaneously (SC) every morning for 4 days. At about 2200 hours, on day 4, plerixafor was administered at a dose of 0.24 mg/kg. The next morning, day 5, G-CSF was administered and apheresis was initiated. This was repeated daily (G-CSF, apheresis, plerixafor) until patients collected enough cells for transplantation, minimum of 2×10^6 $CD34^+$ cells/kg. *Results*. Of the 401 NHL patients in the CUP database, 48 (12%) had prior therapy with fludarabine. Complete data on number of cycles of fludarabine and total $CD34^+$ cells collected was available for 33 patients. The mean age was 56.5±7.9 years and 14/33 (42.4%) of the patients were men. The median number of fludarabine cycles prior to HSC mobilization was five (range 1-50). Table 1 shows the median number of $CD34^+$ cells collected and the percentage who collected $\geq2\times10^6$ $CD34^+$ cells/kg for those who had received prior fludarabine versus patients who were fludarabine naïve in the CUP. Among the patients that received prior fludarabine, administration of plerixafor + G-CSF resulted in a median collection of 2.8×10^6 $CD34^+$ cells/kg (range $0.3\text{-}6.6\times10^6$ $CD34^+$ cells/kg). A total of 21/33 (63.6%) of the patients collected $\geq2\times10^6$ $CD34^+$ cells/kg in a median of two apheresis sessions (range 1-6 apheresis days). Overall, 27/33 (81.8%) of the patients proceeded to ASCT. Median time to neutrophil and platelet engraftment was 12 days and 22 days, respectively. *Conclusions*. These preliminary results suggest that the majority of patients with NHL pretreated with fludarabine who have failed a previous mobilization regimen can successfully and predictably mobilize $CD34^+$ HSC with plerixafor + G-CSF and that they do not appear to differ from the larger group of NHL patients.

Table 1.

	Prior Fludarabine	No Prior Fludarabine
Median number of $CD34^+$ cells/kg (x 10^6)	2.8	2.5
Percent Patients collecting ≥ 2 x 10^6 $CD34^+$ cells/kg	63.6	64.4

COMPARABLE OUTCOMES AFTER REDUCED-INTENSITY AND MYELOABLATIVE ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN FIRST OR SECOND REMISSION: A MATCHED-PAIR ANALYSIS

S. Lee,[1] J. Kwak,[2] J. Kim,[1] S. Park,[3] B. Cho,[1] K. Eom,[1] Y. Kim,[1] H. Kim,[1] C. Min,[1] S. Cho,[1] D. Kim,[1] J. Lee,[1] W. Min,[1] C. Kim[1]

[1]Catholic BMT Center, The Catholic University of Korea, SEOUL; [2]Chonbuk National University Medical School, CHONJU; [3]Soonchunhyang University Medical School, SEOUL, South-Korea

Background. It is reasonable to look to reduced-intensity conditioning (RIC) allogeneic stem cell transplantation (SCT) as a way to provide a graft-versus-leukemia effect with reduced toxicity for adults with high-risk acute lymphoblastic leukemia (ALL) with low leukemic cell burden who are considered poor candidates for myeloablative conditioning (MAC). Results of RIC-SCT have not been compared to those after MAC-SCT in adult ALL. *Aims*. With this aim, we compared the outcomes of 40 consecutive adults with high-risk ALL who underwent RIC-SCT in first or second remission to a historical group of 160 matched controls receiving MAC-SCT. *Methods*. The indications for RIC-SCT were: (1) aged more than 50 years 18 (45%) and (2) decreased organ function or active infections 22 (55%). Matching criteria included patients receiving SCT from a matched sibling or unrelated donor who (1) were aged 15-65 years; (2) were diagnosed as *de novo* ALL; (3) had received the same policy of pretransplantation chemotherapy; (4) were transplanted in first or second remission between 2000 and 2007; (5) had received RIC with fludarabine (150 mg/m^2) plus melphalan (140 mg/m^2); (6) had received MAC with total body irradiation (12 or 13.2 Gy)-based regimen. Both groups were comparable in terms of main patient-, disease-, and transplant-related factors. However, patients in the RIC group were older (median age, 46 years versus 29 years, $p<0.001$), had Philadelphia chromosome more frequently (48% versus 29%, $p=0.029$), and received peripheral blood stem cells more frequently (85% versus 13%; $p<0.001$) as compared to patients in the MAC group. All patients received the same graft-versus-host disease prophylaxis consisting of calcineurin inhibitor (cyclosporine for sibling transplants; tacrolimus for unrelated transplants) plus methotrexate. *Results*. During the observation period, the cumulative incidence of acute (grade II-IV) and chronic graft-versus-host disease was comparable in both groups. In the RIC group, 9 (23%) of the 40 patients relapsed. Fourteen patients (35%) had died; 6 of these 14 died of causes other than leukemic relapse, and the remaining 8 patients died of relapse and progression. After a median follow-up of 36 months (range, 12-103 months) for surviving transplants, the 3-year cumulative incidence of relapse and non-relapse mortality were 25% and 19%, respectively, and the 3-year disease-free survival and overall survival rates were 60% and 62%, respectively. In the MAC group, 28 (18%) of the 160 patients relapsed. Fifty-six patients (35%) had died; 30 of these 56 died of causes other than leukemic relapse, and the remaining 26 patients died of leukemia relapse and progression. After a median follow-up of 59 months (range, 12-103 months) for surviving transplants, the 3-year cumulative incidence of relapse and non-relapse mortality were 21% and 19%, respectively, and the 3-year disease-free survival and overall survival rates were 64% and 67%, respectively. Overall transplantation outcomes were not significantly different between the two groups. *Conclusions*. RIC-SCT may represent a valid therapeutic approach for adults with high-risk ALL in first or second remission who are not eligible for MAC-SCT. Large prospective studies are needed to elucidate the role of RIC in adults wit high-risk ALL.

0712

UNRELATED STEM CELL TRANSPLANTATION FOLLOWING TOTAL BODY IRRADIATION-BASED MYELOABLATIVE CONDITIONING IN ADULTS WITH PHILADELPHIA-NEGATIVE HIGH-RISK ACUTE LYMPHOBLASTIC LEUKEMIA

S. Lee,[1] J. Kwak,[2] J. Kim,[1] S. Park,[3] B. Cho,[1] K. Eom,[1] Y. Kim,[1] H. Kim,[1] C. Min,[1] S. Cho,[1] D. Kim,[1] J. Lee,[1] W. Min,[1] C. Kim[1]

[1]Catholic BMT Center, The Catholic University of Korea, SEOUL; [2]Chonbuk National University Medical School, CHONJU; [3]Soonchunhyang University Medical School, SEOUL, South-Korea

Background. Stem cell transplantation (SCT) from a matched sibling or unrelated donor clearly benefits certain patients with high-risk acute lymphoblastic leukemia (ALL), such as those with Philadelphia chromosome (Ph)-positive ALL. In contrast, whether SCT from an unrelated

donor is a treatment option of equal value in Ph-negative ALL cases lacking a matched sibling donor remains unclear. Considering recent progresses including the improvement of human leukocyte antigen matching and the development of supportive care facilities, a detailed analysis is needed to clarify the role of unrelated SCT in adults with high-risk Ph-negative ALL. *Aims*. The aim of the present study was to identify graft-versus-leukemia effects and the factors that affect outcome in 53 consecutive adults with high-risk Ph-negative ALL who received unrelated SCT using total body irradiation (TBI)-based myeloablative conditioning (1997-2007). *Methods*. Median age was 21 years (range, 15-47 years). Patients in first complete remission (CR1) at SCT had at least one adverse prognostic factor, including (1) t(4;11), (2) high presenting leukocyte counts (>30×10^9/L for B-precursor ALL, >100×10^9/L for T-precursor ALL), or (3) CR requiring more than 28 days of induction therapy. Thirty-nine patients (74%) were transplanted in CR1; 3 (5%) in CR2; and 11 (21%) were resistant to chemotherapy before transplantation. All patients received unmodified stem cell grafts (43 bone marrow; 10 peripheral blood) following TBI-based myeloablative conditioning [TBI (13.2 Gy) + cyclophosphamide (120 mg/kg) for CR1; TBI (12 Gy) + cytarabine (12 g/m^2) + melphalan (140 mg/m^2) for >CR1]. Graft-versus-host disease (GVHD) prophylaxis was uniformly attempted by administering tacrolimus plus methotrexate. Antithymocyte globulin (2.5 mg/kg) was administered to 18 patients who received allele-mismatched grafts. *Results*. After a median follow-up of 59 months (range, 12-137 months) for surviving transplants, incidences of acute (grade II-IV) and chronic GVHD were 60% and 56%, respectively. The 5-year cumulative incidence of relapse and non-relapse mortality were 29% and 27%, respectively, and the 5-year disease-free survival (DFS) and overall survival rates were 51% and 51%, respectively. Disease status at transplantation (CR1 versus >CR1) was the most powerful predictive factor affecting relapse (14% versus 71%, p=0.001) and DFS (61% versus 21%, p=0.006) in multivariate analysis. The presence of chronic GVHD was also found to be significantly associated with lower relapse (10% versus 49%, p=0.005) and better DFS (79% versus 42%, p=0.006). *Conclusions*. TBI-based myeloablative unrelated SCT, especially in CR1, provides a curative option for high-risk Ph-negative ALL patients lacking a matched sibling donor. The presence of chronic GVHD results in better transplantation outcome, indicating a clinically important graft-versus-leukemia effect.

0713

ALLOGENEIC VERSUS AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH RELAPSING FOLLICULAR LYMPHOMA: USE OF THE PROPENSITY SCORE TO REDUCE RECRUITMENT BIAS IN A RETROSPECTIVE COMPARATIVE STUDY

F. De Fontbrune, D. Sibon, M. Resche-Rigon, S. Chevret, J. Brière, C. Gisselbrecht, C. Thiéblemont, G. Socié

Hopital Saint Louis, PARIS, France

Autologous stem cell transplantation (autoSCT) is the standard treatment for relapsed follicular lymphoma (FL) in patients (pts) younger than 65. Allogeneic SCT (alloSCT) may offer higher curative potential but treatment related mortality (TRM) limits its use. Allografting with non-myeloablative conditioning (NMA-C) has therefore been considered to improve survival. Owing to non-randomized available data, there was a need to correct for potential recruitment bias. The propensity score (PS) methodology allows coping with the presence of such a bias. To assess the place of alloSCT for relapsing pts with FL, we compared pts who underwent consecutive allo or autoSCT at Saint Louis Hospital from 1989 to 2007 after propensity score (PS) matching (Stukel TA, JAMA 2007). PS was defined as the probability of receiving allo or autoSCT knowing age at relapse, number of pretransplant regimens and time from relapse treatment to SCT. To remove bias, matching 1/1 was done using PS and period of transplant (before/after 2000). Cox models were performed to compare allo vs autoSCT on OS and EFS with a fixed period effect. 27 pts were allografted (Figure). 5y-OS and 5y-EFS of alloSCT pts were 58% and 58% with a median follow up (FU) of 4 years (y). 13 pts (48%) died (TRM: 12/13) and 1/27 relapsed. 6 (22%) had grade 3-4 acute graft versus host disease (GvHD), and 9 experienced chronic extensive GvHD. 116 pts had autoSCT (Figure). 5y-OS and 5y-EFS were 73% and 46% with a median FU of 4.4 y. PS allowed 19 pairs to be matched, similarly distributed between allo and autoSCT pts. Based on these matched pairs, 5y-OS estimations were 67% and 77% (p=0.71), and 5y-EFS estimations were 66% and 52.4% (p=0.18) after allo and autoSCT (median FU 4.9 and 3.8), respectively. In conclusion, there was no significant difference in OS and EFS between allo and autoSCT matched-pts using PS between 1989 and 2007, despite a trend toward better EFS in alloSCT. For pts transplanted after 2000, this trend was confirmed, due to larger use of NMA-C alloSCT. As expected with the use of NMA-C we observed lower TRM and associated with very low relapse rate (none in our cohort) these data suggest that longer FU may result in significant better OS and EFS after alloSCT.

Table. Patients and disease characteristics of the entire cohort.

	AlloSCT	AutoSCT
Number of patients	27	116

TREATMENT OF MANTLE CELL LYMPHOMA BY ALLOGENEIC STEM CELL TRANSPLANTATION - A PRELIMINARY REPORT FROM THE TRIALS #060 AND #074 OF THE EAST GERMAN STUDY GROUP FOR HAEMATOLOGY AND ONCOLOGY (OSHO)

W.H. Krüger,[1] N. Basara,[2] F. Schüler,[1] D. Niederwieser,[2] G. Behre,[3] N. Grobe,[4] H. Sayer,[5] G. Maschmeyer,[6] A. Haas,[6] T. Kiefer,[1] T. Neumann,[1] G. Dölken[1]

[1]University-Hospital Greifswald, GREIFSWALD; [2]University-Hospital Leipzig, LEIPZIG; [3]Martin-Luther University, HALLE/SAALE; [4]Dietrich-Bonhoeffer-Hospital, NEUBRANDENBURG; [5]Friedrich-Schiller-University, JENA; [6]Hospital Ernst-von-Bergmann, POTSDAM, Germany

Introduction. Mantle cell lymphoma (MCL) has a poor prognosis under conventional therapy. Allogeneic stem cell transplantation (SCT) after reduced-intensity conditioning is here a promising approach. Graft-versus-lymphoma effect has the power to eradicate minimal residual disease as shown by PCR-detection of chromosomal translocation t(11;14) or clone-specific CDR-III regions. *Aims and Methods*. To investigate the efficacy of chemotherapy-based conditioning followed by allogeneic SCT for treatment of MCL, two ongoing protocols have been established: Trial #074 is open for patients with *de novo* MCL and #060 for patients requiring salvage therapy. At least a partial remission to (re)-induction therapy is mandatory for proceeding to allogeneic SCT. Con (12 g/m^2) and fludarabin (150 mg/m^2). Busulphan (16 mg/kg) and cyclophosphamide (120 mg/kg) is optional for younger patients. ATG is given prior to mismatched or mud SCT. *Results*. 26 patients have been recruited into both ongoing trials (#060: n=10, #074: n=16) so far. Eighteen patients (69%) are male and 8 (31%) are female with a median age of 60 years (range: 32,6-69,1). Induction therapy prior to TX consisted mainly of R-CHOP or R-DHAP. Twenty patients proceeded to allo-TX from matched related or matched unrelated donors so far. One patient died from progressive disease prior to TX. Sixteen patients (80%) were conditioned with treosulfan/fludarabine and four (20%) with busulphan/cyclophosphamide. Sixteen patients are well (KI: 80-100%) and alive after SCT with a median follow-up of 12 months (0,3-78,9) in CCR. Three patients have died from early infections and one from infection related to an acute GvHD IV° due to DLI for relapse (blastic variant) ten months after SCT in complete remission of the lymphoma. Molecular analyses showed a 2-4log reduction of circulating lymphoma cells after chemotherapy alone. Blood became negative by qPCR after allogeneic SCT in all 5 patients analysed so far. An intermediate increase of circulating lymphoma cells in two patients was successfully treated by rituximab and withdrawal of Cy-A. *Conclusions*. Allogeneic SCT is a promising approach for treatment of MCL. Clinical long-term remissions can be reached and negativity of minimal-disease analyses by quantitative PCR strongly supports curative potential of allogeneic SCT for MCL.

0715

PRE-TRANSPLANT RISK ASSESSMENT FOR AML PATIENTS: COMBINED RISK FACTOR ANALYSIS MAY BE USED TO PREDICT OUTCOME AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOLLOWING REDUCED INTENSITY CONDITIONING

P. Hemmati,[1] T. Terwey,[1] G. Massenkeil,[2] P. Le Coutre,[1] S. Neuburger,[1] L. Lam,[1] B. Dörken,[1] R. Arnold[1]

[1]Charité Universitätsmedizin Berlin Campus Virchow Klinikum (CVK), BERLIN; [2]Medizinische Klinik II, Klinikum Gütersloh, GÜTERSLOH, Germany

Purpose. Allogeneic stem cell transplantation (AlloSCT) following reduced intensity conditioning (RIC) expands potentially curative therapy to patients with high-risk AML ineligible to transplantation following standard conditioning due to advanced age, a history of severe infectious complications, or major organ dysfunction. In addition to a number of disease-specific variables the overall outcome of these patients is determined by comorbidities, as indicated by an unfavorable hematopoietic cell transplantation-specific comorbidity index (HCT-CI), and transplantation-specific factors, i.e. the lack of an HLA-identical donor. Here, we investigated whether a combined risk-factor analysis may predict the overall outcome of AML patients after RIC-alloSCT. *Patients and Methods*. 90 patients with high-risk AML (median age 51 (17-68) years) who underwent alloSCT at our institution were retrospectively analyzed. 62/90 patients (71%) were in CR1 or CR2 and 26/90 (29%) had active disease. 57/90 patients (63%) had *de novo* AML and 33/90 patients (37%) had either secondary AML (sAML) or therapy-related AML (tAML). 4/90 patients (4%) had a favorable risk karyotype, 51/90 patients (57%) or 29/90 patients (32%) had an intermediate-risk or a poor-risk cytogenetics as defined by the SWOG/ECOG criteria. 18/90 (20%) patients had an intermediate-risk HCT-CI (1-2 points) and 72/90 patients (80%) had an unfavorable score (≥3 points). 74/90 patients (82%) were transplanted from a matched related or a matched unrelated donor. A mismatched unrelated donor was available in 16/90 patients (18%). As a preparative regimen all patients received RIC (fludarabine 180 mg/m^2 + oral busulfane 8 mg/kg + antithymocyte globulin 40 mg/kg). *Results*. Projected overall survival (OS) or disease-free survival (DFS) of all patients at 1, 3, and 5 years was 60%, 44%, and 39% or 56%, 46%, and 39%. 49/90 patients (54%) are in CCR. Causes of death were relapse [23/90 patients (26%)] or TRM [18/90 patients (20%)]. Depending on the presence or absence of at least one additional leukemia-specific risk factor (tAML, unfavorable-risk karyotype, disease status prior to alloSCT >CR2), or transplantation from a mismatched unrelated donor, patients were grouped into four categories: group I (HCT-CI <4, no additional risk factor), group II (HCT-CI >4, no additional risk factor), group III (HCT-CI <4, additional risk factor), and group IV (HCT-CI >4, additional risk factor). Projected OS in at 1, 2, and 4 years after alloSCT was 75%, 63%, and 63% (group I), 100%, 67%, and 67% (group II), 58%, 45%, and 36% (group III), or 31%, 15%, and 15% (group IV), which differed statistically significant between the 4 subgroups (p=0.016). In turn, there was no statistically significant difference in TRM between groups I - IV (p= 0.27). *Conclusions*. These results indicate that the combined risk-factor analysis may be useful in predicting the overall outcome of patients with AML after RIC-alloSCT.

0716

REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION DURING APLASIA IN PRIMARY HIGH-RISK AND RELAPSED ACUTE MYELOID LEUKEMIA

F. Stölzel,[1] J. Schetelig,[1] U. Platzbecker,[1] C. Thiede,[1] T. Illmer,[1] M. Schaich,[1] M. Füssel,[2] C. Theuser,[1] M. Hänel,[3] R. Mahlberg,[4] G. Ehninger,[1] M. Bornhäuser[1]

[1]Medizinische Klinik I, DRESDEN; [2]DKMS, DRESDEN; [3]Klinikum Chemnitz, CHEMNITZ; [4]Krankenanstalt der Borromäerinnen Trier, TRIER, Germany

Background. High risk acute myeloid leukemia (AML) as well as relapsed disease after conventional chemotherapy remains a challenging disease category. Immediate allogeneic hematopoietic stem cell transplantation (HSCT) during aplasia after cytoreductive chemotherapy harnessing reduced intensity conditioning regimens seems to be an option for remission induction and potential cure. *Methods*. This retrospective analysis reported here summarizes 82 consecutive patients with a median age of 50 years (range 17-71) who underwent allogeneic HSCT using reduced intensity conditioning on a chemotherapy- (n=67) or total body irradiation- (n=15) based regimen after a median of 34 days (range 11-91) after primary diagnosis or relapse of AML. Included were high risk AML patients defined by poor risk cytogenetics referring to SWOG criteria (n=38) or inadequate blast clearance after induction chemotherapy (n=20) and patients with relapsed AML (n=24). Allogeneic HSCT from related (n=29) or unrelated (n=53) donors occurred with engraftment in 81 patients. *Results*. With a median follow up of 39 months for patients alive (range 9 - 119 months) the probability of overall survival was 47% at two years after HSCT. The cumulative incidence of non-relapse mortality (NRM) and relapse were 25% and 35%, respectively. Reasons for death besides relapsing AML and acute or chronic Graft-versus-Host-Disease were bacterial infections (n=8), fungal infections (n=6), bleeding hemorrhage (n=3) and CMV infections (n=2). Analysis indicates that FLT-3 ITD mutations account for a lower OS and DFS in these patients as well as for a higher risk of relapse after HSCT. Age, karyotype and blast count after preceding chemotherapy were not predictive for overall outcome. Patients receiving transplants as part of primary therapy had a more favorable outcome (OS 53% vs. 27%, respectively, p=0.03). Patients with a Sorror score of 0 to 2 (n=63) had a better OS compared to patients with a Sorror score of 3 to 6 (n=19) (OS 54% vs. 30%, respectively, p=0.013). *Conclusions*. Immediate allogeneic HSCT performed during aplasia after induction or salvage chemotherapy is a feasible approach increasing the rate of remission and durable response in patients with high-risk AML. The identification of a suitable donor is an important part of this strategy. Given the increasing availability of unrelated volunteer donors, about 60-70% of patients with high-risk AML should be eligible for this treatment algorithm.

0717

IMPROVED SURVIVAL AFTER STEM CELL TRANSPLANTATION WITH KILLER-CELL-IMMUNOGLOBULIN-LIKE RECEPTOR (KIR)/HLA MISMATCHED ALLOGRAFTS IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA

H. Martin,[1] R. Richter,[2] G. Bug,[1] H. Serve,[1] E. Seifried,[2] C. Seidl[2]

[1]Goethe University, Frankfurt, FRANKFURT; [2]Institute of Transfusion Medicine, Department of Transplantation Immunology, FRANKFURT, Germany

Background. HLA class I antigens are ligands for killer cell immunoglobulin-like receptors (KIRs). These receptors are expressed by NK and T-cells and thus modulate innate and adaptive immunity. KIR mismatches have been suggested to modify the outcome after stem cell transplantation. The clinical impact of killer cell receptors may vary between disease entities and pre- and post transplant therapeutic regiments. We have therefore performed a retrospective study with patients transplanted in our centre between 1998 and 2007. *Aims*. To analyze the impact of KIR / HLA mismatches on posttransplant relapse, transplant-related mortality and overall survival in allografted AML-patients. *Patients and Methods*. In a consecutive single center cohort of 147 AML patients, samples from 54 donor/patients, pairs were evaluable for retrospective KIR-ligand matching. The median patient age was 47 (25-66) years. Patients were transplanted with G-CSF-stimulated PBSC (n=51) or bone marrow (n=3) from HLA matched unrelated (n=31) donors or family related donors (n=23). KIR typing was performed as previously described. Patients were categorised according to their HLA inhibitory KIR ligand group C1, C2, Bw4, A3/A11 and presence or absence of KIR.

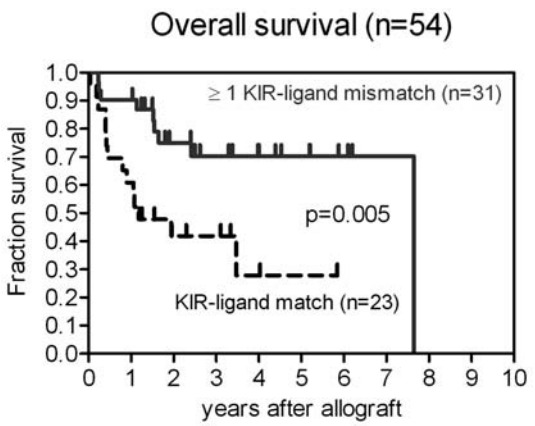

Figure 1. Survival in allografted AML patients.

Results. Overall survival (OAS) of all 54 evaluable patients at 5 years is 53%. The median follow up of surviving patients is 2,6 (range 1 - 6.2) years. A total of 23 patients died due to relapse (n=14) or non-relapse mortality (NRM, n=9). Patients with KIR-mm had a lower NRM (3/31 vs. 5/23, p=0.12) and a lower mortality due to relapse (6/31 vs. 8/23, p=0.15). OAS was superior in patients with KIR-ligand mismatches (KIR-mm) compared to the group of patients without mismatches (70% versus 28%, log rank p=0.005). Patients with 2 KIR mismatches (C1 and/or C2) had even better survival compared to patients with single KIR mismatches. *Conclusions*. Patients with AML benefit from KIR-ligand mismatched allografts. Allografted AML-patients with KIR mismatch have a significantly superior survival. The mortality due to both relapse and as well as NRM is reduced. KIR typing would be a useful tool to be included to define optimal histocompatibility of donor patient pairs.

0718

PLERIXAFOR CAN PREDICTABLY MOBILIZE HEMATOPOIETIC STEM CELLS IN PATIENTS WITH MULTIPLE MYELOMA PREVIOUSLY TREATED WITH LENALIDOMIDE

I.N.N. Micallef,[1] S.R. Tarantolo,[2] P.A. McSweeney,[3] L.M. Klein,[4] G. Calandra,[5] D. Huebner[5]

[1]Mayo Clinic, ROCHESTER; [2]Nebraska Methodist Hospital, OMAHA; [3]Rocky Mountain Cancer Center, DENVER, CO; [4]Advocate Lutheran General Hospital, NILES, IL; [5]Genzyme Corporation, CAMBRIDGE, MA, USA

Background. Emerging literature suggests that lenalidomide negatively affects the ability to collect CD34+ cells in patients with multiple myeloma (MM) undergoing hematopoietic stem cell transplantation. *Aims*. The aim of this retrospective subgroup analysis is to examine the efficacy of mobilization with plerixafor + G-CSF (P+G) among patients previously treated with lenalidomide. *Methods*. Patients with MM who participated in a phase III study (3102) assessing the safety and efficacy of plerixafor in hematopoietic stem cell mobilization, or in a compassionate use program (CUP) who received P+G and who had complete data on number of cycles of lenalidomide and total CD34+ cells collected were analyzed. Trial designs of the aforementioned studies have been described previously (DiPersio ASH 2007, Calandra BMT 2007). Briefly, in study 3102, patients received P+G as a first line mobilization regimen, whereas patients in the CUP received P+G as rescue therapy after failing other mobilization regimens.

Table 1.

	Study 3102 n=5	CUP n=22	All Patients n=27
Median Number of Lenalidomide Cycles (Range)	4 (1-5)	4.5 (2-20)	4 (1-20)
Median Collection of CD 34+ (x10^6 cells/kg) (Range)	14.8 (4.6-22.2)	3.29 (0.45-13.53)	4.3 (0.45-22.2)
Percent of Patients that Collected ≥ 5 x 10^6 CD34+ cells/kg	4/5 (80%)	7/22 (32%)	11/27 (41%)
Percent of Patients that Collected ≥ 2 x 10^6 CD34+ cells/kg	5/5 (100%)	15/22 (68%)	20/27 (74%)
Median Time (in days) to Neutrophil Engraftment (Range)	12 (11-13)	11 (10-16)	11.5 (10-16)
Median Time (in days) to Platelet Engraftment (Range)	18 (13-22)	18.5 (11-42)	18 (11-42)

Results. Of the 148 patients randomized to P+G in 3102, seven patients were previously treated with lenalidomide. In the CUP database, 60/708 patients were previously treated with lenalidomide. Complete data on number of cycles of lenalidomide and total CD34+ cells collected was available for 27 patients; five from 3102 and 22 from CUP. The mean age was 61.2 7.9 years and 14/27 (52%) of the patients were men. The median number of lenalidomide cycles prior to mobilization was four (range, 1-20). Administration of P+G resulted in a median collection of 4.3×10^6 CD34+ cells/kg. A total of 20/27 (74%) of the patients collected 2×10^6 CD34+ cells/kg in a median of two apheresis sessions. All the patients in 3102 collected 2×10^6 CD34+ cells/kg compared to 15/22 (68%) of the patients in CUP. Overall, 22 (81.5%) patients proceeded to transplant. The median time to neutrophil and platelet engraftment was 11.5 days and 18 days, respectively. *Conclusions*. These preliminary results suggest that the majority of patients with MM pretreated with lenalidomide can be successfully mobilized (collection of 2×10^6 CD34+ cells/kg) with plerixafor plus G-CSF

0719

INTRAVENOUS BUSULFAN IN AUTOLOGOUS STEM CELL TRANSPLANTATION CONDITIONING REGIMEN FOR ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA. MULTICENTRE RETROSPECTIVE ANALYSIS

C. Grande,[1] P.J. García Sánchez,[2] J. de la Rubia,[3] D. Serrano,[4] M. López Duarte,[5] R. García Boyero,[6] P. Rosique,[7] I. Heras,[8] R. Martínez,[2] J.J. Lahuerta[1]

[1]Hospital 12 de Octubre, MADRID; [2]Hospital Clínico San Carlos, MADRID; [3]Hospital La Fe, VALENCIA; [4]Hospital Gregorio Marañón, MADRID; [5]Hospital Marqués de Valdecilla, SANTANDER; [6]Hospital General Castellón, CASTELLÓN; [7]Hospital Arrixaca, MURCIA; [8]Hospital Morales Meseguer, MURCIA, Spain

Background. Busulfan (Bu) is a common drug used in myeloablative hematopoietic stem cell transplantation (SCT) conditioning regimes for acute myelogenous leukaemia (AML) treatment. The incidence of sinusoidal obstructive syndrome (SOS) is 3 to 10% when oral Bu is used. Intravenous (Iv) Bu has a predictable pharmacocynetic profile and therefore, a reduced toxicity. *Aims and Methods*. In this retrospective analysis,

we show the results of autologous SCT with Iv Bu based conditioning regimen in 60 AML patients (27 males; 33 females) treated in 8 Spanish centres from 2003 to 2008. Median age at SCT was 56 years (18-76); 7 were more than 70. SCT was performed in first complete remission (RC1) in 55 (91.7%) patients, in second remission (RC2) in 4 (6.6%) and in partial response in one case. Cytogenetic risk at diagnosis was low in 6.9%, intermediate in 44.8% and high in 48.3%. The conditioning regimen was BuCy (Iv Bu 0.8 mg/kg/6 hours x 4 days + cyclophosphamide 60 mg / kg x 2 days), in 38 patients (63.3%); BEA (Iv Bu 0.8 mg / kg / 6 hours x 4 days + etoposide 40 mg/Kg + Ara-C 3 g / m^2 x 4) in 21 (35%); and other schema was used in one case. *Results*. Median time to obtain 0.5×10^9/L neutrophils was 11 days (7-52). Adequate platelet recovery was not reached in 3 cases (2 of them relapsed few months later); in the other 57 cases, median time to 20 $\times10^9$/L platelets was 15 days (7-122). One patient died before day +100 post SCT because an early relapse, thus, SCT related mortality was 0%. Only 1 patient died during complete response due to septic shock in the fourth month post SCT, with a global 2 year cumulative non relapsed mortality incidence of 1.6%. There were no cases of SOS. With a median follow up of 10.5 months for alive cases, the 2 year cumulative probability of overall survival (OS) was 53% (median OS: 38 months in RC1; 8 months RC2) and event free survival (EFS) was 44% (median EFS: 18 months in RC1; 6 months RC2). OS and EFS were better in patients < 60, although toxicity in older patients was no different. There was not any difference in OS or EFS in SCT conditioned with BuCy versus BEA. *Summary*. In this retrospective study of autologous SCT in AML patients with Iv Bu in the conditioning regimen, toxicity was low and results encouraging, with no worse EFS than the one obtained with other SCT modalities.

0720

HIGHER INFUSED CD34+ HEMATOPOIETIC STEM CELL DOSE CORRELATES WITH EARLIER LYMPHOCYTE RECOVERY AND BETTER CLINICAL OUTCOME AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN'S LYMPHOMA

C. Suh, D.H. Yoon, B.S. Sohn, J.E. Kim, C.H. Yoo, S. Kim, D.H. Lee, C.J. Park, J.R. Huh

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Lymphocyte recovery after autologous stem cell transplantation (ASCT) has been shown to be associated with positive clinical outcome in non-Hodgkin's lymphoma (NHL). Among the factors known to affect lymphocyte recovery following ASCT are infused lymphocyte count and NK cell count. However, the relationship between infused autograft CD34+ cell dose and lymphocyte recovery following ASCT has not been firmly established, although the number of CD34+ cells is commonly used to predict the potential engraftment of ASCT. *Aims*. This study sought to identify variables that affect lymphocyte recovery including infused lymphocyte count and CD34+ cell dose, and survival in patients with NHL receiving ASCT *Methods*. A retrospective analysis of outcomes in 97 consecutive patients who underwent ASCT for NHL in a single center from August 1999 to January 2008 was conducted. The relationships between infused lymphocyte count and infused CD34+ cell count with days to recovery of absolute lymphocyte count (ALC) were analyzed using the Spearman correlation coefficient. *Results*. We did not observe a significant relationship between infused lymphocyte count and days to recovery of ALC ≥500/mm^3 following ASCT (ALC500) (r=0.139, p=0.176), but there was a significant inverse correlation between infused CD34+ cell count and days to ALC500 (r=-0.333, p=0.001). Many prognostic factors were associated with OS and/or EFS by univariate analyses, including age-adjusted IPI (0-1 vs. 2-3), stage (I-II vs. III-IV), disease status at the time of ASCT (complete remission [CR] vs. not CR), immunophenotype (B- vs. T/NK-cell NHL), recovery of ALC500 (<20th vs. ≥20th day), collected CD34+ cell count (<10.4 vs. ≥10.4×10^6 cells/kg) and infused CD34+ cell dose (<8.2 vs. ≥8.2 $\times10^6$ CD34+ cells/kg). The median OS and EFS were not reached for patients with ALC500 < 20th day while they were 10.3 months and 4.8 months for patients with ALC500 ≥20th day, respectively (p=0.006 for OS and p=0.024 for EFS). The median OS and EFS were significantly longer in patients who received ≥8.2×10^6 CD34+ cells/kg than in those who received <8.2×10^6 CD34+ cells/kg (OS, not reached vs. 11.6 months, p=0.001; EFS, not reached vs. 4.8 months, p=0.003). No differences in OS and EFS by infused lymphocyte count (<0.98×10^8/kg vs. ≥0.98×10^8/kg lymphocytes) were observed (p=0.612 for OS and p=0.744 for EFS). Multivariate analysis showed that infused CD34+ cell dose was the most important independent predictor of OS (HR=0.314, p=0.017) and EFS (HR=0.175, p=0.002) for this sample set of patients who received ASCT for NHL. It did not provide evidence that other variables found to be significant by univariate analyses were independent predictors of survival once CD34+ dose is taken into account. *Summary and Conclusions*. In contrast to previous reports, we did not observe any association between infused lymphocyte count and kinetics of ALC recovery following ASCT. We found, instead, that higher infused CD34+ cell dose correlated with earlier lymphocyte recovery and better clinical outcome after ASCT in patients with NHL.

Table 1.

Prognostic factors	OS			EFS		
	P-value	HR	95% CI	P-value	HR	95% CI
Immunophenotype (B- vs T/NK-cell)	0.378	1.335	0.703-2.536	0.757	1.106	0.585-2.090
Stage <II vs ≥III	0.175	1.818	0.766-4.315	0.122	1.986	0.833-4.731
CR vs not CR	0.468	1.462	0.524-4.077	0.376	1.585	0.572-4.391
Age-adjusted IPI, 0-1 vs 2-3	0.174	2.023	0.733-5.577	0.281	1.758	0.631-4.896

SEARCH OF AN UNRELATED DONOR FOR PATIENTS WITH HIGH RISK ACUTE LYMPHOBLASTIC LEUKEMIA: RESULTS OF A PROSPECTIVE, UNICENTRIC STUDY

A.P. Iori,[1] V. Valle,[2] A. Piciocchi,[2] G.F. Torelli,[2] L. Malandruccolo,[2] G. Meloni,[2] A.M. Testi,[2] W. Barberi,[2] A. Vitale,[2] F. Milano,[2] B. Lucarelli,[2] E. Iannella,[2] F. Natalino,[2] M. Perrone,[2] L. Laurenti,[2] R. Ricci,[2] C. Minotti,[2] W. Arcese,[3] R. Foà[2]

[1]Hematology, ROME; [2]Hematology Sapienza University of Rome, ROME; [3]Hematology, University Tor Vergata, ROME, Italy

Background. Allogeneic hematopoietic stem cell transplantation (HSCT) plays a major role in the treatment of patients with high risk (HR) acute lymphoblastic leukemia (ALL) because of the features at diagnosis or in >II complete remission (CR); the search of an unrelated donor is therefore a common strategy for patients (pts) lacking a family compatible donor. *Aims*. To assess the effectiveness of the search on the outcome of pts with HR ALL. *Methods*. We analyzed prospectively 136 pts, 81 males and 55 females, median age 11 years (1-59), who were addressed, at our Center, to a search of an unrelated donor through the BMDWW Registry and cord blood (CB) banks between April 1995 and August 2008. *Results*. At the start of the search, 37 pts were in I CR, 70 in II CR, 3 in >II CR and 26 in relapse. The probability of finding a donor, CB or volunteer donor (VD), by cumulative incidence (CI) was 62% and 72% at 3 and 6 months, respectively; after this time, no increase in the CI of finding a donor was registered. The median time from the start of the search to finding a donor was 1.5 months for a CB and 3.5 months for a VD. Fifty % of the 110 patients who entered the search in CR showed a relapse at a median of 4 and 2 months from the start of the search for pts in I-II CR and >II CR, respectively. Of the 102/136 pts with a donor, 62 underwent a transplant: 25% of pts were in a more advanced phase compared to the start of the search; 35% of the pts who started the search in relapse obtained a CR at a median of 3 months and received an HSCT. Forty % of pts with a donor failed to undergo a transplant because of lost eligibility due to disease progression. The 10 year probability of OS was 23% for the whole population. In univariate analysis, relapse vs no relapse during the search (HR: 4.1; CI% 95: 2.75-6.12) and transplant vs no transplant (HR: 0.62; CI% 95: 0.4-0.98) significantly affected OS. For pts who underwent an HSCT, the phase of the disease at the time of transplant was the most important factor affecting OS. *Conclusions*. By decreasing the length of the search (waiting for more than 3 months increased the probability of finding a donor only by 10%, while half of the pts relapsed), the risk of relapse can be reduced, increasing the possibility of performing a transplant. The possibility of addressing simultaneously the search for a VD and a CB allows to

increase the probability of carrying out a transplant prior to the median time of relapse. During the search of a donor for pts with HR ALL, the major strategic factor should be "the time" of the transplant, rather than the type of the transplant; based on this strategy, the possibility of performing an haploidentical transplant must be considered.

0722

SINGLE CENTER COMPARATIVE STUDY OF UNRELATED UMBILICAL CORD BLOOD TRANSPLANTATION VERSUS HLA MATCHED FAMILY DONOR TRANSPLANTATION IN ADULTS WITH ACUTE LEUKEMIA AND HIGH RISK MYELODISPLASTIC SYNDROME

A. de Laiglesia, I. Vicuña, A. Sebrango, G. Bautista, C. Regidor, R. Forés, E. Ojeda, J.A. García-Marco, S. Gil, I. Krsnik, B. Navarro, I. Sanjuan, J.R. Cabrera, M.N. Fernández

Hospital Universitario Puerta de Hierro, MADRID, Spain

Background. Allogenic cord blood transplantation (CBT) is usually considered as a secondary option for adult patients with acute leukemia, being the prioritary option a peripheral blood stem cell transplantation from HLA matched related donor (PBSCT). *Aims*. To show that cord blood can be a valid source of hematopoietic stem cells for adults with hematologic malignancies, with, at least, similar outcomes than PBSCT. *Methods*. We here present a retrospective study comparing outcomes of CBT done with our method of co-infusion of third party donor (TPD)-derived peripheral blood mobilized hematopoietic stem cells (MHSC), and outcomes of peripheral blood stem cell transplantation from HLA-matched related donors (PBSCT). 88 transplantations (in 79 patients) realized in our center between March 1999 and February 2008 have been included. All the patients undergoing CBT received a myeloablative conditionning regimen with reduced extra-hematologic toxicity. They were made with cord-blood units having 0-3 HLA missmatches and relatively low cell number: Total nucleated cell count after decongelation 1.14-4.57×10^7/Kg (median 2.39×10^7/kg) and $CD34^+$ cells precryopreservation 0.035-0.37×10^6/Kg (median 0.11×10^6/kg). All patients undergoing PBSCT received a sub-myeloablative conditionning regimen. *Results*. Medians and ranges of survival observed for both groups were similar, and Kaplan-Meier analysis determines a five-year overall survival slightly superior (0.53 vs. 0.41) for CBT (no statistical significance). In the cases of PBSCT, five-year OS is similar regardless of the diagnosis, with a slightly better OS for the patients with MDS diagnosis. In the cases of CBT there were no statistically significative differences in the OS depending on the diagnosis. Our study included comparative analysis of times from diagnosis to transplantation, disease status at transplantation (disadvantageous for CBT), as well as engraftment data, post-transplantation morbility (infectious complications, GVHD) and causes of death (data not shown). *Conclusions*. Our data are demonstrative of the safety and effectiveness of CBT as compared to PBSCT in adults with acute leukemia or high risk myelodisplasia. Thus, CBT must be considered as a primary unrelated stem cell source for these patients.

0723

SECOND ALLOGENEIC STEM CELL TRANSPLANTATION AS SALVAGE TREATMENT IN RELAPSED HAEMATOLOGICAL MALIGNANCIES: FEASIBILITY AND OUTCOME IN 26 PATIENTS

M.T. Lupo Stanghellini, A.A. Assanelli, R. Crocchiolo, D. Clerici, M. Tassara, V. Calbi, M. Bernardi, M. Marcatti, C. Corti, M.G. Carrabba, F. Lunghi, E. Guggiari, L. Camba, C. Bonini, J. Peccatori, F. Ciceri

San Raffaele Scientific Institute, MILAN, Italy

Background. Allogeneic hematopoietic stem cell transplantation (allo-SCT) provides for many patients (pts) with high risk acute leukaemia the best chance for long-term survival. Beside the classical matched related donors, a considerable amount of information about the use of unrelated volunteer donors (VUD), family mismatched donors (HAPLO) and unrelated umbilical cord blood (UCB) has recently become available. Instead of the deep effort in exploitation of allo-SCT, still remain a significant incidence of disease relapse. Often such pts still present with good general condition thanks to reduced toxicities conditioning regimens and better supportive therapy. In selected cases a viable options is represented by the possibility of a second allo-SCT, often an haploidentical one, in order to exploit the maximum graft-versus-leukaemia (GVL) effect through the haplotype mismatch. *Aims of study.* We report the retrospective analysis of outcome of 2nd allo-SCT at our Institution in the last 4 years. *Patients and Methods.* Between August-2004 and January-2009 26 pts -median age 45 years, range (r) 27-66, 9 male- received at our Institution a 2nd allo-SCT due to relapse after a previous one. Diagnoses were AML (n=21), ALL (n=3), CML (n=1) and multiple myeloma (n=1). First donor was an HLA identical sibling in 10 cases, an HAPLO in 11, a VUD in 4, a UCB in 1. Eleven pts were in complete remission (CR) at 1st transplant. Fifteen pts received a treosulfan based conditioning regimen. Median time from 1st allo-SCT to relapse was 153-days (r29-1174), median time from 1st to 2nd allo-SCT was 213-days (r53-1220), median time from relapse to 2nd allo-SCT was 47-days (r10-572). Thirteen pts received a 2nd allo-SCT from the same donor, 13 from an different one (all HAPLO); second donor was a VUD in 1 case, an HLA identical sibling in 5, an HAPLO in 20. Only 5/26 were in CR at 2nd allo-SCT. Eighteen pts received a treosulfan based conditioning regimen. The CMV host/donor serostatus was: +/+ 20, ±5, -/+1. *Results*. Engraftment was evaluable in 22pts, median time to neutrophils >500/ucl 17-days (r6-33) and to platelets >20.000/ucl 21-days (r10-39). Fourteen pts presented acute GVHD (grade I 1 pt, grade II 6, grade III 4, grade IV 3), 1 out of the 13 evaluable pts presented chronic GVHD. Overall there were 17 (65%) deaths, 8 caused by disease progression or relapse, 9 by infection (6), acute GVHD grade IV (2) and III (1). Of 22 evaluable pts 19 achieved CR, and currently 9 are alive and in CR (7/9 after a 2nd HAPLO). The median follow-up for pts alive is 234-days (range 28-687). At 1-year, the probability (95% confidence interval) of disease free survival is 25 (3-47)%, the non-relapse mortality is 44 (16-72)% and the overall survival is 34 (10-58)%. *Conclusions*. Second allo-SCT represents an effective therapeutic option for pts relapsed after a 1st allo-SCT. HAPLO will be a valid choice to better exploit GVL effect. A deeply evaluation of the state of the art and effectiveness of HAPLO as 2nd allo-SCT is now ongoing within EBMT Acute Leukaemia Working Party.

0724

OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN 30 ACUTE MYELOID LEUKEMIA PATIENTS AGED 60 YEARS OR OLDER

A. Candoni, E. Simeone, A. Sperotto, M. Tiribelli, A. Geromin, M. Cerno, F. Patriarca, M. Battista, R. Fanin

Division of Hematology, UDINE, Italy

Introduction. Older age is considered one of the most important adverse prognostic factors in Acute Myeloid Leukemia (AML). Allogeneic stem cell transplantation (allo-SCT) is one of the most recommended approach in poor prognosis AML but there are limited data about this procedure in elderly AML patients (pts). We report our experience about the feasibility and outcome of allo-SCT in AML pts aged 60 years or older. *Patients and results*. Between 2003 and 2008, 30 consecutive AML pts aged 60 years or older (median age 63; range 60-70 years) received an allo-SCT at our Center, and all of them were high risk at diagnosis. The median time from diagnosis to transplant was 7 months. At the time of transplant 12/30 cases (40%) had an advanced disease (relapsed or refractory), while 18/30 (60%) were in complete remission (CR). The hematopoietic cell transplantation comorbidity index (HCT-CI) was two or less in 12/30 cases (40%) and three or more in 18/30 cases (60%).

Donor were MUD in 12 (40%) and sibling in 18 (60%) of 30 allo-SCT. Twenty-six of 30 pts (87%) received a reduced intensity conditioning regimen (RIC). Conditioning regimen consisted of Thyotepa + Cyclophosphamide±ATG 14/30(46%), Fludarabine-based RIC 10/30(33%), Busulfan + Cyclophosphamide ± ATG 4/30(14%) and other regimens 2/30(7%). All patients engrafted. Acute GvHD was observed in 17/30 cases (57%) with 13 having grades I-II and 4 having grades III-IV. Data on chronic GvHD was available for 22/30 pts (73%); of those 3/22 (14%) developed extensive chronic GvHD. One year Nonrelapse mortality (NRM) rate was 20% (6/30 cases). At the time of analysis, after a median follow-up of 16 months (range 1-64), 17/30 pts (57%) were alive and in CR while 13/30 (43%) have died (leukemia refractory or relapse 7/13 and NRM 6/13). One year probability of Overall Survival (OS) of the whole population was 57%. The OS did not differ between unrelated and related donors. The pts transplanted in CR and those with a HCT-CI < 3 have a significantly better OS compared to those with refractory or relapsed AML at transplant or with HCT-CI > 3 (log rank=0,04 and 0,01, respectively). CONCLUSIONS. Our data indicate that allo-SCT is a feasible treatment option in selected poor prognosis AML pts older than 60 years. In this experience NRM rate is only 20% and OS rate (1 year 57%) is promising taking into account the poorer outcome of elderly AML pts. Favourable outcome was observed in cases with a low HCT-CI (2 or less) and in those transplanted while in CR. For older AML patients lacking a suitable family donor MUD can provide a suitable alternative option.

TANDEM AUTO-SCT AND REDUCED-INTENSITY CONDITIONING (RIC) ALLO-SCT FOR RELAPSED OR TRANSFORMED AGGRESSIVE B CELL NON-HODGKIN'S LYMPHOMA (NHL)

M.D. Clavert

Hotel Dieu CHU, NANTES, France

Background. Allogeneic stem cell transplantation (allo-SCT) can provide a potentially curative graft-versus-lymphoma effect. However, such benefit is usually offset by a significant incidence of non-relapse mortality (NRM), especially in advanced and/or elderly patients. With this background, RIC regimens for allo-SCT have arisen as an attractive modality in patients with NHL, but the role of RIC allo-SCT in aggressive B cell NHL remains a matter of debate because of a higher incidence of disease relapse/progression. *Aims*. This single centre study aimed to assess the potential benefit of a tandem auto-allo-SCT approach as salvage therapy in 23 consecutive patients with relapsed or transformed aggressive B cell NHL. *Methods*. Median age at time of allo-SCT was 55 (range, 44-65) y. NHL histology at diagnosis included 5 cases (22%) of DLBCL, 12 (52%) follicular NLH, and 6 (26%) other subtypes. Aggressive transformation was documented in 18 patients (78%; 26% of primary and 52% of secondary transformation). Patients received a median of 2 (range, 1-4) lines of previous chemotherapy regimens prior to allo-SCT, and all patients (n=21; 91%) but 2, could actually proceed to auto-SCT prior to allo-SCT. At time of allo-SCT, 9 patients (39%) were in first CR, 6 patients (26%) were beyond first CR and 8 (35%) in PR. Median times between diagnosis and allo-SCT and auto-SCT and allo-SCT were 25 (range, 7-131) and 4 (range, 2.4-71) m. respectively. The RIC regimen consisted of Fludarabine, Busulfan and ATG in 20 patients (87%) and Fludarabine and low dose TBI (2 Gy.) in 3 patients (13%). *Results*. After RIC allo-SCT, engraftment was achieved in all patients. With a median follow-up of 38 (range, 3-86) m., 13 patients had grade 2-4 acute GVHD (56%) and 10 patients had extensive chronic GVHD (48%). Overall, 9 patients died (3 from progression, 2 from acute GVHD, 2 multiorgan failures, and 2 other causes). The incidence of NRM was 26%, (95%CI, 8-44%). At last follow-up, 13 patients (57%) were in sustained CR. The Kaplan-Meier estimate of progression-free and overall survival rates were 51% and 64% respectively at 4 years. *Conclusions*. We conclude that a tandem auto-RIC allo-SCT approach is a potentially efficient salvage therapy for relapsed or transformed aggressive B cell NHL, with a relatively low toxicity, likely overcoming the poor prognosis usually associated with this phenotype. These results can also likely be improved with strategies aiming to enhance the GVL effect (e.g. inclusion of Rituximab as part of the RIC regimen, and/or as maintenance therapy).

0726

COMPLETE HEMATOLOGIC REMISSION BUT NOT MOLECULAR REMISSION IS ASSOCIATED WITH PROLONGED SURVIVAL IN PATIENTS WITH ACUTE LEUKEMIA BEFORE HEMATOPOIETIC STEM CELL TRANSPLANTATION

F. Folber, M. Doubek, I. Palasek, D. Dvorakova, J. Mayer

University Hospital Brno, BRNO, Czech Republic

Background. In patients with acute myeloid (AML) or acute lymphoblastic leukemia (ALL), many trials proved that low or negative minimal residual disease (MRD) during consolidation treatment or after/before hematopoietic stem cell transplantation (SCT) is associated with prolonged survival. *Aims*. In this retrospective analysis we searched for significant risk factors including MRD level affecting progression-free (PFS) and overall survival (OS) in patients with AML and ALL before SCT. *Methods*. A total number of 34 hematopoietic stem cell transplantations performed in years 2003 to 2008 in 30 patients with a median age of 39.4 years (range: 18.3 to 60.8) were included. A molecular marker for MRD monitoring was available in all patients; fusion genes (NPM1, MLL, AML1/ETO, CBFβ/MYH, or CEBPA) in AML and bcr/abl or TCR/IgH gene rearrangements in ALL. The data were analyzed for complete hematologic remission (CR) and molecular remission rate, relapse rate, time to molecular and hematologic relapse, causes of death and risk factors affecting survival. *Results*. There were 29 allogeneic (9 sibling, 10 matched unrelated and 10 partially matched or mismatched unrelated donors) and 5 autologous SCT performed in 23 AML and 11 ALL patients. Myeloablative conditioning regimen was used in 20 (59%) cases, reduced intensity conditioning in 14 (41%) cases. Before SCT, 23 (68%) patients were in CR and 11 (32%) in molecular remission. After SCT, 28 (82%) patients achieved CR and 26 of 27 (96%) evaluable patients achieved molecular remission. Molecular relapse occurred in 15 (58%) cases within a median of 167 days (range: 56 to 490). Hematologic relapse occurred in 13 (46%) cases within a median of 212 days (range: 85 to 1128), while in all but one cases it was preceded by molecular relapse. Median PFS and OS of the whole set were 9.8 and 26.8 months, respectively. Out of all risk factors analyzed, only CR before SCT was associated with significantly longer PFS and OS (p=0.004 and p=0.005, respectively). Molecular remission before SCT had neither influence on PFS nor OS (p=0.30 and p=0.26, respectively). At the end of the follow-up period with a median of 9.9 months (range: 0.3 to 47.9) there were 16 (47%) patients alive in complete remission, 5 (15%) relapsed and 13 (38%) dead, with multiple organ failure, infection and disease progression being the most common causes of death. *Summary and Conclusions*. According to our analysis, in patients with acute leukemia before hematopoietic stem cell transplantation, complete hematologic remission but not molecular remission is associated with prolonged progression-free and overall survival.

SMALL HUMAN ,-DEFENSIN-3 DERIVED PEPTIDE INDUCES RAPID AND PREFERENTIAL MOBILIZATION OF MOUSE HEMATOPOIETIC PROGENITOR CELLS VIA SDF-1 SECRETION

A. Kalinkovich, A. Schajnovitz, S. Shivtiel, A. Ludin, O. Kollet, M. Fridkin, T. Lapidot

Weizmann Insitiute of Science, REHOVOT, Israel

Mobilization of stem cells from the bone marrow (BM) to the circulation by repeated G-CSF stimulations is widely used for clinical transplantation protocols. The chemokine stromal-derived factor-1a (SDF-1, CXCL12), expressed and secreted by BM stromal cells, and its major receptor CXCR4, expressed both by the stromal cells and hematopoietic stem/progenitor cells, are key players in G-CSF-induced mobilization (Petit *et al.*, Nat Immunol, 2002). The CXCR4 antagonist AMD3100 induces fast mobilization of hematopoietic stem/progenitor cells. Preliminary results from our studies revealed that rapid mobilization of immature murine progenitor cells (but not mature leukocytes) by AMD3100 is regulated by accelerated release of SDF-1 to the circulation from BM stromal cells in a CXCR4-dependent manner (Dar *et al.*, ASH abst., 2006). In addition, it has been found that human ß-defensin-3 (HBD3), a 45-amino acid peptide, is able to internalize CXCR4 and decrease SDF-1-induced migration of human T cells (Feng *et al.*, JI, 2006). ß-defensins are cysteine containing antimicrobial peptides that are major components of the innate immune system. We synthesized a short, 10-amino acid peptide comprising the C-terminal part of HBD3, named TL-1, which is not toxic. Unexpectedly, upon a single s.c. injection to C57BL/6 mice, TL-1 efficiently mobilized hematopoietic progenitor cells (but not mature leukocytes) within 1-2 hrs post injection in a dose dependent manner. Importantly, TL-1 synergized with G-CSF and with AMD3100 in their capability to mobilize both mature leukocytes and immature progenitor cells. In addition, injection of TL-1 was accompanied by a significant elevation in plasma SDF-1 levels, which is important for rapid progenitor cell mobilization. As expected, *in vitro* TL-1 treatment was accompanied by specific down-regulation of membrane CXCR4 expression, as well as by inhibition of SDF-1-induced (but not spontaneous) leukocyte migration in a dose and time dependent manner. The strongest effect (90% inhibition at 0.5-1.0 mM) was found upon testing immature $CD34^+$ enriched human cord blood cells. *In vitro* studies with isolated BM stromal cell cultures revealed that TL-1 directly targets the BM stroma, inducing them to release SDF-1 from intracellular storages to the culture medium, independently from *de novo* protein synthesis. In addition, TL-1 directly induces cultured BM stromal cells to release metalloproteinase-2. Altogether, these findings show that TL-1 is a potential, non-toxic small peptide, capable of preferential mobilization of hematopoietic progenitor cells. The reasons for preferential progenitor cell mobilization by TL-1 and mechanistic insights, in addition to SDF-1 release, as well as the physiological roles of ß-defensins with regards to hematopoietic progenitor cell motility are currently investigated.

HEMATOPOIETIC CELLS RECEIVE A STRONG IMPRINTING WHEN PASSING THROUGH BONE MARROW: RESULTS OF A COMPARISON BETWEEN INTRABONE VERSUS INTRAVENOUS TRANSPLANTATION

M. Massello,[1] F. Frassoni,[2] V. Pinto,[2] C. Marini,[3] S. Morbelli,[1] G.L. Ubezio,[2] A. Ibatici,[2] R. Varaldo,[2] G. Curti,[1] M. Podesta,[2] F. Frassoni,[2] G.M. Sambuceti[1]

[1]Nuclear Medicine University of Genova, GENOVA; [2]Centro Cellule Staminali e Terapia Cellulare, GENOVA; [3]CNR institute of bioimages and molecular physiology Pisa, PISA, Italy

Background. Intravenous infusion (IV) is the method conventionally used to transplant hematopoietic stem cells (HSC) despite the relatively low seeding efficiency. To overcome this problem, intrabone transplant (IBT) of HSC has been introduced to improve HSC homing and engraftment and to reduce the incidence of graft versus host disease. However, the mechanisms underlying the possible beneficial effect of IB are largely unknown. *Aims*. To investigate whether the improved results of IBT derive from an increased local engraftment or from an improved kinetic behavior of HSC. *Materials and Methods*. Thirty-three male Sprague Dawley rats, were included in the study. CD90 positive cells were selected by FACS/Sorting. Labeling was performed by incubating 2×10^6 cultured cells with 37 MBq of TC-99m exametazime (HMPAO, Ceretec, GE Healthcare) according to a procedure validated in our lab that provides a labelling yield (defined as HSC counts / total dose counts) ranging 10-13%, by a remarkable stability (up to 98% of bound activity still present at 24 hours) and by the lack of effect on HSC survival. Labelled CD90+cells were infused via tail vein (IV, n=7) or directly into the tibia (n=7) of anesthetized rats positioned over the head of a large field gamma-camera. Regions of interest (ROIs) were positioned on lungs, heart, liver, spleen and forearms to plot time activity curves of ROIs counting rate (counts per second) after decay correction. At the end of the study, animals were sacrificed and lungs, spleen, liver and axillary/inguinal lymphonodes were harvested. Organ radioactivity was expressed as [%] of injected dose, to estimate [%] of injected cells present in each organ. *Results*. Fifteen seconds after IBT, >90-95% of cells escaped from the tibia. Despite this the short permanence in the bone marrow, these cells showed a remarkably different behaviour with respect to the same HSC injected intravenously: faster blood clearance (heart activity at 40 min 2±0.7% vs. 5±1.5% of the dose, $p<0.01$), lower lung sequestration (5.22±0.5% vs. 13±2.5%, $p<0.01$) and lower lymphonode uptake (0.01±.005% vs .04±.008% of the dose, $p<0.01$). Logan plot analysis - performed to define the ratio between cells delivered and cells released by the forelimb - documented an increased HSC uptake in the bone marrow after IBT with respect to IV (ratio between trapped and released cells 2.2±.8 vs. 1±0.2, respectively $p<0.01$). By contrast, no differences were observed in the time activity curves in the liver and in the spleen. The preconditioning of rats with total body irradiation (TBI) selectively decreased cell recruitment of injected cells in the forelimb after ITB (N=7) but not after IV (n=7). On the contrary, TBI aspecifically increased lung sequestration of donor HSC both after intravenous and intrabone administration. Kinetics of hepatoma line cells injected intrabone (n=5) displayed a virtually absent uptake in the forelimb and a very high sequestration in the lung (38.63±4.94%). *Conclusions*. Despite its extremely short duration, the contact with the bone marrow environment changes HC behaviour and this experience modifies the kinetic features of these cells by enhancing their migration in far bone marrow sites.

HUMAN MESENCHYMAL STEM CELLS CAN AMELIORATE HEMATOPOIETIC FUNCTION AFTER CHEMO-RADIOTHERAPY INDUCED STROMAL DAMAGE

S.C. Carrancio, F.M. Sanchez-Gujo, N. Lopez-Holgado, P. Hernandez-Campo, S. Olave, B. Blanco, L.I. Sanchez-Abarca, O. Lopez, M. Diez-Campelo, J.A. Perez-Simon, J.F. San Miguel, M.C. Cañizo

Hospital Universitario de Salamanca, SALAMANCA, Spain

Background. It has been shown that bone marrow (BM) stroma is damaged after allogeneic bone marrow (BM) stem cell transplantation and previous data from our group confirmed that although peripheral blood cell counts are recovered, BM hematopoietic function, assessed *in vitro*, is impaired. Mesenchymal stem cells (MSC), an important component of BM stroma, support and regulate hematopoiesis. *Aims*. We hypothesized in the context of allogeneic transplantation that if recipient MSC are altered, the addition of normal MSC may result in a better hematopoiesis in both, *in vitro* and *in vivo* models. *Methods*. For the *in vitro* experiments, stromal damage was induced by adding etoposide (50 µM) for 48 hours on human MSC (hMSC) confluent layers. Hematopoietic stem cell ($CD34^+$) with or without MSC were added to the layers. To be used as controls, both $CD34^+$ cells with or without MSC were plated on non etoposide-treated layers. Cultures were maintained for 5 weeks in all cases. Number of CFU-GM, adipocytes and cobblestone area were weekly calculated. For the *in vivo* assays human $CD34^+$ cells were administrated either by intravenous (IV) or intrafemoral (IF) injection in NOD/SCID mice after 300cGy total body irradiation. In order to see whether or not MSC favour engraftment both IV or IF $CD34^+$ cell-treated mice received or not IF MSC. Human BM cell engraftment was measured by flow cytometry using anti-human CD45, CD13 and CD19 antibodies at 3 and 6 weeks after transplantation. To test human chimerism at the stromal level in the mice transplanted with MSC, BM mononuclear cells from both femurs (the injected and the contralateral) were obtained and MSC were *in vitro* expanded following standard methods until 3rd passage, when FISH for human X,Y chromosomes was performed. *Results*. Our *in vitro* data showed that the number of cobblestone areas and adipocytes were significantly lower ($p<0.05$) in etoposide-treated layers as compared to non damaged cultures. After 5 weeks, the median number of CFU-GM was 720 (range: 50-907) in treated stromas versus 1727 (range: 645-5005) in normal ones ($p<0.05$). Nevertheless, when normal MSC were added to the damaged layers all the

above mentioned parameters returned to normal ranges. Regarding the *in vivo* engraftment assay results are shown in Table 1. At 3 weeks, the number of human CD45+ cells in BM was significantly higher in mice co-transplanted with human MSC. At 6 weeks, human chimerism was higher when IB infusion was performed independently of the addition of MSC. Regarding stromal chimerism, hMSC engraftment was detected in those femurs where human MSC were previously injected but not in the contralateral ones. *Conclusions*. Our data show that MSC can favour the hematopoietic function after chemo-radiotherapy stromal damage. However in the longer follow-up, IB injection enhanced hematopoietic chimerism.

CXCL12 RS1801157 POLIMORPHISM IS ASSOCIATED WITH DECREASED MRNA CXCL12 EXPRESSION AND HIGHER HEMOPOIETIC PROGENITOR CELL MOBILIZATION

B. Martín Antonio, M. Carmona, P. Trujillo, J. Alcántara, A. Freire, J. Falantes, I. Espigado, A. Urbano Ispizua

Hospital Universitario Virgen del Rocio, SEVILLE, Spain

Background. Interaction between CXCL12 and its receptor CXCR4 is critical for hemopoietic progenitor cell (HPC) homing in bone marrow. Administration of G-CSF leads to degradation of CXCL12 and mobilization of HPC to peripheral blood. This is the basis of peripheral blood collection of HPC for hemopoietic transplantation. *Aims*. To evaluate a possible association between polymorphisms in CXCL12 and in other genes involved in homing and migration of HPC with the degree of CD34+ cell mobilization after G-CSF administration. *Methods*. Twenty-seven SNPs described in 15 genes (CXCL12, CXCR4, VCAM-1, VLA-4, G-CSF, CSF3R, CD34, ADRB3, CXCL2, CXCR2, CD44, Kit ligand, c-Kit, MMP-9, CTSG) were analyzed by allelic discrimination PCR in 112 healthy donors receiving G-CSF (filgrastim; 10 µg/kg; 5 days) in a single institution. Univariate and multivariate multiple regression analysis were performed to assess potential association between SNPs and the end points of the study. mRNA was measured by real-time quantitative PCR for those genes with SNPs found to influence CD34+ cell count at fifth day.

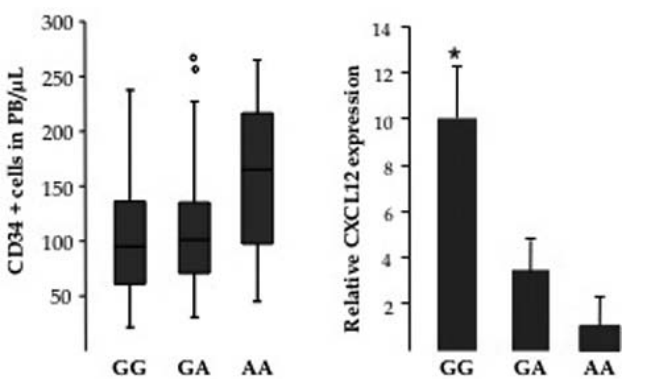

Figure 1.

Results. CD34+ cells/µL of peripheral blood after 5 days of G-CSF was of median 99 (21-267), and the total number of CD34+ cells collected with the first leukapheresis was of median 478x106 (83-2006). AA genotype corresponding to the homozygous less frequent variant at rs1801157 in CXCL12 was associated with a higher count of CD34+ cells in peripheral blood (median and range, AA 165, 44-265 vs. GA/GG 99, 21-267; p=0.018). Of note, AA genotype showed significantly lower mRNA CXCL12 level than GA and GG genotype, with a 3.5 fold and 10 fold lower expression, respectively (p<0.0001; Figure). CC genotype at rs3917924 in CSF3R corresponding to the homozygous most frequent variant and CC genotype at rs1041163 in VCAM1 corresponding to the homozygous less frequent variant were associated with a lower CD34+ cell count (median and range, CC 81, 21-176 vs CT/TT 106, 31-267; p=0.002 and CC 74, 53-141 vs TC/TT 102, 21-267; p=0.018, respectively). No differences were found in mRNA levels of CSF3R and VCAM1 classifying the groups by the pattern of SNPs. *Conclusions*. Genetic individual variability in CXCL12, VCAM1, and CSF3R seems to influence HPC mobilization. CXCL12 variant AA at rs18001157 was associated to lower mRNA levels of CXCL12, which may explain the higher CD34+ cell mobilization of this group of individuals. These findings might be useful in planning mobilizing strategies.

REPORT OF 15-YEAR EXPERIENCE OF THE MILANO CORD BLOOD BANK: CLINICAL OUTCOMES OF SINGLE UNRELATED CORD BLOOD TRANSPLANTS

A. Ruggeri,[1] L. Lecchi,[2] I. Ionescu,[1] D. Purtill,[1] K. Boudjedir,[1] E. Gluckman,[1] V. Rocha,[1] P. Rebulla[2]

[1]Eurocord-Saint Louis, PARIS, France; [2]Centro di Medicina Trasfusionale, Terapia Cellulare e Criobiologia, IRCCS, MILANO, Italy

Umbilical cord blood (UCB) is a useful alternative hematopoietic stem cell source for patients lacking a suitable donor. More than 400000 UCB units are stored in public cord blood banks and over 20000 procedures have been already performed worldwide. CB banks support this increasing clinical activity and aim to store good quality units and to maintain an inventory of CB units (CBU) with a large HLA diversity and adequate cell dose. Netcord works in collaboration with Eurocord to ensure good practice in CBU storage and to establish international standards and accreditation processes (eg Netcord-FACT). Eurocord provides annual analysis of biological and clinical outcomes of units provided by cord blood banks for accreditation requirements. We report the annual Eurocord analysis of the Milano cord blood bank (MICBB) activity as of December 2008. From 1994 to 2008, 379 CBU shipped by MICBB were reported to Eurocord. The units were used for 362 UCB transplants (UCBT) including 350 unrelated UCBT, 11 related transplants and one autologous transplant. Five CBU were not used (3 for disease relapse, 2 for unknown reasons). The 350 unrelated transplants included: 217 single unmanipulated UCBT (191 first transplant), 44 double UCBT, 2 single expanded UCBT, 2 single UCBT + haplo-identical PBSCT, 84 preliminary UCBT, 1 missing data. The CBU were issued to 24 countries and 122 centers (84 EBMT, 38 non EBMT). Forty-three percent of the units collected underwent volume reduction by semiautomated procedure. All units were cryopreserved in DMSO. At collection median volume was 117 mL (25-276); median TNC, CFU-GM and CD34+ counts were 16×10^8 (2.3-40.3), 6.44×10^5 (0.7-46) and 4×10^6 (1-19.8), respectively for units with available data. Among 191 first single unrelated transplants, analysis of outcomes was performed on 186 with available follow-up data. One-hundred-sixty hematological malignancies (acute leukemia=106, MDS=20, lymphoproliferative disorders=13, CML=11, histiocytosis=9, MM=1) and 26 non-malignant diseases (BMFS=9, metabolic disorders=9, immunodeficiency=8) were reported. Median age at transplant was 8.3y (0.2-65), (126 children, 60 adults) and median weight 27Kg (4-110). Nine percent of CBU were 6/6 matched to recipients, 53% of units had 1 HLA mismatch and 38% had 2 or 3 HLA disparities. Conditioning regimen was myeloablative in 86% of transplants. Graft-versus-host disease prophylaxis consisted of cyclosporine and corticosteroids in 60% of patients. Eighty percent of patients received ATG/ALG before day0. Median infused TNC dose was 4.02×10^7 TNC/Kg (1-25) and 1.70×10^5 CD34+cells/Kg (0.1-25). Median cell loss after thawing was 17%. Neither microbial contamination nor early post-infusion adverse reactions were reported. Median follow up was 35.2 m (2-122). Cumulative incidence (CI) of 60 day-neutrophil recovery (>500/mm^3), 180 day-platelet recovery (>20000/mm^3), 100 day-acute GVHD, 100 day-TRM were 81±3%, 67±4%, 34±3%, and 25±5%, respectively. Estimated overall survival at 36 months was 38±3%, with better survival for non-malignant diseases

(58±8% vs 34±4%) and for children (45±4% vs. 20±5%). Cord blood units provided by MICBB were of excellent quality according to Netcord-FACT standards guidelines and allow a high engraftment rate comparable with other reports on UCBT outcomes. Analyses such these are important in maintaining continuous high quality in UCBT.

0732

IRON OVERLOAD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) EVALUATED BY SUPERCONDUCTING QUANTUM INTERFERENCE DEVICE (SQUID)

A. Busca,[1] M. Falda,[1] P. Manzini,[2] S. D'Antico,[2] F. Longo,[3] F. Locatelli,[1] A. Chiappella,[1] S. D'Ardia,[1] R. Calabrese,[3] A. Piga[3]

[1]Hematology 2, AOU San Giovanni Battista, TURIN; [2]Transfusional Medicine Unit, AOU San Giovanni Battista, TURIN; [3]Biological and clinical sciences, Pediatric Dpt, University of Turin, ORBASSANO, Italy

Background. Iron overload (IO) is an adverse prognostic factor in patients who undergo allogeneic HSCT for thalassemia and appears to play a similar role in patients with other hematological disorders. *Aims*. to quantify IO by SQUID after HSCT and evaluate the impact on hepatic function and infections. Additionally, the feasibility of iron-depletion has been investigated. *Methods*. Between December 2005 and December 2007, 102 consecutive patients who received an allogeneic HSCT have been analyzed. Clinical characteristics were: median age 47 years (21-67), diagnosis of acute leukemia/MDS 61%, lymphomas 25% and others hematological malignancies in 14%. Assessment of IO after HSCT included serum ferritin; in those with hyperferritinemia (> 1000 ng/mL), liver iron concentration (LIC) was evaluated by SQUID magnetic susceptometry. Iron removal therapy was offered to patients with moderate (LIC 1000-2000 microg/gww) or severe (LIC >2000 microg/gww) IO. *Results*. Fifty-seven patients had a ferritin level <1000 ng/mL and the median time from HSCT to ferritin assessment was 1006 days, significantly different from the median time of 183 days of the 45 patients who had a ferritin level >1000 ng/mL. LIC evaluated by SQUID was available for 42/45 patients with elevated ferritin values. Overall, 29 patients had moderate to severe IO: median LIC values were 1493 microg/gww (range 1030-3253); 5 patients had normal LIC values (LIC<400 microg/gww) and 8 had LIC values between 400-1000 microg/gww. Potential confounding factors (hepatitis, cronicGVHD, disease status, timing of ferritin assessment) were tested in a multivariate analysis showing a significant correlation between ferritin levels >1000 ng/mL and the occurrence of liver dysfunction defined by the presence of at least one abnormal liver function test (LFT) on two or more occasions (OR 6.8; 95%CI 2.2-20.6). In addition, the rate of proven/probable invasive fungal disease was significantly higher among patients with hyperferritinemia as compared to patients with normal ferritin levels (13% vs 0%; p=0.006). Nineteen of the 24 patients considered eligible to iron depletion underwent regular phlebotomy: 13 completed the program after a median time of 10 months (3-13), reaching the target of ferritin <500 ng/mL; for 1 patient the program is still ongoing; 5 patients discontinued phlebotomy (relapse n=2; hypotension, n=1; anemia, n=1; fatal GVHD, n=1). Eight patients were revaluated by SQUID at the end of iron depletion program: LIC showed a significant reduction (median 1368 microg/gww to 606 microg/gww; p=0.005) consistent with the decrease of serum ferritin levels; one patient did not show a remarkable reduction of LIC despite serum ferritin normalization. Four of the 5 patients ineligible to phlebotomy were successfully treated with deferasirox and one with deferoxamine. *Conclusions*. The measurement of LIC obtained by SQUID documented the presence of moderate/severe IO in 69% of the patients with high ferritin levels. Our data showed that in HSCT recipients, high ferritin level is an independent risk factor for the occurrence of abnormal LFTs and IO may be considered a potential risk factor for fungal infections. A phlebotomy program resulted feasible in 58% of the patients who might benefit from a procedure of iron depletion.

FREEZE-DRYING OF HUMAN UMBILICAL CORD BLOOD MONONUCLEAR CELLS

Y. Natan,[1] A. Nagler,[2] M. Binyamini,[1] R. Mayerov,[2] A. Arav[1]

[1]Core Dynamics, NESS ZIONA; [2]Chaim Sheba Medical Center, TEL HASHOMER, Israel

Background. Today long term storage of human umbilical cord blood (HUCB) units is mainly done by freezing the mononuclear cell fraction with DMSO which results in 20-30% cell loss upon thawing. The units are usually stored in liquid nitrogen tanks. Long term storage in liquid nitrogen is expensive, requires means to avoid transient warming events and there is a risk (although small) of cross contamination between stored samples. Freeze-drying may be a superior alternative to avoid these problems. Freeze-drying is a process in which ice crystals sublimate (form vapor without going through the liquid phase) resulting in a dry, stable and low weight sample. We have developed a freezing apparatus, which is based on directional solidification technology, named the Multi Thermal Gradient (MTG) device. This device enables the precise control of ice crystals morphology during the freezing process, thus making the use of intracellular cryoprotectant agents redundant. *Methods*. The study was performed on mononuclear cells derived from HUCB. A freezing solution named IMT-2 was added prior to freezing. Freezing was done using the MTG-1314 freezing device. We tested the viability, number of $CD34^+$-presenting cells and ability of the rehydrated hematopoietic stem cells to differentiate into different blood cells in culture before freezing and after freeze thawing and freeze-drying. *Results*. The viability of the MNCs after freeze-drying and rehydration with pure water was 88%-91%. The total number of $CD34^+$-presenting cells and the number of colonies did not change significantly when evaluated before freezing, after freeze-thawing and after freeze-drying ($5.4\pm4.7\times10^4$, $3.49\pm6\times10^4$ and $6.31\pm12.27\times10^4$ cells, respectively, and 31±25.15, 47±45.8 and 23.44±13.3 colonies, respectively). *Summary*. In summary, we have developed a freeze-drying technique for maintaining the viability and functionality of cells. Using this technique hematopoietic stem cells have survived complete desiccation while maintaining their clonogenicity capabilities upon rehydration.

0734

IMPACT OF VITAMIN D RECEPTOR GENE POLYMORPHISMS ON CLINICAL OUTCOMES OF SIBLING HLA-MATCHED HEMATOPOIETIC STEM CELL TRANSPLANTATION

H.J. Cho,[1] J.H. Kim,[2] N. Kim,[2] E.K. Ra,[2] S.S. Yoon,[2] Y.C Hong,[2] H.K. Kim,[2] S.S. Park,[2] D.S. Lee,[2] S. Park,[2] M.H. Park,[2] B.K. Kim,[2] I. Kim[2]

[1]Seoul National University Hospital, SEOUL; [2]College of Medicine, Seoul National University, SEOUL, South-Korea

Background. Vitamin D is a main regulatory hormone of calcium metabolism and bone mineralization. Its immunoregulatory action has been investigated recently, and polymorphisms of the vitamin D receptor (VDR) gene has been associated with some diseases, such as immune dysfunction, infection and malignancy. We hypothesized that polymorphisms of VDR may affect the clinical outcome of allogeneic hematopoietic stem cell transplantation (HSCT). *Aims*. This study was conducted to determine whether genotypes or haplotypes of VDR were associated with post-transplant clinical outcomes. *Methods*. Three VDR polymorphisms (BsmI G>A, ApaI G>T and TaqI T>C) were genotyped in 152 patients and their donors who underwent sibling HLA-matched allogeneic HSCT in single institution between 1998 and 2005. The median age of recipients were 40 years (range, 16-70) and eighty-six patients (57%) were male. The most common diagnosis was acute myeloid leukemia (AML 51, ALL 21, CML 21, MDS 12, NHL 10, Others 37). Reduced intensity conditioning was performed in 82 patients (54%) and conventional conditioning in 70 patients. Frequency of infection and graft-versus-host disease (GVHD), overall survival (OS) and disease-free survival (DFS) were compared according to genotypes and haplotypes.

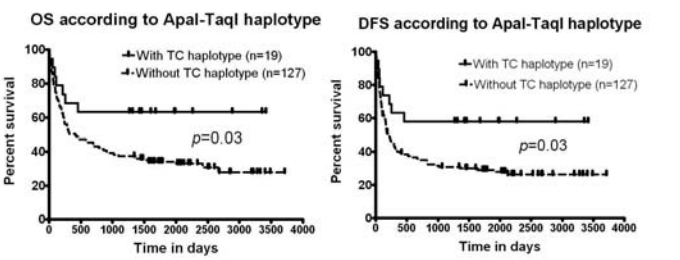

Figure 1.

Results. Patients with the ApaI TT genotype had less frequent infection and showed a tendency of less frequent acute GVHD than non-TT genotypes (p=0.01 and p=0.06, respectively). OS and DFS were longer for TT genotype (p=0.08 and p=0.045, respectively). For TaqI genotypes, there were no statistical difference in frequency of infection and acute GVHD (p=0.64 and p=0.30, respectively) but patients with the TC geno-

type showed longer OS and DFS than those with the TT genotype (p=0.03, both). These differences were not observed between BsmI GG/GA genotypes. In the ApaI-TaqI haplotype analysis, patients with the TC haplotype had significantly longer OS and DFS compared with those without the TC haplotype (p=0.03, both). In multivariable analysis to estimate the effects of VDR genotype or haplotype on survival, TaqI genotype and ApaI-TaqI haplotype of recipients were significant indicators of both OS and DFS. We found no associations between donor genotypes and clinical outcomes. *Conclusions*. Our results suggest that patient genotype and haplotype of VDR associate with clinical outcome of sibling HLA-matched HSCT. We need further studies to confirm these results in other populations and to reveal underlying mechanisms for these associations.

IMMUNOBIOLOGICAL EFFECTS OF NKT CELLS FROM ACUTE MYELOID LEUKEMIA PATIENTS IN A PRE-CLINICAL ANTI-LEUKEMIC TRIAL

H.J. Kim, J.B. Choi, J.H. Moon, T.H. Lee, H.S. Kang, W.S. Min

Catholic HSCT Center, SEOUL, South-Korea

Background. Recently, it was shown that natural killer T (NKT) cells play key roles in anti-tumor immune responses, and there is increasing evidence that NKT cells and NK-like T cells are involved in tumor resistance. However, their response to certain tumor cells and the molecules that are functionally critical are not known. *Aims*. In a new trial using an acute myeloid leukemia (AML)-specific animal model, we explored ways in which the anti-tumor activity of NKT and NK-like T cells could be used in cell therapy to suppress or even kill a patient's leukemia cells. *Methods*. First, we investigated the profiles of NK and NKT cells from both AML patients (n=46) and the HLA-matched normal donor population (n=20), using flow cytometry. We also used enzyme-linked immunosorbent assays (ELISA) to determine the expression of cytokines such as interferon-γ, interleukin (IL)-13, and IL-4 after stimulating peripheral blood mononuclear cell (PBMC) cultures with IL-2, IL-12, IL-18, and α-galactosylceramide, a CD1d-restricted NKT cell ligand. A cytotoxicity assay using the chromium release method was employed to examine the functional effects of defined NK and NKT cells against a patient's primary leukemic cells and leukemic cell lines. The NOD/SCID mice were transplanted with patient-derived leukemic cells at a dose of 2-106 bone marrow mononuclear cells (BMCs) and then infused with the same dose of either leukemic or normal PBMCs that had been cultured for 4 h with one of 4 cytokines at 1-week interval. The surviving mice were sacrificed and analyzed 8 to 24 weeks post-transplant; mice that died were analysed at the time of death. *Results*. The proportions of both $CD16^+CD3^-$ and $CD56^+CD3^-$ NK cells were lower in the AML group than in the control group, but the difference was not statistically significant. Based on a flow cytometric α-galactosylceramide-tetramer assay, the proportion of CD1d-restricted human NKT cells ranged from 0.2~0.4% of gated lympho-monocytic region in the AML group, compared with 0.2~0.7% in the normal controls. According to the cytotoxicity assay, the patient-derived and normal NK/NKT cells had similar cytotoxic activity at effector:target ratios of 1:20 to 1:40 against both primary leukemic cells and K562 cells. Of note, the CD56+CD1d-restricted cells in AML were more responsive to IL-12, IL-18, and α-galactosylceramide, whereas the CD16+CD1d-restricted cells were more responsive to IL-2. Of the 39 mice transplanted with cultured leukemic or normal PBMCs after exposure to each cytokine, only three mice were alive at 24 weeks. The other mice died beginning 10 days after transplant. Interestingly, after sacrifice, we found a much higher proportion (with 3.1~30.8% gated human $CD45^+$ bone marrow cells) of CD1d-restricted human NKT cells in the three mice serially transplanted with cultured leukemic and normal PBMCs in order, whereas splenic cells did not produce comparable results. *Conclusions*. These preliminary results suggest the high potency of autologous and allogeneic NKT cells specifically responsive to primary AML cells, as we had expected. We plan to develop a more practical AML-specific animal model for examining the clinical potential of certain immunobiological cells.

THE EFFECT OF HUMAN UMBILICAL CORD BLOOD $CD34^+$ PROGENITOR CELLS TRANSPLANTATION ON DIABETIC MICE

M. Attia,[1] A. Husein,[1] M. Awad,[1] A. Abdelal,[1] M. Elbarbary[2]

[1]Faculty of Medicine - Ismailia University, ISMAILIA; [2]Faculty of medicine - Ismailia Universit, ISMAILIA, Egypt

Background. Curative therapy for diabetes mellitus mainly implies replacement of functional insulin-producing pancreatic , cells, with pancreas or islet-cell transplants. However, shortage of donor organs spurs research into alternative means of generating, cells. Stem cells might represent a potential source of tissues for cell therapy protocols, and diabetes is a candidate disease that may benefit from cell replacement protocols. *Aims*. We examined the effect of transplanted human umbilical cord blood $CD34^+$ cells on some detailed parameters in streptozotocin- (STZ) induced diabetic mice. *Methods*. Thirty male albino mice 8-12 weeks were included and subdivided into 3 groups, first group served as normal control group, second group as diabetic control after induction of diabetes with STZ and third group treated diabetic mice by injection of positively selected CD34 progenitor cells from human umbilical cord blood(UCB) with a dose of one million cells/mouse. Blood glucose and serum insulin were measured at specific time interval and immunohistochemical analysis (IHC) and histopathology on pancreas were conduced. *Results*. Intravenous injection of $CD34^+$ cells caused significant improvement in blood glucose level (277.9±102.5 mg\dL in treated group vs 530.3±99 mg\dL in untreated group, p<0.01). Blood level of mouse insulin was higher in the treated group as compared with untreated diabetic mice (0.77±0.2 ng/mL intreated group versus 0.26±0.09 in untreated group, p<0.001). IHC analysis for detection of human insulin producing cells in pancreas of treated mice revealed that 33.3% positive cellular staining and 55.6% positive sinusoidal staining were detected. In conclusion, Transplantation of UCB - $CD34^+$cells appear to be a modality of stem cell therapy in diabetes mellitus of animal model.

A COCKTAIL TO BYPASS FETAL BOVINE SERUM LIMITATIONS FOR THE PRODUCTION OF UMBILICAL CORD DERIVED MESENCHYMAL STROMAL STEM CELLS FOR CLINICAL USE

K. Chieregato, S. Castegnaro, D. Madeo, F. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Wharton's jelly, which surrounds the two arteries and a vein of human umbilical cord (UC), derives from a mesenchymal precursor cell population. This primitive connective tissue contains a subpopulation that exhibits a functional mesenchymal phenotype and a fibroblast like appearance. In contrast to bone marrow (BM) and other adult derived mesenchymal stromal cells (MSCs), they have greater and faster expansion capability, higher frequency of colony forming unit fibroblast (CFU-F) than BM and UC blood (UCB) MSCs and an isolation efficiency of 100% when cultured in the presence of fetal bovine serum (FBS). They are karyotypically stable over many passages and easier to isolate than UC_MSCs, but they are slower to differentiate into adipocytes than BM. This aspect is partially in contrast with minimal criteria for defining multipotent MSCs established by the International Society for Cellular Therapies. *Aims*. Although the *in vivo* functions of UC_MSCs still need to be further investigated, we believe that these cells may represent a population able to potentially generate multiple doses of cells for cellular therapies. In addition, not all lots of FBS are equivalent in terms of their ability to maintain MSCs and there is a significant immunogenicity of FBS proteins. This has led many researchers to investigate alternative supplements. We investigated the effect of a growth factors (GFs) cocktail on UC_MSCs expansion, differentiation and phenotype, to define a FBS-free culture medium. *Methods*. MSCs were isolated from enzimatically digested UC (n=5). Cells were seeded at 1500 cells/cm^2 at the end of passage 0 (P0) and cultured in DMEM supplemented with FBS (10%); human platelet poor plasma (hPPP, 3%); hPPP (3%) with epidermal growth factor and platelet-derived growth factor-bb (EGF_PDGFbb, each at 10 ng/mL). Cells were harvested, counted and analysed by flow cytometer every 7 days for five passages (P5). The population doubling (PD) was determined at each passage to calculated the cumulative PD (cPD). Differentiation assays into adipogenic and osteogenic lineages were performed at the end of P2 and detected with Oil Red and von Kossa stain. *Results*. GFs cocktail supported UC_MSCs expansion better than hPPP (17.68±1.29 at the end of P5 and 12.00±2.06 respectively) and it showed a cPD similar to FBS (17.40±1.20. Figure 1A). In addition surface markers expression did not differ markedly in all culture conditions and

remained constant ($CD45^-/CD105^+/CD90^+$ about 96%, $CD45^-/CD105^+/CD44^+$ about 90%). Mineralization in the osteogenic differentiation was not appreciable. Cells cultured in the adipogenic medium appeared enlarged compared with negative control, but without lipid vacuoles in all medium supplements (Figure 1B). This result confirms that UC_MSCs are early-stage cells and that our cocktail does not induce maturation or differentiation. *Conclusions*. We defined a medium supplement, hPPP (3%) with EGF_PDGFbb (10 ng/mL), which permits us to bypass same limitations connected with FBS, including potential transmission of prion disease and the immunogenicity of the xenogeneic proteins. Furthermore, it allows us to fully exploit the potential of UC which represents a unique, easily accessible and not controversial source of early stem cells for cell therapy with low risk of viral contamination.

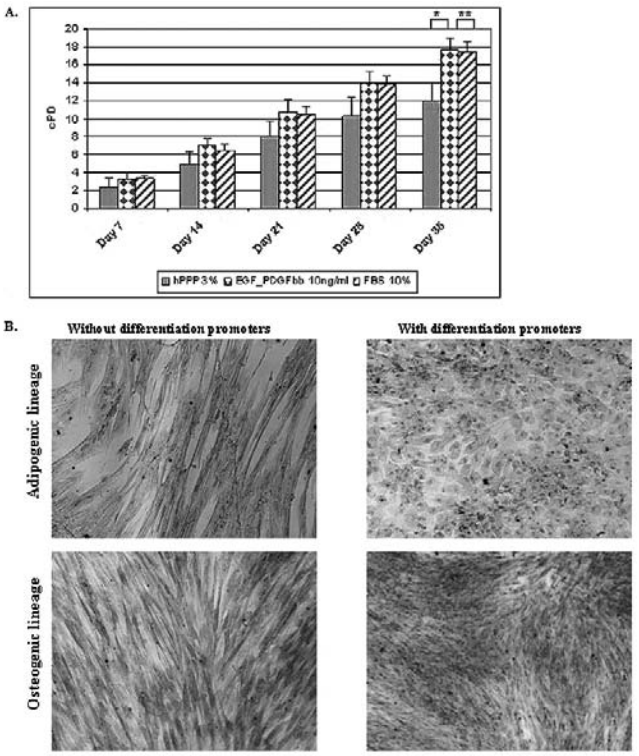

Figure 1. A. UC_ MSCs cPD (n=5) in three different medium supplements: FBS (10%); hPPP (3%) with and without EFG_PDGFbb each at 10 ng/mL. Our cocktail, defined in a previous study, can substitute FBS. *p<0.005; **not significant. B. Differentation of human UC_MSCs into adipogenic and osteogenic lineages after pre-treatment of 14 days with GFs cocktail. Differentation was detected with Oil Red O or von Kossa stain. Magnification 10X.

0738

POLYMORPHISMS OF MTHFR AND CLINICAL OUTCOMES IN ALLOGENEIC STEM CELL TRANSPLANTATION

S. Giammarco, P. Chiusolo, S. Bellesi, S. Marietti, D.G. De Ritis, E. Metafuni, S. De Matteis, G. Leone, S. Sica

Università Cattolica S. Cuore, ROME, Italy

Background. Methotrexate (MTX) is an antifolate drug used to prevent graft versus host disease (GVHD) in allogeneic stem cell transplantation (alloSCT). Its function is due to inhibition of dihydrofolate reductase and limitation of function of other enzymes like MTHFR. It is well known that MTHFR 677 polymorphisms results in reduced activity of this enzyme and that the use of MTX in patients with 677 CT/TT variations may influence side effects like mucositis and bone marrow toxicity. *Aims.* In this study we try to correlate the impact of these polymorphisms on clinical outcome of patients submitted to alloSCT which received MTX in their GVHD prophylaxis. *Methods*. Samples of 47 pts submitted to alloSCT from 2002 and respective donors were analyzed for 677CT polymorphism. Pts' characteristics were: 30M/17F, median age 37years (range10-58). Underlying disease were 23 AML, 17 ALL, 2 IMF, 2 SAA, 2 CML and 1 CLL. In 39 case pts were submitted to standard conditioning regimen and in 8 cases pts were submitted to reduced intensity conditioning regimen. All pts were submitted to GVHD prophylaxis with CSA and short-course MTX. Stem cell source was BM in 5pts, PBSC in 38pts and CBU in 4pts. The donor were HLA identical siblings or parents in 32 cases and MUD in 11 pts. All CBU were unrelated. *Results*. Seven pts died early after tx (14.8%) at a median time of 45d (range 30-90) for progression of disease. Twenty-two out of 47 (46.8%) developed hepatic toxicity and the median time for PMN (>0.5×10^9/L) and PLT (>20×10^9/L) recovery was respectively 20 and 15 days (range 10-48 and 11-55days). Twenty-two pts developed aGVHD grade II-IV at a median time of 26d after tx (range 10-70). Twenty-five pts relapsed after tx at a median time of 4 months (range 1-34). At this time 24pts are alive with a median follow-up of 31 months (range 1-51). OS, RFS, NRM and GVHD curves were obtained by the Kaplan Meier method and statistically compared by log-rank test; while incidence of toxicities was evaluated with chi2test. Our data revealed that there was no correlation between 677CT polymorphisms and development of hepatic toxicity and/or delayed engraftment (χ^2 test=ns); aGVHD was significantly correlated with CC polymorphism in the donor (p=0.05) and there was a trend toward a lower incidence of aGVHD in pts with TT polymorphism. Regarding NRM at 100days after tx we found a strong correlation with CC polymorphism in pts (p=0.006), whilst we found a trend toward a higher incidence of relapse in pts with TT polymorphisms. *Conclusions*. We conclude that greater immunosuppressive effect of MTX due to low MTHFR enzyme activity in mutated pts (TT) decreases the risk of GVHD but increases the risk of relapse.

0739

PROGNOSTIC FACTORS FOR SUCCESSFUL MOBILIZATION AND COLLECTION OF PERIPHERAL BLOOD STEM CELLS (PBSC) IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES. A STUDY OF 209 PATIENTS

M.K. Angelopoulou,[1] T.P. Vassilakopoulos,[1] S. Masouridis,[1] M. Moschogiannis,[1] P. Tsirkinidis,[1] V. Pappi,[1] Z. Galani,[1] V. Kalotychou,[1] K. Konstantoudakis,[1] E. Dimitriadou,[1] C. Kalpadaki,[2] M. Dimopoulou,[1] S. Kokoris,[1] N.-A. Vyniou,[1] E. Variamis,[1] M.P. Siakantaris,[3] Y. Rombos,[1] M.-C. Kyrtsonis,[1] P. Panayiotidis,[1] G.A. Pangalis[1]

[1]National and Kapodistrian University of Athens, ATHENS; [2]University of Crete, HERAKLION; [3]National & Kapodistrian University of Athens, ATHENS, Greece

Background. High dose therapy and autologous stem cell transplantation is frequently applied in patients with multiple myeloma (MM), Hodgkin lymphoma (HL) and non-Hodgkin's lymphoma (NHL). This procedure requires successful mobilization and collection of PBSC. However there are patients, who are poor mobilizers and require multiple mobilization courses and/or apheresis procedures, or fail completely to collect PBSC. *Aims*. To study various clinical and laboratory parameters as possible predictive factors for successful mobilization and collection of PBSC in MM, HL and NHL patients. *Methods*. 209 patients who were mobilized in our Unit between 2004 and 2008 were studied. The following parameters were analyzed: age, gender, underlying disease, number of previous chemotherapies, mobilization regimen, disease status pre-mobilization and baseline laboratory parameters. Since more than one mobilization courses and/or apheresis procedures were performed in some patients, two methods of analysis were applied. Method A: All mobilization courses were analyzed with the following endpoints: maximum absolute number of circulating $CD34^+$ cells and number of $CD34^+$ cells collected for each mobilization procedure. Method B: Each patient was considered only once with the following endpoint: mean number of $CD34^+$ cells collected per apheresis. *Results*. Median age at mobilization was 42 years (13-70), 64% were men, 64% had received 0-1, 34% 2-3 and 2% 4 or more previous chemotherapy regimens, 43% had HL, 33% NHL, 21% MM and 3% acute leukemia. Eleven % received G-CSF as mobilizing regimen, 33% cyclophosphamide + G-CSF, 35%, 17% and 4% regimens containing platinum, ifosfamide and high dose cytarabine + G-CSF, respectively. Before mobilization, median Hb was 11.4g/dL (7.8-16), median WBC 5.96×10^9/L (0.79-27.3), median PLT 260×10^9/L (70-853) and median absolute lymphocyte counts 1.1×10^9/L (0.1-3.4). The maximum absolute number of circulating $CD34^+$ cells, as well as the number of $CD34^+$ cells collected per kg of body weight were statistically significantly higher for ifosfamide-, platinum-, high dose cytarabine-, cyclophosphamide- and G-CSF- containing mobilizing regimens in this order (p<0.001). The mean number of $CD34^+$ collected cells per kg of body weight was 8.89×10^6, 5.14×10^6 and 1.30×10^6 for patients who had received £1, 2-3 and 4 or more previous chemotherapies (p=0.001). Other significant factors were age (p<0.001), and base-

line PLT count (p<0.001). Underlying disease and disease status before mobilization were also statistically significant. Thus, HL patients achieved a higher number of CD34+ collected cells compared to NHL and MM patients (p=0.002). Interestingly, patients with refractory disease prior to mobilization had a higher number of CD34+ collected cells compared to patients in relapse and those in remission, (p=0.003). Similar results were obtained with the 2nd method of analysis. *Conclusions*. Factors that affect successful mobilization and collection of PBSC include the mobilizing regimen (superior outcome with ifosfamide-containing regimens), the number of previous chemotherapies (inferior collection with 4 or more), age, baseline PLT count, disease status pre-mobilization (superior collection in refractory patients) and underlying disease (best outcome n HL patients).

0740

AXP IN ROUTINE CORD BLOOD BANKING: CRITICAL ANALYSIS OF DIFFERENT VOLUME REDUCTION METHODOLOGIES

P. Solves, V. Mirabet, A. Blanquer, F. Delgado, L. Larrea, A. Torres, A. Andres, I. Aznar, M. Guillen, R.J. Roig

Transfusion Center, VALENCIA, Spain

Background. Volume reduction of cord blood (CB) units is a proceeding used in most cord blood banks in order to reduce cryogenic space. To date, many methods have been described for this purpose as red blood cell (RBC) sedimentation with hydroxyethyl starch (HES), semi-automated methods as top and bottom and automated systems as Sepax. The AXPTM system is an automatic method for CB volume reduction recently developed, that consists of a microprocessor-controlled device and disposable closed bag set. *Aims*. Our objective was to compare different volume reduction methodologies in routine CB banking. *Methods*. We compared three different methodologies for volume reduction in routine CB banking: 1. HES: HES was added to the anticoagulated CB in a proportion of 1:4 HES solution to blood and then centrifuged at 45 x g for 7 minutes at 10°C according to the method developed by Rubinstein and coworkers. The removed supernatant was centrifuged again at 600 x g for 15 minutes. 2. Top and Bottom: CB units collected in triple-bag system were centrifuged at 3000 x g for 12 minutes. A standard protocol programmed into Compomat G4 was used to process the CB units. 3. AXPTM: Cord blood was transferred to the bag set and centrifuged in the AXP device for 30 minutes. All CB units were volume-reduced to less than 30 ml. Volume and cell counts were determined before and after volume reduction process. *Results*. Final CB volume containing cryopreservation solution was 25.5±1.2 mL, 28.3±0.4 mL and 24.1±0.5 mL for HES, G4 and AXP systems respectively (p<0.001); while total nucleated cell content (TNC) recovery was 76.4±11.2% for HES, 71.9±6.8% for G4 and 76.7±8.0% for AXP (HES vs AXP p=ns). Red blood cell depletion was higher for HES and AXP (86.1±5.8% vs 86.8±4.7, p=ns) and lower for G4 (69.5±8.0, p<0.001). *Conclusions*. HES sedimentation and AXPTM CB volume reduction systems provide similar cell recoveries and RBC depletion. AXP system reduces CB volume automatically in a less-time consuming process, achieving acceptable cell recoveries and high red blood cell depletion in a closed system without HES.

PLATELET ENGRAFTMENT IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES FOLLOWING UNMANIPULATED HAPLOIDENTICAL BLOOD AND MARROW TRANSPLANTATION: EFFECTS OF CD34+ CELL DOSE AND DISEASE STATUS

H. Xiao-Jun, Y.J. Chang, L.P. Xu, D.H. Liu, K.Y. Liu, W. Han, Y.H. Chen, Y. Wang, H. Chen, J.Z. Wang, X.H. Zhang, X.Y. Zhao

Peking University People's Hospital & Peking University Institute of Hematology, BEIJING, China

Background. Unmanipulated haploidentical blood and marrow transplantation has been developed as an alternative transplant strategy for patients without a human leucocyte antigen (HLA)-matched related or unrelated donor [Annals of Medicine, 2008,40:444; Bone Marrow Transplant,2006,38:291]. In this transplant setting, factors associated with hematopoietic recovery have not been completely defined. *Aims*. The aim of this study was to investigate the effects of donor and recipient characteristics on neutrophil and platelet engraftment following unmanipulated haploidentical transplantation. *Methods*. Unmanipulated haploidentical blood and marrow transplantation was performed on 348 patients with hematologic malignancies at a single institution between 2002 and 2007. Factors correlating with neutrophil and platelet engraftment post-transplant were analyzed retrospectively. *Results*. All patients reached an absolute neutrophil count (ANC) of 500/μL in a median of 13 days (range, 9-49 days). Three hundreds and thirty-one of 348 patients (95.11%) reached an untransfused platelet count of more than 20 000/μL in a median of 16 days (range, 7-356 days). In the univariate analysis, six factors were found to be associated with platelet engraftment, age of recipients (p=0.022), HLA-match (p=0.022), disease status (p=0.011), infused nuclear cells/kg of recipient weight (p=0.045), infused CD8+ cells/kg of recipient weight (p=0.031), and infused CD34+ cells/kg of recipient weight (p<0.001). Among patients who reached a sustained platelet count of more than 20 000/μL, an increased CD34 cell dose was suggestively associated with a shorter time to platelet recovery, although the strength of the association was relatively weak (R=-0.237, p<0.001). A trend towards an association of sex (female vs. male) with neutrophil engraftment was observed (p=0.084). Finally, a trend for association between time to transplantation after diagnosis (≤210d vs. >210d) and disease stage (advanced stage vs. early stage) with neutrophil engraftment was also demonstrated (p=0.056, and 0.089, respectively). Multivariate analysis showed that infused CD34+ cells/kg of recipient weight (CD34+ cells>2.19-106/kg vs ≤2.19-106/kg, HR=1.695; 95% CI 1.361-2.112; p<0.0001), and disease status (advanced vs early, HR=0.724; 95% CI 0.577-0.907; p=0.005) were independently associated with an increased risk of platelet engraftment.(Figure 1A and 1B) *Conclusions*. Our results suggest that low number of CD34+ cells in allografts and advanced stage disease may be critical factors associated with delayed platelet engraftment after unmanipulated haploidentical transplantation.

A VON WILLEBRAND FACTOR INHIBITORY ANTIBODY EFFECTIVELY INHIBITS ARTERIAL THROMBOSIS IN A HIGH SHEAR RATE MODEL IN BABOONS

W.J. Janse van Rensburg,[1] J.P. Roodt,[2] S. Lamprecht,[2] P.N. Badenhorst,[2] S.M. Meiring,[2] S. Hou,[3] H. Mottl[3]

[1]Universirty of the Free State, BLOEMFONTEIN, South Africa; [2]University of the Free State, BLOEMFONTEIN, South Africa; [3]Glenmark Pharmaceuticals S.A., LA CHAUX-DE-FONDS, Switzerland

Background. Given the high incidence of cardiovascular events, there is a need for safer and more effective antithrombotic therapies. The fact that von Willebrand factor (vWF) plays a pivotal role in primary haemostasis, by initiating adhesion of circulating platelets to exposed subendothelium and aggregation of platelets at high shear stress conditions, makes the development of an antithrombotic agent with vWF as target a very attractive option. *Aims*. To determine the efficacy and associated bleeding risk of a vWF inhibitory (Anti-vWF A1-domain) antibody as antithrombotic agent in non-human primates, and to compare it with clopidogrel in the same model. *Methods*. The efficacy of the antibody was evaluated in a high shear rate arterial thrombosis model in baboons. Different concentrations of the vWF inhibitory antibody were tested in three baboons, and three baboons were tested with clopidogrel for comparison. The femoral artery of the baboon was shunted to the femoral vein. The artery was mechanically injured and external stenosis applied. This resulted in thrombus formation measured by decreased blood flow. Thrombi were mechanically dislodged resulting in a pattern of cyclic flow reductions (CFRs). Escalating doses of antibody were infused and the effect of this treatment on the CFRs measured. Bleeding was assessed with an incision bleeding model as well as a template bleeding time. A Full Blood Count (FBC), Prothrombin Time (PT) and activated Partial Thromboplastin Time (aPTT) were performed and Factor VIII (FVIII) and vWF levels determined. *Results*. The anti-vWF antibody completely inhibited arterial thrombus formation in a dose dependant manner. After complete inhibition, infusion of epinephrine did not reverse the inhibition, unlike observations with clopidogrel. This is significant in view of the fact that epinephrine levels drastically increase during stressful situations. Considerably less bleeding was observed than with clopidogrel. vWF levels were reduced in the course of the experiment, but FVIII levels were not affected by either surgical procedure or antibody. The FBC, PT and aPTT were not adversely affected. *Conclusions*. A vWF inhibitory antibody is an effective antithrombotic agent in a high shear rate arterial thrombosis model in baboons, and compares favourably with clopidogrel, but with less bleeding risk and better efficacy during stressful conditions.

LEUKEMIA INDUCED BY ALTERED TRK-SIGNALING IS SENSITIVE TO TREATMENT WITH MTOR INHIBITORS IN A PRECLINICAL MODEL

Z. Li, M. Rhein, A. Schwarzer, M. Yang, V. Kaever, J. Meyer, A. Ganser, C. Baum

Hannover Medical School, HANNOVER, Germany

Neurotrophins (NTs) and their receptors play a key role in neurogenesis and survival. The TRK (tropomyosin-related kinase) receptor protein tyrosine kinases (TRKA, TRKB, TRKC) are high affinity NT-receptors that are expressed in a variety of human tissues. Their role in normal and malignant hematopoiesis is poorly understood. Recently, we and others have obtained evidence for potential involvement of this receptor system in leukemia. In a prospective study involving 94 adult patients, we demonstrated for the first time cell surface expression of the three TRKs and constitutive activation in blasts from patients with *de novo* or secondary acute leukemia. At least one TRK receptor was expressed in 55% of the analyzed cases (Li Z *et al.*, Blood 2009 in press). Altered TRK signaling efficiently transformed murine hematopoietic stem/progenitor cells (Meyer J *et al.*, Leukemia 2007; Li Z *et al.*, Blood 2009 in press). We observed constitutive activation of mammalian target of rapamycin (mTOR) both in murine and human leukemic cells. Murine leukemic cells induced by altered TRK signaling were very sensitive to rapamycin or RAD001 treatment *in vitro*. We next tested the therapeutic effect of rapamycin on altered TRK-induced leukemia in a mouse model (C57Bl/6J). Leukemic cells isolated from #483 mouse transplanted with primary hematopoietic stem/progenitor cells modified with deltaTrkA, an active mutant of TRKA isolated from a patient with acute myeloid leukemia, grew factor-independently. Treatment of #483 cells with rapamycin or RAD001 (10-50 nM) induced apoptosis and induced a dose-dependent growth inhibition (up to 100%) in colony forming assays. Consistently, mTOR was strongly dephosphorylated. In pilot studies, we found that i.v. injection of 10E6 #483 cells into recipients conditioned with sublethal irradiation (7.5Gy) induced leukemia in all animals after a latency of 8 weeks. Furthermore, daily i.p. injection of 2mg/kg rapamycin or 1mg/kg RAD001 in healthy animals mediated a high drug level in whole blood (around 50ng/mL and 175ng/mL, respectively). Thus, 20 sublethally irradiated animals were i.v. injected with 10E6 #483 cells and randomized in two groups. One group was treated daily with rapamycin 2mg/kg i.p., the other received only carrier (placebo). The treatment begun 3 weeks after cell injection and continued until the last animal succumbed to leukemia. Rapamycin treatment significantly prolonged the survival of animals compared with control group (mean survival 48.5 and 32 days, respectively, p=0.0087) (Figure 1). Concentration of rapamycin in whole blood at the time of end point analysis ranged 26- 151ng/mL. In a separate experiment RAD001 treatment (1 mg/kg) had a similar effect (Figure 2). Two RAD001-treated animals were even free of leukemia upon termination of the experiment (11 weeks). Concentration of RAD001 in whole blood at the time of end point analysis ranged 53-347ng/mL. Our findings suggest that mTOR plays an important role in leukemogenesis induced by altered TRK signaling, and might serve as a therapeutic target.

PRELIMINARY EVIDENCE OF CLINICAL ACTIVITY IN A PHASE 1 STUDY OF CAL-101, A POTENT SELECTIVE INHIBITOR OF THE P110DELTA ISOFORM OF PHOSPHATIDYLINOSITOL 3-KINASE, IN PATIENTS WITH B-CELL MALIGNANCIES

W. Flinn,[1] J. Byrd,[2] R. Furman,[3] J. Brown,[4] T. Lin,[2] C. Bello,[5] N. Giese,[6] A. Yu[6]

[1]Sarah Cannon Research Institute, NASHVILLE; [2]The Ohio State University, COLUMBUS; [3]Cornell University, NEW YORK; [4]Dana Farber Cancer Institute, BOSTON; [5]Moffitt Cancer Center, TAMPA; [6]Calistoga Pharmaceuticals Inc, SEATTLE, USA

Background. The class I phosphatidylinositol 3-kinases (PI3Ks) regulate a variety of cellular functions relevant to oncogenesis, including metabolism, proliferation and survival. The PI3K p110delta isoform is highly expressed in cells of hematopoietic origin and plays a key role in B cell maturation and function. CAL-101 is an oral, potent inhibitor of PI3K p110delta (IC50 of 2.5 nM against purified enzyme) with 40 to 300-fold selectivity compared to other PI3K isoforms. The lack of inhibitory activity against the PI3K p110α isoform should minimize the potential to alter insulin signaling and may provide a better therapeutic index relative to pan-PI3K inhibitors currently in development. *In vitro* studies of 0.1 to 10 uM CAL-101 showed inhibition of pAKT expression and/or apoptotic effects against primary chronic lymphocytic leukemia (CLL) and acute myeloid leukemia (AML) cells and against a range of leukemia and lymphoma cell lines. A Phase 1 study of CAL-101 in healthy volunteers showed that the drug was well tolerated and did not affect serum glucose or insulin levels at drug exposures that resulted in target inhibition. *Aims*. Evaluate the initial safety and clinical activity of CAL-101 in patients with select hematologic malignancies. *Methods*. In an ongoing phase 1 dose escalation study in sequential cohorts of 3 patients with relapsed/refractory CLL or select B-cell non-Hodgkin's lymphoma, CAL-101 is administered orally twice daily for 28 days per cycle. Clinical response is evaluated according to NCI criteria at the end of Cycles 1 and 2 and every 2 cycles thereafter. *Results*. To date, 9 patients have been treated in the first 3 cohorts at dose levels of 50 mg, 100 mg and 200 mg twice daily, with durations ranging from 1 to 7 months. Dose limiting toxicity has not been observed. There have been no significant adverse effects on hematological parameters or blood glucose. Mean peak and trough drug concentrations at the end of the first cycle were 1.5 uM and 0.3 uM in the 50 mg cohort, 2 uM and 1 uM in the 100 mg cohort and 6 uM and 1 uM in the 200 mg cohort, respectively. The trough concentrations are in the range required to inhibit PI3K p110delta in primary patient cells and cell lines *in vitro*. To date, three patients with the following diagnoses have attained partial responses: mantle cell lymphoma with 6 prior therapies (50 mg cohort); follicular lymphoma with 6 prior therapies and autologous stem cell transplant (100 mg cohort); CLL with 11 prior therapies and 17p deletion (200 mg cohort). Dose escalation is continuing and disease specific cohort expansion will occur at the maximally tolerated dose, at which time patients with AML will be added. Updated data will be presented at the meeting. *Conclusions*. Early results from a phase 1 study of the oral PI3K p110delta inhibitor CAL-101 show that it is well tolerated and has preliminary clinical activity in patients with B-cell malignancies.

EPIGENETIC THERAPY WITH 5-AZACITIDINE, VALPROIC ACID, AND ATRA IN PATIENTS WITH HIGH-RISK AML OR MDS: RESULTS OF THE FRENCH VIVEDEP PHASE II STUDY

E. Raffoux,[1] C. Recher,[1] C. Gardin,[2] J.P. Marolleau,[3] O. Reman,[4] A. Cras,[5] P. Turlure,[6] S. Maury,[7] A. De Labarthe,[1] L. Degos,[1] S. Chevret,[1] C. Chomienne,[1] H. Dombret[1]

[1]Hopital Saint Louis, PARIS; [2]Hopital Avicenne, BOBIGNY; [3]CHU d'Amiens, AMIENS; [4]CHU Caen, CAEN; [5]INSERM UMR S 940, PARIS; [6]CHU Limoges, LIMOGES; [7]Hopital Henri Mondor, CRETEIL, France

Introduction. Promising results have been reported recently with a combination of 5-azacitidine (AZA), valproic acid (VPA), and all-trans retinoic acid (ATRA) in patients with AML/MDS (Soriano *et al.* Blood 2007). We report here on a similar study conducted in 9 centers between 7/2006 and 8/2007. *Methods*. Patients with high-risk AML (AML in patients aged 70y+ unsuitable for intensive chemotherapy or early relapsing/refractory AML) or MDS (int-2/high IPSS without possibility of allogeneic SCT) were eligible. Treatment consisted of 6 cycles with AZA 75 mg/m^2/d SC (d1-7), VPA 35 to 50 mg/kg/d PO (d1-7), and ATRA 45 mg/m^2/d PO (d8-28). Cycle 1 was initiated at the hospital but cycles 2-6 were planned monthly in out-patients if possible. Response was assessed after cycle 1, 3, and 6 (IWG AML criteria). VPA was started at 35 mg/kg/d, and then increased at 50 mg/kg/d if well tolerated. Sixty-five patients were enrolled and 62 are evaluable for response. *Results*. Patients characteristics were: M/F, 27/38; median age, 72y (50-87); median WBC, 2.3×10^9/L. Fifty-five patients had AML (42 untreated, 13 relapsed AML) and 10 had MDS. Cytogenetics was available in 58 patients with high-risk features in 30 of them (complex, -7, -5, 3q abnormalities). Thirty-one patients stopped the treatment after 1-5 cycles: 23 disease progression or early deaths, 5 toxic events (SAE), and 3 patient decision despite stable disease. VPA was associated with CNS toxicity at 50 mg/kg, but not at the 35 mg/kg dose level. ATRA-related symptoms (headaches, mucosal dryness) were noted. In the 34 patients who received the 6 cycles, 13 reached CR (8 after cycle 3), 2 reached PR (4 after cycle 3) and 14 had Stable disease. The overall CR/PR rate after 6 cycles was thus 24%, reaching 38% in the 34 patients who did not interrupt the treatment in the absence of progression or toxic event. Analysing best response obtained (14 CR + 4 PR), cumulative incidence of response or death before response after 6 cycles is 31% and 31%, respectively. Table 1 gives prognostic factors for CR/PR and deaths (for cumulative incidence of response or death before response). Advanced age, high-risk cytogenetics and poor PS did not influence the response rate, but were prognostic for early death before response. Median OS was 12.4 months for all patients and 19.6 months in responders. *Conclusions.* This study confirms that epigenetic therapy with AZA, VPA, and ATRA yields a promising 25 to 30% response rate in patients with high-risk AML/MDS. Although randomized studies are needed (AZA±HDAC inhibitors), this combined approach appears to be a good option to treat older patients, whatever their cytogenetics.Maintenance options should be investigated in responding patients.

Table 1.

	CR/PR (P value)	Death(P value)
Age > or = 70y	24% (0.50)	53% (0.025)
Female	25% (0.21)	47% (0.03)
OMS > or = 2	0% (0.10)	57% (0.008%)
WBC > or = 1,5.10^9/L	26% (0.47%)	31% (0.96)
Platelets < 50.10^9/L	19% (0.02%)	39% (0.10)
Marrow Blasts >30%	29% (0.44)	42% (0.05)
High-risk cytogenetics	24% (0.52)	48% (0.003)
Relapsed AML	31% (0.72)	62% (0.01)

PRECLINICAL EXPERIENCES WITH THE NOVEL CALICHEAMICIN-CONJUGATED CD22 ANTIBODY INOTUZUMAB OZOGAMICIN (CMC-544) IN THE TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

F. de Vries,[1] C.M. Zwaan,[2] M. de Bie,[3] J.S.A. Voerman,[3] J.J.M. van Dongen,[3] H.H. Patel,[4] V.H.J. van der Velden[3]

[1]Erasmus MC, ROTTERDAM, Netherlands; [2]Dept of Pediatric Oncology/Hematology, Sophia Children's Hospital/Erasmus MC, ROTTERDAM, Netherlands; [3]Dept of Immunology, Erasmus MC, ROTTERDAM, Netherlands; [4]Wyeth Pharmaceuticals, CAMBRIDGE, USA

Background. Although conventional treatment with chemotherapy results in 80% survival in children with acute lymphoblastic leukemia (ALL), long-term side effects are frequently observed. Inotuzumab ozogamicin (CMC-544; Wyeth) is a newly designed drug consisting of a humanized CD22 antibody coupled to the anti-tumor antibiotic calicheamicin. CD22 antigens are specifically expressed on both immature and mature B cells, and it has already been shown that CMC-544 is effective in patients with B-cell lymphomas. *Aims*. To study the effectiveness of CMC-544 in precursor-B-ALL *in vitro* and to analyze which parameters determine its efficacy. *Methods*. Various ALL cell lines and primary precursor-B-ALL cells were tested for their sensitivity to CMC-544 and calicheamicin by quantitative flowcytometric measurement of viable ALL cells after 0 till 72 hours of incubation. CD22 saturation, defined as the percentage of CD22 antigens occupied by CMC-544, was determined by comparing the amount of bound CMC-544 with the maximal amount of CMC-544 that can bind to the cells. Binding of CMC-544 was analyzed by flow cytometry using anti-human IgG4-biotin and streptavidin-PE. The percentage of internalization of the CD22-CMC-544 complex was determined by comparing maximal CMC-544 binding at t=0 with maximal CMC-544 binding at the respec-

tive time point. *Results*. CMC-544 induced dose-dependent cell kill in ALL cell lines, with IC50 values at 72 hours of incubation varying from 1-10 ng/mL. High concentrations of CMC-544 (≥100 ng/mL) caused non-specific inhibition of proliferation and/or cell death in CD22 negative cells. Differential sensitivity of ALL cell lines to CMC-544 could not be attributed to differences in their sensitivity to calicheamicin, but seemed to be related to CD22 expression levels. However, if ALL cells expressing only moderate CD22 levels were incubated with CMC-544 for a longer time (>200 h), >99% of cells died, indicating that prolonged intracellular accumulation of CMC-544 contributes to killing these cells. Importantly, analysis of CD22 saturation and CMC-544-induced cell death showed that maximal saturation was not required to achieve efficient cell lysis. This is in contrast to earlier Mylotarg studies, where prolonged complete saturation was required to cause efficient cell death. CMC-544 was rapidly internalized both at low and at high CD22 saturation levels. Cell cycle analysis showed that, similar to calicheamicin, CMC-544 induced a G2/M arrest in its target cells. Primary ALL cells were also sensitive to CMC-544 treatment showing comparable IC50 values as ALL cell lines. CD22 expression levels were analyzed in a panel of 55 pediatric ALL patients. In all cases, ALL cells expressed CD22 and in >90% the CD22 expression exerted the expression level of CMC-544-sensitive cell lines. *Summary and Conclusions*. CMC-544 induced dose-dependent cell death in ALL cells, which seems to be related to the CD22 expression level. In contrast to previous data on Mylotarg-induced lysis of AML cells, our data indicate that prolonged and maximal saturation is not required for CMC-544-induced cell death of ALL cells. These data suggest that a fractionated scheme of administration of CMC-544 is less important than for Mylotarg, which has important implications for the design of future studies in children with relapsed/refractory ALL.

G. Tridente,[2] G. Pizzolo,[1] S. Sartoris,[2] M. Krampera[1]

[1]Department of Clinical and Experimental Medicine, VERONA; [2]Department of Pathology, Section of Immunology, VERONA; [3]Department of Oncology and Surgical Sciences, Section of Oncology, PADOVA, Italy

Background. Multipotent mesenchymal stromal cells (MSCs) are non-hematopoietic progenitor cells with multilineage differentiation potential. Exogeneously administered MSCs preferentially survive and proliferate in the presence of malignant cells, become stromal cells and support tumor growth. Thus, MSCs are attractive candidates to deliver biologically active molecules in the tumor environment *in vivo* and to enhance specific immune responses. Interferon-α (IFNα) has been used for years for the maintenance treatment of multiple myeloma (MM), but its administration is limited by the temporary efficacy and the significant toxicity when used sistemically at high doses. *Aims*. We used bone marrow-derived MSCs (BM-MSCs) from Balb/c mice as cellular vehicles for IFNα, after their transduction with a lentivirus-derived vector carrying the murine IFNα gene (BM-MSCs/IFNα), to assess their effects *in vivo* in the Sp6 mouse model of myeloma. *Methods*. BM-MSCs were transduced with a lentiviral vector containing murine IFNα cDNA (efficiency = 70%). Two month-old Balb/c mice (Balb/cByJIco, Charles River Italia, Calco, LC, Italy) (H-2d), were injected subcutaneously (s.c.) with the tumorigenic dose of 0.5×10^6 Sp6 cells (H-2d). The same mice were then weekly injected with 0.5×10^6 BM-MSCs/IFNα (1, 4 or 8 doses), in the same anatomical quarter. As controls, some mice were injected s.c. either with Sp6 or with BM-MSCs/EGFP s.c. or intravenously (i.v.) to test *in vivo* homing. Tumor sections were processed for immunohistochemistry/immunofluorescence using the following antibodies: anti-CD31, anti-von Willebrand factor (vWF), anti-α-smooth muscle actin (α-SMA), anti-CD4, anti-CD8, anti-asialo GM1, anti-CD45, anti-CD90, anti-murine IFN-α and then analyzed using a Zeiss Axiovert Z1 microscope. *Results*. BM-MSCs were capable of homing into the subcutaneous Sp6 tumor and formed small clusters of cells inside the tumor. Treatment with BM-MSCs/IFNα resulted in a statistically significant delay in the onset of palpable tumors (event free survival, EFS, of 50% at day +17 for 1 dose, day +20 for 4 doses and day +64, for 8 doses; by contrast, with Sp6 alone or coinjected with BM-MSCs the tumor incidence was 100% 10-13 days after injection). The weekly administration of BM-MSCs/IFNα induced a statistically significant decrease of the tumor growth rate and improved the overall survival (OS) (median OS was 19 days in the control mice, 17 days for mice receiving unmanipulated BM-MSCs, 30-31 days for mice treated with 1 and 4 doses of BM-MSCs/IFNα, 77 days for mice treated with 8 weekly doses). The anti-tumor effect was associated with ischemic tumor necrosis, reduction in microvessel density, and NK cell infiltration. *Conclusions*. These findings show that transduced BM-MSCs are capable of delivering anti-cancer molecules in the microenvironment of myeloma and may be a promising tool for specific, low-toxic, and long-lasting anti-myeloma therapy.

[1]Medical University of Vienna, VIENNA, Austria; [2]IMVS, University of Adelaide, ADELAIDE, Australia; [3]Sojo University, KUMAMOTO, Japan

We have recently shown that Hsp32 is expressed in leukemic cells in Ph^+ chronic myeloid leukemia and serves as potential therapeutic target. In the current study, we examined the expression and functional role of Hsp32 in acute lymphoblastic leukemia (ALL). Leukemic cells were obtained from patients with Ph^+ ALL (n=8) and Ph- ALL (n=12). In addition, Ph^+ ALL cell lines (Z-119, BV-173, TOM-1, NALM-1) and Ph- lymphoblastic cell lines (RAJI, RAMOS, REH, BL-41) were used. As assessed by immunostaining and qRT-PCR, ALL cells were found to display the Hsp32 protein as well as Hsp32 mRNA in all patients and cell lines examined. The Hsp32-inductor hemin was found to promote expression of Hsp32 in leukemic cells. To determine the functional role of Hsp32 in lymphoblasts, an siRNA against Hsp32 was applied. The siRNA-induced knock down of Hsp32 in RAJI and TOM-1 cells led to reduced growth and apoptosis compared to a control siRNA ($p<0.05$). Next, two pharmacologic inhibitors of Hsp32, pegylated zinc protoporphyrine (PEG-ZnPP) and styrene maleic acid-micelle-encapsulated ZnPP (SMA-ZnPP) were applied. As assessed by 3H-thymidine uptake, both agents were found to inhibit proliferation in $BCR\text{-}ABL^+$ cell lines and BCR-ABL-negative ALL cell lines. The effects of PEG-ZnPP and SMA-ZnPP on these cells were dose-dependent with IC_{50} values ranging between 1 and 10 μM, and were found to be associated with apoptosis as determined by microscopy as well as by flow cytometry and AnnexinV-staining. In NALM-1 cells, PEG-ZnPP and SMA-ZnPP also produced apoptosis and growth arrest, but the IC_{50} for SMA-ZnPP was slightly higher (20 μM). Hsp32-targeting drugs were also effective in producing growth inhibition in primary ALL cells (Ph^+ ALL and Ph^- ALL), with IC_{50} values ranging between 1 and 10 μM. No major differences were found when comparing results in imatinib-sensitive and imatinib-resistant patients. In drug combination experiments, Hsp32-targeting drugs were found to cooperate with imatinib and with nilotinib in producing growth-inhibition and apoptosis in all Ph^+ ALL cell lines. Moreover, cooperative antileukemic effects were obtained when Hsp32-targeting drugs were combined with bendamustine. Overall, these results suggest that Hsp32 may be a novel molecular target in ALL.

Background. Protein kinase C beta (PKCbeta), a pivotal enzyme in B-cell signaling and survival, is over-expressed in most cases of mantle cell lymphoma (MCL) and results in activation of PI3K/AKT pathway. Enzastaurin, an oral serine/threonine kinase inhibitor, suppresses signaling through PKCβ/PI3K/AKT pathways, induces apoptosis, reduces proliferation, and suppresses tumour-induced angiogenesis. Recently, a phase II study showed that enzastaurin is able to prolong the time free from progression in a subset of pre-treated refractory MCL. *Aims*. To optimize the treatment options with this promising inhibitor the goal of this study was to elucidate the molecular pathways influenced by Enzastaurin treatment in MCL. *Methods*. Four documented MCL cell lines (GRANTA 519, HBL-2, Jeko-1, Rec-1) were treated with Enzastaurin in a proliferation inhibiting dose of 10 μM, defined in initial pilot experi-

ments. After 2-8h of treatment, cells were harvested and analyzed by two-dimensional polyacrylamide gel-electrophoresis (2D-PAGE)-based protein screening and mass spectrometric identification. The identified candidate proteins were mapped in a functional interaction network and pathway-selected candidate proteins were verified by Western blotting. *Results*. Enzastaurin (10 nM) exposure led to significant reduction of cell viability in all cell lines (15-20%). One hour after treatment distinct alterations of the protein pattern were recognized in the 2D-PAGE gels of all cell lines. Of a total of 977 concurrent protein spots 115 (12%) spots exhibited significantly (>3fold) altered protein levels after 4h of enzastaurin exposure, including increased (57 spots; 5,8%) and decreased (58 spots; 5,9%) protein levels. Sixty-two concurrent differentially expressed protein spots (39 increased at 4h; 23 decreased at 4h) were chosen for mass spectrometric identification. Mass spectrometry identified 108 different candidate proteins with significant identification confidence. The identified candidate proteins were classified in functional groups, including DNA-repair and -replication (RAD50, PCNA, RFC1, PSMC4), apoptosis (HIST1H1E, PSMC4, VIM, PLEC1, GDIR2), signal transduction (GRB2, ARHGAP25, EF1D, SNX25) and gene expression/mRNA processing (RPS20, EEF1D, HNRPF, SFRS7; SMC1A). The results were verified by Western blot in selected candidate proteins of the apoptosis (VIM, PLEC1), DNA-repair (RAD50, PCNA, RFC1) and gene expression (EEF1D, SMC1A) as well as several additional proteins mapped to the interaction networks (BMF, NOXA). *Summary and Conclusions*. Enzastaurin-treatment affects several crucial cellular pathways including apoptosis, DNA repair and gene expression. It thus affects three main cellular control mechanisms. Ongoing experiments incorporate this knowledge to select optimal combination partners of Enzastaurin.

THE BH3 MIMETIC GX015-070 (OBATOCLAX) INDUCES APOPTOSIS AND GROWTH INHIBITION IN NEOPLASTIC MAST CELLS

B. Peter,[1] K Aichberger,[1] K.V. Gleixner,[1] E. Hadzijusufovic,[1] K. Schuch,[1] W.F. Pickl,[1] M. Willmann,[2] P. Valent[1]

[1]Medical University of Vienna, VIENNA; [2]University of Veterinary Medicine Vienna, VIENNA, Austria

Background. Advanced systemic mastocytosis (SM) is an incurable neoplasm with short survival times. So far no effective therapy is available for these patients. We have recently shown that neoplastic mast cells (MC) in SM express various anti-apoptotic members of the Bcl-2 family including Mcl-1. *Aims and Methods*. In this study, we examined the effects of the Mcl-1-targeting BH3 mimetic Obatoclax® (GeminX, Montréal, Quebéc, Canada) on growth and viability of primary neoplastic MC obtained from patients with SM (n=3), the human MC leukemia cell line HMC-1, and the canine mastocytoma cell line C2. Two HMC-1 subclones, one lacking KIT D816V (HMC-1.1) and one expressing KIT D816V (HMC-1.2) were examined. *Results*. As assessed by RT-PCR and immunostaining, primary neoplastic MC and both HMC-1 subclones were found to express Mcl-1 mRNA and the Mcl-1 protein, but did not express proapoptotic Bim. Transfection of HMC-1 cells with Mcl-1-specific siRNA resulted in increased apoptosis compared to cells transfected with a control siRNA. Obatoclax was found to inhibit 3H-thymidine uptake and thus proliferation in HMC-1 cells in a dose-dependent manner, with higher IC_{50} values obtained in HMC-1.2 cells (0.5 µM) compared to HMC-1.1 cells (0.05 µM). Obatoclax also inhibited the growth and survival of the canine mastocytoma cell line C2 (IC_{50}: 0.5-1 µM). Moreover, Obatoclax was found to inhibit the proliferation of primary human neoplastic MC in all SM patients tested (IC_{50}: 0.05-0.1 µM). In all cell line models, Obatoclax induced apoptosis as determined by microscopy, Tunel assay, and caspase cleavage. We next combined obatoclax with a modulator of Mcl-1/Bim expression in MC, in order to enhance drug effects. Since Bim is degraded via the proteasome, we applied the proteasome inhibitor bortezomib. As assessed by real time PCR, bortezomib was found to promote Bim mRNA expression in these cells. In addition, bortezomib was found to suppress 3H-thymidine uptake in both HMC-1 subclones, and to cooperate with Obatoclax in producing apoptosis in neoplastic MC. Finally, Obatoclax was found to synergize with the KIT D816V-targeting drug PKC412 in producing apoptosis in HMC-1 cells and C2 cells. *Conclusions*. The Mcl-1-targeting drug Obatoclax exerts apoptosis-inducing effects on neoplastic MC. Whether Obatoclax will also act antineoplastic in patients with advanced MC disorders remains to be determined in clinical trials.

0751

QUANTITATIVE MEASUREMENT OF NUCLEAR TRANSLOCATION OF NF-KB AND STAT-3 AS PARAMETER OF RESPONSE TO TARGETED TREATMENTS IN IMMUNOPHENOTYPICALLY DEFINED CELLS IN ACUTE MYELOID LEUKEMIA

H. Minderman,[1] K. O'Loughlin,[1] C. Collins,[1] V . Venkatachalam,[2] T. George,[2] P.K. Wallace[1]

[1]Roswell Park Cancer Institute, BUFFALO; [2]Amnis Corporation, SEATTLE, USA

Background. Acute Myeloid Leukemia (AML) has been associated with aberrant activities of various signaling cascades including FMS-like tyrosine kinase-3 (FLT3), signal transducer and activator of transcription-3 (STAT3), nuclear factor-κB (NF-κB) and vascular endothelial growth factor (VEGF) and the leukemia-specific nature of these anomalies make them attractive therapeutic targets in this disease. Activation of the VEGF and FLT3 cell surface receptors triggers the activation of key signaling pathways involved in cell proliferation and survival including the PI3K/AKT, Ras/MAP-K, STATs and protein kinase C pathways. STAT3 and NF-κB are down stream targets at the convergence of these and/or other signaling cascades. *Aims*. the aim of the study is to demonstrate the applicability of flow cytometry-based image analysis to quantitatively evaluate nuclear versus cytoplasmic localization of NF-κB and STAT-3 in immunophenotypically defined (target) cells as a parameter of response to treatments that target the activity of these pathways. *Methods*. Dose- and time-kinetics of NF-κB and STAT-3 nuclear localization following *in vitro* cytokine exposure was studied in AML cell lines and leucocytes from AML patients and healthy volunteers. Following the desired treatment, cells were stained with combinations of cell surface lineage specific antibodies (eg CD33), anti-p65 or anti-STAT3 antibodies and a nuclear DNA stain (DRAQ5). Multi-spectral images of at least 5,000 cells were then acquired with the ImageStream platform. Following hierarchical gating strategies to identify single, in-focus and $CD33^+$ cells, image analysis algorithms were applied to each cell to determine the 'similarity' of its nuclear image (defined by DRAQ5) and its p65 or STAT3 image (defined by FITC-labeled anti-p65 or anti-STAT3). Sensitivity and specificity was determined by titrating treated cells with nuclear translocation into untreated cell populations for which no or little nuclear translocation is expected. Image analysis results were compared with western blot and microscopy analysis. *Results*. the correlation between STAT3 or NF-κB images and DRAQ5 images was quantified for each individual cell by a 'similarity score', a log transformed Pearson's correlation between corresponding pixel values of each image. As such the similarity score is a measure of nuclear translocation that is measured as a continuous variable from -infinity to +infinity. The higher the score the higher the degree of nuclear translocation. In all model systems tested, dose- and time-kinetic changes of similarity scores corresponded well with expected nuclear translocation of NF-κB and STAT3 following exposure to TNF-alfa and IL-6, respectively. Cells with nuclear translocation events could be detected among cells without nuclear translocation with a sensitivity of at least 0.1%. The applied analysis was shown to be less bias prone than microscopy and more sensitive than western blot analysis. *Summary and Conclusions*. the data demonstrate that the ImageStream technology allows the quantitative study of nuclear translocation of NF-κB and STAT3 in immunophenotypically defined cells. These examples illustrate the applicability of this approach to study nuclear translocation events as a parameter of response in immunophenotypically defined target cells in patients undergoing therapy with agents targeted against these signaling pathways. Supported by NIH 1R21 CA126667.

ACTIVITY OF MLN4924, A NOVEL FIRST IN CLASS SMALL MOLECULE INHIBITOR OF THE NEDD8 ACTIVATING ENZYME, IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

T. Swords,[1] K. Kelly,[1] P. Smith,[2] D. Mahalingam,[1] M. O'Dwyer,[3] S. Nawrocki,[1] F. Giles,[1] J. Carew[1]

[1]Cancer Therapy and Reseach Center, SAN ANTONIO, USA; [2]Millenium Pharmaceuticals, CAMBRIDGE, MA, USA; [3]University College Hospital, GALWAY, Ireland

Background. The ubiquitin-proteasome system (UPS) is responsible for the timed destruction of many proteins including key players in signaling cascades and critical regulators of cell cycle progression and transcription. The Nedd8 activating enzyme (NAE) has been identified as an essential regulator of the Nedd8 conjugation pathway, which controls the activity of a subset of ubiquitin E3 ligases, specifically, the cullin dependant E3 ligases. The cullins control the timely ubiquitination and

subsequent degradation of many proteins with important roles in cell cycle progression, DNA damage, stress response and signal transduction. Acute myeloid leukemia (AML) is a disease of the elderly and prognosis is extremely poor with a median overall survival of just 2 months for untreated patients. Novel therapeutic strategies are urgently needed for these patients. Considering that Nedd8-mediated control of protein homeostasis is vitally important for the survival of AML cells, we evaluated the pre-clinical anti-leukemia activity of MLN4924, a novel first in class small molecule inhibitor of the Nedd8 activating enzyme. *Aims*. (1) To determine the activity of MLN4924 in pre-clinical models of AML; (2) To elucidate the mechanisms of action of MLN4924 in AML cells. *Materials and Methods*. FLT3$^+$ and FLT3$^-$ AML cell lines, normal PBMCs and bone marrow stromal cells, and primary AML patient specimens were used to evaluate the preclinical activity of MLN4924. Cell viability and induction of apoptosis were assessed using PI/FACS and an ATP bioluminescence method. The prolonged *in vitro* effects of MLN4924 were assessed by MethoCult colony formation assays. Effects on protein neddylation and caspase activation were measured by western blot analysis. VEGF secretion was quantified by ELISA. *Results*. MLN4924 induced rapid and selective cell death at low nanomolar concentrations (mean IC_{50} of 175 nM) in AML cell lines independent of FLT3 expression, but not in peripheral blood mononuclear cells from healthy donors. Clonogenic assays confirmed impaired colony formation at 10 days in a dose dependant fashion. Importantly, MLN4924 also demonstrated significant activity in primary AML cells from patients. Kinetic analysis of drug-induced effects on cell cycle distribution revealed that AML cells treated with MLN4924 initially arrested at the G1 transition prior to their subsequent accumulation in the sub-G1 compartment. Activation of both caspases-8 and -9 following 2 hours of drug exposure confirmed potent pro-apoptotic effects. Notably, the activity of MLN4924 was preserved when cells were co-cultured with bone marrow stromal cells. MLN4924 induced a dose and time dependant increase in the expression of phospo-IKB, an important target for degradation through the Nedd8 conjugation pathway. The inhibitory effects of MLN4924 on NFKB were confirmed by demonstrating that the transcriptional activity of the NFKB p65 subunit and the secretion of VEGF, an NFKB transcriptional target were both reduced significantly. *Conclusions*. MLN4924, a novel first in class NAE inhibitor, overcomes the protective effect of the bone marrow microenvironment and rapidly and selectively induces apoptosis through caspase 8 and 9 activation and inhibition of the NFKB pathway. MLN4924 is a promising novel agent for the treatment of AML and warrants further evaluation in clinical trials.

0753

OVERCOMING DRUG RESISTANCE WITH SGI-1776: A NOVEL PIM KINASE INHIBITOR WITH POTENT PRECLINICAL ACTIVITY IN ACUTE MYELOID LEUKEMIA

T. Swords,[1] K. Kelly,[1] D. Mahalingam,[1] M. O'Dwyer,[2] S. Nawrocki,[1] F. Giles,[1] J. Carew[1]

[1]Cancer Therapy and Reseach Center, SAN ANTONIO, USA; [2]University College Hospital, GALWAY, Ireland

Backgroud. The PIM kinases (PIM1, PIM2, PIM3) are a small family of proto-oncogenes within the CAMK super-family. Overexpression of PIM kinases significantly augments cell survival and accelerates c-myc and N-myc-driven tumorigenesis in mouse models. Accordingly, overexpression of PIM kinases has been reported in a wide range of malignancies including clinical cases of acute myeloid leukemia (AML). In models of FLT3 positive AML, prolonged exposure to FLT3 inhibitors leads to resistance via activation of parallel signaling pathways, and resultant altered gene expression, including high levels of PIM1. Resistance to the mTOR inhibitor rapamycin, has also been reported as result of over-expression of PIM1 in AML cell lines. PIM1 is directly involved in the activation of efflux pumps which are strongly associated with clinical drug resistance in AML. Drug resistance is a major cause of treatment failure, particularly in the elderly, where the median survival is just 2 months for untreated patients. New treatments are desperately needed for these patients. Therefore, given the important roles of the PIM kinases in cell survival signalling and drug resistance in AML these kinases become very attractive targets for pharmacological inhibition. SGI-1776 is a novel orally available small molecule inhibitor of PIM kinase activity that has entered Phase I clinical trials. We hypothesized that SGI-1776 would have significant anticancer activity against AML cells due to their high intrinsic expression of PIM-1. *Aims*. 1)To determine the activity of SGI1776 in pre-clinical models of AML; 2) To elucidate the mechanism of action of SGI1776 in AML cells. *Materials and methods*. FLT3 positive and FLT3 negative AML cell lines, normal peripheral blood mononuclear and bone marrow stromal cells were used to evaluate the preclinical activity of SGI1776. Cell viability and induction of apoptosis were assessed using PI/FACS and MTT assays. The prolonged *in vitro* effects of SGI1776 were assessed by MethoCult colony formation assays. Effects on PIM kinase inhibition and caspase activation were measured by western blot analysis. FLT3 positive xenograft mouse models and primary patients specimens were used to establish the *in vivo* effects of SGI1776. *Results*. *In vitro* assays conducted in a panel of human AML cell lines demonstrated that low nanomolar concentrations of SGI-1776 potently diminished cell viability (IC_{50} 6NM). Clonogenic assays confirmed impaired colony formation at 10 days in a dose dependant fashion. SGI-1776 induced apoptosis in AML cells in a dose-dependant manner that correlated with a reduction in intracellular levels of phosphorylated BAD. FLT3 ITD positive AML cells were particularly sensitive to SGI-1776, likely due to the dual inhibitory effects of this agent against PIM and FLT3 kinase activity. Oral administration of SGI-1776 to immunodeficient mice bearing xenografts of human AML cell lines was very well tolerated. SGI-1776 inhibited tumor growth significantly and demonstrated a greater than additive effect when combined with the standard of care agent, cytarabine. *Conclusions*. These exciting data support the clinical study of SGI-1776 in patients with AML and further investigation of the role of PIM kinase in AML pathophysiology.

INTERFERENCE WITH AML1/ETO LEUKEMOGENIC FUNCTION BY CELL-PENETRATING PEPTIDES TARGETING THE OLIGOMERIZATION DOMAIN

Y. Becker, C. Wichmann, M. Grez

Georg-Speyer-Haus, FRANKFURT, Germany

Background. The leukemogenic fusion protein AML1/ETO is generated by the chromosomal translocation t(8;21) which appears in about 12% of all *de novo* acute myeloid leukemias (AMLs). It consists of the DNA-binding domain of the hematopoietic transcription factor AML1 and almost the entire ETO protein which functions mainly as a transcriptional repressor. Essential for the block in myeloid differentiation of AML1/ETO transformed cells is the oligomerization of the chimeric proteins and the formation of high molecular weight complexes (HMWCs). The α-helical nervy homology region 2 (NHR2) within ETO mediates oligomerization by tetramer formation as well as binding of AML1/ETO to members of the ETO protein family and corepressor molecules. *Aims*. Recent studies suggest the NHR2 domain as the only essential ETO domain crucial for AML1/ETO leukemogenic potential. Thus, selective interference with the oligomerization domain could inhibit the tumorigenic potential of AML1/ETO. *Methods*. By using retroviral transduction, the effect of different NHR2-containing peptides on the ability to prevent proliferation and induce differentiation of transformed cells was investigated. In order to directly deliver the inhibitory peptides to AML1/ETO expressing cells, the NHR2 domain was fused to the HIV-1 Tat protein transduction domain and the recombinant peptides were purified from bacteria and tested in cell culture. *Results*. We could show that expression of peptides containing the NHR2 domain inhibits AML1/ETO oligomerization. The binding affinity of NHR2 peptide mutants to ETO directly correlates with the degree of growth inhibition. A derivative of NC128 which retained all NHR2 amino acids (N89) maintained full binding capacity to ETO as well as antiproliferative effects, whereas a mutant of N89 lacking 7 C-terminal amino acids (N82) significantly lost binding capacity and its antiproliferative effect. A codon optimized expression construct was developed in order to increase the cellular expression levels of N89. Compared to N89, expression of this construct enhances growth arrest suggesting that the NHR2 peptides act in a dose dependent manner. Upon protein transduction into mammalian cells, recombinant NHR2 polypeptides were successfully detected in cellular lysates. Addition of the endosome inhibitor cloroquine further enhanced the intracellular stability of the cell-penetrating polypeptides. By co-immunoprecipitation experiments we could show that the transduced polypeptides are able to specifically interact with ETO protein in stably transfected cells. Protein transduction into the myeloid cell line Kasumi-1, which depends on AML1/ETO expression for growth, is possible in the absence of serum and can be further increased by pre-incubation of the cells with dextran. Treatment of Kasumi-1 cells for several days with the cell-penetrating NHR2 polypeptides resulted in a 22% reduction of c-kit surface marker expression. *Conclusions*. Our results propose that selective interference with NHR2-mediated oligomerization could provide a promising strategy for the inhibition of the oncogenic properties of AML1/ETO. The application of cell-penetrating polypeptides is possible but requires further improvement to achieve high bioavailability.

0755

TUMOR MEMBRANE-BOUND DIMERIC IL-2 AND A BISPECIFIC CD3X19 ANTIBODY INDUCE CYTOTOXIC T-CELL STIMULATORY CAPACITY OF B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

M. Notter

Charité, BERLIN, Germany

The graft versus-leukemia-effect in B-cell chronic lymphocytic leukemia (B-CLL) appears to be less efficient compared to myeloid leukemias. Since the aberrant coexpression of CD5 in association with CD19 is a hallmark of B-CLL, we asked if both molecules might serve as a combinatorial T-cell target. B-CLL cells as third party in mixed-lymphocyte reactions (MLR) confirmed their capacity to induce T-cell anergy. We used recombinant proteins comprising a single chain (sc) FvCD5 antibody (Ab) fused to human interleukin (IL)-2 via the hinge region of human immunoglobulin (Ig)G1 in conjunction with a bispecific CD3x19 Ab (bsAb; clone OKT3xHD37) to saturate CD19 and CD5 binding sites on B-CLL cells. Consistent with the absent immunogenic potential, B-CLL cells pretreated with scFvCD5 Ab, native IL-2 and CD3x19 bsAb were not recognized by allogeneic resting T cells. In contrast, B-CLL coated with the dimeric scFvCD5-IL-2 and CD3x19 bsAb induced profound stimulator cell dependent allogeneic and autologous T-cell proliferation. In addition, T cells from fresh peripheral blood mononuclear cell samples from B-CLL patients (n=4) pretreated with dimeric scFvCD5-IL-2 and cultured in the presence of CD3x19 bsAb expanded by 2-3 log within 7 days. Notably, addition of soluble exogenous IL-2 to both types of culture remained inferior compared to the CD5-targeted IL-2 delivery. T-cell proliferation and expansion also translated to cell-mediated cytotoxicity. In conclusion, a dual targeting approach directed against aberrantly expressed surface molecules for membrane delivery of dimeric IL-2 molecules and a surrogate second signal as shown for B-CLL represents a strategy to reverse tumor-induced T-cell anergy.

0756

BI-213 LABELED ANTI-CD20 MONOCLONAL ANTIBODIES INDUCE APOPTOSIS AND OVERCOME CHEMORESISTANCE IN NON-HODGKIN'S LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

C. Friesen,[1] M. Roscher,[1] I. Hormann,[1] A. Morgenstern,[2] F. Bruchertseifer,[2] C. Apostolidis,[2] Th. Zenz,[3] S. Stilgenbauer,[3] E. Miltner[1]

[1]Institute for Legal Medicine, University Ulm, ULM; [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, KARLSRUHE; [3]Department of Internal Medicine III, University of Ulm, ULM, Germany

Background. Radioimmunotherapy (RIT) is an emerging treatment option for non-Hodgkin's lymphoma and chronic lymphocytic leukemia (CLL). The development of RIT with α- emitters such as Bi-213 is promising for treatment of a variety of cancer and is attractive because of the high linear energy transfer (LET) and short path length, allowing higher tumor cell kill and lower toxicity to healthy tissues. *Aims*. In the present study we examined induction of apoptosis and the role of activation of apoptosis pathways using Bi-213 labeled anti-CD20 monoclonal antibodies ([Bi-213]anti-CD20) in sensitive and chemoresistant non-Hodgkin's lymphoma cells and CLL cells. *Methods*. Bi-213 was eluted from an Ac-225 generator and conjugated to anti-CD20 antibody (rituximab) with CHX-A'-DTPA as a chelator. The human non-Hodgkin's lymphoma cell line DoHH2 ($CD20^{+/+}$) and CLL cells, isolated from patients sensitive or resistant to fludarabine, were treated with 225, 75, 22.5, and 7.5 kBq/mL of [Bi-213]anti-CD20, using the specific activity of 3.6 MBq/μg anti-CD20. 24h and 48h after treatment with [Bi-213]anti-CD20, cell death, cell cycle and apoptosis were measured by flowcytometry and activation of apoptosis pathways was determined by Western Blot analyses. *Results*. 24h and 48h after treatment with 225, 75, 22.5, and 7.5 kBq/mL of [Bi-213]anti-CD20 we found a strong induction of apoptosis and activation of caspases and PARP cleavage in DoHH2 cells. [Bi-213]anti-CD20-induced apoptosis was completely inhibited by zVAD.fmk, a specific inhibitor of activation of caspases, indicating that caspases play an important role in [Bi-213]anti-CD20 induced cell death. Mitochondria were activated after [Bi-213]anti-CD20 treatment, resulting in caspase-9 activation. Bax, a death-promoting protein, was upregulated and Bcl-xL, a death-inhibiting protein, was downregulated after [Bi-213]anti-CD20 treatment. p21 were upregulated and cells showed a G2/M cell cycle arrest after treatment with [Bi-213]anti-CD20. In addition, [Bi-213]anti-CD20 induced cell death in CLL cells as well as in fludarabine-resistant CLL cells isolated from patients *ex vivo*, indicating that [Bi-213]anti-CD20 overcomes fludarabine-resistance. Furthermore, [Bi-213]-triggered apoptosis was not inhibited by the DNA-repair mechanism of non homologous endjoining, predominant for repairing double strand breaks in mammalian cells. *Summary and Conclusions*. Taken together, we found that [Bi-213]anti-CD20 antibodies induce apoptosis, arrest cell cycle in G2/M and activate apoptosis pathways through caspase activation in non-Hodgkin's lymphoma cells and in CLL cells *in vitro* and *ex vivo* and break fludarabine-resistance. [Bi-213]-mediated α-radioimmunotherapy seems to be a promising therapeutic approach for selectively killing tumor cells with limited side effects.

LEUKEMIA CELL-SELECTIVE UPTAKE OF CYTARABINE AND DAUNORUBICIN IN THE BONE MARROW COMPARTMENT MEDIATED BY CPX-351 LIPOSOME INJECTION

D. Mayer, S. Lim, G. Tardi, X. Xie, M Fan, X Huang, O Harasym

Celator Pharmaceuticals, VANCOUVER, Canada

Background. Anticancer drug combinations such as cytarabine plus daunorubicin can act synergistically, additively or antagonistically depending on the ratio of the agents being combined. We have shown that delivering synergistic cytarabine:daunorubicin drug ratios *in vivo* using nano-scale liposomes (CPX-351 Liposome Injection) provides dramatic efficacy improvements compared to the free drug cocktail in a wide range of preclinical leukemia models without exacerbating myelosuppressive effects. This enhanced efficacy is associated with increased and prolonged delivery of the synergistic drug ratio to bone marrow. Promising signs of efficacy have been observed with CPX-351 in previously treated AML patients with poor prognosis. *Aims*. To investigate the pharmacodynamic basis for the potent therapeutic activity of CPX-351. *Methods*. A bone marrow-engrafting CCRF-CEM human leukemia xenograft model was developed. CPX-351 was injected i.v. and the bone marrows of femurs from tumor bearing mice were subsequently harvested. Cells were analyzed by flow cytometry and leukemia cells were separated from normal bone marrow cells using anti-CD45 coated magnetic nanoparticles. Cells were analyzed for intracellular cytarabine: daunorubicin and liposome content using 3H-Cyt, HPLC and 14C-lipid, respectively. *Results*. Twenty-eight days after i.v. tumor inoculation, femurs contained approximately equal numbers of CCRF-CEM and normal bone marrow cell populations which could be readily separated and quantitatively harvested by antibody coated magnetic nanoparticle-mediated isolation. Eighteen hours after CPX-351 i.v. injection, bone marrows of the tumor bearing mice contained 82.6 ng cytarabine, 63.0 ng daunorubicin and 1.2 μg liposomal lipid per total femur aspirate. Within the separated cell populations, leukemia cells contained 5.9 ng cytarabine, 8.2 ng daunorubicin and 0.16 μg liposomal lipid per 10^6 cells. These intracellular levels were 9.5-, 2.2- and 1.9-fold higher than those observed in the normal bone marrow cell population. Confocal microscopy on cells incubated with CPX-351 *in vitro* demonstrated that CPX-351 liposomes are taken up intact by human leukemia cells and subsequently release the drugs intracellularly. *Conclusions*. CPX-351 was designed to enhance the antitumor efficacy of cytarabine:daunorubicin combination therapy by encapsulating both agents within a drug carrier that maintains the synergistic molar ratio for extended times after injection. The potent anti-leukemic activity obtained in the absence of significant non-hematological toxicity with this formulation may be due, in part, to the selective accumulation of CPX-351 into leukemia cells.

0758

INDUCTION OF APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUCEMIA CELLS BY THE PARA-ISOMER OF NITRIC OXIDE-DONATING ACETYLSALICYLIC ACID (P-NO-ASA) AT LOW MICROMOLAR CONCENTRATIONS

R. Razavi, I. Gehrke, R.K. Gandhirajan, J. Paesler, A. Filipovich, F. Erdfelder, M. Hertweck, S. Uhrmacher, M. Hallek, K.-A. Kreuzer

Uniklinik Koeln, KOELN, Germany

Background. Chronic lymphocytic leukemia (CLL) is characterized by an accumulation of mature, non functional B cells. We and others have shown that WNT/β-catenin (CTNNB1)/TCF/Lef-1 signaling appears to be constitutively and aberrantly activated in these cells. Furthermore, it is already known that several compounds related to the non-steroidal antiinflammatory drugs (NSAID) can inhibit CTNNB1 stability and/or function in WNT active cancers *in vitro*. However, so far clinical studies with such substances generated disappointing results which is likely to the fact that therapeutic plasma concentrations could not be reached without producing significant toxicities; hence, these required high concentrations limit their clinical use. Recently, nitric oxide-donating acetyl-

salicylic acid (NO-ASA) has been shown to achieve high plasma levels in doses not leading to any side effects in humans. It consists of a traditional molecule of acetylsalicylic acid with a NO-moiety is covalently bound via a spacer part. In addition NO-ASA could disrupt complexation of CTNNB1 and TCF-4 *in vitro*, whereas the latter belongs to the transcription factors which posses a central function in mediating WNT signaling. *Aims*. Because the general structure features enable more variants of NO-ASA the aim of our study was to evaluate whether para-, and meta-NO-ASA have an effect on CLL cells and in affirmative case if the impact is dependant on the isoform. Further we were interested in the actual concentration range of the reagents and if the mechanism of action is based on β-catenin/Lef-1 disruption and subsequent downregulation of target genes. *Methods*. Primary CLL cells as well as healthy peripheral blood monocytes (PBMC) and healthy B-cells were treataed with varying concentrations of p- and m-NO-ASA. Cytotoxicity was assessed by microscopic cell viability testing and an ATP assay. Induction of apoptosis was investigated by Annexin V-FITC/Propidiumiodid (PI) staining and immunoblotting of PARP, caspases 3 and 9. Further, CTNNB1 protein amount was measured by immunoblotting and expression of WNT effector proteins like cyclin D1 (CCND1), C-MYC and LEF-1 was evaluated with immunoblot analysis as well. *Results*. The meta-isoform of NO-ASA did not have any effect on CLL cells whereas the para-isomer showed a selective cytotoxic effect. Mean lethal concentrations (LC50) values were 4.83 µM and 4.64 µM in CLL cells, respectively. LC50 values for healthy controls were more than 25-fold higher. Annexin V-FITC/PI staining revealed that the induced cell death is mediated by apoptosis and by Immunoblot analysis we show that p-NO-ASA cleaves PARP, caspase 3 and caspase 9, decreases CTNNB1 protein levels and downregulates WNT pathway target genes in a concentration dependent manner. *Summary and Conclusions*. Our findings show that the para- but not the meta-isomer of NO-ASA induces caspase-mediated apoptosis in CLL cells selectively. The mechanism of action might be mediated by inhibition of β-catenin/Lef-1 signaling since we observed downregulation of specific target gene expression. Therefore p-NO-ASA might be a valuable compound for the treatment of CLL. More investigations of the exact mechanism of action and the specific difference between the positional isomers are indicated.

ZALYPSIS, A NOVEL AND SELECTIVE ANTILEUKEMIC AGENT TARGETING INMATURE BLAST CELL POPULATIONS

E. Colado,[1] P. Maiso,[2] L. González,[1] E.M. Ocio,[1] M.B. Vidriales,[1] A. Pandiella,[2] J.F. San Miguel[1]

[1]Hospital Universitario de Salamanca- Centro de Investigación del Cáncer-IBMCC (U, SALAMANCA; [2]Centro de Investigación del Cáncer-IBMCC USAL, SALAMANCA, Spain

Background. Acute Myeloid Leukemia (AML) is a heterogeneous group of diseases in which coexistence of leukemic cells at different stages of differentiation is frequently found. Zalypsis® is a novel alkaloid from marine origin with promising anticancer activity. *Aims*. To evaluate the activity, potential toxicity and mechanism of action of Zalypsis in AML *Methods*. The efficacy of Zalypsis® was analyzed in four AML cell lines, including drug resistant cell lines, and in cells from fresh bone marrow samples from eight newly diagnosed AML patients. We have used a multiparametric flow cytometry (MFC) technique that allowed us to study both mature and immature blast cell compartments. In addition, fresh bone marrow cells from 4 newly diagnosed Multiple Myeloma (MM) patients were used to evaluate the toxicity on normal hematopoietic progenitor cells (HPC). *Results*. Zalypsis showed a very potent antileukemic activity, with IC50s in the low nanomolar ranges. Zalypsis® potentiated several other antileukemic agents with a synergistic effect observed for the combinations with Doxorubicin, Cytarabine and Fludarabine. Regarding the mechanism of action, Zalypsis® provoked apoptosis with a prompt induction of Annexin V, and PARP, caspase-3, -8, and -9 cleavage in Western-Blot. Zalypsis® also induced loss of mitochondrial membrane potential measured by DioC6, decrease of Bcl-XL and BCL2 and cleavage of Mcl-1. Selective inhibition of caspases with Z-VAD-FMK, did not abrogate Zalypsis®-induced apoptosis, suggesting a role for caspase-independent apoptosis. Zalypsis® induced the phosphorylation of H2AX and increase of GADD45B, suggesting a DNA damage response which was concordant with the results of the GEP that demonstrated the deregulation of many genes involved in DNA damage response. Zalypsis® was also very effective in *ex vivo* experiments on freshly isolated patients' cells. Our MFC technique allowed us to study both mature and immature (defined as $CD34^+$, $CD38^-$ Lin^-) blast cells compartments in AML samples. Zalypsis® efficiently induced apoptosis in the inmature blast cell population, where leukemic stem cells are found. Interestingly, HPC from MM patients (and, therefore, theoretically, normal) were found not to be affected by Zalypsis while antimyeloma activity was preserved, suggesting that normal HPC are not affected by Zalypsis®. *Summary and Conclusions*. Zalypsis® induces a very potent and selective antileukemic effect *in vitro* and *ex vivo*, targeting inmature blast cell populations, which is, at least partially, mediated through a DNA damage response. Moreover, Zalypsis® is sinergistig with conventional anti-AML drugs. These results provide the rationale for the use of Zalypsis® in clinical trials for patients with AML.

K-RAS SHRNA POTENTIATES FARNESYLTRANSFERASE INHIBITOR (FTI) EFFICACY IN CHRONIC MYELOID LEUKEMIA

A. Morgan, F. Onono, M. Scherr, L. Venturini, I. Dallman, A. Ganser, C.W.M. Reuter

Hannover Medical School, HANNOVER, Germany

Approximately 95% of chronic myeloid leukemia (CML) cases are characterized by the Philadelphia translocation t(9;22)(q34;q11), which generates the constitutively active BCR-ABL fusion tyrosine kinase. Major down-stream effectors of BCR-ABL include signal transducers and activators of transcription (STATs), c-Jun NH2-terminal kinase, phosphoinositide 3-kinase and RAS. Deregulated RAS signaling plays an important role in the molecular pathogenesis of myeloid leukemias, and while strategies which target RAS signaling pathways are promising, their full therapeutic potential has yet to be realized. Blockade of RAS membrane localization by inhibiting post-translational modification (e.g. by farnesyltransferase inhibitors = FTIs) is one strategy to impede oncogenic RAS function *in vivo* and FTIs are currently being tested in clinical trials in myeloid leukemias. Importantly, alternative geranylgeranylation of K-RAS and N-RAS by geranylgeranyl transferase I (GGTase I) in the presence of FTIs allows membrane localization of RAS proteins and thus might represent a mechanism of FTI resistance. The aim of this study was to investigate the role of K-RAS in cellular resistance to FTI treatment. To analyze FTI effects on RAS post-translational prenylation, K562 cells were titrated with drugs, harvested, lysed, total cell proteins were separated by 15% SDS-PAGE and RAS-specific protein bands were detected by immunoblotting. Unprocessed RAS proteins were identified as band shifts, which migrate as slightly greater apparent mass than the farnesylated form. Induction of FTI-induced apoptosis was quantified by FACS analysis of Annexin-V stained cells. We generated shRNA constructs targeting two different regions of K-RAS, produced lentiviral supernatants and transduced K562 cells with greater than 96% efficiency as quantified by FACS analysis. Successful knock-down of K-RAS protein levels was detected by immunoblotting. We evaluated two clinically tested FTIs, namely BMS-214,662 (Bristol-Myers Squibb) and L-778,123 (Merck). Both FTIs blocked H- and N-RAS prenylation in K562 cells, but only FTI L-778,123, which possesses an additional activity against GGTase I, also inhibited K-RAS prenylation. FTI BMS-214,662 elicited apoptosis when used as a monotherapy, whereas no apoptotic effects were observed for L-778,123. The BMS-214,662-induced apoptosis was further enhanced by co-administration of FTI L-778,123. These results suggest that while inhibition of K-RAS alone is insufficient to elicit apoptosis, K-RAS inhibition does sensitize K562 cells to BMS-214,662-induced apoptosis. To further test this hypothesis, lentiviral sh-RNA constructs designed to target K-RAS were produced and used to transduce K562 cells. Interestingly, knock-down of K-RAS substantially potentiated BMS-214,662-induced apoptosis. Our results demonstrate that inhibition of K-RAS expression or blockade of its post-translational prenylation increase the ability of FTI BMS-214,662 to induce apoptosis in CML. As oncogenic K-RAS has been demonstrated to play an important role in generation of leukemic stem cells and as FTI BMS-214,662 is the first agent shown to specifically eradicate leukemic stem cells from CML patients, our observations may be useful in directing development of more effective therapeutic strategies.

EXPLOITING THE UNIQUE MECHANISM OF ACTION OF SAPACITABINE (CYC682) TO OBTAIN SYNERGY WITH OTHER THERAPEUTIC AGENTS FOR CLINICAL USE IN ACUTE MYELOID LEUKEMIA

S.M. Frame, R.H. MacKay, M. Hogben, C. Connolly, S. Anderson, I.N. Fleming, S. Davis, D. Blake, S.R. Green

Cyclacel Ltd, DUNDEE, UK

Background. The nucleoside analogue cytarabine (AraC) forms the backbone of therapy for AML. As with other agents in its class, cytarabine is administered intravenously to patients and is thought to act by blocking DNA synthesis, causing cells to arrest in S phase. Sapacitabine (CYC682) is a novel nucleoside analogue that is orally available, is extremely well tolerated and has a unique mechanism of action involving the induction of DNA strand breaks, G2/M accumulation and apoptosis. As a result of promising clinical activity, sapacitabine is currently being evaluated in a Phase 2 trial comprising elderly patients with AML, as well as patients with myelodysplastic syndrome and is in a Phase 2 trial in cutaneous T-cell lymphoma (CTCL). *Aims*. Given that AraC, along with the majority of other anticancer agents are used in combination therapy in the clinic, we sought to perform a screen to evaluate the potential for combining sapacitabine with diverse classes of agents representing those in use or in testing in AML, such as daunorubicin, methyltransferase inhibitors and inhibitors of the histone deacetylases, together with compounds that exploit the mechanism of action of sapacitabine, including inhibitors of DNA repair, cell cycle checkpoints and cell survival. *Methods. In vitro* synergy was assessed in multiple cell lines including AML and CTCL using the Chou and Talalay median effect model, examining both sequential and concomitant treatments. The molecular basis for synergy was explored and the most promising schedules and drug combinations were tested in xenograft models. *Results*. Synergy was observed with demethylating agents, HDAC inhibitors, several topoisomerase inhibitors and inhibitors of the chk1 or aurora kinases. The HDAC combination was analysed further. Synergy was observed independently of the schedule of drug administration and resulted in synergistic increases in cell death. This was attributed to the activation of multiple BH3-only proteins, greater than additive depletion of several anti-apoptotic proteins, including MCL-1 and bclXL and activation of the pro-apoptotic proteins bax and bak. This combination has been evaluated in an MV4-11 model, where significant tumour growth delay and extension of survival was observed over the single agent treatments. Further mechanism of action and xenograft experiments are underway evaluating the most promising additional combinations. Results of the screen and more in-depth analysis of several of the most promising combinations will be presented. *Summary*. This screen has provided the basis for selecting several combinations of further interest and for consideration as part of the clinical development strategy for sapacitabine.

Red blood cells and Iron III

THE EFFECT OF DEFERASIROX ON MYOCARDIAL IRON OVERLOAD AND CARDIAC FUNCTION: A PROSPECTIVE INDEPENDENT MONOCENTRIC STUDY USING CARDIOVASCULAR MAGNETIC RESONANCE T2*

A. Roghi,[1] E. Cassinerio,[2] P. Proto,[2] P. Pedrotti,[1] S. Pedretti,[1] A. Marcon,[2] L. Zanaboni,[2] M.D. Cappellini[2]

[1]Azienda Ospedaliera Niguarda Ca'Granda, MILAN; [2]Hereditary Anemia Center, Department of Internal Medicine, Policlinico IRCCS, MILAN, Italy

Background and Aims. Although deferoxamine in thalassemia major patients reduced organ damage and significantly prolonged life expectancy, its use has limitations that promote inconsistent adherence to treatment. Deferasirox, a new oral iron chelator, has been studied in adults and children. The aim of the study is to evaluate the impact of desferasirox treatment in thalassemia major patients in removing myocardial iron and in improving cardiac function by magnetic resonance T2* (MRI T2*). *Methods*. Forty-one patients (22 females, 19 males, mean age 32±6 years) affected by TM and treated with deferasirox performed 2 MRI evaluations. MRI was performed at baseline (T0) after a variable period of exposure to deferasirox (median: 12 months, range 4-48). The second one (T1) was after 13.6±2.5 months from T0. The MRI studies were performed using a 1.5 Tesla MR scanner (Avanto Siemens, Erlangen). Heart T2* normal values were defined above 20 ms, values under 10 ms were considered as severe iron overload. *Results*. In the overall population at T0 the mean cardiac T2* value was 27.41±10.48, the mean ferritin was 1300±985 and the mean iron intake in the last six months 0.34±0.07. The mean deferasirox dose was 26±7 mg/Kg/day. Despite a different length of deferasirox exposure and a different myocardial iron overload, an average improvement of myocardial T2* from 27.41 ms up to 29.83 ms was observed at T1 (p=0.004). Similarly, a trend of reduction in both end-systolic and end-diastolic left ventricular volumes was observed with an improvement of left ventricular ejection fraction (LVEF) from 63.59 up to 66.46% (p=0.013). The patients have been divided into two groups according to the myocardial iron overload at T0: group A with a T2* > 20 ms and group B with T2* between 10 and 20 ms. Only one male patient had a baseline cardiac T2* value under 10 ms (8.8 ms): at T1, after 13 months, with a daily dose of 40 mg/Kg/day of deferasirox he showed a significant improvement in cardiac T2* (8.8 vs 15.84 ms). In group A myocardial T2* changed from 33.10 to 34.71 ms (p=0.4) while in group B myocardial T2* changed from 15.67 to 19.61 ms (p<0.03). In group A LVEF increased from 65% at T0 to 68% at T1 (p= 0.01). End-diastolic volume (EDV) decreased from 142,7 to 134.8 mL (p=0.01), meanwhile end-systolic volume (ESV) passed from 48.89 to 43.43 mL (p=0.001). In group B LVEF increased from 59.66 up to 64.25% (p=0.04) at T1. EDV decreased from 139.83 to 130.41 mL (p<0.11) and ESV decreased from 56 to 48.25 ml (p=0.03). *Discussion and Conclusions*. Deferasirox reduces myocardial iron overload and improve left ventricular function in thalassemia major patients. Its efficacy is evident not only in those patients with cardiac iron overload but even in patients with heart T2* values above 20 ms. Myocardial T2* improves in concert with cardiac function in a relative short period of time. This confirm the prognostic significance of myocardial T2* and the relevance of the intensification of chelation therapy in patients with moderate/severe iron overload.

DEFERASIROX REDUCES CARDIAC IRON BURDEN IN CHRONICALLY TRANSFUSED B-THALASSEMIA PATIENTS WITH MILD-TO-MODERATE CARDIAC SIDEROSIS AS DEMONSTRATED BY MRI T2*

J. Wood,[1] A.A. Thompson,[2] C. Paley,[3] B. Kang,[3] P. Giardina,[4] P. Harmatz,[5] T Glynos,[3] T. Coates[1]

[1]Children's Hospital of Los Angeles, LOS ANGELES; [2]Children's Memorial Hospital, CHICAGO; [3]Novartis Pharmaceuticals, EAST HANOVER; [4]Weill Cornell Medical Center, NEW YORK; [5]Children's Hospital Oakland, OAKLAND, USA

Background. Cardiomyopathy and congestive heart failure (CHF) resulting from myocardial iron deposition are the leading causes of death in regularly transfused patients with β-thalassemia major (TM). Preclinical and ongoing clinical studies suggest once-daily deferasirox effectively removes cardiac iron as well as controlling liver iron. *Aims*. To evaluate the effects of deferasirox on cardiac iron as examined by cardiac T2* magnetic resonance imaging (MRI) in patients with TM. *Methods*. Patients with MRI-evidence of cardiac iron (T2*<20 ms) and normal left ventric-

ular fraction (LVEF) [≥56%] were enrolled in a prospective, single-arm, multicenter trial. Deferasirox was administered at 30 mg/kg/day with the option to escalate to 40 mg/kg/day if there was <25% improvement in cardiac T2* compared with baseline, provided liver iron concentration (LIC) was ≥3 mg Fe/g dry weight (dw). Serum ferritin (SF) was assessed monthly and MRI assessments of LIC, cardiac T2* and LVEF performed every 6 months. Serum creatinine (SCr), biochemical and hematological status were also monitored. *Results*. Preliminary results from 26 evaluable patients (7 male:19 female; age 10-44 years) are reported. Mean baseline SF was 4307±613 ng/mL (312-12,655), geometric mean cardiac T2* 8.5±1.1 ms (7.7-9.4), mean LIC 19.3±3.2 mgFe/g dw (3.6-62.3) and mean LVEF 61.8±0.8% (55.6-73.3). At 12 months, 8/18 patients were receiving 40 mg/kg/day deferasirox. Cardiac T2* increased from baseline by 1.2 ms (n=18;+14.0%; p=0.02) and LIC decreased by 2.6 mgFe/g dw (n=18; -25%; p=0.02). SF fell by 606 ng/mL (n=17;-23%; p=0.13). LVEF remained stable. At 18 months, 6/15 patients were receiving 40 mg/kg/day deferasirox. Cardiac T2* increased from baseline by 3.2 ms (n=12;+33%; p=0.001) and LIC decreased by 4.7 mgFe/g dw (n=12;-50%; p=0.003; Figure). SF fell by 1057 ng/mL (n=15;-40%; p=0.03). Mean LVEF trended upward by 2.2% (n=12; p=0.15). Of 18 patients completing 12 months, 11 (61.1%) responded to treatment with >4% improvement in cardiac MRI T2*. Of 12 patients completing 18 months, 10 (83.3%) responded to treatment. Baseline cardiac T2* for all responders was ≥6 ms. The most common drug-related adverse events (AEs) were nausea (n=7), diarrhea and rash (n=5). One patient experienced a suspected serious AE (abdominal pain and vomiting requiring hospitalization) but completed the study. Six patients discontinued: two patient decisions, two AEs and two abnormal laboratory/test procedures. Both patients who withdrew due to AEs died; one enrolled with elevated baseline cardiac iron (T2*=1.8 ms) and died secondary to CHF 4 days after withdrawing. The other was due to sepsis and multi-organ failure 3 months after patient withdrawal. Three patients developed SCr >upper limit of normal (ULN) on two consecutive occasions. Two patients (8%) had abnormal transaminases (≥5xULN) on ≥2 occasions; both had abnormal values at baseline and were considered treatment-related. Both patients remained on study. *Conclusions*. Deferasirox (30-40 mg/kg/day) resulted in significant improvements to cardiac and hepatic iron after 12 and 18 months. Patients whose cardiac T2* improved over the course of treatment had a baseline T2*>6 ms, suggesting that for patients below this threshold, more intensive therapy is warranted. AEs were consistent with previous observations.

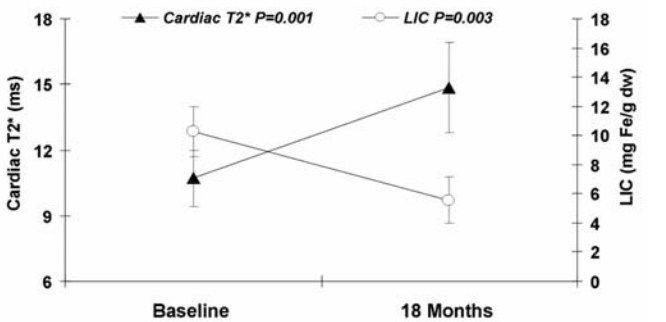

Figure. Mean change (±SEM) in cardiac T2* and LIC from baseline in patients completing 18 months of deferasirox therapy (n=12).

0764

FLUCTUATION OF CYSTATIN C CONCENTRATION DURING DEFERASIROX TREATMENT IN THALASSEMIC PATIENTS MAY REFLECT HEMODYNAMIC CHANGES

I. Papassotiriou,[1] A. Margeli,[2] E. Hantzi,[2] P. Delaporta,[3] V. Ladis,[3] A. Kattamis[3]

[1]*Aghia Sophia Childen's Hospital, ATHENS;* [2]*Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, ATHENS;* [3]*First Department of Pediatrics, Athens University Medical School, ATHENS, Greece*

Background. Deferasirox (Exjade®, ICL670) is an once-daily, oral iron chelator for the treatment of transfusional iron overload and its efficacy and tolerability have been established in adults and children with a range of transfusion-dependent anemias, such as thalassemia. We observed alterations in cystatin C plasma concentration during longterm treatment of thalassemia patients with deferasirox. Cystatin-C is a non-glycosylated protein that belongs to the cystatin superfamily of cysteine protease inhibitors. Plasma cystatin-C has been suggested to be an ideal endogenous marker of glomerular filtration rate (GFR). *Aims*. To investigate if these changes in cystatin C concentration were solely due to deferasirox treatment, or whether other factors contribute to these changes. *Methods*. 150 β-thalassemia patients treated with deferasirox at doses between 20-40 mg/Kg/day were followed longitudinally. Cystatin C concentrations were measured by an immunonephelometric technique (Dade Behring, Siemens Healthcare Diagnostics) at regular monthly intervals (5-12 monthly serial measurements per patient), while GFR was calculated according to the recently proposed cystatin C-based prediction equation using only its concentration in mg/L: GFR [mL/min/1.73m(exp)2] = 76.7 x Cystatin C(exp)-1.18. To further evaluate the effect of deferasirox on renal function we measured: a) plasma levels of Neutrophil-Gelatinase-Associated-Lipocalin (NGAL) (R&D Systems) a protein expressed on tubular cells and which production is markedly increased in response to harmful stimuli, such as ischemia or toxicity, b) N-terminal pro-B-type natriuretic peptide (NT-proBNP) (Roche Diagnostics), in order to correlate cystatin C fluctuation with left ventricular ejection fraction (LVEF) and c) ferritin level, as a marker of iron overload/mobilization. *Results*. The main results of the study showed that cystatin C concentration fluctuated during deferasirox treatment (ANOVA repeat measures p>0.850). Baseline mean values were 0.97±0.27 mg/L and reached a maximum of 1.01±0.29 mg/L at 4 months of treatment. According to the guidelines and as no significant increase of creatinine levels was observed, the drug dose was not reduced. Analysis of data showed that: a) there is no correlation between cystatin C fluctuation and NGAL levels, p>0.6745, evidence that the tubuloglomerular feedback is not activated b) cystatin C and NT-proBNP levels correlated positively with a binomial equation (p<0.004) and c) cystatin C and ferritin levels correlated positively with also a binomial equation (p<0.001). *Conclusions*. These findings suggest that cystatin C fluctuation during deferasirox treatment do not reflect renal injury. Hemodynamic signals, LVEF alterations and iron mobilization seem to play central role on changes of cystatin C.

0765

MALE AND FEMALE FERTILITY AND PREGNANCY IN THALASSAEMIA MAJOR, THE WHITTINGTON EXPERIENCE

J. Muthalali,[1] F. Shah,[2] E. Prescott[2]

[1]*University College Hospital London, LONDON;* [2]*The Whittington Hospital NHS Trust, LONDON, UK*

Background. Advances in the care with transfusion and chelation therapy has improved survival into adulthood and the health of adult thalassaemics giving us new challenges.Quality of life has improved as has expectation to have a family.The pituitary and hypothalamus are very sensitive to iron damage and hypogonadotrophic hypogonadism is a frequent complication.Ovulation induction or spermatogenesis techniques can be used to induce fertility. *Aims*. To examine both male and female fertility and pregnancy outcomes in patients with transfusion dependant thalassaemia who are under the care of the Whittington Hospital Thalassaemia Unit. *Methods*. An observational study spanning a twenty year period. *Results*. In total there were 41 successful pregnancies and 1 reported miscarriage in a total of 30 patients with transfusion dependant thalassaemia. Of 21 pregnancies in 16 female patients 11 were assisted conceptions, the majority being ovulation induction. 2 women had moderate cardiac iron overload at the time of conception one of which was given desferrioxamine from 25/40, and one woman had mild cardiac iron overload.2 women had severe liver iron overload at the time of conception one of which was started on desferrioxamine at 20/20. 4 had moderate liver iron overload and 2 had mild liver iron overload. Of the deliveries the majority were caesarean section. Of 21 conceptions in 14 male patients 6 were assisted either by spermatogenesis or invitrofertilisation (IVF)/intracytoplasmic sperm injection (ICSI). At the time of conception there was one patient with severe, 2 with moderate and 2 with mild cardiac iron overload.1 patient had severe liver iron overload with 5 having moderate and 5 having mild liver iron loading. *Conclusions*. Just over half of female thalassaemia major patients require assisted conception techniques. Pregnancy has been relatively uncomplicated for the majority even with some degree of cardiac iron overload. Desferrioxamine on a reduced dosing schedule in the second trimester onwards in patients with cardiac or liver iron overload has been used successfully. In male patients around a quarter require assisted conception techniques and there is often the need for intracytoplasmic sperm injection (ICSI). There have also been uncomplicated pregnancies with successful outcomes in patients who were on deferiprone at the time of conception.

0766

INFLAMMATORY MEDIATORS INDUCE AUGMENTED ADHESIVE PROPERTIES IN NEUTROPHILS FROM CONTROL AND SICKLE CELL DISEASE INDIVIDUALS, IN ASSOCIATION WITH ALTERED INTRACELLULAR CYCLIC AMP

I. Miguel, A. Canalli, B. Almeida, T.O. Saad, F. Costa, N. Conran

UNICAMP, CAMPINAS, SP, Brazil

Background. Leukocytes play a role in the initiation and propagation of vaso-occlusion in sickle cell disease (SCD). *Aims*. To investigate whether the chronic inflammatory state, characteristically observed in SCD, may participate in the activation of SCD leukocytes, this study evaluated whether inflammatory mediators that are typically elevated in SCD plasma are capable of increasing the adhesive properties of neutrophils from healthy controls and from SCD patients and the signaling pathways that may be involved in this adhesion. *Methods*. Neutrophils (neu) were separated from the peripheral blood of healthy control individuals (CONneu) and SCD patients in steady state (SCDneu) over a ficoll-paque gradient. Following washing and lysis of contaminating red cells, neu were resuspended in RPMI medium and allowed to adhere to recombinant fibronectin (FN)-coated 96-well plates (5×10^6 cells/mL; 30 min, 37oC, 5% CO_2) in the presence of inflammatory mediators. Adhesion to FN was calculated as the percentage of the original cell suspension adhered. *Results*. As previously demonstrated, SCDneu adhesion to FN is significantly higher than that of CONneu (18.7±2.2%; 10.6±1.3%, respect. N≥10, $p<0.001$). The inflammatory mediators, prostaglandin E1 (PGE1, 10-50 μM) and Prostaglandin E2 (PGE2, 10-50 μM), did not significantly alter the adhesion of neither CONneu nor SCDneu to FN (results not shown, $p>0.05$). Co-incubation of neutrophils with the growth factor, GM-CSF (1-100 ng/mL), found in elevated levels in the plasma of our population of SCD patients, was capable of significantly increasing both CONneu and SCDneu adhesion to FN (11.7±2.4% basal adhesion, increased to 20.8±3.3% with 100ng/mL GM-CSF; n=7, $p<0.001$ for CONneu and 18.7±3.3% increased to 36.0±4.5% with 100ng/mL GM-CSF; n=4, p0.05). IL-8 (500ng/mL) and IL-6 (10pg/mL) also significantly increased both CON and SCD neu adhesion to FN. CONneu adhesion increased from 9.4±1.4% to 27.6±1.2% and 12.8±1.9% with IL-8 and IL-6, respect. (n≥3, $p<0.001$ and $p<0.05$, respectively). SCDneu adhesion increased from 16.7±3.0% to 30.3±4.5% and 22.4±3.5% with IL-8 and IL-6, respect., (n≥3, $p<0.05$). TNF-α significantly increased SCDneu adhesion (17.9±3.3% increased to 38.2±6.2% and 39.7±6.8% with 0.5 and 1.0 μg/mL TNF-α), but not CONneu adhesion (*data not shown*). Augmentation of CONneu adhesion by GM-CSF, IL-8, IL-6 and TNF-α is accompanied by significant increases in intracellular cAMP levels, a second messenger known to be encountered in elevated concentrations in SCDneu. Basal cAMP in CONneu was augmented by 135.8±20.3%; 127.7±22.1%; 60.1±24.2% and 64.7±20.2% following incubation (30 min, 37oC) with 10 ng/mL GM-CSF, 500 ng/mL IL-8, 10pg/mL IL-6 and 100 ng/mL TNF-α, respectively. N≥4; $p<0.05$. *Conclusions*. Results indicate that the chronic inflammatory state that is characteristic of SCD may contribute to the activation of leukocytes and their augmented adhesive properties, which in turn play an important role in the vaso-occlusive process. Alterations in adhesive properties are accompanied by alterations in intracellular cAMP, a second messenger known to alter leukocyte adhesive properties. Further studies may indicate whether the cAMP-protein kinase A pathway may represent a therapeutic target for the inhibition of leukocyte adhesion to the vascular wall.

NEUTROPHILS ARE SUBJECT TO BOTH ANTI AND PRO APOPTOTIC STIMULI IN THE SERUM OF SICKLE CELL DISEASE INDIVIDUALS

C. Almeida, F. Pereira, I. Lorand-Metze, C. Franco-Penteado, S. Saad, F. Costa, N. Conran

Unicamp, CAMPINAS, Brazil

Background. Leukocytes play a central role in the sickle cell disease (SCD) vaso-occlusive process by adhering to the vascular endothelium and participating in oxidative stress and inflammation mechanisms. The relevance of neutrophil (neu) death to inflammatory disease pathogenesis is recognized, since alterations in leukocyte apoptotic processes may affect cellular function and inflammatory processes. *Aims*. This study investigated the effect of serum from control individuals (CON), SCD steady-state patients (SCD) and SCD patients on hydroxyurea therapy (SCDHU; 20-30 mg/kg/dayHU) on the apoptotic processes of neutrophils. *Methods*. Neu were separated from whole blood using ficoll-paque. Pools of serum were prepared by mixing serum from 18 individuals from each subject group. Neu (4×10^6cells/mL) were cultured in the presence of serum (10%v/v) for 16h (37°C, 5%CO_2) in RPMI. Apoptosis was evaluated by detection of annexin V binding; SOD levels were determined by ELISA. *Results*. CONneu and SCDneu were cultured in the presence of CONserum; SCDneu presented increased cell survival at 16h compared to CONneu cultured with CONserum (51.3±3.4; 40.6±3.0%; n≥12; p=0.02). In contrast, when CONneu were cultured in the presence of SCDserum, cells demonstrated a significantly lower percentage of non-apoptotic cells (40.9±15.1%; n=8), compared to CONneu cultured with CONserum (53.6±12.2%; n=8; p=0.0001 comp. SCD) or SCDHUserum (52.9±13.6%; n=8; $p<0.0001$ comp. SCD). CONneu were further co-incubated with serums and cytokine-neutralizing antibodies (IL-6; IL-8; TNF-α; GM-CSF). Anti-IL-8 (10μg/mL) reduced the number of non-apoptotic neutrophils following their culture in SCDserum (reduced from 42.1±2.3% to 37.3±2.5%; n=7; $p<0.05$); combinations of the anti-IL-8 with other cytokine-neutralizing antibodies did not further reduce CONneu survival when cultured in SCDserum ($p>0.05$). Despite the induction of apoptosis by SCDserum, activities of the caspase 3 and 8 enzymes were not significantly altered in CONneu cultured for 16h in SCDserum, compared to cells cultured in CON/SCDHUserum (data not shown), suggesting that SCDserum may exert a caspase-3-independent effect upon apoptosis. Intracellular reactive oxygen species (ROS) production has been reported to induce caspase-independent neutrophil apoptosis. Interestingly, significantly lower levels of superoxide dismutase (SOD), an enzyme that degrades superoxide, were found in SCDserum, compared to CONserum (12.4±2.8; 8.7±2.2; 14.2±4.7 U/mL; for CON, SCD, SCDHU resp, n≥8; $p<0.01$). When CONneu were co-incubated with serums and SOD (300U/mL), we observed a higher cell survival, compared to cells not incubated with SOD (survival increased by 24.8±8.2; 19.3±9.6; 11.9±5.4% for CON, SCD, SCDHU, resp.; n=7; $p<0.02$ comp to without SOD), indicating that superoxide production appears to contribute to neutrophil apoptosis. Conclusions: Whilst Neu from SCD may present an increased cell survival that could contribute to leukocytosis, these cells are subject to both anti- and pro-apoptotic stimuli in the serum of these individuals. Circulating cytokines, such as IL-8, may increase cell survival and production of ROS while decreased levels of serum antioxidants may augment cell death. Since alterations in neutrophil apoptotic processes may have significant effects on neutrophil function and number, in turn contributing to inflammatory processes and cellular damage at sites of inflammation, studies to understand the complex balance of these mechanisms in SCD are necessary.

CREATING A EUROPEAN NETWORK OF EXPERT CENTRES ON RARE ANAEMIAS: A NEW CHALLENGE FOR ENERCA 3

J.L. Vives Corrons, M.d.M. Mañú Pereira

Hospital Clínic, BARCELONA, Spain

Background. ENERCA "European network for Rare and Congenital Anaemias" is co-funded by the European Commission (Public Health and Consumer Protection Directorate). Its website www.enerca.org is functional since 2001. The purpose of ENERCA is to improve the quality of life of patients with rare anaemia (RA) by increasing the efficacy of diagnosis, treatment and follow up. *Objective.* The main objective of ENERCA 3 is the establishment of a European Reference Network (ERN) of Expert Centres (EC) in RA. The ERN will serve as a platform for the provision of high quality information and services to health professionals, patients and other stakeholders such as health authorities and pharmaceutical industry. *Methods.* The partners involved in the Project will be 48 in total: 24 Associated and 24 collaborating covering the majority of MS. Most of the partners have been working together since 2002, and all are well known and recognized experts in their respective field. General methodology is designed on the basis of three transversal Work packages (WPs): WP1 "Networking of expert centres"; WP2 "Quality of patient care" and WP3 "Education and training" and three specific WP devoted to the public health issues and management of patients with RA: WP4 "Sickle Cell Disorders"; WP5: "Thalassaemia"; and WP6 "Very rare Anaemias". Three additional WP have been also designed in order to guarantee the Project management: WP7 "Evaluation", WP8 "Dissemination" and WP9 "Coordination". The methods to be undertaken are focused on creation of a consensus criteria proposal necessary to be fulfilled by an Expert Centre of the European Reference Network in Rare Anaemias, analysis of legal framework for referral of patients and samples among Member States in order to overcome the current legal barriers existing due to the different national rules and laws, the establishment of close links between experts in order to gather epidemiological data by means of the creation of a European Registry for patients with Rare Anaemias, elaboration of standardized guidelines for clinical procedures and the development of educational and training activities such as medical courses, continuous e-learning and material for the popularization of rare anaemias knowledge and assure quality services for patients. *Results*. Project outcomes will include the consolidation of the European Reference Network of Expert Centres in rare Anaemias, the promotion of the harmonization of diagnostic procedures by means of the elaboration of a comprehensive catalogue of External Quality Assessment Schemes (EQAS) in RA and the production of standardized guidelines, comparable epidemiological data and a better knowledge of the status of RA in the Member States due to the creation of the European Registry for patients with RA, and the increase of knowledge and awareness about RA by health professionals, patients and public in general by means of the production of training and educational material for professionals and patients. *Conclusions*. The achievement of the Project's objectives and outcomes will contribute to the improvement of health and quality of life of patients with RA by increasing the efficacy of patient's diagnosis, treatment and follow up.

BILIRUBIN LEVELS AND TATA BOX POLYMORPHISM OF UGT1A1 GENE ASSOCIATED TO GILBERT'S SYNDROME IN THE DIFFERENT CLINICAL FORMS OF HEREDITARY SPHEROCYTOSIS

S. Rocha

Faculdade de Farmácia/Instituto de Biologia Molecular e Celular (IBMC), PORTO, Portugal

Hereditary Spherocytosis (HS) is the most common non-immune hemolytic anemia in individuals of northern European ancestry, ranging from an asymptomatic condition to a severe life-threatening anemia. HS is usually classified as mild, typical or severe according to the severity of the symptoms and analytical presentation, namely, hemoglobin (Hb) concentration, reticulocyte count and serum bilirubin levels. Splenectomy, when performed, corrects the anemic state. In HS, because of hemolysis and consequent heme breakdown, plasma bilirubin increases. This toxic compound is metabolized in the liver by uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1); however, when the activity of this enzyme is decreased, as occurs in Gilbert's syndrome (GS), a mild hyperbilirubinemia may arise. The co-inheritance of HS and GS can increase hyperbilirubinemia, and therefore, it may difficult the clinical classification of HS. The aim of our work was to evaluate bilirubin levels in HS patients according to UGT1A1 gene polymorphisms. We studied 132 Portuguese subjects: 106 were diagnosed with HS by standard screening tests (38 were splenectomized) and 26 were healthy individuals. The unsplenectomized patients were classified as having mild (n=43), moderate (n=18) and severe (n=7) HS, according to Guidelines for the diagnosis and management of Hereditary Spherocytosis (Bolton-Maggs *et al.*; Br. J. Haematol.; 2004). The TA insertion in the repetitive TATA box sequence (usually of 6 repeats) of the UGT1A1 gene promoter was screened by acrylamide gel (15%) analysis of polymerase chain reaction products. The studied subjects were grouped according the gene polymorphisms, namely, (TA)6/(TA)6 for homozygote individuals with normal UGT1A1 transcription, (TA)6/(TA)7 for heterozygote individuals and (TA)7/(TA)7 for individuals with decreased enzyme activity associated GS. We found that in splenectomized HS patients Hb concentration was similar to controls and that reticulocyte count and bilirubin levels were statistically and significantly increased. In unsplenectomized patients the same results were observed, with the exception of Hb concentration which was significantly lower. Also, Hb concentration decreased significantly and reticulocytes and bilirubin increased significantly with HS severity. Regarding the UGT1A1 polymorphism, we found that, in all of the studied groups (controls, splenectomized and total unsplenectomized patients), bilirubin was higher in (TA)7/(TA)7 individuals, followed by the (TA)6/(TA)7 and (TA)6/(TA)6 subjects, respectively. When we evaluated the unsplenectomized patients according to HS severity, we observed that in mild HS patients, (TA)7/(TA)7 individuals presented significantly higher values of bilirubin in relation to the other genotypes. Moreover, these individuals presented higher bilirubin levels even in relation to (TA)6/(TA)6 and (TA)6/(TA)7 moderate HS patients. Because we had only one patient with moderate HS and no severe HS patients with the (TA)7/(TA)7 genotype we could not ascertain about their bilirubin levels. Our data show that in mild HS patients with co-inheritance of GS, the observed hiperbilirubinemia was not in agreement with the typical mild HS presentation. Therefore, in HS clinical severity classification, it should always be considered the observed and the expected bilirubin values in accordance with the other clinical and analytical parameters used to classify HS.

This study was supported by a PhD grant (SFRH/BD/22442/2005) attributed to S. Rocha by FCT and FSE.

CARDIAC IRON OVERLOAD AFTER TREATMENT WITH ANTHRACYCLINES IS MODULATED BY HFE GENOTYPE

A. Cascales,[1] B. Sanchez-Vega,[2] F. Pastor,[2] J. Corral,[1] V. Vicente,[1] F. Ayala[3]

[1]Centro Hemodonacion, MURCIA; [2]Hospital Reina Sofia, MURCIA; [3]Hospital Morales Meseguer, MURCIA, Spain

The key role of iron in anthracycline-related cardiotoxicity, have raised the question that pre-existing genetic iron overload may amplify the iron-based toxicity of anthracyclines. Miranda *et al.* (Blood, 2003), in a murine model showed that mutations in the HFE gene are associated with higher anthracycline cardiotoxicity than expected in the presence of normal iron metabolism, however, there is not clinical data relating HFE mutations and anthracycline cardiotoxicity. *Aims*. The aim of this work was to evaluate the cardiac iron deposits induced by anthracyclines in necropsies obtained from cancer patients, and determine if iron deposits after treatment with anthracyclines is modulated by the HFE genotype of the patients. *Methods*. We retrospectively studied 97 clinical necropsies from patients with a solid or haematological tumour treated in the Hematology and Oncology Department between 1996 and 2005. Inclusion criteria were histologically confirmed diagnosis of cancer, availability of complete clinical record, existence of archived heart and liver histological tissue. Clinical, histopathology, molecular and iron deposition studies were performed. Determination of heart and liver iron concentration (iron mg/g of dry tissue) was determined in all cases in which formalin fixed tissue was available for atomic absorption spectroscopy. HFE gene mutation (C282Y, H63D), was determined by Light Cycler polymerase chain reaction. Statistical analysis was performed using SPSS program version 15.0 and SNPStats software. *Results*. DNA of enough concentration and integrity for genotyping C282Y and H63D polymorphisms was obtained in 93 cases. The distribution of HFE genotypes in the group of patients with data of heart iron load showed 13 cases heterozygous for H63D (G/C), and 4 for C282Y (C/T). Iron load was determined in 47 cardiac and 48 liver samples. 30 (63%) of them were included in the subgroup of patients treated with anthracyclines-based chemotherapy. C282Y heterozygous patients showed a trend to have higher iron deposits than patients not carrying mutations

(0.58 vs 0.31 mg/gr dw, p=0.08). Moreover, C282Y heterozygous patients treated with anthracyclines had a tendency to have higher iron load in heart (0.75 vs 0.08 mg/g dw, p=0.06) than patients not treated with anthracyclines, although these differences were not statistically significant. Haplotype analysis showed an association between higher iron deposits in heart tissue and the haplotype C282Y-T/H63D-G (OR: 0.3, 95% CI 0.02-0.57; p=0.03). Anthracycline treatment increased the OR to 0.55 (0.22-0.87, p=0.09) in patients with this haplotype. A cumulative anthracycline dose greater than 200 mg/m^2 was associated with a higher iron concentration in heart tissue (0.49 vs 0.24 mg/gr; T-Student, p=0.01). Although the number of red-cell transfusions was correlated with liver iron load (R: 0.75; p<0.001), an association of transfusion history with heart iron deposit was not found in our series (p=0.32). Ferritin plasma levels (p=0.31), liver iron load (p=0.24), or diagnosis of hemosiderosis (p=0.16) were also not related to heart iron load. *Conclusions*. Our study strongly sustains that anthracycline treatment induces a specific heart iron overload independent of systemic iron load. Furthermore, anthracycline induced heart iron overload can be influenced by the HFE genotype of the patient, which is in accordance with previously published experimental data.

MRI LIVER IRON MEASUREMENT IN PATIENTS WITH TRANSFUSIONAL IRON OVERLOAD: DIFFERENT TECHNIQUES, DIFFERENT RESULTS, DIFFERENT THERAPEUTIC CONSEQUENCES?

H. Cario, A. Schulz, M. Juchems, A. Wunderlich

University Hospital, ULM, Germany

Background. Liver iron measurement plays a central role in the management of patients with transfusional iron overload. The development of non-invasive methods to assess liver iron requires calibration by parallel liver iron analysis in biopsy samples. For institutions with a limited number of patients this is not feasible. Therefore, the use of elsewhere established algorithms to calculate liver iron using locally generated MRI data represents an attractive alternative diagnostic possibility. *Aims*. To compare the results of liver iron measurement assessed by two MRI methods based on published validated protocols for liver iron calculation from standardized MRI sequences. *Methods*. Twenty-four patients with transfusional iron overload (median age 18.3yrs., range 2.9-38) underwent MRI for liver iron measurement. Examination with spin echo (SE) was performed according to the protocol developed by St. Pierre *et al.*[1] Gradient echo (GRE) sequences were acquired as published by Gandon *et al.*[2] In four patients with high liver iron additional GRE sequences were evaluated as proposed by Rose *et al.*[3]

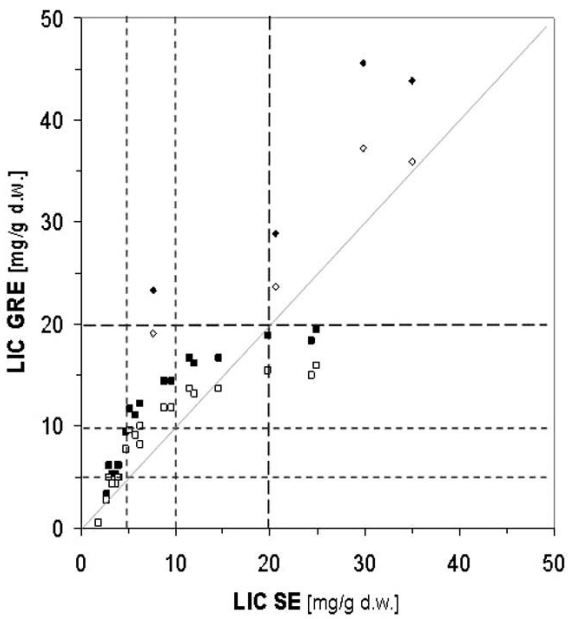

Figure 1. Liver iron assessed by GRE and SE MRI. Filled symbols represent GRE values before, empty symbols those after conversion (F=0.818). GRE values > 20mg/g d.w. were calculated according to Rose et al.[3], lower values according to Gandon et al.[2]

Results. The two MRI methods revealed different results for the liver iron concentration although a significant correlation between them was found (r=0.89, p=0.001). Values generated by GRE sequences (median 13.3mg/g dry weight (d.w.), range 0.6-45.6) were generally higher than those obtained by SE examinations ((median 6.9mg/g d.w., range 0.8-35). Since the calibration of both methods based on direct liver iron analysis in differently processed biopsy specimen (paraffin-embedded samples vs. fresh tissue) published conversion factors were applied to harmonise the results. However, even thereafter, data obtained by GRE remained higher than those from SE analyses. Regarding suggested values defining the optimal range for chelation therapy and the increased risk of cardiac complications, the discrepancies between both MRI methods may be of clinical relevance: 15/24 SE and 12/24 GRE liver iron values (after conversion) were lower than 9.6 mg/g d.w., 4/24 SE and 9/24 GRE values were greater than 9.6 but lower than 20 mg/g d.w., and 5/24 SE and 3/24 GRE values were above the critical threshold of 20 mg/g d.w.. Both, SE and GRE liver iron values correlated to serum ferritin levels (r=0.85 and r=0.81, p=0.00025). *Conclusions*. According to the original publications both MRI methods compared here were accurately calibrated and validated. Nevertheless, in our study they revealed different results which in individual patients could lead to different decisions concerning the management of chelation therapy. Further studies are necessary to confirm this single centre experience. If absolute values of a specific method are used to adjust treatment in an individual patient it is essential to consider the original source of the calibration data of the MRI method with regard to the processing of liver biopsy specimen.

EFFICACY AND SAFETY OF DEFERASIROX IN CHELATION-NAÏVE PATIENTS WITH B-THALASSAEMIA MAJOR: RESULTS FROM THE LARGE-SCALE EPIC STUDY

A. Taher,[1] A. Koren,[2] H. Tamary,[3] M.D. Cappellini,[4] J.B. Porter,[5] D. Habr,[6] G. Domokos,[7] B. Roubert,[7] V. Viprakasit[8]

Background. Patients with β-thalassaemia major are diagnosed during infancy, requiring lifelong transfusions and early chelation therapy to prevent complications related to iron overload. Previous deferasirox studies in β-thalassaemia major patients predominantly included those who had received prior chelation therapy; a further focus of clinical interest is to assess the safety and efficacy of deferasirox in patients who are chelation-naïve. The large, 1-year, prospective, multicenter EPIC trial, evaluating the efficacy and safety of the once-daily oral chelator deferasirox in patients with transfusion-dependent anaemias, included 937 patients with β-thalassaemia major, of whom 66 were chelation-naïve. *Aims*. To assess the efficacy and safety of deferasirox in chelation-naïve patients with β-thalassaemia major participating in the EPIC study. *Methods*. Patients enrolled in the EPIC study were aged ≥2 years with transfusional iron overload as shown by serum ferritin (SF) levels of b1000 ng/mL, or <1000 ng/mL, but with a history of multiple transfusions (>20 transfusions or 100 mL/kg of blood), and liver iron concentration (LIC) of >2 mg Fe/g dry weight confirmed by R2 magnetic resonance imaging. Deferasirox was dosed at 10-30 mg/kg/day dependent on transfusion requirements; dose adjustments of 5-10 mg/kg/day (range 0-40 mg/kg/day) were performed every 3 months based on SF trends and safety markers. The primary efficacy endpoint was change in SF from baseline to 52 weeks. *Results*. 66 patients with β-thalassaemia major (37 male:29 female; mean age 6.5±5.97 years) aged b2-<6 (n=40), 6-<12 (n=20), 12-<16 (n=1) and 16-<50 years (n=5), who were chelation-naïve at study entry were included in this analysis. Median SF at baseline was 3080, 6045, 8526, and 3745 ng/mL in the b2-<6, 6-<12, 12-<16, and 16-<50 years age groups, respectively. The Table 1 below summarizes the SF results by age group. Of 66 patients, two (3%) discontinued due to

gastrointestinal adverse events (AEs) and abnormal laboratory values (both n=1). The most common investigator-assessed drug-related AE was rash (n=3, 4.6%). There were no investigator-assessed serious drug-related AEs. 23 patients (34.8%) had serum creatinine >33% above baseline on two consecutive visits, and one patient (1.5%) had serum creatinine >33% above baseline and the upper limit of normal (ULN) on two consecutive visits; there were no progressive increases.

Table 1. Median change from baseline in SF (ng/mL) by age group.

			Baseline		End of study	
Age groups	Mean actual dose ± SD, mg/kg/day	Mean iron intake ± SD, mg/kg/day	n	Median SF	n	Median change from baseline in SF
≥2–<6 years	23.8 ± 3.0	0.72 ± 0.28	40	3081	39	440
6–<12 years	23.7 ± 2.8	0.61 ± 0.21	20	6045	20	–620
12–<16 years	25.1	0.48	1	8526	1	–2174
16–<50 years	23.0 ± 4.9	0.43 ± 0.39	5	3745	4	21
All patients	23.7 ± 3.0	0.66 ± 0.28	66	3439	64	98

Summary and conclusions. In this cohort of chelation-naïve patients with β-thalassaemia major, the effect of deferasirox on SF was reflective of baseline SF, transfusional iron intake and average actual dose received during the study. This effect is similar to that seen in the overall population of patients with thalassemia major enrolled in the study, which included 93% of patients who had received prior chelation therapy.[1] Patients aged 6-<12 years had a substantial reduction in SF with an average actual dose of 23.7 mg/kg/day. In patients aged ≥2-<6 years, despite receiving a similar average actual dose, this dose was suboptimal because of the high transfusional iron intake and known pharmacokinetic profile (lower steady state exposure compared to adults) in paediatric patients.[2] These results further highlight the need of having individualized dose titration guided by iron burden, iron intake and SF trends. In this chelation-naïve young patient population, deferasirox was safe and generally well tolerated with a very low discontinuation rate.

GENE EXPRESSION OF THE IL-6/STAT-3/HAMP SIGNALING PATHWAY IN MONONUCLEAR CELLS IN SICKLE CELL DISEASE

S. Gambero,[1] M.A.C. Bezerra,[1] C. Lanaro,[1] C.F. Franco-Penteado,[1] K.Y. Fertrin,[1] M.R.B. Mello,[1] D.M. Albuquerque,[1] S.T.O. Saad,[1] A.S. Araujo,[2] F.F. Costa[1]

[1]UNICAMP, CAMPINAS; [2]HEMOPE, RECIFE, Brazil

Hepcidin is a key regulatory hormone of iron metabolism and its upregulation in monocytes causes ferroportin internalization and iron retention in patients with anemia of inflammation mediated by stimulation of the IL-6/STAT-3 signaling pathway. Sickle cell disease has been recently associated to a chronic inflammatory state. We hypothesized that sickle cell disease could cause elevation of the expression of hepcidin, leading to iron retention in mononuclear cells by activating the same pathway. We determined gene expressions of the IL-6/STAT-3 pathway in samples of healthy controls (n≥10), steady-state sickle cell anemia (SCA) patients, SC disease (SC) and three groups of HbS-β thalassemia (HbS/β0-CD39 C->T; HbS/IVS1-nt5 G->C and HbS/IVS1-nt6 T->C) (n≥5 for each group), transfusion-independent patients and not on hydroxyurea treatment. Mononuclear cells were separated from whole blood before extracting mRNA, and synthesizing cDNA. Quantification of gene expression was performed by Real-Time PCR for the following genes: HAMP (hepcidin), SLC40A1 (ferroportin) and IL-6 relative to β-actin and GAPDH genes. HAMP gene expression was significantly increased in sickle cell anemia compared to controls (0.97±0.27 vs. 0.20±0.03, p=0.017), but not in other sickle cell disease groups (SC 0.62±0.35, HbS/β0-CD39 0.54±0.43, HbS/IVS1-nt5 0.24±0.06, HbS/IVS1-nt6 0.40±0.08, p>0.05). SLC40A1 (SS 0.51±0.13, SC 0.57±0.12, HbS/β0-CD39 0.71±0.11, HbS/IVS1-nt5 0.65±0.13, HbS/IVS1-nt6 0.38±0.06, control 0.57±0.08, p>0.05) and STAT-3 (SS 1.16±0.23, SC 1.02±0.23, HbS/β0-CD39 0.82±0.13, HbS/IVS1-nt5 1.23±0.32, HbS/IVS1-nt6 0.82±0.08, control 0.89±0.21, p>0.05) expression did not differ among groups. IL-6 was studied only in sickle cell anemia samples and confirmed no difference compared to controls (SS 0.18±0.02 vs. control 0.17±0.06, p>0.05). Our data suggest that although hepcidin is upregulated in mononuclear cells of sickle cell anemia patients, it is probably not influenced by the IL-6/STAT-3 pathway since there is no accompanying upregulation of IL-6 or STAT-3. Absence of downregulation of SLC40A1 probably correlates with the fact that hepcidin is able to internalize ferroportin, rather than downregulate SLC40A1 gene transcription. Iron retention in mononuclear cells in sickle cell disease has different physiopathological mechanisms from those found in mononuclear cells in anemia of inflammation and further studies should elucidate the underlying pathway and its function in sickle cell disease monocytes.

OXIDATIVE STRESS AND GENE EXPRESSION OF INFLAMMATORY MEDIATORS IN MONONUCLEAR CELLS IN SICKLE CELL DISEASE

K. Fertrin, M. Bezerra, C. Lanaro, C. Franco-Penteado, S. Gambero, M. Mello, D. Albuquerque, S. Saad, A. Araujo, F. Costa

UNICAMP, CAMPINAS, Brazil

Inflammation, cell adhesion to vascular endothelium, and endothelial injury appear to contribute to sickle cell anemia (SS) vaso-occlusion. Furthermore, blood levels of inflammatory and anti-inflammatory cytokines (TNF-α, IL-6, IL-10), as well as reactive oxygen species (ROS) are reported to be elevated, both in steady state and during crisis, but reports have been conflicting and a conclusive role for these molecules in the disease remains to be established. The aim of this study was to evaluate gene expression of inflammatory mediators and ROS production in mononuclear cells in healthy controls (n≥6) and SS, SC disease and three groups of HbS-β thalassemia (HbS/β0-CD39 C->T; HbS/β+-IVS1-nt5 G->C and HbS/β+-IVS1-nt6 T->C, n≥5 for each group), transfusion-independent patients, not on hydroxyurea treatment. qRT-PCR analysis was use to examine expression of the following genes: TNF-α, IL-8, IFN-γ, IL-10 and heme oxygenase-1 (HMOX-1), which breaks down heme released during hemolysis and protects tissue against oxidative stress. For ROS measurement, the isolated cells were incubated with 2'-7'-dichlorofluorescin diacetate (DCF) and analyzed by flow cytometry. TNF-α expression was significantly higher in SS individuals, when compared to control individuals (0.34±0.06 vs. 0.13±0.03, p=0.0089), but not in the remaining groups (SC 0.07±0.04, HbS/β0-CD39 0.06±0.02, HbS/β+-IVS1-nt5 0.02±0.004, HbS/β+-IVS1-nt6 0.08±0.03, p>0.05). IL-8 expression was significantly higher in SS, HbS/β0-CD39 and HbS/β+-IVS1-nt5 individuals, when compared to control individuals (0.07±0.02, 0.15±0.05, 0.12±0.02 vs. 0.02±0.006, respectively, p<0.05), but not in the remaining groups (SC 0.06±0.04, HbS/β+-IVS1-nt6 0.08±0.02, p>0.05). No differences were found in IFN-gamma expression among groups or compared to controls (SS 0.20±0.06, SC 0.16±0.14, HbS/β0-CD39 0.16±0.10, HbS/β+-IVS1-nt5 0.15±0.07, HbS/β+-IVS1-nt6 0.13±0.05, control 0.29±0.06, p>0.05). IL-10 expression was significantly higher in SC, HbS/β0-CD39 and HbS/β+-IVS1-nt5 individuals, when compared to control individuals (1.20±0.43, 0.89±0.02, 0.38±0.06 vs. 0.17±0.04, respectively, p<0.05), but not in the remaining groups (SS 0.28±0.05 and HbS/β+-IVS1-nt6 0.34±0.03, p>0.05). HMOX-1 expression was significantly higher compared to healthy controls in all groups (SS 1.14±0.45, HbS/β0-CD39 2.20±0.43, HbS/β+-IVS1-nt5 2.15±0.64, HbS/β+-IVS1-nt6 1.30±0.30, SC 1.70±0.34, control 0.24±0.11, p<0.01). ROS production was significantly increased in mononuclear cells compared to the same cells in control individuals (SS 1339±56, HbS/β0-CD39 1160±121, HbS/β+-IVS1-nt5 1166±100, HbS/β+-IVS1-nt6 633±94, SC 909±148, control 369±50, p<0.05). An investigation of the production of inflammatory cytokines, anti-inflammatory cytokines and oxidative stress in SCD patients may further elucidate the pathogenesis of the disease and its complications and help in assessing disease severity and prognosis according to genotype.

ACUTE HUMAN PARVOVIRUS B19 INFECTION AND NEPHROTIC SYNDROME IN PATIENTS WITH SICKLE CELL DISEASE

S Quek, C. Sharpe, N. Dutt, D. Rees, S. Height, M. Zuckerman, S.L. Thein

King's College Hospital NHS Trust London, LONDON, UK

Background and Aims. Human Parvovirus B19 (HPV B19) infection has previously been thought to be a trigger of nephrotic syndrome. The virus is associated with significant morbidity in patients with sickle cell disease (SCD) and a major cause of transient red cell aplasia (TRCA). We investigated possible links between acute HPV B19 infection and the development and nephrotic syndrome in our cohort of SCD patients. *Methods*. We also examined the HPV B19 seroconversion status and indices of proteinuria and renal function in a cohort of SCD patients who attended our specialist clinic between July and December 2008, as well as 37 cases of acute HPV B19 infection in SCD patients admitted to King's College Hospital between November 2002 and July 2008. *Results*. Of the 37 cases (average age 11 years) of acute HPV B19 infection, 29 cases were in children below the age of 16 years, 8 in patients over the age of 16 years. Three patients developed NS within 4 months of acute HPV B19 infection and TRCA. Two of these patients were aged 17 and 26 years at diagnosis (patient 1 and 2 respectively), whereas the third was a child aged 11 (patient 3). Renal histology demonstrated the collapsing variant of focal segmental glomerulosclerosis (FSGS) in the acute phase of NS in patient 1, a characteristic finding associated with HPV B19-associated nephrotic syndrome. A subsequent biopsy in the same patient two years later demonstrated non-collapsing FSGS and marked interstitial fibrosis. Patient 2 had a renal biopsy performed 4 months after the onset of NS. This demonstrated non-collapsing FSGS, acute sickle nephropathy and significant chronic tubular atrophy. Patient 3 also had a renal biopsy 1 year after her acute HPV B19 infection which demonstrated the cellular variant of FSGS. All 3 patients have persistent significant proteinuria, with impaired renal function in the 2 older patients. *Conclusions*. Consistent with previous reports, we observe that NS is a relatively rare complication of HPV B19 infection in young children with SCD (one case in 29 in our cohort). However, 2 out of 8 patients older than 16 years developed this complication. Proteinuria in patients with SCD is common and gradual in onset, and eventually may progress to NS. NS of acute onset in adults with SCD is rare, only two cases were observed during a 6-year period among our cohort of over 400 adult patients with SCD. In both cases, they were associated with recent HPV B19 infection. It has previously been noted that acute HPV B19 infection in older patients with HbSC SCD has a more severe clinical course than younger children (Smith-Whitley *et al.*, 2004). Our data, though limited by small numbers in the cohort, suggest that older SCD patients with acute HPV B19 infection may be more susceptible to chronic complications including the development of NS and progressive renal fibrosis.

C-TERMINAL DELETION IN THE ALAS2 GENE AND X-LINKED DOMINANT PROTOPORPHYRIA

E. Di Pierro,[1] V. Brancaleoni,[1] D. Tavazzi,[2] M.D. Cappellini[1]

[1]Foundation Policlinico-University of Milan, MILAN; [2]University of Milan, MILAN, Italy

Background. Erythropoietic protoporphyria is an inherited disorder caused by partial mitochondrial deficiency of ferrochelatase (FECH), the terminal enzyme of heme biosynthesis. Most patients have autosomal-dominant EPP (dEPP), in which clinical expression normally requires coinheritance of a FECH mutation that abolishes or markedly reduces FECH activity trans to a hypomorphic FECH IVS3-48C allele. About 4% of families have autosomal-recessive EPP. In Italy, mutational analysis fails to detect FECH mutations in about 20% of EPP families, of which about 50% are homozygous for the wild-type FECH IVS3-48T allele, suggesting possible involvement of another locus. Recently, Whatley *et al.* described a previously unreported form of X-linked dominant protoporphyria (XLPP) associated to c.1706-1709 delAGTG and c.1699-1700delAT deletions in ALAS2 exon 11. In their paper the authors suggested that a modification of the C-terminal region of ALAS2 may be responsible for a protophorphyria phenotype by gain of function mechanism. The marked increased ALAS2 activity in these cases that could explain the over-production of protoporphyrin IX, despite of normal FECH activity, and the reduction of iron stores that are often observed in these patients. *Aims*. In view of this report we re-examined 7 Italian unrelated FECH-negative EPP families for a total of 19 subjects. *Methods*. The ALAS 2 exon 11 has been amplified by PCR and submitted to direct automated sequencing. *Results*. In 4 families, 6 males and 3 females carried the deletion c.1706-1709 delAGTG. This supports Whatley observation and suggest that defects in ALAS2 could be an alternative genetic background for protoporphyria. In contrast to the authors, we found a remarkable heterogeneity of phenotypes between females that could result from X-chromosome inactivation. Out of three unrelated females with the ALAS2 deletion, one, mother of a proband, was asymptomatic while the other two showed increased level of protoporphyrin causing severe photosensitivity, despite normal FECH activity and homozygosis for the wild-type FECH IVS3-48T allele. Otherwise we found no evidences that x-inactivation could lead to a milder disease in symptomatic females. In fact, these latter showed a similar erythrocytes protoporphyrin concentration and liver involvement as symptomatic males. *Conclusions*. The molecular defect in 3 FECH-negative EPP families remain still unknown, indicating that new gene targets can potentially offer new opportunities for diagnosis and treatment of EPP.

Platelets and thrombocytopenia II

ACCURACY OF PLATELET COUNTING BY HAEMATOLOGY ANALYSERS AND ITS POTENTIAL IMPACT ON THE TRANSFUSION DECISION-MAKING PROCESS

M. Lopez Rubio,[1] E. Magro,[1] T. Pascual,[1] J. Garcia Suarez,[1] J.J. Gil Fernandez,[1] M.A. Calero,[1] Y. Martin Guerrero,[1] M. Callejas,[1] C. Perez Calvo,[2] C. Burgaleta[1]

[1]Hospital Universitario Principe de Asturias, ALCALA DE HENARES; [2]FJD-Capio, MADRID, Spain

Background. Although haematology analysers provide reliable full blood counts, they are known to be inaccurate at enumerating platelets in severe thrombocytopenia. If the thresholds for platelet transfusion, currently set at 10×10^9/L, are to be further reduced, it is vital that the limitations of current analysers are fully understood. Almost all automated haematology cell analyzers use methods based on either the impedance (PLTi) or the optical (PLTo) properties of the cells to count platelets. Cell-Dyn automated blood analyzers have incorporated in the last years methods based on the use of anti-GPIII (CD61) monoclonal antibodies (ImmunoPLT method) to improve the accuracy of platelet counting in peripheral blood (PB). *Aims.* To evaluate the correlation among the three technologies using two different analyzers and its potential impact on the transfusion decision- making process. *Study design and Methods.* A comparative evaluation was made among the three methods currently available in the Cell-Dyn Saphire (optical, impedance and CD61-ImmunoPLT) and the two methods in Sysmex XE-2100 (Impedance and optical fluorescence). We have measured platelet counts in 300 PB samples from patients with >100 platelets $\times10^9$/L and in 66 PB samples from patients with chemotherapy-induced thrombocytopenia and <100 platelets $\times10^9$/L. We have considered the inmunoPLT method with anti-CD61 our gold-standard. The statistical analysis has been performed with the SPSS software (v15). We have analysed the intraclass correlation among the different parameters. *Results*. PB platelet counts showed a very good correlation among the PLTo, PLTi of both analyzers (intraclass correlation >0.97) when the platelet count is $>100\times10^9$/L. The correlation is good when the count lies between $20\text{-}100\times10^9$/L, especially between the inmunoPLT method and the PLTi used by the Sysmex analyzer. On the contrary, when platelet count is $<20\times10^9$/L the correlation among the CD61 and the optical or impedance counts is very poor. *Conclusions*. Our results suggest that the immunoPLT method should be used with counts $<20\times10^9$/L since the optical and the impedance methods do not provide reliable counts. The use of this method in the transfusion decision-making process could avoid a number of unnecessary platelet transfusions.

0779

CLINICAL OUTCOME AND RISK FACTOR ANALYSES IN THROMBOTIC THROMBOCYTOPENIC PURPURA-HEMOLYTIC UREMIC SYNDROME PATIENTS WHO UNDERWENT THERAPEUTIC PLASMA EXCHANGE

J.W. Kim, I. Kim, S.S. Yoon, K.S. Han, S. Park, B.K. Kim

Seoul National University Hospital, SEOUL, South-Korea

Background. Plasma exchange (PE) is widely used for treatment of patients with thrombotic thrombocytopenic purpura-hemolytic uremic syndrome (TTP-HUS). Various responses to PE have been reported according to etiology of TTP-HUS. Factors related to treatment response or survival in these patients need to be elucidated. *Aims.* The objectives of this study were to evaluate clinical outcomes of therapeutic PE according to etiology of TTP-HUS and to analyze factors related to treatment response or survival in TTP-HUS patients who received PE. *Methods*. We analyzed patients who were treated with PE due to TTP-HUS between August 1998 and October 2008 at the Seoul National University Hospital. Response to PE was defined as the achievement of a platelet count 150×10^9/L or more. *Results*. A total of 52 patients (male, 20) were included. Median age was 47 years (range, 17-81). Secondary causes were identified in 38 patients (73.1%): drugs (25.0%), stem cell transplantation (SCT) (19.2%), malignancies (11.5%), pregnancy (5.8%), autoimmune diseases (5.8%), and surgery (1.9%). The other 14 cases (26.9%) were classified as idiopathic TTP-HUS. All patients had thrombocytopenia and microangiopathic hemolytic anemia. Renal dysfunction (serum creatinine >1.4 mg/dL), fever (>38.0'), and neurologic symptoms were observed in 40 patients (76.9%), 23 patients (44.2%), and 32 patients (61.5%), respectively. Neurologic symptoms were as following: motor weakness (17.3%), involuntary movement (1.9%), decreased consciousness (15.4%), seizure (9.6%), disorientation (7.7%), headache (7.7%), and dizziness (1.9%). Patients underwent median 5 sessions of PE (range, 1-32). Twenty seven patients (51.9%) responded to PE and 4 patients (7.7%) relapsed despite initial responses. Response rate in idiopathic and secondary TTP-HUS was 71.4% and 44.7%, respectively. No patients with SCT-related TTP-HUS responded to PE. Median overall survival (OS) was 5.2 months (95% confidence interval (CI), 0-27.3) and estimated 1-year survival rate was 47.8%. Patients with SCT-related TTP-HUS had significantly shorter OS than those with the other etiologies ($p<0.001$). Patients with high baseline serum creatinine (>1.4 mg/dL) had lower response rate (42.1%) than the others (78.6%) in univariate analysis ($p=0.029$) and multivariate analysis including etiology adjustment (relative risk 0.10 (95% CI, 0.02-0.58), $p=0.010$). In addition, patients with fever (>38.0') or neurologic symptoms had significantly shorter OS in univariate analysis ($p=0.027$, $p=0.050$, respectively). In multivariate analysis including etiology adjustment, existence of neurologic symptom was the only significant risk factor for OS (hazard ratio 2.74 (95% CI, 1.11-6.76), $p=0.029$). PE-related adverse events were observed in 18 patients (34.6%): allergic reactions (28.8%), chest discomfort (7.7%), abdominal discomfort (5.8%), transient hypoxemia (3.8%), paresthesia (3.8%), headache (3.8%), and arm pain (1.9%). All adverse events were manageable. There was no fatal event. *Summary and Conclusions*. PE could be an effective treatment in idiopathic TTP-HUS patients. Secondary TTP-HUS patients had various treatment responses according to etiology. High baseline serum creatinine level (>1.4 mg/dL) was predictive factor for poor treatment response and existence of neurologic symptoms was poor prognostic factor. PE-related adverse events were mild and manageable.

0780

AUDIT ASSESSING POSSIBLE RISK FACTORS FOR THROMBOTIC MICROANGIOPATHIES IN A SINGLE CLINICAL APHERESIS UNIT

J. Catlow,[1] K. Douglas,[1] K. Pollock[2]

[1]The Beatson West of Scotland Cancer Centre, GLASGOW; [2]Health Protection Scotland, GLASGOW, UK

Background. Thrombotic microangiopathies (TMA) are a rare, clinically diverse set of conditions sharing the same pathophysiological mechanism of microvascular endothelial injury leading to microthrombi, red cell fragmentation, platelet activation / accelerated consumption and hypoxic damage to multiple organs. It includes the conditions Thrombotic Thrombocytopenic Purpura, Haemolytic Uraemic Syndrome and HELLP syndrome. *Aims*. ADAMTS13 deficiency and E.coli O157 infection alone cannot explain the variable manifestations of TMA. Population studies have revealed sepsis, hypertension and immunosuppression as possible TMA precipitants. We decided to assess risk factors of TMAs in a cohort of patients from a large regional clinical apheresis unit. *Methods.* Analysis of patient records from October 1997 to December 2008 of those receiving therapeutic plasma exchange in a single clinical apheresis unit with the following criteria: 1) Microangiopathic haemolytic anaemia with red cell fragmentation on blood film. 2) Thrombocytopaenia with a platelet count $<150\times10^9$L-1. 3) Elevated lactate dehydrogenase (LDH) >150% of upper limit of local reference range. Data was collected on basic demographics, laboratory variables including platelets, LDH and creatinine, clinical information including presenting features, pre-morbid conditions and previous medications, and clinical outcome at discharge. SPSS version 15.0 was used for statistical testing, significance level 5%. *Results*. 65 patients met our criterion, median age 52 (range 1-81 years) and female to male ratio of 2:1. Outcome at discharge was available from 54 patients, 11 (20%) died, 35 (65%) fully recovered, and 8 (15%) remained impaired, 7 due to dialysis dependent renal failure and one due to cerebrovascular disease (CVA). Only age was related to outcome: older patients were more likely to die ($p=0.018$ on Kruskal-Wallis testing). 39 (60%) patients suffered gastrointestinal symptoms immediately prior to their TMA, of which 27 cases (42%) were due to diarrhoea. 45 patients (69%) either had documented infection on admission or experienced acute GI symptoms before admission. However, E. coli O157 was cultured in just nine cases (14%). Previous to admission 17 patients (26%) were on antihypertensive medication and six patients (9%) were taking calcineurin inhibitors (ciclosporin A or tacrolimus). Nine patients (14%) had a history of autoimmune disease. On admission 24 patients (38%) experienced CNS symptoms; type was significantly associated with age. 11 patients experienced seizures and were younger than those who did not (Median 21 versus 54 years, $p=0.018$, Mann-Whitney testing); six patients experienced a CVA and were older (Mean 72.5 versus 45 years, $p=0.004$, Mann-Whitney testing). We observed a positive correlation between referral platelet count and serum creatinine (r=0.38, $p=0.002$, spearman's

(two tailed) correlation coefficient). *Summary*. This cohort had high rates of infection and diarrhoea immediately before their TMA, and high rates of antihypertensive therapy. These data fit with the hypothesis of acute endothelial damage acting as a trigger in patients predisposed either by genetic susceptibility or by pre-existing anti-ADAMTS13 antibody. Our cohort could be expanded and compared to a large age matched control group to ascertain further risk factors (Figure 1). Limitations of this audit included unavailability of ADAMTS13 testing, and recall bias due to its prospective nature.

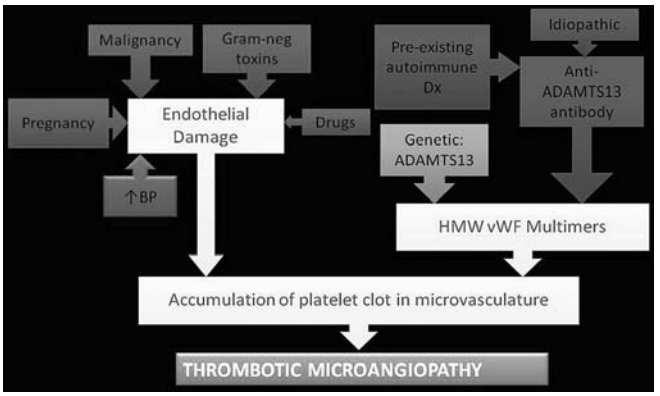

Figure 1. Multifactorial Model for TMA.

ANALYSIS OF CARBONYLATED PROTEINS IN HUMAN BLOOD PLATELETS

A. Sobotkova,[1] K. Pimkova,[1] P. Majek,[1] M. Maly,[2] J. Suttnar,[1] J.E. Dyr[1]

[1]Institute of Hematology and Blood Transfusion, PRAGUE 2; [2]Department of Cardiology, Motol University Hospital, PRAGUE 5, Czech Republic

Background. During platelet activation the reactive oxygen and nitrogen species (RONS) are produced. These unstable molecules participate in activation cascade as second messenger and they can also modify other macromolecules (lipids, proteins) in their close vicinity. Generation of new carbonyl groups is one of the first steps in oxidative damage of proteins. Modified proteins can loose their physiologic properties - cooperation in cytoskeleton reorganization during platelet activation. The objective of the study was to propose methods suitable for large-scale oxidative stress studies, e.g. production of platelet's carbonylated proteins. *Aims.* The aim of this work was isolation and identification of carbonylated proteins in human blood platelets both in resting platelets and in platelets activated with various agonists. *Methods*. Platelets were isolated from blood of healthy volunteers who had not taken any antithrombotic drugs. Washed platelets were activated by three different types of agonists: thrombin, collagen and arachidonic acid. Platelet activation was detected photometrically by measuring aggregation response. Carbonylated platelet proteins were derivatized using biotine-hydrazide chemistry with subsequent affinity capture on avidine-agarose. Biotinylated proteins were eluted by biotine and were either analyzed by SDS-PAGE with immunoblotting or digested by trypsine. Resulting peptides were analysed using 2D-HPLC/ESI-MS/MS and carbonylated proteins were identified. The results were compared with 2D-SDS-PAGE of non-biotinylated samples that were subsequently electroblotted, carbonylated proteins were modified by dinitrophenylhydrazine and vizualizated by immunochemical detection. *Results*. The largest amount of carbonylated proteins were found in collagen activated platelets. The data showed that the biotine-based immunocapture of carbonylated proteins as a simple technique can be used to isolation of carbonylated subproteome of (platelet) proteins with minimum false-positive results. The method is suitable for high-throughput screening of carbonylated proteins either using parallel sample processing or due to its easy automation using HPLC systems. *Conclusions.* Human platelets undergoes many oxidative reactions during activation with various agonists, in patients suffering with oxidative stress which is present in different kinds of diseases and also in stored platelet's concentrates. Therefore our results can improve the knowledge of protein processing in platelets both in health and disease.

PLATELET MICROPARTICLES IN PEDIATRIC IMMUNE THROMBOCYTOPENIC PURPURA

A. Tantawy, R. M.Matter, A. A.S.Hamed, M. A.S.Eltelbany

Faculty of Medicine, Ain Shams University, CAIRO, Egypt

Background. Immune thrombocytopenic purpura (ITP) is one of the most common hemorrhagic disorders encountered in childhood. Platelet microparticles (PMP) arise in association with platelet activation with procoagulant activity. Elevated PMP were observed in adult ITP and high concentrations of active PMP were reported to be thrombogenic in certain settings. However, the clinical significance of PMP in pediatric ITP has not been studied.Objectives: This study aimed to assess PMP levels in ITP in children and adolescents, and its correlation with clinical status, bleeding score, and response to therapy. *Methods*. Fourty patients with ITP were randomly selected from the Hematology Clinic, Children's Hospital, Ain Shams University,Cairo,Egypt. Twenty patients (14 females and 6 males) with acute ITP (mean age 10.5±3.4 y) and 20 patients (12 females and 8 males) with chronic ITP (mean age 11.1±3.1 y) and thirty sex and age matched healthy controls (20 females and 10 males) with mean age 10.7±4.4 y.Patients were subjected to detailed history, calculation of bleeding score, complete blood count, cytological bone marrow examination and PMP quantitation in peripheral platelets by flow cytometry. *Results*. Compared to controls, acute ITP patients had significant increase in PMP, PMP/platelet count, PMP % (p<0.0001, p<0.0001, p<0.0001; respectively).There was non significant difference in PMP in chronic ITP compared to controls (p>0.05), but highly significant increase in PMP/platelet and PMP % in chronic ITP compared to controls (p=0.0009, p=0.03; respectively). There was significant increase in PMP, PMP/platelet count, PMP % in acute ITP compared to chronic ITP patients (p=0.001, p=0.003, p<0.0001; respectively). No significant correlation was evident between PMP and platelet count in either group (p>0.05). Neither mucosal bleeding, petichiae nor thrombotic manifestations were observed in the studied patients with high PMP. Conclusions:Immune thrombocytopenic purpura in the pediatric age group is associated with elevated PMP which may be protective against severe bleeding events rarely seen in this age group. The role of PMP studies in deciding the management plan of childhood and adolescent ITP needs further evaluation.

0783

INCREASED LEVELS OF PLATELET-LEUCOCYTE COMPLEXES IN BEHCET'S DISEASE PATIENTS WITH MAJOR VASCULAR INVOLVEMENT

G.E. Pamuk,[1] Ö.N. Pamuk,[2] H. Örüm,[3] M. Demir,[1] B. Turgut[1]

[1]Trakya University Medical Faculty, Division of Hematology, EDIRNE; [2]Trakya University Medical Faculty, Division of Rheumatology, EDIRNE; [3]Trakya University Medical Faculty,Department of Internal Medicine, EDIRNE, Turkey

Background. Venous thrombosis, which is quite rarely observed in other vasculitides, is a frequent finding in Behcet's disease (BD). The exact explanation for the thrombotic tendency in BD is unknown. It was suggested that endothelial dysfunction caused by vascular endothelial injury in a prothrombotic milieu might have a role. Nevertheless, activation of platelets and neutrophils might contribute to vascular damage, thereby resulting in hypercoagulability *Aims.* We determined platelet-leucocyte complexes in BD patients with and without major vascular involvement (MVI) and in healthy controls. *Methods*. We included 36 BD patients (22 M, 14 F, mean age: 34.4±8.3 years) and 20 healthy subjects (14M, 6F, mean age: 31.8±4.4 years). All participants gave written informed consent and the protocol was approved by the our university's research ethical committee. BD patients with MVI were taken as a separate group (8 M, 5 F, mean age: 37±8 years). MVI was defined as the presence of pulmonary arterial aneurysm, deep venous thrombosis, vena cava inferior or superior thrombosis, or venous sinus thrombosis. Flow cytometry was used to determine platelet-monocyte complexes (PMC), platelet-neutrophil complexes (PNC), basal and adenosine diphosphate (ADP)-stimulated platelet CD62P expression. *Results*. BD patients with and without MVI and the control group were not significantly different in their ages and sex distribution. Pathergy test was significantly more frequently positive in BD group with major vascular involvement (p=0.01). When active BD patients were compared with inactive BD patients, it was seen that basal and ADP-stimulated CD62P expression, PMC and PNC were not significantly different between the groups (p>0.05). BD patients with MVI had significantly higher PNC (23.3±16.9) than BD patients without MVI (12.8±7.9) and healthy controls (12.8±5.3) (p values <0.01). PMC levels in BD patients with MVI (43±28.8) were signif-

icantly higher than healthy controls (21.1±10.1) (p=0.01); and tended to be nonsignificantly higher than BD patients without MVI (30±20) (p=0.15). The groups were similar in basal and ADP-stimulated platelet CD62P expression (p>0.05). The evaluated parameters were not significantly different in BD patients with and without uveitis, and pathergy-positive and -negative groups. In addition, corticosteroids (8 cases), low-dose aspirin (5 cases), warfarin (4 cases), colchicine (20 cases), azathioprine (7 cases) did not have significant effect on the evaluated parameters. In BD patients, PMC correlated with PNC (r=0.89, p<0.001), CD62P expression correlated with ADP-stimulated CD62P expression (r=0.72, p<0.001). None of these parameters correlated with ESR and CRP. Only in BD patients with MVI, CD62P expression had a negative correlation with CRP level (r=-0.65, p=0.03). *Conclusions*. Our results demonstrate that the formation of platelet-leucocyte complexes might be playing a pathogenetic role in BD patients with MVI. The formation of platelet-leucocyte complexes, independent of an increase in platelet activation parameters, made us consider the role of leucocytes especially neutrophil hyperactivation in MVI of BD.

HELICOBACTER PYLORI ERADICATION IMPROVES PLATELET COUNT IN INFECTED CHILDREN WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA

M. Ferrara

Second University of Naples, NAPLES, Italy

Background. Recent reports have suggested, particularly in adults, an association between Helicobacter Pylori infection (HPI) and chronic idiopatic thrombocytopenic purpura (cITP) with improvement of platelet count after eradication therapy. *Aims.* We investigated the association of HPI and cITP and the effect of HP eradication therapy on thrombocytopenia children. *Methods*. Twenty-four children of both sexes mean age 8.0±0.28 years (range 5.4-10.7 yrs), affected by cITP (PLT ≤50×10^9/L) without other causes, lasting more than 6 months, were enrolled. None patient received immunosuppressive therapies at last one year or was splenectomised. HPI was investigated by an enzyme immunoassay for H. pylori antigens in faeces (HpSA). Bacterial eradication was performed by Amoxicillin (50 mg/kg/die), Clarithromicin (15 mg/kg/die) and Omeprazole (20 mg/die) for 7 days. HP status was evaluated before and immediately after eradication and, successively, every 3 months in the first year after treatment. A follow-up of platelet count was performed during 1 year after HpSA. Statistical analysis was performed by t-test. A p value < 0.05 was considered statistically significant. *Results*. Six out 8 patients (75%) had total recovery of platelet count during the first year after bacterium eradication (PLT before therapy 32.5±3.5×10^9/L; after 1 year 275±106.06×10^9/L) with significant increase (p< 0.05), 2 patients (25%) had partial recovery (PLT before therapy 30×10^9/L, after 1 year 103.5×10^9/L) but non significant increase (p>0.05). Non significant differences were found in platelet count between infected and uninfected patients before eradication treatment (PLT 33.0±2.8×10^9/L vs 34.0±5.75×10^9/L) (p>0.05), while significant differences were observed after eradication therapy (PLT 315.0±7.07×10^9/L vs 43.5±2.12×10^9/L) (p<0.05). *Conclusions*. HP assessment should be performed in all cITP patients and eradication therapy should be attempted in positive cases.

0785

DOES ANTI-TNF THERAPY CAUSE ANY CHANGE IN PLATELET ACTIVATION IN ANKYLOSING SPONDYLITIS PATIENTS?

G.E. Pamuk,[1] Ö.N. Pamuk,[2] H. Örüm,[3] B. Turgut,[1] M. Demir[1]

[1]*Trakya University Medical Faculty, Division of Hematology, EDIRNE;* [2]*Trakya University Medical Faculty, Division of Rheumatology, EDIRNE;* [3]*Trakya University Medical Faculty,Department of Internal Medicine, EDIRNE, Turkey*

Background. Inflammation, which has an important role in endothelial dysfunction, plays an important role in the development of atherosclerotic vascular disease. Platelets have a major role in the interplay among inflammation, thrombosis and atherogenesis. Some of their important roles are their interaction with leucocytes and their ability to modify the functions of leucocytes, their adhesion upon the endothelium and ability to activate endothelial cells, their potential to interact with vascular smooth muscle cells. Recently, it has been reported that ankylosing spondylitis (AS) was characterized by endothelial dysfunction and the development of atherosclerotic complications. *Aims.* In our study, we evaluated parameters of platelet activation (platelet-monocyte complexes [PMC] and platelet-neutrophil complexes [PNC], CD62P, sCD40L) and endothelial activation (E-selectin) in AS which is a chronic inflammatory disease. In addition, we searched for the variation in these parameters with disease activation and after anti-TNF therapy. *Methods*. Fiftynine AS patients and 22 healthy controls were included. The clinical features and acute phase parameters were evaluated. All participants gave written informed consent and the protocol was approved by the our university's research ethical committee. In all patients and healthy controls, platelet-monocyte complexes (PMC), platelet-neutrophil complexes (PNC), basal and ADP-stimulated P-selectin (CD62P) expression were determined by flow cytometry; soluble E-selectin (sE-selectin) and soluble CD40L (sCD40L) were determined by ELISA. AS patients were divided into two groups as active and inactive by using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). In 15 AS patients, the evaluated parameters were assessed before and after 12 weeks of anti-TNF therapy. *Results*. The mean age of AS patients (36.7±9.1 years) was not significantly different from mean age of the healthy control group (33.1±6.3 years) (p=0.1). ESR and CRP were significantly higher in AS patients than in controls (p<0.001). PMC in AS patients (31.7±22.3) were significantly higher than in the control group (22.3±10.6) (p=0.013). PNC tended to be higher in the former group (p=0.079). Basal and ADP-stimulated CD62P-positive platelets were similar between AS and control groups (p>0.05). sCD40L level in AS group (1.5±0.7) was significantly higher than in the control group (1.1±0.4) (p=0.016). sE-selectin level in AS patients (22.6±7.8) tended to be lower than in the control group (27.2±9.5) (p=0.064). The evaluated parameters were similar in active and inactive AS groups (all p>0.05). After TNF-blocker therapy, there were significant decreases in mean ESR (p=0.018), CRP (p=0.039), and BASDAI (p=0.002) in the AS group; however, there were no significant changes in other parameters (p>0.05). In AS group, PMC correlated with PNC (r=0.832, p<0.001), CRP (r=0.313, p=0.017) and platelet count (r=0.428, p=0.001). PNC correlated with platelet count (r=0.272, p=0.039). There was a positive correlation between sCD40L level and platelet count (r=0.349, p=0.04). *Conclusions*. In our study, we found that PMC, PNC, and sCD40L were higher in AS patients than in controls. This might be contributing to endothelial dysfunction and atherosclerosis which are said to be present in AS in association with chronic inflammation. Nevertheless, disease activity did not seem to be related to these parameters. In addition, there has been no change in any of the parameters after anti-TNF therapy.

0786

IDIOPATHIC THROMBOCYTOPENIC PURPURA AND AUTOIMMUNE HEMOLYTIC ANEMIA IN THE PATIENTS WITH COMMON VARIABLE IMMUNODEFICIENCY

K. Moazzami, N. Rezaei, A. Aghamohammadi

University of Tehran, Medical School, TEHRAN, Iran

Background. Common Variable Immunodeficiency (CVID) is a heterogeneous group of disorders characterized by hypogammaglobulinemia and an increased susceptibility to recurrent infections as well as autoimmunity and malignancies. Idiopathic Thrombocytopenic Purpura (ITP) and Autoimmune Hemolytic Anemia (AIHA) are two autoimmune disorders which may be seen in association with CVID. *Aims*. To describe the clinical features and outcome of ITP and/or AIHA among patients with CVID, we report clinical and laboratory characteristics in 7 CVID patients who manifested autoimmune hematologic disorders. *Methods*. A two-page questionnaire was designed to collect all necessary information from studied patients, including: past medical histories, the onset of CVID, onset and episodes of ITP and/or AIHA, other associated complications of CVID and the required treatments. *Results*. Among 85 CVID patients, seven cases had ITP and/or AIHA (8%). Four of these patients had one or more episodes of ITP, one patient had AIHA, and two patients had both ITP and AIHA (Evans syndrome). Almost, all patients experienced chronic and recurrent infections mostly in respiratory and gastrointestinal systems during the course of the disease. Among the seven patients, five presented their underlying disease with recurrent respiratory and/or gastrointestinal tract infections, while in two remaining patients, CVID was presented with ITP. Three patients died until now; two because of hepatic failure and one due to pulmonary hemorrhage. *Conclusions*. As CVID is prone to autoimmune disorders, it should be considered as a differential diagnosis of adult-onset ITP and possibly in children. Chronic and recurrent ITP, especially in the presence of propensity to respiratory and gastrointestinal infections mandate the evaluation for an underlying immune dysregulation such as CVID.

ABNORMAL HEPATOBILIARY LABORATORY VALUES AMONG PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

D. Bennett,[1] C. Enger,[2] K.L. Dawson,[1] A. Brainsky,[1] M. Aivado,[1] D. Theodore[1]

[1]GlaxoSmithKline, PHILADELPHIA, PA; [2]I3 Drug Safety, ANN ARBOR, USA

Introduction. Idiopathic thrombocytopenic purpura (ITP) is a disease caused by inadequate platelet production as well as increased platelet destruction. Several ITP therapies may cause abnormal hepatobiliary laboratory values, but the epidemiology of these abnormalities is unknown in this patient population. *Objective*. To estimate the prevalence, incidence rates, and the relative risk of hepatobiliary laboratory abnormalities (HBLA) among a cohort of patients with ITP. *Methodology*. This was a retrospective database analysis using eligibility and medical claims data from a large U.S. health plan affiliated with i3 Drug Safety. Chronic ITP patients were identified using the following criteria: a) at least two physician claims separated by at least six months with ICD-9 CM diagnosis code 287.3 for primary thrombocytopenia, b) at least 12 months of continuous enrollment prior to the date of the diagnosis code eligibility, and c) at least 18 years of age between January 1, 2000 and December 31, 2006 with follow up through September 30, 2007. Study outcomes were elevated levels of alanine transaminase (ALT), aspartate aminotransferase (AST), total bilirubin, and alkaline phosphatase (ALP) based on laboratory database results. Serious HBLA was defined as >3x ULN for ALT and/or AST and >1.5x for bilirubin and/or ALP. *Results*. Within the chronic ITP cohort (n=3.244), 805 (25%) patients had at least one hepatobiliary laboratory test result during the 12-month baseline period. After excluding patients with recorded evidence of HBLA at baseline, 2.557 (79%) patients were eligible for the incidence sub-cohort. The baseline prevalence of ALT and AST > 3x ULN was 4.6% and 3.7%, respectively. The baseline prevalence of total bilirubin and ALP >1.5x ULN was 4.2% and 3.2%, respectively. The incidence of new HBLA in this cohort was 1.24/1,000 person-years (95% CI: 0.52-2.56) for ALT >3x ULN and 0.41/1,000 person-years (95% CI: 0.08-1.32) for AST >3x ULN. These incidence rates for total bilirubin >1.5x ULN and ALP >1.5x ULN were 2.69/1,000 person-years (95% CI: 1.51-4.47) and 1.03/1,000 person-years (95% CI: 0.39-2.26), respectively. Factors significantly associated with new or repeat occurrence of ALT > 3x ULN were male gender, history of diabetes, history of liver disease, history of other comorbidities related to secondary immune mediated thrombocytopenia such as lupus erythematosis, malignant neoplasm of lymphatic or hematopoetic tissue, HIV infection, history of alcohol use requiring medical attention, high use of systemic corticosteroids, and treatment with interferon or cyclosporine. Factors significantly associated with new or repeat occurrence of total bilirubin > 1.5x ULN were age, male gender, history of congestive heart failure, history of liver disease, history of alcohol use requiring medical attention, and treatment with interferon. *Conclusions*. The prevalence of HBLA among the chronic ITP population is relatively high compared to other disease populations. Abnormal hepatobiliary laboratory test results were significantly associated with male gender, liver disease and several other comorbidities, thus making identifying drug-induced liver injury in this population more challenging.

CHRONIC AND RECURRENT IDIOPATHIC THROMBOCYTOPENIC PURPURA IN CHILDHOOD - SINGLE INSTITUTION EXPERIENCE

K. Martinova, O. Muratovska, S. Glamocanin, Z. Antevska-Trajkova, B. Coneska-Jovanova, S. Koceva

University Children's Hospital, SKOPJE, Macedonia

Background. Idiopathic thrombocytopenic purpura (ITP) is the most frequent hemorrhagic disease in children. There are three forms of ITP: acute, chronic and intermittent. In chronic forms the platelet count remains low for six months after diagnosis, and in recurrent forms the drop in platelet count appears after a period of normality. *Aims.* To asses treatment response and outcome in children with chronic and recurrent ITP admitted at a single pediatric medical center. *Methods and Results*. A retrospective chart review was made for all children ages 2 months-15 years diagnosed with ITP and treated at the University Children's Hospital in Skopje between 1997 and 2006. Follow up period was 1-11 years. Tow hundred and twenty five patients with diagnosis ITP were identified. Chronic ITP (persistence > 6 months) was noted in 24 patients (11%), and recurrent ITP in 13 patients (5.8%). Chronic patients presented at an older age; median age at diagnosis was 8,8 years (range from 3-15 years), with females being affected more frequently than males (f:m=1,6:1). Bone marrow aspiration confirmed the diagnosis in all cases. The risk of chronic ITP was partially predicted by presenting platelet count > 30×10^9/L at 11 patients (45,8%) and age >10 years at 10 patients (41,6%), but not by both. Just 5 patients (20,8%) presenting by these two features developed chronic course Treatment consisted of: 1. glucocorticosteroids (GS) in 13 patients (6 responded with CR, 6 had persistent mild thrombocytopenia and 1 patient with ICH died. 2. GS + Immunoglobulins (IVIG) in 4 patients (3 are in CR). 3 GS + Splenectomy in 5 patients: 2 are in CR, 3 in PR (two of them without treatment). 4. GS + IVIG + Splenectomy in 1 patient with CR. 5. GS + IVIG + Immuran + Splenectomy in 1 patient with CR. Among the patients with recurrent disease-13 patients (5,8%) from 225 with ITP, 8 ware males. All of them had platelet count <30×10^9/L at the presentation of the disease and almost all 12 (92.3%) presented with mild to moderate hemorrhagic manifestations at the onset of the disease and during the recurrence (just 1 girl had serious bleeding-gross metrorrhagio). The median time to recurrence was 11,8 months (range 4-84 months). All of them achieved CR (11 with GS, 1 with IVIG and 1 with both GS and IVIG) as a first treatment and 6 with GS, 1 with IVIG and 6 with no treatment at the recurrence of the disease. *Conclusions*. Chronic and recurrent ITP in childhood run a benign course in most cases and the therapeutic intervention has to be individualized.

0789

ITP AND CELIAC DISEASE: A NON SPORADIC ASSOCIATION

F. Cecere,[1] G. Pollio,[2] A. Mangione,[1] A.G. De Anseris,[1] R. Albano,[1] G. Menna[3]

[1]Aorn S.Giovanni di Dio e Ruggi d'Aragona, SALERNO; [2]Department of Pediatrcs S.Giovanni di Dio e Ruggi D'Aragona Hospital, SALERNO; [3]Department of Onco-Haematology, Pausilipon Hospital, NAPLES, Italy

Background. Idiopathic thrombocytopenic purpura (ITP) is an autoimmune condition caused by platelet auto antibodies, that leads to increased platelets destruction. The typical presentation in childhood consists in sudden onset of petechiae, bruising and bleeding manifestation in patients otherwise in good health. The estimated incidence of ITP ranges between 10-125 new cases/one million (adults and children) year. ITP is often associated with other autoimmune disorders. Celiac Disease (CD) is a very frequent autoimmune condition due an intolerance of the gluten (estimated incidence in Italy is 1/100-150 people) whose more common clinical manifestations are gastrointestinal symptoms, and/or sideropenic anaemia, and/or failure to thrive. Several published studies has shown associations between ITP and CD with a median range of 1/100. *Aims.* The aim of this investigation is to evaluate and verify the real incidence of autoimmune disease and especially of CD in a group of new diagnosed ITP patients. Patients and *Methods*. Since December 2007 till December 2008 have been enrolled 17 children (9 M and 8 F) mean age 5yrs, ranged between 8 mts-14 yrs with new diagnosed ITP. All patients were screened for CD determining the anti transglutaminase antibodies (TTG) and anti endomisial antibodies (EMA). All patients were evaluated also for other autoimmune conditions determining serum levels of antinuclear antibodies (ANA), anti smooth muscle antibodies (ASMA), anti mitochondrial antibodies (AMA), C3 and C4, thyroidal function and anti tireoperooxhidase antibodies (AbTPO) and anti tireoglobulin antibodies (AbTg), Direct Coombs test. Serologically positive patients to EMA and TTG were submitted to upper endoscopy with jejunal biopsy. *Results*. 2 patients of 17 (1/8.5) were positive to EMA and TTG. Jejunal biopsy was positive for CD (grade 3rd-4th Marsh Classification), confirming diagnosis of CD. Both patients had no gastrointestinal manifestations and only one of two had a mild sideropenic anaemia (Hb 10.2 gr/dL, MCV 72 fL, iron serum levels 24 mcg/dL, ferritin serum levels 10 mgL).Gluten free diet gave only partial remission of ITP and both patients needed treatment with oral corticosteroids.1/2 still had low platelet count after 1 year of diet (PLt>50.000) but didn't required other treatment than gluten free diet. *Summary and Conclusions*. Our investigation has shown a frequency of the association between ITP and CD in our patients significantly superior compared with previous literature reports (1/8.5 vs. 1/100) and that gluten free diet alone would not conduce to a complete remission of ITP. We suggest to introduce the CD screening as a first step procedure in ITP patients. Otherwise further studies are needed to establish the real incidence of the ITP/CD association, considering the short period of the investigation and few number of patients and a possible bias of population.

CLINICAL AND RADIOLOGIC EVALUATION OF CYTOMEGALOVIRUS-INDUCED THROMBOCYTOPENIA IN INFANTS BETWEEN 1 MONTH AND 6 MONTHS OF AGE

S.Y. Kim,[1] E.S. Park,[2] H.J. Kim[3]

[1]Chungnam National University, DAEJEON, South-Korea; [2]Gyeong Sang National university, JIN JU, South-Korea; [3]Samsung Medical Center Sungkyunkwan University School of Medicine, SEOUL, South Africa

Background and Aims. Neonates with congenital or perinatal infection with cytomegalovirus (CMV) are asymptomatic in up to 90% of case. However, 10~15% of them develop sequelae such as sensorineural hearing loss, microcephaly, mental retardation, and chorioretinitis lateron. Infants with CMV infection may also have thrombocytopenia, which recently gains attention due to its association with neurological sequelae. However, little is known about the CMV infection-associated thrombocytopenia after the neonatal period. In this regard, the authors investigated the clinical findings of a series of infants diagnosed with CMV infection and with thrombocytopenia. Method. From July 2005 and July 2008, infants with thrombocytopenia less than 6 months of age were screened for CMV infection by CMV IgM. Those who were positive for CMV IgM were further tested for CMV IgG and polymerase chain reaction (PCR) for CMV, CMV pp65 Ag, and urine culture, along with brain magnetic resonance imaging (MRI) and otologic and ophthalmologic evaluations. *Results*. A total of 21 patients aged between 1 month to 6 months (11 boys and 10 girls) were admitted because of thrombocytopenia and were tested for CMV infection. Six among the patients (28.6%) were positive for CMV IgM: four were further positive for CMV IgG, CMV PCR, pp65 Ag, and urine culture, and two were positive for all those test except for pp65 Ag. The median gestational period was 39 weeks (range, 32.3~40.0), and the median age of the patients at diagnosis was 2 months (1.8~4) The median count of platelets at admission was 6,500/μL (range, 2,000~105,000). Except for one patient with a platelet count 105,000/μL, all patients had a platelet count lower than 10,000/μL and were treated with intravenous immunoglobulin at 2 g/kg. All patients recovered a normal platelet count; no patient progressed to chronic thrombocytopenia. One patient (16.7%) was diagnosed with Evan's syndrome and had microcephaly and calcifications on brain MRI. One patient was born at preterm and had a small nodular GRE-dark signal intensity lesion in the caudothalamic notch on the left side, which was thought to be due to intracerebral bleeding. One patient had unilateral sensorineural hearing loss. Conclusions. CMV infection needs to be considered in patients with thrombocytopenia aged between 1 to 6 months, and close follow-up is needed for neurodevlopmental sequeale.

NATIONAL SURVEY ON PREVALENCE AND TREATMENT OF IMMUNE THOMBOCYTOPENIC PURPURA IN POLAND - PLATE QUESTIONNAIRE

M. Zawilska,[1] M. Podolak-Dawidziak,[2] K. Chojnowski,[3] J. Windyga,[4] J. Zdziarska[5]

[1]J.Strus Hospital, POZNAN; [2]Hematology, Blood Neoplasms and Bone Marrow Transplantation, Medical University, WROCLAW; [3]Hematology, Medical University, LODZ; [4]Haemostasis, Institute of Hematology and Blood Transfusion, WARSAW; [5]Hematology, Jagiellonian University School of Medicine, KRAKOW, Poland

Forty-one treatment centers in Poland participated in the study and responded the PLATE questionnaire concerning prevalence, clinical picture and treatment policies of immune thombocytopenic purpura (ITP) in the previous 12 months. The study was conducted from October 2007 till September 2008. Retrospective data on 3238 patients with ITP were collected, 1331 of whom were new cases (3.5/100,000 per year). The patients were referred to the specialist mostly by primary care physicians (69% of cases) and presented with asymptomatic thrombocytopenia (52,7%) or bleeding symptoms: easy bruising following minor trauma (16,6%), spontaneous bruising (21,9%), mucosal bleeds (17,5%), hematuria (2%) and severe bleeding episodes (internal bleeding: 0,5%, intracranial bleeding 0,2%). Of all 3238 patients participating in the study 41% were untreated, 32% treated with glycocorticosteroids (GCS) only, 11% unsuccessfully treated with GCS before splenectomy and 16% after splenectomy (either untreated or receiving GCS or refractory to GCS). Of all patients diagnosed with ITP who initially do not require treatment a mean of 31% (median 23%) progress and need to start therapy. Initial therapy with GCS lasted on average 14 weeks (median 12 weeks, minimally 4 weeks, maximally 55 weeks). As the most common cause of GCS cessation half of the centers named "therapy failure", 10 centers "complete remission", 10 centers "improvement" and only one center "GCS side effects". Danazol was administered to a total of 320 patients,174 patients received intravenous immunoglobulins (IVIG), 27 patients rituximab and 13 patients anti-RhD immunoglobulin (not available for routine use in ITP patients in Poland). At all centers during the previous 12 months a total of 197 patients (5%) required splenectomy. The most common indication for this procedure (55%) was refractoriness to GCS. Splenectomy proved unsuccessful in 29% of cases (mean; median 30%) *Conclusions*. A national registry of ITP cases would be helpful in surveillance and optimizing of treatment strategies.

DYNAMICS OF PLATELET MORPHOFUNCTIONAL STATUS IN ANTICOAGULANT THERAPY

E.A. Vlasova,[1] I. Vasilenko,[1] V. Suslov,[2] V. Samoylenko[2]

[1]Russian gerontological scientific clinical center, MOSCOW; [2]MONIKI, MOSCOW, Russian Federation

Background. In patients with chronic renal failure (CRF), treated with hemodialysis (HD), platelet hemostasis, the regulation of coagulation and fibrinolytic systems can be disturbed, thus contributing to either thrombotic or bleeding complications. The conventional management of thrombotic disorders is based on the use of heparin, oral anticoagulants and aspirin. Unfractionated heparin (UFH) and low molecular weight heparins (LMWHs) are a routine anticoagulant in HD. Despite progress in the sciences, these drugs still remain a challenge and mystery. The purpose of this study was to investigate the influence of UFH and LMWHs (nadroparin) on morphofunctional status of living platelets, spontaneous platelet aggregation; adenosine diphosphate (ADPH), collagen, ristomycin induced platelet aggregation before and after HD in patients with CRF. *Methods*. 30 healthy volunteers (the control group) and 45 patients with CRF before and after carrying out HD procedures have been examined. Morphofunctional status of platelet peripheral blood we determined by method of vital computer morphometry with using computer phase-interference microscope (CPM) "Cytoscan" (Moscow, Russia). We measured and compared spontaneous platelet aggregation; adenosine diphosphate (ADPH), collagen, ristomycin and adrenaline induced platelet aggregation. *Results*. The results of studies showed that in patients with CRF who use UFH mean metric platelets parameters (diameter, perimeter, high, area and volume) were constituted 3,1±0,8 mkm; 9,2±2,8 mkm; 0,96±0,3 mkm; 5,7±3,2 mkm^2; 2,2±1,4 mkm^3 (p<0,05). We identified 4 platelet forms that have different morphological features and different parameters of size distribution. In the cell population we distinguished 4 morphologic forms of platelet with according to various activation levels: I - resting platelets, II - platelets with low activation level, III - platelets with high activation level and IV degenerate functionally incomplete platelets. The proportion of different morphological cell types were 52.3%; 36.6%; 10.3%; 0.8%, respectively. In patients with CRF who use nandroparin consisted 2,7±0,6 mkm; 8.1±2.0 mkm; 1.1±0.4 mkm; 4.3±2.0 mkm^2; 1.9±1.1 mkm3 (p<0.05); morphological forms were I - 57.2%; II - 33.5%; III - 9.3%; IV - 0.5%. In patients with CRF who used UFH spontaneous and adrenaline induced platelet aggregation were increased by 15-50% in according to control group; ADPH and collagen induced platelet aggregation were decreased by 10-16,8%; ristomycin induced platelet aggregation was in norm. As to nadroparin in patients with CRF spontaneous and adrenaline, ADPH induced platelet aggregation were in norm; ristomycin induced platelet aggregation was increased not significantly; collagen induced platelet aggregation increased almost by 20%. *Conclusions*. The computer morphometry of living platelets is guarantied rapid and objective analysis of the platelet hemostasis, showing early appearances of platelet complications in patients with CRF. Morphofunctional status of living platelets can be as markers of intravascular thrombogenesis during HD. Single bolus of nadroparin ensures efficient and convenient anti-thrombotic protection during HD procedure. In spite of UFH remains the gold standard of treatment in patients with CRF, our results demonstrated that LMWHs are as safe and efficient compared to UFH. However, due to their renal elimination, they have to be monitored by measuring hemostasis parameters.

PROMOTER HYPERMETHYLATION STATUS OF THE MEG3 AND SNRPN IMPRINTED GENES IN MYELODYSPLASTIC SYNDROMES

L. Benetatos,[1] E. Hatzimichael,[1] G. Dranitsaris,[2] A. Dasoula,[1] M. Syrrou,[3] S. Tsiara,[1] G. Vartholomatos,[1] M. Voukelatou,[1] K. Bourantas[1]

[1]University Hospital of Ioannina, IOANNINA, Greece; [2]Department of Medical Oncology, Princess Margaret Hospital, TORONTO, Canada; [3]Department of General Biology, IOANNINA, Greece

Background. MEG3 gene (located on chromosome 14q32) and SNRPN gene (located on chromosome 15q11-q13) belong to the family of imprinted genes and are involved in the pathogenesis of chromosome 14 uniparental disomy and Prader-Willi syndrome respectively. *Aims.* As both genes have been demonstrated to act as tumor suppressor genes, we sought to investigate whether promoter hypermethylation of the differentially methylated region (DMR) occurs in patients with myelodysplastic syndromes (MDS). *Methods*. We studied 43 patients, 31 males and 12 females, with previously untreated MDS.Patients were classified according to WHO and WPSS risk stratification systems and according to cytogenetic analysis in good, intermediate and poor prognosis karyotypes. Median age was 73 years (range 16-92). DNA methylation pattern was determined by methylation-specific PCR of bone marrow samples previously subjected to bisulphite modification, according to standard protocols. Twelve subjects investigated for borderline thrombocytopenia, that were proven to have no malignancy, uniparental disomy 14 or Prader-Willi syndrome served as controls. *Results*. The normal pattern of the MEG3 gene consists of 2 alleles, one corresponding to the methylated paternal allele, and one corresponding to the unmethylated maternal allele, while the normal pattern of the SNRPN gene consists of a band deriving from the methylated maternal chromosome and deriving from the unmethylated paternal chromosome. No abnormal methylation pattern was observed in any of the control group subjects. We found that alterations of the DMR (presence of the methylated allele only) of the MEG3 and SNRPN genes were present in 15 (34.88%) of the patients studied, while 8 patients (18.6%) presented abnormal methylation pattern of both genes. There was a trend in patients with abnormal MEG3 methylation for reduced overall survival (HR 2.15; p=0.072,). No association was found between methylation of SNRPN and overall survival (HR=1.08; p=0.85). However, patients who presented with abnormal methylation of both genes had poorer overall survival (HR=2.14; p=0.147). We observed no significant association between WPSS risk group, cytogenetic risk group and MEG3 or SNRPN aberrant methylation. However, patients with RAEB-I disease were 20 fold more likely to have the MEG3 gene methylated (OR=20, p=0.027). *Summary and Conclusions*. MEG3 and SNRPN promoter hypermethylation occurs in MDS patients, and may be implicated in disease's pathogenesis. The impact of the methylation status of these genes on overall survival warrants further investigation.

SERUM ERYTHROPOIETIN AT DIAGNOSIS IN LOW GRADE MYELODYSPLASTIC SYNDROME CORRELATES WITH BOTH RED CELL ZINC PROTOPORPHYRIN AND SERUM LDH AND MAY REFLECT SEVERITY OF INEFFECTIVE ERYTHROPOIESIS

P.T. Murphy, S.M. McPherson, K.D. Breen, J.S. Slaby

Beaumont Hospital, DUBLIN, Ireland

Background. Anemia in low grade myelodysplastic syndromes (MDS) (refractory anemia (RA), refractory cytopenia with multi-lineage dysplasia (RCMD), refractory anemia with ring sideroblasts (RARS) and refractory cytopenia with multi-lineage dysplasia and ringed sideroblasts (RCMD-RS)) is characterised by ineffective erythropoiesis due to increased proliferation and increased apoptosis of erythroid precursors. Previously, we detected elevated percentages of hypochromic red cells (%HRC) in many low grade MDS cases, as well as a strong correlation between %HRC and red cell zinc protoporyphyrin (ZnPP) levels, suggesting that functional iron deficiency can contribute to ineffective erythropoiesis, probably as a result of mitochondrial dysfunction with abnormal transport and incorporation of iron into heme. A recent meta-analysis suggests that recombinant erythropoietin therapy (R-EPO) use in MDS results in better hemoglobin (Hb) responses in patients with lower baseline serum EPO levels. *Aims*. We wished to investigate for correlations between serum EPO levels at diagnosis and other baseline characteristics in low grade MDS. *Methods*. We measured complete blood count (CBC), reticulocyte count, serum LDH (normal range 0-500 IU/L), serum iron and percentage transferring saturation, serum ferritin, red cell ZnPP (normal range 0-3 ug/g Hb) and serum EPO (normal range 5.7-19.4 IU/L) in 22 untreated patients (15 male, 7 female, mean age 67) with *de novo* low grade MDS at diagnosis (16 RCMD, 6 RCMD-RS). All patients had normal/increased iron stores on bone marrow aspirate. *Results*. Mean±SD for Hb, serum LDH, serum EPO and red cell ZnPP (results available for 17 patients) were 11.17±1.5 g/dL, 414.36±90.84 IU/L, 77.63±87.13 IU/L and 4.57±4.12 ug/g Hb respectively. We found statistically significant correlations between serum EPO and red cell ZnPP levels (Pearson correlation coefficient, r=0.647, p=0.005), between serum LDH and red cell ZnPP (r=0.571, p=0.013) and between serum EPO and serum LDH levels (r=0.45, p=0.04). However, there were no significant correlations between either serum EPO, serum LDH or red cell ZnPP levels and serum iron, percentage transferring saturation, serum ferritin or Hb concentration. *Conclusions*. We detected statistically significant correlations between serum EPO and red cell ZnPP, between serum LDH and red cell ZnPP and between serum EPO and serum LDH. One possible interpretation is that red cell ZnPP and serum LDH reflect the degree of ineffective erythropoiesis in low grade MDS and that there may be a compensatory increase in EPO production in proportion to the degree of ineffective erythropoiesis, possibly due to impaired oxygen carrying capacity of red cells with increased red cell ZnPP. A correlation between ineffective erythropoiesis and serum EPO in low grade MDS could partially explain why R-EPO therapy may be less effective in patients with higher baseline serum EPO levels. However, other possible effects, by heme oxygenase/heat shock protein 32 inhibition or otherwise, of chronically elevated red cell ZnPP levels within the myelodysplastic bone marrow microenvironment remain unknown and a possible area of future research.

0795

ANALYSIS OF EXPRESSION OF THE WNT-ANTAGONIST SFRP1 AND QUANTIFICATION OF ITS PROMOTER METHYLATION BY PYROSEQUENCING IN BONE MARROW MONONUCLEAR CELLS FROM PATIENTS WITH DIFFERENT RISK-TYPES OF MDS, ALL, AND AML

J. Reins,[1] M. Mossner,[1] A. Kmetsch,[1] U. Platzbecker,[2] E. Thiel,[1] W.K. Hofmann[1]

[1]Charite Campus Benjamin Franklin, Department of Hematology and Oncology, BERLIN; [2]University Hospital Dresden, Department of Hematology and Oncology, DRESDEN, Germany

Secreted frizzled related proteins (SFRPs) belong to a family of extracellular antagonists of Wnt-dependent signaling. The loss or decrease of SFRPs leads to activation of the Wnt pathway and may play an important role in the pathogenesis of solid tumours and hematopoietic malignancies. Epigenetic alterations of SFRP genes have been previously examined in acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). However, in myelodysplastic syndrome (MDS), the role of SFRPs in dyserythropoiesis has not been investigated. SFRP1 is one of five known secreted frizzled related proteins whose expression was recently observed to be down-regulated due to hypermethylation in various malignancies. Therefore we have examined whether the RNA expression of this gene is correlated with the promoter methylation of SFRP1 in bone marrow cells derived from patients with MDS, AML and ALL as compared to healthy individuals. RNA and DNA was isolated from bone marrow mononuclear cells from patients with different subtypes of MDS (low risk, n=16; int-1, n=24; int-2, n=14; high risk, n=13), ALL (n=20) and AML (n=24) at the time of initial diagnosis. Bone marrow mononuclear cells from 24 healthy individuals served as normal controls. RNA expression of SFRP1 was analyzed by real time reverse transcription PCR. Promoter methylation was quantified by DNA-pyrosequencing. A transcriptional down-regulation was observed in 13 (86%) low risk, 21 (87%) int-1, 14 (82%) int-2 and 11 (84%) high risk MDS samples. Twenty-two (91%) of AML and 17 (85%) of ALL samples showed marginal expression of SFRP1. The down-regulation compared to normal controls was as follows: 3.2 fold for low risk, 2.9 fold for int-1, 8.3 fold for int-2, 10.7 fold for high risk MDS, 16 fold for AML and 19.3 fold for ALL. In all 4 MDS risk types a low promoter methylation for SFRP1 was detected. In AML and ALL samples, we confirmed as previously reported, a significant correlation between transcriptional down-regulation and quantitative promoter hypermethylation. Independent of the risk type, all MDS samples showed a significant lower expression in comparison to healthy controls (n=19) but no aberrant promoter methylation could be observed. In summary, epigenetic inactivation of SFRP1 caused by hypermethylation may

be one underlying mechanism in AML and ALL but can not be applied in our MDS cohort. Therefore, the regulation of SFRP1 seems to be different in MDS as compared to acute leukemia. Current studies explore other regulatory mechanisms of SFRP1 including its role in Wnt-dependent signaling in myelodysplastic syndrome.

A NOVEL PEDIGREE WITH HETEROZYGOUS GERMLINE RUNX1 MUTATION CAUSING FAMILIAL MDS-RELATED AML - CAN THESE FAMILIES SERVE AS A MULTISTEP MODEL FOR LEUKAEMIC TRANSFORMATION IN MDS AND AML?

T. Ripperger,[1] D. Steinemann,[1] G. Göhring,[1] C.M. Niemeyer,[2] B. Strahm,[2] B. Schlegelberger[1]

[1]Hannover Medical School, HANNOVER; [2]University of Freiburg, FREIBURG, Germany

Background. Heterozygous germline mutations in RUNX1 are causative genetic alterations in familial platelet disorder with a propensity to myeloid malignancy (FPD/MM). To discuss the potential use of FPD/MM as a multistep model for leukaemic transformation in MDS and AML, we report here on a father and daughter with familial MDS-related AML (MDR-AML) and differing clinical course caused by a heterozygous germline mutation in RUNX1 and different secondary chromosomal aberrations. *Subjects*. Following a brief history of symptomatic anaemia, the female index patient presented with MDS-related AML (MDR-AML) at age 13. While her twin brother, her one younger and one older brother, and her mother are clinically healthy, MDR-AML was diagnosed in her 47-year-old father six months earlier. No history of thrombocytopenia or platelet defects was reported in the family. *Results*. In both patients, a heterozygous nonsense mutation was detected in RUNX1 (NM_001001890.2) by direct sequencing. The mutation c.520C>T (p.Arg174X) causes a premature truncation at the end of the runt homology domain (RHD). Chromosome analysis of bone marrow cells from the index patient showed a deletion of 5q (del(5q)) and a structural aberration of 2q. In addition, array-based comparative genomic hybridization (aCGH) confirmed the del(5q) and pointed to an unbalanced translocation t(2;6)(q36;q23), finally confirmed by fluorescence *in situ* hybridization using a specific probe for MYB. In contrast, the only aberration identified in bone marrow cells of the diseased father was a loss of the Y chromosome (-Y). *Conclusions.* Currently less than 30 pedigrees with FPD/MM are known. While most RUNX1 mutations in FPD/MM cluster in RHD and are unique to individual pedigrees, a broad range of intra and interfamilial clinical variability characterizes FPD/MM. Whereas -Y is a typical chromosome aberration of adult MDS associated with a good prognosis, del(5q) is rarely seen in childhood MDS and usually occurs within complex clones associated with a more unfavourable prognosis. Notably, del(5q) is frequently accompanied by aberrations of chromosome 6. In the index patient, the gain of 6q led to an additional copy of the proto-oncogene MYB, an essential transcription factor in haematopoietic cells. While heterozygous mutations in RUNX1 are not sufficient for leukaemogenesis, somatically acquired secondary events may promote transformation leading to overt MDS and AML. The recruitment of different secondary alterations may partially explain the variable penetrance and clinical heterogeneity seen in FPD/MM. Consequently, rare FPD/MM-related myeloid malignancies may serve as a model for multistep leukaemogenesis in MDS/ AML and, as illustrated here, aCGH may lead to the identification of candidate genes involved in malignant transformation in familial and sporadic myeloid malignancies.

DECREASE IN INTRA- AND EXTRA-CELLULAR FREE IRON SPECIES AND OXIDATIVE STRESS PARAMETERS AND INCREASE IN SERUM AND URINARY HEPCIDIN DURING TREATMENT WITH DEFERASIROX IN IRON-LOADED PATIENTS WITH MDS

H. Ghoti,[1] E. Fibach,[2] D. Merkel,[3] J. Amer,[2] A. Nagler,[3] I. Levi,[4] S. Grisariu,[2] E. Naparstek,[5] A. Ackerstein,[6] G. Olbina,[7] M. Westerman,[7] T. Ganz,[8] E.A. Rachmilewitz[1]

[1]Edith Wolfson Medical Center, HOLON, Israel; [2]Hadassah - Hebrew University Medical School, JERUSALEM, Israel; [3]Chaim Sheba Medical Center, TEL-HASHOMER, Israel; [4]Soroka University Medical Center, BEER-SHEVA, Israel; [5]Tel Aviv Sourasky Medical Center, TEL AVIV, Israel; [6]Novartis, PETAH TIKVA, Israel; [7]Intrinsic LifeSciences LLC, LA JOLLA, CA, USA; [8]David Geffen School of Medicine at UCLA, LOS ANGELES, CA, USA

Background. Chronically transfused patients with acquired or congenital haemolytic anaemias, including myelodysplastic syndromes (MDS), eventually develop iron overload. The major criteria used to quantify the degree of iron overload are the number of transfusions and serum ferritin levels >1000 ng/mL. Recently, increased levels of intra- and extra-cellular free iron species, which catalyze the generation of reactive oxygen species (ROS) and consequently induce oxidative stress, have been identified in iron-overloaded patients. These include non-transferrin-bound iron and the redox-active fractions of labile plasma iron (LPI) pool and cellular labile iron pool (LIP) [Cytometry 73:22, 2008], both susceptible to iron chelation. *Aims*. To measure LPI, LIP, serum ferritin, and serum and urinary hepcidin, in iron-overloaded patients with low-risk MDS following treatment with the once-daily oral iron chelator, deferasirox. Changes in parameters of oxidative stress, such as ROS, reduced glutathione (GSH) and membrane lipid peroxidation, were also determined. *Methods*. Nineteen patients (7 males, 12 females, mean age 68±13 years) with low-risk MDS (IPSS 0-1) who received a mean of 62 packed cell (PC) units were treated with deferasirox 20 mg/kg/day for a mean of 95 (63-163) days. Mean baseline serum ferritin level was 3008±1797 ng/mL. ROS, GSH, lipid peroxidation and LIP were measured using flow cytometry techniques in red blood cells (RBCs), platelets and polymorphonuclear leukocytes (PMN) [Eur J Haematol 79:463, 2008]. LPI was measured using fluorescence-based methods [Blood 102:2670, 2003], and serum and urinary hepcidin levels were measured by enzyme-linked immunoassay [Blood 112:3922, 2008]. *Results*. In RBCs, there were significant decreases in mean ROS (18%, p=0.01) and lipid peroxidation (72%, p=0.002), with concomitant increases in mean GSH in RBCs (108%, p=0.0001), platelets (53%, p=0.003) and PMN (66%, p<0.02). LIP in RBCs and platelets decreased from 21±2 to 15±2 and 26±13 to 19±10 MFC (mean fluorescence channel; p<0.02), respectively [Blood 112:924a, 2008]. In 16 patients with available data, LPI (normal ≤0.4 U) decreased from 0.39±0.43 to 0.11±0.45 U (p=0.02). RBC indices, serum ferritin and haemoglobin levels did not change throughout the study. Five and 10 patients with normal mean baseline serum (178±65 ng/mL) and urinary hepcidin (929±529 ng/mL), respectively, received a mean of 51 PC units. Fourteen and nine patients with high mean baseline serum (634±193 ng/mL) and urinary hepcidin (5840±4112 ng/mL), respectively, received a mean of 68 PC units. After treatment, hepcidin increases of 28% and 60% were found in patients with high baseline serum and urinary hepcidin, respectively. *Conclusions*. These data suggest that treatment with deferasirox for a mean of 95 days reduced toxic free iron species (LPI and LIP) and parameters of oxidative stress in low-risk, iron-overloaded patients with MDS. The novel methodologies applied in this study may be useful for evaluating the severity of iron overload and for monitoring iron chelation efficacy. The different baseline hepcidin levels were correlated with the number of transfusions received prior to treatment, effecting erythropoietic activity. ROS mediates hypoxic suppression of hepcidin [BBRC 356:312, 2007], therefore amelioration of oxidative stress resulted in an increase in serum and urinary hepcidin levels.

COMPARISON OF ALTERNATIVE SPLICING OF THE RETROVIRAL RECEPTOR/HEME EXPORTER FLVCR1 IN MYELODYSPLASTIC SYNDROMES AND NORMAL ERYTHROPOIESIS WITH DIAMOND BLACKFAN ANEMIA

D.P. Steensma, J.C. Porcher

Mayo Clinic, ROCHESTER MINNESOTA, USA

Background. Recent observations suggest enhanced alternative splicing of transcripts encoding feline leukemia virus subgroup C cellular receptor (FLVCR1) and subsequent FLVCR1 insufficiency may be a contributing factor to the erythropoietic defect observed in Diamond Blackfan anemia (DBA) primary cells (Rey MA *et al.*, Haematologica November 2008 93:1617.) Because there are parallels between the erythropoietic defects in DBA and myelodysplastic syndromes (MDS), including generation of a 5q- syndrome phenocopy by RNA-mediated interference of expression of ribosomal protein subunit RPS14 (Ebert BL *et al.* Nature 2008; 451:335), we studied FLVCR1 mRNA splicing patterns in primary cells from MDS patients. *Methods*. We examined density centrifugation-isolated peripheral blood or bone marrow mononuclear cells from 15 normal donors and 20 patients with various forms of MDS lacking del5q31. In a subset of samples, CD71+ (enriched for erythroid precursors) and CD71- cell populations were separated immunomagnetically and compared. RNA was isolated, and cDNA generated and amplified by PCR using primers complementary to the FLVCR1 transmembrane 1 and 12-encoding sequences. Splicing isoforms identified by gel or on-chip electrophoresis were then cloned into competent cells using TOPO cloning, and sequenced. *Results*. We identified 5 different FLVCR1 iso-

forms: the full-length, 10-exon, 2008 bp transcript encoding a 555 aa protein ("FL"), and 4 variants lacking exons 2 (E2-), 6 (E6-), and combinations thereof (lacking exons 2 and 6 (E2-6-); and a novel isoform lacking exons 2,3, and 6 (E2-3-6-)). We did not identify variants lacking exon 3 alone (E3-) or exons 3 and 6 (E3-6-), previously reported in a single DBA sample. Patterns in CD71+ and CD71- cells in the same sample were identical. The E2, E2-6-, and E2-3-6- isoforms include a premature termination codon, whereas E3- and E3-6- encode variant FLVCR1 that renders transfected cells only weakly susceptible to subgroup C feline leukemia virus. A previous analysis (Rey MA *et al.* Haematologica 2008) had reported FL and E6- in healthy cells and in DBA cells, but observed E2-, E2-6-, E3-, and E3-6- exclusively in patients with DBA. In contrast, we detected the E2-6- FLVCR1 isoforms in 6/15 healthy controls and 9/20 MDS; E2- and E2-3-6- were MDS-restricted (1 patient each). Notably, 4 MDS patients lacked full-length FLVCR1 transcripts and exhibited only shorter transcripts, predicted to encode proteins with diminished function. *Conclusions*. Variant transcripts of FLVCR1 generated by alternative pre-mRNA splicing identical to those recently detected in DBA are observed in MDS, and may contribute to the defective erythropoiesis seen in those acquired disorders. However, one FLVCR1 transcript previously reported to be restricted to DBA was observed in multiple healthy control samples.

CD34 CELLS ARE UNDER OXIDATIVE STRESS - POSSIBLE IMPLICATION IN MDS PATHOGENESIS

A. C. Gonçalves,[1] E. Cortesão,[2] V. Alves,[3] A. I. Espadana,[4] L. Rito,[4] E. Magalhães,[4] S. Pereira,[5] C. Moucho,[6] A. Pereira,[5] I. Sousa,[4] A. Teixeira,[4] A.B. Sarmento-Ribeiro[3]

[1]Faculty of Medicine, University of Coimbra, COIMBRA; [2]University Hospital of Coimbra, Faculty of Medicine and CIMAGO, COIMBRA; [3]Faculty of Medicine and CIMAGO, University of Coimbra, COIMBRA; [4]Clinical Hematology Service, University Hospital of Coimbra (HUC), COIMBRA; [5]Hospital Distrital da Figueira da Foz, EPE, FIGUEIRA DA FOZ; [6]University Hospital of Coimbra (HUC), COIMBRA, Portugal

Myelodysplastic syndromes (MDS) are a heterogeneous bone marrow disorders characterized by hemopoietic insufficiency associated with cytopenias and an additional risk of leukemic transformation. The aetiology and pathogenesis of MDS remain poorly characterized and a therapeutic impasse persists because of the disease's multifactorial pathogenetic features, heterogeneous stages, and the late onset (patients aged 65 and older). Reactive oxygen species (ROS) are highly reactive oxygen derivatives produced mainly as byproducts of aerobic respiration and reduced glutathione (GSH), an antioxidant defense, reacts with them to prevent oxidative damage to intracellular molecules (DNA, proteins, and lipids). Oxidative stress, resulting from an imbalance between ROS production and antioxidant defenses, contributes to cell damage, apoptosis and ineffective hematopoiesis, and may be involved in MDS aetiology and pathogenesis. Indirect evidences observed by other authors suggest a role for oxidative stress in MDS pathogenesis. The elevated plasma levels of malondialdehyde, the lipid peroxidation product, the higher expression of the antioxidant enzymes glutathione peroxidase 1 (GPx1) and manganese superoxide dismutase (MnSOD), and the *in vitro* stimulation of MDS progenitor cells by thiol antioxidants, such as N-acetyl cysteine, provide some support for this hypotesis. With this study we hope to contribute to the clarification of the involvement of oxidative stress and mitochondrial dysfunction in the pathogenesis of MDS and correlate these mechanisms with risk prognostic groups, prognosis, namely the evolution to acute leukemia. For this purpose we have examined the expression levels of ROS, peroxide and superoxide, GSH and mitochondrial membrane potential, in CD34 bone marrow cells populations collected at diagnosis from 22 patients with *de novo* MDS and in 6 Immune thrombocytopenic purpura (ITP) (non-malignant controls). The expression of these oxidative stress parameters was evaluated by flow cytometry using the fluorescent probes, H2DCF-DA, DHE, mercury orange and JC1, respectively. The results are expressed as mean intensity fluorescent (MIF) arbitrary units. The patient group median age was 77 years (33-84), gender M/F=12/11, WHO subtypes: RCMD (n=9), RA (n=5), RAEB-1 (n=1), RAEB-2 (n=6), 5q- syndrome (n=1) and IPSS: low (n=9), intermediate-1 (n=9) and intermediate-2 (n=4). Our results show that CD34 MDS cells have higher peroxides levels expression (519±626 MIF), although a lower statistically significative superoxide (205±98 MIF) and GSH (170±148 MIF) expression levels, when compared with controls (334±187 MIF, 332±170 MIF, 171±70 MIF, respectively). However, we observed that ROS and GSH expression is MDS subtype-dependent. The higher peroxide and superoxide levels were observed in RA patients (1459±373 MIF and 252±126 MIF, respectively), and the lower GSH levels were observed in RAEB-2 patients (32±15 MIF). On the other hand, we observed that RCMD patients have lower mitochondrial membrane potential (0,947±0,530 JC1 M/A) than controls and others subtypes (0,643±0,448 MIF, 0,601±0,319 MIF, 0,516±0,356 MIF, respectively). Our study suggests the involvement of oxidative stress and mitochondrial dysfunction in pathogenesis of MDS, mainly in subtypes RA and RAEB-2.

Introduction and Aims. The JAK2 V617 mutation, a molecular hallmark of typical myeloproliferative disorders (MPDs) has been reported to occur in myelodysplastic syndrome (MDS), yet its clinical significance remains unclear. Furthermore, there is a paucity of data on the prevalence of JAK2 V617F among MDS cases with deletion of the long arm of chromosome 5 [del(5q)]cytogenetic abnormality. *Methods*. We retrospectively reviewed the case files of the participating hematology departments based in tertiary-level hospitals to identify primary MDS,that fulfill the WHO 2001 diagnostic criteria. We studied 265 primary MDS cases representative of the MDS population referred to the collaborating hospitals. To establish the frequency of JAK2 V617F among MDS cases with the del(5q), we screened an additional cohort of 65 MDS cases known to harbor this abnormality by conventional G-banded cytogenetics. We also screened 22 CMML cases, 6 RARS-T cases and 10 MDS/MPD-unclassified (MDS/MPD-U) cases. Clinical and laboratory characteristics of JAK2 V617F positive cases were compared to JAK2 V617F negative cases DNA isolated from peripheral blood or bone marrow fresh samples or from archived bone marrow smears. The JAK2 V617F mutation was detected using a tetra-primer amplification refractory mutation system (ARMS) polymerase chain reaction (PCR) assay with a sensitivity of 1%. *Results*. Overall, we identified 12 cases carrying the JAK2 V617F mutation within the primary MDS cases. With respect to MDS subtype, one had the del(5q) syndrome, 2 had RA, 3 had RARS, and 6 RAEB. Among the 265 MDS cases representing the general MDS population, 9 patients (3.4%; 95% CI 1.6% to 6.3%) carried the mutation. Among del(5q) MDS patients, the JAK2 V617F mutation was more common (8%; 95% CI 3% to 16.6%). Among JAK2 V617F positive cases the del(5q) (p=0.016) was more common Patients carrying the V617F mutation also had higher neutrophil (p=0.039) and platelet counts (p=0.017). There were no differences between JAK2 V617F positive and wild-type patients regarding age, International Prognostic Scoring System (IPSS) grouping, or hemoglobin values. In multivariable analysis, only platelet count at diagnosis was associated with JAK2 V617F positivity (p=0.015). The JAK2 V617F mutation was not associated with decreased transfusion requirements or recombinant erythropoietin use and did not appear to influence the odds of transformation to acute leukemia. Among, MDS/MPD cases, 3 CMML cases, 5 RARS-T cases and 2 MDS/MPD-U carried the mutation. *Conclusions*. JAK2 V617F mutation is a rare event in primary MDS, occurs commonly in association with del(5q) and correlates with increased platelet counts at diagnosis. The mutation does not appear to carry prognostic significance or modify the clinical course of the disease. JAK2 V617F is common among MDS/MPD overlap cases.

SUPPRESSION OF THE DNA DAMAGE RESPONSE IN ACUTE MYELOID LEUKEMIA VERSUS MYELODYSPLASTIC SYNDROME

S. Boehrer,[1] L. Adès,[1] C. Gardin,[1] W.K. Hofmann,[2] P. Fenaux,[1] G. Kroemer[3]

[1]Hôpital Avicenne, BOBIGNY, France; [2]University Hospital B Franklin, Charité, BERLIN, Germany; [3]Institut Gustave Roussy, VILLEJUIF, France

Background. The molecular mechanisms responsible for the evolution from the preleukemic entities of low-risk myelodysplastic syndrome (MDS) to the less favorable forms of high-risk MDS, as well as those enabling transformation to acute myeloid leukemia (AML), are still incompletely understood. Evidence from solid tumors demonstrates that preneoplastic lesions activate signaling pathways of a DNA damage response (DDR), which functions as an "anti-cancer barrier" hindering tumorigenesis. *Aims and Methods*. To test the hypothesis that alteration of the DDR underlies evolution/transformation of MDS, we assessed markers of DDR (phosphorylation of ATM, Chk-1, Chk-2 and H2AX, apoptosis; G2/M arrest) in cell lines representing different entities of MDS (P39, MOLM-13) and AML (MV4-11, KG-1) before and after γ-irradiation. In addition, the expression pattern of DDR proteins in *ex vivo* patient material was determined by immunohistochemistry. Thus bone marrow biopsies of normal controls (n=2), MDS (n=27; IPSS: Int1: n=7, Int2: n=14, High: n=6) and AML (n=5) patients (pts) were stained for expression of P-ATM-Ser1981, P-Chk-1-Ser317, P-Chk-2-Ser68, and γ-H2AX. *Results*. While γ-irradiation induced apoptosis and G2/M arrest and a concomitant increase in the phosphorylation of ATM, Chk-1 and H2AX in MDS-derived cell lines, this radiation-response was attenuated in the AML-derived cell lines. Noteworthy, KG-1 but not P39 cells exhibit signs of an endogenous activation of the DDR. In addition, immunohistochemical assessment of BM biopsies provides evidence that i) normal controls exhibit <5% P-ATM+, γ-H2AX+, P-Chk-1+ and P-Chk-2+ cells; ii) the percentage of P-ATM+ cells increases in samples from AML pts (median: 75% P-ATM+) as compared to high-risk MDS samples (IPSS high: median 42% P-ATM+, Int-2: median: 26% P-ATM+) and significantly correlates with the percentage of BM blasts (p<0.01); iii) the frequency of γ-H2AX+ cells is heterogeneous in all subgroups of AML and MDS and is not correlated with the percentage of BM blasts; iv) whereas intermediate-1 MDS samples contain as little P-Chk-1+ and P-Chk-2+ as healthy controls, staining for checkpoint kinases increases in intermediate-2 and high-risk MDS (median P-Chk-1+: 32%, median P-Chk-2+: 51%) yet declines to near-to-background levels in AML samples (median P-Chk-1+: 2%, median P-Chk-2+: 8%). P-Chk-1+ and P-Chk-2+ expression are not correlated with the percentage of BM blasts. Nevertheless P-Chk-1+ expression significantly correlates with the P-Chk-2+ expression (p<0.001). Conclusions: Thus the activation of Chk-1 and Chk-2 behaves in accord with the paradigm established for solid tumors, while ATM is activated during and beyond transformation. We hereby demonstrate the heterogeneity of the DDR response in MDS and AML and provide evidence for its selective suppression in AML due to the uncoupling between activated ATM and inactive checkpoint kinases.

IMMUNE EFFECTORS AND REGULATORY T CELLS IN MYELODYSPLASTIC SYNDROMES (MDS)

F. Alfinito, M. Sica, L. Luciano, R. Della Pepa, C. Palladino, I. Ferrara, U. Giani, G. Ruggiero, G. Terrazzano

University of Naples Federico II, NAPLES, Italy

Background. Primary MDS identify a heterogeneous group of hematological clonal disorders characterized by ineffective and dysplastic hemopoiesis with a varying degree of cytopenias and a substantial risk of progression to acute leukemia. Relevance of immune response dysregulation in the pathogenesis of BM failure conditions has been suggested; several studies in MDS patients have described occurrence of oligoclonal $CD8^+$ T cell repertoire, ability of $CD8^+$ T lymphocytes to impair *in vitro* development of the erythroid and granulocytic progenitors, primary defects of tolerance control as well as targeting of myelodysplastic BM precursors by Cytotoxic T lymphocytes (CTL). *Aims*. Our study focuses on the immunological networks that characterize the first stages of MDS. Here we describe bone marrow (BM) and peripheral blood (PB) distribution of immune effectors and their activation status in order to identify more homogeneous groups of MDS patients in which the pathogenetic involvement of immune-mediated mechanisms might be inferred. *Methods*. We examined whole BM and PB specimens of 51 MDS patients that were categorized according to WHO classification and IPSS score: 27 belonged to the Low Risk Group (9 RA, 1 RAS, 16 RCMD, 1 MDSU), 17 to the Intermediate-1 (Int-1) Risk Group (3 RA, 12 RCMD, 1 RAEB 1, 1 MDSU), 3 to the Intermediate-2 (Int-2) Risk Group (1RAEB 1 and 2 RAEB 2)and 4 to the High Risk Group (4 RAEB 2). Analysis of immune effectors and $CD4^+CD25^{high}Foxp3^+$ (T reg) were performed by using immune fluorescence and flow cytometry. Mann-Withney test, Wilcoxon matched-pairs signed-rank test were used when appropriate. In order to evaluate the hypothesis that in the Low and Int-1 category the immunological variables could have a no homogeneous distribution, a multistep cluster analysis algorithm was applied. *Results*. This study reveales an altered distribution of adaptive immune effectors in BM versus PB of Low and Int-1 Risk MDS patients, with increased BM Treg levels in the Int-2/High Risk Group. More intriguingly, BM Treg cells cluster a Low Risk sub-group characterized by significant BM recruitment of CD8 effectors, while a clustered distribution of CD54 expression on BM CD8 T lymphocytes and of CD4 cells are observed in Int-1 Risk Group. *Conclusions*. The clustered distribution of immunological variables in MDS patients highlights the relevance of BM analysis for a more homogeneous grouping of MDS patients. Taken in all our data point to the involvement of immune-mediated mechanisms in the first stages of the disease. We suggest that the clustered BM distribution of immunological parameters could represent an useful criterion for a more homogeneous grouping of MDS patients. This approach could shed light over the intra-group heterogeneity of current MDS classification also representing a potential tool to improve the clinical management of patients.

NANOG MRNA IS HIGHLY EXPRESSED IN MDS CELLS AND DURING ERYTHROID DIFFERENTIATION

J. Xavier

Hemocentro UNICAMP, CAMPINAS, Brazil

Background. Myelodysplastic syndrome (MDS) is a group of hematopoietic disorders characterized by abnormal differentiation and by a risk of progression towards acute myeloid leukemia (AML). In MDS, NFκB activation is responsible for the progressive suppression of cell apoptosis, contributing to the progression towards AML. The family of NFκB proteins is essential in many physiologic responses such as immunity, differentiation and development. NFκB is repressed by NANOG binding in the cytoplasm, resulting in inhibition of the transcriptional activity of NFκB proteins. This process cooperates with Stat3 to maintain pluripotency. *Aims*. Verify NANOG expression in bone marrow cells and during $CD34^+$ erythroid differentiation of MDS patients. *Methods*. Bone marrow samples were collected from 12 MDS (9 RA, 2 RARS and 1 RAEBt) patients, 8 AML and 7 healthy donors. The erythrocytes were lysed and the RNA was extracted for relative analysis by Real Time PCR, using the gene ABL as endogenous control. CD34+ cells were isolated from bone marrow of 4 patients with MDS and 3 healthy donors for erythroid differentiation. Briefly, CD34 cells were cultured in methylcellulose with SCF(50ng/mL), IL3 (30UI/mL) and EPO (3U/mL) for 6 days. The colonies were then washed and the cells incubated in a liquid culture medium α-MEM with EPO (2U/mL), 30% of FBS, 8% of BSA, 300 mg/mL of holotransferrin and 10-5M of ß-mercaptoethanol. The cells were kept in culture for 9 more days. The cells were collected on days 0, 3 and 6 of this second phase for RNA extraction.

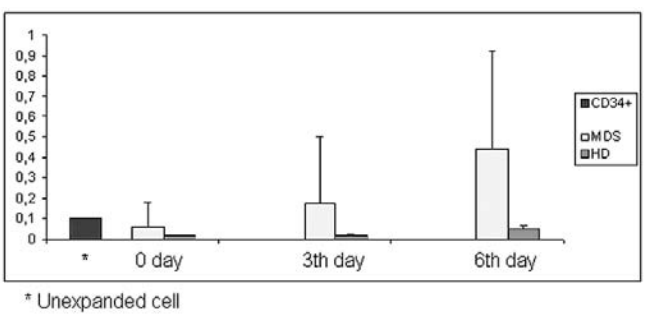

Figure 1. NANOG mRNA expression during erythroid differentiation of $CD34^+$ cells from MDS patients and healthy controls (HD). Results are presented as mean± SD, of cells collected on days 0, 3 and 6 of second phase of erythroid differentiation. NANOG expression of unexpanded $CD34^+$ sample obtained from one healthy donor is showed for comparison.

Results. NANOG was overexpressed in MDS cells, as compared to AML patients and healthy donors [median (min-max); MDS = 3.16 (0.93 -14.11); AML = 1.23 (0.27-4.88); healthy donors = 1.16 (0.16-3.24); MDS vs AML p=0.0082; MDS vs normal, p= 0.0141]. NANOG overexpression in MDS was also higher throughout all phases of CD34$^+$ erythroid differentiation when compared to healthy donor cells. The higher expression of NANOG was observed in MDS patients, on the 6th day of culture, being at least 4 times higher than in unexpanded CD34$^+$ cells from healthy donors. These results are presented in the Figure 1 as mean ± SD. *Conclusions*. The reduced expression of NANOG in AML cells compared to MDS may be related to the increased activity of NFκB during MDS progression. It is known that the inhibition of PI3K results in both NANOG mRNA and protein decrease. Taken together these results lead us to suggest that the increased transcription of NANOG during the erythroid differentiation may be related to PI3K activation.

EXPRESSION PATTERNS OF CELL CYCLE AND DNA REPLICATION GENES DISCRIMINATE EARLY AND ADVANCED MDS

A. Vasikova,[1] M. Belickova,[1] E. Budinska,[2] J. Cermak[1]

[1]Institute of Hematology and Blood Transfusion, PRAGUE; [2]Institute of Biostatistics and Analyses, BRNO, Czech Republic

Background. MDS is a heterogeneous group of clonal disorders characterized by ineffective hematopoiesis resulting in peripheral cytopenia. MDS pathogenesis is still uncertain and identification of deregulated genes may contribute to detection of pathogenetic mechanisms involved in the disease at the molecular level. *Aims*. We studied differential gene expression in various MDS subtypes to identify possible molecular mechanisms participating on MDS pathogenesis and/or progression towards advanced stages or AML. Due to frequent transformation of MDS into AML, we also included patients with AML with multilineage dysplasia (MLD) evolved from MDS. *Methods*. Our study comprised 51 bone marrow samples from patients with primary MDS, AML with MLD and 7 controls. To determine MDS subtype specific gene expression pattern, we performed gene expression profiling using Illumina BeadChips on CD34$^+$ haematopoietic progenitors. *Results*. In an attempt to distinguish controls from patient samples, we identified set of 825 genes and based on this gene set hierarchical clustering clearly separated controls from patients. Several pathways were identified to be deregulated in MDS: B cell receptor signaling pathway, chronic myeloid leukemia, small cell lung cancer and adipocytokine signaling pathway for down-regulated genes, while basal transcription factors and toll-like receptor signaling pathway were found for over-expressed genes. Highly down-regulated genes were involved in haematopoietic cell differentiation and maturation (VPREB1, VPREB3, EBF1, NR4A2) or have been reported to be associated with tumour progression and invasion (NPY, CTGF). On the contrary, genes being highly up-regulated in MDS participate in haemoglobin synthesis (HBG1, HBG2), cell growth and proliferation (MYC) or angiogenesis (ANGPT1). To determine expression differences among MDS subtypes, we grouped the patients into 6 categories according their diagnosis. Hierarchical clustering performed on the set of 241 significant genes grouped early MDS with RAEB-1 while RAEB-2 were clustered to AML with MLD patients, suggesting high difference between RAEB-1 and RAEB-2 diagnosis with respect to gene expression profiling. Further, clustering analysis resulted in identification of 5 distinct gene clusters - for each cluster functional annotation by DAVID database was done. Genes involved in cluster 3 and 5 showed inverse expression pattern between early MDS and RAEB-2 or AML with MLD patients. Within cluster 3, we found genes involved in mitotic cell cycle, DNA replication and chromosome segregation up-regulated in early MDS. Up-regulation of these genes may reflect increased proliferative activity of bone marrow. Since annotation of genes from cluster 5 was not successful (p<0.05) we focused on the particular genes showing the highest up-regulation in RAEB-2 and AML with MLD patients and we identified genes involved in the regulation of gene expression (BMI1), signal transduction (EMR1, proto-oncogene MERTK), anti-apoptosis (VNN1). This finding may reflect defective proliferation and decreased rate of apoptosis in advanced MDS. *Summary*. To conclude, we defined set of genes differentially expressed between controls and MDS or AML with MLD samples. Furthermore, our data demonstrate distinct expression patterns of early and advanced stages of MDS, where RAEB-1 patients showed more similarity to early MDS in contrast to RAEB-2 with profiles corresponding with AML with MLD.

LEUKEMIC TRANSFORMATION OF MDS PATIENTS DYSPLAYING ABNORMAL CYTOGENTICS WITHOUT DEFINITE DYSPLASIA IN BONE MARROW CELLS

S.Y. Kim,[1] M.S Kim,[2] K.J Han,[2] M. Lee,[1] W.S. Min,[3] J.W. Lee[3]

[1]KonKuk University Medical Center, SEOUL; [2]The Catholic University of Korea, SEOUL; [3]Catholic Hematopoietic Stem Cell Transplantation Center, SEOUL, South-Korea

Background. In 2008, the WHO classified patients with cytopenia that had cytogenetic abnormalities without dysplasia of bone marrow cells as myelodysplastic syndrome, unclassifiable (MDS-U). Because of the rarity of this disease category, its clinical course has not been fully studied. *Aims*. We performed a retrospective study to determine the prognosis and clinical course of this disease category. *Methods*. Thirty one patients with the characteristics of this category of MDS at the time of the initial diagnosis were studied. The bone marrow of these patients initially showed no definite dysplasia and less than 1% of blasts. The risk of leukemic transformation and leukemic transformation-free survival of the patients were analyzed by the Kaplan-Meier survival analysis. Allogeneic stem cell transplantation was considered as a censoring event. *Results*. The most common cytogenetic abnormality of the patients was trisomy 8 (n=18), followed by monosomy 7/deletion 7q (n= 5) and deletion 1q (n=5). Other chromosome abnormalities included isochromosome 17q (n=1), trisomy 15 (n=1), and monosomy 21 (n=1). The initial diagnoses of the patients were aplastic anemia (n=26), Behcet's disease (n=2), paroxysmal nocturnal hemoglobinuria (PNH) (n=1), systemic lupus erythematosus (n=1), and drug related cytopenia (n=1). During the follow-up period, we observed three cases of typical MDS and three cases of AML transformation. The time to AML evolution, from the initial diagnosis, was 2.4, 2.7, and 3.3 years, respectively. The 5-year cumulative leukemic transformation risk was 0% in the trisomy 8 group of patients and 37.5% for the other abnormal chromosome findings (p= 0.15). The 5-year probability of leukemic transformation-free survival was 92.9% in the trisomy 8 group and 52.1% for all other chromosome abnormalities (p=0.014). *Conclusions*. The results of this study support the 2008 WHO classification where cytopenia that have cytogenetic abnormalities without dysplasia of bone marrow cells is a subtype of MDS and associated with a risk for AML transformation. In addition, the presence of trisomy 8 as the sole cytogenetic abnormality, in the absence of bone marrow dysplasia, was not associated with the diagnosis of MDS.

THE USE OF IRON CHELATION THERAPY FOR TRANSFUSION DEPENDENT MYELODYSPLASTIC SYNDROME PATIENTS: A CROSS-SECTIONAL STUDY IN BELGIUM

M Delforge,[1] D. Selleslag,[2] A. Triffet,[3] P. Mineur,[4] Y. Beguin,[5] L. Noens,[6] W. Pluymers,[7] C. Ravoet[8]

[1]University Hospital Gasthuisberg, LEUVEN; [2]AZ Stin-Jan, BRUGGE; [3]CHU Charleroi, CHARLEROI; [4]Hopital St. Joseph, GILLY; [5]ULG, LIEGE; [6]Universitair Ziekenhuis, GENT; [7]Novartis, VILVOORDE; [8]J.Bordet Institute, BRUSSELS, Belgium

Background. MDS is a hematological disorder of older adults, with a median age at diagnosis of approximately 70 years.[1] Patients with isolated erythroid lineage involvement have a good prognosis; however, more than 90% of patients with MDS suffer from anemia, with 50-60% of patients having a hemoglobin level below 10 g/dL. Almost all patients with MDS are likely to receive red blood cell (RBC) transfusions at some time, and in 40% this is in reality the sole therapeutic option that can be offered. Irrespective of the strategy adopted to determine which patients with MDS should receive transfusions, transfusion dependency significantly worsens the survival. There is a lack of information on patient properties and treatment patterns in Belgium. *Aims*. To describe patients in terms of MDS subtypes, prognostic scores, selected laboratory values, treatment modalities, transfusion needs, and iron chelation therapy and to determine the percent of transfusion dependent MDS patients with serum ferritin levels ≥1000 μg/L. *Methods*. A cross-sectional observational study was conducted with the aim of assessing treatment patterns of transfusion-dependent MDS in Belgium. Though not validated, it was assumed that the majority of MDS patients in Belgium are seen in hematology centers, hence patients for the study were recruited in 30 large hematology centers. Patients were identified from patient files and current active case load. Transfusion dependence was defined as having received at least one RBC transfusion every 8 weeks over a period of 4

months prior to inclusion. *Results*. During the 2 month recruitment period we have identified a cohort of 193 transfusion dependent MDS patients in 30 participating centers. The median age of the patients was 76 yrs (range 44-103) and the median age at diagnosis was 74 yrs (range 39-95). Half of the patients received growth factor support for a median duration of 9 months. The average number of RBC units patients received in the past 4 months was 12 units (range 2-40). Transfusion need was higher in patients with higher IPSS scores than patients with lower IPSS scores. From the 176 patients whose serum ferritin values were available, 126 (65%) of these had levels above 1000 µg/L. 90 patients (47%) received iron chelation therapy with either Deferoxamine or Deferasirox. No difference in age was reported between chelated and non-chelated patients. 56 of the 92 non-chelated patients with available serum ferritin values reported values above 1000 µg/L. 74% of these 56 patients had an IPSS score of Low to Intermediate 1, making the majority of them potential candidates for iron chelation therapy, according to international recommendations.[2] *Summary and Conclusions*. This Belgian cross-sectional study identified a cohort of 193 transfusion dependent MDS patients and provides valuable information concerning treatment patterns. Many patients did not receive iron chelation therapy, although they were suitable candidates. Additional data on the reasons for not initiating iron chelation therapy will be presented at the meeting.

LENALIDOMIDE TREATMENT MODULATES CELL SURFACE MOLECULE EXPRESSION AND CYTOKINE SECRETION OF HUMAN MESENCHYMAL STROMAL CELLS FROM HEALTHY DONORS AND MDS PATIENTS

M. Wobus, G. Duennebier, M. Bornhaeuser, G. Ehninger, U. Platzbecker

University Hospital Dresden, DRESDEN, Germany

Background. Recent studies in patients with MDS have clearly demonstrated the clinical efficacy of lenalidomide. However, its exact mechanisms of action have not been elucidated yet. Myelosuppression is the most common adverse event and seems to dependent on dose as well MDS subtype, being rather infrequent in patients other than del5q. *Aims*. The aim of this study was to investigate whether lenalidomide affects the bone marrow microenvironment. Therefore, we analyzed properties of isolated mesenchymal stromal cells (MSCs) from MDS patients and from healthy controls. *Methods*. Bone marrow samples were collected from healthy donors (n=5) and patients with MDS (n=10; del5q MDS n=5, RA n=2, RAEB1/2 n=3). After density centrifugation MSCs were isolated according to the standard adhesion protocol and cultured in the presence or absence of lenalidomide (50 µM). We examined its effects on cell growth and proliferation; the expression of cell surface molecules, cytokine secretion as well as the potential for osteogenic differentiation. *Results*. Lenalidomide treatment of MSCs caused no phenotypical changes but proliferation was slightly increased. Interestingly, lenalidomide provoked an upregulation of mean fluorescence intensity of CD29 by 17.8±4.4% and of CD73 by 24±5.7%. Furthermore, the secretion of IL-6 and IL-8 was increased in lenalidomide treated cells whereas VEGF levels remained unchanged. We found osteoblastic differentiation to start as early as on day 5 with lenalidomide whereas in the control cells first calcium deposits were visible after 7 days. All described effects were observed in both normal and MDS MSCs. *Summary*. In conclusion, lenalidomide influences the expression of distinct cell surface molecules, cytokine secretion as well as the potential for osteogenic differentiation of MSCs by a yet unknown mechanism. Whether these in-vitro effects are associated with the clinical efficacy of this compound in patients with MDS remains to be investigated.

INCREASE IN BONE MARROW IMMATURE NON-LYMPHOID EARLY PRECURSORS PREDICTS A SHORT SURVIVAL IN MYELODYSPLASTIC SYNDROMES

I. Lorand-Metze,[1] S.C. Reis,[1] F. Traina,[1] E. Ribeiro,[1] S.T.O. Saad,[1] K.M. Metze[2]

[1]State University of Campinas, CAMPINAS; [2]Department of Pathology / State University of Campinas, CAMPINAS, Brazil

Background. Bone marrow (BM) $CD34^+$ cell population is composed mainly by myeloblasts and B-lymphoid precursors, besides minor populations and non-classifiable early precursors. Their increase is associated with disease progression. *Aims*. to compare the influence on survival of SSCint/CD34+/CD13-/117- (early) progenitors measured by flow cytometry at diagnosis with established risk factors. *Methods*. in newly diagnosed patients BM was examined by flow cytometry. Monoclonal antibody combinations: CD15/CD34/CD45/CD117, CD16/CD34/CD45/CD13 and CD3/CD34/CD45/CD19. In the CD34/SSC plot the subsets: SSC low/$CD34^+CD19^+$ cells, SSC int/$CD34^+/CD13^+$ and SSCint/$CD34^+CD19^-/CD13^-$ were separated. The influence on overall survival of age, PB counts and IPSS and subsets of $CD34^+$ cells were analyzed with the Cox model. *Results*. 35 cases were studied: 11 RA, 2 RARS, 12 RCMD, 10 RAEB. IPSS: 14 cases were low risk, 12 intermediate-1, 3 of intermediate-2 and 6 high risk. Median follow-up time: 17 months. The number of early progenitors was correlated with the total number of $CD34^+$ cells (r=0.58; p=0.0005), with myeloblasts (r=0.68; p<0.0005), with $CD34^+/CD117^-$ cells (r=0.93; p<0.0005) and with $CD34^+/CD117^+$ cells (r=0.75; p<0.0001). In univariate Cox regressions, patients with a high percentage of early progenitors (p=0.01), an elevated percentage of $CD34^+$ cells (p=0.0005) and a reduced platelet count (p=0.04) had shorter overall survival. In the multivariate Cox regression only the percentage of early progenitors (p=0.001) and platelet count (p=0.03) were independent risk factors. *Conclusions*. the increase in early progenitors may indicate the presence of a maturation block in the abnormal clone and predict a poor survival of the patients.

LINK BETWEEN OCCUPATIONAL EXPOSURE TO HEAVY METALS AND HIGH RISK MYELODYSPLASTIC SYNDROMES

A. Divies, F. Hérin, K. Delavigne, E. Bart-Delabesse, N. Dastugue, G. Laurent, D. Adoue, O. Beyne-Rauzy

CHU Purpan, TOULOUSE, France

Background. Secondary myelodysplastic syndromes (MDS) occur upon cancer therapy (chemotherapy and radiotherapy) or occupational/environmental exposure to toxics (benzene and radiations). They represent 20% of MDS and are characterized by high-frequency chromosomal abnormalities. The link between exposure to other solvents, heavy metals, pesticides, cigarette smoking and secondary MDS remains unclear. *Aims*. To evaluate the relationship between occupational exposure to these toxics and MDS cytogenetics. *Methods*. History of occupational activities was obtained for 261 MDS patients referred to our clinical department over a two-year period. Two French employment status classifications (encoded NAF and PCS, respectively) were used to quantify occupational exposure to solvents, heavy metals, pesticides and cigarette smoking. MDS characteristics were recorded (bone marrow evaluation, karyotype, IPSS) and data were analyzed using the stata9.2.analysis software. *Results*. Exhaustive data were obtained for 184 patients (119 men; 65 women); with median age at diagnosis of 73 years. Patients without cytogenetic data (n=36), therapy-related MDS (n=17), incomplete professional history (n=12) or CMML (n=12), were excluded. Distribution of MDS categories according to WHO classification was as follows: RA (18.5%), RARS (26.1%), RCMD (15.2%), 5q-syndrome (5.5%), RAEB1 (27.7%), and RAEB2 (5.5%). Abnormal karyotype was observed in 34.8% of patients, and consisted mainly of del5q (8.7%), trisomy 8 (3.8%), del20q (3.8%), and complex karyotype (3.8%). High-risk MDS represented 13.6%. Occupational activities were mainly related to farming and agriculture (20%), building (14.1%) and textile (7%) industries. Eleven men (9%) and 36 women (55%) were exempted from any toxic exposure. Exposure to solvents, heavy metals and cigarette smoking was significantly higher in men than women, while no difference in exposure to pesticides was found according to sex. Bivariate analysis did not reveal any association in relation to exposure to either solvent, or cigarette smoking, or pesticide. On the contrary, expo-

sure to heavy metals (20 men; no women) was significantly linked to high-risk MDS (OR= 8.18 [2.36; 29.09]; $p<0.001$). Within this group, RAEB2 represented the main target population (OR= 8.00 [1.20; 58.21]; $p=0.015$). Among the karyotype abnormalities, the presence of del20q or abnormal 11 was associated to metal exposure ($p<0.04$). *Conclusions*. Our data revealed a potential link between exposure to heavy metals and chromosomal abnormalities. Larger cohorts and case-control studies are required to confirm our results. Using job-exposure matrix, the precise level of exposure to each toxic should be determined and provide further knowledge regarding the developmental conditions and process of MDS.

DIFFERENCES IN EXPRESSION OF GENES INVOLVED IN NUCLEAR FACTOR KAPPA B(NFKB) PATHWAY AFTER ANALYSIS BY QUANTITATIVE POLYMERASE CHAIN REACTION ARRAYS IN MYELODYSPLASTIC SYNDROMES (MDS) PATIENTS

E. Rouka,[1] D. Adamidou,[1] M. Alexandrakis,[2] K. Lilakos,[1] A. Melidou,[1] N. Stathakis,[1] D. Kyriakou,[1] T. Kourelis[2]

[1]University Hospital of Larisa, LARISA; [2]University Hospital of Crete, HERAKLION, Greece

Background. Nuclear factor-kappaB (NFkB) is a transcription factor used by most eukaryotic cells as gene regulator over cell proliferation and cell survival. It is believed that persistent NFkB activation promotes oncogenesis and enhances metastasis, invasion and angiogenesis of tumor cells. According to myelodysplastic syndromes (MDS) pathogenesis, as the disease progresses a survival advantage of the neoplastic clone takes place changing the original pattern from increased apoptosis and ineffective haemopoiesis to accelerating clonal proliferation and leukemic transformation. *Aims*. The aim of the present study was to investigate whether NFkB pathway contributes in MDS pathogenesis and to determine the pathway's activation status in terms of MDS grade. *Meethods*. Eight MDS patients (2 males, 6 females) were included in the study. Four of them suffered from low grade MDS (RA -RARS) and the rest from high grade MDS (RAEB / RAEB-T). Our control group consisted of 4 healthy, age matched individuals. Informed consent was obtained from all participants. RNA was extracted from peripheral blood by Total RNA Blood purification kit (Invitrogen) according to manufacturer's instructions. A second purification was conducted using Array Grade Total RNA isolation kit (SuperArray).Reverse transcription was performed using RT2 First Strand kit (SuperArray).Real time quantitative polymerase chain reaction (qPCR) followed using the RT2 Profiler PCR Array system of SAbiosciences. In this method 84 genes of NFkB pathway were analyzed simultaneously. The Ct values were compared according to ΔΔCt method. *Results*. In general we found fold up-regulation of the NFkB relevant genes pathway in low grade MDS compared to control group while the opposite was observed in high grade MDS. IRAK1, TLR7, NLRP12 genes were found up regulated in early MDS ($p<0.05$) while IL1B and TNFSF10 were down regulated in advanced MDS ($p<0.05$).Statistical analysis revealed significant differences in most of the genes examined when we compared the MDS subgroups. The following genes (49/84)AGT,ATF1,BCL3,CFB,CASP8,CCL2,CD40,CHUK, CSF2,CSF3,EDARADD,EDG2,ELK1,F2R,FADD,FASLG,HMOX1,HTR2 B,IFNA1,IFNB1,IKBKE,IKBKG,IL10,IL1A,IL1B,IL1R1,IL6,IRAK2,LTA,LT BR,MALT1,NLRP12,NFKB1,NFKB2,RELB,RIPK1,TBK1,TICAM2,TLR4, TLR6,TLR7,TLR9,TNF,TNFRSF10A,TNFRSF10B,TNFRSF1A,TNFSF14,T RADD,TICAM1 were down regulated in high grade MDS compared to low ($p<0.05$),while the comparison of all the remaining examined genes showed tendency to significance. *Conclusions*. We used peripheral blood as our study material. The high expression of most examined genes involved in NFkB pathway in early MDS may be in part explained by an attempt to balance the established increased apoptosis of MDS marrow cells. We may speculate the opposite for advanced MDS. The above findings are in contrast with what is reported so far for $CD34^+$ marrow MDS cells. Our results indicate that probably peripheral blood cells behave differently from progenitors although they may belong to the same MDS clone. These findings suggest that NFkB activation does not contribute much in MDS progression and thus may not be an attractive therapeutic target.

0811

INFLUENCE OF SERUM FERRITIN LEVELS ON OVERALL SURVIVAL IN PATIENTS WITH MYELODISPLASTIC SYNDROME

A. Jerez, A. Fernández, C. Martínez, V. Roldán, M.L. Lozano, M.M. Osma, F. Ortuño, V. Vicente

Hospital Universitario J.M. Morales Meseguer, MURCIA, Spain

Background. Recent studies have suggested that iron overload may be independently associated with a poor survival in patients diagnosed of myelodisplastic syndrome (MDS). Whether iron overload is a surrogate marker of the severity of the disease or if it affects outcome independently by end organ damage, is still controversial. *Aims*. To determine if high levels of ferritin are independently associated with a poor survival and to determine which variables at diagnosis can identify those patients at risk for iron overload. *Patients and Methods*. Between January 1994 and September 2008, 248 patients were diagnosed with MDS. We excluded patients treated with iron chelation, erythropoietin, or any chemotherapy regimen that could affect survival or transfusion requirements. We included patients with, at least, a ferritin determination during follow-up. One hundred and seventy six patients remained for analysis. Variables included as potential prognostic factors were: age, gender, IPSS score, platelet mass, LDH levels, transfusion requirement at diagnosis and maximum ferritin level reached thorough follow up. *Results*. Median follow-up was 22 months (range 1-171). Ninety eight patients (56%) were male and 78 (44%) female. Of these patients, 28 (16%) transformed to acute myelogenous leukemia, and 73 (41%) remained alive. Median ferritin level was 438 ng/mL (interquartile range 176-1131). By univariate analysis, characteristics associated with worse survival ($p<0.05$) were low platelet mass, older age, high LDH level, transfusion requirement at diagnosis and a high IPSS score. Higher ferritin ($p=0.08$) levels were not significantly associated with worse survival in univariate analysis although a trend was noted. On multivariate analysis, age [OR 1.1 (1.05-1.7); $p<0.001$], IPSS stage [OR 1.9 (1.63-2.34); $p<0.001$], and transfusion requirement at diagnosis [OR 1.6 (1.35-1.9); $p=0.035$] were all independently associated with a poor prognosis. An intermediate IPSS score ($p=0.038$) and transfusion requirement at diagnosis ($p=0.02$) were independently correlated with a combined endpoint of maximum ferritin higher than 1500 ng/mL and/or more than 20 red blood cell units transfused. *Conclusions*. Our data show that iron overload, a variable associated with transfusion requirements at diagnosis and with intermediate IPSS score, is not independently correlated with a worse survival in the whole group of MDS. Further trials in highly transfused patients are expected to help us establish the real impact of ferritin levels on prognosis of MDS.

0812

PHOSPHOINOSITIDE-PHOSPHOLIPASE C (PI-PLC) BETA1 SIGNALLING IS INVOLVED IN ERYTHROPOIETIN RESPONSE OF LOW RISK MDS PATIENTS

C. Finelli,[1] M. Follo,[2] S. Mongiorgi,[2] C. Clissa,[1] F. Chiarini,[2] N. Testoni,[1] M. Baccarani,[1] L. Manzoli,[2] G. Martinelli,[1] A. Martelli,[2] L. Cocco[2]

[1]Institute of Hematology Seràgnoli, BOLOGNA; [2]University of Bologna, BOLOGNA, Italy

Background. The phosphoinositide 3 kinase (PI3K)/Akt signaling and phosphoinositide-phospholipase C (PI-PLC) beta1 pathways are involved in many different cellular processes, including proliferation, differentiation, and apoptosis. An impaired regulation of the PI3K/Akt axis has often been associated with hematologic malignancies, including acute and chronic human leukemias. Our group previously demonstrated not only that Akt is activated in high-risk MDS patients, but also that there is an inverse correlation between PI-PLCbeta1 expression and Akt activation, in that low levels of PI-PLCβ1 were correlated to high levels of activated Akt and vice versa (Follo MY *et al.*, Leukemia 2008). Moreover, recent results proved that PI-PLCbeta1 mono-allelic deletion is associated with a higher risk of evolution into AML in MDS patients (Follo MY *et al.* JCO 2009). Erythropoietin (EPO) treatment is effective in correcting anemia in a variable portion (40-60%) of low risk MDS patients. However, little is known about the molecular mechanisms underlying the effect of this drug in MDS, and the reasons why some patients do not respond to EPO, or subsequently lose response. The EPO signalling, and particularly the activation of the EPO receptor, has been linked to the activation of the PI3K/Akt axis, which in turn is connected with both PI-PLCβ1 and PI-PLCgamma1 signalling. As a consequence, EPO could affect the survival and apoptotic pathways of MDS cells. *Aims*. In this study we further investigated the role of PI-PLCbeta1 and Akt in MDS, focusing on patients at lower risk of evolution into AML,

treated by EPO. Methods. We studied 16 patients, with IPSS risk low or intermediate-1: 8/16 patients (50%) showed a favourable response to EPO. We also studied Akt and PI-PLCbeta1 expression. Firstly, we analyzed the presence of PI-PLCbeta1 mono-allelic deletion in the MDS patients by FISH anayses. Subsequently, we quantified the expression of both PI-PLCbeta1 mRNAs. Finally, we investigated the degree of Akt activation, as well as PI-PLCbeta1 protein expression, before and during the EPO treatment. *Results*. Our data show not only that 31% (5/16) of our low risk MDS patients displayed the PI-PLCbeta1 mono-allelic deletion, but also that 3 of the patients bearing the deletion were refractory to EPO treatments. Moreover, in responder patients we observed an increase in activated Akt levels. *Summary and Conclusions*. Our data confirm the hypothesis of a possible involvement of inositides in the EPO signalling, in that the patients who showed the mono-allelic deletion of PI-PLCβ1 did not respond to EPO treatment, whilst responder patients showed an activation of Akt. Therefore, our findings indicate that MDS patients bearing the PI-PLCbeta1 mono-allelic deletion, even if they belong to the low or intermediate-1 IPSS risk group, are characterized by a worse prognosis, as they show a higher risk of AML evolution and a lower probability to respond to EPO treatment.

0813

EFFECT OF AZACITIDINE (AZA) ON TRANSFUSION INDEPENDENCE (TI) AND OVERALL SURVIVAL IN PATIENTS (PTS) WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES

J. Seymour,[1] V. Santini,[2] P. Fenaux,[3] A. Giagounidis,[4] G. Sanz,[5] A.F. List,[6] D. McKenzie,[7] J. Backstrom,[7] C.L. Beach[7]

[1]Peter MacCallum Cancer Centre, EAST MELBOURNE, Australia; [2]UF Ematologia Aou Careggi University of Florence, FIRENZE, Italy; [3]Hopital Avicenne/Université Paris 13, PARIS, France; [4]St. Johannes Hospital, DUISBURG, Germany; [5]Hospital Universitario La Fe, VALENCIA, Spain; [6]H. Lee Moffitt Cancer Center, TAMPA, USA; [7]Celgene, SUMMIT, USA

Background. The international, multicenter AZA-001 trial established that AZA significantly improves overall survival (OS) in pts with higher-risk myelodysplastic syndromes (MDS) compared with conventional care regimens (CCR) (Fenaux, Lancet Oncol 2009). Red blood cell (RBC) transfusion requirements have been shown to be predictive of OS in pts with MDS. This descriptive analysis examined OS in AZA pts in AZA-001 relative to their transfusion status. *Methods*. 179 pts with higher-risk MDS (FAB: RAEB, RAEB-t, or CMML, and IPSS: Int-2 or High) were randomized to AZA (75 mg/m^2/d SC x 7d q 28d). Randomization was stratified on FAB and IPSS. Erythropoietic stimulating agents were not allowed. Transfusion independence (TI), RBC or platelet, was defined as a transfusion-free period of ≥56 consecutive days. Baseline (BL) transfusion dependence was defined as requiring ≥1 transfusion during the 28-day pretreatment period. Survival curves were plotted using the Kaplan-Meier (KM) method for groups based on BL transfusion status. *Results*. Overall, 50/111 (45.0%, 95% CI: 35.6, 54.8) BL RBC transfusion-dependent pts in the AZA group achieved RBC TI and 16/38 (42.1%) BL platelet-dependent pts achieved platelet TI. Pts who were TI at some point during treatment regardless of BL transfusion status had a longer duration of AZA therapy and longer OS (Table). Median OS was not reached (NR) in pts who were BL RBC dependent and achieved RBC TI and in pts who were BL platelet dependent and who achieved platelet TI during AZA treatment. *Conclusions*. Pts who became, or remained, transfusion independent received more AZA treatment cycles and had prolonged OS compared with pts who were transfusion dependent.

Table 1.

BL Transfusion status	On Treatment Transfusion Status	N patients (ITT Population)	Median Number of Treatment Cycles (range)	Median OS months (95% CI)
RBC Dependent	Independent	50	14.0 (3-29)	NR (25.1, NR)
	Dependent	61	4.0 (1-13)	7.3 (4.8, 10.5)
RBC Independent	Independent	58	11.0 (2-39)	NR (26.3, NR)
	Dependent	10	2.0 (1-12)	9.3 (1.4, 17.2)
Platelet Dependent	Independent	16	11.0 (4-26)	NR (15.9, NR)
	Dependent	22	3.0 (1-11)	4.6 (1.9, 10.6)
Platelet Independent	Independent	126	10.0 (2-39)	34.7 (25.1, NR)
	Dependent	15	2.0 (1-4)	2.0 (1.2, 3.9)
NR = Not reached				

0814

EVALUATION OF APOPTOTIC MOLECULAR MARKERS AND GENE METHYLATION STATUS IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

E.N. Cortesao,[1] A.C. Gonçalves,[2] M.I. Sousa,[1] C. Moucho,[1] L. Rito,[1] E. Magalhães,[1] A.I. Espadana,[1] M.A. Pereira,[3] A. Teixeira,[1] J. Nascimento Costa,[1] A.B. Sarmento Ribeiro[2]

[1]University Hospital of Coimbra, COIMBRA; [2]2-Faculty of Medicine and Cimago, University of Coimbra, COIMBRA; [3]Distrital Hospital of Figueira da Foz, FIGUEIRA DA FOZ, Portugal

The apparent discrepancy between cellular marrow and peripheral blood cytopenias in MDS may be related with programmed cell death(apoptosis), which occurs with increased frequency in MDS marrow. Apoptotic cell death may be triggered by several mechanisms involving death receptors and/or mitochondria where Bcl-2 family proteins have an important role. Although increased apoptosis in MDS may occur as an early rescue or compensatory response to deregulated clonal proliferation, it may also represent a pathophysiologic consequence of the epigenetic changes, particularly altered DNA methylation. Global hypomethylation is believed to induce proto-oncogene activation and chromosomal instability, whereas regional hypermethylation is strongly associated with transcriptional silencing of tumor suppressor genes as those involved in cell cycle regulation, DNA repair, growth signaling, angiogenesis, and apoptosis. Although the cause of altered patterns of DNA methylation in cancer remains unknown, it is believed that serum folate/vitaminB12 concentrations might strongly influence DNA methylation patterns. We hope to contribute for the identification of molecular markers involved in apoptotic signalling pathways and the role of folate status and epigenetic gene modulation in MDS, its interference with prognosis, evolution to AML and therapeutic approach. We have examined the expression levels of proteins involved in apoptotic pathways(Bax, Bcl-2, p53, Fas/FasL, TRAIL/TRAIL-Rs, cytochrome c, survivin) by flow cytometry using monoclonal antibodies, the methylation status of the cell cycle regulators p15/p16 using a methylation specific PCR and the serum folate/vitaminB12 concentrations in CD34 BM cells populations collected at diagnosis from 23 patients with MDS and in 8 controls(ITP). The median age was 77 years(33-84), gender M/F=12/11, WHO subtypes: RCMD(n=9), RA(n=5), RAEB-1(n=3), RAEB-2(n=5), 5q-syndrome(n=1) and IPSS: low(n=6), intermediate-1(n=12) and intermediate-2(n=5). Six of the patients(RAEB and IPSS intermediate-1/2) evolve to AML. Our preliminary results show that CD34 MDS cells patient's have higher Bax, survivin(p0.0048), p53, Fas-L, cit c, TRAIL-Rs expression levels and Bax/Bcl-2 ratio, and lower levels of Bcl-2, TRAIL, Fas and R1+R2/R3+R4 ratio compared with controls. CRDM patients have the higher survivin levels compared with the others subtypes (p0.03) and higher R3 levels compared to RA patients(p0.03). This subtype of patients(RA) also shows higher R3 levels when compared to RAEB-2(p0.03). We found 74% of cases with at least one methylated gene promoter: p15 methylation occurred in 37%, while p16 methylation occurred in 68% of MDS patients. p15 methylation was present in all the RA and 5q- syndrome patients and in 25% of RCDM patients. P16 methylation was observed in all subtypes except RAEB-2(75%-RA and RCDM; 100%-5q-syndrome and RAEB-1).The highest quintiles of serum B12 had 100% p16 methylation. All the quintiles of serum folate had similar p16 methylation. However, the p15 methylation increased progressively in the second to the fifth quintile. P15 and p16 seem to be an event in the MDS development and high concentrations of serum folate/vitaminB12 might be associated with the risk of promoter methylation in tumor-specific genes, especially p16 gene. Apoptosis deregulation may be implicated in MDS. In RA and RCDM subtypes an increase in apoptosis predominates while in RAEB the resistance to apoptosis may contribute to a less favourable prognosis.

REPRESSION OF THE MYST2 ACETYLTRANSFERASE IN LEUKEMOGENESIS AND ITS ASSOCIATION WITH HEMATOPOIETIC CELL GROWTH

F. Isken, S. Göllner, C. Hoemme, S. Koschmieder, W.E. Berdel, C. Müller-Tidow

University Hospital Münster, MÜNSTER, Germany

The histone acetyltransferase Hbo1/Myst2 is a member of the MYST family of acetyltransferases. Several members of this family, e.g. Tip60, Moz and Morf play important roles in leukemia development. Myst2 is the main acetyltransferase for histone H4 and plays an important role in replication licensing. Its involvement in leukemogenesis is unknown. In a ChIP-Chip based approach we recently identified Myst2 as a transcriptionally repressed target of PML-RARα. The aim of the current study was to elucidate its potential role in leukemic cells and leukemia development. We used ChIP-Chip to identify PML-RARα target genes. To further validate the role of Myst2 in leukemia we analyzed Hbo1/Myst2 expression in primary patient samples. We used overexpression of Myst2 in murine bone marrow cells as well as shRNA mediated repression of Myst2 in a cell line model to further show the role of this protein in the growth regulation of leukemic cells. The Myst2 promoter was directly bound by PML-RARα. The mRNA expression of Myst2 was significantly reduced in APL as well as other AML patients compared to normal bone marrow and $CD34^+$ progenitor cells. Myst2 was induced during monocytic differentiation in U937 cells and repressed during granulocytic differentiation in HL60 cells. Total histone 4 acetylation levels at lysines 5 and 8 were altered accordingly. PML-RARα repressed the differentiation-dependent induction of Myst2 with a concomitant decrease in histone H4 lysine 5 and lysine 8 acetylation in PML-RARα expressing cells. In functional experiments, Myst2 expression in Lineage negative murine bone marrow cells resulted in decreased colony formation and proliferation. On the other hand, shRNA mediated repression of Myst2 in the leukemic cell line Kcl22 enhanced growth and colony formation compared to cells containing scrambled shRNA sequences. These data establish that Myst2 is a direct target of PML-RARα. Its widespread repression in AML suggests other regulatory mechanisms as well. Its regulation and growth suppressive functions suggest a potential role in leukemogenesis.

RADIOIMMUNOTHERAPY USING ANTI-CD33 ANTIBODIES RADIOLABELED WITH THORIUM-226 OR BISMUTH-213 OVERCOME CHEMO- AND RADIORESISTANCE IN MYELOID LEUKEMIA CELLS

C. Friesen,[1] M. Roscher,[1] A. Morgenstern,[2] F. Bruchertseifer,[2] K. Abbas,[3] C. Apostolidis,[2] E. Miltner[1]

[1]Institute for Legal Medicine, University Ulm, ULM, Germany; [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, KARLSRUHE, Germany; [3]European Commission, Joint Research Centre, Institute for Health&Consumer Protec, ISPRA, Italy

Background. One of the primary causes for therapeutic failure in radiotherapy and chemotherapy of leukemia and solid tumors is the resistance to radiation and chemotherapeutic drugs. Attempts to improve the results of chemotherapy and radiotherapy by increasing the total radiation absorbed dose, by increasing the concentration of chemotherapeutic drugs, or by changing chemotherapeutic drugs have only partly been successfull. Targeted radiotherapy using monoclonal antibodies radiolabeled with α-particles such as Bi-213 is a promising treatment approach for high-risk leukemia. The therapeutic efficacy of the anti-CD33 mAb HuM195 labeled with the single α emitter Bi-213 is currently under study in a phase I/II trial of leukemia. The α-particle emitter Th-226 is a novel therapeutic nuclide emitting a rapid cascade of four α particles in its decay chain. *Aims*. In the present study we compared cell death and activation of apoptosis pathways induced by bismuth-213 bound to anti-CD33 ([Bi-213]anti-CD33) with thorium-226 bound to anti-CD33 ([Th-226]anti-CD33) in sensitive and chemo- and radioresistant CD33 positive myeloid leukemia cells. *Methods*. The human myeloid sensitive cell line HL-60 (CD33 +/+) and the HL-60 (CD33 +/+) cell lines resistant to radiation and chemotherapy and the human lymphoblastic leukemia T-cell line CEM (CD33 -/-) were treated with 225, 75, 22.5, 7.5 and 2.25 kBq/mL of [Bi-213]anti-CD33 or [Th-226]anti-CD33, using comparable specific activities. 24, 48 and 72h after irradiation cell death and apoptosis were measured by flowcytometry and activation of apoptosis pathways were determined by Western Blot analyses. *Results*. We found that [Bi-213]anti-CD33 and [Th-226]anti-CD33 induced cell death and activated apoptosis pathways with different efficiencies in CD33 positive myeloid leukemia HL-60 cells. In contrast, CD33 negative lymphoblastic leukemia CEM cells were not killed using anti-CD33 antibodies radiolabelled with Th-226 or Bi-213. [Th-226]anti-CD33 triggered higher apoptosis rates in myeloid leukemia HL-60 cells in comparison to [Bi-213]anti-CD33 at equal activity concentrations using comparable specific activities. The differences in cell death induction were found between 35 and 85% depending on activity concentrations and time points. [Th-226]anti-CD33 or [Bi-213]anti-CD33 activated caspase-3 and cleaved PARP in myeloid leukemia HL-60 cells. In addition, after treatment with [Th-226]anti-CD33 or [Bi-213]anti-CD33 mitochondria were activated resulting in caspase-9 activation. Bcl-xL, a death-inhibiting protein of the Bcl-2 family, was down regulated after treatment with [Th-226]anti-CD33 or [Bi-213]anti-CD33. This indicates that both [Th-226]anti-CD33 and [Bi-213]anti-CD33 activate the intrinsic mitochondrial pathway. However, [Th-226]anti-CD33 activated the apoptosis pathway earlier and with higher efficiencies than [Bi-213]anti-CD33. Furthermore, both [Th-226]anti-CD33 and [Bi-213]anti-CD33 killed chemo- and radioresistant myeloid leukemia cells. *Summary and Conclusions*. Our findings demonstrate that both [Th-226]anti-CD33 and [Bi-213]anti-CD33 induce apoptosis by specific activation of the intrinsic mitochondrial pathway and break chemo-and radioresistance specifically in CD33 positive myeloid leukemia cells. Notably, anti-CD33 labeled with the α cascade emitter Th-226 induces cell death and activates apoptosis pathways with higher efficiencies in comparison to anti-CD33 labeled with Bi-213 emitting one α particle per decay. This suggests that Th-226 seems to be a more potent α-particle emitter for leukemia therapies than Bi-213.

CBL MUTATIONS IN ACUTE MYELOID LEUKEMIA AND MYELOPROLIFERATIVE NEOPLASMS

V.I. Gaidzik,[1] A. Becker,[1] F. Stegelmann,[1] L. Bullinger,[1] J. Krönke,[1] B. Schlegelberger,[2] A. Ganser,[3] R.F. Schlenk,[1] H. Döhner,[1] K. Döhner[1]

[1]Universitätsklinik Ulm, ULM; [2]Institut für Zell- und Molekularpathologie, HANNOVER; [3]Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, HANNOVER, Germany

Background. Deregulation of tyrosine kinase (TK) activity is one hallmark in the pathogenesis of acute myeloid leukemia (AML) and myeloproliferative neoplasms (MPN). In both, AML and MPN mutational activation of receptor TK (RTK) genes such as FLT3, KIT or JAK2 has been shown to play a key role in leukemic transformation and progression of the disease. In addition, activation of RTK can occur independently from the mutation; as an example more than 80% of adult AML cases show high levels of FLT3 expression. Recent data suggest that FLT3, KIT, JAK2 or other RTKs can be active in cells containing inactivating mutations within the linker region of the proto-oncogene Casitas B-lineage lymphoma gene (CBL). CBL functions as E3 ligase that ubiquitinates and regulates activated RTKs, such as FLT3. First studies on CBL mutations in AML and MPN showed that these mutations occur with a low frequency. However, recent studies demonstrated that CBL mutations are highly associated with 11q acquired uniparental disomy (UPD) in MPN. *Aims*. To evaluate the frequencies of CBL mutations in myeloid leukemias. *Methods*. A large cohort of adult AML [n=287; normal karyotype (CN), n=119; various, n=5; core-binding factor (CBF) leukemia, n=162; karyotype not evaluable, n=1] and MPN patients (pts) [n=95; essential thrombocythemia (ET), n=29; polycythemia vera (PV), n=37; primary myelofibrosis (MF), n=17; post-ET-MF, n=2; post-PV-MF, n=7; MPN not classified, n=3] were analyzed by using a DNA-based PCR assay for amplification of exons 8 (including introns 7 and 8) and 9 (including intron 9) followed by direct sequencing. *Results*. Mutation analysis revealed 14 CBL mutations (exon 8, n=11; exon 9, n=3) in 13 AML cases and 3 mutations in the 95 MPN pts [exon 9, n=3). In AML, CBL mutations affected intron 7 in five cases, intron 8 in one case, exon 8 in five cases, whereas two mutations occurred in intron 9 and one in exon 9 of the gene. All three MPN associated mutations were located in exon 9. Most of the mutations have already been described and the majority of them were substitutions as well as frameshift mutations. Of note, 10 of the 14 CBL mutations were detected in CBF leukemias [t(8;21), n=3; inv(16), n=6)], including one inv(16)-positive AML having two CBL-mutations. The other four mutations occurred in CN-AML. Interestingly, all 3 CBL-mutated MPN pts (one ET, two PV) also had a JAK2V617F mutation. In addition, SNP array data were available in 26/119 CN-AML cases as well as in 40/95 MPN cases revealing one case with 11qUPD in each group.

However, both cases showed CBL wildtype. *Summary*. In this large cohort of myeloid leukemias, CBL mutations occurred at low frequencies. In AML, CBL mutations were associated with CBF leukemias, a finding that is in accordance with a previous study. Therefore, it will be of interest to further investigate the potential cooperative activity of mutant CBL with the CBF-related fusion proteins CBFB-MYH11 and RUNX1-RUNX1T1 as well as with other CBF-associated gene mutations (e.g. FLT3, KIT).

CYTOPLASMIC NPM1 DETECTION BY FLOW CYTOMETRY AS SURROGATE FOR THE PRESENCE OF MUTATIONS IN THE NPM1 GENE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Oelschlaegel, S. Koch, M. Schaich, F. Kroschinsky, S. Parmentier, G. Ehninger, C. Thiede

University Hospital Dresden, DRESDEN, Germany

Background. In about 30% of patients with AML the predominantly nucleolar protein nucleophosmin (NPM1) is dislocated into the cytoplasm (NPM1c), caused by mutations in exon 12 of the NPM1 gene. NPM1-mutations are associated with a specific subgroup of AML with particular clinical, cytogenetic, and prognostic characteristics. AML with NPM1-mutations are part of the new WHO classification, making the detection an important diagnostic aspect. Thus far, NPM1 mutations can be detected either using molecular techniques or immunocyto- or -histochemistry. We reasoned that by the cytoplasmic dislocation, the protein might be also accessible for rapid diagnostics using intracellular flow cytometry. *Aims*. The aim of the present work was to evaluate this procedure *in vitro* and prospectively in newly diagnosed patients with AML. *Methods*. Therefore, cell lines and bone marrow (BM) of 23 healthy donors as well as 254 newly diagnosed AML patients, enrolled in two different treatment protocols, were prospectively investigated by a lyse-wash flow cytometric procedure including an anti-NPM1 monoclonal antibody labelled with Zenon technology. NPMc was measured after fixation and permeabilisation. Thereafter, mean fluorescence intensity (MFI) was evaluated. All patient samples were routinely analyzed for NPM1-exon 12 mutations using PCR followed by high resolution fragment analysis. *Results*. Cell lines with known mutational status (mutant: OCI-AML3 and wt: MV4-11) showed a clear separation (MFI: 44.6 vs. 3.7). In healthy BM the median MFI for the NPMc expression was 3.8±1.7. Thus, the threshold MFI for NPM positivity was set to 8.0. Overall in 95% of samples (243/254) flow cytometry and PCR showed concordant results - positivity in 32% (mNPM1c=82) and negativity in 63% (wtNPM1-=161) of patients. Thus, the MFI was significantly higher in mNPM1c cases than in PCR negative patients and BM donors (MFI: 16.7 vs. 3.1 vs. 3.8; $p<0.0001$). The mNPM1c group presented with significantly lower CD34, HLA-DR, and without aberrant CD2 and CD19 expression (17% vs. 75%, $p<0.0001$; 78% vs. 89%, $p=0.0192$; 0% vs. 10%, $p=0.0014$); 0% vs. 7%, $p=0.0178$), but a comparable expression of other myeloid and aberrant antigens. FLT3 mutations were detectable in significantly more mNPM1c patients (57% vs. 14%, $p<0.0001$). Interestingly, the few mNPM1c patients with CD34 expression (14/82) showed distinct diagnostic features compared to the CD34neg patients, such as lower MPO expression ($p=0.0528$), presence of FLT3-ITD in almost all patients ($p=0.0028$), and a significantly lower proportion of type A mutations ($p=0.0075$). Taking PCR results for exon 12 as reference, discrepant results regarding flow cytometric NPM1c detection occurred in 5% as 5 false negative and 6 false positive cases. Interestingly, two patients with wtNPM1 in exon 12 but NPM1c by flow cytometry showed truncating mutations in exon 10 and 11, respectively. *Conclusions*. Flow cytometry allows a reliable and rapid detection of NPMc expression as surrogate for the presence of NPM1 mutations and could thus guide further molecular analyses. It might help to identify patients having mutations outside the mutational hotspot in exon 12.

Background. Acute myeloid leukemia (AML) is a clinically and genetically heterogeneous but aggressive disease. Although AML is a relatively rare malignancy in the pediatric population, representing only 15 to 20% of the acute leukemias in this age group, it remains a challenging disease with an inferior treatment outcome as compared to pediatric acute lymphoblastic leukemia. Several factors are known to predict the long-term survival in both childhood and adult AML. Among these, cytogenetic findings are considered to be the most powerful single prognostic factor in AML. Most patients belong to the category with standard-risk disease and the stratification of this heterogeneous group appears to be insufficient. New molecular markers are continuously being defined and not only have prognostic significance but also and more importantly, offer the potential for biologically targeted therapy. Very few studies have been performed in pediatric populations. *Aims*. The main aims of the study were to evaluate the prognostic impact of eight gene mutations including the Wilms' tumor 1 (WT1) mutation in pediatric acute myeloid leukemia and to determine whether these molecular lesions could be used to improve the molecular risk stratification to better predict the response to therapy. *Methods*. We studied the mutational status of the FMS-like tyrosine kinase 3 (FLT3), kit proto-oncogene, RAS, CCAAT/enhancer binding protein α (CEBPα), nucleophosmin (NPM1) and WT1 genes in 76 cases of *de novo* AML. Patients were treated between 1995 and 2002 and enrolled in the Leucémie Aiguë Myéloblastique de l'Enfant (LAME) 89/91 and LAME 99/01 pilot study protocols. All mutations were screened by direct sequencing. *Results*. At diagnosis 8%, 6.5%, 4%, 9%, 5%, 10.5%, 1.3% and 8% of the patients had FLT3-ITD, FLT3-TKD, c-KIT, CEBPα, NPM1, N-RAS, K-RAS and WT1 mutations, respectively. Overall 40 mutations were detected in 34 cases with a prevalence of 45%. With a median follow-up of 72 months, event-free survival (EFS) was 59±6% and overall survival 67±5%. Patients with NPM1, FLT3-TKD or c-KIT mutations were all alive at 5 years without any events. In contrast, patients with FLT3-ITD and/or WT1 mutations displayed a significant reduction in 5-year EFS (17% vs. 63% for the wild-type, $p=0.004$ and 0.01). In a multivariate analysis, the presence of a WT1 mutation remained an independent prognostic factor for risk of relapse ($p=0.004$). *Conclusions*. We report an exhaustive study of the mutational status of genes in pediatric AML and provide evidence that WT1 mutations predict an extremely high risk of relapse. NPM1 and WT1 mutations should be prospectively researched at diagnosis in pediatric AML and could be suitable for treatment stratification.

'CUP-LIKE' ACUTE MYELOID LEUKEMIA: A REPORT FROM A SINGLE CENTER

E. Griva-Kritikou,[1] E. Goumakou,[2] G. Androutsos,[3] V. Xanthopoulos,[3] G. Paterakis,[3] S. Papadhimitriou,[3] A. Agelidis,[3] E. Voukouti,[4] T. Marinakis,[3] G. Gortzolidis,[3] N. Anagnostopoulos,[3] M. Georgiakaki[3]

[1]G.Gennimatas District Hospital, ATHENS; [2]G. Gennimatas District Hospital, ATHENS; [3]"G.GennimatasDistrict Hospital, ATHENS; [4]G.Gennimatas"Distrct Hospital, ATHENS, Greece

Introduction. "Cup-like" nuclei in *de novo* acute myeloid (AML) blasts is a morphologic finding that has recently been associated with a normal karyotype, a characteristic immunophenotype and nucleophosmin (NPM) mutations.We investigated cup-like nuclear morphology of both *de novo* and secondary AML blasts and its association with hematologic findings, immunophenotype, cytogenetic data and cytoplasmic expression of NPM (NPMc). *Material and Methods*. Bone marrow and peripheral blood slides from 116 randomly selected AML patients (83 *de novo* of all FAB subtypes

and 33 secondary to myelodysplastic syndromes or therapy-related) were investigated at diagnosis for cup-like nuclei by 3 independent morphologists. Cup-like positive AML was defined as >5% of blasts with a cup-like nuclear invagination spanning at least 25% of the nuclear diameter. Immunocytochemistry (APAAP method) was performed with the monoclonal antibodies NPMAb-1 and C23 used as control (Thermo Scientific), in order to look for cytoplasmic (mutated) NPM. Immunophenotypic data by flow cytometry and karyotypes were recorded at diagnosis. Statistical analysis was performed with the Fischer's exact test. *Results*. Cup-like nuclear morphology was found in 24/83 *de novo* AMLs (29%), classified as: 2M0, 5M1, 7M2, 7M4, 1M5b,1M6(pure erythroid) and 1 mixed-lineage and in 4/33 secondary AML cases (12%). A normal karyotype was found in 70% of the cup-like(+) AMLs (vs 39.5% of the cup-like negative cohort, p=0.004). Cytoplasmic NPM was found in 76.4% of the cup-like(+) AMLs (vs 44.2%, p= 0.02). Cup-like (+) AMLs presented with a significantly higher white blood cell count (median WBC=102,8×10^9/lt vs 26,7×10^9/lt, p<0.0001). Cup-like(+) blasts were associated with low or absent CD34 expression (64,3% vs 21.5%, p<0.0001), as well as with low or absent HLA-DR (33,3% vs 6,45%, p=0.0019).Interestingly, 6 cup-like (+) AML cases with agranular blasts had been initially misdiagnosed as acute promyelocytic leukemias by immunophenotype, but AML-M3 was later excluded by karyotype. *Conclusions*. Cup-like morphology of AML blasts was observed in 24% of the AML cases studied and it was more frequent in *de novo* than in secondary AML, especially in the presence of hyperleukocytosis. It was not specific to any FAB subtype. This morphologic finding predicted a normal karyotpe and NPM1 mutations. Morphologic and immunophenotypic similarities of cup-like(+) AML with variant types of APL should be kept in mind when a quick differential diagnosis is mandatory.

0821

DEFINING T(15;17)(Q22;21) TRANSLOCATION MECHANISM IN THERAPY RELATED AND *DE NOVO* ACUTE PROMYELOCYTIC LEUKEMIA

S.K. Hasan,[1] T. Ottone,[1] R. Schlenk,[2] M.E. Mitra,[3] E. Ammatuna,[1] P. Bernasconi,[3] F. Di Raimondo,[4] M.T. Lupo Stanghellini,[5] P. Marco,[6] A.N. Mays,[7] D. Grimwade,[7] H. Dohner,[2] F. Lo-Coco[1]

[1]University Tor Vergata, ROME, Italy; [2]University Hospital of Ulm, ULM, Germany; [3]Division of Hematology, University of Palermo, PALERMO, Italy; [4]Division of Hematology, University of Catania, CATANIA, Italy; [5]Unità di Ematologia, Osseo, Ospedale San Raffaele, MILAN, Italy; [6]Servicio de Hematología, Hospital General de Castellón, VALENCIA, Spain; [7]Department of Medical and Molecular Genetics, King's College London, LONDON, UK

Background and Aims. Most of the proposed mechanisms mediating chromosomal rearrangements in *de novo* leukemias are sequence-dependent and it has been suggested that various recombination-promoting sequences play a role in the genesis of translocations. Therapy-related acute myeloid leukemias (t-AMLs) provide an extraordinary opportunity to investigate key mechanisms of leukemogenesis by relating specific genetic abnormalities to the biologic effects of chemotherapeutic agents. We and others (Hasan *et al.* Blood 2008, Mistry *et al.* NEJM 2005) have shown that mitoxantrone induced topoisomerase II (topoII) mediated DNA damage at the PML and RARA breakpoint loci and their subsequent repair via error prone non homologous end joining (NHEJ) pathway lead to the formation of the t(15;17)(q22;q21) in therapy-related acute promyelocytic leukemia (t-APL). Here we characterized genomic breakpoints in 9 previously unreported cases of t-APL to investigate the sequence specific distribution of translocation breakpoints and their relationship to therapy given for the primary disorder. *Patients and methods*. Nine patients with t-APL developing after treatment of breast cancer (n=1), corpus uteri carcinoma (n=1), Hodgkin lymphoma (n=1) and multiple sclerosis (n=6) were studied, of whom 7 had received topo II targeted therapy. A long-range nested PCR strategy followed by direct sequencing was adopted to identify PML and RARA breakpoints at the DNA level. A web based tool (http://transpogene.tau.ac.il/cgibin/tg/alugene/transpogene.pl) was used for the identification of Alu recombination sequences in the vicinity of the breakpoint regions. *Results*. Genomic analysis revealed the occurrence of breakpoints within the mitoxantrone targeted hotspot DNA region in two out of seven cases with breakpoints in PML intron 6. Chromosome 17 translocation breakpoints in 7 topoII inhibitor related cases were concentrated at the 3'end of RARA intron 2, whereas for patients who did not receive topoII targeted therapy RARA breakpoints were observed to fall at the opposite end of the intron, which is ~17kb in length (Figure 1). The 5' region of RARA intron 2 containing the *de novo* APL breakpoints included 9 Alu repeat elements. V(D)J hepta- and nonamer consensus sequences were detected near 2 of the 9 analysed RARA breakpoints (matching sequences were 4 per heptamer and 7 per nonamer). In one patient the RARA breakpoint was located within a recombination signal sequence between the last nucleotide of a 23 bp spacer and the first base of a nonamer. *Conclusions*. This study suggests a different distribution of breakpoints in the RARA locus in *de novo* and therapy-related APL implying differences in t(15;17) translocation mechanism according to disease context. While there is evidence supporting a role for recombination mechanisms underlying *de novo* APL, cases arising following exposure to topoII targeted agents involve DNA damage followed by repair mediated by the error prone NHEJ pathway.

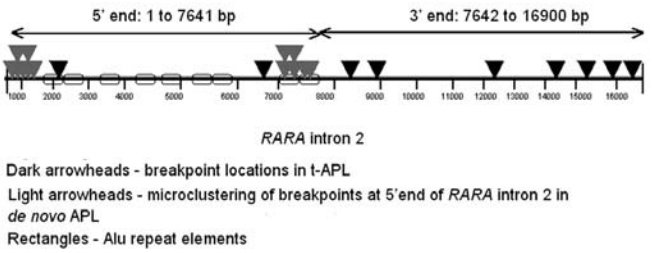

Figure 1. Distribution of RARA breakpoints

0822

SPECIFIC ACTIVITY OF ANTI-CD33 ANTIBODIES RADIOLABELED WITH THORIUM-226 OR BISMUTH-213 PLAYS A CRITICAL ROLE IN EFFICIENT KILLING OF LEUKEMIA CELLS DURING RADIOIMMUNOTHERAPY

C. Friesen,[1] M. Roscher,[1] A. Morgenstern,[2] F. Bruchertseifer,[2] K. Abbas,[3] C. Apostolidis,[2] E. Miltner[1]

[1]Institute for Legal Medicine, University Ulm, ULM, Germany; [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, KARLSRUHE, Germany; [3]European Commission, Joint Research Centre, Institute for Health&Consumer Protec, ISPRA, Italy

Background. Targeted radioimmunotherapy of bone marrow using monoclonal antibodies radiolabelled with α-particles is a promising treatment approach for high-risk leukemias and lymphomas. Different specific activities are used during radioimmunotherapy. However, the effect on cell killing using different specific activities were not well examined *Aims*. In the present study we examined the effect of different specific activities (MBq/µg antibodies) on induction of cell death and activation of apoptosis pathways in CD33 positive myeloid leukemia cells using the anti-CD33 antibody HuM195 radiolabeled with the single α emitter bismuth-213 ([Bi-213]anti-CD33) or with the α cascade emitter thorium-226 ([Th-226]anti-CD33). *Methods*. The human myeloid sensitive cell line HL-60 (CD33 +/+) was treated with 225, 75, 22.5, 7.5 and 2.25 kBq/mL of [Bi-213]anti-CD33 or [Th-226]anti-CD33, using different specific activities (0.023, 0.09, 0.23 and 0.9 MBq/µg anti-CD33). 24, 48 and 72h after treatment induction of cell death, induction of apoptosis, cell cycle, caspase activation and activation of apoptosis pathways were determined using flowcytometry and Western Blot analyses. *Results*. Our results demonstrate that specific activities of anti-CD33 antibodies radiolabeled with Bi-213 or Th-226 play a critical role in induction of cell death, apoptosis and in activation of apoptosis pathways in CD33 positive myeloid leukemia cells. The efficacy of cell death induction depends on both dose and specific activity. At a specific activity of 0.23 MBq/µg anti-CD33, it was possible to kill 80% of leukemia cells at a very low activity concentration of 7,5 kBq/mL of Th-226 after 72h. Further decreasing the specific activity to 0.09 MBq/µg anti-CD33 of Th-226 reduced cell killing to 40% and decreasing the specific activity to 0.023 MBq/µg anti-CD33 of Th-226 made it impossible to kill leukemia cells at comparable activity concentrations. Similar results were observed for Bi-213. However, in contrast to Th-226 higher activity concentrations of Bi-213 were needed. Only at specific activity of 0.9 MBq/µg anti-CD33, it was possible to kill 80% of myeloid leukemia cells at activity concentration of 7.5 kBq/mL of Bi-213. At specific activity of 0.23 MBq/µg anti-CD33 only 15% were eradicated at comparable activity concentrations of Bi-213. Similar results were also found after examination of the effect of different specific activities of radiolabeled anti-CD33 antibodies with Th-226 or Bi-213 in activation of apoptosis pathway at comparable concentrations. Only at a specific activity of 0.23 MBq/µg anti-CD33 for Th-226 and a specific activity of 0.9 MBq/µg anti-CD33 for Bi-213 at the activity concentration of 7.5 kBq/mL a strong activation of caspase-3, caspase-2, caspase-10, caspase-9 and

PARP cleavage were found. Activation of apoptosis pathway were strongly decreased at lower specific activities. *Summary and Conclusions*. Our findings suggest that not only the activity concentrations of anti-CD33 antibodies radiolabeled with Th-226 or Bi-213 play an important role in killing leukemia cells and in activation of apoptosis pathways but also the specific activities are crucial. These findings have important implications for leukemia therapies using radiolabeled antibodies with different α-particle emitters such as Th-226 and Bi-213 during radioimmunotherapy.

0823

ANGIOGENESIS IN ACUTE PROMYELOCYTIC LEUKEMIA IS MEDIATED BY THE HEPATOCYTE GROWTH FACTOR

A. Aires, N.C. Gutiérrez, J.J. Pérez, P. Maiso, E.M. Ocio, M.C. Chillón, F.V. Ticona, L. Díaz, J.F. San Miguel

Servicio de Hematología, Hospital Universitario. Centro de Investigación del Cán, SALAMANCA, Spain

Background. Angiogenesis is critical in the pathogenesis of different hematological malignancies. An increased angiogenesis in the bone marrow of patients with acute promyelocytic leukemia (APL) has been demonstrated in previous studies and VEGF is believed to be the major positive mediator of angiogenesis. Gene expression profiling has demonstrated that the hepatocyte growth factor (HGF), another potent angiogenic factor, is highly expressed in APL, while its expression is absent in all remaining acute myeloid leukemias. *Aims*. 1) To investigate the involvement of HGF as a mediator of angiogenesis in APL. 2) To explore the effect of all-trans retinoic acid (ATRA) on HGF expression. *Methods*. Functional assays were performed using the human promyelocytic cell line NB4, which was cultured in RPMI 1640 with L-glutamine and supplemented with antibiotics and 10% fetal bovine serum. The secretion of HGF and VEGF was measured using ELISA kits (Quantikine, R&D Systems). Ten APL samples were cultured for HGF quantification in the media. Neutralizing antibody for HGF (R&D Systems) was used at 5 microg/mL concentration. Migration of HUVECs was assessed by the CytoSelect Cell Migration kit (Cell Biolabs). Transmigration was quantified by counting the migrated cells using an inverted microscope and by measuring absortion at 560 nm. All the experiments were repeated three times with similar results. *Results*. The overexpression of HGF observed at mRNA level in APL was correlated with the quantification of HGF content in the media of cell cultures from 10 APL samples as well as in the conditioned media from NB4. To explore the angiogenic potential of the NB4 cells, the conditioned media was tested in the endothelial cell migration assay. After incubation for 6 hours, endothelial cell migration was significantly stimulated compared to control. When neutralizing antibodies to HGF were added to the conditioned media a strong inhibition of endothelial cell migration was observed. In order to know if the antiangiogenic effect of ATRA was related to a putative effect of this drug on HGF production, NB4 cells were treated with ATRA (1 microM) during 5 days. Quantitative ELISA assay showed that ATRA treatment induced a significant reduction of HGF production by the NB4 cells at 72 hours (more than 80% of control production), whereas a similar decrease of VEGF was reached after 120 hours, indicating that the inhibition of angiogenic factors by ATRA in APL occurs significantly earlier for HGF. *Conclusions*. The HGF produced by promyelocytic blast cells promotes endothelial cell migration. The inhibition of HGF secretion by ATRA represents a new mechanism by which ATRA abrogates angiogenesis.

ANALYSIS OF SUBCELLULAR COMPARTMENT EXPRESSION OF SURVIVIN WILD-TYPE AND SPLICING VARIANTS 2B AND DELTAEX3 IN PATIENTS DIAGNOSED WITH ACUTE MYELOID LEUKEMIA: IMPACT ON CLINICAL OUTCOME

J. Serrano-Lopez,[1] J. Serrano,[2] J. Sanchez-Garcia,[2] L. Hermosin,[3] V. Martin-Palanco,[2] S. Tabares,[2] J. Roman-Gomez,[2] C. Herrera-Arroyo,[2] A. Torres-Gomez[2]

[1]University Hospital Reina Sofia, CODOBA; [2]Hematology Department. University Hospital Reina Sofia, CORDOBA; [3]Hospital de Jerez, JEREZ, Spain

Background and Aims. Suppression of apoptosis is a major contributing factor to oncogenesis in acute myeloid leukemia (AML). Survivin wild-type (WT) (142aa) is a member of inhibitor of apoptosis protein family (IAP) regulating both apoptosis and cell cycle progression. Survivin binds to several structural components of the mitotic apparatus and can block apoptosis by inhibiting caspases 9, 3 and 7. Recently, different splicing variants have been described such as Survivin-2B (165aa) and Survivin-DeltaEx3 (137aa). Survivin WT and 2B can localize to both nuclear and cytoplasmic compartments whereas DeltaEx3 localizes only in the nucleus. Survivin is undetectable in differentiated adult tissue but is over expressed in most cancers. In this study we analyzed the subcellular compartment distribution of Survivin WT and splicing variants in AML, the correlation with proliferative status and the impact on outcome. *Methods*. We included 68 AML consecutive patients. Median age was 62 years (range 8-89). Median leukocyte count was 10.3×10^9/L (range 0.8-285). FAB subtypes were: M0=8, M1=20, M2=13, M3=8, M4=11, M5=7 and M6=1 with the following cytogenetic findings: t(15;17)=8, t(8;21)=2, complex karyotype=8, del7=1, 11p23=2, normal karyotype=16 and others= 9. There were 11.3% patients with FLT3-ITD and 16.9% with NPM1 mutation. Bone marrow samples were obtained at diagnosis. Nuclear and cytoplasmic proteins were harvested with Q-proteome cell compartment (Qiagen) and protein concentration assayed using Protein Assay Kit (Bio-Rad). Survivin protein was detected by Western Blot Protein with Primary antibody for human-Survivin and specificity of each isoform was assessed by blocking peptide experiments. We used beta-actine and Laminin A (Cell Signaling Tecnology) to test compartment specificity. Proteins were visualized by enhanced chemiluminescence (ECL-Plus, GE Healthcare) in Chemigenius-2 and quantified using GeneTools software. Proliferative status was measured by total Akt and Akt-pSer473 and cell cycle analysis was assessed by double Hoechst 33342-Pyronin Y staining and flow cytometry. *Results*. In cytoplasmic protein extracts, Survivin WT and 2B were detected in 45% and 45.2% of patients respectively but DeltaEx3 was never detected. Nuclear isoforms were detected in 46.7%, 30% and 28.3% of cases for WT, 2B and DeltaEx3 respectively. Considering all isoforms, 23.3% of samples expressed Survivin in both nucleus and cytoplasm. 21.7% only in nucleus and 23.3% only cytoplasmic. Interestingly, there was strong statistical correlation between the levels of p-Ser473 Akt (detected in 56% in marrow samples with high levels in 27%) with Survivin-WT in cytoplasm (p=0.01) and inverse correlation between p-ser473 Akt with nuclear Survivin-WT (p=0.002). Meaningfully, lack of cytoplasmic Survivin WT was associated with an increased proportion of cells in Go cell cycle phase (11.1% vs. 3.6%, p=0.04). Finally, cytoplasmic Survivin WT localization and high p-Ser473 Akt levels, were both significantly correlated with CR achievement with one induction cycle (p<0.01), less relapse rate (p=0.01) and less mortality rate. By contrast, nuclear Survivin localization was associated with a significant increased relapse rate (p=0.03). *Conclusions*. Cytoplasmic localization of WT and 2B Survivin is associated to an increased proliferative status with constitutive activation of PI3k/Akt and more favourable outcome. However, nuclear localization of Survivin WT and isoforms could represent an adverse finding.

WILMS' TUMOR 1 GENE MUTATIONS ARE ASSOCIATED WITH A HIGHER RISK OF RELAPSE IN YOUNG ADULTS WITH ACUTE MYELOID LEUKEMIA: A STUDY FROM THE ACUTE LEUKEMIA FRENCH ASSOCIATION

A. Renneville,[1] N. Boissel,[2] V. Zurawski,[3] L. Llopis,[3] V. Biggio,[3] O. Nibourel,[3] N. Philippe,[3] X. Thomas,[4] H. Dombret,[5] C. Preudhomme[3]

[1]CHRU of Lille, LILLE; [2]Department of Adult Hematology, Saint-Louis Hospital, PARIS; [3]Department of Hematology, CHRU of Lille, LILLE; [4]Department of Hematology, Edouard Herriot Hospital, LYON; [5]Department od Adult Hematology, Saint-Louis Hospital, PARIS, France

Background. Wilms' Tumor 1 (WT1) is a transcription factor overexpressed in most cases of acute myeloid leukemia (AML). Recently, several groups reported that WT1 mutations occur in approximately 10% of normal karyotype AML (CN-AML) and cluster to exons 7 and 9, and that these mutations independently predict poor outcome in patients with CN-AML. *Aims*. The objectives of this study were to evaluate the frequency, the main clinical and biological associated features and the prognostic significance of WT1 mutations in a retrospective cohort of young adults with AML, excluding acute promyelocytic leukemia. *Methods*. We studied a cohort of 268 young adults (15-50 years) with AML uniformly treated in the Acute Leukemia French Association-9802 (ALFA-9802) trial. WT1 exon 7 and 9 mutations were retrospectively screened by PCR and direct sequencing. The patients were also assessed for the presence of FLT3 internal tandem duplication (FLT3-ITD), FLT3-

D835/I836, NPM1 and CEBPA mutations. *Results*. 14 out of 268 AML patients (5%) harbored a WT1 mutation. Among the 106 patients with CN-AML, WT1 mutations were detected in 9 cases (8.5%). All WT1 mutations detected within this cohort of patients were heterozygous frameshift mutations in exon 7. WT1 mutations were associated with a younger age (p=0.02) and a FLT3-ITD (p=0.03). No association was found between the presence of WT1 mutations and FAB subtype or white blood cells (WBC) count at diagnosis. The karyotype of WT1 mutated AML was predominantly normal (9/14, 64%). None of these cases was found in the favorable cytogenetic risk group defined by the presence of either a t(8;21)(q22;q22) or an inv(16)/t(16;16)(p13;q22). Out of 268 patients, 243 (91%) achieved complete remission (CR) after induction chemotherapy. The CR rate was lower in WT1 mutated patients compared with wild-type cases, but without reaching significance (79% versus 92%, p=0.13). The median follow-up for patients who remained alive was 3.8 years. Patients with WT1 mutations were found to have a shorter overall survival (OS at 4 years: 22% versus 56%, p=0.01) and a higher risk of relapse (RR at 4 years: 82% versus 46%, p=0.0008) compared with wild-type cases. Within the subgroup of patients with CN-AML (n=106), the presence of a WT1 mutation was also associated with an increased risk of relapse (p=0.0006, 4y-RR: 86% versus 40%). In multivariate analysis considering WBC count, molecular risk group (NPM1 mutated/FLT3-ITD negative or CEBPA mutated/FLT3-ITD negative versus other genotypes), and WT1 mutational status as covariates, the presence of a WT1 mutation remained an independent adverse prognostic factor for the risk of relapse in CN-AML. Even after adjustment on other covariates, WT1 mutation was not predictive of OS. *Conclusions*. We showed that WT1 mutations represent an adverse prognostic factor in young adults with AML. Prospective trials should confirm the clinical relevance of WT1 mutations in relation to other prognostic factors in AML.

Background. The EVI1 (ecotropic virus integration-1) gene plays an important role in hematopoiesis especially in megakaryocyte development. The MDS1 gene is located upstream of EVI1, and its function is currently unknown. Normally the MDS1/EVI1 intergenic splice variant is co-expressed with EVI1. In adult acute myeloid leukemia (AML) overexpression of EVI1 (EVI1+) can be found in patients with chromosome 3q26-rearrangements. Often, these patients do not co-express MDS1/EVI1. Recently EVI1+ was also discovered in a separate subgroup of patients that did not have 3q26-rearrangements. Occasionally, they did not show overexpression of MDS1/EVI1. In these patients cryptic inversions of chromosome 3 were identified with fluorescence *in situ* hybridization (FISH). Of interest, EVI1+ was found to be an independent poor prognostic marker in adult AML (Lugthart *et al.*, Blood 2008). *Aim and Methods*. In pediatric AML, 3q26-rearrangements are rare and the role of EVI1 is unknown. In this study, we investigated the frequency and clinical relevance of EVI1+ in pediatric AML. EVI1 expression was analyzed in 233 pediatric AML patients, of whom microarray gene expression profiling data were available. *Results*. EVI1+ was found in 25 pediatric AML patients (11%), and confirmed with real-time quantitative PCR. This included 13/49 (26%) patients with MLL-rearranged AML: 5/22 (23%) cases with t(9;11); and all (n=4) cases with t(6;11). Moreover, EVI1+ was found in 4/7 (57%) cases with AML M7; in 2/3 (66%) cases with AML M6; in both cases with monosomy 7; in 1/43 (2%) cases with normal cytogenetics; in 2 patients with random cytogenetics, and in 1 patient with a cytogenetic failure. EVI1+ was not found in the t(8;21), inv(16) and t(15;17) subgroups. 3/25 EVI1+ patients lacked the MDS/EVI1 transcript, but no cryptic 3q26-rearrangements were detected with FISH. Molecular analysis showed that one patient had a CEBPα mutation; one patient had an FLT3-ITD; and 3 patients showed a mutation in the RAS oncogene. EVI1+ was not correlated with sex or white blood cell count. Survival analysis was restricted to the subset of patients who were treated using uniform DCOG and BFM treatment protocols (n=204). In this cohort, EVI1+ patients had a worse 5-years event-free survival (pEFS) compared to patients without EVI1+ (30 vs. 43%, p=0.02). However, multivariate analysis, including cytogenetics, age and WBC, showed that EVI1+ was not an independent prognostic factor for survival. Moreover, within the unfavorable/normal cytogenetic subgroup, there was no difference in outcome between patients with and without EVI1+. *Summary and Conclusions*. We conclude that EVI1+ is found in ~10% of pediatric AML, and highly correlated with specific cytogenetic (MLL-rearrangements) and morphologic (FAB M6/7) subtypes. In contrast to adult AML, no 3q26-rearrangements or cryptic inversions were found, and EVI1+ was not an independent prognostic factor. This difference in prognostic relevance may be due to differences in treatment. Alternatively, these results may indicate that EVI1 plays a different role in disease biology between adult and pediatric AML. This is at least suggested by the lack of 3q26 aberrations in pediatric AML.

EXPRESSION OF ANGIOTENSIN-CONVERTING ENZYME (ACE, CD143) AND SHAPERONS (BIP, CALNEXIN, CALRETICULIN) BY LEUKEMIC DENRITIC CELLS IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS

I. Galtseva,[1] L. Pashin,[1] E. Parovichnikova,[1] A. Sudarikov,[1] S. Danilov,[2]
I. Vorobiev,[1] V. Savchenko[1]

[1]National Research Center for Hematology, MOSCOW, Russian Federation; [2]Anesthesiology Research Center, CHICAGO, USA

Background. The dendritic cells (DC) play a key role in the induction of primary and adoptive immune response. AML blast cells can be induced to differentiate into leukemic dendritic cells (LDC), which are quite similar to monocytes derived DC by the expression profile of integrins and co-stimulatory molecules. The only difference between LDC and DC is absence of surface ACE expression on LDC in contrast to high level of ACE on DC. *Aims*. We propose that the absence of surface ACE expression in LDC is due to the block of normal ACE transport to the cell surface, normally controlled by shaperons. To confirm this hypothesis we quantified the level of intracellular and surface ACE and Bip. At the same time mRNA expression levels of ACE and shaperons Bip, Calnexin, Calreticulin in DC and LDC were measured. *Methods*. Blood samples were collected from 12 AML patients at diagnosis before induction chemotherapy and 10 healthy donors. Mononuclear cells were isolated using gradient centrifugation with Ficoll-Paque and were differentiated into dendritic cells by culturing with 180 ng/mL calcium ionophore for 4 days at 37°C and 33°C (activated factor for shaperons' induction). DC were stained for surface and intracellular ACE (two mAbs - clones1D8 and 9B9) and Bip (mAb KDEL) analyzed by flow cytometry, simultaneously the mRNA expression levels of ACE and shaperons Bip, Calreticulin, Calnexin were evaluated with RT PCR. *Results*. The surface ACE expression on LDC cultured at 37°C was 3±2% of positive cells (mAb 9B9), 2±1% (mAb1D8), surface Bip expression was 6±1% and were increased up to 45 ±10% (mAb 9B9), 57±8% (mAb1D8) and 63±7% for Bip with lowering culture temperature to 33°C. The surface ACE expression on DC cultured at 37°C was 46±9% (mAb 9B9) and 5±2% (mAb 1D8), surface Bip expression was 36±4%, at 33°C - 34±3% (mAb 9'9), 6±2% (mAb 1D8), 21±4% for Bip. The intracellular ACE expression in LDC cultured at 37°C was 71±9% (mAb 9'9), 52±8% (mAb1D8), intracellular Bip expression was 92±7%, and were lowered to 6±2% (mAb 9B9), 5±2% (mAb 1D8), 52±6% for Bip with lowering culture temperature to 33°C. The intracellular ACE expression in DC cultured at 37°C was 50±10% (mAb 9B9), 27±7% (mAb 1D8), intracellular Bip expression was 69±7%, at 33°C - 40±10.3% for 9B9, 33±7% for 1D8, 88±4% for Bip. Gene expression had been measured by real time PCR using TaqMan procedure and calculated in relative units using GapDH expression for normalization. Expression of ACE was increased in 57,1% cases of DC cultured at 33°C compared to DC cultured at 37°C and in 89% cases of LDC cultured at 33°C compared to LDC cultured at 37°C. Expression of Bip, was increased in 87,5% cases of DC and in 55,5% cases of LDC. For Calnexin appropriate measures showed 62,5% for DC and 55,5% for LDC; for Calreticulin 28,5% for DC and 66,6% for LDC respectively. *Conclusions*. The data demonstrate the block of ACE transport to the cell surface of LDC at normal human temperature 37°C and thus provide the evidence of the altered expression of normal antigens by LDC. We confirmed not only differences of LDC and DC discovered by standard cultivation but the different reactions of these cells on the stress conditions. Hence, this LDC behaviour may be responsible for inadequate antitumor immune response.

0828

CHARACTERISATION OF A NEW MONOCLONAL ANTIBODY RAISED AGAINST THE MUTANT A OF THE NPM1 PROTEIN: ITS APPLICATION IN THE DIAGNOSIS OF THE NPMC+AML

M. Gruszka

European Institute of Oncology, MILAN, Italy

Background. Nucleophosmin (NPM) gene mutations occur in up to 35% of the human AML cases (60% of cases with otherwise normal karyotype). Twenty-two different mutations have been described, six of which, including type A (75-80% of all cases), encode for the same protein. Mutations introduce a nuclear export signal, which relocalises NPM to the cytoplasm (NPMc+AML). Methods used for the detection of NPM mutations include: DNA sequencing, real-time Q-PCR, denaturing high-performance liquid chromatography, capillary electrophoresis, and allele-specific (ASO)-RT-PCR assay. Detection of cytoplasmic NPM dislocation by immunofluorescence (IF) or immunohistochemistry (IHC) can also be utilised. To date there is no well-functioning mutant-specific monoclonal antibody (MAb) for the diagnosis. *Aims*. The aim of the study was the production and characterisation of a NPM mutation-specific MAb for the diagnosis and follow-up of minimal residual disease, as well as mutant identification in molecular complexes and the studies of its in-cell dynamics. *Methods*. Standard mouse immunisation/hybridoma screening method was used to raise a MAb against a 19-mer polypeptide (CQEAIQDLCLAVEEVSLRK) corresponding to the C-terminal part of the NPM mutant A. The antibody's efficacy was evaluated by ELISA, Western blotting (WB), immunoprecipitation (IP), IF and IHC. A series of 95 *de novo* AML patients was studied by capillary electrophoresis and ASO-RT-PCR and, in parallel with our antibody, by IF on bone marrow smears and/or peripheral blood films; marrow/blood samples of 41 of these patients were also tested in parallel by flow cytometry. *Results*. The antibody is specific for the mutated NPM, does not cross-react with the wtNPM, as seen in a series of human and murine cells, or with any other unrelated protein. It works well in ELISA, WB, IP, IF, IHC and flow cytometry. It allows for the detection of as few as 0.01% of positive cells as revealed by flow cytometry analysis performed mixing mutant-positive and negative cell lines. Of the 95 consecutive *de novo* AML cases 38(40%) were found to be positive for the presence of the mutant by IF; by flow cytometry 15/41(37%) patients showed positivity. There were no discrepancies with the results obtained by capillary electrophoresis and ASO-RT-PCR. The percentage of positive cells within the blast gate varied between 2-88%(mean 28%). Moreover, 3/38(8%) positive patients were non-A mutations: two D (amino acid sequence identical to A) and one B (differing by one amino acid from mutant A). *Summary and Conclusions*. NPM mutant is usually detected by its cytoplasmic dislocation as a surrogate marker of the mutation using anti-NPM antibodies and confirmed by different molecular biology tests. Here, we present a mutant-specific MAb that can be applied in IF and flow cytometry for the diagnosis of NPMc+AML. Although, it was raised against the mutant A, it recognised also mutants B and D that together with type A are by far the most frequent of all mutations identified so far. This is the first time that a leukaemia-associated mutant has been used for the establishment of a specific diagnostic marker, as the presence of a positive staining is an unequivocal sign of the mutation.

0829

SURVIVIN EXPRESSION IMPACTS ON SURVIVAL IN ACUTE MYELOID LEUKEMIA PATIENTS

J. Greiner,[1] B.A. Guinn,[2] H. Döhner,[1] K.I. Mills,[3] L. Bullinger[1]

[1]University of Ulm, ULM, Germany; [2]King's College, LONDON, UK; [3]Queens University Belfast, BELFAST, UK

Survivin, coded by the gene BIRC5 (baculoviral IAP repeat-containing 5), represents an important tumor-associated antigen that is involved in critical cellular pathways like control of cell proliferation and viability. Of particular note, survivin is a key player of the survivin-Borealin-INCENP core complex that regulates important proteins involved in cell division like aurora B kinase or polo-like kinase 1. However, little is known of the role of survivin in acute leukemia. In order to further address the impact of survivin expression in acute myeloid leukemia (AML), we evaluated its expression in two large independent microarray data sets comprising 618 AML cases. Both data sets showed no correlation of BIRC5 expression levels and age, BM blasts, LDH, preceding malignancy or overall survival. However, with regard to overall survival we found a negative prognostic impact of high BIRC5 expression levels in inv(16) core binding factor AML: in CBF AML cases lower BIRC5 expression was associated with better clinical outcome (p=0.004). Notably, this was mainly due to inv(16) cases with low BIRC5 expression (p=0.007). For AML cases with t(8;21) we found no significant difference, despite the fact that survivin seems to be a critical regulator of AML1/ETO-induced oncogenicity in AML. Furthermore, we found expression of BIRC5 correlated with a number of genes involved in cell cycle regulation. In addition, both data sets showed a correlation of survivin with aurora B kinase (AURKB) expression underlining the recent findings that survivin regulates the expression of this protein via the survivin-Borealin-INCENP core complex. Several clinical studies are ongoing to inhibit AURKB in an effort to target genes involved in the survivin cancer network. This strong correlation between BIRC5 expression and aurora B kinase (AURKB) and polo-like kinase 1 (PLK1) suggested that a combination of survivin and AURKB and/or PLK1 inhibition might prove to be valuable, especially in AML cases with an inv(16). In addition, we observed a strong association between BIRC5 and other leukemia-associated antigens (LAA) like SSX2IP (SSX2 interacting protein) and HMMR (hyaluronan-mediated motility receptor, also known as RHAMM) expression (p<0.001), thereby suggesting that survivin might also provide an effective immunological target in therapy of AML. In conclusion, in patients with CBF AML, and particularly patients with inv(16), high BIRC5 expression is a negative prognostic factor and an interesting structure for a targeted strategy against survivin expressing leukemic cells. Down-regulation of this complex system involved in tumorigenesis might be an important target for tumor cell control in acute leukemias.

HUMAN MYELOID LEUKEMIA BLASTS ARE HIGHLY SENSITIVE TO IRON DEPRIVATION

C. Callens,[1] S. Coulon,[2] J. Naudin,[2] N. Boissel,[3] V. Asnafi,[1]
R. Monteiro,[4] H. Dombret,[3] E. Macintyre,[1] I. Moura,[4] O. Hermine[1]

[1]Hôpital Necker, PARIS; [2]CNRS UMR8147, PARIS; [3]Hôpital Saint Louis, PARIS; [4]INSERM U699, PARIS, France

Objectives. Iron is a cofactor critical for energy metabolism and cell proliferation. Targeting iron homeostasis induces cell cycle arrest and apoptosis particularly in cancer cells which have been shown to be more sensitive to iron depletion than their normal counterparts. We sought to evaluate the efficacy of iron homeostasis targeting therapies in human acute myeloid leukemia (AML). For this purpose, we investigated the sensitivity of AML blasts or leukemic cell lines to iron chelators (deferoxamine and deferasirox) and A24, an anti-transferrin receptor (TfR) monoclonal antibody. A24 binds TfR and competes with Fe-Tf for TfR binding. In addition, it impairs cell surface receptor expression by inducing TfR endocytosis and sequestration in lysosomal compartments. Therefore, A24-targeted cells are profoundly impaired in iron uptake and undergo apoptosis. *Material and Methods.* A total of 15 AML patients peripheral blood were obtained from Necker and Saint Louis Hospital (Paris, France). They were collected at the initial diagnostic assessment and previously to treatment administration, after informed consent. Mononuclear cells were separated by Ficoll-hypaque density centrifugation and cultured in IMDM medium supplemented with 15% FCS, Stem Cell Factor, IL3 and FLT3-L with or without A24 (0.02 to 20 µg/mL) or iron chelators (deferoxamine: 0.07 to 50 µM and deferasirox: 0.04 to 10 µM) Cell proliferation was assessed by 3H-thymidine incorporation and cell death was evaluated by the annexinV/propidium iodide staining. For *in vivo* experiments, leukemia cells were subcutaneously xenografted in nude mice. *Results*. Iron deprivation inhibited cell proliferation and induced apoptosis in all AML subtypes. Nevertheless, myeloid cells seemed to be more sensitive than monocytic cells to iron-deprivation. These results were confirmed using the two leukemic cell lines HL60 and U937. Leukemic cell apoptosis was dependent on mitogen-activated protein kinases (MAPK) activation and inhibitors of JUNK and p38 prevented apoptosis induced by iron-chelating agents. *In vivo*, a single injection of A24 completely prevented tumor development in xenografted mice, whereas iron-chelators delayed tumor growth. *Discussion and Conclusions*. Acute myeloid leukemia are aggressive hemopathies and patients prognostic is poor because of a high degree of relapse after conventional chemotherapy. We show here that that iron deprivation impairs AML cell proliferation and induces apoptosis through the activation of MAPK pathway. *In vivo* experiments validated the efficacy of iron-chelating therapies. Altogether these findings indicate iron metabolism is a target in AML therapies which could be combined with chemotherapy opening new therapeutic alternatives in AML treatment.

Acute myeloid leukemia - Clinical II

COMBINATION OF IDARUBICIN, HIGH DOSE CYTARABINE AND SORAFENIB IS HIGHLY EFFECTIVE IN ACHIEVING REMISSION IN NEWLY DIAGNOSED, FLT3-MUTATED ACUTE MYELOID LEUKEMIA

F. Ravandi,[1] M. Andreeff,[1] G. Garcia-Manero,[1] S. Faderl,[1] M. Konopleva,[1] S. O'Brien,[1] A. Byrd,[1] M. Brandt,[1] W. Zhang,[1] D. Jones,[1] M. Levis,[2] J. Cortes,[1] H. Kantarjian[1]

[1]University of Texas - M D Anderson Cancer Center, HOUSTON; [2]Johns Hopkins University Medical Center, BALTIMORE, USA

Background. Sorafenib is an orally active multi-kinase inhibitor with potent activity against FLT3 kinase and the ability to induce apoptosis in FLT3-mutant human acute myeloid leukemia (AML) cell lines at nM concentrations. It has less plasma protein binding than several other FLT3 inhibitors. In a phase I study of single agent sorafenib in patients (pts) with AML, escalating doses were well tolerated with no myelosuppression and with significant clinical activity predominantly (but not exclusively) in FLT3 mutated pts. *Aims*. This is a phase I/II study to determine the clinical activity and tolerability of combination of sorafenib with standard AML chemotherapy. *Methods*. Cytarabine 1.5 g/m^2 over 24 hrs daily x 4 (x 3 for pts over 60) and idarubicin 12 mg/m^2 daily x 3 are administered with sorafenib. In the phase I portion of study, pts with relapsed AML were treated with escalating doses of sorafenib (400 mg qod, 400 mg daily and 400 mg bid) for 7 days during induction. Pts achieving CR receive up to 5 courses of consolidation with idarubicin 8 mg/m^2 daily x 2 and cytarabine 0.75 g/m^2 daily x 3 in addition to continuous sorafenib 400 mg bid for up to 28 days per cycle. Cycles are repeated every 4 to 6 weeks. Maintenance with sorafenib 400 mg bid would continue for up to a year after consolidation. *Results*. Ten pts (median age 34, range 21-58) with relapsed AML (median prior therapy 2, range 1-6) were treated on the phase I portion. Seven were FLT3-ITD positive and 4 achieved CR; sorafenib 400 mg bid was established as a safe dose in induction. In the phase II portion 48 pts (12 with FLT3-ITD and 2 with FLT3-TKD) have been treated. Median age is 53 (range 18 - 66). Cytogenetics were diploid in 20, +8 in 5, -5/-7 in 5, t(9;11) in 3, miscellaneous in 11, and unavailable in 4. The median presentation WBC was 5.2×10^9/L (range 0.6 - 122.7×10^9/L). FLT3 mutation burden was low in blasts from 4 pts, and high in 10. 7 pts were FLT3-ITD+/NPM1- and 1 was FLT3-D835+/NPM1-. 45 pts are evaluable for response (3 too early) and 38 (84%) have achieved CR (n=34), or CRp (n=4), including 14 of 14 FLT3 mutated patients. 3 died during induction from pneumonia, 4 were resistant. The regimen is well tolerated with grade 3 and higher adverse events possibly related to the addition of sorafenib during induction including hyperbilirubinemia (6), elevation of transaminases (3), diarrhea and colitis (4), rash (3), pancreatitis (1), pericarditis (1), elevated creatinine (1), and cardiac/hypertension (3). With a median follow-up of 28 weeks (range, 1 - 59 weeks), the probability of survival at 6 months is 85%; 9 pts have relapsed with a median CR duration of 8 months (range, 0.5+ - 12+ months). Among the patients with FLT3 mutation, 6 have relapsed and 8 remain in CR. Peripheral blood samples from 8 pts were evaluated prior to and 24-48 hrs post sorafenib administration, and prior to chemotherapy. In six pts (75%), sorafenib alone induced apoptosis (determined by flow cytometry) in blasts and in CD33/CD34 positive leukemia progenitor cells. Expression of phospho-ERK (pERK) was detectable by flow cytometry in 5 of 7 samples tested at baseline; 24-hour exposure to sorafenib resulted in >50% downregulation of pERK in 3 of the 5 samples. Plasma inhibitory assay was performed using day 7 samples from 10 pts; mutant FLT3 was suppressed by all samples with 5-fold more potent suppression against mutant versus wild-type FLT3. *Summary*. Sorafenib can be safely combined with idarubicin and cytarabine; it has a high CR rate particularly in patients with FLT3 mutations. Correlative studies confirm potent activity of sorafenib against ERK and FLT3 signaling.

0832

IMPROVED OUTCOME BY ADDITION OF LOMUSTINE (CCNU) TO IDARUBICIN AND CYTARABINE IN ELDERLY PATIENTS WITH *DE NOVO* ACUTE MYELOID LEUKEMIA. A REPORT FROM THE GOELAMS GROUP

P. Pigneux,[1] J.l. Harousseau,[2] F. Witz,[3] M. Sauvezie,[1] M.C. Bene,[4] I. Luquet,[5] T. Leguay,[1] M. Hunault-berger,[6] C. Recher,[7] N. Vey,[8] B. Lioure,[9] C. Himberlin,[5] F. Dreyfus,[10] J. Reiffers,[11] N. Milpied,[1] N. Ifrah[6]

[1]CHU Bordeaux, PESSAC; [2]CHU Nantes, NANTES; [3]Hopital Brabois, NANCY; [4]Faculté de Medecine, NANCY; [5]Hopital Robert Debre, REIMS; [6]Chu Angers, ANGERS; [7]CHU Toulouse, TOULOUSE; [8]IPC, MARSEILLE; [9]Hopital de Hautepierre, STRASBOURG; [10]Hopital Cochin, PARIS; [11]Institut Bergonié, BORDEAUX, France

In elderly patients with acute myeloid leukemia (AML) treated intensively, no improvement has been shown in the last 20 years. We performed a retrospective study in 847 patients over 60 years old, prospectively enrolled in 3 trials conducted in France between 1995 and 2005, with the aim to investigate prognostic factors for complete remission (CR) achievement and survival. Induction therapy consisted in the association of Idarubicin 8 mg/m^2 d1-5 and Cytarabine 100 mg/m^2 d1-7 (Group I, 339 patients) or the same drugs with the addition of lomustine (10mg\m^2 orally at day 1)(Group II, 508 patients). Consolidation therapy consisted of anthracycline and cytarabine courses at lower doses, preceded or not by a first course with intermediate dose cytarabine. The patients' characteristics were similar between the two groups concerning sex, WBC count, ECOG, and cytogenetics, yet patients were older in Group II versus Group I (55% versus 45% over 69 years of age, p<0.0001).The CR rate was significantly higher for patients in Group II compared to Group I (67% vs. 57%, p=0.002). The toxic death rate was not different between groups. In multivariate analysis, three good prognostic factors emerged for achieving complete remission: good or intermediate cytogenetics (p<0.0001), ECOG < 2 (p<0.0001), and adjunction of lomustine to induction chemotherapy (p=0.002). The median overall-survival was significantly improved for patients treated with lomustine (12.7±2.2 months vs 8.7±2.7 months, p=0.004). In multivariate analysis, five prognostic factors affected positively overall survival: adjunction of lomustine to induction chemotherapy (p<0.0001), age <69 years (p=0.001), ECOG <2 (p=0.001), FAB other than AML0,6 or 7 (p=0.004) and good or intermediate cytogenetics(p=0.007). The median event-free-survival was also improved for patients treated with lomustine (10.7± 2.2 months vs 7± 2.7 months, p=0.002). Event-free survival was affected by the same prognostic factors as overall survival. We conclude that lomustine might be added in standard induction therapy as it allowed to obtain both better CR rate and survival in this retrospective study.

PROLONGED EXPOSURE TO LINTUZUMAB MONOTHERAPY IN ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES - RESULTS OF A PHASE 1 TRIAL

A. Raza,[1] J.G. Jurcic,[2] E.J. Feldman,[3] M. Maris,[4] J. Stephenson,[5] A.E. Frankel,[6] M. Cooper,[7] J. Wade,[8] B.L. Wood,[9] N. Galili,[1] M. Siadak,[10] E.L. Sievers,[10] J.G. Drachman,[10] G.J. Roboz[3]

[1]St. Vincent's Comprehensive Cancer Center, NEW YORK; [2]Memorial Sloan-Kettering Cancer Center, NEW YORK; [3]Weill Medical College of Cornell University, NEW YORK; [4]Rocky Mountain Blood and Marrow Transplant Center, DENVER; [5]Cancer Center of the Carolinas, GREENVILLE; [6]Scott & White Memorial Hospital, TEMPLE; [7]Indiana Oncology-Hematology Consultants, INDIANAPOLIS; [8]Cancer Care Specialists of Central Illinois, DECATUR; [9]University of Washington, SEATTLE; [10]Seattle Genetics, Inc., BOTHELL, USA

Background. Lintuzumab (SGN-33, HuM195) is a humanized antibody that binds CD33, a sialoglycan protein expressed on the majority of myeloid malignancies and on normal myeloid and monocytic progenitors. *In vitro*, binding of CD33 by lintuzumab induces antibody-dependent cellular cytotoxicity, complement-dependent cytotoxicity, and antibody-dependent cellular phagocytosis. In prior clinical testing at lower dose levels, lintuzumab monotherapy elicited objective responses in patients with relapsed and refractory acute myeloid leukemia (AML) without dose-limiting toxicity. *Aims*. A phase 1, single-arm, dose-escalation trial was performed to assess the safety, immunogenicity, pharmacokinetics, and antileukemic activity of lintuzumab at higher doses and increased dosing frequency than previously studied. *Methods*. Cohorts of

3-6 patients with advanced myeloid malignancies and CD33 expression on >50% of marrow blasts received intravenous lintuzumab as outpatients at weekly doses of 1.5 to 8 mg/kg for 5 weeks (Cycle 1); the 8 mg/kg dose was used to treat a planned expansion cohort of 50 patients with AML or myelodysplastic syndrome (MDS). Outpatient infusions were continued every other week for patients who demonstrated clinical benefit. Informed consent was obtained prior to initiating therapy. *Results*. A total of 82 patients [AML (59), MDS (19), and chronic monomyelocytic leukemia (4)] with a median age of 74 years (range 50-89) were treated at 9 study centers. Dosing cohorts included 1.5 (6), 2.5 (4), 4 (4), and 8 mg/kg (68). Significant toxicity was not observed and a maximum tolerated dose was not established. The most common adverse events (AEs) were chills (37%), fatigue (35%), pyrexia (30%), and nausea (27%). Serious AEs related to lintuzumab in more than 1 patient were febrile neutropenia (3 patients) and rectal hemorrhage (2 patients). No anti-therapeutic antibodies were detected in any patient. Lintuzumab accumulation occurred during weekly dosing and Cmin/Cmax values increased with dose level. Among 59 patients with AML, 4 achieved complete remissions (CRs), 3 had partial remissions, and 2 were classified in morphologic leukemia-free state. Five of these 9 objective responses were at the 8 mg/kg dose level. In addition, 7 patients with AML who did not achieve objective response at the 8 mg/kg dose level had ≥50% reduction of marrow blasts. Twelve patients with AML (20%) received lintuzumab treatment for over 16 weeks. One of these patients achieved and maintained a CR while receiving lintuzumab treatment for over 1 year. In patients with MDS, 14 of 19 had a best response of stable disease; of these, 1 patient at the 8 mg/kg dose level had major hematologic improvement. Five of 19 patients with MDS achieved marrow blast percentage reductions ≥50%. Overall, 42 patients (51%) received more than 1 cycle of therapy. *Summary and Conclusions*. Lintuzumab was reasonably well tolerated at doses up to 8 mg/kg/week, achieving serum lintuzumab exposures approximately 20 times higher than in prior studies. There was evidence of antitumor activity in both AML and MDS patients. Further studies of lintuzumab in combination with low-intensity chemotherapy in AML and MDS are ongoing.

0834

AS1411 IN COMBINATION WITH CYTARABINE IN RELAPSED AND REFRACTORY ACUTE MYELOID LEUKEMIA

K. Stuart,[1] K. Stockerl-Goldstein,[2] M. Cooper,[3] M. Devetten,[4] R. Herzig,[5] B. Medeiros,[6] G. Schiller,[7] A. Wei,[8] G. Acton,[9] D. Rizzieri[10]

[1]Hollings Cancer Center, CHARLESTON, USA; [2]Washington University, ST LOUIS, USA; [3]St. Francis Hospital and Health Center, BEECH GROVE, USA; [4]Nebraska Medical Center, OMAHA, USA; [5]University of Louisville, LOUISVILLE, USA; [6]Stanford University School of Medicine, STANFORD, USA; [7]UCLA Medical Center, LOS ANGELES, USA; [8]The Alfred Hospital, MELBOURNE, Australia; [9]Antisoma, LONDON,UK; [10]Duke University Medical Center, DURHAM, USA

Background. AS1411 is the first nucleic acid aptamer to be tested in oncology clinical trials. It is an aptamer that binds to nucleolin, which is upregulated in the cytoplasm and on the surface of cancer cells. AS1411 exerts its cytostatic, followed by cytotoxic, action on the cell upon translocation into the cell by nucleolin, a multi-faceted protein that can interact with DNA, RNA and proteins and ultimately promotes cell proliferation. AS1411 has been shown to kill a wide variety of cancer cell lines. Acute myeloid leukemia (AML) cell lines KG-1 and MV4-11 have an IC50 of approximately 2 μM in the presence of AS1411. MV4-11 cells have been shown to upregulate nucleolin on the cell surface, and also to localise AS1411-FITC to the nucleus. The sensitivity of AML cells to AS1411 has also been seen in *ex vivo* patient cell blasts treated with AS1411. When AS1411 is combined with cytarabine, a standard treatment for AML, a synergistic effect is produced against MV4-11 cells. A synergistic effect has also been seen *in vivo* with AS1411 in combination with cytarabine in an MV4-11 subcutaneous xenograft model. AS1411 has been studied in a dose-escalating phase I study in solid tumours, where objective responses were seen and the safety profile was good. *Methods*. This randomized, multi-centre phase II trial compares AS1411 plus high-dose cytarabine (HiDAC) to HiDAC alone as treatment for relapsed or refractory AML. Patients in cohort I were randomized 2:1 to receive AS1411 10 mg/kg/day as continuous IV on days 1-7 + HiDAC 1.5 g/m^2/ twice daily on days 4-7 or HiDAC alone for 4 days. Following safety assessment, a second cohort was randomized to receive AS1411 40 mg/kg/day + HiDAC or HiDAC alone. All patients randomised to receive HiDAC alone who did not achieve remission could cross-over to receive HiDAC + AS1411 at the dose at which they were randomised. Study objectives were comparison of response rates (CR+CRp), safety and tolerability between treatment arms. *Results*. Accrual to the study has been completed with 71 patients randomized: 22 to AS1411 10 mg/kg/day + HiDAC (AS1411-10), 26 to AS1411 40 mg/kg/day + HiDAC (AS1411-40) and 23 to HiDAC alone (control). Safety findings are currently available for 44 patients (AS1411-10, 21; AS1411-40, 9; control, 14). The main grade 3 and 4 toxicities were hematological, notably febrile neutropaenia, neutropaenia and thrombocytopaenia; and infections. Safety findings were similar across groups, except that grade 3 hypokalaemia was more frequent with AS1411-40. Deaths within 28 days of treatment were: AS1411-10, 1/21; AS1411-40, 1/9; and control, 2/14. Response data are currently available for 39 patients; response rates (CR+CRp) were: AS1411-10, 16% (3/19); AS1411-40, 14% (1/7); and control, 0% (0/13). Full response data for the study will be presented. *Conclusions*. These data provide preliminary evidence suggesting that AS1411 in combination with HiDAC has antileukaemic activity and an acceptable safety profile in patients with relapsed and refractory AML.

CLASSIC II: UPDATED REMISSION DURATION AND SURVIVAL RESULTS OF SINGLE AGENT CLOFARABINE IN PREVIOUSLY UNTREATED OLDER ADULT PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA AND AT LEAST ONE UNFAVORABLE BASELINE PROGNOSTIC FACTOR

M Kantarjian,[1] P. Erba,[2] F. Claxton,[3] M.L. Arellano,[4] R.M. Lyons,[5] T.J. Kovacsovics,[6] J. Gabrilove,[7] S. Eckert,[8] S. Faderl[1]

[1]University of Texas MD Anderson Cancer Center, TEXAS; [2]University of Michigan Health System, ANN ARBOR; [3]Penn State College of Medicine, PENNSYLVANIA; [4]Emory University School of Medicine Winship Cancer Institute, ATLANTA; [5]Cancer Care Centers South Texas/US Oncology, SAN ANTONIO; [6]Ctr. for Hematological Malignancies OHSU, PORTLAND; [7]Mount Sinai School of Medicine, NEW YORK; [8]Genzyme Oncology, SAN ANTONIO, USA

Background. The CLASSIC II trial has previously reported an independently confirmed overall remission rate of 45.5% (37.5% CR and 8.0% CRp) and 30- and 60-day mortality rates of 9.8% and 16.1%, respectively (Blood 112: 558, 2008). We now report updated duration of remission (DOR), disease-free survival (DFS), and overall survival (OS). *Methods*. Single-arm, multi-center, Phase II, open-label, 2-stage study of patients with untreated acute myeloid leukemia (AML), ≥60 years old, and at least one unfavorable prognostic factor: age ≥70 years, antecedent hematologic disorder (AHD), PS=2, and/or intermediate/unfavorable risk myeloblast karyotype. Clofarabine (CLO) administered days 1-5 at 30 mg/m^2 during induction and 20 mg/m^2 during re-induction/consolidation for maximum 6 cycles. *Results*. 116 patients enrolled, 112 in full analysis set. Median age 71 years. Median duration of follow-up from first dose for all patients was 36 weeks (range, 1-85). Median DOR (censored at alternative therapy) for CR/CRp was 56 weeks (95% CI, 33 weeks - not yet estimable [n/e]). Median DFS (not censored at alternative therapy) for CR/CRp was 37 weeks (95% CI, 26-56 weeks). Median OS for all patients was 41 weeks (95% CI 28 - 53 weeks), for CR/CRp 59 weeks (95% CI, 50 weeks - n/e), and for CR was 72 weeks (95% CI, 53 weeks - n/e) Thirty-day mortality was 9.8% for all patients with 4.7% and 13.0% for age <70 and age ≥70 years, respectively. *Conclusions*. These data expand on the previously reported efficacy and safety data of single agent CLO in adult AML. Complete remissions appear durable, and DFS and OS compare favorably to historical experience with other regimens, particularly in patients with these unfavorable prognostic factors. These results suggest that single agent CLO is an effective option for older adult patients with untreated AML and one or more unfavorable baseline prognostic factor(s). Patients continue in long-term follow-up, with 42 alive at the most recent data cut-off (Nov. 2008).

0836

PROGNOSIS OF PATIENTS WITH AML CARRYING 11Q23/MLL RECIPROCAL TRANSLOCATIONS: A RETROSPECTIVE STUDY OF 191 CASES FROM THE FRENCH AML-INTERGROUP

A. Banos,[1] A. Jaquet,[2] A. Auvrignon,[3] N. Dastugue,[4] S. Castaigne,[5] G. Michel,[6] P. Fenaux,[7] C. Recher,[4] J. Reiffers,[8] G. Socié,[9] J.L. Harousseau,[10] D. Blaise,[11] B. Lioure,[12] C. Bastard,[13] N. Ifrah,[14] H. Dombret,[9] A. Pigneux[15]

[1]Centre Hospitalier de la Côte Basque, BAYONNE; [2]Medical Information processing Faculte Bordeaux II, BORDEAUX; [3]Hematology, Hopital Trousseau, PARIS; [4]Hematology, Hopital Purpan, TOULOUSE; [5]Hematology, Hopital André Mignot, VERSAILLES; [6]Paediatric Heamatology, Hopital La Timone, MARSEILLE; [7]Hematology, Hopital Avicenne, BOBIGNY; [8]Centre anti-cancéreux, Institut Bergonié, BORDEAUX; [9]Hematology, Hopital saint-Louis, PARIS; [10]Hematology, hopital Hôtel-Dieu, NANTES; [11]Hematology, Institut Paoli-Calmettes, MARSEILLE; [9]Hematology, Centre Hospitalier de Hautepierre, STRASBOURG; [13]Hematology, Centre Henri Becquerel, ROUEN; [14]Hematology, Centre hospitalier Universitaire, ANGERS; [15]Hematology, Hopital haut-Lévèque, PESSAC, France

Background. Acute myeloid leukemias (AMLs) carrying 11q23/MLL reciprocal translocations are usually associated with a bad prognosis. However, this AML subtype constitutes a heterogeneous group and the major factor influencing prognosis seems to be the MLL partner involved in the translocations. *Aims*. To determine the impact of AML with 11q23/MLL abnormalities according to the partner chromosome, to investigate another prognosis factors for outcome and compare the results of allogeneic SCT with chemotherapy alone. *Methods*. We thus performed a large retrospective study in 191 patients, including 102 adult and 89 children, prospectively enrolled in 11 different trials conducted in France between 1987 and 2002 (BGMT 87, BGMT 91, BGMT 95, LAM 2001, LAM-SA-2002, Alfa 9801, Alfa 9802, Alfa 9000, Goelam02, LAME89-91, LAME2000). Patients with MLL were not included. All patients received induction treatment with cytarabine and an anthracycline followed by an intensive consolidation with either high-dose cytarabine (HDAC) based chemotherapy or autologous or allogeneic stem cell transplantation. *Results*. In adult population: Median age was 37,7 years. The majority of patients (56%) had AML-M5. 38% carried t(9;11), 20% carried t(6;11), 20% carried t(11;19), 7% carried t(10;11) and 15% carried other reciprocal translocations. Overall CR rate was 86%. At 5-year, DFS and OS were 20% and 25%. Only patients with t(11;19) indicated a relatively favorable outcome with a 5-year DFS and OS of 42% and 50%. This outcome was significantly better than for patients with any other translocation (p=0.001). In patients with t(9;11) or other various translocation, 5-year DFS and OS were 20% and 25%. In patients with t(6; 11), 5-year DFS and OS were 0%. Results in pediatric population: Median age was 1,8 years. The majority of children (56%) had AML-M5. 58% carried t(9;11), 15% carried t(10;11), 9% carried t(11;19), 7% carried t(1;11) and 11% carried other translocations including t(11; 17), t(4; 11) or t(6; 11). Overall CR rate was 89%. At 5 years, estimated DFS and OS were 60% and 65%. In children with a t(9;11) translocation, 5-year DFS and OS were 72% and 78%. This outcome was significantly better than for patients with any other translocation (p=0.013). In children with t(10;11) or t(11;19), 5-year DFS and OS were 47% and 50%. In those with other various translocations, 5-year DFS and OS were 18% and 13%. In adults and children, the prognosis was not modified by a presentation with complex karyotype or by the type of consolidation received (HDAC, autologous or allogeneic transplantation). *Conclusions*. 1) AML with 11q23/MLL constitutes a heterogeneous group and the major factor influencing prognosis is the MLL partner involved in the translocation. For adults, we showed a better outcome with t(11;19) and this translocation might be considered as intermediate cytogenetic risk. For children the good prognosis of t(9;11) is confirmed. 2) In adults and children, prognosis of these translocations is no modified by complex karyotype or by the type of post-remission treatment received. 3) The t(9;11) translocation is the most common recurrent one but with a very different prognosis in adults as compared to children.

0837

IMPROVED OUTCOME WITH ANDROGENS AS MAINTENANCE TREATMENT IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA AFTER ICL REGIMEN AS INDUCTION THERAPY: RESULTS OF THE GOELAMS SA-2002 MULTICENTER PHASE III RANDOMIZED OPEN TRIAL

P. Pigneux,[1] C. Himberlin,[2] M. Hunault-berger,[3] F. Witz,[4] T. Leguay,[1] C. Recher,[5] J.l. Harousseau,[6] B. Lioure,[7] N. Milpied,[1] I. Luquet,[2] M.C. Bene,[8] N. Ifrah,[3] F. Dreyfus,[9] F. Perry,[10] J. Sotto,[11] P. Guardiola[3]

[1]CHU Bordeaux, PESSAC; [2]Hopital Robert Debre, REIMS; [3]Chu Angers, ANGERS; [4]Hopital Brabois, NANCY; [5]CHU Toulouse, TOULOUSE; [6]CHU Nantes, NANTES; [7]Hopital de Hautepierre, STRASBOURG; [8]Faculté de Medecine, NANCY; [9]Hopital Cochin, PARIS; [10]Chu Bordeaux, PESSAC; [11]Chu Grenoble, GRENOBLE, France

The French group, GOELAMS, performed a multicenter phase III randomized open trial to evaluate whether adding androgens to post-remission induction therapy was associated with an improved outcome of elderly patients with *de novo* AML. All patients received the ICL induction protocol (idarubicin 8mg/m^2 day1-5, cytarabine 100mg/m^2 day1-7 & lomustine 200 mg/m^2 day1). Patients in complete or partial remission received maintenance therapy consisting in 6 reinduction courses (idarubicin 8 mg/m^2 day1, cytarabine 100 mg/m^2 day1-5.), once every 3 months, with a continuous regimen of methotrexate and 6-mercaptopurine in-between these. At diagnosis, patients were randomized to receive (AndroG arm) or not (Control arm) norethandrolone 10 to 20 mg per day, according to body weight. Norethandrolone was started after recovery from aplasia, between day-20 and day-30 following induction chemotherapy, and was to be continued during the 2-year maintenance therapy period if a complete or partial remission was achieved following induction chemotherapy. The two randomized arms were well-balanced for known prognostic factors such as cytogenetics. Between June 2002 and January 2005, 330 patients with *de novo* AML and age ≥60 y at diagnosis (median 70, range 60-86) were included. For pts alive at last news, median follow-up from induction chemotherapy start was 3.6 and 1.1 y for the overall group. Complete remission incidence, by day-40 and day-80, was 56% vs 52%, and 83% vs 79% in the Control arm and the AndroG arm, respectively (p=0.52, Gray test). Fine & Gray competing-risk model was used to estimate relapse incidence and the effect of norethandrolone. As for the previous endpoint, the potential benefit of norethandrolone on 5-year leukemia-free survival (LFS), event-free survival (EFS), and overall survival (OS) was analyzed on an intention-to-treat basis, using univariate and multivariate adjusted models. S-Plus2000Pro software was used for all analyses.

Tables 1-2.

Table 1	Full time period from diagnosis				
Endpoints	Control	AndroG	Gray test p-val	HR; 95%CI	Cox p-val
Relapse	66%	54%	0.21	--	--
LFS	23%	33%	--	0.79; 0.58-1.09	0.15
EFS	16%	22%	--	0.95; 0.75-1.22	0.69
OS	19%	26%	--	0.96; 0.74-1.23	0.72

Table 2	Time period starting 1 year from diagnosis				
Endpoints	Contro l	Andro G	Gray test p-val	HR; 95%CI	Cox p-val
Relapse	55%	33%	< 0.01	--	--
LFS	37%	54%	--	0.56; 0.33-0.94	0.028
EFS	32%	52%	--	0.57; 0.36-0.89	0.013
OS	37%	60%	--	0.63; 0.41-0.96	0.034

HR, hazard ratio; 95%CI, 95% confidence interval; Cox p-val, p-value of Cox regression model

Results. Crude univariate analyses regarding the effect of androgen randomization on 5-year relapse incidence, LFS, EFS and OS are listed in Table 1. Of note, the effect of norethandrolone on relapse incidence, DFS, EFS, and OS, was not verifying the proportional hazards assumption (analysis of scaled Schoenfeld residuals). Since the 2 hazards rate functions crossed each other, which would result in ineffective comparisons if using log-rank tests, time-dependent models were considered. For all these endpoints, as estimates for the 2 arms were not significantly different during the first year, but diverged during the following years, favoring the AndroG arm (Table 2), a step-function at 1 year from diagnosis was considered. Thus, for patients alive and in complete remission at 1 year from

diagnosis, relapse incidence was lower, while LFS, EFS and OS were higher in the AndroG arm, even after adjusting for other significant covariates (p=0.029 for Relapse; p=0.038 for LFS; p=0.028 for EFS; p=0.029 for OS). *Conclusions*. the addition of low-dose norethandrolone to maintenance chemotherapy is associated with an improved outcome in elderly patients with AML; especially in patients who achieve and remain in remission for at least a year.

0838

THE COMBINATION OF FLOW-CYTOMETRY MINIMAL RESIDUAL DISEASE ASSESSMENT AND CYTOGENETIC/GENETIC PARAMETERS ALLOWS A PROPER RISK STRATIFICATION OF ADULT AML PATIENTS: IMPLICATION FOR TRANSPLANT CHOICE AND POST CONSOLIDATION THERAPY

F. Buccisano, L. Maurillo, M.I. Del Principe, G. Del Poeta, M.A. Irno Consalvo, D. Fraboni, S. Lavorgna, T. Ottone, S. Campagna, E. Ammatuna, M. Rizzo, L. Giannì, M. Postorino, W. Arcese, F. Lo Coco, S. Amadori, A. Venditti

Tor Vergata University Hospital, ROME, Italy

Background. prognostic stratification of patients with acute myeloid leukemia (AML) mostly relies on the cytogenetic/genetic risk profile assessed at diagnosis. We have shown by flow cytometry, that minimal residual disease (MRD) negativity (bone marrow residual leukemic cells $\leq 3.5 \times 10^{-4}$) at the end of consolidation therapy was independently associated with a significantly longer relapse free survival (RFS) and overall survival (OS). The aim of the study was to develop a comprehensive risk stratification of AML, integrating information derived from the initial cytogenetic/genetic assessment with those inherent the status of MRD. *Methods*. 158 patients affected with non-M3 AML were entered into the EORTC/GIMEMA protocols AML10/AML12 (age <61yrs) or AML13/AML15 (age >61 yrs); cytogenetics categories were defined according to MRC classification. *Results*. at the end of consolidation, 48 and 110 patients were MRD negative and MRD positive, respectively. Those MRD negative had a significantly longer OS and RFS (p<0.001 for both); multivariate analysis confirmed that post-consolidation MRD status was an independent factor affecting OS and RFS (p<0.001 for both). The combined analysis of MRD, FLT3-ITD and karyotype suggested that post-consolidation MRD status allows good and intermediate-risk karyotype categories to be further stratified in subgroups with remarkable differences in terms of OS (p=0.014 and 0.018, respectively) and RFS (p=0.02 and <0.001, respectively). Accordingly, we generated an integrated approach of AML risk assessment which allowed two populations of patients to be recognized: 1) high-risk: with FLT3-ITD mutations, unfavorable-risk karyotype or favorable/intermediate karyotype MRD positive at the post consolidation time-point. For this subgroup the clinical outcome is very poor with long-term OS and RFS below 20%. 2) low-risk: MRD negative at the post consolidation time-point, with no FLT3-ITD mutations and/or unfavorable karyotype. This category has a favorable outcome, with a long term RFS higher than 70%. *Conclusions*. Based on these observations, we believe that allogeneic transplant is recommended, not only for poor-risk karyotype or FLT3 positive AML, but also for good, intermediate and FLT3 unmutated categories not gaining MRD negativity, being this option able to provide a superior chance of prolonged RFS. On the other hand, patients who can experience a long term survival approaching 70-80%, such as those belonging to MRD negative good, intermediate and FLT3 unmutated categories, may have their life expectancy hampered by the choice of a therapeutic strategy with a disadvantageous risk/benefit ratio. Thus, the combined evaluation of baseline prognosticators (gene mutation, cytogenetics) and parameters inherent the quality of response (MRD), is useful to refine risk assessment of AML and to facilitate the decision making process in the direction of tailored options which take into account the actual clinical risk of the patients.

PROGNOSTIC AND PREDICTIVE FACTORS FOR SURVIVAL AFTER COMPLETE REMISSION IN INDUCTION THERAPY OF ACUTE MYELOID LEUKAEMIA

M. Pfirrmann,[1] S. Soucek,[2] M. Bornhaeuser,[2] T. Illmer,[2] G. Ehninger,[2] M. Schaich[2]

[1]*Ludwig-Maximilians-University, MUNICH;* [2]*University Hospital Carl Gustav Carus, DRESDEN, Germany*

Background. In the AML 96 study of the German Study Initiative Leukaemia (DSIL), 622 patients with *de novo* or secondary acute myeloid leukaemia (AML) achieved complete remission (CR) after two cycles of induction therapy consisting of mitoxantrone, cytarabine, and etoposide in the first course and cytarabine and amsacrine in the second. *Aims*. Apart from the 36 patients with karyotype t(8;21), 586 patients were classified as patients with intermediate or poor cytogenetic risk for treatment success. For these 586 non-favourable-risk patients with CR, we sought to identify parameters evaluated at diagnosis which reveal prognostic information with respect to overall survival. Furthermore, the predictive value of these parameters for survival with specific post-remission therapies comprising allogeneic haematopoietic stem cell transplantation, chemotherapy with cytarabine and mitoxantrone, or autologous stem cell transplantation (autologous SCT) was investigated. *Methods*. Since survival probabilities depend on the kind of post-remission therapy, the prognostic influence of the candidate variables was evaluated by a stratified Cox regression model. Stratification by therapy allowed elimination of the correlation between treatment and survival. In order to estimate the predictive value for a particular therapy, within the sample of patients who were treated accordingly, ordinary Cox regression was applied. Candidate variables were diagnosis (*de novo*, post-myelodysplastic syndrome, or treatment-induced AML), age at diagnosis, sex, cytogenetic risk (intermediate or poor), white blood cell count, platelet count, FLT3-ITD mutant-to-wild-type ratio, NPM1 mutation status, and the percentages of CD34 expression, POX-positive blasts, and blasts in bone marrow at day 15 after start of induction therapy. *Results*. It proved to be appropriate to define an unfavourable-risk group by either poor cytogenetic risk or treatment-induced AML. All other patients formed the intermediate-risk group. The final multiple model comprised the variables age, risk group, platelet count, FLT3-ITD mutant-to-wild-type ratio, and the percentages of CD34 expression and of POX-positive blasts (all p<0.005). Of 449 patients with data to the six variables in the final model, 229 (51%) had died. As post-remission therapy, chemotherapy was allocated to 160 patients (36% of 449, 102 died). Here, age lost its significance (with α=0.05) whereas the five other variables remained to define the best predictive model. In the 155 patients (35%, 68 died) with autologous SCT, all six variables constituted the best model, again. When allocated to transplantation with a related donor (106 patients, 24%, 44 died), platelet count had to be removed to leave the remaining variables with significant information on survival. Patients transplanted with an unrelated donor (n=28, 6%, 15 died) were too few to estimate an own model. Conclusions: Stratified for post-remission therapy, six variables were identified as independent prognostic factors for survival after CR in induction therapy. Apart from age for chemotherapy-treated patients and platelet count for matched-related donor transplantation, all variables remained significant in the predictive models whereas none of the parameters not part of the common prognostic model reached significance in any predictive model. Further data will be collected and treatment-depended risk groups will be defined. The final results should boost risk-adapted therapy in AML.

0840

AMONAFIDE (AS1413) IS UNAFFECTED BY MULTIDRUG RESISTANCE AND IS ASSOCIATED WITH A HIGH RESPONSE RATE IN PATIENTS WITH SECONDARY AML

S. Lundberg,[1] M. Chau,[1] H.P. Erba,[2] A.L. Dressel,[2] G. Acton,[1] R.L. Capizzi,[1] M.R. Baer[3]

[1]*Antisoma, CAMBRIDGE;* [2]*Univ of Michigan Health Syst, ANN ARBOR;* [3]*Univ of Maryland, COLLEGE PARK, USA*

Background. Secondary AML (sAML) is commonly associated with the multi-drug resistant (MDR) phenotype through overexpression of P-glycoprotein (Pgp) and other efflux transporters. A review of 80 studies including over 4500 patients with AML has identified a 1.7-fold reduction in complete remission (CR) rate associated with MDR+, as compared to MDR-, AML blast cells (Ajami *et al.*, in preparation). Amonafide is a DNA intercalator that, unlike anthracyclines such as daunorubicin, is unaffected by MDR. We evaluated amonafide plus cytarabine in a phase II trial of patients with secondary AML (sAML), and sought to assess whether the response to amonafide could be related to the ability of the drug to evade MDR. Leukemic blasts were obtained from 15 patients in this trial and analyzed for Pgp function and for efflux of daunorubicin and amonafide. *Methods*. Patients received amonafide 600 mg/m^2/day over 4 hours days 1-5 with cytarabine 200 mg/m^2/day IV continuous infusion days 1-7. Fourteen patients received a second course on day 14 for persistent leukemia. Post-remission therapy with either transplant or intermediate-/high- dose cytarabine was given, depending on age. Central bone marrow review was employed. The primary end-

point was CR + CRi. Secondary endpoints included duration of CR/CRi, survival and safety. AML blasts from 15 patients in this trial were retrospectively assessed for Pgp expression and function as well as amonafide and daunorubicin uptake and retention in the presence and absence of the Pgp inhibitor cyclosporine A. Pgp-mediated efflux was assessed by comparing uptake of the Pgp substrate DiOC2(3) in the presence and absence of the Pgp inhibitor PSC-833. Pgp-mediated transport (efflux) was calculated as differential uptake and retention of the drug (either amonafide or daunorubicin) in the absence or presence of a Pgp inhibitor, normalized to apparent influx, reported as the mean±s.e.m. *Results*. 88 patients were treated with amonafide + cytarabine: 47% were male; the median age was 62.5 years (range 23-87); the median performance status was 1; 48% had unfavorable cytogenetics. The overall CR+CRi rate was 42% (CRi: 3%); among the 42 patients with unfavorable cytogenetics it was 23.8%. AML blasts from the group of 15 sampled patients showed significantly less efflux of amonafide (5.32±3.2%) than of daunorubicin (16±2.1%; p=0.0083). Blasts from patients belonging to poor-risk subsets of sAML also showed significantly less efflux of amonafide than of daunorubicin (e.g. unfavorable cytogenetics, n=12; 0.13 ±3.7% vs 16±2.1%; p=0.015). *Conclusions*. The lack of Pgp-mediated efflux of amonafide, as compared to daunorubicin, from sAML blasts may provide a rationale for the efficacy observed with amonafide in the phase II trial described here. Further prospective assessment of these MDR parameters is underway in a randomized phase III clinical trial (ACCEDE), which compares amonafide + cytarabine with daunorubicin + cytarabine (7+3) for remission induction in patients with sAML.

PRE- AND POST-TRANSPLANT FACTORS PREDICT LONG TERM SURVIVAL AFTER REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKAEMIA

C. Craddock,[1] S. Nagra,[1] N. Duncan,[1] S. Mackinnon,[2] N. Russell[3]

[1]*Queen Elizabeth Hospital, BIRMINGHAM;* [2]*Royal Free Hospital, LONDON;* [3]*Nottingham City Hospital, NOTTINGHAM, UK*

Background. Allogeneic stem cell transplantation utilising a reduced intensity conditioning (RIC) regimen represents an important new therapeutic modality in older patients with acute myeloid leukaemia (AML). Graft-versus-host disease (GVHD) is a major cause of morbidity and mortality after RIC allografts and T cell depletion is increasingly used. The factors determining outcome after a T cell depleted RIC allograft in AML have not been determined. *Aims*. We wished to identify pre and post transplant factors determining survival in patients with AML transplanted using a T cell depleted reduced intensity regimen. *Methods*. The outcome of 168 patients with AML transplanted using an alemtuzumab based RIC regimen was analyzed. The median age was 54 years (range 18-71 yrs). 76 patients were transplanted using an HLA identical sibling and 92 using a volunteer unrelated donor. 150 patients were in remission at the time of transplantation. 40 patients had adverse risk cytogenetics. The median duration of follow-up was 37 months. All patients received intravenous cyclosporine A (CsA) at a dose of 5 mg/kg on day-1. Patients were switched to oral CsA prior to discharge. Trough CsA levels were measured thrice weekly for the first three weeks post-transplant and the dose of CsA adjusted to achieve levels in the region of 200-300 microg/l during this period. Trough levels obtained during the first 21 days post-transplant were used to calculate CsA exposure for individual patients during this period using a previously determined regression equation. *Results*. The 100 day transplant related mortality was 10%. 7% of patients developed Grade III-IV acute GVHD and 21% chronic GVHD. The 3 year overall survival was 44%. 29% of patients relapsed. Multivariate analysis demonstrated that survival was influenced by status at transplant (p=0.008) and presentation cytogenetics (p=0.01). Patient age was not of prognostic significance and there was no difference in outcome between recipients of sibling or unrelated grafts. Increased post-transplant exposure to cyclosporin A (CsA) was associated with an increased relapse risk (p<0.0001) and decreased overall survival (p<0.0001) in univariate and multivariate analysis. *Conclusions*. Disease stage and presentation cytogenetics are important determinants of outcome after a T depleted RIC allograft for AML. A potent GVL effect is demonstrable even in this setting and post-transplant exposure to CsA represents an important, and manipulable, determinant of relapse and survival.

0842

MLN8237, A NOVEL ORALLY ACTIVE AURORA A KINASE INHIBITOR, IS HIGHLY ACTIVE ALONE AND IN COMBINATION WITH CYTARABINE IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

R. Kelly,[1] R. Swords,[1] D. Mahalingam,[1] S. Nawrocki,[1] E. Medina,[1] S. Smith,[1] S. Padmanabhan,[1] J. Ecsedy,[2] F. Giles,[1] J. Carew[1]

[1]*Institute for Drug Development, SAN ANTONIO;* [2]*Millennium Pharmaceuticals, CAMBRIDGE, USA*

Background. Acute Myeloid Leukemia (AML) most frequently affects the elderly, many of whom are unable to tolerate intensive chemotherapy. Therefore, improvements in clinical outcomes for patients with AML depend upon the development of novel targeted therapies. Aurora A is a serine/ threonine kinase that plays a key role in mitosis by regulating the G2-M transition, centrosome separation, spindle assembly and chromosome segregation. It is over-expressed in AML and has been implicated in genetic instability, disease progression and drug resistance. MLN8237 is a novel orally available Aurora A inhibitor that has entered Phase I and II trials in solid tumors and lymphoma. Based on the critical role of Aurora A in cell cycle regulation and its intrinsic overexpression in AML cells, we hypothesized that MLN8237 possesses significant antileukemic activity. *Aims*. To investigate the efficacy and mechanism of action of MLN8237 and to determine whether MLN8237 increases the efficacy of the standard of care agent, cytarabine in preclinical models of AML. *Methods*. We used MOLM13, MV411, HL60 and Kasumi1 AML cell lines and primary AML patient specimens to evaluate the preclinical activity of MLN8237. Induction of apoptosis and cell viability were assessed using PI/FACS and MTS assays. The prolonged *in vitro* effects of MLN8237 were assessed by MethoCult colony formation assays. Effects of MLN8237 on Aurora A activity and caspase activation were measured by western blot analysis. An *in vivo* model of AML was generated by injecting Molm13 cells into the flanks of immunodeficient mice. *Results*. Nanomolar concentrations of MLN8237 potently inhibited the *in vitro* growth and survival of all AML cell lines. MLN8237 reduced Aurora A kinase activity as evidenced by reduced phosphorylation of Aurora A at Thr288. MLN8237 treatment disrupted cell cycle kinetics and induced apoptosis in a dose- and time-dependant manner characterized by the accumulation of G2/M and aneuploid cells prior to the onset of apoptosis. MLN8237 effectively inhibited survival of primary human AML cells including those from patients with resistant disease at concentrations consistent with those achieved in humans following oral administration of the drug. We next investigated the ability of MLN8237 to increase the efficacy of cytarabine in AML. Treatment with the combination of MLN8237 and cytarabine resulted in significantly greater apoptosis and more effective inhibition of clonogenic survival than treatment with either agent alone. MLN8237 and cytarabine cooperated to enhance mitochondrial mediated apoptosis as evidenced by increased processing of caspases-9 and -3 to active forms. Daily oral administration of MLN8237 to immunodeficient mice bearing AML xenografts was well tolerated, effectively reduced tumor growth and significantly enhanced the activity of cytarabine (Figure 1).

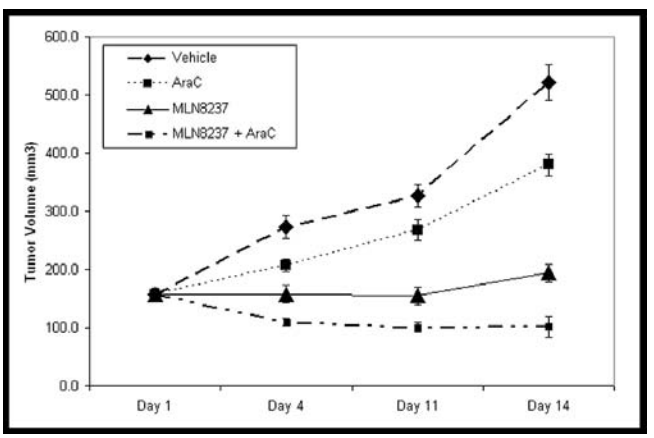

Figure 1. MLN8237 is active *in vivo* in AML.

Conclusions. Our data demonstrates that MLN8237 is highly active against AML cell lines, animal models and primary patient cells and has a multifaceted mechanism of action comprised of pro-apoptotic and growth inhibitory effects. Moreover, MLN8237 significantly potentiat-

ed the efficacy of cytarabine leading to tumor regression in animal models of AML. The combination of MLN8237 and cytarabine represents a novel and very promising therapeutic strategy for AML and clinical evaluation of this combination is warranted.

IMPACT OF MYELODYSPLASIA-RELATED CHANGES AS DEFINED BY THE 2008 WHO CLASSIFICATION SYSTEM IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) TREATED INTENSIVELY

C. Gardin,[1] C. Terré,[2] N. Gachard,[3] I. Tigaud,[4] F. Desangles,[5] C. Bastard,[6] O. Maarek,[7] J.-L. Lai,[8] A. Bernheim,[9] C. Perot,[10] V. Eclache,[1] P. Turlure,[3] X. Thomas,[4] S. Castaigne,[2] M. Michallet,[4] C. Preudhomme,[8] T. Fagot,[5] D. Bordessoule,[3] P. Fenaux,[1] H. Dombret[7]

[1]Hopital Avicenne-APHP, Univ.Paris13, BOBIGNY; [2]Hopital Mignot, VERSAILLES; [3]Hopital Dupuytrein, LIMOGES; [4]Hopital Herriot, LYON; [5]Hopital Percy, CLAMART; [6]Centre Hopital Becquerel, ROUEN; [7]Hopital Saint-Louis, AP-HP, PARIS; [8]Hopital Huriez, LILLE; [9]Inst.G. Roussy, VILLEJUIF; [10]Hopital Saint-Antoine, AP-HP, PARIS, France

Background. Increased incidence of AML with myelodysplasia features with age is one factor often invoked to explain the poor outcome of elderly patients with AML. In two recent large studies, the presence of multi-lineage dysplasia at diagnosis has, however, not been found to be associated by itself with a worse outcome when unfavorable chromosome abnormalities commonly found in this age group were taken into account. In 2008, the revised WHO (WHO Classification of Tumors of Hematopoietic and Lymphoid Tissues 4th edition, SH Swerdlow *et al*. IARC, Lyon 2008) has expanded this AML category into "AML with myelodysplasia-related changes" (AML-MRC) now including: 1) AML with multi-lineage dysplasia; 2) AML arising from prior myelodysplastic syndrome (MDS); or 3) AML with so-called MDS-related cytogenetic changes that include, but not exclusively, the most frequent standard unfavorable abnormalities. An individual case may fall into this category by meeting any of these criteria. *Methods*. We studied the prognostic value of this new AML-MRC category on complete remission (CR) rate, cumulative incidence of relapse (CIR), and overall survival (OS), but not considering the first multi-lineage dysplasia criterion. We compared it to prior categorization relying on standard cytogenetic subsets and presence of prior MDS in 391 elderly patients (median age, 71 years) prospectively included and intensively treated in the Acute Leukemia French Association (ALFA)-9803 trial (Gardin *et al.* Blood 2007). According to the British MRC classification, cytogenetics was favorable, intermediate, unfavorable, and failure in 13, 262, 61, and 55 of these patients, respectively. *Results*. Overall, 124 patients (32%) had AML-MRC, including 61 patients with post-MDS AML and 81 patients with WHO MDS-related chromosome abnormalities (18 patients had both criteria; p=0.08). Among these 81 patients, 59 and 22 had MRC unfavorable and intermediate anomalies, respectively (p<0.001). Patients with AML-MRC had more resistant disease (CR rate, 48 vs 61%, p=0.01; 2y CIR, 89 vs 67%, p=0.001) and shorter OS (2y OS, 21 vs 32%, p<0.001). Interestingly, the incidence of smoldering MDS relapses was significantly higher in the AML-MRC subgroup (2y cumulative incidence of MDS relapse, 32 vs 8%, p<0.001). Multivariate analyses revealed, however, that standard MRC unfavorable cytogenetics was a stronger predictive factor than AML-MRC for the three CR, CIR, and OS endpoints. Actually, when excluding patients with standard unfavorable karyotypes (-5/del(5q), -7, 3q abn, complex) from comparisons, AML-MRC was no longer predictive of lower CR rate (56 vs 62%, p=0.48), higher 2y CIR (85 vs 67%, p=0.13), or lower 2y OS (31 vs 32%, p=0.24). *Conclusions*. The newly defined WHO category of AML-MRC exhibits a worse clinical outcome when compared to non AML-MRC in this elderly population. The higher incidence of smoldering MDS relapses in patients with AML-MRC reinforced the interest of this new categorization. However, the predominant role of standard unfavorable cytogenetics pushes to still recommend to base treatment decision-making on this well-known simpler criterion. This also confirms that prior MDS by itself has no significant prognostic impact in this selected population of elderly AML patients included into an intensive chemotherapy program.

0844

FLUDARABINE-BASED INDUCTION THERAPY DOES NOT OVERCOME THE NEGATIVE EFFECT OF ABCG2 (BCRP) OVER-EXPRESSION IN ADULT ACUTE MYELOID LEUKEMIA PATIENTS

M. Tiribelli, A. Geromin, A. Michelutti, M. Cavallin, A. Candoni, E. Toffoletti, R. Fanin, D. Damiani

Azienda Ospedaliero-Universitaria, UDINE, Italy

Background. Breast cancer resistance protein (BCRP), a recently identified multidrug resistance (MDR) protein of the ATP-binding cassette family, is associated with a worse prognosis in AML patients. On the other hand, fludarabine-based induction therapy displayed interesting results in AML, with high rates of complete remission (CR), and has been shown to overcome the negative effect of P-glycoprotein (PGP), another MDR-related protein, over-expression. No specific data are available about fludarabine effect on the outcome of AML patients with BCRP over-expression. *Aims*. We measured the levels of BCRP in 138 cases of AML, treated with a fludarabine-based induction therapy, to evaluate the possible effect of this regimen on CR rates and long-term survival according to BCRP expression. *Methods*. One hundred and thirty-eight patients with a diagnosis of *de novo* AML were included in our study. Cases with PML/RARα rearrangement were excluded. Median age was 56 years (range: 16-84), 21 patients had an unfavourable cytogenetics and 47 (37%) displayed a mutation of FLT-3 gene (33 ITD and 14 TKD). All patients were treated with an induction regimen containing fludarabine, cytarabine and idarubicin, and at least one consolidation course with high-dose cytarabine and idarubicin. BCRP expression was measured at diagnosis with flow cytometric analysis. *Results*. BCRP protein was over-expressed in 67/138 (48%) patients. A strong correlation was found between BCRP positivity and PGP (p<0.01) and MRP (p<0.001), and with immature (i.e. M0-M1) morphology, while no statistically significant differences were seen according to age, WBC count, karyotype, CD34 expression and FLT3 status between BCRP-positive and BCRP-negative cases. Ninety patients (65%) attained a CR after induction therapy. Advanced age, unfavourable cytogenetics and FLT3-ITD negatively affected remission rate. As expected, neither BCRP or other MDR-related protein over-expression was associated with CR obtainment. Relapse occurred in 30/90 patients (33%), with a higher relapse rate in BCRP+ cases (20/45) than in BCRP- patients (10/45, p=0.04). Moreover, relapse occurred earlier in the BCRP+ group (12 vs 24 months, p=0.01). As for disease-free survival, also overall survival was affected by BCRP status (RR 2.2, p=0.005), and a particular negative prognosis was found in the subset of patients with BCRP and PGP co-overexpression. *Conclusions*. BCRP over-expression did not influence the achievement of CR in fludarabine-treated AML patients, but significantly affected relapse rate, CR duration and overall survival. The inclusion of fludarabine in induction chemotherapy confirms its capacity to overcome the negative effect of MDR over-expression, but BCRP-positive patients have an unfavourable long-term prognosis, and could take advantage of an intensive post-remission therapy.

0845

SIX-YEAR OUTCOMES UPDATE FROM A RANDOMIZED PHASE 3 TRIAL IN AML: DURABLE EFFECT OF REMISSION MAINTENANCE IMMUNOTHERAPY WITH HISTAMINE DIHYDROCHLORIDE AND LOW-DOSE IL-2

L. Brune,[1] J.M. Rowe,[2] M.E. Buyse,[3] P. Squifflet,[3] S. Castaigne,[4] S.E. Allard,[5] K. Hellstrand[1]

[1]Sahlgrenska Academy, GOTHENBURG, Sweden; [2]Rambam Medical Center, HAIFA, Israel; [3]International Drug Development Institute, LOUVAIN-LA-NEUVE, Belgium; [4]Hôpital André Mignot, LE CHESNAY, France; [5]EpiCept Corporation, TARRYTOWN, NY, USA

Background. A randomized multinational Phase 3 trial in adult AML patients (median age=56.5 years) in complete remission (CR; n=320) treated with histamine dihydrochloride (HDC) in conjunction with low-dose interleukin-2 (IL-2) met its primary endpoint, leukemia-free survival (LFS) at 3 years. A significant benefit on LFS over standard-of-care (controls; no treatment) (p=0.008 and 0.011) was observed in the overall and first remission (CR1) populations, respectively (Brune *et al.* Blood 2006; 108:88-96). Follow-up to determine long-term patient outcomes has been ongoing (Brune *et al*. Blood 2007;110:1846a) since the trial ended in 2004. *Aims*. To assess the durability of the treatment effect on the primary endpoint of LFS and on the secondary endpoint of overall survival (OS) in AML patients after treatment with HDC/IL-2 for up to 10 - 3-

week cycles over 18 months compared to controls. *Methods*. The randomized study of immunotherapy with HDC/IL-2, aimed at prolonging LFS, included 261 AML patients in CR1 and 59 in subsequent remission (CR>1). Study arms were balanced for all prognostic factors known at the time the study was conducted. HDC and IL-2 doses, both given sc BID, were 0.5 mg and 16,400 U/kg, respectively. In June 2008, 92 months after randomization of the last study patient, follow-up data captured whether patients were alive and still in CR, dates of relapse or death, and causes of death. Between-group differences were evaluated using log-rank tests of Kaplan-Meier estimates stratified by country and CR status. *Results*. Outcomes data were retrieved for 88% of 124 patients (median follow-up 7.4 years) who were alive at the original database lock. At 6 years, 26% of HDC/IL-2-treated patients remain leukemia-free vs. 21% of controls in all patients enrolled. For CR1 patients, 30% of HDC/IL-2-treated vs. 22% of controls remain leukemia-free. This enduring treatment benefit was statistically significant for both the overall and CR1 populations (hazard ratio [HR]=1.41; 95% CI: 1.08 to 1.82; p=0.011 and HR=1.43; 95% CI: 1.07 to 1.91; p=0.015, respectively) (Figure). The trial was not powered to detect a significant benefit in the secondary OS endpoint. However, a trend in OS favoring treatment was noted for both the overall and CR1 populations (HR=1.15; 95% CI: 0.87 to 1.52; p=0.33 and HR=1.18; 95% CI: 0.86 to 1.60; p=0.31, respectively). *Conclusions*. After a minimum of 6 years of follow-up, immunotherapy with HDC/IL-2 in AML patients provides enduring protection from leukemia relapse by maintaining a statistically significant benefit in LFS over no treatment.

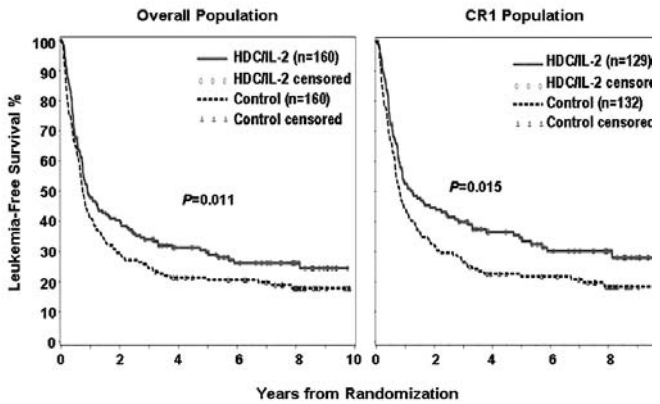

Figure. Long-term effect of HDC/IL-2 on LFS

CXCR4 AS A PREDICTOR OF RESPONSE IN ACUTE MYELOID LEUKAEMIA

M. Giannoccaro,[1] A. Mestice,[1] D. Pastore,[1] A. Liso,[2] M.C. Longo,[1] V. Fesce,[1] C. Ingrosso,[1] N. Sgherza,[1] P. Manduzio,[1] P. Mongelli,[1] R. Angarano,[1] A. Mazzone,[1] V. Liso,[1] G. Specchia[1]

[1]Hematology - University of Bari, BARI; [2]Hematology - University of Foggia, FOGGIA, Italy

Background. The expression of CXCR4 (CD184) has been associated with poor prognosis in Acute Myeloid Leukemia (AML) and it has also been suggested that the CXCL12(SDF-1a)/CXCR4 interaction contributes to the resistance of leukemia cells to chemotherapy-induced apoptosis. Inhibition of CXCR4 was found to enhance chemotherapy-induced apoptosis in a subset of leukemic myeloblasts that carry Flt3 mutations and to overcome chemoresistance associated with stromal activity. NPM variants with a cytoplasmic localization represent the most common mutation detected in myeloid malignancies and are associated with a favourable clinical outcome. A recent study provides biological evidence of a novel role for NPM as a negative regulator of CXCR4 signalling induced by CXCL12. Suppression of NPM expression enhanced chemotactic responses to CXCL12, and conversely, overexpression of a cytosolic NPM mutant reduced chemotaxis induced by CXCL12. *Aims*. We investigated whether CD184 expression could be a negative predictive factor for response to chemotherapy and if there is clinical evidence that NPM mutations could overcome chemoresistance to induction therapy in this subset of patients. *Patients and Methods*. The expression of CD184 was analyzed by flow cytometric methods in a group of 81 cases (42 males, 39 females; median age 56 years, range 15-75) of adult AML at onset of disease, diagnosed at our Institution since January 2006. The diagnosis was performed according to FAB/WHO criteria; all patients received intensive chemotherapy according to institutional protocols. AML cells were gated based upon their CD45 expression and samples were considered positive if CD184 was expressed by more than 20% of blasts. *Results*. CD184 was positive in 56 (69%) and negative in 25 (31%) cases. There was no significant difference between the two groups in terms of sex, age, Hb level, WBC and Plt counts, percentage of blasts, and occurrence of the NPM mutation. The CR rate was 44% in CD184$^+$ and 70% in CD184$^-$ (p=0.03); among CD184$^+$ cases, the CR rate was significantly lower in NPM unmutated cases, (p=0.002). *Summary*. Our results show that CD184 expression is associated with a lower rate of CR after induction therapy and this association is stronger in NPM unmutated cases, suggesting that CD184 expression is a negative predictive factor for response to chemotherapy. Further data are needed to verify if the biological role of the cytosolic NPM mutant as a negative regulator of CXCR4 signalling induced by CXCL12 could have a clinical role contributing to overcome the resistance of leukemic cells to induction chemotherapy.

0847

RASGRP1/APTX RATIO STRONGLY CORRELATES WITH CLINICAL RESPONSE AND SURVIVAL IN AML PATIENTS TREATED WITH TIPIFARNIB-BORTEZOMIB COMBINATION

Oncologia Medica, IRST, MELDOLA, FORLÌ, Italy

Background. Outcome of elderly acute myeloid leukemia (AML) patients is dismal. Targeted-therapies might improve current results by overcoming drug-resistance and reducing toxicity. In particular, the farnesyl-transferase inhibitor Tipifarnib (Zarnestra®), and the proteasome inhibitor Bortezomib (Velcade®), appeared synergistic in AML cells *ex vivo*, and their association was shown to be safe *in vivo* in a phase I trial by our group. *Aims*. We conduced a phase II study aiming to assess efficacy and toxicity of Tipifarnib-Bortezomib association in AML patients >18 years, unfit for conventional therapy, or >60 years, in relapse. Furthermore, we aimed to identify biological features potentially predictive of clinical response. In particular, we focused on the RASGRP1/APTX ratio, which was previously found to be effective in predicting treatment response in patients treated with Tipifarnib alone. *Methods*. Bortezomib (1.0 mg/m^2) was administered as weekly infusion for three consecutive weeks (days 1, 8, 15). Tipifarnib was administered at dose of 300-600 mg BID for 21 consecutive days. Response was assessed at the end of each cycle (28 days). Patients' withdrawn was planned in case of progression or stable disease after six cycles. Real-time quantitative-PCR (q-PCR) was used for RASGRP1/APTX quantification. *Results*. Seventy-two patients were enrolled. Median age was 70 years (42-84); 49% were secondary-AML. WBC at diagnosis was 3.05×10^9/L (0.3-40.3). Sixty-two patients actually initiated the treatment, 50 completed at least the first cycle while 12 early dropped out for non-leukemia related adverse event. Six patients achieved complete remission (CR) and 2 partial response (PR). Three patients obtained a hematological improvement (HI), and 3 patients died during marrow aplasia. Thirteen had progressive disease (PD) and the remaining showed stable disease (SD). The median time to response was 88 days, corresponding to 3 cycles. Marrow response (CR+PR) was significantly associated with overall survival (OS) (p<0.0001). RASGRP1/APTX was evaluated before treatment initiation on bone marrow (BM) and/or peripheral blood (PB). The median RASGRP/APTX value on BM was 15.3 (15-19.8) in responder patients and 2.2 (0.5-25.9) in non responders, respectively (p=0.00006). Its median value on PB was 31.6 (19.3-35.5) in responders and 6.4 (0.5-27.1) in non responders, respectively (p=0.00001). Interestingly, no marrow responses were recorded in patients with marrow RASGRP1/APTX ratio <15, while the response rate was 73% in patients with RASGRP1/APTX >15 (p<0.0001). Finally, RASGRP1/APTX levels significantly correlated with OS (p=0.005). Conversely, there was no correlation between WBC, age, FLT3 and NMP status, and response or overall survival. Toxicity was overall mild, the most common adverse event being febrile neutropenia. *Conclusions*. We conclude that the clinical efficacy of the combination

Tipifarnib-Bortezomib was similar to what reported for Tipifarnib alone. However, noteworthy, we could confirm that the RASGPR1/APTX BM or PB level is an effective predictor of response. Though higher RASGRP1/APTX is relatively rare (~10% of cases), Tipifarnib (±Bortezomib) may represent an important option in a subset of high risk/frail AML patients.

IMPACT OF MOLECULAR MARKERS AND CYTOGENETIC ABNORMALITIES ON LONG-TERM OVERALL SURVIVAL AND DISEASE FREE SURVIVAL IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS RECEIVING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATIONS

M. Michallet, M. Sobh, F. Barraco, F.E. Nicolini, C. Dumontet, Y. Chelghoum, G. Cannas, E. Nicolas-Virelizier, N. Plesa, S. Ducastelle, J. Troncy, X. Thomas

Edouard Herriot Hospital, LYON, France

We performed a retrospective analysis from our registry on first allogeneic hematopoietic stem cell transplantation (HSCT) for AML patients (pts). Principal objective: to analyze the impact of molecular markers on the long-term OS and DFS after first allo-HSCT. We found 364 pts, only 63 pts had available conserved cells at diagnosis. Among these 63 pts, there were 27 (43%) males and 36 (57%) females, median age of 41 years [18-64]. Concerning the karyotype, 6 pts were good prognostic, 24 intermediate and 32 poor. Four (6%) pts had Flt3mut, 19 (30%) FLT3 ITD+, 3 (5%) MLLmut, 10 (16%) Hoxa9 over-expression, 7 (11%) Evi1 over-expression, 15 (24%) NPMmut, 25 (40%) WT1 over-expression and 1 CEBPαmut(evaluated in 12 pts) (Table1).

Table 1. OS and DFS for different karyotype subgroups and molecular markers.

	OS	DFS
FLT3 ov-ex	50%(25-75)	50%(25-75)
FLT3 nomal	40%(33-47)	34%(32-46)
FLT3 ITD+	27%(16-38)	25%(15-35)
FLT3 ITD -	46%(38-54)	47%(41-55)
Hoxa9 ov-ex	50%(35-65)	50%(35-65)
Hoxa9 nomal	38%(31-45)	38%(31-45)
EVI1 ov-ex	28%(11-45)	28%(11-45)
EVI1 normal	43%(36-50)	42%(35-49)
NPM1mut+	32%(20-44)	33%(21-45)
NPM1mut-	43%(35-55)	42%(35-49)
WT1 ov-ex	37%(22-47)	34%(25-43)
WT1 normal	43%(34-52)	44%(35-53)
Fav. Prognosis	83%(67-98)	83%(67-98)
Int. Prognosis	50%(39-61)	52%(42-62)
Poor. Prognosis	24%(16-32)	24%(16-32)

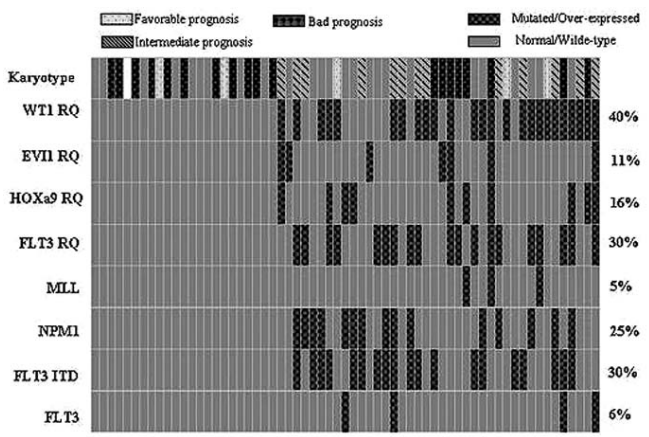

Figure 1. Frequencies and distribution of different markers, mutations, and karyotype subgroups.

Twenty three(36%)pts had no abnormal molecular markers and 40(54%) pts with at least one abnormal marker: 10(16%) 1 marker, 10(16%) 2 markers, 12(19%) 3 markers, 4(6%) 4 markers and 4(6%) 5 markers. Concerning the karyotype, among the 23 negative molecular pts, there were, 9 (41%) normal, 11(55%) poor and 2(4%) good; and among the 40 positive pts, 16(40%) were normal, 8(20%) poor, 13(32.5%) intermediate and 3(7.5%) good. The median interval diagnosis-transplantation was 6 months (2.6-68.5). Before conditioning, 41 pts were in CR (26 CR1, 14 CR2 and 1 CR3), 8 in PR and 14 in relapse. Twenty five (40%) pts received a non-myelo-ablative conditioning and 38 (60%) a myelo-ablative one. There were 34 sex-mismatched (21 M'F and 13 F'M), 21 ABO incompatibility (6 minor and 15 major), 55 were HLA matched and 8 mismatched. Twenty three (36.5%) pts received PBSC, 37 (59%) bone marrow and 4 (6.5%) cord blood cells from 47(75%) HLA siblings and 16(25%) unrelated donors. Fifty nine(94%) pts engrafted, 42 developed AGVHD (21gr1, 13 gr2 and 8 gr4), and among 51 evaluable pts, 13 developed cGVHD (7 limited and 6 extensive) and 20 pts relapsed. At the last follow-up 29 pts are alive (28 CR and 1PR) and 34 died [18(53%) from TRM and 16(47%) from relapse].At the median follow-up of 48 months, the OS and DFS for the whole population were 40% (33-47) and 40%(34-46) respectively, and for the different subgroups according to karyotype and molecular markers are shown in Table 1. The univariate analysis only showed a significant impact of FLT3 ITD and over-expression of FLT3RQ on long-term DFS, (p=0.03 and p=0.02) respectively, and a trend on long-term OS (p=0.08).Concerning the karyotype and some other markers (MLL, EVI1, NPM1 and Hoxa9), we did not observe any significant difference because of small number of pts in each subgroup. The known benefic impact of NPM1 muted, was erased because the majority of this group presented an FLT3 ITD+. We are performing a multivariate analysis that will be presented. In conclusion, the allo-HSCT in this high risk population of pts, allowed a good probability of long term OS and DFS, despite the presence of high number of bad molecular markers and cytogenetic abnormalities. Finally, AML pts with FLT3 ITDmut seem not benefit from allogeneic HSCT even if FLT3 ITDmut was associated to NPM1mut

PHASE 1B/2 PHARMACOKINETIC/PHARMACODYNAMIC (PK/PD) STUDY OF COMBINATION VORELOXIN AND CYTARABINE IN RELAPSED OR REFRACTORY AML PATIENTS

J. Lancet,[1] G. Roboz,[2] L. Cripe,[3] J. Karp,[4] C. Berman,[5] R. Hawtin,[5] T. Chen,[5] J. Fox,[5] G. Michelson[5]

[1]Moffitt Cancer Center, TAMPA; [2]Cornell University, NEW YORK; [3]Indiana University, INDIANAPOLIS; [4]Johns Hopkins University, BALTIMORE; [5]Sunesis Pharmaceuticals Inc, SOUTH SAN FRANCISCO, USA

Background. Voreloxin is a naphthyridine analog that intercalates DNA and inhibits topoisomerase II, inducing apoptosis. Clinical activity is observed in ovarian cancer and AML. Voreloxin combined with cytarabine shows supra-additive activity preclinically. Interim results from a Phase 1b/2 study in relapsed or refractory AML are reported. *Aims*. Safety and MTD of escalating doses of voreloxin in combination with cytarabine; voreloxin pharmacokinetics; clinical activity by IWG; pharmacodynamic markers of patient response; *ex vivo* voreloxin sensitivity in bone marrow aspirates (BMA). *Methods*. Phase 1b dose escalation in relapsed/refractory AML patients with ≤3 prior induction regimens; Phase 2 expansion in first relapse patients (CR1 ≥3 months) at MTD. Voreloxin given D1 and D4, combined with one of 2 cytarabine schedules: A, continuous infusion 400 mg/m^2/d x 5d cytarabine (CIV), or B, bolus 1 g/m^2/d IV x 5d cytarabine. Voreloxin starting dose: A, 10 mg/m^2/dose; B, 70 mg/m^2/dose. Treatment: induction, reinduction if needed, and up to 2 courses for consolidation. DLT for dose escalation, PK and PD were assessed in cycle 1. Patients' PBMC were evaluated for induction of DNA damage response markers. *Ex vivo* sensitivity of patient BMA to voreloxin and cytarabine was evaluated by CellTiter-Glo® proliferation assay. *Results*. 70 patients treated to date (A: 39 patients, dose-escalation; 15 patients Phase 2; B: 16 patients dose-escalation). A: MTD is 80 mg/m^2/dose voreloxin. Infections are the most common G3 or higher toxicity. Voreloxin PK were dose proportional to 50 mg/m^2, then plateaued. Evaluation of PBMC pre- and post-treatment suggests modulation of pDNA-PKcs and pChk2 may reflect response. *Ex vivo* BMA assay results suggest that voreloxin is the primary contributor to the majority of CRs observed and that the combination of voreloxin and cytarabine can overcome resistance. Phase 1b: A: 9 CR + CRp were observed in multiply relapsed or 1° refractory patients. B: 70 mg/m^2: No DLT or remission; 80 mg/m^2: 1 CR, 2 in heme recovery, 3 PD and 1 DLT. Currently, patients are enrolling at 90 mg/m^2. Phase 2: A: 8 patients currently evaluable for response: 4 CR (50%), 3 PD and one

death. *Conclusions*. Phase 1b: voreloxin in combination with CIV cytarabine is generally well-tolerated, with CRs observed in relapsed/refractory patients. Voreloxin in combination with bolus cytarabine has shown early evidence of activity. Dose escalation continues. Phase 2 voreloxin activity with CIV cytarabine in first relapse patients appears robust thus far, with remissions observed in poor prognosis patients with CR1 < 1 year. *Ex vivo* activity assay results suggest that voreloxin is the primary contributor to the majority of CR and that the combination of voreloxin and cytarabine can overcome resistance. Induction of pDNA-PKcs and pChk2 in PBMCs from treated patients may reflect response.

THE SAFETY AND EFFICACY OF AZACITIDINE IN PATIENTS WITH NEWLY-DIAGNOSED AND REFRACTORY/RELAPSED AML NOT ELIGIBLE FOR OR RESISTANT TO CHEMOTHERAPY: A MULTI-CENTER PHASE I/II-STUDY OF THE EAST GERMAN HAEMATOLOGY AND ONCOLOGY STUDY GROUP (OSHO)

H.K. Al-Ali

University of Leipzig, LEIPZIG, Germany

5-azacitidine is an approved treatment for MDS. In this multi-center phase I/II-study the safety and efficacy of a 5 days-schedule of azacitidine in patients with newly-diagnosed and refractory/relapsed AML not eligible for intensive chemotherapy were studied. *Patients and Methods*. From April-October, 2008, 40 pts with AML [19m/21f, median age 72(range 32-84)years] were included. Median WBC was 3.6(range 0.7-187)×10^9/L. Median marrow blasts were 42%. High-risk cytogenetics were found in 12/38 (32%), FLT3mut in 9/34 (26%) and NPM1mut in 7/34 (21%) pts. Median WT1-level was 1209copies/10000ABL. All pts [newly-diagnosed AML (groupA, n=20) and refractory/relapsed AML (groupB, n=20) received azacitidine 75 mg/m^2/day sc for 5 days every 4 weeks. Hematological response was assessed according to the International Working Group Criteria for AML. For non-hematologic toxicity, the NCI CTC and for hematologic toxicity the NCI CTC hematology criteria for leukemia studies or bone marrow infiltrative/myelophthisic processes were used. *Results*. GroupA pts were older (median age 78years) compared to groupB (median age 67years) (p=0.001). To date, a total of 164 treatment-cycles with a median of 3 cycles/patient (groupA, n=6, groupB, n=2) were applied. 29 (73%) patients received at least 2 treatment-cycles. Overall response was 68% [CR, PR, hematologic improvement (HI) n=11 (28%) and stable disease (SD) n=16 (40%)]. Response occurred after a median of 2 months. The probability of response in groupA was 69% compared to 15% for groupB (p=0.07). Similarly, median survival time in groupA (8 months) tended to be higher compared to groupB (3 months) (p=0.09). Interestingly, median survival time for pts with SD was similar to pts with CR,PR, or HI. High-risk cytogenetics had no negative impact on response or survival. Marrow blasts on day 15 of the first azacitidine course correlated with response (p=0.01) but not with survival. Patients achieving CR, PR or HI after 2 courses had a median of 13% marrow blasts day 15 compared to 52% for pts achieving SD only. Lower WT1-expression at screening and on day 15 of the first course correlated with a higher response as well as survival (p=0.03). Pts with WT1-levels >1000copies/10000ABL at screening had a median survival time of only 3 months compared to pts with WT1-levels <1000copies/10000ABL with a plateau at 6 months and a median survival time which is not yet reached. FLT3mut tended to be associated with a shorter survival (p=0.007) but had no impact on response. Surprisingly, NPM1mut also tended to correlate with shorter survival time (p=0.03). Non-hematologic events >grade III were reported 39 times (infections n=21, hepatotoxicity n=5, bleeding n=5, nephrotoxicity n=3, myocardial infarction n=1, and hyperkalemia.n=1, tumorlysis n=1, diarrhea n=1, hypoglycaemia n=1). Neutropenia and thrombocytopenia >grade III occurred in 26 (65%) and 29 (73%) patients respectively. *Conclusions*. Azacitidine applied in a 5 days schedule every 4 weeks is well tolerated in patients with AML and can often be given in an outpatient setting. It induces remarkable hematologic responses especially in patients with newly-diagnosed AML. Patients achieving only SD have a similar survival time to patients with CR, PR or HI.

Chronic myeloid leukemia - Biology and Clinical

NILOTINIB SIGNIFICANTLY INDUCES APOPTOSIS IN IMATINIB RESISTANT K562 CELLS, AS EFFECTIVELY AS IN PARENTAL SENSITIVE COUNTERPARTS

Y. Baran,[1] G. Can,[2] H.A. Ekiz[2]

[1]Izmir Institute of Technology, IZMIR; [2]Izmir Institute of Technology, IZMIR, Turkey

Background. Chronic myeloid leukemia (CML) is a hematological malignancy characterized by increased numbers of immature white blood cells. BCR/ABL fusion protein, resulting from a translocation between long arms of chromosomes 9 and 22, is the main cause of CML. BCR/ABL is a strong oncogenic protein which has significant roles in the regulation of cell growth, proliferation, apoptosis, migration, differentiation and adhesion. Thus, inhibition of BCR/ABL activity will prevent leukomogenesis. Although there were significant hematologic and cytogenetic responses to imatinib, resistance cases were observed in patients during treatments and this was the major drawback of imatinib treatment. After imatinib era, a more effective anticancer agent, nilotinib, was developed and started to be used for the treatment of Philadelphia chromosome positive hematological malignancies. *Aims*. In this study, we aimed to examine the apoptotic effects of novel BCR/ABL inhibitor, nilotinib, on parental and 3 μM imatinib resistant human K562 chronic myeloid leukemia cells (K562/IMA-3) in addition to investigating the development of possible cross resistance of these cells to nilotinib. *Methods*. The Ph^+ human K562 cells were exposed to step-wise increasing concentrations of imatinib for a two-year time period starting from 50 nM. Subpopulations of cells that were able to grow in the presence of 3 μM imatinib, were then selected, and referred to as K562/IMA-3. The IC50 values of imatinib (drug concentration that kills 50% of the cell population) were determined from cell survival plots obtained by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined using the caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured using JC-1 MMP detection kit. *Results*. We calculated IC50 value of imatinib as 0.24-, and 14.5 μM in parental and K562/IMA-3 cells, respectively. These results showed that K562/IMA-3 cells are 60 times more resistant to imatinib as compared to parental sensitive counterparts. To examine cytotoxic effects of nilotinib on parental and resistant cells, both cells were exposed to low concentrations of nilotinib for 72 hours and the changes in caspase-3 enzyme activity and MMP were determined. The results revealed that there were 1.29 and 1.25-fold increases in caspase-3 enzyme activity in 1 nM nilotinib applied K562 and K562/IMA-3 cells, respectively, as compared to untreated controls. On the other hand, steady state levels of caspase-3 enzyme activity were 2% decreased in resistant cells comparing to parental sensitive cells. When we compare changes in caspase-3 enzyme activity in 1 nM nilotinib applied K562/IMA-3 cells with untreated counterparts, there were 1.27-fold increase in the activity. In order to examine the changes in MMP in response to nilotinib, K562 and K562/IMA-3 cells were exposed to 10 nM nilotinib for 72 hours. There were 1.55-, and 1.23-fold increases in cytoplasmic/monomeric JC-1 in K562 and K562/IMA-3 cells as compared to untreated controls. Steady state levels of cytoplasmic/monomeric JC-1 were decreased 13% in K562/IMA-3 cells compared to parental sensitive cells. When we compare changes in cytoplasmic/monomeric JC-1 in 10 nM nilotinib applied K562/IMA-3 cells with untreated counterparts, there were 1.41-fold increase in cytoplasmic/monomeric JC-1 ratio. *Conclusions.* In this study, we have shown that nilotinib application induces apoptosis in K562/IMA-3 cells as effectively as the parental sensitive K562 cells. Nilotinib induces apoptosis through the increase in caspase-3 enzyme activity and decrease in MMP almost at the same levels both in parental sensitive and K562/IMA-3 cells. Taking all these data together supports the usage of nilotinib as an anti-cancer drug in imatinib-resistant CML patients. The effectiveness of nilotinib at the lower concentrations might provide a more target-oriented therapy while reducing the risk of the undesired cytotoxic effects to the remaining healthy cells in the body.

LACK OF KRAS MUTATIONS IN BCR-ABL MUTATION NEGATIVE CML PATIENTS RESISTANT TO FIRST AND SECOND GENERATION TYROSINE KINASE INHIBITORS

P. Erben, M. Agrawal, M.C. Mueller, T. Schenk, H. Daikeler, R.D. Hofheinz, R. Hehlmann, A. Reiter, A. Hochhaus

Universitätsmedizin Mannheim, MANNHEIM, Germany

Introduction. BCR-ABL kinase domain mutations are the dominating cause of resistance to tyrosine kinase inhibitors (TKI) in CML. BCR-ABL independent mechanisms are heterogeneous and include clonal evolution and activating of pathways bypassing BCR-ABL signal transduction. Recently, downstream activation of signal transduction by an activating KRAS mutation in codon 58 was demonstrated in an imatinib-resistant CML patient. The mutation was associated with resistance to imatinib and dasatinib in experimental models (Agarwal A, Leukemia 2008). *Aims*. We therefore established and compared strategies for the detection of KRAS point mutations: (i) Light CyclerTM based High Resolution Melting (HRM) and (ii) conventional direct sequencing of cDNA. The aim of this study was to determine the frequency of KRAS mutations in a group of BCR-ABL mutation negative CML patients resistant to imatinib, nilotinib, and dasatinib with unmutated BCR-ABL. *Methods*. The assays were established on serial dilutions of the colorectal cancer cell line Colo678 bearing a codon 12 KRAS mutation in the HCC 827 cell line with wildtype KRAS. BCR-ABL mutations were excluded by D-HPLC and conventional sequencing. A cohort of 157 TKI resistant CML patients with unmutated BCR-ABL (chronic phase, n=96; advanced phase, n=61) were investigated. Eighty-two patients (43 male, 39 female; median age 59, range 23-85 years) were resistant to imatinib, 39 resistant to second line nilotinib (13 male, 16 female, median age 65, range 22-82 years) or dasatinib (18 male, 18 female, median age 61, range 32-76 years), respectively. In addition, a group of 20 patients with chronic myelomonocytic leukemia (CMML) known to harbor KRAS mutations at a higher frequency were screened for assay validation and as positive controls. *Results*. HRM analysis was optimized for the detection of 1-5% Colo678 cells in a background of wildtype cells. The detection limit for G12D KRAS point mutations by conventional sequencing was 10-15%. The median transcript ratio BCR-ABL/ABL ratio at the time of resistance was 46% (range 11-152%). There was not a single KRAS mutation found in this series of 157 resistant CML patients by HRM analysis as well as by direct sequencing. In comparison, in the CMML control group 20% of cases (4/20) showed KRAS mutations G12R, G13D, G14S, and G59H. *Conclusions*. (i) HRM analysis offers a more sensitive KRAS mutation screening compared with direct sequencing. (ii) KRAS mutations causing activation of the signal transduction downstream of BCR-ABL are very rare events in BCR-ABL mutation negative CML patients with resistance to first and second generation TKI.

0853

ACQUIRED IMATINIB RESISTANCE IN CML IS ASSOCIATED WITH TKD MUTATIONS OF BCR-ABL AND/OR ADDITIONAL CHROMOSOMAL ABERRATIONS: CERTAIN TKD MUTATIONS ARE ASSOCIATED WITH CHROMOSOME INSTABILITY

F. Dicker, W. Kern, T. Haferlach, C. Haferlach, S. Schnittger

MLL Munich Leukemia Laboratory, MUNICH, Germany

Imatinib resistance in CML was correlated to secondary mutations in the BCR-ABL tyrosine kinase domain (TKD) in 50% of all cases. Besides,additional chromosomal abnormalities (ACA) secondary to the Philadelphia translocation have been implicated in resistance. In this study 88 CML pts with acquired imatinib resistance were analyzed in parallel for ACAs and TKD mutations. In 40 of the 88 pts (45.5%) at least one TKD mutation was detected. Of the 40 mutated cases 6 (15%) revealed two different TKD mutations whereas in 48 pts (54.5%) no mutation was detected with a sensitivity of 10-20%. In the group not affected by TKD mutations 15 of 48 (31.3%) cases showed ACAs. In the group with resistance mutations a nearly equal number of 15/40 (37.5%) cases revealed ACAs and the spectrum of aberrations was very similar. Thus the total amount of pts with ACAs, the spectrum of ACA as well as the number of ACAs per patient is nearly equal in the mutated and the unmutated cohort. In the 40 TKD mutated cases 16 different mutations were detected. Most of the recurrent mutations are distributed equally in the groups with or without ACAs. Solely in 12 cases with M244V, G250E or Y253H we never observed ACAs indicating that mutations within this region are strong enough to cause high resistance. In comparison 5 of 11 cases with T315I and 3 of 4 with H396R mutations are associated with multiple or complex chromosomal aberrations (p=0.014). Five pts were analyzed at 2-4 times under dose escalation of imatinib and show that ACAs can preceed TDK mutations and vice versa. TP53 was sequenced in 16 TKD mutated cases (8 with and 8 w/o ACAs) but no TP53 mutation was detected. In conclusion, 1) ACAs are equally distributed between TKD mutated and unmutated cases. 2) AA exchanges in the region 244-253 are not observed together with ACA whereas T315I and F359C are associated with multiple aberrations. 3) TP53 mutations probably do not underly the genetic changes associated with imatinib resistance.

0854

ROLE OF ABC TRANSPORTERS IN THE DEVELOPMENT OF IMATINIB RESISTANCE

L. Gromicho, J. Dinis, C. Martins, A. Laires, J. Rueff, A. Rodrigues

Human Molecular Genetics Research Centre (CIGMH), LISBON, Portugal

Background. Imatinib mesylate (IM), the front-line treatment of Chronic Myeloid Leukemia (CML) induces complete cytogenetic remission in more than 80% of newly diagnosed patients. Drug transporters are among the mechanisms underlying primary resistance observed in the remaining 20% and in most patients in advanced phase. It is now well-established that different (ATP)-binding cassette (ABC) efflux transporters such as P-glycoprotein (P-gp or ABCB1), multidrug resistance-associated proteins (MRPs, e.g. ABCC1) or the breast cancer resistance protein (BCRP or ABCG2) actively regulate the traffic of small molecules across the cell membrane being therefore key determinants of intracellular drug concentrations, including IM. *Aims.* To assess expression levels of the genes ABCB1, ABCG2 and ABCC1 in sub-lines of cells resistant to different concentrations of IM in order to evaluate if alterations in the efflux activity of these transporters are one of the molecular mechanisms underlying resistance. *Methods*. The K562 cell line (CML cell line expressing BCR-ABL) was incubated with increasing concentrations of IM to establish 0.25, 0.5, 1.0, 2.0 and 5.0 μM IM-resistant sub-lines, enabling us to study different resistance levels. The final concentration was chosen to reach approximately a 5x concentration of that normally encountered in patients' plasma. After RNA extraction and cDNA synthesis, TaqMan quantitative real-time PCR was used to evaluate expression level of ABCB1, ABCG2 and ABCC1 transporter genes and also the expression level of the BCR-ABL transcript. The threshold cycle (Ct) values of all the samples were first normalized to the Ct value of an endogenous housekeeping gene (GAPDH for transporters and GusB for BCR-ABL) in the same sample and then this normalized value was compared to the normalized value of the reference sample. *Results*. All drug transporters were found to be overexpressed in all (ABCB1) or some (ABCG2 and ABCC1) resistant sub-lines (Figure 1).

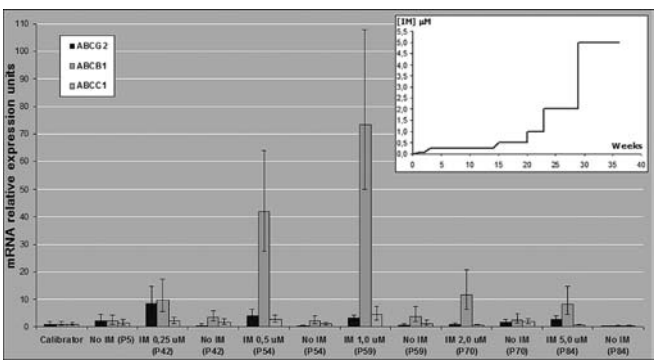

Figure 1.

The most significant overexpression was observed for the ABCB1 gene in the 1.0 μM IM-resistant sub-line. Albeit lower, also ABCC1 presented the same trend as ABCB1: both increased their expression up to the 1.0 μM IM-resistant sub-line and then decreased in the following sub-lines. ABCG2 attained its higher expression in the 0.25 μM IM-resistant sub-line. In 2.0 and 5.0 μM IM-resistant sub-lines the role of the drug transporters is reduced. The overall levels of BCR-ABL transcripts in the different resistant sub-lines as compared with each corresponding control and with the starting population did not present any significant variation. *Summary and Conclusions*. The overexpression of the drug transporters (mainly ABCB1) is probably a major cause for the acquisition of the initial resistant phenotype. BCR-ABL amplification

with its consequent overexpression is unlikely to contribute significantly to resistance in the IM-resistant K562 sub-lines studied. The involvement of other mechanisms like mutations, elevated expression of anti-apoptotic proteins, unfaithful DNA repair and increased biotransformation in the development of resistance in sub-lines of cells resistant to higher doses of IM is currently being evaluated. In agreement with other studies, we show that resistance is the result of multiple mechanisms.

EIGHTEEN YEARS EXPERIENCE WITH AUTOGRAFTING FOLLOWED BY IFN-A AND IMATINIB IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CP-CML). THE GENOA EXPERIENCE

A.M. Carella,[1] G. Beltrami,[1] G. Garuti,[2] G. Catania,[1] G. Pica,[1] S. Biasco,[1] S. Nati,[1] A. Congiu,[1] R. Vimercati,[1] E. Rossi,[1] M. Spriano[1]

[1]Divisione di Ematologia 1, Azienda Ospedaliera Universitaria San Martino, GENOVA; [2]Dipartimento Medicina Interna, Università degli Studi di Genova, GENOVA, Italy

Background. Our team was able to demonstrate many years ago that diploid stem cells could be collected after conventional chemotherapy and G-CSF in the peripheral blood of patients with CP-CML (Carella *et al.* JCO 1997;15:1575-82). *Methods*. In the period 1991-2000, 50 patients with "early" CP-CML were autografted with myeloablative therapy and Ph-negative cells rescue. High-dose therapy consisted of Cy/TBI or high-dose busulfan. After autograft, one patient died of fulminant hepatitis and another patient progressed in blastic phase. The remaining 48 patients were given IFN-a after stem cell engraftment. *Results*. At a median of 95 months (range, 65-128 months) 8 patients evoluted in blastic crisis and died. Forty patients are alive: 12 patients under IFN-a, of whom 9 in CCyR/MMR and 3 CCyR/CMR and 28 patients, relapsed cytogenetically under IFN-a, received Imatinib. Nowdays, 5 patients have been relapsed under Imatinib and have been treated with other TK inhibitors (2 patients) or allografted (3 patients); 4 patients are in CCyR, 6 in CCyR/CMR, 13 in CCyR/MMR. *Conclusions*. These data confirm the previous results published many years ago. A possible explanation for these very good results could be due to the leukemic stem cell debulky with myeloablative therapy in the first months of diagnosis; this intensive approach might have been capable of eliminating a major fraction of the progeny of the Ph-positive stem cells. Subsequently IFN-a, with its specific ability to induce myeloblastin-specific T-cell response, was able to control the disease in some patients. For IFN-a relapsed patients, after 2000 Imatinib was available and it was able to reduce or eliminate in many patients the target cells, though not the stem cell itself, for disease progression.

0856

COMPARISON OF HIGH PREFORMANCE LIQUID CHROMATOGRAPHY-ULTRAVIOLET DETECTION (HPLC-UV) VS LIQUID CHROMATOGRAPHY/TANDEM MASS SPECTROMETRY (LC/MS/MS) TO DETERMINE IMATINIB PLASMA LEVELS IN CML-CP PATIENTS

A. Awidi,[1] I.I. Salem,[2] N. Najib,[2] R. Mefleh,[1] B. Tarawneh[1]

[1]Jordan University, AMMAN; [2]International Pharmaceutical Research Center, AMMAN, Jordan

Background. Sensitive, efficient, and readily available methods for determining imatinib blood levels are needed for therapeutic drug monitoring, pharmacokinetic and metabolic studies. Liquid chromatography followed by tandem mass spectrometry (LC/MS/MS) is the standard method for determining imatinib blood levels. This approach is highly sensitive but is expensive and not readily available. HPLC-UV is more readily available and represents a potential alternative to LC/MS/MS. *Aims*. To compare LC/MS/MS and HPLC-UV for their applicability and for the quantitation of imatinib in human plasma. *Methods*. Fifty patients with chronic myeloid leukemia (CML) in chronic phase (CP) receiving 400 mg/day imatinib for a minimum of 1 month were enrolled. Blood samples were taken 1 hour before the next dose of imatinib and plasma was divided in 2 equal aliquots. One aliquot (500 µL) was tested by the HPLC-UV method while the second (200 µL) was tested by LC/MS/MS. Both analytical methods were validated adhering to international guidelines under GLP environment. Analysis of variance (ANOVA) was performed to test if drug concentrations assayed by the 2 methods were statistically different. *Results*. The HPLC-UV method exhibited an acceptable linear range over the imatinib concentration range 100-4000 ng/mL with an approximate correlation coefficient of 0.99. Intra-day accuracy of the HPLC-UV method ranged from 93.68% - 96.00%, while intra-day precision ranged from 1.26-3.79% at the concentrations of 300, 2000 and 3500 ng/mL. Inter-day precision of the method ranged from 3.74% -7.23% for the same drug concentrations. The lower limit of quantitation (LLOQ) for HPLC-UV was 100 ng/mL using 500 µL of plasma. LC/MS/MS led to short retention times of 0.5 min for the drug and internal standard, respectively (total runtime 2.5 min) and high selectivity and sensitivity. Correlation coefficients >0.999 confirmed that the calibration curves for LC/MS/MS were linear over the imatinib concentration range 10 - 4000 ng/mL. The LLOQ was 10 ng/mL using 200 µL of plasma, at which the calculated accuracy and precision were 98.32% and 5.75%, respectively. The intra- and inter-day precisions of LC/MS/MS ranged from 1.94-7.99% and from 2.11-12.01%. The accuracy ranged from 89.72-106.29%. These values were within the acceptable range and demonstrated that the method was accurate and precise. *Summary and Conclusions*. In this study the HPLC-UV assay performed well and demonstrated high concordance with the LC/MS/MS method, suggesting that HPLC-UV could be substituted as an imatinib quantitation method. Disadvantages of the HPLC-UV system include relatively longer run times, less sensitivity leading to the need for larger sample, and less selectivity for drug of interest over endogenous compounds and comedications. However, the large number of patients tested here demonstrates that the UV method has sufficient selectivity and accuracy for the analysis of patients' samples. It was proved there were no significant differences between the two methods at the 0.05 level after logarithmic transformation of the concentrations. The correlation coefficient between both methods was 0.95.

0857

NO INHIBITION OF WARFARIN PHARMACOKINETICS AND PHARMACODYNAMICS BY NILOTINIB IN HUMAN SUBJECTS

O. Yin,[1] N. Gallagher,[2] D. Fischer,[1] L. Zhao,[1] W. Zhou,[3] G. Golor,[4] H. Schran[1]

[1]Novartis Pharmaceuticals Corporation, FLORHAM PARK, USA; [2]Novartis Pharma AG, BASEL, Switzerland; [3]Novartis Institutes for Biomedical Research, EAST HANOVER, USA; [4]PAREXEL International GmbH, BERLIN, Germany

Background. Nilotinib (Tasigna®), a highly selective and potent BCR-ABL tyrosine kinase inhibitor, is approved for the treatment of patients with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. Nilotinib has shown competitive inhibition of CYP2C9 *in vitro*, but its effect on CYP2C9 activity in humans is unknown. Aims. This study was to evaluate the effects of nilotinib on the pharmacokinetics and pharmacodynamics of warfarin, a sensitive CYP2C9 substrate, in healthy subjects.

Table 1.

	Warfarin N=20	Warfarin+nilotinib N=22
S-warfarin PK parameters		
C_{max} (ng/mL)	1092 (19.9)	1094 (19.6)
$AUC_{0\text{-}inf}$ (h.µg/mL)	49.1 (32.2)	48.6 (24.0)
T_{max} (h)	4.94 (2.97 - 7.97)	5.06 (1.97 - 12.0)
$T_{1/2}$ (h)	34.1 (21.3)	32.5 (17.0)
R-warfarin PK parameters		
C_{max} (ng/mL)	1129 (18.8)	1149 (19.9)
$AUC_{0\text{-}inf}$ (h.µg/mL)	70.7 (23.5)	72.3 (22.9)
T_{max} (h)	5.50 (3.97 - 10.0)	7.00 (3.93 - 12.0)
$T_{1/2}$ (h)	44.8 (18.9)	42.7 (18.5)
Warfarin PD parameters		
PT_{max} (s)	31.7 (25.8)	30.7 (25.0)
PT_{auc} (h.s)	2539 (20.7)	2475 (19.9)
INR_{max}	1.72 (21.6)	1.68 (22.3)
INR_{auc} (h)	182 (16.0)	179 (15.4)

Values are median (range) for T_{max}, and geometric mean (CV%) for all other parameters.

Methods. Twenty-four subjects (6F, 18M, age 21-65 years) were enrolled to receive a single oral 25 mg warfarin with either 800 mg nilotinib or matching placebo (all administered 30 minutes after consumption of a high-fat meal) in a cross-over design. Serial blood samples were collected post-dose for determination of nilotinib, S- and R-warfarin concentrations. Prothrombin Time (PT) and International Normalized Ratio (INR) were determined as pharmacodynamic measures for warfarin. CYP2C9 genotyping was performed in all subjects using TaqMan assay. *Results*. Sixteen subjects were identified as CYP2C9 extensive metabolizers (EM)

and 8 as intermediate metabolizers (IM), but none was poor metabolizer. Pharmacokinetic parameters of S- and R-warfarin were found to be similar between two treatments (warfarin+nilotinib versus warfarin alone) for both EM and IM groups. The geometric mean ratios (90% CIs) for the Cmax and AUC0-° of S-warfarin in all subjects were 0.98 (0.95-1.02) and 1.03 (0.99-1.07) respectively, and for R-warfarin were 1.00 (0.96-1.04) and 1.02 (0.99-1.06) respectively. Mean ratios for the maximum value and AUC of PT were 1.00 (0.96-1.04) and 1.00 (0.98-1.02) respectively, and for INR were 1.00 (0.97-1.01) and 1.00 (0.99-1.01) respectively. Nilotinib Cmax was 1872±560 ng/mL, which is comparable to the mean steady-state Cmax in patients with CML or gastrointestinal stromal tumors (GIST) who receive nilotinib 400 mg twice daily doses. Adverse effects observed following either treatment were generally consistent with the known safety profiles of both drugs, and there were no new safety issues observed. *Summary and Conclusions*. The study results demonstrate that nilotinib has no effect on the pharmacokinetics and pharmacodynamics of warfarin. This implies that nilotinib does not inhibit CYP2C9 activity in human subjects. These findings suggest that warfarin and nilotinib can be used concurrently without the risk of increased anticoagulant effect and irrespective of CYP2C9 metabolizer status.

EFFICACY AND SAFETY OF IMATINIB IN THE FIRST LINE CHRONIC MYELOID LEUKEMIA (CML) TREATMENT. AN ANALYSIS OF A COMPREHENSIVE POPULATION-BASED DATABASE

D. Zackova,[1] H. Klamova,[2] M. Doubek,[1] Z. Pospisil,[3] D. Dvorakova,[1] T. Jurcek,[1] J. Moravcova,[2] K. Machova,[2] J. Rulcova,[2] B. Dobesova,[1] J. Rysava,[2] P. Cetkovsky,[2] F. Razga,[1] J. Mayer[1]

[1]Dept. of Internal Med. and Hemato-Oncology, Univ. Hosp. and Masaryk Univ. Brno, BRNO; [2]Institute of Hematology and Blood Transfusion, PRAGUE; [3]Dept. of Mathematics and Statistics, Masaryk Univ., BRNO, Czech Republic

Background. Imatinib has revolutionized the treatment of CML and is particularly effective in newly diagnosed patients in chronic phase (CP). Most of the data about the efficacy and safety of imatinib in first-line setting have originated from the IRIS trial and recently from published single centre experience. However, confirmatory data from real life are still needed. Aims. To describe and evaluate the results of imatinib in the first line treatment of a consecutive unselected population of CML patients in CP. *Methods*. Data about 1st CP CML patients from the defined region were collected into the database called INFINITY (tyrosine kinase Inhibitors iN the FIrst aNd followIng CML Treatment) One of the main goals was to include all consecutive patients treated with imatinib between June 2003 and December 2008. Rates of hematologic, cytogenetic and molecular responses in defined time-points were evaluated. We assessed also adverse events, time to progression according to IRIS trial including events of failure according to European LeukemiaNet recommendations, time to alternative treatment and survival. *Results*. A total of 147 patients (median age 54 years, 22-77; 67 males and 80 females) underwent the analysis. The median follow-up on imatinib treatment was 22 months (1-56). Imatinib was commenced at a median of 1.7 months (0-35) from the time of diagnosis and the median of actually administered dose was 400 mg. The response rates at 3, 6, 12 and 18 months were as follows: complete hematologic response (CHR): 84%, 87%, 90% and 94%, major cytogenetic response (MCgR): 82%, 82%, 85% and 81%, complete cytogenetic response (CCgR): 35%, 49%, 62% and 74%. Major molecular responses (MMolR) at 12, 18 and 24 months were 41%, 49% and 52%, respectively, with undetectable transcript levels in 5%, 10% and 20% of patients, respectively. Non-hematological toxicity of any grade decreased from 67% (month 3) to 31% (month 24) with gr.3/4 in only 13 cases. Hematological toxicity decreased from 51% to 12% at the same time points. In total, 28/147 patients (19%) permanently discontinued imatinib after a median of 15.5 months (1-51) from various reasons: allogeneic stem-cells transplantation (alloSCT) (n=4), non-hematological (n=5) and hematological intolerance (n=1; the patient subsequently died from septic shock), progression to the accelerated phase or blast crisis (n=2), failure to achieve CHR (1), failure to achieve MCgR or CCgR (n=5) and loss of MCgR or CCgR (n=8). In total, 25 patients (17%) were given on alternative treatment: aloSCT (n=4), dasatinib (n=18), nilotinib (n=1) and hydroxyurea (n=2) in a median of 15 months (1-51). There were 5 deaths in total: 1 case is described above, 2 patients died while on imatinib from the not-CML related reasons and 2 patients died after the discontinuation of imatinib because of disease progression. *Summary*. We confirmed very good efficacy and tolerability of imatinib with improving tendency over time also in unselected patient population managed outside of clinical trials. Early identification of small subgroup of patients with no or little benefit from imatinib could further improved the results.

Supported by The CzEch Leukemia Study Group for Life, CELL.

CHRONIC MYELOID LEUKAEMIA PATIENTS WITH THE E13A2 BCR-ABL TRANSCRIPT HAVE INFERIOR RESPONSE TO IMATINIB THAN E14A2 PATIENTS

C.M. Lucas, R.J. Harris, L. Wang, K. Knight, S.J. Watmough, R.E. Clark

Royal Liverpool University Hospital, LIVERPOOL, UK

Background. The reciprocal t(9;22) translocation that characterises CML creates the functional fusion gene BCR-ABL. The breakpoints in chromosome 22 almost always occur between exon e13 and e14 or between e14 and e15, and fuse with ABL exon 2. This leads to the creation of e13a2 and e14a2 BCR-ABL transcript types (differing in length by 75bp; 25 amino acids). The clinical significance of the BCR-ABL transcript type in newly diagnosed chronic phase (CP) patients treated with imatinib 400mg from initial diagnosis remains unknown. *Aims*. Here, we investigate the effect of BCR-ABL transcript type on clinical outcome in 71 newly diagnosed imatinib treated CP patients. *Methods*. All patients aged 16 or over in our geographical area with newly diagnosed CML between January 1st 2003 and October 31st 2007 with either e13a2 or e14a2 transcripts are included in this study if they received imatinib 400mg daily from original diagnosis (preceded only by up to 6 weeks of hydroxycarbamide). Measurement of BCR-ABL transcripts was conducted by real-time quantitative PCR, using a LightCycler. *Results*. Thirty-two patients presented with e13a2 transcripts and 39 with e14a2 transcripts. During the first 12 months of treatment, three e14a2 cases failed imatinib treatment (2 disease progression and 1 intolerance), while eight e13a2 cases failed (7 disease progression and 1 intolerance). After 12 months of treatment, 53.8% of e14a2 patients achieved a complete cytogenetic response (CCR), compared to 25% of e13a2 patients (p=0.01). Similar trends were seen after 18 and 24 months of treatment. Kaplan-Meier analysis of the time to achieve CCR revealed that e14a2 patients demonstrated more rapid response rates, compared to e13a2 patients, which continues throughout treatment (p=0.006). e14a2 patients demonstrated a higher event-free survival in the first 12 months of treatment, though overall survival did not differ significantly different between the transcript types. During the period of study, a total of five additional cases presented in blast crisis of CML; all expressed the e13a2 transcript type. hOCT1 mRNA levels did not differ between the transcript types. The pre-treatment pCrKL/CrKL ratio (a surrogate marker of BCR-ABL tyrosine kinase activity) was higher in e13a2 than e14a2 patients (p=0.017) Furthermore, *in vitro* treatment of samples from e14a2 patients with 5μM imatinib produced a greater suppression of pCrKL/CrKL ratio than in e13a2 samples. *Conclusions*. In conclusion, e14a2 patients have a higher and more rapid CCR rate than e13a2 patients. Knowledge of the transcript type may yield additional prognostic information, though this requires testing on larger datasets.

0860

OVERVIEW OF CHRONIC MYELOID LEUKEMIA AND CURRENT DIAGNOSIS AND TREATMENT PATTERNS FROM 15 HOSPITALS IN CHINA

J.X. Wang,[1] Y. Wang,[1] L.G. Qiu,[1] X.J. Huang,[2] B. Jiang,[2] D.P. Wu,[3] A.N. Sun,[3] J.D. Hu,[4] T.B. Liu,[4] T. Liu,[5] H.L. Zhu,[5] Y. Hu,[6] T. Guo,[6] F.Y. Meng,[7] D. Xv,[7] X.Q. Background. The prevalence data including CML patients characteristics are not clear in China due to lack of a mature nationwide leukemia registration system. Limited available data show that the estimated inci-

dence of CML in China is from 0.22 to 0.36 per 100,000 per year. It seems lower than the incidence in western countries.Imatinib mesylate (Glivec) is becoming the first line choice for CML patients who are not appropriate for HSCT. However, it has not been covered by insurance since launch. The price strongly limits CML patients to access it.CML treatment pattern in China was changed much but might be some differ with the pattern in western countries. *Aims*. To explore demographic characteristics, current diagnosis and treatment patterns of chronic myeloid leukemia (CML) patients in China. *Methods*. Data of hospitalized CML patients in 2005 and outpatient information (July 1 through September 30 in 2006) from haemotology departments of 15 hospitals throughout Chinese were reviewed and analyzed. *Results*. A total of 1,824 CML cases were analyzed, including 722 inpatients and 1,102 outpatients. M/F ratio was 1.78:1. The median age at diagnosis was 40.02 (2.45~83.29) years old, 90.41% of the patients were diagnosed at the chronic phase. Proportion of accelerated phase or blast crisis patients increased to 21.66% during study period. 93.20% patients received routine blood testing and bone marrow morphologic examination at diagnosis and monitoring; 70.29% patients were diagnosed and monitored by routine blood testing, bone marrow morphologic examination, and cytogenetic analysis. Only 51.54% patients received hematological test, cytogenetic examination and molecular measurement. The most common drug for CML treatment was hydroxycarbamide. Proportion of patients treated with imatinib and interferon were 37.45% and 25.55%, respectively. 164 cases (22.72%) out of 722 inpatients received hemopoietic stem cell transplantation (HSCT). Proportion of chronic phase, accelerated phase and blast crisis patients treated with imatinib were 35.94%,48.28% and 48.42%, respectively ($p<0.05$). The mean imatinib dosage in three phases did not differ significantly. Imatinib resistance rates were 6.87% and 16.28%, for outpatient and inpatient, respectively. In the outpatient group, resistant to imatinib occurred primarily as secondary resistance (68.75%) while primary resistance was the majority of the inpatient group (65.71%). The intolerance rates of imatinib for outpatient and inpatient were 3.21%, 11.63%, respectively. The majority of patients treated with imatinb were not monitored in time: 63.38% patients evaluated hematologic response after 3 months treatment proportions of patients received cytogenetic examination after 6 months and 12 months treatment were 41.41% and 27.35%, respectively. Mean cost for HSCT was 213092±125890 RMB. *Conclusions*. CML in China tends to afflict a younger population than in Western countries. Most patients were diagnosed in the chronic phase. Due to restriction of funds, only one third CML patients in China were treated with imatinib; the majority of the treated ones were not monitored in time. Lastly, clinicians should pay attention to resistance and intolerance to imatinib treatment.

Cervello, PALERMO, Italy

Background. Neither studies on the effects of alkylating agents and topoisomerase inhibitors nor epidemiological studies on secondary leukaemias following cytotoxic therapy have so far indicated a relationship between chemical exposure and increased risk of BCR-ABL-positive CML. Although cases of treatment-related CML are increasingly reported in the literature, few are the studies focusing on the survival of patients with CML occurring after a prior malignancy. Moreover, it is not clear if the previous exposure to an antiblastic treatment can modify the clinical course of a "secondary-CML" and its response to tyrosine-kinase inhibitors. *Aims*. To examine the incidence, the presenting clinical and biological features and the outcome of CML diagnosed after a prior malignancy. *Methods*. All incident cases of CML diagnosed during the last 10 years by 12 hematological centres of Southern Italy were reviewed and those occurring after a prior malignancy were included in the present analysis. *Results*. Among the 569 patients with CML, 47 (8.2%) were diagnosed following a previous malignancy. Of them, nineteen (40.5%) were male with a median age at the time of diagnosis of the primary malignancy and of CML of 52 yrs (range 22-84) and 60 yrs (range 29-86) respectively. The most common preceding malignancy was breast cancer (23.4% of all preceding cancers), followed by colon/rectum (21.3%), prostate (8.5%), lymphoma (8.5%) and hypophysis (6.4%). The median time from primary malignancy to CML was 54 months (range 2-328) with the following distribution according to Sokal's score: 36% low, 45% intermediate, and 18% high. Only two patients showed additional cytogenetic abnormalities besides Ph chromosome. Thirty-one patients received treatment with Imatinib and all attained at least an haematological response at 3 months (48.4% Major or Complete Cytogenetic response and 6.4% molecular response); at 12 months 54% achieved a molecular response (complete 9.1%) and 31.8% a Cytogenetic Response (Complete 27.3%) and at 18 months the percentage of complete molecular responses raised up to 31.8% with only two patients (9%) losing response or progressing. With a median observation time of 28 months (range 1- 166) only one out of 37 patients treated with Imatinib and 3 out of 10 who received alternative therapies died of CML (overall survival at 5 yrs 94% vs 60% $p=0.017$). Looking at the series according to the treatment received for the primary neoplasm, 19 patients had received chemotherapy and/or radiotherapy while 28 surgery with or without hormonal therapy. The median age at primary tumor diagnosis was similar in the two groups (52 vs 57 yrs) while in the former group the median age at CML diagnosis was significantly lower (57 vs 65 $p=0.04$) and a trend toward a shorter interval between first neoplasm and CML diagnosis was detected (62 vs 103 months; $p=0.06$). *Conclusions*. CML secondary to other neoplasms emerges from this study as a well-defined entity with biological, clinical and prognostic features paralleling those of primary CML and in which the role of a prior chemotherapeutic treatment seems to be related to the progression of the leukaemic clone more than to its rise.

Dasatinib is a potent second-generation ABL kinase inhibitor (TKi). Its activity against nearly all imatinib-resistant BCR-ABL mutations has been confirmed clinically. From May 2006 to June 2007 93 pts with CML imatinib resistant or intolerant and 33 ALL Ph1+ with same characteristic have been treated with dasatinib in a compassionate use. Forty-five patients were affected from CML-Chronic phase (CP), 19 accelerate-phase, 29 blast crisis and 33 were ALL Ph1+. Dasatinib was administered 70 mg BID, and dose escalation to 100mg BID and reduction to 50 mg or 40 mg BID were allowed for inadequate response or adverse events (AEs), respectively. Imatinib resistance was primary (39 pts) and acquired (68 pts), median age was 55 years (range 17-76). The median time from CML/ALL Ph+ diagnosis to enrolment in the compassionate use was 48 months. All pts received prior imatinib at median dose 439mg/d for CML-CP, 449 mg for CML-advanced phases (AdP) and 600 mg for ALL Ph+, for a median time of 1191 days for CP, 1020 for AdP and 277 for ALL Ph+. The best previous response to imatinib was CCyR in 27% of CML-CP, 42% in ALL Ph1+, and 31% in CML-AdP. Prior treatment for CML included IFN-α in 2 ALL Ph1+ pts (1,5%) and in 46 CML pts (36%), chemotherapy in 44 ALL Ph1+ pts (35%) and stem cell transplantation in 7 ALL Ph1+ pts (5,5%) and in 9 CML pts (7%). Twenty-seven patients

(21,4%) received other TKi before dasatinib administration. With a median follow-up of 24 months, the CHR rate was 84% for CML-CP, 71% for CML-AP, 68% for ALLPh1+, respectively. The CCyR rate was 40% in CML-CP, 16% in AdP and 42% in ALLPh1+. The median dose of dasatinib has been 111 mg for CML-CP, 108 mg for CML-AP and 140 mg for ALLPh1+. Thirty-five pts (27,7%) required a dose interruption; 4,7% were due to hematologic toxicity and 11% due to non-hematologic toxicity. Fifty pts remain on treatment with a median of 485 days (33 CML-CP, 11 AdP, 6 ALL Ph1+); 43 had progression of disease. Seven patients had allogeneic bone marrow transplantation. AEs (all grades) considered drug related included headache 4,2%, diarrhea 10,4%, nausea 16%, fatigue 10,4%, rash 8,3%, edema 2,1%, dyspnea 6,3%, pleural effusion 9%, myalgia 7%, arthralgia 4,2%, pneumonia 6,3%, and gastrointestinal hemorrhage 1%. The PFS at 24 mo was 86% in CML-CP, 39% in CML-AP and 18% in ALLPh1+. OS at 24 mo was 90% for CML-CP, 35% for CML-AP and 21% for ALLPh1+. An update with molecular response data and a durable stable disease condition will be considered.

0863

EFFECT OF THE PROTON PUMP INHIBITOR ESOMEPRAZOLE ON THE ORAL ABSORPTION AND PHARMACOKINETICS OF NILOTINIB

O. Yin,[1] N. Gallagher,[2] D. Fischer,[1] E. Demirhan,[1] W. Zhou,[3] G. Golor,[4] H. Schran[1]

[1]Novartis Pharmaceuticals Corporation, FLORHAM PARK, USA; [2]Novartis Pharma AG, BASEL, Switzerland; [3]Novartis Institutes for Biomedical Research, EAST HANOVER, USA; [4]PAREXEL International GmbH, BERLIN, Germany

Background. Nilotinib (Tasigna®), a highly selective and potent BCR-ABL tyrosine kinase inhibitor (TKI), is approved for the treatment of patients with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. The solubility of nilotinib is pH dependent, with lower solubility at higher pH. *Aims*. This study was to evaluate whether esomeprazole, a potent proton pump inhibitor that can significantly increase gastric pH, could affect the oral absorption and pharmacokinetics of nilotinib in healthy subjects. *Methods*. Twenty-two subjects (6 F, 16M, age range 18-64 years) were enrolled to receive nilotinib alone or in the presence of steady-state esomprazole during two treatment periods. Nilotinib was given as a single oral 400 mg dose on Days 1 and 13, and esomeprazole 40 mg once-daily on Day 8 through Day 13. Serial blood samples were collected up to 72 hours after nilotinib dosing for determination of nilotinib serum concentrations by a validated liquid chromatography-tandem mass spectrometry assay. Gastric pH was monitored in all subjects at baseline (prior to nilotinib and esomeprazole dosing), before and during the first 4 hours of esomeprazole steady state dosing (5th dose on Day 12).

Table 1.

Nilotinib PK Parameter	Nilotinib alone (n=22)	Nilotinib + esomeprazole (n=15)
C_{max} (ng/mL)	387 (23.2)	275 (45.4)
AUC_{last} (h.µg/mL)	9.75 (34.3)	6.08 (54.4)
$AUC_{(0\text{-}inf)}$ (h.µg/mL)	10.4 (45.6)	6.28 (58.5)
T_{max} (h)	4.00 (2.00 - 10.0)	5.98 (2.00 - 10.0)
$T_{1/2}$ (h)	15.2 (52.4)	14.7 (43.4)
Cl/F (L/h)	38.4 (45.6)	63.7 (58.5)
V_z/F (L)	843 (29.1)	1350 (56.0)

Values are median (range) for T_{max}, and geometric mean (CV%) for all other parameters.

Results. When co-administered with esomeprazole, nilotinib Cmax was decreased by 27% and AUC0-° decreased by 34% respectively. The median time to reach nilotinib Cmax was slightly prolonged from 4.0 hours to 6.0 hours, but its elimination half-life was not altered. Median gastric pH was increased from 0.8 at baseline to 2.0 at pre-dose, and to 3.9, 5.8, 5.5 and 5.7 at 1, 2, 3 and 4 hours after esomeprazole dosing. Administration of nilotinib alone or in combination with esomeprazole was generally well tolerated in the study subjects. *Summary and Conclusions*. The study results suggest a modest reduction in the rate and extent of nilotinib absorption when co-administered with esomeprazole. Such an effect is unlikely to have clinically significant consequences for nilotinib therapy. Thus nilotinib is a TKI that can be used concurrently with esomeprazole or other proton pump inhibitors as needed.

IMATINIB TREATMENT IN ELDERLY PATIENTS (>65 YEARS) WITH CHRONIC MYELOGENOUS LEUKEMIA (CML) IN EARLY CHRONIC PHASE

R. Latagliata, M. Breccia, I. Carmosino, M. Mancini, D. Diverio, R. De Cuia, L. Cannella, C. Stefanizzi, L. Napoleone, P. Volpicelli, F. Vozella, G. Alimena

Ematologia - Università La Sapienza, ROME, Italy

Background. Data concerning Imatinib treatment in elderly patients with CML in early chronic phase are still very scarce. Aims and Methods. The impact of age was evaluated in a cohort of 117 consecutive newly diagnosed CML patients observed at our Institution from 9/02 to 3/08 and treated with Imatinib as first-line treatment. *Results*. Of them, 40 were aged > 65 years and 77 <65 years. In the elderly group, 34 patients (85%) had at least 1 concomitant disease compared to 39 patients (50.6%) in the younger group (p<0.001). Thirty-four elderly patients (85%) assumed at least 1 concomitant drug compared to 33 younger patients (42.9%) (p<0.001); in addition, 12 elderly patients (30%) needed ≥4 different concomitant drugs compared to 4 younger patients (5.2%) (p<0.001). Complete cytogenetic response (CCyR) was achieved by 33/37 evaluable elderly patients (89.1%) while 4/37 (10.9%) were resistant; among younger patients, 70/75 evaluable patients (93.3%) achieved CCyR and 5/75 (6.7%) were resistant. No statistical differences in the CCyR and resistance rates between the 2 groups were observed. Severe haematological toxicity (grade 3-4 WHO) was observed in 10 elderly patients (25%) as compared to 7 younger patients (9.1%) (p=0.02). Severe extra-haematological toxicity (grade 3-4) was recorded in 11 elderly patients (27.5%) compared to 8 younger patients (10.4%) (p=0.017). As to the follow-up of Imatinib treatment, the rates of both permanent discontinuation (5/40 or 12.5% vs 1/77 or 1.3%, p=0.009) as well as dose reduction to 300 mg or less (12/40 or 30% vs 7/77 or 9.1%, p=0.001) were significantly higher in elderly patients. Conclusions. Imatinib treatment in elderly with newly diagnosed CML seems to produce same cytogenetic results as in younger patients, but higher haematological and extra-haematological toxicities, leading to increased rate of Imatinib permanent discontinuation or dose reduction. To overcome this problem, future trials addressing the best dosage in this subset of patients could be useful.

EXPANDING NILOTINIB ACCESS IN CLINICAL TRIALS (ENACT) STUDY IN ADULT PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA (CML): FINAL SAFETY ANALYSIS OF 117 CHINESE CML PATIENTS

Z. Shen,[1] X. Huang,[2] F. Meng,[3] J. Wang,[4] T. Liu,[5] J. Hu,[6] J. Wang,[7] Y. Zhao,[8] R. Woodman,[7] P. Zou[9]

[1]Shanghai Jiao Tong University School of Medicine, SHANGHAI, China; [2]Beijing University, BEIJING, China; [3]Nanfang Medical University, GUANGZHOU, China; [4]Chinese Academy of Medical Sciences & Peking Union Medical College, TIANJIN, China; [5]Sichuan University, CHENGDU, China; [6]The Affiliated Union Hospital of Fujian Medical University, FUJIAN, China; [7]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA; [8]Novartis Pharma Co., Ltd, BEIJING, China; [9]Tongji Medical College of Huazhong University of Science and Technology, WUHAN, China

Background. Nilotinib, a potent and highly selective BCR-ABL kinase inhibitor, approved for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogeneous leukemia (Ph+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy, including imatinib. *Aims*. The ENACT study, which is a Phase IIIb, open label, multicenter study, was initiated to obtain additional safety information in pts with imatinib-resistant or -intolerant CML in chronic, accelerated, or blast (BC) phase in a clinical practice setting outside of a registration study. *Methods*. Pts received nilotinib 400 mg twice daily (BID). Dose escalation was not permitted. Pts who required dose reduction to 400 mg once daily due to toxicity were allowed to have a dose re-escalation to 400 mg BID after resolution of the adverse events (AEs), lack of response, or persistent disease at the investigator's discretion. Efficacy was provided by investigator assessment. *Results.* A total of 117 Chinese pts enrolled in the ENACT study between 01/2006 and 10/2008, including 82 CP pts (70%), 14 AP pts and

21 BC pts. The median age of all pts was 39 years and 75% were imatinib-resistant. The majority of patients had received prior interferon (72.6%). At study completion, 55 (47%) pts were continuing on nilotinib. Median (range) duration of nilotinib exposure was 302 (19-520) days for CP pts, 178 (18-534) days for AP pts, and 58 (1-428) days for BC pts; median average dose intensity was 760, 798 and 700 mg/day, respectively. The main reasons for treatment discontinuation were inadequate responses (26%) and AEs (13%). The majority of study drug related grade 3/4 AEs were hematologic and the most common of these toxicities were thrombocytopenia (32.5%) and anemia (17.9%). Non-hematologic AEs were mostly grade 1/2 and included rash, headache and fatigue. Study drug related grade 3/4 non-hematologic AE's were infrequent. Death on study was reported for 4 pts, equally divided among AP (n=2; 14%) and BC (n=2; 10%) pts. No incidence of grade 3/4 QT prolongation (QTcF > 500 msec) was observed. Grade 3/4 lipase elevation was observed in 3 patients (2.6%) but none were associated with treatment discontinuation. None of the patients experienced pancreatitis or discontinued treatment due to hyperglycemia. No patient experienced pleural effusion on study. Dose reductions were 49.6% and interruptions were 58.1% and are similar to that observed in the overall study safety cohort. Overall major cytogenetic response (MCyR) rates were 44% in CP, 29% in AP and 19% in BC pts. Likewise, complete hematologic response (CHR) rates were 59% in CP, 21% in AP and 14% in BC pts. *Conclusions*. This final safety analysis of the Chinese subset of a large expanded access study further demonstrates that nilotinib is generally well tolerated in heavily pretreated pts in all phases of CML with safety profile similar to that observed in Caucasian patients. This data supports the use of nilotinib at 400 mg bid as the recommended dose in Chinese patients.

PROANGIOGENIC CYTOKINES IN CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB MESYLATE

K. Kotlyarchuk, L. Lukavetsky, O. Danysh, A. Lukjanova, M. Kolisnyk, Z. Maslyak

SI Institute of Blood Pathology and Transfusion Medicine, UAMS, LVIV, Ukraine

Background. although there are many publications that address elimination of Ph^+ clone in patients with chronic myelogenous leukemia (CML) treated with tyrosine kinase inhibitors (TKIs), other biological features of these drugs are not yet clear. *Aims*. of this study was to investigate antiangiogenic and proapoptotic features of imatinib in order to search for additional criteria for treatment efficiency assessment and leukemia monitoring. *Materials and Methods*. 75 patients with Ph^+ chronic phase CML: 11 with first diagnosis, 30 pretreated with Interferon alfa (IFN) and 34 pretreated with cytostatics were studied. Methods of conventional cytogenetics and fluorescent *in situ* hybridization (FISH) were used. Levels of proangiogenic cytokine - vascular endothelial growth factor (VEGF), proapoptotic cytokine - tumor necrosis factor alfa (TNF-alfa) and its soluble receptors of type I and II (TNF-RI, TNF-RII) were determined by immunoenzyme method using standard kits: "Human VEGF ELISA Kit", "Human TNF-alfa ELISA Kit", "sTNF-RI (p55) ELISA" "sTNF-RII (p75)" (Biosource USA); blood chemistry and serum proteins were tested as well. *Results*. Investigation of clinical efficiency of particular CML treatment options showed that the highest levels of hematological and cytogenetic remissions were achieved with imatinib mesylate (IM), the result was obtained quicker and it was the best in first diagnosed patients. Therefore conclusion was made that optimum first line treatment of CML was IM. Patients with prior ineffective treatment with IFN treated subsequently with IM showed response rate and time to its achievement similar to those in the first line IM patients. Patients with and without major cytogenetic response (MCyR) (97% vs 63%), but all of them with hematological remission, had significantly different disease free survival (DFS). Time to progression in patients with complete hematological response (CHR) but without MCyR was 25 months. In all the patients significantly increased serum levels of VEGF were revealed prior to IM treatment, simultaneously levels of TNF-α and its soluble receptors (type I and II) were also several times higher than normal. Comparance of the levels of these cytokines with the results of clinical, hematological and cytogenetic tests showed that increased level of VEGF reflects adequately the activity of leukemic process, particularly regulation of angiogenesis. Similar results were obtained for TNF-alfa which belongs to proapoptotic and proangiogenic cytokines. Level of serum VEGF got several times lower already after 1,5 months of IM initiation when no reduction of Ph^+ clone was yet detected. At the same time in those patients who later did not achieve MCyR (after 12-24 months of treatment), VEGF level stayed high after 3, 6 and 12 months of IM initiation. During the course of IM treatment serum levels of TNF-alfa and its soluble receptors decreased to normal ranges irrespective of cytogenetic results. *Conclusions*. The obtained results apparently reflect process of myelopoiesis suppression. Importantly this effect can be detected at the early stages of treatment before the cytogenetic signs of leukemic clone reduction. Therefore determination of serum (plasma) levels of VEGF and TNF-alfa in CML patients treated with IM could be recommended as independent prognostic factor for treatment monitoring.

0867

IMATINIB DOSE ESCALATION FOR CML RESISTANT PATIENTS IS USEFUL IN GENERAL PRACTICE: IMPACT ON CYTOGENETIC REMISSION

Yu Zaritskey

Centre of Heart, Blood&Endocrinology, STPETERSBURG, Russian Federation

Imatinib has become a golden standard in general practice for CML treatment. Few data about efficacy of dose escalation for resistant CML patient are available. This topic is of special value for general practice. The aim of the study was the evaluation of efficacy of Imatinib and its dose escalation, The starting dose of Imatinib was 400 mg. Patients were regularly monitored by cytogenetics and the data were reported. Physicians were free to escalate the dose either in case of suboptimal response or 'failure'(ELN criteria). Physicians had access to unlimited dose escalation in case of any kind of resistanse in CML chronic phase patients.The data of all patients were reported, retrospectively resistant patients were revealed. The data base was analyzed with SPSS. The whole group comprised 134 chronic phase CML patients (m-53, f-82, median age 49). Median time to Imatinib treatment was 14 mons. 35 patients appeared to be primary or secondary resistant and needed Imatinib dose escalation(m-20, f-15, median age 43). Median time to Imatnib therapy was 22 mons in this group of patients. In the whole group, probability of major cytogenetic response(MCyR) was 82% by 18 mons, the median time to MCyR was 6.8 mons.The probability of MCyR loss was 33% by 5 years, the rate was 11.5%. In resistant patients, probabilty of MCyR after dose escalation was 18% by 6 mons, 52% by 12 mons, 71% by 18 mons. The rate of MCyR was 49% with median time to MCyR 10mons. The rate of MCyR in patients dose escalated for ' suboptimal response' was significantly higher than in 'failure' patients (75% vs 51%). Probability of MCyR loss was 11% by 3 years after dose escalation, whereas in patients without resistance the probablity of MCyR loss was 17% (p=0.7). *Conclusions*. Dose escalation is effective tool for achievement of CyR in resistant patients. Early dose escalation revealed better results. CyR after dose escalation is stable.

IDENTIFICATION OF A NOVEL MODE OF KINASE INHIBITOR RESISTANCE: AN F604S EXCHANGE IN FIP1L1-PDGFRA MODULATES FIP1L1-PDGFRA PROTEIN STABILITY IN A SRC-DEPENDENT MANNER

S. prasad Gorantla, N. von Bubnoff, C. Peschel, J. Duyster

Klinikum Rechts Der Isar, MUNICH, Germany

FIP1L1-PDGFR α is a constitutively activated protein kinase which was reported in chronic eosinophilic leukemia (CEL) and in cases of hypereosinophilic syncrome and mastocytosis with eosinophilia. Imatinib is clinically active against FIP1L1-PDGFRA positive disease. However, clinical resistance to imatinib has been observed in FIP1L1-PDGFRA positive leukemia and was shown to occur due to a secondary mutation (T674I) in the PDGFR α kinase domain. Using a screening strategy to identify imatinib resistant mutations, we generated numerous imatinib resistant cell clones. Analysis of the PDGFRA kinase domain in these cell clones revealed a broad spectrum of resistance mutations including the clinically reported exchange T674I. Interestingly, one of the abundant mutations was a Phe to Ser exchange at position 604 (F604S), which occurred alone or in combination with other exchanges. Surprisingly, FIP1L1-PDGFRA/F604S in contrast to D842H and F604+D842H did not increase the biochemical or cellular IC50 value to imatinib when compared to wild-type (wt). However, F604S and F604S+D842H transformed Ba/F3, NIH3T3 and mouse bone marrow more efficiently compared to wt and D842H, respectively. Also, F604S and F604S+D842H showed strong activation of Stat5, ERK and Akt compared to wt and D842H. Immunoprecipitation and immunoblotting indicated increased amounts of FIP1L1-PDGFRA protein in F604S versus wt cells. Moreover, SRC coimmunoprecipitated with FIP1L1-PDGFRA in wt, but not F604S cells. We hypothesized that F604S might interfere with FIP1L1-PDGFRA protein stability, and that SRC might be involved in this process. GST pull down experiments using SRC-SH2 domain showed lesser binding of FIP1L1-PDGFRA/F604S compared to wt. Similarly, using a GST-PDGFRA fragment, more SRC was precipitated with wt compared to F604S. Importantly both, the SRC inhibitor PD166326 and SRC siRNA mimicked the F604S phenotype and resulted in stabilization of the wt protein. Also, co-expression of SRC in 293T cells augmented degradation of wt, but not F604S FIP1L1-PDGFRA, indicating that SRC is a negative regulator of FIP1L1-PDGFRA protein stability. Similar results were obtained with an exchange in near proximity to F604. However, kinase-defective SRC had no effect on FIP1L1-PDGFRA stability, indicating that kinase activity of SRC is necessary for its effect on FIP1L1-PDGFRA stability. Moreover, kinase defective FIP1L1-PDGFRA (G610R) was not degraded indicating that kinase activity of FIP1l1-PDGFRA is necessary for its own degradation. Taken together, imatinib resistance screening in FIP1L1-PDGFRA identified a novel class of resistance mutations, that do not act by impeding drug binding to the target, but rather increase target protein levels by interfering with its SRC mediated degradation.

0869

C-ROS IS AN ORPHAN TYROSINE KINASE RESPONSIBLE FOR ABNORMAL PROLIFERATION AND ADHESION IN CHRONIC MYELOMONOCYTIC LEUKEMIA

D. Cilloni,[1] S. Carturan,[1] E. Bracco,[1] C. Maffè,[1] P. Fornaciari,[1] F. Messa,[1] F. Arruga,[1] M. Pradotto,[1] M. Pautasso,[2] E. Giugliano,[1] I. Iacobucci,[3] E. Messa,[1] G. Martinelli,[3] G. Saglio[1]

[1]University of Turin, TURIN; [2]S. Luigi Hospital, ORBASSANO; [3]Seragnoli Institute, University of Bologna, BOLOGNA, Italy

Background. Chronic myeloproliferative disorders are usually characterized by an abnormal activation of tyrosine kinases although in the majority of the cases these are completely unknown. Perturbation of RTK signalling by genetic alterations results into an abnormal proliferation advantage and finally into a malignant transformation. c-Ros is an orphan RTK displaying transforming activity whose role has been established in the development of neuronal neoplasia. *Aims*. of this study were to evaluate the involvement of c-Ros in the pathogenesis of chronic myelomonocytic leukemia (CMML) and to establish the effects of c-Ros activation. *Methods*. c-Ros expression was evaluated by RQ-PCR in 133 samples collected from 96 CMML patients at diagnosis (96 BM and 37 PB) and 60 healthy donors (30 PB and 30 BM). The protein amount and localization was analyzed by westen blot and immunofluorescence assay. In order to establish the effects of c-Ros activation we generated a chimeric receptor containing the extracellular domain derived from epidermal growth factor receptor (EGFR) and the transmembrane and cytoplasmic domains from c-ros (ER). The chimeric receptor was then transfected in NIH3T3 and HEK293T cells. Transfected and control cells were then stimulated with 100 nM EGF ligand and proliferation and apoptosis evaluated by incorporation of 3H timidine and MTT assay and by FACS for the detection of annexin V, respectively. *Results*. The study demonstrates that Ros it is overexpressed in both BM and PB cells collected from CMML (p<0,0001) with a median value of 2-ΔΔCt of 380 in BM (range 10-63303) and 212 in PB (range 6-30012). By contrast, it is undetectable in healthy subjects. WB confirmed the presence of c-Ros protein in CMML cells but not in normal controls. Immunofluorescence staining localized the protein within the cytoplasm. We found that ROS is highly expressed in $CD34^+$ cells and monocytes from CMML patients but not in their normal counterparts. Sequence analysis revealed the absence of mutations of c-Ros promoter. SNPs analysis exclude the presence of duplications or deletions of the gene. Moreover we found that the EGF induced activation of c-Ros affects proliferation by increasing of 3.5 folds the proliferation rate as compared to cells transfected with the empty vector and stimulated with EGF under the same conditions. Furthermore cell adhesion was 4 folds decreased as compared to control. By contrast apoptosis is not affected by c-ROS activity (p=0,2). *Conclusions*. This study demonstrates the aberrant expression of c-Ros in CMML. The ectopic expression of c-Ros results in loss of adhesion and increased proliferation. Therefore c-ROS is likely to be involved in the pathogenesis of CMML and could represent a target for future molecular therapies.

MIR-28 EXPRESSION IN PLATELETS OF MYELOPROLIFERATIVE PATIENTS VIA STAT5 CONSTITUTIVE ACTIVITY

N. Constantinescu

Ludwig Institute for Cancer Research, BRUSSELS, Belgium

Polycythemia vera (PV), Essential Thrombocythemia (ET), Primary Myelofibrosis (PMF) are three distinct myeloproliferative neoplasms (MPNs) characterized by a key molecular determinant: JAK2 V617F. Along with the erythropoietin and G-CSF receptors, the thrombopoietin receptor (MPL, TpoR) is a major JAK2 coupled receptor postulated to play a key role in JAK2 V617F signaling. Furthermore, platelet TpoR levels exhibit an inverse correlation with JAK2 V617F allele burden in these diseases. In order to explore the mechanisms of MPL/TpoR regulation, we assessed whether known microRNAs could target the MPL/TpoR 3'UTR sequence. We found that miR-28 and two other related miR interact with the MPL 3'UTR sequence and inhibit the luciferase activity of a reporter vector, when the MPL 3'UTR is cloned downstream of the luciferase coding region. Interestingly, miR-28 was overexpressed in approximately one third of PV, ET and PMF patients' platelets. In such patients TpoR protein levels were down-modulated, but TpoR down-modulation was not restricted only to the miR-28 positive patients. miR-28 was also overexpressed in MPN patients negative for JAK2 V617F. In the JAK2 V617F-positive group, platelet miR-28 overexpression correlated with a JAK2 V617F allele burden >50%, suggesting that high JAK2 V617F signaling may induce miR-28 expression. Indeed, JAK2 V617F, TpoR W515A, TpoR Δ5, Bcr/Abl and the constitutively active STAT5-1*6 were all able to induce miR-28 in retroviraly transduced cell lines, indicating that miR-28 expression is induced by high STAT5 constitutive activation. Moreover, miR-28 is expressed from an upstream alternative promoter in the presence of JAK2 V617F, as shown by 5'RACE and ChIP using antibodies against STAT5 and RNA polII. Finally, in addition to MPL, we identified other miR-28 targets involved cell cycle regulation. We propose that induction of miR-28 in approximately 30% of MPN patients reflects STAT5 activation and that it might play, via down-modulating its targets, a significant role in the evolution of an important fraction of MPNs.

JAK2V617F-INDEPENDENT OVEREXPRESSION OF AUTOCRINE/PARACRINE HEPATOCYTE GROWTH FACTOR (HGF) AND/OR INTERLEUKIN-11 (IL-11) IN POLYCYTHEMIA VERA AND INHIBITION OF CLONAL EYTHROID PROGENITOR GROWTH BY BLOCKING THE HGF/IL-11 PATHWAYS

S. Hermouet, M. Boissinot, C. Cleyrat, M. Vilaine, Y. Jacques, I. Corre, S. Hermouet

INSERM UMR 892, NANTES, France

Background. Polycythemia vera (PV) is a clonal myeloproliferative disorder arising from a multipotent progenitor and resulting in excessive erythropoiesis. Activating mutations of JAK2, a key signalling molecule for hematopoietic cytokines, are found in almost all PV. However, other abnormalities may affect clonal proliferation and disease phenotype. The known dependence of PV erythroid progenitors on cytokines prompted us to investigate the possibility of abnormal production in PV of pro-erythroid cytokines. *Aims*. To identify JAK2-activating cytokines with altered production in PV, on which clonal erythroid progenitors might depend for their growth. *Methods*. We used cytokine antibody arrays (Raybiotech Inc.) to establish the cytokine profile of serum from 20 PV patients and 27 patients with second erythrocytosis (SE) and of bone marrow (BM) plasma (21 PV, 21 SE). Molecules of interest were then measured by ELISA in serum (32 PV, 33 SE) and in BM plasma (27 PV, 26 SE). Quantitative RT-PCRs were used to analyse cytokine expression in cells purified from PV and SE patients: BM mesenchymal stromal cells (BMMSC), $CD3^+$ lymphocytes, $CD34^+$ progenitors, GPA+ erythroblasts. Correlations between cytokine levels, blood cell counts and %JAK2V617F were analysed using Pearson's or Spearman's rank correlation tests. *Results*. Analysis of serum, BM plasma and purified cells of PV patients revealed overproduction of hepatocyte growth factor (HGF) and interleukin 11 (IL-11). The main producers of the two cytokines, known to promote erythroid cell proliferation, were BMMSC and erythroblasts. Exposure of PV BMSC to HGF induced a dose- and time-dependent increase in IL-11 production. Over-expression of HGF and IL-11 in PV erythroblasts is unlikely to be a consequence of JAK2V617F as: i) HGF and IL-11 mRNA levels did not correlate with those of JAK2V617F; ii) hematocrit of patients correlated with IL-11 levels in serum, not with JAK2V617F; iii) expression of JAK2V617F in BaF-3/EpoR cells had no effect on HGF and IL-11 mRNA expression. The relevance of HGH and IL-11 deregulation in PV was then investigated using neutralizing antibodies specific for c-MET, the receptor for HGF, or for IL-11 in *in vitro* cultures: both types of antibodies inhibited the growth of JAK2V617F-mutated erythroblasts from PV patients, as well as JAK2V617F+/+ HEL cells. *Conclusions*. We found JAK2V617F-independent deregulation of autocrine/paracrine HGF and IL-11 in PV, and provide evidence that targeting the c-MET/HGF/IL-11 pathways may be of interest in PV.

CIRCULATING ENDOTHELIAL COLONY-FORMING CELLS ARE INCREASED IN PATIENTS WITH PRIMARY MYELOFIBROSIS, DO NOT BEAR THE JAK-2V617F MUTATION, AND COEXIST WITH JAK-2V617F-POSITIVE MATURE ENDOTHELIAL CELLS

V. Rosti,[1] E. Bonetti,[1] L. Villani,[1] M. Primignani,[2] G. Bergamaschi,[1] M. Massa,[1] R. Campanelli,[1] R. Riboni,[1] F. Novara,[3] S. Lo Po',[1] P. Guglielmelli,[4] M. Lucioni,[1] S. Pozzi,[5] M. Paulli,[1] F. Frassoni,[5] O. Zuffardi,[3] A. Vannucchi,[4] G. Barosi[1]

Background. Primary myelofibrosis (PMF) is characterizaed by increased angiogenesis both in the bone marrow and in the spleen. Recently, a role for circulating endothelial progenitor cells (cEPCs) in new vessel formation has been hypothesized. *Aims*. To evaluate the frequency of cEPCs, grown as endothelial colony-forming cells (ECFCs) *in vitro*, in patients with PMF and other Ph-negative chronic myeloproliferative disorders (CMPDs), and to assess the presence of the JAK-2V617F mutation both in ECFCs and in mature endothelial cells derived from the spleen of PMF patients. *Methods*. cEPCs were studied in 121 PMF patients, 32 patients with PV or ET, and 12 healthy subjects. Spleen sections were obtained from 5 patients undergoing therapeutical splenectomy. ECFCs were grown *in vitro* according to Yoder *et al.*, whereas the JAK-2V617F mutation was evaluated by semi-nested PCR both in ECFC-derived colonies and in endothelial cells obtained from spleen sections by laser microvascular dissection. In two patients carrying major chromosomal abnormalities in their granulocytes, ECFCs were also studied by array-comparative genomic hybridization (array-CGH). *Results*. The median frequency of ECFC per 10 mL of peripheral blood (PB) was statistically higher ($p<0.05$) in PMF patients (0.48, range 0-6) than in PV patients (0.13, range 0-0.57), ET patients (0.25, range 0-1), and normal subjects (0.14, range 0-0.5). Frequency was higher ($p<0.05$) in patients with prefibrotic PMF (0.8 ECFC/10 mL PB; n=33) than in patients with fibrotic MFI (0.45/10 ml PB; n=88). In patients with PMF, a history of previous splancnic vein thrombosis was associated to statistically higher ($p<0.01$) ECFC frequency (1.45 ECFC/10 mL; n=17) compared to patients without thrombosis (0.46/10 mL; n=104), as well as to healthy subjects, either with or without history of thrombosis (0.5 and 0.14, respectively, $p<0.05$ for both). ECFC frequency of all PMF patients also inversely correlated with patients' age (r=-0.22, $p<0.02$), whereas no correlation was found with the JAK-2 mutational status. However, at a multivariate regression analysis, the only parameter that independently correlated with ECFC frequency was a history of previous vein thrombosis ($p<0.001$). The presence of the JAK-2V617F mutation was assessed in 49 ECFC-derived colonies obtained from 28 PMF patients with the mutation in their granulocytes, and in 15 ECFC-derived colonies from 18 JAK-2V617F-positive PV or ET patients. All colonies harbored only the wild type allele. Array-CGH showed the absence of chromosomal abnormalities in all ECFC-derived colonies (n=7) from 2 PMF patients whose granulocytes were characterized by trisomy 8 and by del(4)(21.21-q25), del(7)(pter-p13), and del(7)(q21.11-qter), respectively. Surprisingly, in 2 out of 5 splenectomized PMF patients, homozygous for the JAK-2V617F mutation in their granulocytes, mature endothelial cells obtained by laser microdissection of splenic vessel walls showed the presence of the mutation. *Summary*. cEPCs, assessed as ECFC, are increased in PMF patients compared to healthy subjects and do not belong to the JAK-2V617F mutated clone. The presence of the JAK-2V617F mutation in mature endothelial cells derived from splenic vessels suggests that contribution of the malignant clone to neoangiogenetic processes is possibly accomplished by other cells endowed with angiogenic potential but derived from the hematopoietic lineage

Background. Chronic Myeloproliferative disorders (MPD) are clonal hematopoietic stem cell malignancies characterized primarily by hypercellular bone marrow, proliferation of cells from one or several myeloid lineages and hematopoietic progenitor independence of or hypersensitivity to cytokines. The apoptotic machinery deregulation may be associated to MPD physiopathology. *Aims*. To quantify ciap-1 and ciap-2 gene expression in bone marrow $CD34^+$ hematopoietic stem cells (HSC) and peripheral leukocytes in Essential Thrombocythemia (ET) and Myelofibrosis (MF). We also attempted to correlate the gene expression results with JAK2V617F allele burden. *Subjects and Methods*. 24 TE, 12 MF patients and 53 healthy subjects. Patients were 13 males and 23 females with a mean age of 61.1y and controls were 23 males and 30 females with a mean age of 45.9y. Bone marrow $CD34^+$ HSC were separated using Ficoll-Hypaque protocol followed by Miltenyi CD34 isolation kit and peripheral leukocytes was obtained by Haes-Steril method. Total RNA from $CD34^+$ HSC and leukocytes was extracted according to Trizol® method, High Capacity® Kit was used to synthesize cDNA and real time PCR to quantify ciap-1 and ciap-2 expression. The gene expression results were given as $2^{(-\Delta\Delta Ct)}$. The JAK2 V617F mutation was detected by real time allelic discrimination PCR assay. Statistical analyses were performed by Mann-Whitney and Spearman tests. *Results*. In $CD34^+$ HSC, ciap-1 mRNA levels were increased in ET (median=5.71) and MF (22.84) patients in comparison to controls (0.75) ($p=0.004$; $p=0.009$, respectively). ciap-2 are also overexpressed in ET (11.32) and MF (31.37) patients compared to healthy subjects (0.73) ($p=0.005$;

p=0.002). In leukocytes, we found no statistically difference in ciap-1 or ciap-2 expression between patients and control group. Interestingly, we observed that CD34+ HSC from ET patients who are negative for the JAK2V617F mutation showed higher ciap-2 expression (41.57) than that positive (15.22) (p=0.04) and we found a negative correlation between JAK2V617F allele burden and ciap-2 expression in ET patients CD34+ HSC (r=-0.3882; p=0.04). *Conclusions*. The deregulation in ciap-1 and ciap-2 expression in MPD patients might reduce the degree of CD34+ HSC apoptosis, consequently increasing the accumulation of myeloid cells in MPD patients. Moreover, a negative correlation between ciap-2 and JAK2V617F allele burden suggests that ciap-2 overexpression is not linked to JAK2V617F mutation.

Myeloproliferative disorders (MPD) are clonal hematopoietic diseases that include essential thrombocytosis (ET), polycythemia vera (PV) and primary myelofibrosis (PMF) as well as BCR-ABL+ chronic myelogenous leukemia (CML). In the past several years, studies with cDNA microarrays have defined patterns of gene expression corresponding to specific molecular abnormalities, oncologic phenotypes, and clinical outcomes in hematologic malignancies. This study was aimed at the description of a gene expression signature in MPD which would eventually present a new pathogenetic approach and also diagnostic as well as prognostic information. Using cDNA microarray analysis, involving 25,100 unique genes, we studied the gene expression profile of the pluripotent hematopoietic CD34+ stem cells and mature granulocytes obtained from peripheral blood of ET, PV, PMF and CML patients compared with healthy individuals. The average number of CD34+ cells (cells/μL) in peripheral blood was approximately 6 in PV and ET, 111 in PMF and 2880 in CML as measured by flow cytometry. A somatic point mutation JAK2V617F was detected in 93% of PV, 73% of PMF and 55% of ET patients within genetically homogenous populations. The JAK2V617F mutant allele burden was the highest in PV (60%), less prominent in PMF (42%) and low in ET (11%) patients. The JAK2V617F mutation negative patients were also negative for exon 12 mutations. By microarray analysis, approximately 420, 680 and 1130 genes were uniquely over expressed in CD34+ cells derived from ET, PV and PMF patients, respectively. When we analyzed EPO and JAK-STAT signaling pathways-related genes in MPD, we found that FOS, RAF1 and JAK2 genes, related to EPO signaling pathway, were elevated in ET, PV, PMF and reduced in CML compared to healthy controls. Interestingly, JAK2V617F mutation homozygous and heterozygous patients generally displayed more significant differences compared to patients with no mutation for FOS, RAF1 and JAK2 genes. STAT5 gene expression was decreased in all MPD patients. CSF3R, STAT1 and STAT3 gene expression, related to JAK-STAT signaling pathway, was elevated in ET, PV, PMF and reduced in CML compared to healthy controls. The nuclear transcription factor cAMP-response elements-binding protein (CREBB) gene expression was reduced in CD34+ cells of ET, PV and PMF patients, but during maturation its expression was enhanced in granulocytes. Compared to previous microarray reports, related to JAK-STAT signaling pathway in MPD, we found similarities in SOCS2 and PIM1 increased genes expression in favor of JAK2V617F-positive patients. In conclusion, molecular profiling of CD34+ cells and granulocytes from MPD patients revealed gene expression changes that is beyond their recognized function in disease pathogenesis and can be related to patients' clinical characteristics and may have imminent prognostic relevance.

THREE NOVEL MUTATIONS IN THE PROLYL HYDROXYLASE DOMAIN PROTEIN 2 GENE OF THE OXYGEN SENSING PATHWAY IN PATIENTS WITH ISOLATED ERYTHROCYTOSIS

E. Albiero, M. Ruggeri, S. Fortuna, S. Finotto, D. Madeo, M. Bernardi, F. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Cellular and physiological responses to changes in oxygen tensions in mammalians are mediated via the post-translational oxidation of hypoxia-inducible transcription factor (HIF). Hydroxylation of conserved prolyl residues in the HIF-α subunit is catalyzed by HIF prolyl-hydroxylases (PHDs), belonging to the Fe(II) and 2-oxoglutarate (2OG)-dependent oxygenase family. Such hydroxylation promotes interaction with the von Hippel-Lindau E3 ubiquitin ligase (VHL) and, consequently, proteolytic destruction by the ubiquitin-proteasome pathway. PHD2 isoform employs molecular oxygen as obligatory substrate and its inhibition mimics the hypoxic response, including an increased erythropoietin (Epo) production. Heterozygous PHD2 mutations in humans are associated with erythrocytosis. *Aims.* To identify the genetic lesion in a cohort of subjects with isolated erythrocitosis (defined by the presence of absolute polyglobulia, normal platelet and white blood cell count, absence of splenomegaly, decreased level of serum erythropoietin), either sporadic or familial (almost one first-degree relative with the same diagnosis). *Methods*. Peripheral blood samples at diagnosis from 67 consecutive patients were collected. 12 subjects with familial erythrocitosis, and 55 cases of isolated erythrocytosis were included in the study. PCR of the PHD2 coding region (exon 1-5) and sequencing analyses were performed under standard conditions. To confirm the identity of the newly identified mutations, allele-specific PCR were carried out for each variant. The three VHL exons, HIF2A-exon 12, JAK2 exon 12 and JAK2V617F mutations were also analyzed. *Results*. We identified three novel PHD2 heterozygous mutation (Figure 1 A, B). N203K occurred in a subject with erythrocytosis resulted positive for the JAK2 (547insL+I540F547dup8) mutation in the exon 12, with low serum Epo level.

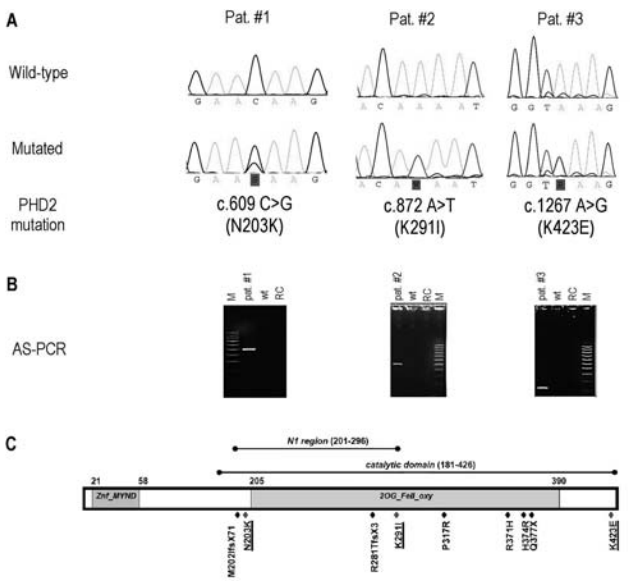

Figure 1. Mutational analysis results and localization of the PHD2 mutations (**A**) Sequencing results of wild-type and mutated alleles in 3 patients. Nucleotide positions (GenBank accession, NM 022051), nucleotide changes and corresponding amino acid changes are indicated below (**B**) Confirmation of the new mutations by allele-specific PCR (AS-PCR) and agarose gel electrophoresis. AS-PCR fragments lenghts agree with the respective primers positions. Lane M: molecular weight marker, lane pat #: patient's DNA amplified with mutation specific primer, lane wt: control DNA amplified with mutation specific primer, lane RC: reaction control (no template) (**C**) Schematic diagram of the human *PHD2* gene. *Znf_MYND*: Zinc finger MYND-like domain, *2OG_FeII_oxy*: 2-oxoglutarate and Fe(II)-dependent oxygenase-type domain. Diamonds indicate the location of the mutations, underscored are the novel genetic variations described in this study. Numbers indicate amino acid residue positions.

Figure 1.

One of his niece and her respective son were erythrocytosic as well, but they did not carry the N203K mutation and they were both JAK2 wild-types. The second mutation, K291I, was found in a 29-year-old male, that referred a familial history of erythrocytosis. The last mutation, K423E, was found in a case of sporadic idiopathic erythrocytosis.

The patients with a PHD2 mutation did not carry VHL, HIF2A-exon 12 genetic lesions or JAK2V617F mutation. *Conclusions*. The three erythrocytosis-associated PHD2 mutations described above are likely to be all of the "partial-loss type", as the six previously reported, and involve the catalytic domain of the protein (Figure 1 C). N203 and K291 map in the region responsible for the differential target preference of PHD2 (N1 region, Figure 1 C). K423E causes the loss of a positive charged side chain with the acquisition of a complementary negative charged glutamate. K423 is an evolutionally conserved residue in orthologues forms of PHD2 but it was absent in the two closely related human isozymes, PHD1 and PHD3. It is possible that removal of the C-terminus of the enzyme actually promotes uncouples turnover of 2OG. Identification of the disease-causing genes will enable better classification of familial and acquired erythrocytosis as, to date, in many cases of this disorder the molecular basis remain unknown. The co-presence of PHD2 and JAK2 exon 12 mutation in a patient and the contrasting Epo levels highlight the difficulties in clearly classify primary or secondary forms rather than acquired or hereditary cases. It will be of interest to asses the substrate binding affinity and the differential effect of these new mutations on HIF-α hydroxylation.

REACTIVE OXYGEN SPECIES ARE DIFFERENTIALLY REGULATED IN CHRONIC MYELOID LEUKEMIA VERSUS PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Guerin

CHU, PESSAC, France

Background. Reactive Oxygen Species (ROS), generated by cellular metabolism, are deleterious for the cells when produced in excess. Their production is increased by tyrosine kinase activation and can be responsible for additional mutations favouring the evolution of myeloproliferative neoplasm from chronic phase to more aggressive acute leukemias. The role of ROS in generating genetic aberrations has been mainly studied in cell lines. *Aims*. In this work, we compared the basal and stimulated ROS production in primary cells of CML or Philadelphia-negative myeloproliferative neoplasm (Ph-MPN) as an approach to ROS metabolism in these diseases and a potential predictor of adverse evolution. *Methods*. Cells were obtained from patients diagnosed with CML [22 from bone marrow (BM), 18 from peripheral blood (PB)], or with Ph-MPN (PB: 6 Polycythemia Vera, 9 Essential Thrombocythemia, 4 Primary Myelofibroses, 2 atypical CML) and from healthy donors. They were incubated with DCFDA (a fluorogenic probe revealing ROS production), labelled with an anti-CD45 antibody or an anti-CD34 antibody, and then stimulated with either the oxidant hydrogen peroxide (H_2O_2) or the PKC activator Phorbol Myristate Acetate (PMA). ROS production was analysed by flow cytometry in granulocytes, monocytes, lymphocytes and $CD34^+$ cells. In some experiments, $CD34^+$ cells were sorted using magnetic beads. *Results*. In our study, the basal level of ROS was not higher in myeloproliferative neoplasms cells as compared to healthy donors, including in $CD34^+$ cells. This is in contrast to some reports based on cell lines or smaller populations of patients. ROS levels was even significantly lower in CML lymphocytes, either from the BM (2.8 Arbitrary Units vs 8.3 AU, $p<10\text{-}6$) or PB (2.9 AU vs. 7.4 AU, $p<10\text{-}6$) and in CML granulocytes from PB (14 AU vs 45 AU, $p<10\text{-}8$), but not from bone marrow. The ROS levels of Ph-MPN cells were similar to control cells, except for granulocytes from peripheral blood (29 AU vs 45 AU, $p=0.01$). Upon H_2O_2 stimulation however, ROS production increased significantly more in CML cells as compared to normal cells (5 fold increase in lymphocytes and 10 fold increase in granulocytes) whatever their origin (PB or BM). Interestingly, H2O2-dependent ROS increase in $CD34^+$cells correlated with that observed in PB granulocytes, indicating that studying granulocytes is a possible alternative to CD34 cells for this aspect of ROS regulation. In contrast, for Ph-MPN cells, ROS production was close to that of normal cells (only two fold higher than control BM granulocytes and lymphocytes). After PMA stimulation, which yielded a more modest ROS production than H_2O_2, CML cells behaved similarly to normal cells whereas ROS production was four fold higher in Ph-MPN cells, whatever their type and origin. *Conclusions*. ROS levels at the basal stage are not higher in primary cells of myeloproliferative neoplasms, but CML cells are more sensitive to oxidants whereas Ph-MPN cells respond more to the "cytokine mimicking PMA". These results suggest that the mechanisms of ROS generation and thus of genetic instability are differently regulated in CML and Ph-MPN cells. Some of these elements could be easily appreciated in peripheral blood cells.

TYROSINE PHOSPHORYLATED SOCS3 IS UNABLE TO REGULATE THE MYELOPROLIFERATIVE NEOPLASM ASSOCIATED- JAK2 V617F KINASE

J. Elliott,[1] Y. Suessmuth,[1] K. Nahlik,[1] M.F. McMullin,[1] S. Constantinescu,[2] J.A. Johnston[1]

[1]Queens University Belfast, BELFAST, UK; [2]Ludwig Institute for Cancer Research, BRUSSELS, Belgium

Backgound. JAK2 V617F, identified in the majority of patients with myeloproliferative neoplasms (MPN), tyrosine phosphorylates SOCS3 and escapes SOCS3 inhibition. We have demonstrated that the JAK2 exon 12 mutants described in a subset of V617F-negative MPD cases, also stabilise tyrosine phosphorylated SOCS3. We have also observed SOCS3 tyrosine phosphorylation in peripheral blood mononuclear cells and/or granulocytes isolated from patients with JAK2 V617F, H538QK539L or JAK2 F537-K539delinsL mutations. *Aims*. We hypothesise that inappropriate SOCS3 tyrosine phosphorylation by JAK2 V617F prevents the SOCS3-Elongin C interaction rendering SOCS3 unable to function as an E3 ligase to degrade the mutant JAK2 kinases. *Methods*. We use co-expression studies in 293T cells to investigate which tyrosine residues within SOCS3 V617F phosphorylates. Protein pull down assays are also employed to determine how tyrosine phosphorylation of SOCS3 affects its interaction with ElonginC. We also use cycloheximide treatment to track the turnover of wild-type JAK2 or V617F in the presence of wild-type SOCS3 and a SOCS3 tyrosine mutant. *Results*. In this study we demonstrate that JAK2 V617F phosphorylates SOCS3 at Y204 and Y221. We also establish that phosphorylation of both Y204 and Y221 prevents the SOCS3-ElonginC interaction. Consequently, wild-type SOCS3 is unable to form a function E3 ligase in the presence of V617F and therefore unable to ubiquitinate JAK2 V617F. However a SOCS3 mutant lacking Y204 and Y221 can. This SOCS3 tyrosine mutant can also regulate the phosphorylation status of JAK2 V617F. *Summary*. In this study we address the relevance of SOCS3 phosphorylation as a potential mechanism by which JAK2 V617F can overcome the suppressive function of SOCS3.

0878

A ROLE FOR TIF1GAMMA IN CHRONIC MYELOMONOCYTIC LEUKAEMIA

R. Aucagne, L.D. Delva

Inserm U866, DIJON, France

Background. Transcriptional Intermediary Factor 1 gamma (TIF1γ) belongs to the TIF1 family of transcriptional co-regulators. In mice, Tif1γ deletion is embryonic lethal (R. Losson, unpublished data), demonstrating a crucial role of this gene during development. In zebrafish, tif1γ gene mutation disrupts embryonic and adult haematopoiesis with severe red blood cell aplasia. *Aims*. Our goal is to investigate the role of TIF1γ in haematopoiesis. *Methods*. Mice expressing the Tif1γ floxed allele were crossed with mice in which the Cre recombinase is expressed under the human cFES promoter. *Results*. Mice transplanted with Tif1γΔ/Δ bone marrow (BM) survived from lethal irradiation, and cells in which Tif1gamma gene was deleted were detected in the peripheral blood (PB) of these mice confirming that the deletion occurred in HSCs. Tif1γΔ/Δ mice older than 6 months exhibited a monocytic hyperplasia associated with an increase in the number of megakaryocytes harbouring morphologic abnormalities, together with dysmegakaryopoiesis, dyserythropoiesis, and dysgranulopoiesis. Flow cytometry analyses confirmed the increased population of monocytes in the BM and in the spleen. The Tif1γΔ/Δ mice with monocytosis also displayed a hepatosplenomegaly. Altogether, the dysplastic and myeloproliferative features observed recapitulate the human chronic myelomonocytic leukaemia (CMML). We showed that the number of $Lin^-Sca1^+cKit^+$ (LSK) cells was increased in Tif1γΔ/Δ before 6 months of age, then returned to normal values as mice develop a CMML-like phenotype. We also identified an abnormal differentiation of produced mature monocytes. The CMML phenotype associated with Tif1γ deletion in mice suggests that Tif1gamma deficiency may contribute to transformation by a loss of proliferative control at the stem/progenitor stage or in a committed myeloid lineage. Since the phenotype observed in the Tif1γΔ/Δ mice recapitulated the human CMML, we studied the expression level of TIF1gamma in monocytes obtained from 22 CMML patients compared to 12 healthy donors, after that informed consent was obtained. RQ-PCR analysis demonstrated that TIF1gamma gene expression was almost undetectable in 8 out of the 22 patients. In addition, a three days exposure of PB monocytes

from CMML patients to decitabine, a demethylating agent that was recently shown as a potentially efficient therapeutic in about 30% of these patients, increased the expression of TIF1γ. Several reports have described TIF1γ as a member of TGF-β/BMP signalling pathways even if its mechanism of action is still unclear. Among the TGF-beta family members, BMP4 has demonstrated a crucial role in haematopoietic stem cells maintenance and megakaryopoiesis. We showed that Bmp4 transcript is strongly decreased in Tif1γΔ/Δ BM cells. By IHC, we also started to study the expression and cell localisation of Smad4. *Conclusions*. In conclusion, our animal model not only closely mimics human CMML, but also allows genomic analysis of a large series of primary patient samples leading to the identification of a subset of patients expressing low levels of TIF1gamma. Furthermore, this animal model will be useful as a powerful system to identify other hits in CMML pathogenesis, but it will also permit to assess the therapeutic efficacy of molecular agents like DNA hypomethylators.

0879

A NEW PROLYL HYDROXYLASE DOMAIN PROTEIN 2 MUTATION IN A JAK2(V617F) POSITIVE PATIENT WITH A FAMILIAL MYELOPROLIFERATIVE DISEASE

E. Albiero, M. Ruggeri, S. Finotto, F. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Polycythemia vera (PV) is the most common cause of primary erythrocytosis, almost always due to the somatic V617F allele in the JAK2 gene, within erythroid progenitor cells, that results in constitutive intracellular signalling and clonal proliferation. Less often, JAK2(V617F) and MPL(W515L/K) mutations are associated with essential thrombocythemia (ET) or primary myelofibrosis (PMF), while JAK2 mutations located in exon 12 have been found in patients with isolated erythrocytosis (IE) or in JAK2(V617F) negative PV cases. There is evidence to support the possibility that diseases alleles other than those described above are involved in the pathogenesis of Philadelphia-negative chronic myeloproliferative disorders (MPDs). Recent insights of the genetic causes of erythrocytosis came from the fuctional and biochemical investigation of the oxygen-sensing (OS) pathway. Aim: To investigate the possibility that diseases alleles other than JAK2 could be involved in the pathogenesis of familial MPDs. *Methods*. Peripheral blood samples at diagnosis from 23 familial PV or ET patients were collected. The von Hippel-Lindau tumor suppressor (VHL), prolyl hydroxylase domain protein 2 (PHD2) and the exon 12 of the 2α-subunit of the hypoxia-inducible factor (HIF2A) genes were analyzed for their role as key proteins of the OS pathway. PCR of the PHD2 (exon 1-5) and VHL (exon 1-3) coding regions and sequencing analyses were performed under standard conditions. To confirm the identity of the newly identified mutation, allele-specific PCR was carried out. JAK2 and MPL mutational status were previously assessed in all the patients. *Results*. We identified a novel PHD2 heterozygous mutation (Figure 1 A, B). Molecular biology studies revealed a G>C missense mutation at coding nucleotide position c.471 resulting in a Q157H replacement in the amino acid sequence. It was found in a PV patient with normal serum Epo level, raised hematocrit (55.2%) and high platelets count (703×10^9/L) previously resulted positive for the homozygous JAK2(V617F) variation. His sister was affected by PV as well. At the time of the study she was already deceased (Figure 1 C).

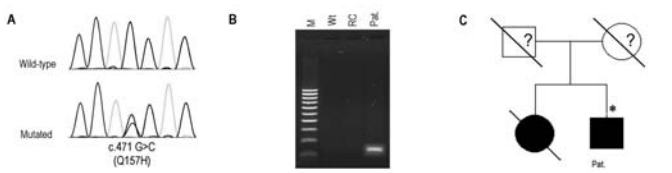

Figure 1. Mutational analysis results. (**A**) Sequencing results of wild-type DNA and mutated alleles of the patient. Nucleotide positions (GenBank accession, NM 022051), nucleotide changes and corresponding amino acid changes are indicated below (**B**) Confirmation of the new mutation by allele-specific PCR (AS-PCR) and agarose gel electrophoresis. Lane M: molecular weight marker, lane Pat.: patient's DNA amplified with mutation specific primer, lane wt: control DNA amplified with mutation specific primer, lane RC: reaction control (no template) (**C**) Pedigree of the family with MPD. Squares represent males, circe females, affected individuals are indicated in black and slashes indicate deceased members. Genetically tested individual is indicated by an asterisk.

Figure 1.

The patient with the new PHD2 mutation did not carries VHL, HIF2A-exon 12, MPL or JAK2-exon 12 mutations. Conclusions: Q157H is the most N-terminal mutation reported to date in the PHD2 protein, lying between the N-terminal MYND zinc finger-like domain (amino acids 21-58) and the highly conserved C-terminal catalytic domain (amino acids 181-426). This amino acidic variation do not directly involves the catalytic domain, it introduces a positively charged histidine, with a bulky and reactive side chain, instead of an indifferent glutamine. A truncated version of PHD2, lacking residues 76-177 from its N-terminal unique region behaved as full-length PHD2, but further studies will be required to estabilish the function of this PHD2 unique region. Noteworthy, for the first time, a mutation affecting PHD2 has been identified in a PV patient, while other partial-loss PHD2 mutations are all erythrocytosis-associated. The co-presence of PHD2 and JAK2(V617F) genetic lesions support the hypothesis that JAK2 mutation is a secondary, not a disease-initiating, genetic event and that the JAK2(V617F) mutation might occur as a secondary event on the background of an inherited genetic predisposition.

SOCS1, SOCS3 AND PTPN6 METHYLATION IN PATIENTS WITH PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISEASES (CMPD)

M. Foedermayr, M. Huber, H. Hauser, A. Weltermann, O. Zach, D. Lutz

Elisabethinen Hospital, LINZ, Austria

Background. The Jak2 V617F mutation can be detected in the majority of CMPD patients and leads to constitutively activated Jak2 proteins. SOCS1, SOCS3 and PTPN6 are members of the Suppressors Of Cytokine Signalling family or Protein Tyrosine Phosphatase family, respectively, thus directly interacting and inhibiting Jak2 kinase activity. Epigenetic gene silencing of these proteins by DNA methylation activates the Jak-STAT pathway similarly as the Jak2 V617F mutation and might be an alternative mechanism in patients without any activating mutation. *Aims*. Elucidation of the methylation status of CpG islands of SOCS1, SOCS3 and PTPN6 in blood of 48 CMPD patients (36 Jak2 V617F mutated, 12 wildtype) as compared to 22 healthy controls. *Methods.* DNA was prepared from blood of 21 patients with polycythemia vera (PV), 19 patients with essential thrombocythemia (ET), 8 patients with myelofibrosis (MF) and 22 healthy controls. Methylation-specific PCR (MSP) for SOCS1 exon2, SOCS3 exon2, and PTPN6 promoter was performed according to Capello D. (Br J Haematol 141, 2007), for SOCS3 intron corresponding to Fernandez-Mercado M. (Leuk Res 32, 2008). *Results*. SOCS1 exon2 was methylated in 46%, 62%, 32% and 13% of healthy controls, PV, ET and MF, respectively. SOCS3 exon2 was methylated in all patients and controls, whereas SOCS3 intron and PTPN6 methylation was only detected by increasing the number of PCR cycles to 40. Accordingly, SOCS3 intron methylation was detected in 36% of healthy controls and in 19% PV, 26% ET and 38% MF, while PTPN6 promoter methylation in 9%, 19%, 0% and 13%, respectively. Between Jak2 V617F positive and negative CMPDs no significant differences in the frequency of methylation of these four genomic regions were observed so far. *Conclusions*. Methylation of CpG islands in the examined Jak2 pathway suppressing genes were found in the peripheral blood from CMPD patients as well as from healthy controls. The methylation status observed in this study joins the conflicting results from previous publications. However, whether differences between PV, ET and MF patients observed is of any clinical relevance should be analysed further on.

0881

AME AFFECTS MEGAKARYOCYTIC DIFFERENTIATION AND INCREASES PRO-PLATELATS FORMATION *IN VITRO*

C.R. Rinaldi,[1] V. Senyuk,[2] P. Rinaldi,[1] G Nucifora,[2] F. Pane,[1] B. Rotoli[1]

[1]Federico II University, NAPLES, Italy; [2]University of Illinois at Chicago UIC, CHICAGO, USA

Background. The t(3;21)(q26;q22) resulting in the AML1/MDS1/EVI1 (AME) fusion gene is associated with several hematological disorders often characterized by severe dysmegakaryopoiesis, suggesting that AME alters the megakaryocytic maturation program. *Methods*. We expressed the AME fusion protein in bone marrow lineage negative cells by retroviral infection. The cells were cultured in presence of TPO to induce megakaryocytic differentiation and on day 2 the morphology was analyzed after Wright Giemsa staining. We also expressed AME in the human erythromyeloblastoid cell line K562. PMA was used to induce megakaryocytic differentiation. The cells were collected after 48 and 96 hours and then compared with the control differentiated K562. The DNA content was measured after propidium iodinate (PI) staining by FACS analysis. *Results*. In the AME positive cultures we counted a 5 fold increase (35%) of MKs percentage compared with the control cells

(7%). AME positive MKs were smaller in size in comparison to the control. In AME cultures we frequently observed micro-megakaryocytes and other features of dismegakaryopoiesis. During 12 days in liquid culture in presence of TPO, while the control MKs persisted for the entire experiment, the AME positive MKs quickly decreased after 7 days. AME positive MKs produced platelets until day 6. The platelets appeared immature, bigger in size with several features of pro-platelets. The AME platelets were found 10 fold increased as compared to controls and their formation was prolonged for more than 7 days while the control MKs produced platelets for only 2 days. AME-K562 showed a block in megakaryocytic differentiation. As previously demonstrated in murine cells, also AME-differentiated-K562 were smaller in size in comparison to the controls. The DNA content measured after 96 hours, pointed out a significant lower (4n) level of polyploidy in the AME positive cells compared with the controls (8n). We also checked in the K562 cell line by semi-quantitative PCR the expression of several regulatory genes implicated in megakaryopoiesis. Before PMA incubation, AME positive cells showed a slight up-regulation of GATA1, cMPL, PF4 and BCL2, while NFE2 and BCL-XL were slightly down-regulated. Interestingly, after PMA stimulation, except GATA1 and BCL-XL that were up-regulated, all the others were strongly down-regulated. *Conclusions*. It seems that AME interferes with the megakaryocytic program, causing impairment in MKs differentiation with arrest in polyploidization, increased apoptosis and overproduction of immature platelets. The molecular mechanism appears complex, affecting concurrently transcription factors essential for MKs differentiation, apoptosis regulatory genes and genes implicated in platelets production.

0882

CONTRIBUTION OF BONE MARROW DERIVED CELL ANGIOGENESIS IN BCR/ABL NEGATIVE CHRONIC MYELOPROLIFERATIVE DISEASE

G. Gritti,[1] U. Gianelli,[2] S. Lonati,[3] I. Silvestris,[3] C. Vener,[1] L. Boiocchi,[4] A. Freyrie,[1] A. Cortelezzi,[5] G. Lambertenghi[5]

[1]IRCCS Foundation Policlinico Mangiagalli and Regina Elena, MILAN; [2]San Paolo Hospital, University of Milan, MILAN; [3]University of Milan, MILAN; [4]San Paolo Hospital, MILAN; [5]IRCCS Foundation Policlinico Mangiagalli and Regina Elena, University of Milan, MILAN, Italy

Background and Aims. Circulating cells derived from bone marrow (BM) have been reported to induce and modulate angiogenesis and vasculogenesis in condition of ischemia and/or cancer. Endothelial progenitor cells (EPCs) are non hematopoietic bone marrow-derived stem cells that can home into the site of active neo-vascularization and are found increased in setting of enhanced angiogenesis. Recent studies underline the role of other subsets of hematopoietic BM-derived cells in triggering vessel growth. They contribute by releasing pro-angiogenic factors and by directly incorporating into nascent blood vessels and are characterized by the expression of the angiopoietin receptor Tie2/Tek or by the presence of VEGFR-1. Increased angiogenesis is thought to have a central role in bcr/abl negative chronic myeloproliferative disorders (CMPDs). To assess the role of BM-derived cells in this setting, we evaluated the level of EPCs, Tie2 and VEGFR-1 expressing circulating cells in a cohort of bcr/abl negative CMPDs. We additionally evaluate microvessel density (MVD) on BM biopsies and a set of cytokines related to angiogenesis. *Methods*.We analyzed 88 patients composed as follow: ET (25), PV (18), CIMF (45) and 25 controls. EPCs (defined as $CD34^+/CD133^+/CD45^-$), $TIE2^+/CD45^+$ and $VEGR1^+/CD45^+$ cells were evaluated by flow cytometry. Serum concentration of VEGF, Ang-1, Ang-2 and FGFb were assessed by commercial ELISA kits. Forty-one BM biopsies were available; MVD was evaluated using the 'hot spots' method. The data were statistically analysed using the Mann-Whitney U test for between-group comparisons and Spearman's correlation coefficient to evaluate the associations between variables. $p<0.05$ was taken as a cut-off point for statistical significance. *Results*. Bcr/abl negative CMPDs were characterized by elevated EPCs (median: 0.17/mcl [range: 0.00-2.40] vs 0.04 [0.00-0.27] $p<0.0001$), VEGF (1940 pg/mL [200-18351] vs 574 [92-1241] $p=0.0005$) and FGFb (33 pg/mL [0.5-269.6] vs 22.4 [7.6-46.1] $p=0.02$) and BM-MVD (24.3 vessels/hpf [5.3-86.2] vs 6.0 [4.6-16.3]). No differences were found regarding the other cytokines evaluated. Absolute and relative number of $VEGFR1^+/CD45^+$ were increased in CMPDs than controls (2086.7/mcl [333.0-9954.6] and 32.9% of total WBC [6.1-90.4] vs 953.2 [436.5-2597.2] and 16.1% [4.9-34.8], $p=0.01$). $TIE2^+/CD45^+$ cell number was not different than controls, they were positively correlated with serum VEGF ($p=0.03$), Ang-1 ($p=0.04$) and bFGF ($p=0.02$). Most of the $TIE2^+/CD45^+$ cells expressed CD14 (73% [21,2-93,1]), and $TIE2^+/CD45^+/CD14^+$ still correlate with the same cytokines while the $CD14^-$ part does not; moreover, they were negatively correlated with BM-MVD ($p=0.007$) *Conclusions*. CMPDs patients have an abnormally enhanced angiogenesis as shown by high EPCs, VEGF, bFGF and BM-MVD. In this group of patients $VEGFR1^+/CD45^+$ cells are found increased while the $TIE2^+/CD45^+$ are correlated with serum markers of angiogenesis and BM-MVD. These preliminary data put forward the concept that different subset of cells can contribute to the pro-angiogenic phenotype of bcr/abl negative CMPDs. It may be therefore interesting to further explore the role of these cells in a setting of pathological maturation and proliferation of the hematopoietic BM compartment as in CMPDs.

STUDY OF MEGAKARYOPOIESIS AND PROPLATELET FORMATION IN PRIMARY MYELOFIBROSIS

A. Balduini,[1] S. Badalucco,[1] M. Massa,[2] V. Rosti,[3] G. Barosi[4]

[1]Department of Biochemistry, University of Pavia, PAVIA; [2]Biotechnology Laboratory, IRCCS San Matteo Foundation, PAVIA; [3]Organ Transplantation Laboratory, IRCCS San Matteo Foundation, PAVIA; [4]Laboraotry of Clinical Epidemiology/ Center for the Study of Myelofibrosis, IRCC, PAVIA, Italy

Background. Primary myelofibrosis (PMF) is an uncommon chronic myeloproliferative disorder. Several abnormalities that could explain the myeloproliferation have been reported, and most important is a striking involvement of the megakaryocyte (Mk) lineage, with hyperplasia and dysplasia resulting in an excessive production of several cytokines and chemokines. Whereas molecular defect(s) associated with the development of PMF have been described, its pathogenesis is not thoroughly elucidated. *Aims*. The general objective of this research is to study the alterations of megakaryopoiesis in PMF and to correlate it to histological and clinical features of the disease. *Patients and Methods*. We analyzed *in vitro* Mk differentiation and maturation, as well as proplatelet formation (PPF) in 8 patients diagnosed with PMF. Mks were differentiated from peripheral blood $CD34^+$ cells for 12 days in the presence of TPO. Mature Mks were grown in suspension or plated onto glass coverslips coated with collagen I or fibrinogen (FNG). Mk differentiation-maturation and PPF were evaluated by phase contrast and fluorescence microscopy upon cell staining with anti α-tubulin and CD41 antibodies. Measurement of Mk diameters was performed on acquired images, at least one hundred Mks were analyzed for each sample. Mk ploidy was evaluated by flow cytometry after staining with propidium iodide. Controls were analyzed in parallel with each patient sample. *Results*. Immunomorphological evaluation of cultured progenitors at day 12 revealed that the percentage of $CD41^+$ cells with Mk morphology was slightly increased, but not significantly different in patients and relative controls. Moreover, classification of Mk morphology, according to standard criteria, revealed no significant differences in the differentiation profiles between patients and controls. However differences were observed in the maturation pattern as, at the end of the culture, patients presented a significant decreased number of very mature, large, polyploid Mks with respect to controls. When reseeded in fresh medium, mature Mks derived from peripheral blood of both patient and control extended proplatelets. However, a time course analysis revealed a reduction of PPF by Mks derived from the patient: in fact, while 10±1.9% of control Mks were forming proplatelets after 16-24 hours of culture, the percentage of Mks with PPF from the patient's peripheral blood was 2.5±1.9%. In morphologic analysis proplatelets derived from patient peripheral blood presented a significant defect in branching, which resulted in a lower number of proplatelet tips formed by each megakaryocyte. Interestingly, some patients presented thrombocytopenia that was positively correlated to proplatelet decreased numbers and branching defects. *Summary and Conclusions*. Mks from patients affected by PMF presented both quantitative and qualitative abnormalities of *in vitro* PPF. The decreased capacity of completing maturation was positively correlated with decreased Mk ploidy and diameter. Altogether these data indicate that, although patients' peripheral blood progenitors easily differentiate through the megakaryocytic lineage, PMF affects the final steps of Mk maturation, proplatelet formation and platelet release.

0884

MURINE MYELOPROLIFERATIVE DISORDER WITH LIVER LESION: CHARACTERISTICS OF LEUKEMIA STEM CELLS AND PHENOTYPE OF CELLS INVADED LIVER

A.E. Bigildeev, I.N. Shipounova, D.A. Svinareva, N.J. Drize

Hematology Research Center, Russian Academy of Medical Sciences, MOSCOW, Russian Federation

Background. Tumors are morphologically and functionally heterogeneous, whether due to their hierarchical structure or due to stochastic processes. The stochastic model predicts that all tumor cells are biologically homogeneous, equally subjected to unpredictable reversible influences resulting in morphological and functional heterogeneity. The hierarchy model suggests the existence of leukemic stem cells (LSC) capable of self-maintenance that can mature to generate heterogeneous progeny that lack stem cell properties. If stochastic model is correct LSC activity may be observed in any tumor fraction and most of leukemic cells have potential for tumor initiation. *Aims*. The aim of this study was the investigation of LSC in different cell populations with phenotype of stem and committed cells in hematopoietic stem cells hierarchy. *Methods*. The model of transplantable MPD-like myeloid leukemia with histiocytic sarcoma was used. Bone marrow (BM) and liver cells of affected mice were fully transplantable, recipients became moribund within 17-32 days since cells injection. All the ill animals had enlarged liver (M 4,1±0,1 g versus normal 1,44±0,03 g) and spleen (M 304,9±15,5 mg versus normal 93,1±1,8 mg). BM and liver cells from the moribund mice were stained with antibodies against different surface markers and analysed with FACS, simultaneously BM cells were sorted by Miltenyi Biotec® MACS® magnetic separation columns and injected into syngeneic recipients. Limiting dilutions of cells were used in some sorted populations to evaluate the concentration of cells initiating leukemia. *Results*. Phenotype of leukemic and normal BM cells didn't differ. Each injected population of the cells led to the development of fatal leukemia: c-kit-CD45- in 23.9, c-kit+ in 22.2, c-kit-CD45+ in 15.4, Ter119+ in 18.2 and Ter119- in 17.7 days. The data suggest that: neoplastic transformation may take place in very early progenitor cells (c-kit-CD45-); myelopoiesis is involved; the ability to give rise to leukemia is present even in cells committed to erythroid differentiation. The analysis of leukemia initiating cells' concentration by limiting dilutions of c-kit+ BM cells and unsorted liver cells of the ill mice was made with Poisson statistics. It turned out to be 1 cell per 37000 c-kit+ cells and 1 cell per 45 unsorted cells from the liver. Taking into consideration the differences in time of disease development, the frequencies of leukemia initiating cells in other cell populations were calculated as 1 LSC per 2500000 c-kit-CD45- cells, 200 c-kit-CD45+ cells, 4500 Ter119+ cells, 2600 Ter119- cells. So, the LSC properties in the described disease preserved in cells committed to erythroid and myeloid lineages. The concentration of cells capable to transfer leukemia increased with differentiation from c-kit-CD45- to c-kit-CD45+ cells population. The frequency of leukemia initiating cells reaches maximum in liver invading population. *Conclusions*. Leukemic stem cells retain hierarchical organization in the studied model and are able to differentiate at least among myeloid and erythroid lineages without the loss of self-renewing ability. However LSC activity was observed in all tested fractions that support the stochastic model of tumor heterogeneity. So, this murine leukemia combines two models of tumor heterogeneity.

0885

EPIGENETIC CHANGES IN JAK2V617F POSITIVE MYELOPROLIFERATIVE DISORDERS

A. Uras, M.A. Fancello, M. Monne, G. Piras, A.D. Palmas, E. Gaviano, A. Noli, A. Bianchi, A. Gabbas

San Francesco Hospital, NUORO, Italy

Background. There is increasing evidence that, in addition to genetic alterations, epigenetic changes play an important role in the pathogenesis of hematopoietic malignancies. Aberrant methylation of CpG islands near gene promoter regions has been established as an important mechanism for gene silencing. Hypermethylation of genes involved in the JAK-STAT signalling pathway has been recently reported in Cronic Myeloproliferative Disorders (CMPDs) in alternative or together with JAK2 mutations. *Aims*. In order to further investigate the role of DNA methylation changes in the pathogenesis of CMPDs, we analyzed the methylation status of the promoter-associated CpG islands of 8 cancer-related genes by methylation-specific polymerase chain reaction after DNA bisulphite modification. *Methods*. Forty-seven patients with Chronic Myeloproliferative Disorders (10PV, 10ET, 5MF, 4CML, 14CMPD unclassifiable) who have been previously characterized for the presence of JAK2V617F mutation were analyzed. Four peripheral blood from controls were also evaluated. The target genes chosen are involved in many cellular pathways as cell cycle regulation (p16INK4a, PTEN), cell-cell adherence (E-cadherin), the canonical Wnt pathway (WIF1, DKK3) and JAK/STAT3 signalling pathway (SOCS1, SOCS3, SHP1). The correlation between methylation and JAK2 mutation status was assessed by Fisher exact test or Chi-square test. *Results*. Overall, 44 out of 47 patients (93%) presented at least one hypermethylated gene and 38% (18/47) had aberrant methylation in more than two genes. Hypermethylation was detected in 22% of patients for p16, 51% for DKK3, 23% for WIF1, 58% for E-cadherin, 14% for SHP1. In our casistics SOCS-1 and SOCS-3 resulted methylated in 83% and 100% of patients, respectively, while PTEN was methylated in only two patients with CML and unclassifiable CMPD. Only 5/47 cases (10.6%) resulted simultaneously methylated for p16, DKK3, E-Cadherin, SOCS1. Methylation frequencies did not differ between mutant and wildtype JAK2 carriers. However, analysis of the methylation patterns among JAK2V617F positive patients showed that WNT antagonist genes were more frequently methylated than p16 and SHP1 and the difference was statistically significant with a p value of 0.002. *Conclusions*. In summary, we found that either aberrant methylation of WNT antagonists or the absence of p16 or SHP1 epigenetic inactivation may be cooperating with JAK2V617F mutation in myeloproliferative disease.

0886

PRIMARY MYELOFIBROSIS CD34+ CELLS SHOW DIFFERENT CXCR4 CHEMOKINE RECEPTOR PROFILES AT SITES OF DISEASE ACTIVITY

M. Massa, R. Campanelli, V. Rosti, E. Bonetti, E. Moretti, L. Villani, S. Lo Pò, G. Barosi

Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy

Background. In previous studies we found that the reduced expression of CXCR4 by peripheral blood (PB) CD34+ cells is a characteristic of Primary Myelofibrosis (PMF). We documented that the number of circulating CD34+CXCR4+ cells in PMF patients, as well as the membrane CXCR4 expression, was directly related to CXCR4 mRNA level and that reduced CXCR4 mRNA level was not due to SDF-1-induced down-regulation but to a hypermethylation of CXCR4 promoter CpG island 1. Therefore, abnormal methylation of the CXCR4 promoter has been suggested to be a mechanism contributing to constitutive migration of CD34+ cells in PMF. *Aims*. To investigate the pattern of CXCR4 receptor expression on CD34+ cells from PB, bone marrow (BM) and spleen of patients with PMF. *Methods*. We studied PB and BM paired samples in 16 patients, and PB and spleen paired samples in 8 patients with PMF. Patients had been splenectomized for refractory and symptomatic splenomegaly. After extensive rinsing, each spleen sample was minced to obtain a single cell suspension. PB, BM, and spleen cells were stained with FITC-CD34 and PE-CXCR4 monoclonal antibodies. The expression of CXCR4 was evaluated as percentage and mean fluorescence intensity (MFI) of CD34+ gated cells. *Results*. In patients with PMF the percentage of PB CD34+ cells expressing CXCR4 (34%, 9.1-68.7%) was significantly higher than that found in BM CD34+ cells (19.8%, 2.7-57.8%)(Wilcoxon paired test, p=0.019), Similarly, MFI of the CXCR4 antigen on CD34+ cells from PB (0.6, 0.1-2.4) was significantly higher than that of BM (0.3, 0.05-2.2) (Wilcoxon paired test, p=0.015). In spleen tissue, percentage of CD34+CXCR4+ cells (10.7%, 3.9-20.0%) and MFI (0.3, 0.2-0.7) were decreased with respect to the values found in PB. We had no paired samples of bone marrow and spleen tissue, but the percentage and the MFI of CD34+CXCR4+ cells from spleen tissues were not statistically different from those of BM. Interestingly, the percentage of CD34+CXCR4+ cells obtained in apheresis samples of 3 healthy subjects mobilized with G-CSF (11.3, 7.6-13.4) was comparable to that found in cells from spleen tissues. Summary These data suggest that CD34+ cells of patients with PMF display different CXCR4 profiles in different sites of disease activity. Micronvironmental factors might play a role in stem cell functional behaviour.

0887

IDIOPATHIC HYPEREOSINOPHILIC SYNDROME IN CHILDREN: MOLECULAR ANALYSIS AND CLONAL EVOLUTION

M.C. Rapanotti,[1] R. Caruso,[2] S. Zaza,[1] M.D. Divona,[1] L. Trotta,[2] G. Federici,[1] S. Amadori,[1] G. De Rossi,[2] F. Lo Coco[1]

[1]Policlinico Tor Vergata, University of Rome, ROME; [2]Ospedale Pediatrico Bambino Gesù, ROMA, Italy

Background. Idiopathic hypereosinophilic syndrome (HES) is a rare hematologic disorder characterized by unexplained sustained overproduction of eosinophils in the bone marrow, persisting eosinophilia (>1.5×10^9/L for>6 months), tissue infiltration and organ damage. In the majority of HES, diagnosis is based on exclusion criteria and frequently remains doubtful due to the lack of genetic markers. Early identification of HES eventually evolving towards a lympho-myeloproliferative disease is relevant in light of its obvious prognostic and therapeutic implications. Only few cases of pediatric HES are described in literature. *Aims*. To analyse molecular features and clinical outcome of 10 pediatric patients with idiopathic HES. *Methods*. BCR-ABL and FIP1L1/PDGFRA fusion genes were analysed by routine RT-PCR. WT1 gene copy number was assessed by RQ-PCR using Taqman technology. TCR clonality was investigated by DHPLC-sequencing of TCRb genomic regions. IgH clonality was performed amplifying CDR-I, CDR-II and CDR-III regions using oligo-degenerate-sequence primers mapping the frameworks FR2 and FR3 of variable and joining-Heavy chain of immunoglobulin genes. *Results*. All patients had normal karyotype on conventional cytogenetics. T-cell receptor analysis disclosed germline configuration in all cases. Five children showed a IgH clonality (FR2-CDRII region) at presentation; of these, 2 developed a B-NHL and a B-lineage ALL at 6 and 12 months, respectively, with tumor cells harbouring the same IgH monoclonal rearrangement documented at diagnosis; 2 had spontaneous reversion to polyclonal IgH profile in the follow-up, and the last one persisted with HES without B-clonal evolution at 19 mos. The PDGFRA/FIP1L1 fusion gene was identified in 1 patient who achieved hematologic and molecular remission after treatment with imatinib mesylate. Three of the 6 patients analysed for WT1 had over-expression and 3 had gene expression levels within normal range. No correlation was found between WT1 expression and HES clonality. *Conclusions*. IgH rearrangement is a frequent molecular feature of pediatric HES (50%) and may precede B-clonal expansion and evolution into B-cell malignancies, although spontaneous regression may occur. The analysis of more cases with detailed molecular characterization including IgH gene status and WT1 is warranted to identify features predictive of clonal evolution.

Myeloproliferative disorders - Biology and Clinical

CONSISTENT UP-REGULATION OF STAT3 INDEPENDENTLY OF JAK2 MUTATIONS IN A NEW MURINE MODEL OF ESSENTIAL THROMBOCYTHEMIA

C.R. Rinaldi,[1] V. Senyuk,[2] P. Rinaldi,[1] B. Rotoli,[1] F. Pane,[1] G Nucifora[2]

[1]Federico II University, NAPLES, Italy; [2]University of Illinois at Chicago UIC, CHICAGO, USA

Background. Janus-activated kinase 2 (JAK2) mutations are common in myeloproliferative disorders; however, although they are detected in virtually all polycythemia vera patients, they are found in approximately 50% of essential thrombocythemia (ET) patients, suggesting that converging pathways/abnormalities underlie the onset of ET. Recently, the chromosomal translocation 3;21, leading to the fusion gene AML1/MDS1/EVI1 (AME), was observed in an ET patient. *Methods and Results*. After we forced the expression of AME in the bone marrow (BM) of C57BL/6J mice, all the reconstituted mice died of a disease with symptoms similar to ET with a latency of 8 to 16 months. Peripheral blood smears consistently showed an elevated number of dysplastic platelets with anisocytosis, degranulation, and giant size. Although the AME-positive mice did not harbor Jak2 mutations, the BM of most of them had significantly higher levels of activated Stat3 than the controls. With combined biochemical and biological assays we found that AME binds to the Stat3 promoter leading to its up-regulation. *Conclusions*. Signal transducers and activators of transcription 3 (STAT3) analysis of a small group of ET patients shows that in about half of the patients, there is STAT3 hyperactivation independently of JAK2 mutations, suggesting that the hyperactivation of STAT3 by JAK2 mutations or promoter activation may be a critical step in development of ET.

0889

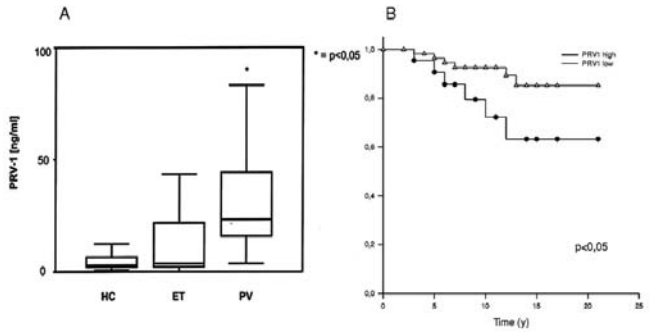
ELEVATED PRV-1 PLASMA LEVEL IS A RISK FACTOR FOR TRANSIENT ISCHEMIC ATTACK (TIA) IN ESSENTIAL THROMBOCYTHEMIA

S. Schwemmers,[1] E. Maerz,[1] H. Gisslinger,[2] F. Schneider,[3] H.L. Pahl[1]

[1]Anaesthesiology, FREIBURG, Germany; [2]Department of Internal Medicine I, Division of Hematology and Blood Coagulation, VIENNA, Austria; [3]Medizinische Klinik und Poliklinik III, Klinikum Gro,hadern, MÜNCHEN, Germany

Background. PRV-1 mRNA overexpression has been described as a molecular marker in patients with myeloproliferative disorders (MPD). The PRV-1 gene is overexpressed in over 90% of Polycythemia vera (PV) patients and approximately 50% of patients with Essential thrombocythemia (ET) and Primary myelofibrosis (PMF). While PRV-1 mRNA overexpression is diagnostically sensitive for MPDs, there is a large overlap between PRV-1 protein surface expression on neutrophils in healthy controls and MPD patients. However, PRV-1, a member of the uPAR/CD59/Ly6 family of GPI-linked cell surface receptors, is shed into the plasma. Since there are very few predictive markers for the development of thromboembolic complications in patients with ET, we assessed the utility of PRV-1 plasma concentration as a biomarker for the prediction of thrombotic episodes. *Aims.We* therefore determined PRV-1 plasma levels in MPD patients and age matched healthy controls. Subsequently we correlated elevated PRV-1 plasma concentrations with clinically recorded thrombo-embolic episodes in a prospectively collected cohort of 89 ET patients. *Patients and Methods*. PRV-1 protein concentration was measured using a sandwich ELISA comprised of two monoclonal antibodies generated in our laboratory. A purified PRV-1 protein-standard curve was used for quantification. PRV-1 plasma levels were detected in a prospectively collected cohort of 89 ET patients, a cross sectional cohort of 55 PV patients as well as 100 age matched healthy controls. Kruskal-Wallis One Way ANOVA on Ranks and the Mann-Whitney Rank Sum test were used to compare PRV-1 plasma level between cohorts. The ET cohort [38 males (43%) and 51 females (57%)] was prospectively monitored for thromboembolic complications including the occurrence of stroke, transient ischemic attack (TIA), deep vein thrombosis (DVT) and occlusive artery disease (OAD) with a median follow up of 12 years (range 2-21 years). Median age at diagnosis was 55 years (range 20-85). Fisher's Exact Test as well as Kaplan Meier survival estimates were used to assess the relationship between PRV-1 plasma-level and thrombo-embolic events. *Results*. PRV-1 plasma levels were significantly elevated in PV patients compared to either healthy controls or ET patients (Figure 1A). However, among ET patients, a large range of PRV-1 concentrations were observed, prompting us to divide this pop-

ulation into two groups. ET patients with PRV-1 plasma levels less than one standard deviation above the median of the healthy controls (<21ng/mL) were considered PRV-1 low (n=64), while ET patients with PRV-1 plasma levels more than one standard deviation above the median (>21ng/mL/n=25) were considered PRV-1 high. Comparison of the thrombotic events in the two groups of ET revealed a significantly higher incidence of TIA in the PRV-1 high patients [p=0,014 with Fisher's exact (one-sided) and p<0,05 with Kaplan Meier survival estimate(Figure 1B)]. Likewise the combined endpoint of TIA and stroke occurred at a significantly higher incidence in PRV-1 high ET patients [p=0,037 with Fisher's exact (one-sided) and p<0,05 with Kaplan Meier survival estimate]. PRV-1 plasma levels were independent of the white blood cell (WBC) count, suggesting that it constitutes an independent parameter for the assessment of thrombotic risk in ET. *Conclusions*. We could identify two different groups of ET patients are heterogeneous with respect to their PRV-1 protein plasma levels. In our prospectively analyzed cohort, individuals with high PRV-1 plasma levels seem to have a higher probability for developing either a TIA or a stroke.



(A) The level of PRV-1 plasma protein was measured with a sandwich ELISA in 55 PV and 89 ET patients as well as 100 age matched healthy controls (HC). PRV-1 concentrations between groups were analyzed using Kruskal-Wallis One Way ANOVA on ranks and the Mann-Whitney Rank Sum test (* p<0,05 for PV vs. healthy control and vs. ET). (B) Kaplan Meier survival estimates for the probability of development of a TIA in ET patients with high and low PRV-1 plasma levels (p<0,05 for PRV-1 high ET vs. PRV-1 low ET).

Figure 1. PRV-1 Plasma levels in MPD.

INCREASED EXPRESSION OF THE ATP9A GENE IN ESSENTIAL THROMBOCYTHEMIA

A. Vaz,[1] E.P. Silva,[1] M.G. Silva,[2] E. Paixão,[1] A.M. Pereira,[3] P. Lúcio,[4] A.S. António,[5] P. Jordan,[1] L.M. Vieira[1]

[1]Instituto Nacional de Saúde Dr. Ricardo Jorge, LISBOA; [2]Instituto Português de Oncologia, LISBOA; [3]Hospital Garcia de Orta, ALMADA; [4]Hospital Militar de Belém, LISBOA; [5]Hospital de São Bernardo, SETÚBAL, Portugal

Essential thrombocythemia (ET) is a chronic myeloproliferative disorder whose molecular pathogenesis has been associated predominantly with a somatic mutation in the JAK2 gene (JAK2V617F). However, JAK2V617F is not present in approximately half of ET patients and those that are positive for the mutation display hematological and clinical features that more closely resemble polycythemia vera. These data indicate that other genetic abnormalities may account for megakaryocyte hyperplasia in ET. We have previously found an ET patient with a 550-kilobase deletion at chromosome 20q13 that included the nuclear factor of activated T-cells cytoplasmic 2 (NFATC2), ATPase class II type 9A (ATP9A) and SAL-like 4 (SALL4) genes. We observed that diminished NFATC2 transcription factor activity as a result of drug-induced inhibition of NFATC2-calcineurin interaction leads to megakaryocyte proliferation and decreased cytokine expression in an ET-derived cell line (SET-2). We now report molecular analysis of the yet uncharacterized ATP9A gene in ET patients. Bioinformatic analyses predicted that ATP9A contains 7 plasma transmembrane regions and shares a 39% aminoacid similarity with plasma membrane Ca^{2+} atpase 4b (PMCA4b) protein including a putative calcineurin-binding domain. This indicates that ATP9A may regulate the activity of NFATC2 through interaction with calcineurin. Screening of the entire coding sequence (28 exons) of ATP9A in granulocyte DNA (6 samples) and mononuclear cell mRNA (16 samples) by polymerase chain reaction (PCR) and direct sequencing showed no presence of mutations in ET patients. We also used quantitative-PCR to determine ATP9A mRNA levels in granulocytes and mononuclear cells isolated from peripheral blood of ET patients and normal individuals. Quantification of ATP9A expression was normalized to ABL transcript numbers. We found that the ATP9A gene is expressed at significantly higher levels in ET patients compared to normal individuals in either granulocytes (t-test: p<0.001) or mononuclear cells (Mann-Whitney test: p<0.05). No significative differences were found between the level of ATP9A expression and JAK2V617F-positivity (14 patients) or JAK2V617F-negativity (10 patients) in granulocyte DNA (Mann-Whitney test: p=0.266). ATP9A mRNA expression levels in SET-2 cells were not affected using siRNA-mediated NFATC2 suppression or inhibition of NFATC2-calcineurin interaction, indicating that NFATC2 does not regulate transcription of ATP9A. In conclusion, our results indicate ATP9A as a novel candidate gene that operates in the calcineurin-NFATC2 pathway and reinforce the notion that this pathway plays a role in the etiology of ET.

0891

SOCS3 TYROSINE PHOSPHORYLATION AS A BIO-MARKER FOR THE MYELOPROLIFERATIVE DISORDER-ASSOCIATED MUTANT JAK2 KINASES

K. Nahlik,[1] J. Elliott,[1] Y. Suessmuth,[1] L.M. Scott,[2] M.F. McMullin,[3] S.N. Constantinescu,[4] A.R. Green,[2] J.A. Johnston[1]

[1]Queen's University Belfast, BELFAST, UK; [2]Cambridge Institute for Medical Research, University of Cambridge, CAMBRIDGE, UK; [3]Dept of Haematology, Belfast City Hospitals Trust, BELFAST, UK; [4]Ludwig Institute for Cancer Research, BRUSSELS, Belgium

Background. Polycythaemia vera (PV) is a myeloproliferative disorder (MPD) attributed to a somatic mutation in Janus kinase (JAK) 2, resulting in a valine-to phenylalanine substitution at position 617 (V617F). Recently, other mutations within JAK2 have been identified in patients with V617F-negative PV. Like JAK2 V617F, these exon 12 mutations render JAK2 constitutively active and confer cytokine-independent growth *in vitro*. Suppressor of cytokine signalling (SOCS) 3 is a key negative regulator of the erythropoietin receptor (EPOR) and the receptor-associated JAK2 kinase. We have shown before that JAK2 V617F tyrosine phosphorylates SOCS3 and escapes its inhibition. *Aims*. To establish if SOCS3 is stabilised and phosphorylated by the other MPD-associated mutant exon 12 JAK2 kinases. *Methods*. Transfection of EPOR, SOCS3 and JAK2 mutants into HEK293T cells followed by analysis of protein expression and phosphorylation; Analysis of proliferation of stable BaF3 cells lines expressing EPOR along with wt and mutant JAK2; Treatment of cells with JAK inhibitors; Analysis of SOCS3 phosphorylation in PBMCs and granulocytes isolated from a healthy control or MPD patients with JAK2 exon 12 mutations. *Results*. The JAK2 exon 12 mutants described in a subset of V617F-negative MPD cases are able to stabilise tyrosine phosphorylated SOCS3. SOCS3 tyrosine phosphorylation was also observed in peripheral blood mononuclear cells and granulocytes isolated from patients with JAK2 H538QK539L or JAK2 F537-K539delinsL mutations. JAK kinase inhibitors, which effectively inhibited the proliferation of cells expressing V617F or K539L, also caused a dose-dependent reduction in both mutant JAK2 and SOCS3 tyrosine phosphorylation. *Conclusions*. We propose therefore that SOCS3 tyrosine phosphorylation may be a novel bio-marker of MPDs resulting from a JAK2 mutation and a potential reporter of effective JAK2 inhibitor therapy currently in clinical development.

0892

CONCURRENT JAK2 V617F MUTATION AND BCR-ABL REARRANGEMENT IN A ESSENTIAL THROMBOCYTHEMIA PATIENT

E Novella, M. Bernardi, F. Pomponi, E. Peotta, F. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Myeloproliferative disorders (MPDs) are clonal hematopoietic diseases, distinct from Philadelphia chromosome positive (Ph^+) chronic myeloid leukemia (CML) for the absence of BCR-ABL. Previously the coexistence of BCR-ABL fusion transcript and JAK2V617F mutation has been reported in a few cases of both Polycythemia Vera (PV) and Myelofibrosis, their coexistence appearing during the evolution of the disease. Only in one case of myelofibrosis and one case of PV these two abnormalities were observed at diagnosis (Cambier 2008). We described here a 46-year old woman referred at our hospital because of marked thrombocytosis (1406×10^3/μL PLTS) and leukocytosis (27.9×10^3/μL WBC); Hb levels were normal and differential leukocyte count showed: neutrophils 70%, eosinophils 1%, basophils 4%, lymphocytes 14%, monocytes 7%, metamyelocytes 1%, myelocytes 3%. She showed erythromelalgia at both feet and complained of intermittent left limbs paresthesia. Molecular investigation showed a BCR-ABL

fusion transcript b2a2b type and AS-PCR detected the JAK2V617F mutation. Conventional karyotype and FISH analysis confirmed the presence of t(9;22) in 100% of cells. *Aims*. To evaluate the concomitant BCR-ABL rearrangement and JAK2V617F mutation in the same clone, we performed clonogenic assays. Patient follow-up was monitored using real-time quantitative-PCR for both molecular abnormalities. *Methods*. Erythroid colonies cultures were prepared by isolating peripheral blood mononuclear cells on Ficoll-Hystopaque density gradient (Sigma-Aldritch); harvested cells were washed and risospended in RPMI medium solution (Sigma-Aldritch). Mononuclear cells were plated at final concentration of 2.5 -105 cells/mL in Methocult medium with 3 units/mL Epo (Methocult GF H4434) and without Epo (Methocult GF H4534), (StemCell Technologies). Cultures were incubated at 37° C in a humidified atmosphere of 5% CO_2. Erytroid colonies were scored on day 14 and 19. Thirty-eight individual colonies were plucked and submitted to RNA extraction following RNAqueous-Micro Micro scale RNA isolation kit instruction manual (Ambion 1931). BCR/ABL rearrangement and JAK2V617F were tested using qualitative-PCR assay. Furthermore quantitative-PCR for bcr/abl and JAK2 was performed at diagnosis and in 3 follow-up samples collected monthly during Imatinib treatment. *Results*. As previously described for chronic phase CML patients the culture pattern was characterized by excessive scattering of CFU-GM and poorly hemoglobinized BFU-E with atypical morphology. None of the colonies showed the coexistence of both molecular abnormalities. During the follow-up, quantitative-PCR analysis showed a 2,37 logarithmic decreased of BCR/ABL copy number, whereas the JAK2 V617F allele burden showed a trend towards a progressive decrease from 46% at diagnosis to 32% in the last sample. *Conclusions*. Here we report the first case of ET with V617F mutation and concomitant Ph^+ CML in a patient at initial presentation. Clonogenic assays suggest the coexistence of two distinct myeloproliferative disorders involving different clones. Imatinib therapy induced normalization of the patient's blood white cells and platelets count within two months, with a decrease in both BCR/ABL fusion transcript and JAK2 V617F allele burden, contrary to previous observations about a JAK2 V617F clone expansion in patients who responded to CML therapy.

0893

NATURAL EVOLUTION OF JAK2V617F ALLELE BURDEN IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA PATIENTS NOT RECEIVING CYTOREDUCTIVE TREATMENT

C. Besses, A. Alvarez-Larran, L. Martínez-Avilés, R. Longarón, S. Serrano, B. Bellosillo

Hospital del Mar, BARCELONA, Spain

Background. The natural evolution of the mutant allele burden in JAK2V617F-positive polycythemia vera (PV) and essential thrombocythemia (ET) patients not receiving cytoreductive therapy has not been extensively studied. *Aims*. To analyze the evolution of the JAK2V617F allelic burden in untreated PV and ET patients. *Patients and Methods*. A cohort of 45 JAK2V617F-positive patients (21 PV and 24 ET) consecutively diagnosed in a single institution according to WHO criteria were included in a prospective study. No patient received cytoreductive treatment during the study period. PV patients were treated with phlebotomies to maintain an Hct below 0.45 L/L (M) and 0.42 L/L (F), plus low-dose of aspirin. ET patients were clinically observed and/or received aspirin. JAK2V617F allelic burden was determined at diagnosis and every 6-12 months during follow-up. JAK2V617F was quantified in purified granulocytes by allele-specific real-time PCR assay. Determination of the relative change of the allelic ratio of JAK2V617F was calculated as follows: (% last JAK2V617F minus % first JAK2V617F) divided by % first JAK2V617F x 100. *Results*. Median follow-up was 49 (9-72) and 45 (9-67) months for PV and ET, respectively (p=0.211). All ET patients and 16 out of 21 (76%) PV patients were heterozygous for the JAK2V617F mutation; the remaining five PV patients were homozygous. A mean number of 5 samples per patient were drawn during the study. Thirty-eight patients (84%) were evaluated at month 24. The mean percentage of JAK2V617F allele load at time of first sample was 45±20 and 25±7 for PV and ET, respectively (p<0.001). The mutant allele load at 24 months was 65±48 for PV patients and 26±7 for ET patients, with the difference being statistically significant (p=0.012). The mean JAK2V617F allele variation was 31±40 and 6±18 for PV and ET, respectively (p=0.02). *Conclusions*. The natural evolution of JAK2V617F allele burden showed a progressive increase in PV whereas it remained stable in ET at 2 years of follow-up.

0894

POLYCYTHEMIA VERA (PV) BUT NOT ESSENTIAL THROMBOCYTHEMIA (ET) REDUCES THE LIFE EXPECTANCY IN ELDERLY

F. Tezza, E. Ruzzon, S. Zambon, E. Manzato, F. Fabris, M.L. Randi

University of Padua, Medical School, PADUA, Italy

Background. Malignancies are more common in old people. Also myeloproliferative neoplasms interest mainly median-advanced age, with a mean age at diagnosis of 60-70 years. A Sweden study has demonstrated that the incidence of PV and ET increases progressively with age, achieving 12-16/100000 inhabitants/year and 5-7/100000/year respectively in patients over 70 years. Life expectancy is the main concern of patients with PV and ET at the time of the disease diagnosis, but the studies on this issue are relatively scarce. There is some evidence that life expectancy of PV patients is reduced when compared with that of the general population, whereas the survival of patients with ET is not significantly shortened. In this prospective observational study over 7 years we evaluated the survival of old patients with PV and ET compared with that of a control population. *Patients*. Our study included 205 patients (PV 102 cases, 45 males and 57 females; ET 103 cases, 30 males and 73 females) diagnosed in our Department in agreement with the criteria in use at the time of first observation. All the patients were older than 65 years at the time of diagnosis. As controls we used 3099 (1245 men and 1854 women) age- and sex-stratified subjects of the Progetto Veneto Anziani (Pro.V.A.) Study, an observational cohort study of the Italian population aged 65 years and older. Both patients and controls lived in the same geographical area of east-south Veneto, Italy. *Statistical analysis*. The Kaplan-Meier product-limit method was used to estimate univariate survival curves and the log-rank test was adopted to compare the survival curves. The chi-square test was used for categorical variables. All analyses were performed using SPSS 16.0 software. *Results*. During the 7 years follow-up period, 64 (62.7%) patients with PV, 42 (40.7%) with ET and 745 (24%) controls were died. The death rate of PV was higher than that of ET (p=0.0016). Therefore, the survival probability of PV patients resulted lower than that of ET (p=0.012). Comparing the survival of patients with that of general population we did not find a significant difference; however, while the survival curve of ET is superimposed to the curve of general population, the survival curve of PV appeared clearly diverging (Figure 1). *Discussion*. This study shows that, among old people, PV patients have a life-expectancy reduced as compared to ET patients, while the life-expectancy of ET does not seem different from that of the general elderly population. In spite of a higher death rate of PV than ET patients the differences of the survival curves is not statistically different. When compared to control population probably because of a low number of PV patients.

ANALYSIS OF BONE MARROW PATHOLOGY, ANGIOGENESIS AND CLINICAL PARAMETERS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE DISORDERS

A.G. Zhelyazkova, L.T. Gercheva, P. Kolova, B. Tonchev

Varna University of Medicine, VARNA, Bulgaria

Background. The abnormal megakaryocytic proliferation, dysplastic changes in megakaryocytes (MKC) and fibrosis are phenomena associated with chronic myeloproliferative disorders (MPD) as idiopathic

myelofibrosis (IM), polycythaemia vera (PV) and essential thrombocythaemia (ET). Substantial data have been accumulated about the increased angiogenic activity in these disorders as well. It is not elucidated the relation between the established histo-pathological criteria and angiogenesis and clinical characteristics in these patients. *Aims*. The present study aimed to analyze patients with Ph-negative MPD according to the proposed clinico-pathological criteria, the level of bone marrow (BM) angiogenesis and MKC pathomorphology. *Materials and Methods*. Totally of 134 patients were analyzed (45 with IM, 38 with PV, 39 with ET and 12 controls) after the informed consents were obtained. We used standard methods for BM analysis (hematoxyllin-eosin and Gomori staining) as well as specific immunoperoxidase technique for immunohistochemistry (anti-von Willebrand Factor (vWF) as an endothelial and megakaryocytic marker and anti-Vascular Endothelial Growth Factor (VEGF) antibodies). SPSS 15.0 for windows was used for the statistical analysis. *Results*. We found most increased microvessel density (MVD) in patients with IM (77,4±23/mm^2), comparing to PV, ET and control groups (50±19/mm^2, 49.4±17.8/mm^2 and 13±5,2 mm^2 resp.). The analysis of the micro-megakaryocytic population showed statistically increased mean number in patients with IM (25,25±11.25/mm^2) comparing to PV and ET (11.97 and 8.10, resp.). The highest VEGF expression by MKC was found in IM patients (VEGF index 3.38±0.72) as compared with PV and ET (2.08±0.65 and 2.31±0.72 resp.). We subdivided the IM patients into the following clinicopathological stages: early-prefibrotic (N=9), manifest (N=6) and advanced stage (N=25). When we reanalyzed the MVD and the level of fibrosis with regard to the stages, the MVD was found to be significantly higher in the advanced stage of IM (p<0.007) and we confirmed a significant positive correlation between these two parameters as well (r=0.51, p<0.001). In IM patients we confirmed significant correlations between MVD and overall survival (OS), degree of fibrosis (DF), transfusion dependency and splenomegaly. In PV group significant positive correlations were shown between MVD and the patient's risk and DF. *Conclusions*. In cases with thrombocytosis and mild fibrosis, the analysis of the level of neo-vascularization, VEGF expression by MKC and micro-megakaryocytes could serve as differentiation markers among the earlier stages of MPDs. The analysis of VEGF and vWF expression by MKC could extend the morphological assessment of MKC dysplasia which is a characteristic feature for IM. MVD could serve as a diagnostic marker as well as a parameter for determining the risk in patients with IM and PV but not in ET. We propose a routine use of anti-vWF antibody as an easily approachable method that could be used in visualizing the micro-vessel density, vessel structure and micro-megakaryocytic populations. In the present study we confirm the predictive value of MVD with respect to the overall survival of IM patients.

0896

THY-1, C-KIT AND TFR EXPRESSIONS ON CD34+ MYELOBLASTS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND THEIR RELATIONS TO IPSS

M. Atfy

Hospital of Zagazig University, ZAGAZIG, Egypt

Background. Myelodysplastic syndromes (MDSs) are heterogeneous diseases of bone marrow cell precursors for which immunophenotypic characterization is still considered irrelevant despite the accuracy and sensitivity of flowcytometry (FCM) techniques. *Aims*. The aim of this study is to estimate the antigenic expression of Thy-1, c-Kit and TfR on the CD34$^+$ blasts in Bone marrow (BM) aspirates from *de novo* and therapy related MDSs (t-MDSs) patients to determine their prognostic values in relation to cytogenetic risk factors as defined by International Prognostic Scoring System (IPSS). *Methods*. this study was carried out on 20 patients with *de novo* MDSs and 12 patients with t-MDSs. All patients were diagnosed by history taking, clinical examination and laboratory investigations including: CBC, BM aspiration for morphological assessment, and cytomorphological classification according to WHO classification, cytogenetic analysis then IPSS formulation and BM immunophenotyping using monoclonal antibodies to select CD34$^+$ blasts in addition to monoclonal antibodies to detect co-expression of Thy-1,c-Kit or TfR on these CD34$^+$ blasts *Results*. clonal chromosomal abnormalities were detected in 55% (11/20) of *de novo* MDSs, [more frequent in the advanced 71.4% (5/7) than in the initial stages 42.9% (6/13)]. T-MDSs show higher frequencies of karyotype abnormalities 91.7% (11/12) most of them 58.3% (7/12) had abnormality in chromosome 5, 7 or both. Blast cells of almost all cases were myeloblasts, (CD13+, CD33+, HLA-DR+), 59.4% (19/32) had CD34 expression, [50% (10/20) of *de novo* MDSs and 75% (9/12) of t-MDSs]. Most patients with CD34$^+$ blasts were belonging to poor prognosis. Thy-1 and c-Kit was co-expressed with CD34 in 26.3% (5/19) and 57.9% (11/19) respectively. 80% of Thy-1 and 81.8% of CD117 were categorized in intermediate-2 and high risk IPSS indicating poor prognosis. TfR was co-expressed with CD34 in *de novo* MDSs only [15.8% (3/19)]. *Summary and Conclusions*. estimation of co-expression of Thy-1, c-Kit or TfR on CD34$^+$ blast cells using FCM in MDSs patients is an easy and reproducible test that allows evaluating the prognosis of MDSs cases with CD34$^+$ blasts. Co-expression of Thy-1 or c-Kit indicate more immature CD34$^+$ blasts, high risk IPSS classification and poor prognosis while co-expression of TfR indicate more mature CD34$^+$ blasts, low risk IPSS classification and good prognosis. So not only the presence of CD34 but its association with other markers plays a major role in MDSs prognosis.

LANGERHANS CELL HISTIOCYTOSIS IN CHILDREN - DIAGNOSIS, TREATMENT AND FOLLOW-UP

S. Glamocanin,[1] O. Muratovska,[1] K. Martinova,[1]
Z. Trajkova-Antevska,[1] B. Conevska,[1] S. Koceva,[1] G. Petrusevska[2]

[1]*University Children's Hospital, SKOPJE;* [2]*Institute of Pathology, SKOPJE, Macedonia*

Background. Langerhans cell histiocytosis (LCH) is a rare disease. It is characterized by the clinical heterogeneity of the disease and by the pathogenesis that is still poorly understood. It is regarded as clonal accumulation and proliferation of abnormal bone marrow derived Langerhans cells. *Aims*. To present the experience of University Children's Hospital in Skopje regarding to epidemiological features, diagnosis, treatment and follow-up of LCH in children. *Methods*. We present a retrospective analysis of 54 patients with LCH treated in Department of Hematology/Oncology from January 1977 to January 2009. Analysis of clinical presentation, diagnostic features, treatment and outcomes was carried out. *Results*. During the study period, 54 cases of histology proven LCH (31 males and 23 females) were analyzed. The age at diagnosis ranged from 3 to 192 months. Six of fifty four children presented with unisystemic LCH involving the skin, 8/54 presented single bone lesion, 7/54 had multiple bone lesions and 32/54 presented with multisystem diseases (12 of them had organ dysfunction). All patients had a bone marrow aspirate examined at diagnosis in order to complete the staging of the disease. Because of a very long period of analysis there were different treatment procedures. The most common regimen until 1997 year was combination of Vinblastine and Prednisone. After 1997 year children were treated according to the international studies LCH-I and LCH-II. From 2003 we started to use LCH-III protocol and 6 patients were treated according to LCH-III. Mortality was 90% in group of patients with multisystem disease and organ dysfunction treated before 2003 year. Chemotherapy was unsuccessful in eight patients younger than 2 years of age with multisystem disease and organ dysfunction. They died in the range of 1 to 13 months after the diagnosis. Four children with multisystem disease and organ dysfunction were treated according to LCH III international study. Three of them are still alive with a survival of 12 weeks to 30 months. *Conclusions*. Patients with localized disease and absence of organ dysfunction benefited from standard therapy. More aggressive treatment is necessary for multisystem disease and organ dysfunction. The young children (younger than 2 years of age) with multisystem disease and organ dysfunction had a very poor outcome in our study. LCH-II and LCH-III protocol achieved more successful results than the treatment procedures used before.

0898

THROMBOSIS IN POLYCYTHEMIA VERA ARE LIKELY TO BE RELATED TO HIGHER JAK2V617F ALLELE BURDEN

I. Bertozzi, M. Scapin, F. Tezza, R. Scandellari, F. Fabris, M.L. Randi

University of Padua, Medical School, PADUA, Italy

Background. Polycythemia vera (PV), one of the Philadelphia-negative myeloproliferative neoplasms (MPD), arises from clonal proliferation of a pluripotent stem cell. In 2005 the JAK2V617F mutation was found in about 90% of patients with PV. Many Authors found some correlations between the presence of the mutation and the clinical course of MPD, however, the results are not all in agreement. Some studies are available regarding the significance of different allele burden in essential thrombocythemia but not in PV. The aim of our study was to compare the JAK2V617F allele burden with ultrasound splenomegaly over 12 cm of cephalocaudad diameter, the occurrence of major thrombosis or hemorrhages at diagnosis or during follow-up and evolution into myelofibrosis, in patients with PV. *Material and Methods*. We studied 72 patients affected by PV (32 males and 40 females, mean age at diagnosis 60.1±14.5 y, median follow-up 7.8 y) diagnosed in agreement with WHO 2008 criteria and, as controls, 9 patients with secondary erythrocytosis (7 males, 2 females, mean age at diagnosis 52.76±17.2 y, median follow-up 1.99 y). The JAK2V617F allele burden was determined with PCR real time, by using Sybr Green as detector and on the basis of these results we stratified our patients in different percentiles of allele burden (<50%, ≥50% and its subgroup ≥80%). Statistical analysis was performed with Student's t test. *Results*. As attended, 0% allele burden was found in controls and in 10 wild type (WT) PV patients. 24 PV had <50% (12.2±10.2%) and 38 ≥50% (79.8±15%) allele burden; within the last group 20 patients had ≥80% (91.7± 6.6%) allele burden. The mean allele burden in the 43 patients with splenomegaly (65.7±30.5%), in the 30 with thrombotic complications (60±36%) and in the 15 evolved into myelofibrosis (77.2±32%) but not in the 17 cases with hemorrhage was higher (respectively p=0.0001, p=0.02 and p= 0.0003) than in patients without complication (splenomegaly 25.6±26.2%, thrombosis 42.8±33% and myelofibrosis 43.7±32.4%). Stratifying the patients, the significance is confirmed for thrombosis in patients with allele burden ≥50% (83.6±16.5 and 75±12.5, p= 0.03) and in a greater way in patients with allele burden ≥80% (93.4±5 and 87.7±6.7, p=0.02) *Conclusions*. In agreement with the literature, most of our PV patients carry JAK2V617F mutation; about half of them had an allele burden >50%. Higher JAK2V617F allele burden were associated with splenomegaly, thrombosis and evolution into myelofibrosis. In particular, thrombosis are more likely to be related to high (>50%) JAK2V617F allele burden. The JAK2V617F allele burden evaluation has a significant value in the prognosis of patients with PV.

Seragnoli, University of Bologna, BOLOGNA, Italy

Background. There is evidence that leukocytosis is associated with an increased risk of first thrombosis in patients with polycythemia vera (PV) and essential thrombocythemia (ET). Whether it is a risk factors for recurrent thrombosis too is currently unknown. *Aims*. In order to investigate the impact of leukocytosis on the risk of recurrent thrombosis in patients with PV and ET, we carried out a multicenter retrospective cohort study. *Patients and Methods*. We recruited 253 patients with PV (n=133) or ET (n=120), with previous arterial (70%) or venous major thrombosis (27.6%) or both (2.4%), and not receiving cytoreduction at the time of thrombosis. The median leukocyte count at that time was 10.2×10^9/L (range 3.1-24.9). The total observation time after thrombosis was 1,602 pt-years (median 5.5). The relative risk of recurrence was estimated as a hazard ratio (HR) using a Cox proportional hazards regression model. The HR was adjusted using recurrence as the dependent variable and selecting as covariates gender, diagnosis (PV or ET), age at the time of the initial thrombosis (>60 or <60 years), presence of one or more vascular risk factors, history of remote thromboses, type of first thrombosis (arterial or venous), leukocytosis at the time of the first thrombosis, and type of treatment following thrombosis. *Results*. Thrombosis recurred in 78 patients (30.7%); after adjustment for potential confounders, age >60 years at the time of the first thrombosis was an independent predictor of recurrence (HR, 1.83, 95%CI 1.12-2.96) and recurrence was prevented either by antiplatelet treatment (HR 0.38, 95%CI 0.18-0.76) and cytoreduction (HR 0.44, 95% CI 0.27-0.70). The patients with a leukocyte count in the highest quartile $>12.4\times10^9$/L at the time of their first thrombosis showed an increased risk for arterial recurrence in respect to all the remaining patients (multivariable HR, 1.95, 95%CI 1.0.3-3.66).The increased risk for arterial recurrence associated with leukocytosis was confirmed among patients <60 years (HR 3.07, 95%CI 1.18-7.96). Leukocytosis was not significantly associated with the risk for recurrence among the patients >60 years neither predisposed to venous recurrences. After the second thrombosis the risk for a further thrombotic event was analyzed by multivariable analysis of the 78 patients having had a recurrence. After adjustment for the potential confounders aforementioned, the hazard for a third thrombotic event between the patients with previous leukocytosis and those without was still increased, but without reaching the statistical significance (HR 2.73, 95%CI 0.86-8.59). *Conclusions*. In the younger patients with PV or ET leukocytosis at the time of first thrombosis is associated with an increased risk of future arterial thrombotic events. It can be suggested that leukocytosis could be an important tool of stratification of the patients not only among the low risk individuals without history of thrombosis but also among the young high risk individuals with a previous history of thrombosis.

EVALUATION OF ZAP-70 EXPRESSION BY MEAN FLUORESCENCE INTENSITY T/B RATIO IS A MORE USEFUL PREOGNOSTICATOR THAN PERCENTAGE OF POSITIVE CELLS IN CHRONIC LYMPHOCITIC LEUKEMIA

F.M. Rossi,[1] D. Rossi,[2] M.I. Del Principe,[3] F. Luciano,[3] A. Zucchetto,[1] P. Bulian,[4] M Irno Consalvo,[3] R. Bomben,[1] M. Dal-Bo,[1] D. Benedetti,[1] M. Degan,[1] G. Gaidano,[2] G. Del Poeta,[3] V. Gattei[1]

[1]Centro di Riferimento Oncologico, AVIANO; [2]Amedeo Avogadro University of Eastern Piedmont, NOVARA; [3]S.Eugenio Hospital and University of Tor Vergata, ROME; [4]Centro di Riferimento Oncologico, Istituto di Ricovero e Cura a Carattere Scien, AVIANO, Italy

Background. Expression of the T-cells constitutive ZAP-70 protein by chronic lymphocitic leukemia (CLL) cells has been the focus of many studies in the last few years, due to its ability to stratify indolent and more aggressive disease subsets. Although the strength of ZAP-70 as independent negative prognosticator was demonstrated by several studies, concerns about its use derive from a lack of multicentric standardization of flow-cytometric protocols. Analyses in clinical settings are usually performed according to two methods, respectively evaluating the percentage of CLL cells expressing ZAP-70 compared to isotypic control (ISO-method), or to autologous T-cells (T-method). Of note, while the two methods yield concordant results in most patients, a fraction of cases may be discordant as for evaluation of ZAP-70 positivity. Moreover, either method suffers of an operator dependent variability, mainly related to subjectivity in cursor placement to determine the percentage of ZAP-70+ cells. *Aims*. To compare the ISO- and T-methods with the expression of ZAP-70 evaluated as Mean-Fluorescence-Intensity (MFI) Ratio between gated T and CLL cells (T/B-Ratio-method), and to assess the prognostic significance of the three approaches. *Methods*. Cytometric files relative to ZAP-70 determination according to the three readouts were retrospectively reviewed with BD-DiVa software on a cohort of 173 patients (test set), all with complete clinical and biological prognostic assessment and time-to-treatment (TTT) available. Findings were then validated in an independent cohort of 187 cases from a different institution (validation set). In the two cohorts, ZAP-70 assessment was accomplished using different antibody combinations and different instrumentations for data acquisition. *Results*. ZAP-70 expression was reviewed in the test set by applying the ISO- and T-methods. Utilizing in both cases the 20% of ZAP-70+ cells, selected as the optimal cut-off with prognostic relevance also in this series, 29 (ISO-method) and 63 (T-method) ZAP-70+ cases were defined. By applying the TRatio-method, a value of 3.0 was identified as the optimal prognostic cut-point. According to this value, 75 ZAP-70+ cases (i.e. with Ratio<3.0) were identified in the test set. Univariate analyses resulted in a better separation of ZAP-70+ vs ZAP-70- CLL patients utilizing the T/B-Ratio-method (p=6.8e-06), compared to T- (p=1.94e-05) or ISO- (p=4.35e-3) methods. In multivariate analyses with RAI stage, β2microglobulin, IGVH, FISH, CD38 and CD49d, ZAP-70 was selected as independent risk factor, irrespective of the readout employed for evaluation of ZAP-70 expression; however, the prognostic impact of ZAP-70 appeared stronger when the T/B-Ratio-method was applied (significative hazard ratio=2.2 vs 1.8 with the ISO- or T-methods). To confirm these findings, we analyzed the 187 cases of the validation set with T-method (cut-off=20%) and TRatio-method (cut-off=3.0). Analyses yielded 99 (T-method), and 66 (Ratio-method) ZAP-70+ cases. Univariate analyses also on this cohort resulted in a better separation with T/B-Ratio-method (p=9.8e-07) than T-method (p=3.15e-05). *Conclusions*. We suggest to evaluate ZAP-70 expression in routine settings using the TRatio-method given the operator and laboratory independent feature of this approach. We propose the 3.0 Ratio value as optimal cut-off to discriminate ZAP-70+ (TRatio less than 3.0) from ZAP-70- (Ratio more/equal than 3.0) cases.

MALDI-TOF MS PROFILING TO EXAMINE THE PROTEIN CONTENT IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

S. Bossio,[1] G. Cutrona,[2] M. Gentile,[1] E. Vigna,[1] E. Lucia,[1] C. Mazzone,[1] S. Matis,[2] S. Franzese,[1] P. Servillo,[1] V. Gigliotti,[1] M. Le Pera,[3] E. Urso,[3] S. Fabris,[4] S. Cavalcanti,[1] A. Neri,[4] M. Ferrarini,[2] A. Qualtieri,[3] F. Morabito[1]

[1]U.O.C. di Ematologia, Azienda Ospedaliera di Cosenza, COSENZA; [2]Divisione di Oncologia Medica C, Istituto Nazionale per la Ricerca sul Cancro, GENOVA; [3]Istituto di Scienze Neurologiche (ISN), CNR Piano Lago, Cosenza, COSENZA; [4]Centro di Ricerca per lo Studio delle Leucemie, Università di Milano, MILANO, Italy

Background. Chronic lymphocytic leukemia (CLL) is characterized by the expansion of monoclonal mature B lymphocytes with an extremely heterogeneous clinical course possibly due to the acquisition of specific chromosomal abnormalities, the mutational status of immunoglobulin variable heavy chain gene (IgVH), and the expression of CD38 and ZAP-70 proteins. However, these prognostic tools have yet to be implemented on a widespread basis due to combinations of cost, test availability, and validation of their clinical specificity. *Aims*. To provide insights into the proteomic complexity of CLL, identifying proteins potentially of prognostic value, and thus offering insight into the underlying biology of the malignant B cell. *Methods*. A panel of highly purified neoplastic cells (>92%) from 25 untreated, newly diagnosed CLL patients in Binet A was investigated. We used the proteomic technologies MALDI-TOF MS profiling to examine the protein content of CLL B cells. Highly purified B lymphocytes were subjected to cell lysis, followed by sub-fractionation of nuclear, microsomal and water-soluble components. An aliquot of this last fraction underwent a desalting/concentration step over ZipTip C18 and peptide/protein profiles were analyzed using a VoyagerDE PRO MALDI-TOF mass spectrometer (PerSeptiveBiosystems). Separate spectra were obtained for a restricted mass-to charge (m/z) range (1000-25000 Da) in linear mode geometry, by applying an acceleration voltage of 25 kV. The acquired spectra, assayed in duplicate, were then processed for automated advanced baseline correction and noise. The peak area of each signal was normalized by presenting as a percentage of the total peak area (individual peak area/total peak area per cent). A hierarchical clustering analysis, with Pearson correlation as similarity metrics and an average linkage as a cluster method, was also performed using Cluster 3 and TreView software. *Results*. Clustering analysis, comprising the CD38 values, [i.e. CD38> 30% (5 cases) versus CD38<30% (20 cases)], separated two well distinct branches. Furthermore, a student's t test applied to CD38 this two groups, allowed the identification of 14 differentially expressed ion signals with statistical significance (p<0.05). The same analysis was conducted using immunoglobulin variable IgVH values,(i.e. mutated (20 cases) versus unmutated (5 cases). Differently to CD38 results, clustering analysis by IgVH mutational status distinguished two not well separated major branches. Nevertheless, applying the student's t-test we have identified 7 differentially expressed ion signals with statistical significance (p<0.05). Moreover, comparing 14 and 7 differentially expressed ion signals achieved by two supervised analyses, 3 m/z values were shared by the two ion signal list (1256, 69; 1311, 55; 4939, 28 m/z values). *Conclusions*. With the delimitation of the number of cases analyzed, these preliminary results demonstrated that the B-CLL neoplastic cells may be classified on the basis of their protein/peptide content using the MALDI-TOF profiling analysis. Future studies might give complementary information concerning the molecular mechanism linked to the variable clinical course of the disease.

CHARACTERIZATION OF 22Q11 DELETION IN CLL PATIENTS

K. Malinova, B. Tichy, J. Malcikova, K. Stano Kozubik, M. Mraz, M. Doubek, J. Mayer, S. Pospisilova

University Hospital Brno and Medical Faculty, Masaryk University, BRNO, Czech Republic

Background. Several prognosticly relevant genomic aberrations have been described in chronic lymphocytic leukemia (CLL). Deletions in 13q14, 17p13, 11q22 and gains on chromosome 12 are present in approximately 80% of cases. However, the genome of CLL patients contains many additional genomic imbalances. Array-based comparative genomic hybridization (arrayCGH) enables detailed whole-genome screening of chromosomal aberrations. *Aims*. We analysed genome of CLL patients using oligonucleotide arrayCGH. In particular, we focused on searching for novel genomic alterations and aberrations poorly characterized so far

which could have a prognostic value. *Methods*. Peripheral blood samples from 40 CLL patients were collected. All commonly used molecular prognostic markers were assessed. Cytogenetic data (FISH or CpG/IL-2-induced metaphase cytogenetics) documented that all samples included to the study harboured at least one chromosomal aberration. DNA isolated from lymphocytes was hybridized on Human Genome CGH Microarray 4 x 44 K (Agilent) and compared to human reference DNA. To provide detailed analysis of the 22q11 deletion, clonal immunoglobulin recombinations detection according to BIOMED-2 protocol and supplementary sequencing was performed. *Results*. Chromosomal imbalances described by cytogenetic methods (FISH and caryotyping) were confirmed by arrayCGH in all cases. Additional aberrations were found in majority of samples (87,5%). Among them, the deletion of 22q11 locus ranging in size up to approximately 0.77 Mb was observed most often. This locus encodes several genes including lambda immunoglobulin light chain (IgL) subgenes. The presence of other coding genes (e.g. miR-650, VPREB1, PRAME) contradistinguishes IgL region from kappa light chain and heavy chain immunoglobulin loci. Gunn *et al.* (2008) previously characterized the minimally deleted region of 22q11 in CLL as 0,34Mb (containing PRAME, ZNF280A, ZNF280B and GGTLC2) and described PRAME (preferentially expressed antigen in melanoma) as a candidate gene with prognostic impact in CLL. We detected this recurrent deletion in 7 (17.5%) patients from our cohort, two cases exhibited biallelic loss. Detection of clonal immunoglobulin recombinations by PCR and sequencing enabled us to determine properly the deletion range and revealed that it corresponds to lambda variable rearrangement. Another six patients with rearranged lambda immunoglobulin gene have deletion smaller than published minimally deleted region, not including PRAME. This was represented by decreased intensity of one or two probes on the arrays thus cannot be reliably designated by statistical algorithm. Altogether, more than 30% patients (13/40) have IgL rearrangement. The deletion of specific genes localized within IgL depends on the subgene rearrangement. In our cohort, PRAME is deleted in about 50% of patients with IgL rearrangement. Another interesting gene miR-650 located between V3-9 and V2-8 lambda variable subgenes is deleted in majority of patients (92%). Based on these results, we assume physiological origin of 22q11 deletion arising from lambda immunoglobulin rearrangement. *Summary*. Recurrent deletion 22q11 is frequently detected in CLL patients. We suggest that deletion is caused by physiological process of lambda immunoglobulin variable region rearrangement. However, the possible pathogenetic or prognostic impact of PRAME or miR-650 deletion/expression cannot be excluded and further analysis is required.

IDENTIFICATION OF PEPTIDE SEQUENCES BINDING SPECIFICALLY TO THE BCR OF B-CLL CELLS

A.C. Carpinteio,[1] S. Keitsch,[2] M. Möllmann,[3] U. Dührsen,[3] J. Dürig,[3] E. Gulbins[2]

[1]University Hospital of Essen, ESSEN; [2]Institute for Molecular Biology, ESSEN; [3]Dept. of Hematology, University Hospital of Essen, ESSEN, Germany

Chronic lymphocytic leukemia of the B-cell type (B-CLL) is the most common leukemia in the Western hemisphere with an annual incidence of 3/100 000 people. Increasing evidence suggests that signals from the haemopoietic microenvironment including chronic antigenic stimulation of the B-cell receptor (BCR) causes a deficiency of apoptosis of B-CLL cells and thus may play an important role for expansion of the leukemic cell clone in the patient. To test the hypothesis of antigenic stimulation of B-CLL cells, we employed a phage display technique to identify peptide sequences binding to the antigenic BCR of leukemic cells. We were able to identify two pentamer peptide sequences with very similar consensus sequences binding to the antigenic B cell receptor of tumor cells from 12 of 15 CLL patients. Phages carrying the identified peptide sequences precipitated BCR immunoglobulins from different B-CLL tumor cell lysates (6 of 12), while no BCR immunoglobulins were precipitated from lysates of healthy B-cells (n=3), Mantle Cell Lymphoma cells (n=2) or Burkitt-Lymphoma cell lines (n=5). Phages carrying a random peptide sequence did not precipitate BCR immunoglobulins from B-CLL cell lysates (n=12). Furthermore, phages carrying the identified peptide sequences activated intracellular signalling in B-CLL cells, while phages carrying random peptide sequences did not. These data support the assumption that specific antigenic stimulation of the BCR may be involved in the selection and expansion of the malignant cell clone in B-CLL.

Background. Heat shock protein 27 (Hsp27, HSPB1) is a member of the small heat shock protein family and inhibits key effectors of the apoptotic machinery. While Hsp27 is expressed in many cell types and tissues, it is absent in all lymphoid cells as well as most lymphoma cells. In previous microarray-analyses, we found Hsp27 to be differentially expressed in the two prognostic subgroups of chronic lymphocytic leukemia (CLL). *Aims*. To evaluate Hsp27 gene-expression as prognostic marker for CLL. *Methods*. Hsp27 gene-expression was assessed in 113 CLL patients diagnosed at our institution using quantitative real-time PCR. Gene expression data were correlated with clinical data and CLL risk factors. Peripheral blood mononuclear cells (PBMC) of CLL patients were analyzed as well as CD19-sorted cells from normal controls and selected CLL patients. *Results*. Hsp27 gene-expression ranged from 0.25 - 27.1 (median: 2.15; mean: 3.318) compared to normal PBMC (set as 1). Expression correlated with LPL-expression (p=0.003) and mutational status (p=0.012). High Hsp27 gene-expression (>3.318) was significantly associated with unmutated IgVH-genes (p=0.007) and shorter time to first treatment (median 40 months vs. 128 months; p=0.008) [Figure 1: Kaplan Meier estimation showing time to first treatment in patients with high and low Hsp27 expression (cut off: 3.318)]. Binet-stages B and C showed significantly higher Hsp27 gene-expression compared to Binet-stage A (p=0.023). Hsp27 levels were higher in CD19$^+$ selected CLL cells compared to CD19 negative cells, healthy donor (HD) and low expression group showing similar values. In contrast, expression values differed up to 2 logs in the high expression group. *Conclusions*. Hsp27 represents a novel prognostic marker for CLL with the potential of a novel therapeutic target.

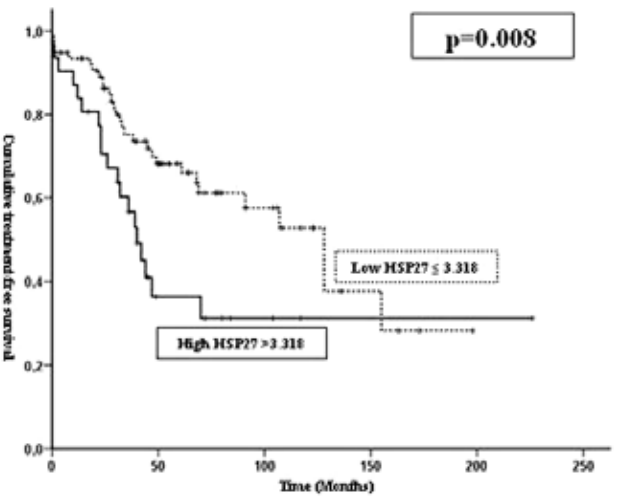

Figure 1. Time to first treatment.

Background. The identification of reliable prognostic factors useful in predicting patient outcome and planning therapeutic strategies is a crucial task to better define the clinical heterogeneity of B-cell chronic lymphocytic leukemia (B-CLL). Gene-specific hypermethylation and global hypomethylation have been previously reported in B-CLL. However, the relationship between aberrant global DNA methylation patterns and clinical and biological risk factors remained unclear. Global hypomethylation of repetitive genomic sequences, such as long interspersed nuclear elements-1 (LINE-1), Alu and satellite α DNA (SAT-α DNA) has been reported to be associated with chromosomal instability in human cancer. *Aims.* In order to investigate the role of global DNA methylation in B-CLL we quantified the methylation levels of Alu, LINE-1 and SAT-α and correlated them with the major biological, molecular and cytogenetic markers known to predict clinical outcome in B-CLL. *Methods.* A quantitative bisulfite-PCR Pyrosequencing method was used to evaluate the methylation patterns of Alu, LINE-1, and SAT-α in a panel of highly purified (>90%) peripheral mononuclear CD19+ cells from 7 healthy donors and 77 B-CLL untreated patients in early stage disease (Binet stage A). FISH, cytofluorimetric and IgVH mutation analyses were performed in all cases. Thirty-three cases carried the 13q14 deletion, 22 of which as the sole abnormality; biallelic 13q14 deletion was identified in 6 cases. Both 11q23 and 17p13 deletions were detected in 12 patients, whereas trisomy 12 was found in 19 patients as a sole exclusive abnormality. ZAP-70 and CD38 expression resulted positive in 29 and 35 cases, respectively, whereas IgVH genes were found to be unmutated in 48 patients. *Results.* The DNA from B-CLLs showed significant ($p<0.001$) decreased levels of methylation of all three types of repetitive elements when compared with controls (median 21.4%5mC vs. 25.9 %5mC, 66.8 %5mC vs. 85.7 %5mC, and 85.7%5mC, vs. 88.2 %5mC, for Alu, LINE-1 and SAT-α, respectively). Concerning the major cytogenetic abnormalities, a statistically significant correlation ($p<0.001$) was found between Alu, LINE-1 and SAT-α hypomethylation levels and the presence of the 17p13 deletion (Alu: 16.8.%5mC, LINE-1: 50.2 %5mC, SAT-α: 52.6%5mC) compared with patients without this lesion (22.4 %5mC, 68.6%5mC, and 85.0 %5mC, respectively). Notably, we found a statistically significant association between the methylation levels of Alu and LINE-1 as well as between Alu and SAT-α DNA and LINE-1 and SAT-α. (Pearson's correlations coefficient rho=0.64, 0.78 and 0.66, respectively; $p<0.001$). Finally, we did not observe any statistically correlation between global DNA methylation level and prognostic parameters such as IgVH mutation status, CD38 or ZAP-70 expression. *Conclusions*. Our study, based on a quantitative approach, extended previous evidence in global methylation in B-CLL and demonstrated a significant hypomethylation associated with high risk patients carrying the 17p deletion. Further studies on larger series would be useful to define whether global methylation levels may have a prognostic relevance in terms of B-CLL clinical outcome.

CHRONIC LYMPHOCYTIC LEUKEMIA CELLS RESCUE THEMSELVES BY INCREASING THE ANTI-APOPTOTIC EFFECT OF BONE MARROW STROMA

M. Plander,[1] S. Seegers,[2] P. Ugocsai,[3] S. Schwarz,[2] E. Orsó,[3] J. Ivanyi,[1] G. Brockhoff[2]

[1]County Hospital of Vas, SZOMBATHELY, Hungary; [2]Institute of Pathology, REGENSBURG, Germany; [3]Institute of Clinical Chemistry and Laboratory Medicine, REGENSBURG, Germany

Background. Chronic lymphocytic leukemia (CLL) cells are characterized by their ability to resist apoptosis. The *in vivo* enviroment seems to be responsible for the prolonged life span, because this biologic feature is lost *in vitro*. *Aims*. Our aim was to characterize the interaction between CLL cells and nourishing stroma and to study the effect of stroma on CLL cell survival. *Methods*. Sorted CLL cells from 21 patients were bred on allogenous, normal bone marrow stromal cells (BMSCs) or in culture medium. CLL cell survival was determined after 84 hours of culture by cell counting and propidium iodide/Annexin V staning. Cytokine secretion of BMSCs was measured by multiplex bead assay and mRNA expression in BMSCs and CLL cells by qRT-PCR. CLL cells were immunophenotyped before and after the cell culture. *Results*. BMSCs rescued CLL from apoptosis. In the presence of CLL cells BMSCs secreted antiapoptotic cytokines such as IL6 and IL8 more intensively and up-regulated ICAM-1 and CD40 mRNA expression. The expression of CXCL12 remained unchanged and VCAM1 was slightly increased. In turn, CLL cells bred on BMSCs up-regulated significantly the expression of CD18, CD49d - ligands for the critical adhesion molecules. *Conclusions*. These results indicate the manipulation of BMSCs by CLL cells in favour of apoptosis resistance.

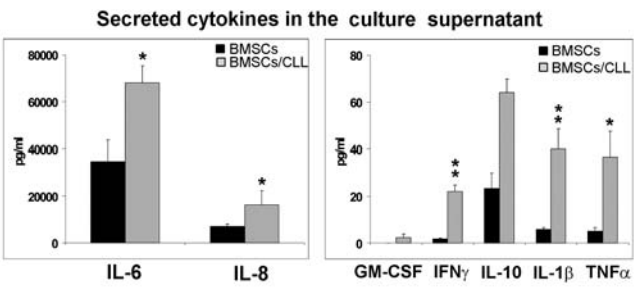

Figure 1.

RELATIONSHIP BETWEEN THERAPY AND CLONAL EVOLUTION OF TP53 ABNORMALITIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

J. Malcikova, J. Smardova, P. Kuglik, Y. Brychtova, M. Doubek, J. Kotaskova, B. Tichy, S. Pospisilova, J. Mayer, M. Trbusek

University Hospital Brno and Medical Faculty of Masaryk University Brno, BRNO, Czech Republic

Background. Although TP53 abnormalities are present at low proportion of CLL patients, their prognostic value is unequivocal. Patients with p53 inactivation are refractory to DNA damaging agents and it was suggested recently that chemotherapy may select resistant clones with inactivated p53. Non-genotoxic therapeutic approaches acting independently on p53 pathway are therefore recommended for patients with TP53 abnormalities. Currently, the monoclonal antibody alemtuzumab is the drug of choice. *Aims*. We studied the relationship between administration of therapy and clonal evolution of TP53 mutation and/or deletion by consecutive monitoring of these abnormalities in patients with originally intact TP53 gene. *Methods*. The deletions at the TP53 locus (17p13.1) were detected using an interphase FISH; mutations in the gene were analyzed by yeast functional analysis (FASAY) coupled to sequencing of templates from yeast colonies bearing mutated TP53 gene. *Results*. Repeated investigation of TP53 status was performed in 112 patients, which manifested no abnormality in this gene in original investigation (median follow-up 29 months, range 4-61 months). 55 patients were treated by at least one course of standard chemo and/or immunotherapy between analyses. In twelve cases a novel TP53 abnormality was

identified; all of them belonged to the subgroup of treated patients. In eight patients the novel TP53 mutation was accompanied by 17p deletion, three cases harboured sole mutation (in one patient FISH result was not available). Surprisingly, five of the patients with novel abnormality were treated with alemtuzumab between the investigations; in two patients alemtuzumab was the only treatment used, with no genotoxic agents administered. Novel TP53 aberrations had crucial impact on patients´ outcome: nine patients died in relation to disease within 1 to 37 months after abnormality detection (median survival 7 months). In contrast, no patient acquired a TP53 abnormality in the subgroup without therapy in the period between investigations. Median time of follow-up was comparable within both subgroups: untreated 27 months; range 4-57 months; group with acquired abnormality 22 months; range 7-51 months. It rules out the possibility that clonal evolution was observed due to a prolonged follow-up. Theoretically, the clonal selection of TP53 defects might be caused not only by the treatment itself, but also by the disease aggressivity (e.g. a more intensive proliferation of the cells). In this respect we have to point out that the proportion of patients with disease progression was lower in the untreated subgroup than in the treated subgroup (61% vs. 89%). *Summary*. TP53 abnormalities were selected during the course of the disease in a significant proportion of patients; they further contributed to disease aggressiveness. Although the exact biological mechanisms, which are involved in the acquisition of TP53 abnormalities, are currently unknown, the therapy plays obviously an important role in their selection. Our data surprisingly suggests that monoclonal antibody alemtuzumab may also contribute to selection of cells with TP53 mutations, probably by providing open niche for proliferation of more aggressive clone after eradication of original CLL population. This issue should be further analysed.

IGVH MUTATION STATUS AND ZAP-70 EXPRESSION AS INDICATORS FOR MOLECULAR PROFILING SIGNATURE IN B-CLL PATIENTS FOR PROGNOSTIC CLASSIFICATION

A. Trojani,[1] B. Di Camillo,[2] A. Tedeschi,[3] M. Lodola,[3] C. Colombo,[4] F. Ricci,[3] S. Veronese,[5] B. Scarpati,[6] E. Morra,[3] M. Montillo[3]

[1]Ospedale Niguarda Cà Granda, MILAN; [2]University of Padova, Department of Information Engineering (DEI), PADOVA; [3]Ospedale Niguarda Cà Granda, Division of Hematology, MILANO; [4]Ospedale Niguarda Cà Granda, Division of Hematology, MILANO; [5]Ospedale Niguarda, Molecular Pathology Unit, MILAN; [6]Ospedale Niguarda Cà Granda, SIMT, MILAN, Italy

Background. Chronic lymphocytic leukemia (CLL) is a heterogeneous disease characterized by a highly variable clinical course. IgVH mutational status and ZAP-70 protein expression have shown to be strong associated and to offer important prognostic information. *Aims*. Our aim was to determine gene expression profiles of 46 CLL patients divided into three classes: the first (n=26) with mutated IgVH and ZAP-70-, the second (n=12) with unmutated IgVH and ZAP-70+, and the third (n=8) included CLL patients with unmutated IgVH and ZAP-70-, or mutated IgVH and ZAP-70+ respectively. Exploration of microarray data was evaluated in order to define prognostic biomarkers and the biological pathways related to B-CLL. *Methods*. We determined gene expression profiles using Affymetrix HG U133 Plus 2.0 in $CD19^+$ leukemic cells. Probe-level data were pre-processed using robust multi-array average (RMA). Differential expression analysis was performed using Statistical Analysis for Microarray (SAM). Selected genes were grouped according to their biological pathways using GenMAPP (Gene Map Annotator and Pathway Profiler). Finally, patients were clustered in groups with similar expression signature using cluster analysis (K-means, Euclidean distance). *Results.* Statistical analysis revealed 154 differentially expressed probe-sets in the first (mutated IgVH and ZAP-70-) vs the second (unmutated IgVH and ZAP-70+) group, corresponding to 88 genes annotated in public databases (probe-sets monitoring the same gene were selected multiple times). Interestingly, six genes were associated to the following biological pathways: MAPKsignaling (heat shock 70kD protein 8 HSPA8), B cell receptor signaling (ZAP-70, CKLF-like MARVEL transmembrane domain containing 3 CMTM3, dual adaptor of phosphotyrosine and 3-phosphoinositides DAPP1), Matrix Metalloproteinasis (transcription factor 20, TCF20), Apoptosis (X-linked inhibitor of apoptosis XIAP) and T cell receptor signaling (ZAP-70). In particular, ZAP-70, HSPA8, CMTM3 were significatively underexpressed while XIAP, TCF20 and DAPP1 were overexpressed in the first class of patients in comparison to the second class, respectively. No differentially expressed genes were identified in the comparison between the first and the third (mutated IgVH and ZAP-70+ or unmutated IgVH and ZAP-70-) class and between the second and the third class of patients respectively. Based on the expression of the 88 genes identified in the comparison between the first and the second class of patients, the 8 patients of the third class were divided in two clusters: 5 subjects were more similar to the first class, while 3 subjects appeared to belong to the second one. In particular, cluster analysis revealed that the 46 patients were better partitioned in two rather than in three classes, based on their expression profiles. *Summary and Conclusions.* In summary, our preliminary data revealed different gene expression signatures in B-cell chronic lymphocytic leukemia prognostic subgroups of patients, defined by IgVH mutational status and ZAP-70 expression. The functional pathways related to: MAPK signaling, B cell receptor signaling, apoptosis and T cell receptor signaling may ultimately influence CLL biology. Gene expression profiling studies are in progress on larger series of CLL patients in order to assess the association of the molecular signature, based on the identified genes and their pathways, with respect to prognostic information.

SENSITIZATION OF LEUKEMIC CELLS TO FLUDARABINE BY MONOCLONAL ANTIBODY RITUXIMAB - IDENTIFICATION OF RESPONSIBLE GENES

L. Rocnova,[1] B. Tichy,[1] S. Cejkova,[1] D. Potesil,[2] Y. Brychtova,[1] S. Pospisilova,[1] J. Mayer,[1] M. Trbusek[1]

[1]University Hospital and Faculty of Medicine, Masaryk University, Brno, BRNO; [2]Faculty of Science, Masaryk University, Brno, BRNO, Czech Republic

Background. Chronic lymphocytic leukemia (CLL) represents an incurable disease with a highly variable clinical course. Modern therapies, especially combined regimens of monoclonal antibodies and chemotherapeutics, may prolong progression-free survival and even overall survival in a subset of patients. We have recently reported (Cejkova *et al.*, Eur J Haematol, 2009;82:133-42) that monoclonal antibody rituximab sensitizes a significant proportion of CLL cultures *in vitro* to the subsequently administered fludarabine, regardless the presence of the high-risk genetic abnormalities, i.e. aberrations of the tumor-suppressors ATM and TP53 (which, however, influences the primary response to fludarabine on its own). *Aims*. The aim of the study was to define differentially expressed genes in CLL cultures sensitized by rituximab to fludarabine as opposed to cultures refractory to the sensitization. The selected genes might serve as the markers of sensitivity (or resistance) to the combination of these drugs and could further elucidate the mechanism of rituximab's activity in CLL cells, which is poorly understood. *Methods*. Sixty primary CLL cultures were tested *in vitro* for their viability using WST-1 metabolic assay. Fludarabine was administered for 48h as a single agent (25; 6.25; 1.6 and 0.4 μg/mL) or in parallel on the cells pre-treated for 72h with rituximab in a standard *in vitro* dose (10 μg/mL). Twenty-one samples were significantly sensitized by rituximab ($p<0.01$). Seven the most prominently sensitized samples were subsequently taken for the microarray analysis and compared with eight non-sensitized cultures. In each culture the treated cells were compared with control cells on the microarray (Agilent Technologies, 4x44K microarray). *Results*. We observed down-regulation of several genes in sensitized samples, while the same genes were up-regulated in non-sensitized samples. The opposite effect has not been, surprisingly, observed. Among the identified genes were the following interesting candidates: metallothionein 2A (MT2A), which has been reported in drug efflux function; ribonucleotide reductase M2 subunit (RRM2), connected with drug resistance and topoisomerase II α (TOP2A), reported to influence a response to therapy. *Summary and Conclusions.* The obtained data point to very interesting genes, which might be responsible for the observed sensitization effect. Their relevance will be further validated on the larger cohort of samples by using quantitative real-time PCR.

THE NOVEL TYPE II CD20 ANTIBODY GA101 MEDIATES SUPERIOR B CELL DEPLETION IN WHOLE BLOOD FROM HEALTHY VOLUNTEERS AND B-CLL PATIENTS

S. Herter,[1] I. Del Giudice,[2] C. Schmidt,[1] T. Fauti,[1] C Klein,[3] P. Umana,[1] M.J.S. Dyer,[4] R. Foa,[5] R. Grau[1]

[1]Glycart Biotechnology AG, SCHLIEREN, Switzerland; [2]Universita La Sapienze, ROME, Italy; [3]Roche Diagnostics GmbH, PENZBERG, Germany; [4]University of Leicester, LEICESTER, UK; [5]University La Sapienza, ROME, Italy

Background. GA101 is a novel fully humanized IgG1-type monoclonal antibody that binds with high affinity to the extracellular part of the human CD20 antigen. In contrast to rituximab and other CD20 antibodies currently in development, GA101 recognizes a CD20 Type II epitope, resulting in enhanced direct cell death induction and reduced CDC induction. Through glycoengineering GA101 also mediates enhanced induction of effector-cell-mediated ADCC. *Aims*. In order to integrate the different mechanisms of action (ADCC-, CDC- and direct cell death-inducing mechanisms) in one assay format and to reflect the *in vivo* situation in peripheral blood, autologous *ex vivo* B-cell depletion assays with whole blood from healthy donors and B-CLL patients containing natural effector cell populations, human complement and physiological concentrations of human IgG were performed. These assays were used to determine the reduction in the number of CD19 positive B cells after incubation with GA101 in whole blood in direct comparison to rituximab. *Methods*. Heparinized blood of healthy volunteers or B-CLL patients was incubated with different antibodies at different concentrations for 24 h before FACS staining was performed. The B cell (CD19 positive cells) to T cell (CD3 positive cells) ratio (CD45 gate) was used to calculate the percentage of antibody dependent B cell killing, setting the untreated control to 0% and the putative complete depletion of B-cells as 100%. *Results*. Whole blood assays with blood from a panel of 10 healthy donors showed that in comparison to rituximab GA101 was 10-25 fold more potent in terms of EC50 values and 1.5-2.5 fold more efficacious in terms of absolute B cell depletion. The efficacy of whole blood B cell depletion by GA101 was significantly different from that of rituximab in all samples tested. In whole blood isolated from B-CLL patients, GA101 mediated superior B cell depletion both in terms of potency and absolute efficacy of B cell depletion in 8/11 patients in direct comparison to rituximab. In 3/11 patients neither GA101, Rituximab or alemtuzumab mediated B cell depletion. The analysis of additional B-CLL samples is currently ongoing. *Summary and Conclusions*. The whole B cell depletion assays performed in this study show that GA101 mediates superior depletion of normal B cells from blood of healthy volunteers as well as of malignant B cells from blood of B-CLL patients in a majority of samples in comparison to rituximab and alemtuzumab. It can be hypothesized that the B cell depletion in these whole blood assays reflects the *in vivo* situation in peripheral blood most closely. Further studies are foreseen to dissect the contribution of the different ADCC-, CDC- and direct cell death-inducing mechanisms to the killing of B cells from whole blood. In addition, it will be of interest to investigate why a proportion of samples showed no B cell depletion at all irrespective of the antibody used.

0911

IN VITRO CYTOTOXICITY AND ZNF331 ARE RELATED TO RESPONSE AND RELAPSE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) TREATED WITH FLUDARABINE, CYCLOPHOSPHAMIDE AND MITOXANTRONE (FCM)

N. Villamor, D. Colomer, F. Bosch, A. Ferrer, M. Aymerich, S. Marce, P. Jares, E. Montserrat, E. Campo

Hospital Clínic de Barcelona, BARCELONA, Spain

Background. The use of fludarabine-based polychemotherapy in patients with CLL has improved the response rate with a fraction of patients achieving complete remission (CR) without evidence of minimal residual disease (MRD). Abnormalities in p53 are associated to worse response to therapy, but there is still a proportion of non-responding patients in whom the mechanism of resistance is unknown. Once CR is achieved, the evolution of responding patients is strongly associated to the persistence or reappearance of MRD, but the underlying mechanisms are not defined. *Aims*. Analyze *in vitro* cytotoxicity, and gene expression profile of CLL patients treated with FCM to identify other parameters related to response and relapse. *Methods*. Clinical results of FCM treatment have been published (Bosch *et al.*, Clin Cancer Res 2008). In addition to standard parameters (cytogenetics and MRD), we have analysed *in vitro* cytotoxicity by a colorimetric assay at 48h of FCM incubation (41 patients), and gene expression profile of purified B cells (>98% after magnetic selection) at diagnosis from 22 patients (14 CR, 6 partial response (PR), 2 failure (F)) by hybridizing to HGU133 Plus 2.0 arrays. Supervised analysis according the type of response and the presence of relapse was conducted with Dchip v2.6. Low density arrays of selected genes (according the magnitude of fold change and the homogeneity within groups) were studied in purified B cells of 48 patients (13 CR-MRD-, 17 CR-MRD+, 18 PR or F) and analysed using Statminer software. *Results*. *In vitro* cytotoxicity correlated with clinical response [CR (n=23): 88% ±6, PR (n=15): 83%±11, F (n=3): 63% ±14)] (p<0.001). Gene expression at diagnosis was highly similar, independent of the type of response achieved, with differences observed in growth, development and cell proliferation pathways. The number of genes (269) differentially expressed between CR and other responses showed a median fold change of 1.7 (percentile 10: 1.48, percentile 90: 2.26). Patients in lasting CR (n=8) differentially expressed 159 comparing with patients who relapsed (n=6). The median fold change was 1.8 (percentile 10: 1.53, percentile 90: 2.8). Low density arrays included 25 genes for long lasting CR versus relapse, and 67 for treatment response. The median of fold change of the selected genes was 2.38 (percentile 10: 1.92, percentile 90: 5.1). Relapse was associated with basal expression ZNF331 (a reactivation of p53 and induction of tumour cell apoptosis), whilst no gene for type of response was identified. *Summary and Conclusions*: In addition to well known parameters for response and relapse, at diagnosis low *in vitro* cytotoxicity is associated to worse response to treatment without identifying genes predicting the response of treatment. In contrast, ZNF331 expression is associated to higher risk of relapse after FCM treatment, identifying a new potential marker for risk of relapse after treatment.

EFFECT OF ZAP-70 ON MIRNA EXPRESSION PROFILE IN CHRONIC LYMPHOCYTIC LEUKEMIA

V. Pede,[1] J. Philippé,[1] P. Mestdagh,[2] J. Vandesompele,[2] B. Verhasselt[1]

[1]Ghent University Hospital, GENT; [2]Ghent University, GHENT, Belgium

Background. Chronic lymphocytic leukemia (CML) is known to show a highly variable evolution. ZAP-70 has been found to be one of the most relevant prognostic parameters in CLL. In order to find out the role of ZAP-70 in CLL, we have optimized a methodology for expressing ZAP-70 in CLL cells (Van Bockstaele *et al.* Leukemia 2008). In this way we are able to compare CLL cells only differing in ZAP-70 expression. *Aims*. We wished to explore if introducing ZAP-70 in ZAP-70 negative CLL cells could influence the miRNA expression profile. Moreover a comparison with miRNA expression profiles with prognostic relevance described previously was made. *Methods*. Isolated mononuclear cells from a CLL patient were electroporated three hours after thawing, as previously described, and were stimulated with anti-IgM 16 hours later. After 3 and 24 hours of stimulation CD19$^+$ cells were selected and RNA was isolated. miRNA expression profiles were measured using the Megaplex reverse transcription format of the stem-loop primer-based real-time quantitative PCR (RT-qPCR) method (Applied Biosystems). The Megaplex reaction provides simultaneous reverse transcription of 450 mature miRNAs. *Results*. Hsa-miR-34a was significantly upregulated after both 3 and 24 hours. Hsa-mir-429 was upregulated after 3 hours, but this effect disappeared after 24 hours. Hsa-mir-624 was downregulated after 24 hours but no difference was observed after 3 hours. *Summary*. Hsa-miR-34a is a well known miRNA in CLL and has been described as an adverse prognostic factor in line with our observation as a ZAP-70 induced miRNA. However, it has been shown that p53 may upregulate hsa-mir-34a which further leads the cell into apoptosis and cell cycle arrest. In analogy with the p53 data, one would not expect ZAP-70 to upregulate hsa-mir-34a, as this would rather be associated with good prognosis. Why the opposite is true, remains to be elucidated. Other miRNAs previously described in prognostic profiles in CLL were not differentially expressed in our experiment.

0913

ZAP-70 HAS HIGHER EXPRESSION IN LYMPH NODES AND BONE MARROW COMPARED TO PERIPHERAL BLOOD IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

O. Jaksic,[1] B. Gizdic,[1] T. Stoos Veic,[1] Z. Miletic,[1] R. Kusec,[1] K. Trutin Ostovic,[1] V. Pandzic Jaksic,[1] V. Pejsa,[1] B. Jaksic[2]

[1]Dubrava University Hospital, ZAGREB; [2]Merkur University Hospital, ZAGREB, Croatia

Background. B-cell chronic lymphocytic leukemia (B-CLL) is characterized by highly variable clinical presentation and course with variable affection of different lymphoid organ compartments. There is well documented both intraclonal and interclonal variability among B-CLL cells with respect to different microenvironment in major lymphoid compartments as we have previously shown (Jaksic *et al.*, Blood 2004). ZAP-70 molecule with significant role in cell signaling and is very important negative prognostic parameter. However its expression is evaluated mainly in peripheral blood which is considered as mostly inert compartment compared to bone marrow and lymph nodes where proliferative centers were documented fueling B-CLL proliferation and progression. *Aims*. To evaluate whether there is difference in ZAP-70 expression in B-CLL lymphocytes associated with distinct microenvironment in major lymphoid compartments. *Methods*. Samples from peripheral blood (PB), bone marrow (BM) and lymph nodes (LN) representing major compartments in B-CLL were taken on the same day by conventional technique. We have measured the expression of ZAP-70 by flow cytometry by previously published method using ZAP-70, CD3, CD56, CD5 and CD19 markers (Letestu, Cytometry 2006). ZAP-70 expressions was expressed as percentage of ZAP-70 positive B-CLL cells according to ZAP-70 expression in T-lymphocytes (%/T-Ly) and as T/CLL mean fluorescence intensity (MFI) ratio. Results were analyzed by paired tests. *Results*. Samples were taken from 42 typical B-CLL patients, median age was 70yr, there were 55% males, mean β-2 microglobulin was 3.9 mg, mean TTM was 9.3, there were 22% of patients with lymphoma-like tumor distribution (TD<0.5). There were 17, 16 and 8 patients in Binet stages A, B and C respectively. ZAP-70 expression as T/CLL ratio (mean ±s.d.) was 4.9±3.7, 2.9±2.1 and 1.7±0.8 for PB, BM and LN respectively (p<0.00001). Results for percentage of positive B-CLL cells (%/T-Ly) were at the same level of statistical significance (p<0.00001) with median percentage in PB 19.7%, in BM 62.3% and in LN 92.9% showing the lowest expression in peripheral blood and the highest expression in lymph nodes. *Summary and Conclusions*. We have shown that B-CLL lymphocytes taken from different lymphoid compartments have significantly different ZAP-70 expression supporting the importance of lymph node and bone marrow compartments in B-CLL pathogenesis.

THE DISTRIBUTION OF XRCC1-399 AND XPD-751 GENOTYPES IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH SECONDARY TUMORS AND RICHTER TRANSFORMATION

N. Bilous,[1] I. Abramenko,[1] A. Chumak,[1] A. Kostin,[1] Z. Martina,[1] I. Dyagil,[1] I. Kryachouk,[2] I. Filonenko,[3] N. Yuschenko[4]

[1]Research Centre for Radiation Medicine, KIEV; [2]National Cancer Institute, KIEV; [3]Poltava Regional Hospital, POLTAVA; [4]Donetsk Regional Hospital, DONETSK, Ukraine

Background. The clinical course of chronic lymphocytic leukemia (CLL) is associated frequently with secondary solid tumors development and transformation to Richter syndrome (RS), represented in most cases by diffuse large B-cell lymphoma. Molecular indicators of the risk as well as mechanisms of the second neoplasm's development are unknown. Some data suggests that several polymorphisms in DNA repair genes have impact on cancer susceptibility. X-ray repair cross-complementing group 1 (XRCC1) and Xeroderma pigmentosum D (XPD) are most extensively studied in cancer. *Aims*. To evaluate association of XRCC1 Arg399Gln and XPD Lys751Gln polymorphisms with tumors development and transformation to RS in patients with CLL. *Methods*. Polymorphisms were genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism analysis (RFLP). Genomic DNA was amplified in PCR using primers designed by Seedhouse *et al.*, 2002, followed by enzymatic digestion of PCR products. The digested products were resolved on 3% agarose gel and analyzed. *Results*. We examined the frequency of 2 polymorphisms in 140 CLL patients divided into three groups: with RS (22), with secondary solid tumor (22) and control group of patients with CLL alone (96). Subgroup of 35 patients with overall survival (OS) more than 3 years was picked out the control group. Patients of these groups were comparable by gender and age. However, all patients with RS were previously treated and most of them had B stage at diagnosis (72.7%) in contrast to the other groups (31.4-36.4%; p<0.001). The distributions of the XRCC1 Arg399Gln as well as XPD Lys751Gln polymorphisms in observed CLL cohort did not differ from healthy Caucasians (Table). Neither the XRCC1-399 nor the XPD-751 genotype distributions showed any differences in CLL patients with secondary tumors. We also found no correlation between XPD-751 genotypes and development of RS. However, the proportion of CLL patients with RS homozygous for XRCC1 Gnl399 allele was higher than in the control group (χ^2 = 5.55) as well as in the subgroup of patients with OS>3y (χ^2 = 5.33). At the same time the frequency of XRCC1 heterozygotes among CLL patients with RS was significantly lower in comparison with two other groups. Since RS developed in previously treated patients only, we examined the XRCC1-399 and XPD-751 genotype distribution in previously treated patients from control group. Those patients as well as previously treated control group patients with OS>3y were uncommon homozygous for XRCC1 Gnl399 allele (9.1% and 7.4% correspondingly) in comparison with RS patients (30%; p<0.01). *Summary*. Our results suggest about possible role of DNA repair mechanisms, specifically XRCC1 and XPD gene polymorphisms in Richter syndrome development in CLL.

Table 1.

	CLL patients				
	Control group		With solid tumors, n = 22	With RS, n = 22	All patients n = 140
	All, n = 96	OS>3y, n = 35			
XRCC1 Arg399Gln p = 0.063					
Arg/Arg	34 (37.8)	9 (28.1)	8 (44.4)	9 (45.0)	51 (39.8)

0915

WHAT IS THE ROLE OF BONE MARROW PATHOLOGICAL EXAMINATION IN CLL? EXTENSIVE HISTOLOGICAL, IMMUNOHISTOCHEMICAL AND MOLECULAR EXAMINATION IN A SERIES OF 137 PATIENTS

M. Fameli,[1] N. Stavroyianni,[2] G. Kannellis,[1] E. Pouliou,[1] C. Lalayanni,[2] R. Saloum,[2] A. Fassas,[2] A. Anagnostopoulos,[2] K. Stamatopoulos,[2] T. Papadaki[1]

[1]Evangelismos Hospital, ATHENS; [2]G. Papanicolaou Hospital, THESSALONIKI, Greece

We analyzed bone marrow biopsy (BMB) samples from 137 patients with CLL and explored associations with clinical features and outcome, CD38 expression, and IGHV mutation status. Patient group: M:F=84:53, median age: 66 years, Binet stage-A/B/C: 111/20/6. Peripheral blood immunophenotype: (1) $CD38^+$: 48/134 cases (2) IgG^+: 20/131 cases. Mutated/unmutated IGHV genes (M-IGHV/A-IGHV): 86/51 cases. Formalin-fixed, decalcified, paraffin-embedded sections of BMBs were examined: (1) morphologically (H&E); (2) immunohistochemically (ABC technique). The following antibodies were used: CD20, CD79a, CD3, BCL-2, CD5, CD23, SIg/CIg (k/l/m/d/g/a), CD27, myeloperoxidase, PGM1 (CD68), glycophorin-C, CD61. All cases showed neoplastic small lymphocytic infiltration (20-95% of BM cellularity) by $CD20^+CD79a^+$ $CD5^+CD23^+$cells. Medium- or large-sized cells were admixed in 6 and 2 cases, respectively. A moderate number of monocytoid-like cells with clear cytoplasm were identified in 6 cases. Six cases exhibited lymphoplasmocytoid differentiation in a small proportion of the neoplastic population. Finally, two additional cases showed pronounced plasmacytic differentiation which was proven (by immunohistochemistry) of identical heavy and light isotype restriction as the CLL neoplastic lympho-

cytic population. Three patterns of neoplastic lymphocytic infiltration were identified: (1) interstitial: 59 cases; (2) nodular/nodular+interstitial: 51 cases; (3) diffuse: 27 cases. Moderate-to-significant reduction of the granulocytic series was observed in 60/137 cases. The remaining cases showed hyperplastic granulocytic series with a left shift and, occasionally, dysplastic changes of mature forms. Hyperplasia of the erythroid and megakaryocytic series -often with dysplastic changes- with normal/decreased hemoglobin levels and platelet counts was observed in 76/137 and 99/137 cases, respectively; the remaining cases showed moderate-to-significant reduction of either series. Significant correlations were identified between: (i) nodular infiltration and M-IGHV genes (p<0.001); (ii) diffuse infiltration and shorter time-to-progression (p=0.05). In conclusion, BMB examination: (1) permits identification of the rare CLL subtypes with plasmocytoid and/or plasmacytic differentiation (WHO); (2) allows evaluation the BM stroma and the hematopoietic marrow and provides important evidence for CLL-associated hematopoietic autoimmunity. Finally, the favorable prognosis of the nodular pattern of infiltration in CLL may be interpreted in view of its association with M-IGHV genes.

0916

CLLU1 GENE EXPRESSION LEVELS PREDICTS VH MUTATIONAL STATUS IN 90% OF CLL PATIENTS

G. Georgiou, M. Roumelioti, D. Palaiologou, V. Mpartzi, A. Markopoulos, G. Stravodimos, M. Dimou, A. Efthymiou, L. Petrikos, T. Vassilakopoulos, M. Aggelopoulou, C. Kyrtsonis, P. Panayiotidis

University of Athens, ATHENS, Greece

CLLU1 is a gene identified by differential display performed in CLL samples with mutated (MU) versus unmutated (UN) VH monoclonal sequence. Initials results using a variety of Q-PCR protocols suggested that CLLU1 overexpression occurs in unmutated CLL patients. Recenly it has been shown that CLLU1 expression level is a stable and inherent feature of CLL clone. CLLU1 gene function is unknown and until now no protein product of the various mRNA splice variants of this gene has been identified. *Aims*. A) To validate a new Q-PCR methodology for the determination of CLLU1 levels in CLL samples and its correlation to VH mutational status. In MCL, B-ALL, MM, tonsilar B, and peripheral blood T cells CLLU1 levels were also determined. B) To analyze if CLLU1 mRNA is inducible upon CLL cell activation *in vitro*. *Methods*. Samples from 69 CLL patients (MU 31 pts, UN 38), 8 MCL (4 MU, 4 UN), 10 B-ALL (5 Ph^+), 5 MM, B cells from 3 tonsils and T cells from 4 healthy subjects were analyzed for CLLU1 expression. Briefly 1μg of RNA was reversed transcribed to cDNA and Q-PCR of CLLU1 gene and β2 microglobulin (control gene) was performed using the CLLU1 profile Quant kit (Ipsogen). Absolute levels of CLLU1 and β2m mRNA are determined and results are expressed as CLLU1/β2m ratio (x10-5). Monoclonal IGVH mutation analysis was performed in all CLL and MCL samples. Two CLL samples with low levels of CLLU1 expression were *in vitro* stimulated with anti-IgM+IL-4 or CD40L+IL-4 for 1-3 days, and examined for levels of CLLU1/β2m and CLLU1/ABL expression. *Results*. In 31 MU CLL pts mean level of CLLU1/,2m was 82, and in 38 UN was 2153 CLLU1 levels in UN pts were in average 26 times higher compared to MU CLL pts levels. Using the cutoff value of CLLU1/β2m of 100, in 90% of all 69 CLL pts VH mutational status could be predicted: 28 of 31 MU had levels less than 100 and 35 of 38 UN CLL pts had levels over 100. No correlation between percentage of VH mutations and CLLU1/β2m ratio was found. MCL CLLU1 average levels was 2.5 with no difference between UN and MU samples. In B-ALL cases, MM, normal tonsilar B cells and T cells were 0.53, 3.23, 4.1, 0.57 respectively. *In vitro* stimulation of MU CLL cells for 1-3 days did not upregulate expression of CLLU1. Anti-IgM/CD40L/IL-4 *in vitro* stimulation of tonsilar B cells and PHA activation of T cells did not increase CLLU1 expression levels. These results were verified by determining CLLU1/ABL ratio. *Conclusions*. Over expression of CLLU1 in the majority of UN CLL pts identifies a unique lineage and disease specific marker, not expressed in other normal cells or B cell malignancies irrespective of VH mutational status. Stable levels of CLLU1 expression during *in vitro* CLL activation suggests that this is a disease/patient specific marker. These results imply that, although this gene function is totally unknown, CLLU1 has a crucial role in the pathogenesis of CLL and it should be further explored.

0917

CD72 EXPRESSION PATTERNS IN ZAP70 POSITIVE AND NEGATIVE CHRONIC LYMPHOCYTIC LEUKEMIA: DIFERENTIAL EXPRESSION OF GENES RELATED WITH BCR SIGNALLING

F.P. de Paula Careta, R.A. Panepucci, D.M.M Mattos, R. Proto-Siqueira, F.S. Araújo, A.B. Garcia, A.G. Araújo, W. Silva-Junior, R.P. Falcão, M.A. Zago

Sao Paulo University, RIBEIRAO PRETO, Brazil

Background. Absence of mutations in IgVH genes or higher number of ZAP70+ cells (as a surrogate marker) in chronic lymphocytic leukemia (CLL) B-cells defines a patient group with a poorer clinical course. These features relate to the role of BCR signalling in the proliferation and survival of CLL B-cells, establishing a link between these markers and the biology of CLL prognostic subgroups. *Aims*. Identify additional molecular mechanisms related to the biology of distinct CLL prognostic subgroups. *Methods*. Imunomagnetically purified $CD19^+$ cells from 3 unmutated and 3 mutated CLL cases were independently pooled and used to generate the transcription profiles, using serial analysis of gene expression (SAGE). Percentage of $ZAP70^+$ and $CD72^+$ cells were evaluated by flow cytometry on gated $CD19^+CD5^+$ cells in 24 CLL samples. Positive cases for ZAP70 and CD72 were defined using a cut-off of 30% and 40% positive cells, respectively. Real time PCR was used to quantify the expression levels of RELB, β-Catenin (CTNNB1) and AKT1 on 15 $CD19^+$ enriched (purity >90%) CLL samples. *Results*. SAGE analysis revealed a significant higher level of CD72 transcripts in unmutated samples, a specific B cell surface glycoprotein known to transmit both positive and negative signals in BCR signalling. In line, median percentage of $CD72^+$ cells was significantly higher in $ZAP70^+$ cases compared to ZAP70- cases (82% and 39%, respectively, p=0.0029). Furthermore, percentages of CD72 and ZAP70 were positively correlated (r=0.5930 and p=0.0009). Interestingly, $ZAP70^+$ cases were restricted to $CD72^+$ cases (n=11, [+/+]), whereas 6 $ZAP70^-$ cases were $CD72^+$ [-/+] and 7 were CD72- [-/-]. No differences among these 3 groups were observed in regard to laboratory parameters (white blood cells, total lymphocytes, lymphocyte percentage, haemoglobin, haematocrit and platelet number). Transcripts for RELB, CTNNB1 and AKT1, all related to BCR-mediated proliferation and survival, were expressed at significantly higher levels in ZAP70+CD72+ samples (n=7), compared to ZAP70-CD72+ (n=4). Interestingly, CTNB1 and AKT1 transcripts (but not for RELB, p=0.095) were expressed at significant higher levels in ZAP70-CD72- samples (n=4), compared to ZAP70-CD72+ samples. *Conclusions*. We have shown that the expression of CD72 and $ZAP70^+$ on CLL cells correlate and that CD72 may have a potential role on signaling mechanisms related to CLL B-cell proliferation and survival. In this way, higher levels of the evaluated transcripts on ZAP70-CD72-, compared to ZAP70-CD72+ cases, indicates that in the absence of ZAP70 expression, CD72 may act as a negative regulator of the BCR pathway. Finally, higher expression of these transcripts on $ZAP70^+CD72^+$, compared to ZAP70-CD72+ cases, further corroborates the proposed role of ZAP70 on BCR-mediated proliferation and survival. This work was supported by FAPESP, CNPq and FINEP.

DIFFERENT CXCR4, CXCR3, CXCR5, CCR7 AND KI-67 EXPRESSION IN PERIPHERAL BLOOD, BONE MARROW AND LYMPH NODES IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)

O. Jaksic,[1] B. Gizdic,[1] T. Stoos Veic,[1] M. Pirsic,[1] R. Kusec,[1] V. Pandzic Jaksic,[1] B. Jaksic,[2] V. Pejsa[1]

[1]Dubrava University Hospital, ZAGREB; [2]Merkur University Hospital, ZAGREB, Croatia

Background. B-cell chronic lymphocytic leukemia has highly variable clinical presentation and course with variable involvement of different lymphoid compartments which translates into variable tumor distribution. Important role in lymphocyte trafficking and homing have adhesion molecules and chemokine receptors. We have previously shown that there is significant variability regarding adhesion molecule expression between lymphoid compartments with significant association with clinical presentation and course (Jaksic *et al.*, Blood 2002). Important role in trafficking and homing as well as regulation of expression of adhesion molecules have been documented in *in vitro* models for chemokine receptors. This points to need to evaluate whether there is an intraclonal variability due to distinct microenvironment *in vivo*, as well as whether different chemokine receptor profile correlates with cell proliferations.

Aims. to evaluate and compare the expression of various chemokine receptors as well as marker of proliferation Ki-67 on B-CLL lymphocytes taken from various lymphoid compartments, ie peripheral blood (PB), bone marrow (BM) and lymph nodes (LN). *Methods*. Samples were taken from peripheral blood (PB), bone marrow (BM) and lymph nodes (LN) representing major compartments in B-CLL, by conventional techniques on the same day. We have measured expression of CXCR3, CXCR4, CXCR5, CCR7 and Ki-67 on $CD5^+CD19^+$ cells by flow cytometry and we have expressed the results as percentage of positive cells and mean fluorescence intensity (MFI). Results were analyzed by paired tests. *Results*. samples were taken from 21 typical B-CLL patients (median age 69 years, males 56%). Mean β-2 microglobulin was 4.5 mg, mean TTM was 10.3, with 35% of patients with lymphoma-like tumor distribution (TD <0.5). There were 7, 10 and 4 patients in Binet stages A, B and C respectively. Median CXCR3 expression was 15.8, 9.7 and 17.3% for PB, BM and LN respectively (p<0.01 PB and LN vs. BM). Median CXCR4 expression was 51, 17 and 12.3% for PB, BM and LN respectively (p<0.01 PB vs. BM and LN). Median CXCR5 expression was 94.1, 87.7 and 64.5% for PB, BM and LN respectively (p<0.01 PB and BM vs. LN). Median CCR7 expression was 98.2, 96.6 and 72% for PB, BM and LN respectively (p<0.01 PB and BM vs. LN). Mean Ki-67 expression (MFI) 0.89, 0.76 and 1.39 for PB, BM and LN respectively (p<0.01 PB and BM vs. LN). CXCR4 expression was higher in PB compared to BM and LN, CXCR3 expression was lower in BM then in PB and LN, CXCR5 and CCR7 expression was higher in PB and BM compared to LN. Ki-67 expression was highest in lymph nodes. *Summary and Conclusions*. There is a significant intraclonal variability for several chemokine receptors regarding different lymphoid compartments. This chemokine receptor profile inversely correlates with proliferative status of B-CLL cells in respective compartments.

Background. Patients with fludarabine-refractory chronic lymphocytic leukemia (CLL) have poor prognosis, and this is particularly true of those also refractory to alemtuzumab (FA-ref) or with bulky (>5 cm) lymphadenopathy (BF-ref) where salvage therapy, including intensive chemoimmunotherapy, has limited activity (20-26% overall response rate [ORR]). Historically, monoclonal antibodies (mAbs) evaluated in this population have no activity; results from a retrospective analysis showed an overall response of 0%, median time to treatment failure of 2 months and median overall survival (OS) of 6 months with mAb salvage therapy (Tam, Leuk Lymphoma 2007;48:1931). Ofatumumab is a unique human mAb that targets a membrane-proximal small-loop epitope on the CD20 molecule and elicits more potent *in vitro* complement-dependent cytotoxicity of B-cell lines and primary CLL cells compared with rituximab (Teeling, Blood 2004;104:1793; Teeling, J Immunol 2006;177:362). *Aims*. To determine whether prior rituximab exposure impacted the efficacy of ofatumumab in patients with FA-ref or BF-ref CLL.

Table 1. Efficacy outcomes by rituximab exposure.

Prior rituximab	FA-ref (n=59)			BF-ref (n=79)		
	n	ORR, % (95% CI)	Median PFS, mo (95% CI)	n	ORR, % (95% CI)	Median PFS, mo (95% CI)
Any prior rituximab*	35	54 (37, 71)	5.5 (3.7, 8.0)	43	44 (29, 60)	5.5 (3.8, 6.4)
FR†	19	53 (29, 76)	4.6 (2.8, 6.4)	27	52 (32, 71)	5.6 (2.5, 7.4)
FCR‡	16	50 (25, 75)	4.6 (2.3, 6.4)	16	44 (20, 70)	5.6 (2.1, 6.6)
No prior rituximab	24	63 (41, 81)	7.1 (4.8, 8.7)	36	50 (33, 67)	6.4 (4.0, 8.0)

*Patients received ≥1 prior rituximab-containing regimen at any time before study entry; †Patients refractory to fludarabine in combination with rituximab (FR), with or without other drugs; ‡Patients refractory to fludarabine in combination with rituximab and cyclophosphamide (FCR), with or without other drugs.
FA-ref=fludarabine- and alemtuzumab-refractory; BF-ref=bulky fludarabine refractory; ORR=overall response rate; PFS=progression-free survival

Methods. Patients with FA-ref or BF-ref CLL received 8 weekly infu-

sions of ofatumumab followed by 4 monthly infusions (Dose 1, 300 mg; Doses 2-12, 2000 mg). Premedications included paracetamol, antihistamine and glucocorticoid. The primary endpoint was ORR (1996 NCI-WG criteria) over 24 weeks assessed by an Independent Review Committee (IRC). Secondary efficacy endpoints included progression-free survival (PFS) and OS. Results from the planned interim analysis of this ongoing, international pivotal study are reported. *Results*. At the interim analysis, 138 treated patients had FA-ref (n=59) or BF-ref (n=79) CLL; 63% had Rai stage III/IV disease at screening and the median number of prior treatments was 5. The ORR (99% confidence interval [CI]) based upon IRC assessment was 58% (40, 74%) in the FA-ref group and 47% (32, 62%) in the BF-ref group. Median PFS (95% CI) was 5.7 months (4.5, 8.0 months) and 5.9 months (4.9, 6.4 months) in the FA-ref and BF-ref groups, respectively, and median OS (95% CI) was 13.7 months (9.4, [upper limit not yet reached] months) and 15.4 months (10.2, 20.2 months), respectively. Prior to receiving ofatumumab, 59% of FA-ref and 54% of BF-ref patients had been treated with a rituximab-containing regimen. Both ORR and median PFS were similar in patients with prior rituximab exposure compared with the overall study population (Table). Response rates and median PFS were also similar in patients refractory to fludarabine in combination with rituximab, with or without cyclophosphamide. *Conclusions*. The activity of ofatumumab was independent of prior rituximab treatment; high response rates were observed irrespective of previous exposure to rituximab-containing regimens, including patients whose disease was refractory to fludarabine-based regimens that contained rituximab.

Gemelli, ROME; [3]Division of Hematology, Amedeo Avogadro University of Eastern Piedmont, NOVARA; [4]Division of Hematology and Transplant, University of Siena, SIENA; [5]Laboratory of Immunogenetics, University of Torino Medical School, TORINO; [6]Divisione Ematologia, A.O. Ospedale Niguarda Ca'Granda, MILANO; [7]Hematology and Stem Cell Transplantation Unit, IRCCS, SAN GIOVANNI ROTONDO, Italy

Background. B-cell chronic lymphocytic leukaemia (B-CLL) is a heterogeneous disease with highly variable clinical course. In a recent report (Wierda *et al.*, Blood 2007,109:4679), a prognostic nomogram and a risk score were proposed to predict overall survival by using 6 clinical and routine laboratory parameters: age, β2 microglobulin, absolute lymphocyte count, sex, Rai stage and number of involved lymph node areas. Prognostic models developed in a single centre in a particular population may not perform equally well when applied to other populations in other centres. *Aims*. We wish to validate the prognostic power of the nomogram and risk score in a multicentric Italian population. *Methods*. We collected 757 complete records from a sample of 1109 patients from 6 centres. We used a nomogram and a prognostic score calculated according to the original publication to estimate median overall survival, 5-year and 10-year survival probability; a score stratified Cox model to estimate relative risk of death; univariate and multivariate Cox models to verify independent prognostic power of all 6 clinical and laboratory parameters. A p value<0.05 was considered to be statistically significant. Survival was measured from diagnosis until death from any cause. Kaplan-Meier method was used to estimate median survival. Median follow-up was calculated by inverted censoring method. β2 microglobulin value was standardized. *Results*. Median age was 65 years, median β2 microglobulin was 1 time upper reference limit, median lymphocyte count was 11×10^9/L, 58% of patients were male, 8% were in Rai stage III/IV, 19% had 3 or more involved lymph node areas. Median follow-up was 5.5 years (5.1-5.8). There were 102 deaths (13%) during follow-up and 44% of patients were treated. According to the nomogram, estimated median survival was approximately 11 years, survival probability was approximately 80% at 5 years and 50% at 10 years. Real data showed a not reached median survival at 21 years, an overall survival probability of 89% (86-92) at 5-years and of 77% (73-82) at 10 years. Using the simplified prognostic index score the agreement with real data at 5-years estimate was better then that obtained with the nomogram, but not satisfactory at 10-years estimate. Relative risk of death was in acceptable agreement. All 6 parameters were significant predictors in univariate models, but β2 microglobulin and lymphocyte count were not independent predictors in multivariate models. *Conclusions*. We could not confirm the independent predictive power of β2 microglobulin and lymphocyte count in our CLL population. Stratification with the simplified prognostic index score was able to correctly estimate relative risk of death, but not absolute value of survival probability. Median survival, 5- and 10-years survival probability was underestimated by using both the nomogram or the prognostic index score. The performance of the 6 parameters prognostic model may depend on the population on which it was developed. Further multicentric studies are needed to evaluate its general applicability.

THE PROGNOSIS OF CLINICAL MONOCLONAL B CELL LYMPHOCYTOSIS DIFFERS FROM PROGNOSIS OF RAI 0 CHRONIC LYMPHOCYTIC LEUKAEMIA AND IS RECAPITULATED BY BIOLOGICAL RISK FACTORS

F. Forconi,[1] A. Puma,[2] L. De Paoli,[2] S. Rasi,[2] V. Spina,[2] A. Gozzetti,[1] M. Tassi,[1] E. Sozzi,[1] E. Cencini,[1] D. Raspadori,[1] F. Bertoni,[3] V. Gattei,[4] F. Lauria,[1] G. Gaidano,[2] D. Rossi[2]

[1]University of Siena / AOUS, SIENA, Italy; [2]Division of Hematology, Avogadro University of Eastern Piedmont, NOVARA, Italy; [3]Laboratory of Experimental Oncology, Oncology Institute of Southern Switzerland, BELLINZONA, Switzerland; [4]Clinical and Experimental Onco-Hematology Unit,I.R.C.C.S., Aviano, Italy, AVIANO, Italy

Background. Monoclonal B-cell lymphocytosis (MBL) is an asymptomatic monoclonal expansion of $<5.0\times10^9$/L circulating CLL-phenotype B-cells. Since the introduction of the new IWCLL guidelines, it has been a matter of debate whether the 5.0×10^9/L CLL-phenotype cell cut-off for CLL diagnosis has a clinical rationale for the definition of MBL. The relationship between MBL and Rai 0 CLL, as well as the impact of biological risk factors on MBL prognosis, are unknown. *Aims*. i) to define whether clinical features at diagnosis, biological profile, and outcome of cMBL are distinguishable from Rai 0 CLL; ii) to identify clinical or biological variables at diagnosis that best predict the risk of evolution from cMBL to CLL requiring treatment. *Methods*. Out of 460 B-cell expansions with CLL-phenotype, 123 clinical MBL (cMBL) were compared to 146 Rai 0 CLL for clinical and biological profile and outcome. *Results*. cMBL had better humoral immune capacity and lower infection risk, lower prevalence of del11q22-q23/del17p13 and TP53 mutations, slower lymphocyte doubling time, and longer treatment-free survival. Also, cMBL diagnosis was a protective factor for treatment risk. Despite these favourable features, all cMBL were projected to progress, and lymphocytes $<1.2\times10^9$/L and $>3.7\times10^9$/L were the best thresholds predicting the lowest and highest risk of progression to CLL. Although IGHV status, CD38 and CD49d expression, and FISH karyotype individually predicted treatment-free survival, multivariate analysis identified the presence of +12 or del17p13 as the sole independent predictor of treatment requirement in cMBL (HR: 5.39, 95% CI 1.98-14.44, p=0.001). *Conclusions*. In this study we confirm that the 5.0×10^9/L cell cut-off can be used to distinguish cMBL from CLL. More importantly, however, we document that: i) cMBL and Rai 0 CLL differ in some biological features and outcome; and ii) cMBL who are destined to progress to symptomatic CLL/SLL requiring treatment can be identified by biological risk factors. Overall, these data show that cMBL has a more favourable clinical course than Rai 0 CLL. Since the biological profile can predict treatment requirement, stratification based on biological prognosticators may be helpful for cMBL management.

SUCCESSFUL TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA SHOWING 17P DELETION WITH FLUDARABINE, CYCLOPHOSPHAMIDE AND ALEMTUZUMAB

M. Montillo, A. Tedeschi, F. Ricci, S. Miqueleiz, E. Vismara, A. Greco, C. Colombo, M.A. Mura, S. Veronese, E. Morra

Niguarda Hospital, MILANO, Italy

B-CLL patients with p53 gene deletions [del(17)(p13.1)] or p53 point mutations have an inferior survival and appear resistant to standard chemotherapy. Alemtuzumab (A) is of potential interest in the treatment of p53-deleted B-CLL as its cytotoxicity is predominantly mediated by mechanism that should not involve the p53 pathway. A is relatively ineffective in pts with substantial lymph node enlargement. This consideration limits the usefulness of A monotherapy in CLL pts with p53 defects, as lymphadenopathy is common among such cases. In an attempt to overcome the limitations of A monotherapy in p53-deleted

CLL a protocol was developed in which the three agents, fludarabine (F), cyclophosphamide (C) and A are given in combination to B-CLL patients showing this high risk genetic profile. The FCC regimen consisted of F 40 mg/m^2/d orally on days 1-3, C 250 mg/m^2/d orally on days 1-3 and A 20 mg sc on days 1-3. This combination was repeated on d 29 for up to 6 cycles. Untreated or relapsed/refractory B-CLL patients carrying a p53 deletional status detected by fluorescent *in situ* hybridization (FISH) were selected to be enrolled in this phase II, open-label, single-centre trial. Chromosome abnormalities were detected by FISH testing at study entry from peripheral-blood or bone marrow cells. Only patients showing 17p with a clone size > 20% were enrolled. Mutational status of the variable region of the immunoglobulin heavy chain (IgVH) gene was also determined. Antimicrobial prophylaxis comprised trimethoprim/sulfamethoxazole (960 mg, every other day) and acyclovir (400 mg, twice daily). In the event of clinical or laboratory cytomegalovirus (CMV) reactivation, acyclovir was replaced by oral or intravenous ganciclovir (5 mg/kg/day). Currently, 14 pts have been enrolled in this trial. Median age was 55 years (range 45-72), 9/14 (64%) were male, 13/14 (93%) were in Binet stage B or C. Seven (50%) pts were untreated. The median time from diagnosis to study entry was 22 (range 3-108) and 59 (range 18-99) months for untreated and pretreated pts respectively. In the 7 pre-treated pts median number of prior regimens was 2 (range 1-3). IgVH unmutated was observed in 11 (79%) pts. The majority of patients had lymphadenopathy and/or splenomegaly. The ORR was 86%, with 7 (50%) pts achieving CR, 5 (36%) pts a PR. One remained in SD, while 1 showed progression of the disease. MRD negativity was achieved in 5/14 (36%) pts. Higher number of CR [6/7(87%)] and MRD- CR [4/7(57%)] were observed in untreated pts. A total of 69 cycles were assessable for toxicity. One patient showed a reactivation of a B virus hepatitis. In one patient therapy had to be stopped because of pneumonia sustained by Nocardia. The last patient showing a fungal pneumonia sustained by Aspergillus terreus was successfully treated with voriconazole. There were three subclinical CMV reactivations successfully treated with oral valganciclovir. Grade III-IV neutropenia episodes were observed in 40% of the administered courses while grade III-IV thrombocytopenia episodes were detected only in 8.6% of cycles. Ten pts are in continuous response after a median follow up of 15 months (range 2-27). In conclusion, results of this 4-weekly regimen with F, C and A suggest that this combination is effective in CLL pts with an high risk genetic profile such as del 17p.

0923

LOW DENSITY LIPOPROTEIN RECEPTOR PROTEIN 4 (LRP4) RS2306029 SINGLE NUCLEOTIDE POLYMORPHISM PREDISPOSES TO TRANSFORMATION OF CHRONIC LYMPHOCYTIC LEUKEMIA TO RICHTER SYNDROME

D. Rossi,[1] S. Rasi,[1] A. Bruscaggin,[1] A. Puma,[1] E. Sozzi,[2] V. Gattei,[3] F. Lauria,[2] F. Forconi,[2] G. Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, NOVARA; [2]University of Siena, SIENA; [3]Centro di Riferimento Oncologico, AVIANO, Italy

Background. The rationale of the study stems from two considerations: i) mechanisms and risk factors of CLL transformation to Richter syndrome (RS) are largely unknown; ii) the identification of a CD38 single nucleotide polymorphism (SNP) as RS risk factor suggests that the host genetic background may be relevant for RS development (Aydin S *et al*. Blood 2008;111:5646). *Aims*. To explore the role of the host genetic background in RS transformation. *Methods*. The study was based on a consecutive series of 331 CLL, of which 21 had transformed to RS. Using an educated guess approach, SNPs were selected according to the following criteria: i) reported association with CLL prognosis; ii) minor allele frequency >5% in Caucasians. Accordingly, 44 SNPs from 44 genes were genotyped on germline DNA extracted from peripheral blood granulocytes by SNP-minisequencing. Primary endpoint of the study was cumulative risk of transformation measured from date of CLL diagnosis to date of biopsy showing that RS transformation had occurred, death or last follow-up. The association between SNPs and risk of RS transformation was actuarially assessed by univariate log-rank analysis considering the minor allele as acting either in a dominant or a in a recessive fashion. Cox proportional hazard regression was used to build multivariate models for survival analysis. False discovery rate (FDR) was used to control for multiple statistical testing. *Results*. Univariate log-rank analysis identified LRP4 rs2306029, a SNP affecting the low density lipoprotein receptor protein 4 gene, as the sole SNP associated with RS transformation. CLL who carried LRP4 rs2306029 TT variant genotype displayed a higher risk of transformation (5-year risk: 14.1%) compared to patients carrying the LRP4 rs2306029 CT/CC genotypes that contained the wild type allele (5-year risk: 4.7%) (HR:4.08; p<0.001) (Figure 1). The association between LRP4 rs2306029 and RS transformation remained significant also after correction for multiple comparisons by FDR (q=0.040). Other variables at CLL diagnosis associated with an increased risk of RS were advanced Binet stage (p<0.001), lymph node size >3 cm, LDH elevation (p<0.001), CD38 expression (p=0.010), ZAP70 expression (p=0.017), unfavorable FISH karyotype (p<0.001), IGHV homology >98% (p<0.001), usage of IGHV4-39 (p<0.001), and stereotyped HCDR3 (p<0.001). None of the clinico-biological categories associated with an increased risk of RS was enriched with the LRP4 rs2306029 TT variant genotype (p>0.050 in all instances), suggesting that LRP4 rs2306029 TT is not a surrogate of other RS risk factors. Multivariate analysis selected LRP4 rs2306029 TT as an independent predictor of RS (HR:3.20; p=0.024), along with stereotyped HCDR3 (HR:3.13; p=0.033), IGHV4-39 usage (HR:5.22; p=0.008) and unfavorable FISH karyotype (HR:3.18; p=0.033). LRP4 rs2306029 is a non-synonymous SNP mapping to exon 31 of LRP4 and leading to Ser1554Gly amino acid substitution. In silico analysis with PupaSuite (http://pupasuite.bioinfo.cipf.es/), PolyPhen (http://genetics.bwh.harvard.edu/pph/) and SNPeffect (http://snpeffect.vib.be/) algorithms predicted LRP4 rs2306029 T variant allele to be dysfunctional and lead to altered LRP4 protein. Conclusions. rs2306029 non-synonymous SNP affecting LRP4 may predispose to CLL transformation to RS. Since LRP4 is involved in Wnt signalling and is expressed in CLL, the gene variant may have pathogenetic relevance for RS development.

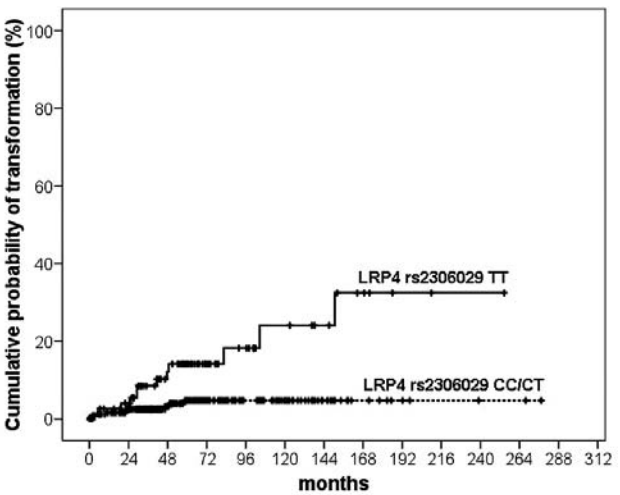

Figure 1. Cumulative risk of trasnformation to RS.

Background. Patients with relapsed or fludarabine refractory CLL have limited treatment options. Lenalidomide is an immunomodulatory drug that demonstrates significant clinical activity in this patient population

and in CLL patients with poor prognostic features including high risk cytogenetics and/or bulky disease. A phase II trial initiated in the relapsed/refractory setting to compare the safety and efficacy of lenalidomide at 25 mg/d with 10 mg/d resulted in 5 cases of tumor lysis syndrome (TLS). Therefore, in an effort to determine a safe dose and schedule the protocol was amended to a stepwise dose-escalation. Herein we present an interim safety data from the amended protocol. *Methods*. Eligible patients had good creatinine clearance (≥60 mL/min), received prior therapy with an alkylating agent and failed or progressed within a year of completing a fludarabine-based regimen. Lenalidomide was started at 2.5 mg daily dose. Intra-patient dose escalation to 5 mg/d occurred after 28 days with further dose escalations in 5 mg increments performed every 28 days, in 6-patient cohorts, until maximum tolerated dose escalation level (MTDEL) was defined, or the 25 mg/d dose level was attained. Patients continued on therapy until disease progression. TLS prophylaxis with 300 mg/d allopurinol and oral hydration were started 3 days before lenalidomide and continued for 3 cycles, with close monitoring for early signs of TLS (Cairo-Bishop Grading), particularly at drug initiation and dose escalations. *Results*. For 30 patients enrolled, median age was 66 years (range 50-76); 23 patients (76.7%) had bulky disease (LAN ≥5cm), and had failed a median 4 prior therapies (range 2-14): 13 patients (43.3%) were refractory to fludarabine and 6 (20.0%) had failed alemtuzumab. Grade 3-4 adverse events (AEs) were consistent with previous studies of lenalidomide in similar patient populations, and included thrombocytopenia (16.7%) and neutropenia (63.3%), of which 3% were febrile neutropenia. Ten patients (33%) developed tumor flare (3 cases were grade 3) at a median dose of 2.5 mg/d and most commonly during the first cycle. Laboratory TLS occurred in 1 patient at the 2.5 mg/d dose level and resolved without drug interruption. There are 14 patients currently on study and 16 patients discontinued therapy. Reasons for discontinuation included lack of efficacy in 7 patients, of whom 5 did not reach the 10 mg/d dose, and 5 patients developed AEs (at 10 mg/d: 1 AIHA, not attributed to lenalidomide and 1 PE in patient with DVT history and on antithrombotic prophylaxis; at 2.5 mg/every other day: 2 Grade 4 thrombocytopenia and 1 Grade 3 neutropenia). At last follow up lenalidomide was deemed tolerable up to the 15 mg/d dose level and the MTDEL had not been reached. Further escalation to the 20 mg/d dose is under investigation and anticipated for presentation. *Conclusions*. A preliminary safety analysis of lenalidomide stepwise dose escalation was found to be tolerable with MTDEL not yet reached at the 15 mg/d dose level. Close monitoring and prophylaxis were effective in the prevention, early detection and treatment of TLS in this heavily pretreated patient population with bulky disease.

Background. The clinical heterogeneity of chronic lymphocytic leukemia (CLL) requires parameters to stratify patients into prognostic subgroups to adapt treatment ranging from 'watch and wait' to allogeneic stem cell transplantation. Different parameters such as lymphocyte doubling time, β-2 microglobulin, CD38 and ZAP-70 expression, immunoglobulin variable heavy chain (IgVH) mutation status and genetic abnormalities have been integrated in clinical practice. By using fluorescence *in situ* hybridization (FISH), cytogenetic abnormalities can be found in approximately 80% of patients. *Aims*. In the present study, we performed FISH analysis to detect the major cytogenetic alterations in a series of patients in Binet stage A included in the prospective multicenter O-CLL1 GISL study started in April 2007. *Methods*. Molecular markers characterization and FISH analyses were previously reported (Cutrona *et al*. Haematologica, 2008; Fabris *et al*. GCC, 2008). *Results*. Up to date, 275 patients have been enrolled in the trial and FISH data concerning trisomy 12 and 13q14, 17p13, 11q23 deletions were available in 192 patients. At least one abnormality was found in 131/192 (68.2%) patients. The most frequent abnormality was del(13)(q14) (100/192, 52%), followed by trisomy 12 (25/192, 13%) (in one case accompanied by 17p13 deletion), del(17)(p13) (6/192, 3%) and del(11)(q22.3) (10/192, 5%). 13q14 deletion was found as a sole abnormalities in 90 patients; in the remaining cases, it was combined with del(17)(p13) (3 pts), trisomy 12 (1 pts) and del(11q)(22.3) (6 pts). Among patients with 13q14 deletions, 71 were monoallelic, 7/100 biallelic, whereas 22 showed combined biallelic and monoallelic deletion patterns. We also analyzed the relationship between each single abnormality and CD38 and ZAP-70 expression, and IgVH mutational status. In particular, the CD38 percentages were 8.4±1.8 (mean value±SD), 19.5±2.8, 45.1±7.1, 30.3±8.4, 52.9±9.9 for del(13)(q14), normal, trisomy 12, del(11)(q22) and del(17)(p13) FISH alterations (p<0.0001), respectively. The percentages of IgVH mutations significantly (p<0.0001) correlated with cytogenetic alterations; namely, 5.3±0.4 for cases with del(13q14), 4.6±0.6 in normal, 1.8±0.6 in trisomy 12, 0.2±0.1 in del(11)(q22) and 1.6±1.7 in the 4 cases with del(17p13). Similarly, a significantly (p=0.0005) lower mean value of ZAP-70 expression was accounted in del(13q14) (29.7±2.3) as compared with normal cases (34.6±3.2), trisomy 12 (43.8±5.4), del(11)(q22) (55.9±9.7) and del(17)(p13) (54.8±11.8). Based on a scoring system in which 1 point was assigned to each unfavorable biomarker (i.e. CD38, ZAP-70 or IgVH mutational status) we stratified our series in three different groups from 0 to 3 according to the absence or presence of one, two or all three biomarkers. Similarly, cytogenetic abnormalities were clustered in 3 risk groups [i.e. low del(13)(q14) and normal; intermediate (trisomy 12); and high risk del(11)(q22) and del(17)(p13)] as suggested by others. Interestingly, 72/77 cases scoring 0 for the biomarkers, gathered in the low FISH group. Conversely, out of the 13 cases with high FISH risk, 10 cluster in scoring 2-3. *Conclusions*. Our preliminary results indicate that in Binet stage A CLL patients at diagnosis cytogenetic abnormalities with an expected negative clinical impact are relatively few (16/192, 8%) but significantly associated with prognostic biomarkers which negatively predict the clinical outcome in CLL.

BETA2-MICROGLOBULIN IS A BETTER PREDICTOR OF TREATMENT-FREE SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA IF ADJUSTED ACCORDING TO GLOMERULAR FILTRATION RATE

J. Delgado,[1] G. Pratt,[2] N. Phillips,[2] J. Briones,[1] C. Fegan,[3] J. Nomdedeu,[1] C. Pepper,[3] A. Aventin,[1] R. Martino,[1] D.W. Milligan,[2] J. Sierra[1]

[1]Hospital de la Santa Creu i Sant Pau, BARCELONA, Spain; [2]Heart of England NHS Trust, BIRMINGHAM, UK; [3]Cardiff University School of Medicine, CARDIFF, UK

Background. Even in the era of newer and sophisticated prognostic markers, β2-microblobulin (B2M) remains a simple but very powerful predictor of treatment-free survival (TFS) and overall survival (OS) in patients with chronic lymphocytic leukaemia (CLL). However, B2M levels are heavily influenced by the patient's glomerular filtration rate (GFR). *Aims*. To evaluate whether GFR-adjusted B2M (GFR-B2M) had improved prognostic value compared to unadjusted B2M in a cohort of over 450 consecutive CLL patients from two separate institutions. *Methods*. Inclusion in this study was base purely on the confirmed diagnosis of CLL as defined by the WHO. Institutional databases from Hospital Sant Pau (HSP), Barcelona, and Birmingham Heartlands Hospital (BHH)

were screened for patient information relating to age; gender; Binet stage; B2M level at diagnosis; creatinine level at diagnosis; time and type of CLL-specific treatment; and overall survival. Results on the IgVH mutation status, genomic abnormalities as detected by FISH; CD38 expression and ZAP-70 expression were available in a proportion of patients. Standard clinical criteria were used for defining the initiation of therapy in all patients. GFR was estimated using the modification of diet in renal disease equation: GFR (ml/min/1.73m^2) = 186.3 x Serum Creatinine (mg/dL)-1.154 x Age (y)-0.203 x 1.212 if black, x 0.742 if female. For the purpose of this study we devised the so-called GFR-adjusted B2M (GFR-B2M) using the following equation: GFR-B2M = B2M (mg/L) x GFR (ml/min) / 100. Receiver operating characteristic (ROC) curves were generated in order to identify the most appropriate cut-off levels for both B2M and GFR-B2M. The area under the ROC curves was also calculated to evaluate the suitability of both B2M and GFR-B2M as predictors for treatment-free survival (TFS). The primary endpoints for comparison were TFS and overall survival (OS). The prognostic impact of each covariate was explored in the HSP cohort and validated in the BHH cohort. *Results*. By multivariate analysis, we observed a significantly shorter TFS in patients who were ZAP-70+ (p<0.001), with increased GFR-B2M (p<0.001), and del(11q) or del(17p) as detected by FISH (p<0.001). These results were validated in the BHH cohort. When OS was evaluated by multivariate analysis, age of 65 years or older (p<0.001) and poor risk FISH abnormalities (p<0.001) had a confirmed adverse prognostic impact, but the predictive value of GFR-B2M was lost in the validation analysis. In all survival models, B2M did not attain independent significance unless GFR-B2M was eliminated from the analysis. *Conclusions*. GFR-B2M is a better predictor of TFS than unadjusted B2M in CLL patients.

Background. Combination of fludarabine, cyclophosphamide and rituximab (FCR) is currently considered the first-line treatment of choice in physically fit patients (pts) with chronic lymphocytic leukemia (CLL) based on the results of CLL-8 study (Hallek *et al*., 2008). Although higher dose of rituximab (500 mg/m^2 from 2nd cycle) was used in CLL-8 as well as landmark phase II study (Keating *et al.*, 2005), it is purely empirical and ideal rituximab dosing remains unknown. Furthemore, there is a very limited amount of data regarding the use of FCR in real practice. *Aims*. to perform a retrospective efficacy and safety analysis of FCR regimen used as routine first-line treatment in CLL. *Patients and Methods*. Between October 2002 and May 2008, we treated 107 pts with active CLL (68% males, median age, 60 years [range, 27-75]) by FCR regimen as first-line therapy at five centers cooperating within Czech CLL Study Group. Diagnosis of CLL, indication for treatment and assessment of response to therapy followed NCI-WG criteria. Patients received standard doses of fludarabine (25 mg/m^2 i.v. or 40mg/m^2 p.o. d1-3) and cyclophosphamide (250 mg/m^4 i.v. or p.o. d1-3). Rituximab was administered i.v. on day 1 of each cycle at the dose of 375mg/m^2 in all cycles (n=87) or 500mg/m^2 from 2nd cycle (n=20). Treatment was repeated every 4 weeks. Antimicrobial prophylaxis and growth factors were not routinely used. Low/intermediate/high risk according to modified Rai staging was present in 1/72/27%. IgVH mutation status and FISH aberrations were available in 85% and 79% of pts. IgVH genes were unmutated in 74%; according to hierarchical model, del 13q was present in 31%, trisomy 12 in 9%, del11q in 26% and del17p in 8%. *Results*. At the time of analysis (February 2009), the median observation time was 22.3 months (mo). Median number of FCR cycles was 5. The overall response rate/complete response rates were 92/47%. Median PFS was 30 mo; median overall survival (OS) was not reached. Patients with unmutated IgVH genes had significantly shorter PFS (p=0.0051). Small numbers of pts in each FISH aberration group precluded a meaningful statistical analysis. Four out of 7 pts with del 17p responded to FCR (1x CR, 3x PR). Patients treated with lower dose of rituximab (375mg/m^2) did not have significantly different ORR, CR and PFS from those treated with 500 mg/m^2 (p=0.79, p=0.24 and p=0.65). Grade III/IV neutropenia occured in 22/14% of cycles and thrombocytopenia grade III/IV in 5/3% of cycles. Serious infections occured in 1% of cycles only. G-CSF was administered in 54% and recombinant erythropoietin in 13% of pts. *Conclusions*. Treatment of CLL patiens in first line with fludarabine, cyclophosphamide and rituximab resulted in high number of overall and complete responses despite unfavourable prognostic factors present in the majority of pts. Toxicity was acceptable and manageable. Further studies are needed to address the question whether lower dose of rituximab (375mg/m^2) in FCR yields the same therapeutical efficacy as 500 mg/m^2.

LENALIDOMIDE ASSOCIATED TUMOR FLARE REACTION CORRELATES WITH CLINICAL RESPONSE IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

T. Sher, K. Miller, M. Patel, A. Whitworth, L. Musial, D. Lawrence, S. Padmanabhan, S. Ailawadhi, G. Wilding, D. DePaolo, N. Bangia, M.S. Czuczman, P.K. Wallace, K.P. Lee, A. Chanan Khan

Roswell Park Cancer Institute, BUFFALO, USA

Introduction. Lenalidomide is an immunomodulatory agent currently under investigation for treatment of chronic lymphocytic leukemia (CLL) and lymphoma. Tumor flare (TFR) is a unique clinical feature observed in CLL patients receiving lenalidomide, and may be related to its antitumor activity. TFR is characterized by painful, tender enlargement of disease involved lymph nodes, spleen and/or liver along with low grade fever. The underlying mechanism and impact of TFR on treatment outcomes remain unclear. To better understand its clinical significance, efficacy results from our phase II trial of patients with relapsed/refractory B-CLL treated with lenalidomide were correlated with the incidence, severity, and duration of TFR. *Methods*. Forty-five patients were divided into 2 groups: A) lenalidomide 25 mg/day for 21 days of a 28-day cycle without TFR prophylaxis (n=29); B) lenalidomide 10 mg/day with dose escalations in 5 mg increments every 1-2 weeks until maximum dose of 25 mg/day was achieved (n=16). Also, during days 1-14 of cycle 1, group B received oral prednisone (20 mg/day for 5 days followed by 10 mg/day for 5 days) as TFR prophylaxis. *Results*. For 45 patients evaluated, median age was 64 years, median baseline ALC was 43.6×10^9/L, and 29 patients (64%) had Rai stage III/IV disease. Patients had a median of 3 prior therapies. Clinically significant TFR developed in 30 patients (67%): 20 (67%) grade I, 7 (23%) grade II, and 3 (10%) grade III. Median time to TFR was 6 days (range 0-56) and median time to TFR resolution was 14 days (95% CI: 10-26). In >90% of cases TFR occurred only during the first cycle. For combined groups A and B, 11 patients required TFR treatment consisting of NSAIDs with or without oral morphine; only 3 patients received morphine. No patient discontinued lenalidomide due to TFR. Median age for those who developed TFR relative to those who did not was 61 and 71 years, respectively (p=0.004). TFR occurred in 19 patients (66%) from group A and in 11 (69%) patients from group B. In groups A and B, grade II/III TFR occurred in 9 (47%) and in 1 (9%) patient, respectively (p=0.05), with a median time to onset of 4 and 9 days, respectively (p=0.01). To date 8 patients achieved a complete response (CR) of who 7 had developed TFR. Among 15 patients without TFR only 1 CR (7%) was observed (p=0.24). Although median progression-free survival (PFS) for patients with and without TFR was 19.9 and 19.4 months, respectively, PFS in group A relative to group B was 23 vs. 17.8 months (p=0.74). This difference did not reach statistical significance potentially due to small patient numbers. *Conclusions*. TFR appears to be an acute inflammatory reaction primarily involving tumor bearing sites. Despite a low sample size our analysis suggests that TFR development may correlate with achievement of a CR with lenalidomide. Steroid prophylaxis decreases the severity but not the incidence of TFR. Whether TFR prophylaxis using steroids is effective remains to be determined in a larger cohort of patients.

0929

ABNORMAL SERUM FREE LIGHT CHAIN RATIO AS A PREDICTOR OF ADVERSE OUTCOME IN CHRONIC LYMPHOCYTIC LEUKEMIA: HAS THE TIME COME FOR A SIMPLE PROGNOSTIC MARKER?

Z.A. Yegin, M. Yagci, Z.N. Özkurt, N. Kursunoglu, S.Z. Aki

Gazi University Faculty of Medicine, ANKARA, Turkey

Background. As chronic lymphocytic leukemia (CLL) is characterized by a highly variable clinical course, recent studies have mainly focused on ‹dentification of a new and simple molecular and biological prognostic marker. An abnormal serum free light chain ratio (FLCR), which is considered to be a reliable predictor of outcome in plasma cell disorders, is reported in approximately 44% of CLL patients. *Aims*. This retrospective study is planned to assess the prognostic value of FLCR in CLL and to estimate its impact on survival and outcome of this specific group of patients. *Methods*. Quantitative levels of serum FLC were measured nephelometrically in sera collected at presentation or before treatment. A normal sFLCR range [kappa(k)/lambda(l)] was defined as 0,26-1,65. ZAP 70 and CD38 expression were quantified by flow cytometry. Chromosomal abnormalities were determined by interphase fluorescence *in situ* hybridization (FISH) on peripheral blood using multicolor probes for chromosome 12 centromere, locus specific 11q22.3, D13S319 and D13S25 and 17p13.1. Patients were stratified as high, intermediate and low risk based on FISH results. *Results*. A study cohort of 101 patients [median age 62(37-90); M/F: 68/33] were eligible for the current study. Median follow-up of the whole cohort was 28(1.1-234) months. An abnormal FLCR was found in 30 patients (29,7%), while 71 patients (70,3%) presented a normal FLCR. Abnormal FLCR was associated with leukocyte count (p=0.009), atypical lymphocyte morphology (p=0.046), clinical stage (p=0.018), lactate dehydrogenase (p=0.046) and CD38 levels (p=0.005). A significant linear relationship was observed between FLCR and CD38 on logistic regression analysis (p=0.03; OR:1,02). The three genetic risk groups, stratified according to FISH, did not differ significantly with respect to FLCR (p>0.05). Time to first treatment (TTFT) was 54,6% for the whole cohort; 57.4% in normal versus 46.1% in abnormal FLCR groups at the end of median 28(1,1-234) months of follow up (p>0.05). Abnormal FLCR was more frequent in patients requiring treatment (p=0.04). Overall survival (OS) was 49.2% for the whole cohort; 74.7% in FLCR normal versus 36,3% in FLCR abnormal groups, at the end of median 28(1.1-234) months of follow up (p=0.05). ZAP 70, CD38, clinical stage and performance status were identified as independent prognostic parameters for OS in multivariate analysis. *Summary and Conclusions*. This study highlighted the potential prognostic value of FLCR in CLL patients. Abnormal FLCR was found to be predictive for reduced OS. The remarkable association of FLCR and CD38 may reflect FLCR's biological prognostic value. Further clinical efforts should focus on the biological role of FLCR to maximize our understanding of this new and simple candidate prognostic marker. Prospective studies are warranted to validate the adverse impact of FLCR on clinical outcome before it is brought into routine clinical practice

0930

HIGH INTRACELLULAR CONTENT OF CYCLIN-DEPENDENT KINASE INHIBITOR P27KIP1 IN EARLY- AND INTERMEDIATE STAGE B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES PREDICTS RAPID PROGRESSION OF THE DISEASE

L. Ciszak,[1] D. Wolowiec,[2] M. Wojtowicz,[3] A. Kosmaczewska,[1] S. Potoczek,[2] D. Urbaniak-Kujda,[2] K. Kapelko-Slowik,[2] K. Kuliczkowski,[2] I. Frydecka[2]

[1]Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, WROCLAW; [2]Medical University of Wroclaw, WROCLAW; [3]Regional Hospital in Opole, OPOLE, Poland

Background. Previous studies showed that peripheral blood lymphocytes of B-cell chronic lymphocytic leukemia (B-CLL) displayed a high intracellular level of cell cycle inhibitory protein p27Kip1. It has been suggested that high expression of p27Kip1 may confer them survival advantage and be associated with unfavorable prognosis, but prognostic significance of p27Kip1 expression for previously untreated, non-advanced B-CLL patients was not established. *Aims*. We studied a relationship between the intracellular level of p27Kip1 of lymphocytes of early- and intermediate stage B-CLL patients and their spontaneous apoptosis *in vitro*, as well as prognostic significance of p27Kip1 in B-CLL lymphocytes for the risk of disease progression. *Methods*. Intracellular p27Kip1 content of peripheral blood lymphocytes obtained from 48 previously untreated 0-II Rai stage B-CLL patients, analyzed by flow cytometry, was determined as the mean fluorescence intensity (MFI). The *in vitro* viability and spontaneous apoptosis of those lymphocytes after 72-hours culture were also assessed. During the follow-up period (6-71 months, median 59.5), we recorded the time elapsed to the doubling of peripheral lymphocyte count, progression to a higher Rai stage and the appearance of indications for cytostatic treatment. *Results*. p27Kip1 expression was not correlated with initial peripheral lymphocytes count, CD38 expression, cell viability nor spontaneous apoptosis ratio after 72-hours culture. In order to assess the possible prognostic significance of cellular p27Kip1 content for the clinical course of B-CLL, we have divided the patients' group into low expressors and high expressors of p27Kip1. We have chosen the cut-off p27Kip1-dependent MIF value at 270 AU, i.e. in such a way that the differences in the occurrence of clinical progression between low- and high expressors were maximal. We observed that doubling of lymphocyte number, progression to higher Rai stage and indications for cytostatic treatment occurred significantly earlier in patients with high p27Kip1 expression than in the group with low p27Kip1 content. Accordingly to that, the frequency of each of three above-mentioned events during the whole follow-up period was markedly higher in the group with p27Kip1 - dependent MIF above 270 AU as compared with low p27Kip1 expressors. We did not find a prognostic significance of *in vitro* cell viability nor apoptosis as to the risk of disease progression. Conclusions: Our results indicate that elevated intracellular expression of p27Kip1 in peripheral blood leukemic lymphocytes has an unfavorable prognostic value in early- and intermediate stage B-CLL patients as to the risk of disease progression. Further studies are required to elucidate the issue of the relationship between p27Kip1 expression and survival of leukemic cells, and to answer the question about the independency of its prognostic significance.

0931

ALEMTUZUMAB ADMINISTERED BY SUBCUTANEOUS ROUTE IS LESS EFFECTIVE THAN INTRAVENOUS ROUTE FOR FIRST LINE THERAPY OF T-CELL PROLYMPHOCYTIC LEUKAEMIA: RESULTS OF A PILOT STUDY (UKCLL05)

A. Khot,[1] E. Matutes,[1] A. Kaczmarek,[1] M. Ethell,[1] M. Hamblin,[2] A. Roy,[3] E. Grand,[4] C. Dearden[1]

[1]Royal Marsden Hospital, LONDON; [2]Colchester General Hospital, COLCHESTER; [3]North Hampshire Hospital, BASINGSTOKE; [4]Salisbury District Hospital, SALISBURY, UK

Background. T-cell prolymphocytic leukaemia (T-PLL) is a rare aggressive post thymic lymphoid disorder with distinctive clinical and pathological features. It is resistant to conventional chemotherapy and has a short median survival of 7 months. Intravenous (IV) alemtuzumab is an effective and well tolerated therapy for this disease, inducing remission in 76% of patients in the relapsed and refractory setting and increasing median survival to 24 months in responders. *Aims*. The aim of this study was to determine the efficacy of subcutaneous (SC) administration of alemtuzumab in previously untreated T-PLL patients. *Methods*. After an initial week of dose escalation, patients were treated with a dose of 30 mg 3 times weekly. Patients could be switched to the IV route if they had local side effects or showed a lack of response. *Results*. Nine patients were enrolled. Male: female Ratio was 2:1; median age was 61 years. All cases were centrally reviewed and confirmed to have a diagnosis of T-PLL. Eight had an immunophenotype typical of T-PLL (CD2, CD3, CD5, CD7 and CD 4 positive). One patient was unusually CD7 negative and also did not have an abnormality of chromosome 14. Seven had a complex karyotype and 8 had chromosome 14 abnormalities. Patients were treated on trial for a median of 7 weeks (range 3-13 weeks). 55% required a change to IV treatment due to a lack of response. This resulted in an increase in overall response (OR) from 33% (1 CR, 2 PR) to 44%.(2 CR, 2 PR). Five patients required addition of pentostatin to alemtuzumab at a dose of 4 mg/m^2 IV weekly to augment response. This increased (OR) to 77% (1 additional CR and 2 PR). 5 patients had haemopoietic progenitor cell transplants (HPCT) as consolidation; 1 autologous and 4 allogeneic. Median overall survival was 20 months (range 1-26 months) and disease free survival was 12 months (range 0-20 months). The treatment was well tolerated; however 2 patients had skin reactions to the SC injections. One patient required treatment for CMV reactivation and 2 patients had Grade 4 haematologic toxicity which was related to disease and not treatment. Four patients remain alive and well in CR with a follow up of between 12 and 23 months, of whom 3 had allogeneic HPCT. The study was terminated early as a data safety monitoring review felt that SC treatment was not efficacious and patients should not be offered SC treatment. 5. *Conclusions*. This pilot

study suggests that the SC route of administration of alemtuzumab is not as effective as IV in the treatment of T-PLL; a series of 16 patients receiving 1st line therapy with IV alemtuzumab has shown an OR of 94% with 88% CR. It is therefore advisable that IV treatment should be used. Pentostatin is an effective agent to augment response. Allogeneic HPCT should be used as consolidation therapy when possible.

0932

INCLUSION OF TOTAL BODY CT SCAN IN THE INITIAL WORK-UP OF CLL PATIENTS WITH EARLY-STAGE ON CLINICAL GROUNDS: PRELIMINARY RESULTS OF A PROSPECTIVE, MULTICENTER O-CLL1- GISL STUDY

Background. The clinical staging systems proposed by Rai and Binet represent the backbone for assessing prognosis in patients with Chronic Lymphocytic Leukemia (CLL). However, staging systems are not devoid of some limitations, among the most significant of which is the lack of recognition of early-stage patients who will progress. Unlike the guidelines for assessing the response to therapy for most other types of non-Hodgkin's lymphomas, the widely-used NCI-WG guidelines for patients with CLL do not incorporate use of computed tomography (CT) scans in the algorithm. However, two recent retrospective study challenged this notion. highlighting the importance of prospective validation of CT scans before routine inclusion in CLL work up. *Aims*. In the present study, we investigated whether total body CT scan allowed to individuate among Binet stage A CLL patients, included in the prospective multicenter O-CLL01 GISL study, cases in more advanced stage and whether this subgroup showed a different expression of clinical and biological prognostic markers. *Patients.* Up to date, 275 patients have been enrolled in the trial started in April 2007 and total body CT scan were available in 87 patients. Fifty-two patients (60%) were male and the median age was 61 years (range, 33 to 71 years). All patients are in Binet stage A, while 83 patients were at low risk (0-I stages) and 4 at intermediate risk (II stage) by Rai classification. LDH was elevated in 11.5% of cases and B2-microglobulin in 24%. Twenty-eight patients (33%) were IgVH unmutated, 31 patients (36%) had a high ZAP-70 expression, 17 patients (20%) were CD38 positive (>30%). Fluorescence *in situ* hybridization (FISH) data are available in 61/87 cases; the most frequent abnormality was del(13)(q14) (29 pts 33%), followed by trisomy 12 (5 pts, 6%), del(17p13) (4 pts 5%) and del(11q22.3) (2 pts 2%), 21 cases (24%) were normal. Cytogenetic abnormalities were clustered in 3 risk groups [i.e. low (del(13q14) and normal), intermediate (trisomy 12) and high risk (del(11q22) and del(17p13)] as suggested by others. *Results*. Considering total body CT scan, 22 out of 83 analyzed (25%) patients were converted into Binet stage B. Notably, 64% were male, LDH was elevated in 18% of cases and B2-microglobulin in 18%, 41% were IgVH unmutated, 27% had a high ZAP-70 expression, 27% were CD38 positive, 4,5% showed a high-risk FISH. Both main clinical characteristics and biological prognostic markers failed to correlate with a more advanced stage. In fact, no statistically different distribution of gender, age, LDH and β2-microglobulin, such as IgVH mutational status, CD38 and ZAP-70 expression and cytogenetic abnormalities were observed between Binet A cases and Binet B. According the Rai classification 14/83 (17%) low risk patients became at intermediate risk with the integration of total body CT scan. Also this subset of patients did not show a statistically different expression of all prognostic markers, but a higher rate of cases with elevated B2-microglobulin (p=0.003), than patients at low risk. Finally, total body CT scan allowed to early individuate a second neoplasia in 2 cases (lung cancer 1 pt, renal cell carcinoma 1 pt). *Conclusions*. In line with literature information, our preliminary data indicate that the integration of total body CT scans in the clinical staging allowed to individuate among Binet A CLL cases on clinical grounds 25% of cases with a more advanced stage. Although a more advanced stage did not correlate with both clinical and biological variables reflecting bad prognosis. A longer follow-up will allow to demonstrate whether the inclusion of total body CT scan in the initial work-up of patients with early-stage on clinical grounds provide relevant prognostic information.

0933

CLL WITH BURKITT-TYPE TRANSLOCATION: A SUBGROUP WITH AN AGGRESSIVE DISEASE COURSE

N. Put1, K. Rack,[2] A. Janssens,[1] P. Meeus,[3] C. Barin,[4] A. Delannoy,[5] V. Eclache,[6] M. Janssen,[7] F. Nguyen-Khac,[8] I. Radford-Weiss,[9] A. Van Hoof,[10] J. Verschuere,[11] E. Wouters,[3] W. Wynendaele,[12] I. Wlodarska,[1] P. Vandenberghe,[1] L. Michaux[1]

Background. Balanced translocations are uncommon in chronic lymphocytic leukemia (CLL), and their significance remains poorly understood. *Aims*. The aim of the present study was to identify the characteristics of CLL patients with a Burkitt-type translocation. *Methods*. Clinical and cytogenetic files from patients referred to Belgian and French institutions between 1990 and 2009 for cytogenetic characterisation of CLL, and displaying a t(8;14)(q24;q32) or a variant translocation, were reviewed. FISH was performed to confirm involvement of MYC gene and to analyze other prognostically significant aberrations, i.e. those affecting 17p, 11q, 12 and 13q. IgVH mutational status was additionally assessed. *Results*. 16 patients displayed a t(8;14) or variant (representing < 0.5% of CLLs referred during the period of study). These were mainly males (ratio M/F: 14/2) with a median age of 69 years (range 46-84). Six patients presented with Binet stage A, 3 with stage B and 7 with stage C. Lymphadenopathy and splenomegaly were present in 9/16 and 10/15 patients, respectively. Anemia and thrombocytopenia were present at diagnosis in 3 and 4 patients, respectively. In 3/10 patients, a monoclonal paraprotein was observed. Morphology was compatible with "typical" CLL in 2 cases, "atypical" CLL in 9 cases (i.e. presence of occasional prolymphocytes (< 10%) in 4, and CLL/PL (10-55%) in 2 cases) and PLL in 3 cases (i.e. > 55% prolymphocytes). Morphological data could not be obtained for 2 cases. Immunophenotypical data matched a Matutes-Catovsky score of > 3 in all but one cases. CD38 was expressed (i.e. > 30%) in 9/15 patients. The Burkitt-type translocation was the sole aberration in 2 cases. The translocation most frequently involved IGH, but variant cases involving the IGK or IGL locus were observed in 4 and 4 cases, respectively. The Burkitt-type translocation was associated with one other abnormality in 7 cases. Complexity (> 3 changes including the t(8;14) or variant) was observed in 7 cases. Associated recurrent aberrations included del(11q) (n=6), trisomy 12 (n=5) cases and del(6q) (n=2). VH was mutated in 6 and unmutated in 3 cases. V3 and V7 family were used in 6 cases and 1 case, and V3-21 was never used. There were no recurrent VDJ combinations. Follow-up data was available in all patients over a median period of 23.5 months (range 1-168). Median time to treatment (TTT) was 0.5 months (range 0.5-36). 11/16 received therapy; 4 were refractory and none of the remaining achieved complete remission. Disease-related death occurred in 8 patients, whereas 6 are still alive and 2 are lost to follow-up. *Conclusions*. CLL with Burkitt-type translocation represents an extremely rare entity with an aggressive disease course, an advanced stage at presentation, adverse cytogenetic findings (i.e. del(11q), complexity), short TTT and poor response to therapy.

Myeloma and other monoclonal gammopathies - Biology II

AN EXPERIMENTAL STUDY FOR PERIPHERAL NEUROPATHY ASSOCIATED WITH WALDENSTRÖM'S MACROGLOBULINEMIA*

A. Tsingotjidou,[1] C. Bekiari,[1] A. Kagiava,[2] G. Theophilidis,[2] C. Emmanouilides[3]

[1]Faculty of Veterinary Medicine, THESSALONIKI; [2]Lab. of Animal Physiology, Department of Zoology, School of Biology, THESSALONIKI; [3]Interbalkan Medical Center, Dept. of Oncology, THESSALONIKI, Greece

Waldenström's macroglobulinemia (WM), is a lymphoplasmacytic lymphoma characterized by IgM production. Neuropathy is a common complication of WM, conferring considerable morbidity but its precise pathophysiology remains obscure. In our previous study an animal model of WM has been described (Tsingotjidou *et al.*, 2007, in press). In the current study an effort has been made to develop the WM-related neuropathy in non-obese diabetic, severe combined immunodeficient (NOD/SCID) mice. For this reason, freshly obtained bone marrow biopsies from WM patients were implanted intra muscularly into the hindlimbs of 10 SCID mice. The animals were monitored for neuropathy with histological and immunohistochemical evaluation along with behavioural tests in the mid- and the end- of the experiment period. Possible sensory neuropathy was estimated with hot-plate and touch-response tests; grip strength and body suspension tests were used to assess for motor neuropathy. Following different survival periods (from 2 to 8 months) electrophysiological data were also obtained to assess possible chances in conduction velocity along the sciatic nerve from the experimental animals just prior to their sacrifice. The light microscopy of semi thin (1 μm) toluidine blue stained sections of affected sciatic nerves revealed areas with reduced number of larger diameter axons and an increase in the density of smaller myelinated and/or unmyelinated axons. These changes are evidence of a neuropathic process and were not present in controls. Immunohistochemical detection of different molecules in the sciatic nerves is under investigation. Based on the hot plate and touch response tests it can be concluded that the developed sensory neuropathy selectively affected the fiber-neural endings responsible for the finer feeling of touch, the Aδ fibers of the peripheral nerves. The results from the grip strength and the body suspension tests test show that the WM implanted mice develop a motor neuropathy since the values of the above mentioned tests are lowered at the experimental animals. Electrophysiological data have been standardized by testing the control animals. For this reason the motor (MNCV) and the sensory (SNCV) nerve conduction velocity of the sciatic nerve of the left hind limb were measured. For the control animals the MNCV was estimated to be 35 ± 1.60 m/s, close to the values estimated by other researchers. Also, in the control animals the SNCV was estimated to be 25.20 ± 0.55 m/s. Upon completion of the planned experimental period, the conduction velocities of the affected nerves will be measured and compared to the established measurements of the control animals.

**This study is supported by a grant from the International Waldenström Macroglobulinemia Foundation (IWMF) to A.S.T. and C.E.E.*

HGF AND IGF-1 POTENTIATE SDF-1 MEDIATED MYELOMA CELL MIGRATION THROUGH ACTIVATION OF PAK

R.U. Holt,[1,2*] U.M Fagerli,[1,3*] T. Holien,[1] H. Hov,[1] A. Waage,[1,4] A. Sundan,[1] M, Børset[1,5]

*[1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; [2]Faculty of Technology, Sør_Trøndelag University College, Trondheim, Departments of [3]Oncology, [4]Hematology and [5]Immunology and Transfusion Medicine, St. Olavs University Hospital, Trondheim, Norway *Equal contribution*

Background. Multiple myeloma (MM) is characterized by the accumulation and dissemination of malignant plasma cells in the bone marrow, a process that requires cell migration. Both SDF-1, IGF-1 and HGF is known to induce MM cell migration and by exploring such processes it could be possible to find new therapies targeting the MM cell and the interaction with the BM environment. *Aims*. SDF-1, IGF-1 and HGF are all potent mediators of migration *in vitro*, and we wanted to study the effects of combinations of these cytokines on migration in myeloma cell lines and patient samples. *Methods*. Migration was studied in a Transwell migration assay and cells were transfected with siRNAs using electroporation. Receptor expression and cell viability was determined using flow cytometry and protein detection was done with Western blot. *Results*. We could show a strong synergistic effect on migration when combining SDF-1 with either HGF or IGF-1; this synergy was dependent on an SDF-1 gradient. However, both HGF and IGF-1 potentiated SDF-1- induced migration irrespective of where they were added, to the upper, to the lower or to both compartments in the migration assay. In JJN-3 cells, which secrete large amounts of HGF, SDF-1- induced migration was reduced when the c-Met inhibitor PHA665752 was added to the cells, demonstrating cooperative activity between autocrine HGF and exogenous SDF-1. HGF and IGF-1 did not affect the level of SDF-1 receptor expressed on the cell surface. There was a clear correlation between degree of migration and PAK activation both in INA-6 and IH-1 cells and in primary myeloma cells. Downregulation of Pak 1 and Pak 2 with siRNA resulted in lower cell migration than in control cells, in agreement with a role for Pak in cytokine-induced myeloma cell migration. *Conclusions*. HGF and IGF-1 potentiated SDF-1 -mediated myeloma cell migration through activation of Pak. The study suggests that PAK could be a target in treatment of multiple myeloma.

SPARC GENE EXPRESSION IN MULTIPLE MYELOMA PATIENTS AND ITS REGULATION BY CYTOTOXIC TREATMENTS IN MYELOMA CELL LINES

R. Kusec, D. Grcevic, M. Martinovic, R. Ajdukovic, V. Haris, O. Jaksic, V. Pejsa

Dubrava University Hospital, ZAGREB, Croatia

Background. SPARC (Osteonectin) is molecule of extracellular matrix with important cell growth, attachment and migration functions. In oncology its role is under intensive investigation since SPARC may support the tumour growth, but may also block its progression acting as tumour suppressor all this depending on the type of neoplasm. We have recently shown that humoral SPARC in MM patients can serve as biomarker. In this study we looked at the SPARC gene expression by MM cells in patients and myeloma cell lines. *Aims*. We have analyzed the expression of SPARC gene in bone marrow (BM) and peripheral blood (PB) of healthy controls, MM patients and 2 myeloma cell lines: Thiel and NCI H929. *Methods*. We includeed 35 MM patients and 17 controls into the study. Expression of SPARC and internal housekeeping gene GAPDH was analyzed using quantitative PCR (Taqman gene expression assaysR) in unfractionated mononuclear cells (MNC) from BM and PB and in cell lines grown in standard cultures. Cell lines were in addition treated with bortesomib (BORT), dexamethasone (DEXA), thalidomide (THAL) and cyclosporine (CSA) in different pharmacological concentrations to evaluate its effect on SPARC expression and rate of viability measured by MTT assay. *Results*. SPARC gene was higher expressed in MM samples compared to controls but only for PB MNCs values reached statistical significance (p=0.0078, Mann-Whitney). We could not demonstrate correlation between expression values in BM and PB. By the disease stage, SPARC was higher in active disease and lower in Durie-Salmon stage 3. In resistant cell line NCI-H929 (MMSET-IgH+), SPARC was basally low expressed but treatment with THAL and CSA increased its expression, whereas decreased cell viability. In Thiel cell line there was higher basal level of SPARC expression, whereasTHAL and CSA suppressed the expression parallel to reduced viability. BORT treatment in Thiel cells strongly reduced viability with little effect on SPARC expression. Finally, DEXA only slightly suppressed SPARC expression in both cell lines without significant effect on cell viability. *Conclusions*. Expression of SPARC gene is increased in active myeloma disease with the decline in the expression by disease progression. *In vitro* results for resistant and non-resistant myeloma cell lines showed different pattern of SPARC gene expression and different response to anti-myeloma drugs. These results warrant further research into the biology of SPARC in MM with future attention to tumour-stroma interaction of marrow microenvironment.

GLOBAL MICRORNA EXPRESSION PROFILING IN MULTIPLE MYELOMA IDENTIFIES DEREGULATED PATTERNS ASSOCIATED WITH DISTINCT MOLECULAR GROUPS

M. Lionetti,[1] L. Agnelli,[1] K. Todoerti,[1] S. Fabris,[1] L. Nobili,[1] S. Leone,[1] S. Matis,[2] G. Cutrona,[2] G. Lambertenghi Deliliers,[1] A. Neri[1]

[1]Università degli Studi, Fondazione IRCCS Ospedale Policlinico, Milano, MILAN; [2]Divisione di Oncologia Medica C, Istituto Nazionale Ricerca Sul Cancro, IST, GENOVA, Italy

Background. The recent discovery of microRNA (miRNA) genes, encoding for a class of small non-coding RNAs involved in the regulation of cell cycle, survival and differentiation programs, has added a further level of complexity to normal and cancer cell biology. Impaired miRNA expression has already been demonstrated in a number of solid tumors and, more recently, in some hematological disorders; nevertheless, to date only little evidence of miRNA expression/deregulation in multiple myeloma (MM) has been reported. *Aims*. To characterize miRNA expression profiling of MM plasma cells (PCs) and integrate miRNA expression data with other molecular features of MM patients (IGH translocations and other genetic abnormalities). *Methods*. A CD138 positive PCs isolation was performed from bone marrow biopsies of 38 newly diagnosed MM, 2 plasma cell leukemia patients, and 3 healthy donors. Total RNA was extracted using Trizol reagent. The miRNA expression data were generated on Agilent miRNA microarrays V2 (representing 723 human mature miRNAs from the Sanger miRBase v10.1), and normalized using the AromaLight Bioconductor package. Hierarchical agglomerative clustering was performed by means of DNA-Chip Analyzer (dChip) software, using Pearson's correlation coefficient and average linkage as distance and linkage methods, respectively. Differentially expressed miRNAs were identified using the "Significant Analysis of Microarrays" (SAM) algorithm. The expression of some miRNAs was validated by means of quantitative real time RT-PCR, using specific TaqMan® microRNA assays (Applied Biosystems). *Results*. An unsupervised analysis of the samples based on the most variably expressed miRNAs across the dataset grouped the PCs from healthy donors separately from MM PCs; among the pathological samples, the most striking finding was that the seven patients with t(4;14) (TC4) were tightly clustered, as were four out of the five samples with translocated MAF genes (TC5). A partial grouping of the TC2 cases (mostly hyperdiploid) was also observed, whereas the TC1 [showing t(11;14)] and TC3 (mostly expressing Cyclin D2) samples were dispersed along the dendrogram. A multiclass supervised analysis of the miRNA expression between the members of the 5 TC groups highlighted specific miRNA signatures, in particular characterizing the TC4 and TC5 groups (upregulation of *miR-34b**, *miR-150*, *miR-1*, *miR-155*, *miR-133a*, *miR-133b*, *miR-155**). A less consistent miRNA signature was observed in t(11;14) cases and TC2 group, whereas we could not identify any TC3-specific miRNA signature. None of the differentially expressed miRNAs in patients with specific IGH translocations maps to the rearranged chromosomal regions. Additionally, no differentially expressed miRNAs were associated with the occurrence of neither 13q14 deletion nor 1 q gain. *Conclusions*. Our data on miRNA expression profiling in a representative panel of MM patients revealed a global deregulation of miRNA expression in myeloma cells, and identified miRNA signatures associated with MM molecular subgroups. These data extend previous limited data and represent the basis for further investigations aimed at functionally characterizing specific miRNAs in MM.

THE COMPARISON OF SERUM LEVELS OF SELECTED BIOMARKERS AND CYTOGENETIC CHANGES IN MULTIPLE MYELOMA

T. Pika,[1] J. Balcarkova,[2] M. Holzerova,[2] J. Minarik,[3] M. Budikova,[4] K. Langova,[5] J. Bacovsky,[3] M. Jarosova,[2] V. Scudla[5]

[1]University Hospital, OLOMOUC; [2]Department of Hemato-Oncology, University Hospital, OLOMOUC; [3]3rd Internal Department, University Hospital, OLOMOUC; [4]Department of Clinical Biochemistry, University Hospital, OLOMOUC; [5]Department of Medical Biophysics, Palacky University, OLOMOUC, Czech Republic

Background. Multiple myeloma (MM) is a malignant neoplasm of plasma cells characterized by production of monoclonal immunoglobulin detectable in the serum and/or urine and various levels of organ damage. In MM chromosomal abnormalities and biochemical markers have biologic and prognostic significance. Some less usual deductable biochemical parameters appear to be very promising as possible markers of neoplastic transformation and also as the markers of advanced stage, progression and monitoring of treatment response in patients with MM. *Aims*. In the present study we compare serum levels of 12 selected biomarkers and cytogenetic changes in 128 MM patients examined at time of diagnosis. *Methods*. We used conventional cytogenetics and FICTION method with locus specific probes 1q21/1p36 (Kreatech, MP Biomedicals, CA, USA), RB1, IgH, IgH/CCND1, IgH/FGFR3 and centromeric probes for chromosomes 7, 9, 11, 15, 17 (Abbott-Vysis, Downers Grove, IL, USA). M-FISH and CGH (MetaSystems, Altussheim, Germany) were also applied in order to determine other chromosomal abnormalities. For evaluation of serum levels of analysed parameters were used following methods: radioenzymatic assay (thymidine kinase), ELISA (β2-microglobulin), radioimmunoanalysis (ICTP, PINP), enzymoimmunoassay (sIL-6R, sVCAM, sICAM-1, sOPG) and quantitative enzymatic immunoassay (sHGF, sVEGF, syndecan-1/CD138 and sFas). Mann-Whitney's test was used for statistical evaluation. *Results*. Significantly higher levels of β2-microglobulin (p=0,010) were consistent with complex karyotype. Gains of 1q21 significantly correlate with higher levels of sIL-6R (p=0,038), but significantly lower levels of sIL-6R (p=0,009) correlate with t(11;14). Lower levels of OPG were associated with deletion of RB1 gene (p=0,013), as well as lower levels of PINP with t(4;14) (p=0,031). Serum levels of selected biomarkers did not correlate significantly with polyploidy. *Conclusions*. This preliminary analysis shows that cytogenetic changes have effect on cytokine network in multiple myeloma, especially on one of key-role factors (sIL-6R) in pathogenesis of multiple myeloma. Important prognostic factors such as HGF and syndecan-1/CD138 are not influenced by analysed cytogenetic changes in our cohort of patients.

NON-PROTEASOME TARGETS OF PROTEASOME INHIBITORS BORTEZOMIB AND CARFILZOMIB

S. Arastu-Kapur, K.D. Shenk, C.J. Kirk, D. Swinarski, T. Muchamuel, M.K. Bennett, F. Parlati

Proteolix, SOUTH SAN FRANCISCO, USA

Background. Carfilzomib is a next generation proteasome inhibitor that is structurally and mechanistically distinct from bortezomib and is currently undergoing clinical investigation in multiple myeloma, non-Hodgkin's lymphoma, and solid tumors. The mechanisms of action of carfilzomib and bortezomib differ due to their unique pharmacophores: bortezomib is a peptide boronate while carfilzomib is a peptide epoxyketone. Phase 1 and 2 studies with carfilzomib suggest a clinical safety profile that has commonalities and distinctions compared to bortezomib (Blood 112, abstract 865). In particular, the painful peripheral neuropathy that is commonly observed with bortezomib (Velcade® package insert) appears to be less severe and possibly less frequent with carfilzomib, raising the possibility that non-proteasome mechanisms may underlie this toxicity. *Aims*. To gain insight into the unique clinical toxicities of bortezomib and carfilzomib, we evaluated their propensity to act as inhibitors of non-proteasomal enzymes. *Methods*. We executed a two-pronged approach consisting of candidate and proteomic strategies to identify the non-proteasomal targets of bortezomib and carfilzomib. Identified targets were validated in human peripheral blood mononuclear cell (PBMC) lysates and IC50 values were determined using FP-biotin, a serine hydrolase-specific fluorophosphonate active site probe. *In vivo* inhibition of the targets was determined in rats following a single dose of each either carfilzomib or bortezomib. To evaluate the contribution of the pharmacophore to target inhibition, a matrix of nine inhibitors consisting of three peptide backbones (derived from bortezomib, carfilzomib, and MG132) coupled to three pharmacophores (boronate, epoxyketone, or aldehyde) were tested. *Results*. In a screen of candidate cysteine, aspartyl, metallo-, and serine proteases, bortezomib significantly inhibited the serine proteases cathepsin G (CatG) and chymase, while carfilzomib did not inhibit these enzymes. IC50 values for these targets were determined in PBMC cell extracts and were found to be 2 and 256 nM for chymase and CatG, respectively. To obtain a global inhibition profile of the serine hydrolases that are targeted by bortezomib, single dimension mass spectrometry analysis was performed on FP-biotin-reactive proteins from PBMC cell extracts. In addition to CatG and chymase, bortezomib was found to inhibit cathepsin A (CatA) and dipeptidyl peptidase II (DPP II) with 0.5 and 410 nM IC50 values respectively. Furthermore, CatG activity in the spleen was inhibited by 60% in bortezomib-treated rats but was unaffected in carfilzomib-treated

animals. Finally, using the panel of inhibitors with equivalent amino acid chains but varying pharmacophores, we observed that the boronate versions of the inhibitors displayed potent activity towards CatG, CatA, and chymase, while the epoxyketone versions were inactive. *Conclusions*. These data demonstrate that non-proteasomal enzymes, CatG, CatA, DPP II and chymase, can be targeted by bortezomib at physiologically relevant concentrations (bortezomib Cmax = 312 nM). Carfilzomib does not inhibit non-proteasomal targets in our assays. Inhibition of these non-proteasomal proteases is dependent upon the boronate pharmacophore; epoxyketone-containing proteasome inhibitors were inactive. *In vivo* inhibition of rat splenocyte CatG together with literature reports (Trends Immuno 28:541-550; Trends Neurosci 26:496-500; British J Pharm 150:176-185) supports the hypothesis that off-target activity of bortezomib may be linked to toxicities such as neuropathic pain.

0940

CXCR4 AND CD43 CO-EXPRESSION IN PLASMA CELL MALIGNANCIES

S. Improta, A. Lucania, M.R. Villa, P. Della Cioppa, M. Esposito, A.A. Quirino, L. Mastrullo

ASL NA1 San Gennaro, NAPLES, Italy

Background. Bone marrow (BM) microenvironment has been envised as a "trap" for circulating multiple myeloma (MM) precursors, which expand and differentiate to malignant plasma cells within the BM, invading the peripheral blood only in the terminal stage of the disease, i.e. plasma cell leukemia (PCL). While several adhesion molecules have been identified that promote the binding of malignant plasma cells to BM accessory cells and extracellular matrix (i.e. CXCR4), little is known on molecules able to prevent such interactions, by eventually favoring the escape of tumor cells from the BM "trap". Previous studies have indicated that the CD43 sialoglycoprotein functions as an anti-adhesion molecule by providing a repulsive barrier around cells due to its extended conformation and negative charge of sialylated residues. *Aims*. We investigated CXCR4 expression and its association with the expression of the CD43 sialoglycoprotein on bone marrow plasma cells of MM and PCL patients. *Methods*. We have analyzed the bone marrow blood of 40 patients with MM and 8 with PCL. 26 out of 40 MM patients presented a IgG component, while the remaining 14 were IgA. On the basis of the staging criteria, 23/40 patients were in stage I-II and 17/40 in stage III. We evaluated CXCR4 and CD43 expression by flow cytometry. Mean fluorescence intensity ratios (MFIRs) were calculated by dividing the mean fluorescence intensity for CXCR4 and CD43 by the mean fluorescence of the respective non-specific isotype control. *Results*. 23/40 MM patients (stage I-II) showed high CXCR4 expression (median MFIR 15.2; range: 10.3-50.4) while 17/40 (stage III) showed lower CXCR4 expression (median MFIR 6.5; range: 5.1-9.5). All MM patients were CD43 negative. By contrast all PCL patients were CD43 positive (MFIR 7.8; range: 6.2-10.1), while CXCR4 expression was like MM stage III patients group (MFIR 6.2; range: 4.8-8.9). *Conclusions*. Our results that malignant plasma cells from MM lack surface CD43 as opposed to PCL in which CD43 expression was found at a high cellular density, indicate that CD43 expression may be related to the biological and clinical progression of MM. Moreover the possible prognostic role of CXCR4 in MM warrants further clinical investigation on a larger series of patients even on the basis of future therapeutic strategies.

NOVEL WHOLE CELL ASSAYS TO MONITOR PROTEASOME ACTIVITY IN MULTIPLE MYELOMA

A. Liggett,[1] T.C. Morris,[2] B. Walker,[1] A.E. Irvine[1]

[1]Queen's University Belfast, BELFAST; [2]Haematology, Belfast City Hospital, BELFAST, Northern Ireland

Background.The proteasome is a multicatalytic complex involved in the regulation of key cellular processes including cell cycle control and apoptosis. Proteasome inhibitors have shown particular efficacy in Multiple Myeloma (MM). We have previously profiled the three main components of proteasome activity using assays based on cell lysates (>5×10^6 cells). This strategy has now been adapted for use in a smaller number of whole cells (1×10^4) to facilitate clinical studies. *Aims*. To develop an assay to profile proteasome activity in small numbers of whole cells for application to clinical investigations. *Methods*. Fluorogenic substrates Z-Leu-Leu-Glu-AMC and Succ-LLVY-AMC, specific for the Peptidyl Glutamate Peptide Hydrolysing (PGPH) and Chymotrypsin-Like (CT-L) proteasome activities respectively were modified by adapting the side chain of glutamic acid as a methyl ester to aid cell entry. These modified substrates have been used with both MM cell lines and clinical samples, where increased fluorescence is directly proportional to proteasome activity. The effects of three proteasome inhibitors, BZ-Leu-Leu-Leu-COCHO (BZLLL), MG132 and PS341, were investigated in the U266 MM cell line, and correlated with initiation of apoptosis using the Enzchek® caspase-3 assay, with confirmation by western blotting. *Results*. The level of CT-L activity was uniformly reduced by each inhibitor to approximately 50% of control (p=0.037). In contrast, PGPH activity was reduced to 29.8±2.7%, 47.3±12.8% and 15.4±0.6% of control (p≤0.019) with BZLLL, PS-341 and MG132 respectively. Addition of BZLLL and PS-341 to whole cell preparations also induced a dose-dependent increase in caspase-3 activity. Maximal inhibition of CT-L and PGPH substrates was observed at 9.9±0.8 hours and 9.4±2.6 hours respectively with 10 μM BZLLL, 7.8±0.6 hours and 7.7±0.6 hours respectively with 10nM PS-341 and 8.5±0.9 hours and 6.7±1.1 hours respectively with MG132. *Conclusions*. Modified fluorogenic substrates specific for the CT - L and PGPH proteasome activities have been shown to efficiently permeabilise whole cells. Together with cell - permeable proteasome inhibitors, these have been applied to the accurate profiling of proteasome activity in small numbers of intact cells, thus facilitating their application to investigations with clinical samples.

GROWTH FACTORS, HGF, IL-6, AND IL-3 DIFFERENTIALLY REGULATE DIFFERENTIATION OF HUMAN MULTIPLE MYELOMA MESENCHYMAL STEM CELLS IN RELATION TO BONE METABOLISM

J. Park,[1] K.-S. Ahn,[2] C. Lee,[1] E.-K. Bae,[3] B.-S. Kim,[4] S.-M. Bang,[5] I. Kim,[6] D.-S. Lee,[7] S. Park,[6] B.-K. Kim,[6] S.-S. Yoon[6]

[1]Seoul National University, College of Medicine, Cancer research institute, SEOUL; [2]Korea University, College of Medicine, Department of Pathology, Medical Research, SEOUL; [3]Han Yang University, College of Medicine, Department of Biomedical Science, SEOUL; [4]Seoul National University Boramae Hospital, Internal Medicine, SEOUL; [5]Seoul National University Bundang Hospital, Internal Medicine, SEOUL; [6]Seoul National University Hospital, Internal Medicine and Clinical Research Inst, SEOUL; [7]Seoul National University Hospital, Clinical Pathology, SEOUL, South-Korea

Background. Along with the progression of multiple myeloma (MM), myeloma-induced bone destruction is the result of an increased function of osteoclasts, which is not accompanied by a comparable increase of osteoblast activity. Various growth factors involved in MM progression and an individual factor differentially affects the balance between osteoblasts and osteoclasts.

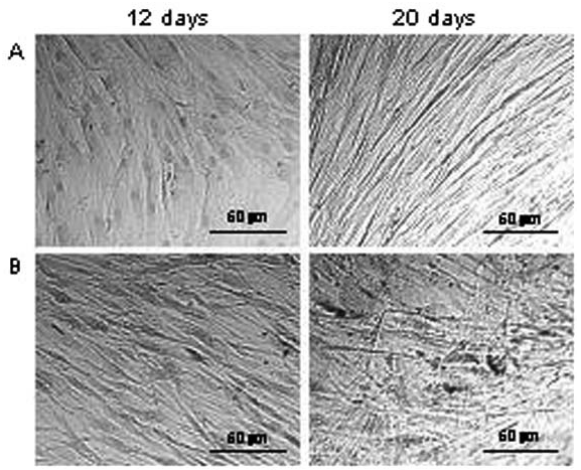

Figure 1. Osteogenic induction of hMM-MSCs. After being cultured in MSC-culture medium (A) or osteogenic medium (B) for 12 and 20 days. Osteogenic induction was detected by Alizarin R staining (ARS).

Aims. To investigate various growth factors or cytokines effect on either osteoblast or osteoclast differentiation of multipotent human mesenchymal stem cells (hMSC) obtained from MM patients. *Methods*. To investigate growth factors affecting osteoblast differentiation of mesenchymal stem cells, osteoblast differentiation related genes (RUNX2, OPG, and ALPL) and osteoclast differentiation related genes (TGF-1, MIP-1, and RANKL) were examined using immunostain, RT-PCR and expressions of

genes related to Wnt pathway by western blot analysis. In addition, effect of osteoblast differentiation by treated with growth factors in co-culture with MM cells was examined by ALP and Alizarin red staining. *Results*. HGF, IL-6 and IL-3 stimulated osteoclast differentiation via osteoblastic factors were down-regulated but osteoclastic factors were up-regulated in hMSC. MM cells treated with rhHGF were reduced β-catenin phosphorytion and activation of DKK1 expression. In this study, blockage of Wnt signaling pathway in MM cells was deregulated osteoblast differentiation on hMSC. Osteoblast differentiation was regulated by different time points after treated with growth factors in hMSC via regulation of different expression patterns accordingly. In addition, When hMSC alone or co-culture with MM cells, osteoblast differentiation was reduced with co-cultured with MM cells. *Conclusions*. We suggested that Wnt signaling pathway was critical in osteoblastic differentiation on hMSC via abrogated Wnt mediated signaling pathway by activation of HGF expression in MM cells. Moreover, when compared with hMSC alone or co-cultured with MM cells, those growth factors were synergistically reduced osteoblast differentiaton in co-cultured with MM cells.

IMMUNOHISTOCHEMICAL EVALUATION OF SARCOGLYCANS AND INTEGRIN IN GINGIVAL EPITHELIUM OF MULTIPLE MYELOMA PATIENTS WITH BISPHOSPHONATE-INDUCED OSTEONECROSIS OF THE JAW

A. Allegra,[1] S. Russo,[1] A. Cannavò,[1] A. Alonci,[1] G. Oteri,[2] A. Favaloro,[2] E. Nastro,[2] F.S. De Ponte,[2] D. Cicciù,[2] G. Anastasi,[2] C. Musolino[1]

[1]Division of Hematology, MESSINA; [2]University of Messina, MESSINA, Italy

Background. Osteonecrosis of the jaw (ONJ) is an adverse outcome associated to bisphosphonate treatment. However, it is not known whether the ONJ lesion originates in the bone, or whether it may initiate in the oral mucosa. *Aims*. Aim of our study was to characterize the distribution of different mucosal proteins after bisphosphonate administration and to evaluate the structural damage of the mucosal in ONJ patients. In particular we evaluated changes in basement membranes and in expression of costameric proteins (vinculin-talin-integrin system), laminin, and type IV collagen.

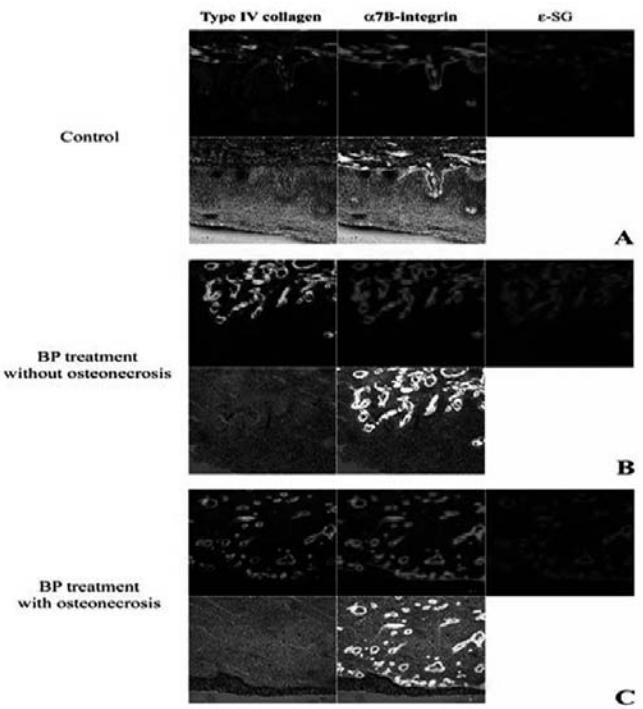

Figure 1. Compound panel showing immunohistochemical finding.

Methods. Samples of human gingival epithelium were obtained from patients treated with zoledronate which no showed the osteonecrosis and from patients treated with bisphosphonates which showed the osteonecrosis. These samples were compared with gingival epithelium of control subjects which had undergone odontoiatric surgery for other reasons. Patients treated with bisphosphonates were affected by Multiple myeloma. Immunohistochemical study was made using confocal laser scanning microscopy. *Results*. All tested proteins were almost absent in basal lamina and oral mucosa of subjects treated with bisphosphonates without osteonecrosis, whereas in oral mucosa with necrosis, they showed a clearly detectable staining pattern of the same proteins, specifically in basal lamina, but less in comparison to control samples. Moreover, in oral mucosa with lesion, a massive neoangiogenesis was detectable. The triple immunofluorescence reaction, performed between type IV collagen, integrin, and ε-sarcoglycan antibodies, in control subjects, showed in fact a clear normal pattern of all proteins in basal lamina, which is perfectly delineated; besides, any vascular structure is detectable while the epithelial side is not detectable for these proteins. The fluorescence analysis of same proteins in samples treated with bisphosphonates of subjects that no showed lesions showed an almost absence of protein staining patterns in correspondence of basal lamina, but clearly detectable staining for all tested proteins in correspondence of vascular structures that are numerous. In the sections of subjects treated with bisphosphonates that showed the osteonecrosis, we observed an increase of protein staining patterns on basal lamina and a qualitatively and quantitatively increase of vessels below the basal lamina. Triple fluorescence reaction performed with laminin, α-sarcoglycan, and β-sarcoglycan in control subject showed a normal staining patterns of all proteins with a clear fluorescence on basal lamina. In bisphosphonates treated subjects that no showed lesions, basal lamina fluorescence is absent whereas the vessels are clearly detectable. In ONJ subjects it was possible to highlight newly an increase of staining patterns on basal lamina and a massive increase of vascular structures. Triple fluorescence reactions using vinculin, integrin, and γ-sarcoglycan antibodies showed the same behaviours of other proteins. Finally, in the samples treated with bisphosphonates showing lesion, it was detectable an increase of staining pattern both in the basal lamina and in vessels. *Conclusions*. The increase of these proteins in basal lamina, in concomitance with formation of the lesion, could indicate a compensative behaviour in the remodelling of the gingival mucosa in order to restore the epithelial architecture. The neoangiogenesis, unexpected feature during bisphosphonate treatment, could confirm this compensative role of tested proteins.

0944

SEQUENTIAL EVALUATION OF SERUM HEPCIDIN IN ANEMIC MYELOMA PATIENTS: A PILOT STUDY OF CORRELATIONS WITH MYELOMA TREATMENT, DISEASE VARIABLES, AND ANEMIA RESPONSE

E. Katodritou,[1] T. Ganz,[2] E. Verrou,[1] O. Olbina,[3] E. Terpos,[1] V. Gastari,[1] C. Hadjiaggelidou,[1] S. Georgiadou,[1] M. Varthaliti,[1] A. Polyzopoulos,[1] S. Zlatintsi,[1] N. Constantinou,[1] M. Westerman,[3] K. Zervas[1]

[1]Theagenio Cancer Center, THESSALONIKI, Greece; [2]David Geffen School of Medicine, UCLA, LOS ANGELES. CA, USA; [3]IntrinsicLifeSciences, LLC, LA JOLLA, CA, USA

Background. Hepcidin is a key modulator of iron metabolism and cancer-related anemia. However, its role in hematological malignancies and particularly in Multiple Myeloma (MM), has not been determined. *Aims*. In this pilot study we examined possible correlations of baseline and sequential serum hepcidin values with disease variables and treatment with Immunomodulatory drug-based regimens (IMiDs group) or conventional chemotherapy (conventional group). In addition, analysis included correlations of serum hepcidin with disease response (DR), duration of response (DOR), and anemia response (AR) in a cohort of anemic MM patients. *Methods*. Thirty-four anemic myeloma patients newly diagnosed or at progression, were studied. Eighteen were treated with IMiDs-based regimens and 16 with conventional therapy. Patients at progression should have remained in partial response for at least 6 months before study. Patients under IMiDs maintenance for the last 6 months, patients with active infection and those treated with erythropoiesis-stimulating agents or iron for the last 2 months prior study initiation were excluded. *Results*. In the IMiDs group, hepcidin level decreased significantly between baseline value and second treatment cycle (cycle 2) (p=0.03) followed by stabilization at significantly lower levels, after three cycles (p=0.01). In the conventional group, hepcidin decreased significantly before cycle 2 (p=0.03) but returned to baseline values between cycles 2 and 4 (p>0.05). In the combined groups, baseline hepcidin was positively correlated with ISS score, β2 microglobulin (β2M), creatinine, ferritin and transferrin saturation and inversely with Hb and PLT (p<0.05). In the same groups, hepcidin before cycle 3 was negatively correlated with DR (p=0.018). In the conventional group, serum hepcidin above the upper normal limit before cycle 2 was negatively correlated with AR (p=0.023). In the same group, baseline hepcidin was inversely correlated with DR at 2 months (DR 2) and DOR (p=0.039,

p=0.006, respectively). Overall, hepcidin before cycle 3 was the only independent predictor for DR and DR 2 (p=0.03 for both end-points). Hepcidin before cycle 2 above the upper normal limit was the only predictor for AR (p=0.02). *Conclusions*. These results suggest that serum hepcidin is correlated with important disease variables such as ISS and β2M that reflect tumor activity and clinical outcome in MM, and thus may serve as a surrogate marker for disease activity. Following the initial treatment cycles, hepcidin was strongly correlated with DR in the combined groups. In the conventional but not in IMiDs group, baseline hepcidin was significantly correlated with DR and DOR suggesting that IMiDs-based regimens may overcome the negative impact of baseline hepcidin on response indicators. Patients in the IMiDs group maintained decreased hepcidin levels through cycle 3 in contrast to the conventional treatment group, where hepcidin returned to baseline highlighting the effectiveness of IMiDs-based regimens on disease control. In contrast with other significant disease biomarkers, serum hepcidin has potential as a predictor for disease and anemia response in MM, particularly during the initial phase of treatment. Overall, our results indicate the utility of serum hepcidin to monitor disease response and guide therapeutic decisions in MM.

0945

FGFR3 IS EXPRESSED AND IMPORTANT FOR SURVIVAL IN INA-6, A HUMAN MYELOMA CELL LINE WITHOUT A T(4;14)

T.K. Våtsveen,[1] A.T. Brenne,[1] H.Y. Dai,[2] A. Sundan,[1] A. Waage,[1] M. Børset[1]

[1]NTNU, TRONDHEIM; [2]St. Olavs University Hospital/ Institute of Pathology and Medical Genetics, TRONDHEIM, Norway

Background. Fibroblast growth factor receptor 3 (FGFR3) might play a role in the survival and proliferation of myeloma (MM) cells. Primary MM cells and MM cell lines (HMCL) with t(4;14) express FGFR3 in 75% of the cases. *Aims*. If FGFR3 plays an important carcinogenic role, one might expect other genetic aberrations than t(4;14) to lead to expression of the gene. We show data suggesting that gene amplification is another mechanism leading to expression of FGFR3. *Methods*. Fluorescence *in situ* hybridization with locus-specific probes for FGFR3 and MMSET was used on metaphase spreads of the t(11;14) INA-6, and array-CGH was used to look at the genomic alterations. Western Blot and qRT-PCR detected the FGFR3 expression. To determine the functional role of the receptor, small-molecule FGFR3-inhibitors SU-5402 and PD-173074 were used in proliferation studies and viability studies. The t(4;14) HMCLs IH-1 was used as a positive control and OH-2 without IGH translocations or FGFR3 expression was used as a negative control. All three HMCLs are IL-6 dependant. FGFR3 was sequenced in INA-6 and IH-1 to look for activating mutations. MMSET expression was also determined by qRT-PCR. *Results*. The FGFR3 was present in INA-6 cells although the cell line is t(4;14) negative. In INA-6 the expression of FGFR3 is dependant on IL-6, and the expression of FGFR3 is decreased when cells are starved for IL-6 over night. The same level of decreased FGFR3 was not seen in IL-6 deprived IH-1 cells. INA-6 has a trisomy of chromosome 4 and there was a duplication of the 4p16.3 locus on one 4p on chromosome 4. The FGFR3 inhibitors, SU-5402 and PD-173074, each reduced proliferation of INA-6 cells, both in the presence and in the absence of aFGF. Similar inhibition was seen in IH-1 cells, a t(4;14) HMCL, whereas OH-2 cells, HMCL without FGFR3 expression, were insensitive to the drugs. The same was also seen when looking at cell viability with flow cytometry. The FGFR3 was not mutated in IH-1 or INA-6 determined by sequencing. MMSET in INA-6 was close to the expression in OH-2 and significantly lower than in IH-1. *Summary and Conclusions*. INA-6 expresses wild type FGFR3 without having a t(4;14). Amplification of the FGFR3 might cause the expression. The FGFR3 level decreases when the cells are deprived of IL-6. The alternative mode of aberrant FGFR3 expression shown in INA-6 cells is supportive of an oncogenic role for this receptor in MM. Since INA-6 it does not express MMSET at a high level, contrary to all the t(4;14) cell lines and, hence, lacks the IGH/MMSET fusion transcript, it might be useful as a model system for investigating FGFR3's role in MM cells independently of the interaction of high levels of MMSET.

0946

ESTABLISHMENT OF AN INTERLEUKIN-6 INDEPENDENT VARIANT (CMA-03/06) OF THE HUMAN MYELOMA CELL LINE CMA-03: BIOLOGICAL AND MOLECULAR CHARACTERIZATION BY A GENOMIC INTEGRATIVE ANALYSIS

D. Verdelli, L. Nobili, K. Todoerti, L. Mosca, S. Fabris, G. Lambertenghi Deliliers, L. Lombardi, A. Neri

Dip Sc. Mediche, Centro Leucemie, Università Milano, Fond. IRCCS Policlinico, MILANO, Italy

Background. The growth and survival of multiple myeloma (MM) cells in the bone marrow microenvironment is regulated by functional complex interactions between the tumor cells and the surrounding bone marrow stromal cells mediated by adhesion molecules and the production of several cytokines of which interleukin-6 (IL-6) has been identified as the most important. Major advances in the investigation of MM biology were made possible by the availability of human myeloma cell lines (HMCLs). The IL-6-dependent CMA-03 cell line was established in our laboratory from a peritoneal effusion of a refractory relapsed MM patient. By gradually decreasing the IL-6 added to the culture, an IL-6-independent variant, CMA-03/06, could be obtained. *Aims*. To perform a biological and molecular characterization of this novel cell line, and to provide insights into the signaling pathways and target genes involved in the growth and survival of CMA-03/06. *Methods*. The growth, immunophenotypic, cytogenetic and fluorescence *in situ* hybridization (FISH) characterization of CMA-03/06 was performed by means of standard procedures. IL-6 production into the culture media was determined using a high sensitivity IL-6 specific ELISA. Global gene expression profiling (GEP) was performed by means of the GeneChip® Human Gene 1.0 ST Arrays (Affymetrix); the supervised analyses were done using the SAM software version 3.0. Genome-wide profiling data were generated by means of Affymetrix GeneChip® Human Mapping 250K Nsp arrays; copy number (CN) alterations were calculated using the DNAcopy Bioconductor package, based on circular binary segmentation method. *Results*. The addition of IL-6 to the culture medium of CMA-03/06 or co-culture with multipotent mesenchymal stromal cells didn't induce an increase in proliferation of the cells. CD45 expression was considerably reduced in CMA-03/06 cells compared with CMA-03, whereas they were found positive for both chains of IL-6 receptor, CD126 and CD130, almost undetectable in CMA-03. Conventional cytogenetic and FISH analyses didn't reveal differences between the two HMCLs. IL-6 could not be detected in the supernatants from either CMA-03 or CMA-03/06. Western blot analysis revealed the IL-6 induced activation of STAT3 and STAT1 in both HMCLs. GEP analysis of CMA-03/06 compared with CMA-03 allowed the identification of 21 upregulated and 47 downregulated genes, mainly involved in cellular signaling, cell cycle, cell adhesion, cell development, regulation of transcription, apoptosis; many of them are known to be involved in myeloma biology. The genome-wide analysis allowed the identification of about 100 altered chromosomal regions common to both HMCLs, mostly DNA gains. Comparison of CMA-03/06 with CMA-03 evidenced a different CN in only 15 small chromosomal regions, eight of which didn't contain any transcript, whereas few genes were located on the other ones. None of the genes differentially expressed in CMA-03/06 compared with CMA-03 except one were positioned on these regions. *Conclusions*. Our data confirm the IL-6 independence of CMA-03/06 and the absence of an autocrine IL-6 loop, even though the IL-6 pathway is still active. Since the cell line uses other signaling pathways for its growth, it may represent a suitable model for studies concerning the pathways involved in cytokine responses in MM.

0947

INHIBITION OF PROTEASOME SUBUNITS BY CARFILZOMIB IN PHASE 1B CLINICAL TRIAL MEASURED USING A NOVEL SUBUNIT-SPECIFIC ELISA

Q Levitsky, S.J. Lee, K.D. Shenk, S. Arastu-Kapur, M.K. Bennett, F. Parlati

Proteolix Inc, SOUTH SAN FRANCISCO, CA, USA

Background. Proteasome inhibition has been validated as a therapeutic approach for the treatment of multiple myeloma (MM) and mantle cell lymphoma. However, the contribution of individual proteasome active sites to the clinical efficacy of bortezomib, an approved agent, and next generation proteasome inhibitors (PIs) such as carfilzomib, NPI-0052 and CEP-18770 are largely unknown. The constitutive and immunoproteasome each contain three catalytic sites characterized as chymotrypsin-like (β5 and LMP7), caspase-like (β1 and LMP2) and trypsin-like (β2 and MECL1), which the aforementioned drugs target with varying selectivity and reversibility, depending on the reactive warhead and backbone structure. These differences may contribute to the distinct properties of these molecules observed in the laboratory and the clinic. Our current understanding of proteasome activity relies on fluorogenic substrate assays that do not adequately represent proteasome subunit activities. New assays that can measure subunit activity in cells are needed in order to establish the relationship between proteasome inhibition and anti-tumor activity. *Aims*. To develop a quantitative assay capable of measuring the activity of each catalytic subunit in the constitutive proteasome and the immunoproteasome in human patient samples. To asses proteasome subunit inhibition in samples from patients enrolled in a Phase 1b carfilzomib/lenalidomide/dexamethasone combination clinical trial. *Methods*. We developed a proteasome constitutive/immuno subunit ELISA (abbreviated ProCISE) to measure the activity of individual proteasome subunits. The assay utilizes a biotinylated peptide epoxyketone probe to label and capture each active subunit, and subunit-specific antibodies for detection. Purified proteasomes and whole blood treated *ex vivo* with carfilzomib and bortezomib, as well as samples from patients receiving carfilzomib as part of a Phase 1b clinical trial were analyzed for levels of individual subunit active sites using the validated ProCISE assay. *Results*. The ProCISE assay was validated using commercially available purified constitutive (c20S) or immunoproteasome (i20S) protein and human RBC or PBMC lysates derived from healthy donors. The assay is capable of measuring proteasome concentrations from 0.23-1.49 µg/mL to 25 µg/mL, depending on the subunit. When compared to bortezomib *in vitro* and *ex vivo*, carfilzomib showed greater selectivity for the chymotrypsin-like subunits β5 and LMP7 in both cases, whereas bortezomib displayed significant activity towards β1 and LMP2 subunits. Preliminary data from patients receiving the 15 mg/m^2 dose of carfilzomib as part of a combination Phase 1b trial, showed strong inhibition of the chymotrypsin-like subunits β5 (74%) and LMP7 (84%) after the first dose. The LMP2 and MECL1 subunits of the immunoproteasome were affected significantly less and inhibition of the constitutive subunits β1 and β2 was found to be minimal. *Summary*. ProCISE is a robust and reproducible assay for measuring proteasome activity in both research and clinical settings. Using ProCISE, we demonstrated that carfilzomib potently and selectively inhibited the chymotrypsin-like activity of the constitutive proteasome and immunoproteasome in purified proteasome, *ex vivo* treated blood and samples derived from MM patients receiving carfilzomib treatment. The ProCISE assay is an important new tool for studying the role of the proteasome and its inhibitors in MM biology and therapy.

0948

EXPRESSION OF CD27 ON PLASMA CELLS IN MULTIPLE MYELOMA

L. Kovarova,[1] I. Buresova,[2] K. Muthu Raja,[2] M. Penka,[1] R. Hajek[1]

[1]University Hospital, BRNO; [2]Masaryk University, BRNO, Czech Republic

Background. Multiple myeloma (MM) is characterised by a clonal expansion of neoplastic plasma cells (PC). These PCs are mostly CD19$^-$ CD56$^+$, but in a small group of patients clonal CD19$^+$ PCs occur. Light chains clonality assessment is widely used to discriminate between clonal and polyclonal PCs, although especially in low infiltration cases results are not convincing. CD27 is expressed on memory B cells and also on normal CD19$^+$ plasma cells, so one can assume that this marker can be used for confirmation of polyclonal CD19$^+$ PCs in MM as well. *Aims*. The aim of this study was to analyse expression of CD27 on CD19$^+$ PCs in different groups of MM patients and to prove that CD27 can be routinely used to confirm polyclonality of CD19$^+$ PCs. *Methods*. A total of 60 patients were analysed and this group consisted of 15 monoclonal gammopathy of undetermined significance (MGUS) patients; 10 newly diagnosed MM pts; 9 relapsed and/or reanalysed MM pts; 14 transplanted MM pts; and 10 control pts without monoclonal gammopathy. Bone marrow PCs were identified as CD38$^+$CD138$^+$ cells and expression of CD19, CD56, and CD27 was analysed on these PCs. Clonality assessment using kappa and lambda light chains was done in almost all cases. *Results*. When analysed MGUS patients correlation between median of CD19$^+$ PCs (37.1%) and CD19$^+$CD27$^+$ PCs (40.9%) was found (0.95). In MM there was found 1 case with clonal CD19$^+$ PCs, but correlation was higher than in MGUS (0.97), although median of CD19$^+$ PCs (0.9%) and CD19$^+$CD27$^+$ PCs (2.0%) was lower. In subgroup of relapsed and/or reanalysed patients were found 3 cases of clonal CD19$^+$ PCs, median of CD19$^+$ PCs (54.0%) was higher than CD19$^+$CD27$^+$ PCs (42.2%) and correlation was lower than in previous subgroups (0.87). In patients after transplantation was found only 1 case of clonal CD19$^+$ PCs, thus correlation between CD19$^+$ PCs (78.5%) and CD19$^+$CD27$^+$ PCs (80.8%) was similar to MGUS and MM subgroups (0.92). In subgroup of patients without monoclonal gammopathy was found high correlation between CD19$^+$ PCs (63.8%) and CD19$^+$CD27$^+$ PCs (64.7%) as was expected (0.94). Finally, in group of 5 patients with clonal CD19+ PCs was the correlation between median of CD19$^+$ PCs and CD19$^+$CD27$^+$ PCs significantly lower (0.36) than in group 55 patients with polyclonal CD19$^+$ PCs (0.96). *Summary and Conclusions*. In our hands expression of CD27 on CD19$^+$ PCs can discriminate between clonal and polyclonal CD19$^+$ PCs and thus can be potentially used instead of labour intensive light chains assessment.

LONGER DURATION OF TREATMENT AND MAINTENANCE OF BEST RESPONSE WITH LENALIDOMIDE + DEXAMETHASONE INCREASES OVERALL SURVIVAL (OS) IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. San Miguel,[1] M. Dimopoulos,[2] M.-L. Bravo,[3] D. Weber[4]

[1]University Hospital of Salamanca, SALAMANCA, Spain; [2]University of Athens School of Medicine, ATHENS, Greece; [3]Celgene International, BOUDRY, France; [4]MD Anderson Cancer Center, HOUSTON, USA

Background. Lenalidomide is an oral immunomodulatory' drug active in relapsed/refractory multiple myeloma (RRMM). Lenalidomide + dexamethasone for treatment of patients with RRMM is well tolerated and can be given for a prolonged period of time. *Aims*. Statistical data were analyzed to determine whether there is a survival benefit to continuing lenalidomide + dexamethasone therapy after achieving best clinical response. *Methods*. Updated, pooled data from the phase-3 trials MM-009 & MM-010 were analyzed. Median follow-up time for surviving patients was 48 months. Kaplan-Meier (K-M) survival estimates for patients achieving a partial response (PR) or better were compared between patients on continuous treatment (defined as ongoing treatment or discontinuation due to progression) and patients discontinuing treatment due to adverse events, consent withdrawal, or other reasons. Unlike a conventional Cox regression, which is biased in favor of patients who continued treatment, time-dependent Cox models summarize the evidence over a range of landmarks. After testing for potential biases between the two patient groups in the K-M analysis, two time-dependent multivariate regressions using dummy variables as proxies for duration of treatment from study entry were run: one evaluating the potential benefit of continuing on lenalidomide + dexamethasone treatment and one measuring the benefit of an additional lenalidomide cycle. *Results*. The K-M estimate of median survival in patients continuing treatment after achieving PR or better (N=174) was 50.9 months [95% confidence interval (CI): 43.0-NA] vs. 34.95 months [26.4-55.7] in patients discontinuing treatment early (N=38; p=0.0594; Figure 1).

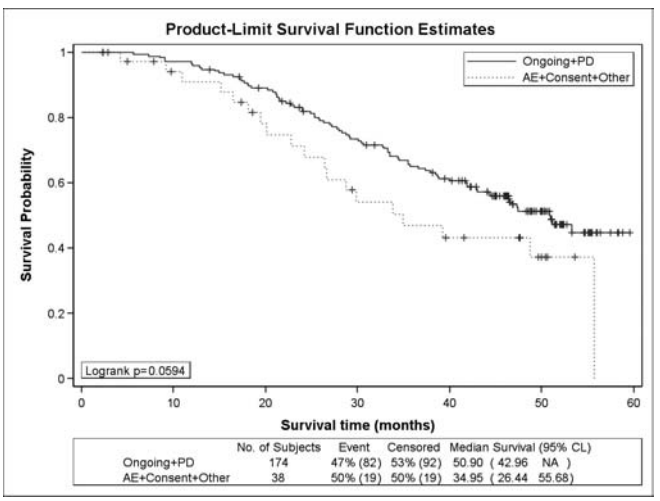

Figure 1. Kaplan-Meier estimates on overall survival.

In order to avoid the potential bias of favorable prognostic features (e.g. age, number of prior therapies, β2-microglobulin (B2M) and best response achieved) between patients on continuous treatment and patients discontinuing treatment due to adverse events, consent withdrawal, or other reasons, Cox proportional hazard regression analyses including lenalidomide + dexamethasone patients with PR or better (N=212) were performed. Longer lenalidomide treatment duration measured as either continued lenalidomide treatment (HR=0.137 [95% CI: 0.045-0.417]; p=0.0005) or an additional lenalidomide cycle (HR=0.921 [95% CI: 0.886-0.957]; p<0.0001) was associated with improved survival outcomes when controlling for other variables. Amongst the statistically significant patient characteristics, more prior anti-myeloma therapies (HR=1.778 [95% CI: 1.126-2.809]; p=0.0136), higher B2M (HR=1.708 [95% CI: 1.085-2.689]; p=0.0208), and a more advanced multiple myeloma stage as measured by Durie-Salmon criteria (HR=1.462 [95% CI: 0.997-2.144], p=0.0515) were all associated with a higher risk of death, whereas the achievement of CR, nCR or VGPR as best response (HR= 0.681 [95% CI: 0.434-1.068], p=0.0942) was associated with a lower risk of death. *Conclusions*. Continued treatment with lenalidomide + dexamethasone has a statistically significant positive impact on overall survival, when controlling for patient characteristics and best response achieved. Ideally, this observation would require further confirmation in form of a randomized clinical trial.

CONFIRMATION OF THE UTILITY OF THE IMWG THROMBOPROPHYLAXIS STRATEGY IN MYELOMA PATIENTS RECEIVING THALIDOMIDE; EXPERIENCE OF A LARGE SINGLE CENTRE INSTITUTION

K. Rabin, K. Fletcher, E. Aghoghovbia, L. Percy, S. Moore, J. Quinn, S. Cheesman, S. D'Sa, K. Yong

University College London Hospitals, LONDON, UK

Background and Aims. The risk of venous thromboembolism (VTE) is increased in multiple myeloma (MM) patients treated with thalidomide, especially in combination with dexamethasone or chemotherapy (reported as between 3-15%). Various VTE prevention strategies have been used, however the optimal prophylactic regime is unknown. Guidelines have recently been published by the International Myeloma Working Group (IMWG, Leukemia 2008, 22, 414-423), suggesting thromboprophylactic strategies should be used if there are risk factors based upon MM therapy (combination of thalidomide with dexamethasone and / or chemotherapy), disease related (hyperviscosity) or patient-related (previous VTE, central catheter, associated disease, surgery or use of erythropoietin). We have reviewed the impact of VTE prophylaxis in MM patients treated with thalidomide at our institutions over the last 4 years. *Methods*. 83 patients were treated with thalidomide, either in combination with dexamethasone and chemotherapy (n=57); with dexamethasone or chemotherapy (n=14), or with single agent thalidomide (n=12). Median age 63 years (range 41-81), male:female ratio 1.18:1, isotypes as follows; IgG (n=51), IgA (n=14), light chain only (n=13), IgD (n=1), non-secretory (n=2), plasma cell leukaemia (n=2). 71 patients receiving combination therapy were treated at relapse (n=45), induction (n=8) or when refractory to induction therapy (n=18). VTE prophylaxis was as follows; low molecular weight heparin (LMWH, n=17), full dose warfarin (target INR 2.5, n=8), low dose warfarin (n=6), low dose aspirin (n=8), or no thromboprophylaxis (n= 32). Additional risk factors (either individual or MM related) were present in 18 /71 patients that received thalidomide in combination with another agent, with 5/18 patients receiving either LMWH or full dose warfarin. 33 patients received thalidomide as maintenance treatment (single agent), with no VTE prophylaxis given to any patient, although additional risk factors were identified in 12 patients. *Results*. VTE occurred in 3/46 (6%) patients treated with either low dose aspirin/warfarin (n=1), or no thromboprophylaxis (n=2). There were no cases of VTE in patients treated with LMWH or full dose warfarin (n=25). VTE occurred in 1/18 patients with at least 1 additional risk factor as defined by the IMWG, in a patient who had a prior VTE (who did not receive any thromboprohylaxis). VTE occurred in 1/33 (3%) patients receiving thalidomide maintenance (this patient had a prior VTE). *Conclusions*. VTE in MM patients treated with thalidomide in combination with dexamthasone or chemotherapy is reduced by using LMWH or full dose warfarin. There is no role for using aspirin or low dose warfarin in this patient group. The incidence of VTE without adequate thromboprophylaxis is 6%, which is lower than has been reported. Maintenance treatment with thalidomide may be associated with an increased risk of VTE in patients where additional risk factors are identified. Careful risk assessment and assignment of patients requiring thalidomide treatment for MM will inform the appropriate use of anticoagulation strategies where needed, and avoid unnecessary use of anticoagulation in patients at low risk.

0951

CLNICAL EFFICACY OF VEL-CTD (BORTEZOMIB, CYCLOPHOSPHAMIDE, THALIDOMIDE, AND DEXAMETHASONE) REGIMEN IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: A PHASE II STUDY

Y.K. Kim,[1] J.S. Ahn,[1] D.H. Yang,[1] S.K. Sohn,[2] J.H. Moon,[2] H.J. Kim,[1] H.J. Shin,[3] J.S. Chung,[3] Y.J. Choi,[3] Y.S. Chae,[2] J.G. Kim,[2] J.H. Lee,[4] J.J. Lee,[1] KMMWP[5]

[1]Chonnam National University Medical School, GWANGJU; [2]Kyungpook National University Medical School, DAEGU; [3]Pusan National University Medical School, BUSAN; [4]Gil Medical Center, Gachon University, INCHEON; [5]The Korean Multiple Myeloma Working Party (KMMWP), SEOUL, South-Korea

Background and Objectives. Bortezomib is a small molecule, dipeptidyl boronic acid proteosome inhibitor and it was largely studied in refractory/relapsed myeloma in the beginning. As a combination with other targeted therapies such as thalidomide or chemotherapeutic agents, the response rate was reported to be up to 50% including 20% complete response. In this study, we assessed the efficacy and safety of the combination with bortezomib, cyclophosphamide, thalidomide and dexamethasone (Vel-CTD) for the patients with relapsed/refractory multiple myeloma. *Design and Methods*. Seventy-three patients who had received at least two cycles of treatment were enrolled. Bortezomib was given at 1.3 mg/m^2 (D1, 4, 8, 11), cyclophosphamide (150mg/m^2 P.O. on D1-4), thalidomide (50 mg/day, daily), and dexamethasone (20mg/m^2 I.V. on D1-5, D15-19). *Results*. There were 37 males (50.7%) and 36 females (49.3%). The median age of patients was 67 years (range, 40~79 years). Median number of the previous treatment regimens were two (range, 1~6). Of total 73 patients, sixty-four patients (87.7%) achieved at least a partial response (PR) including 20 (27.4%) with a stringent complete response (sCR) and 14 (19.2%) with a CR as their best response. Three-year progression-free survival (PFS) was 13.6±6.1% and three-year overall survival (OS) from the start of Vel-CTD was 48.7±9.1%. Patients who achieved a good response at least a PR after four cycles of Vel-CTD showed longer PFS than those with poor therapeutic responses (3yr PFS, 22.7±8.7% vs. 0, p=0.000). Further, patients who achieved a good therapeutic responses also showed significantly longer OS than those with poor responses (3yr OS, 58.1±11.0% vs. 34.7±15.1%., p=0.002). Patients with a good response at least a PR after eight cycles of Vel-CTD also showed longer PFS (2yr PFS 21.3±8.3% vs. 0, p=0.000) and OS (2yr OS, 55.7±1.2% vs. 25.0±2.2%, p=0.006) than those with poor responders. Of 411 evaluable treatment cycles, grade 3 or 4 toxicities included thrombocytopenia (11.5%), neutropenia (4.6%), peripheral sensory neuropathy (4.4%), and thrombosis (0.5%). *Conclusions*. Vel-CTD is an active salvage therapy with manageable toxicity in patients with relapsed/refractory myeloma. However, trials evaluating novel treatment approaches after bortezomib should be offered to reduce the rate of disease progression, particularly in patients who fail to show a good response at least PR after four or eight cycles of therapy.

0952

OPTIMIZATION OF BORTEZOMIB-BASED COMBINATIVE REGIMEN IN ELDERLY RELAPSED MULTIPLE MYELOMA PATIENTS

L. Zahradova,[1] R. Hajek,[1] E. Gregora,[2] M. Schützova,[3] Z. Adam,[1] L. Pour,[1] M. Krejci,[1] P. Pavlicek,[2] V. Koza,[3] A. Krivanova,[1] V. Sandecka,[1] D. Kralova[4]

[1]Faculty Hospital Brno, BRNO; [2]Faculty Hospital Kralovske Vinohrady, PRAHA; [3]Faculty Hospital Plzen, PLZEN; [4]University Research Centre - Czech Myeloma Group, Masaryk University, BRNO, Czech Republic

Background. Bortezomib-based regimens represents a chance for a longer survival for multiple myeloma patients. Despite of the high efficacy in relapsed patients bortezomib has specific toxicity, which often leads to prematurely interruption of the treatment, especially in elderly patients and/or patients with poor performance status. Therefore further optimization of bortezomib-based regimens is essential. *Aims*. We evaluated the potential of combinative regimen CVD (Cyclophosphamide, Bortezomib (Velcade), Dexamethasone) reduced intensity (CVD senior; 50% reduction) in elderly patients and/or patients with poor status performance with relapsed multiple myeloma. The results were compared with CVD junior regimen outcome used in patients aged <65 years and good status performance. *Patients and Methods*. A total of 71 patients (30xCVD senior vs 41xCVD junior) was evaluated in period from February 2007 until December 2008. Regimen CVD senior: Bortezomib (1.3mg/m^2,day 1 and 15); Cyclophosphamide (50mg p.o. daily) and dexamethasone 20mg (day 1-4, 15-18). Regimen CVD junior: Bortezomib (1.3mg/m^2,day 1,4,8 and 15); Cyclophosphamide (500mg/m^2 i.v. day 1 and 15) and dexamethasone 40mg (day 1-4,15-18). Duration of cycle was 28 days in both regimens. There was a significantly higher age in CVD senior in comparison to CVD junior group - median age 71.1 (49.5-81.7) vs 60.0 years (44.3-77.7), p=<0.001; a trend to higher pretreatment - number of previous treatment lines 1-13.3% vs. 31.7%/2-63.3% vs. 53.7%/3 or more-23.3% vs 14.6% (p=0.165); a trend to lower Karnofski status (80 vs. 90%,p=0.109); a higher frequency of clinical stage 3 according to ISS (37.5% vs 20.6%; p=0.118). Median follow-up from the start of therapy was 13.9 vs. 9.1 months (p=0.030). *Results*. The basic results for regimen CVD senior vs junior are: overall response (ORR=CR+PR) was 39.9% vs. 64.9% (CR 3.6% vs. 13.5%, VGPR 14.3% vs. 16.2% and PR 21.4 vs. 35.1%); stable disease 53.6% vs. 21.6% and progression 7.1% vs. 13.5%. Althought there was achieved better overall response in CVD junior group (p=0.027), there was not significant difference for medians of parameters of survival (TTP/PFS 8.9 vs 11.3 months, OS from the start of therapy 12.3 vs 16.3 months, DOR 7 vs 10.3 months) A higher total dose of bortezomib achieved by patients in each group resulted in a better response in both regimens (a trend for CVD senior-p=0.128; significant for CVD junior-p=0.006). Number of grade 3 or 4 AEs was not significantly different (p=0.301), but grade 4 AEs were not observed in CVD senior group (0 vs 18.5%). Dose of bortezomib was reduced in less frequency in CVD senior regimen [6,7% (2/30) vs 26.8% (11/41)], median number of cycles was similar (5.2 vs 5.1;p=0.86). *Conclusions*. The toleration of reduced intensity regimen by elderly patients is similar as toleration of full dose regimen by younger patients. Furthermore there was no grade 4 AEs in CVD senior group. Duration of treatment and number of cycles obtained was similar. Althought there was a worse overall response in CVD senior group, parameters of survival were not significantly different. The reduced intensity CVD regimen seems to be a good option for elderly patients with poor status performance with well balanced efficacy/toxicity ratio.

EFFICACY OF PAD REGIMEN AS AN INDUCTION THERAPY BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IN VAD OR CTD REFRACTORY MYELOMA

M. Kraj, K. Warzocha, R. Poglód, B. Kwasniak, B. Ceglarek

Institute of Hematology and Transfusion Medicine, WARSAW, Poland

Bortezomib induces apoptosis of multiple myeloma (MM) cells, and affects their microenvironment. Combination of Bortezomib, Doxorubicin and Dexamethasone (PAD) gives responses in 95% of newly diagnosed MM (Oakervee *et al*. Br J Haematol 2005; 129: 755-62). *Aims, Patients and Methods*. Aim of this study was to evaluate prospectively response to: 1. bortezomib alone (1.3 mg/m^2 on days 1,4,8,11 in a 21-day cycle for up to 8 cycles) in patients with relapsed or refractory MM (bortezomib group) 2. combination of bortezomib (as above), doxorubicin (9 mg/m^2 days 1-4) and dexamethasone (40 mg days 1-4) as an induction therapy before high-dose therapy in VAD or CTD refractory MM patients and as salvage therapy at relapse (PAD group). *Results*. From November 2004 until February 2009 after informed consent was obtained 50 MM patients have been included: 22M, 28F, median age 59yrs (33-78). Thirty nine was IgG, 7 IgA, 4 only light chain, 84% had osteolysis. According to Durie-Salmon staging system 18% was I, 14% II, 68% III and acc. to ISS 52% I, 32% II, 16% III. The median number of prior therapies was in bortezomib group 2.4 (1-5), in PAD group 1.3 (1-2). Median time from diagnosis to bortezomib therapy was in bortezomib group 44 months (13-149) in PAD group 14 months (2-33). Twenty one patients received bortezomib alone for relapse and 30 patients received PAD-21 as induction treatment and 10 for relapse. Median follow-up time since bortezomib administration was 10 months (1-42) (in bortezomib group 16 months and in PAD group 7 months). Median number of cycles received was in bortezomib group 6 (1-18) in PAD group 6 (1-9). Response acc. to IMWG criteria for the patients who received bortezomib alone was 31.6% (nCR 10%, PR 22%). Median time to progression for responders was 6 months. For MM patients who achieved less than PR after 4 cycles of VAD or CTD and than received PAD as induction therapy response rate was 76.3% (CR 14.3%, nCR 14.3%, PR 47.7%, SD 19.0%, PD 4.7%). In 8 of these patients ASCT was performed and 4 are in process of stem cell collection. Five of 6 evaluable patients with relapsed MM showed partial remission after PAD therapy. *Conclusions*. In relapsed myeloma the rate of response to bortezomib alone is 31%, with median duration of response of 6 months. In VAD or CTD refractory MM patients PAD as induction therapy before high-dose therapy offers response rate of 76%.

0954

INCORPORATION OF THE BONE MARKER CARBOXY-TERMINAL TELOPEPTIDE OF TYPE-1 COLLAGEN (ICTP) INTO A COMBINED ISS-ICTP SCORE IMPROVES THE PROGNOSTIC SIGNIFICANCE OF THE ISS IN SYMPTOMATIC MULTIPLE MYELOMA

C. Jakob,[1] J. Sterz,[1] P. Liebisch,[2] U. Heider,[1] M. Kaiser,[1] M. Mieth,[1] C. Müller,[1] O. Sezer[1]

[1]Charité - Universitätsmedizin Berlin, BERLIN; [2]University Hospital Ulm, HEMATOLOGY/ONCOLOGY, Germany

Background. The prognosis of patients with newly diagnosed symptomatic multiple myeloma (MM) has been improved, but the outcome is still highly variable. Several prognostic markers, including parameters of tumor burden and cytogenetics were adopted to identify high-risk patients. Recently the International Staging System (ISS), including the parameters β2-microglobulin (β2M) and albumin, was introduced for patients with symptomatic MM. In previous studies the bone resorption marker carboxy-terminal telopeptide of type-1 collagen (ICTP) was identified as a sensitive and specific marker of increased bone resorption and as a strong prognostic factor for overall survival (OS) in MM. *Aims*. Since bone disease is a hallmark of MM, we investigated the prognostic impact of the bone resorption marker ICTP in combination with ISS, β2M, albumin and deletion of chromosome 13 (del(13q14)) and high-dose therapy (HDT) in 100 patients with newly diagnosed symptomatic MM. *Methods*. ICTP was detected by a commercially available radioimmunoassay (Orion Diagnostica, Espoo, Finland). The prognostic factors del(13q14), albumin and β2M were evaluated, using previously established cut-off values to dichotomize risk groups for survival analysis. ISS was calculated from albumin and β2M according to the cut-off values given in the original publication by Greipp *et al.* 2005. *Results*. β2M alone, albumin alone, ISS, del(13q14) and ICTP were significant prognostic factors for overall survival. In contrast to ICTP, lytic bone lesions, as detected by conventional radiography, were not an independent prognostic factor for OS (p=0.289). In a multivariate analysis, ICTP was the most powerful prognostic factor (log rank p<0.001, hazard-ratio: 9-fold increase). Furthermore ICTP clearly separated two subgroups with a good and a worse prognosis within each of the three ISS stages (ISS I: p=0.027, ISS II: p=0.022, ISS III: p=0.013). A combined ISS-ICTP score, including β2M (cut off: 3.5 mg/L), albumin (cut off: <3.5 g/dL) and ICTP (cut off: reference limit) significantly (p<0.001) separated four risk groups with a 5-year overall survival rate of 94% in the very low risk group, 65% in the low risk group, 46% in the intermediate risk group and 22% in the high risk group, respectively (Figure 1). In the very low risk group, there was no significant survival benefit with high-dose therapy (p=0.24), while HDT was a favorable prognostic factor in ISS-ICTP risk groups 1-3 (p=0.037, p=0.011 and p=0.012) and in ISS stages I-III (p=0.026, p=0.001 and p=0.052). *Summary and Conclusions*. Our data demonstrate that the inclusion of the bone resorption marker ICTP adds to the prognostic value of ISS.

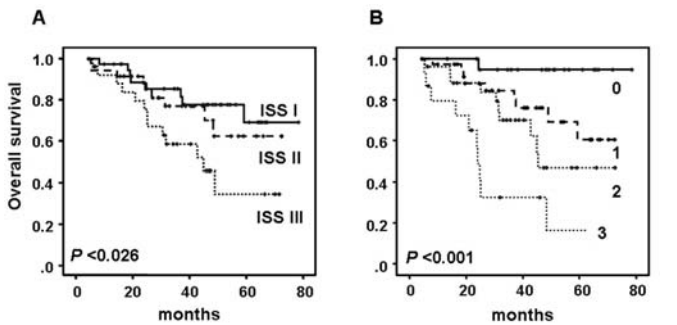

Figure 1. Prognostic value of ISS (A) and combined ISS-ICTP score (B).

0955

A RANDOMIZED PHASE II STUDY (GISL - MM03 TRIAL) WITH ORAL MELPHALAN+ PREDNISONE (MP) VERSUS MELPHALAN, + PREDNISONE + THALIDOMIDE (MPT) FOR NEWLY DIAGNOSED ELDERLY PATIENTS WITH MULTIPLE MYELOMA

S. Sacchi,[1] R. Marcheselli,[1] S. Pozzi,[1] A. Bari,[1] O. Ciarcia,[1] L. Masini,[2] A. Lazzaro,[3] F. Morabito,[4] A. Fragasso,[5] N. Di Renzo,[6] G. Quarta,[7] G. Buda,[8] P. Musto,[9] M.L. Vigliotti,[10] A. Pastorini,[11] M. Brugiatelli[12]

[1]Universita di Modena, MODENA; [2]Ospedale di Reggio Emilia, REGGIO EMILIA; [3]Ospedale di Piacenza, PIACENZA; [4]Ospedale di Cosenza, COSENZA; [5]Ospedale di Matera, MATERA; [6]Ospedale di Lecce, LECCE; [7]Ospedale di Brindisi, BRINDISI; [8]Universita di Pisa, PISA; [9]IRCCS Rionero in Vulture, RIONERO IN VULTURE; [10]Ospedale di Caserta, CASERTA; [11]Ospedale di Sondalo, SONDRIO; [12]Ospedale di Messina, MESSINA, Italy

Background. Several papers showed that MPT compared with MP improved response and survival outcomes. However, side effects increase and toxicity, as neutropenia, neuropathy, deep-vein thrombosis, depression and constipation reduce patients compliance. Thus, several patients have to discontinue or reduce the dose of Thalidomide. *Aims*. Aim of our research is to verify these results in a group of 128 patients not eligible for high dose treatment with stem cells support. *Patients and Methods.* The MM03 trial was approved by Ethical Committee of Modena and registered at Osservatorio Nazionale sulla Sperimentazione Clinica dei Medicinali at the end 2004. A total of 128 patients were enrolled between January 2005 to October 2008: 53% entered MPT arm. Median age of patients were 75 years (range: 63-88 yrs), 50% were female, 55% had Durie and Salmon stage II and 45% had stage III. Distribution of M spike were: 67%, 22% and 11% for IgG, IgA and urine light chains. Univariate analysis of variables at baseline did not show any difference between the two arms. In arm A Melphalan was given at a dose of 0.25 mg/kg and Prednisone 60 mg/m^2 for 4 days every 28 days; in arm B Thalidomide was added at a dose of 100 mg every day; a maximum of ten cycles was planned. At the end of induction therapy, 26 patients who had obtained Complete Response, Partial Response, Minimal Response or Stable disease were randomized for maintenance with Dexamethasone 20 mg, day 1-4 every 28 days or Dexamethasone at the same dose plus Thalidomide 100 mg/day every day. Only 14 patients follow this indication and assumed maintenance treatment for 6-12 months; no differences were observed between the 2 arm of maintenance. The use of growth factors, was at treating physicians discretion. Starting from May 2005 enoxiparin was recommended during the first 4 cycles of MPT arm. *Results*. Of 128 patients, 91 patients are evaluable for response while 20 are still on treatment. The response, including MR among all patients who entered protocol were 76%, while 9% had SD and 15% presented PD. Considering separately the two arm, we observed in arm A 12% CR, 43% PR, 9% MR, 3% SD and 23% PD and in arm B 18% CR, 57% PR, 11% MR, 5% SD and 9% PD. A comparison between 55% of CR plus PR in arm A with 75% in arm B shows a p=0.049, showing an advantage for MPT arm. After a median follow up of 14 months, median Overall Survival at 24 months are not still reached. During treatment or progression 24 patients died. Grade III/IV adverse events were: 6 deep-vein thrombosis, all in MPT arm, 1 during enoxaparin prophylaxis, 1 pneumonitis, 6 neutropenia, 3 neurotoxicities, 3 constipation. *Conclusions*. Our results show that the addition of Thalidomide to MP improve number and quality of response. We are still collecting data for a better definition of OS, FFS and toxicity in arm A in comparison with arm B, and they will be presented during the meeting.

SURVIVAL ANALYSIS OF PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: AN INTERIM REPORT FROM AN INTERNATIONAL ELECTRONIC OBSERVATIONAL STUDY OF BORTEZOMIB

M. Delforge,[1] H. de Samblanx,[2] K. Zervas,[3] E. Katodritou,[4] D. Sargin,[5] C. Hulin,[6] L. Ahlberg,[7] J. de la Rubia,[8] K. Abdulkadyrov,[9] R. Ganguly,[10] J. Diels,[10] R. Dhawan[10]

[1]University Hospital Leuven, LEUVEN, Belgium; [2]ZNA Middelheim, ANTWERP, Belgium; [3]Theageneion Anticancer Hosptial of Thessaloniki, THESSALONIKI, Greece; [4]Theagenion Cancer Center, THESSALONIKI, Greece; [5]Istanbul University, ISTANBUL, Turkey; [6]Centre Hospitalier Universitaire of Nancy-Brabois, NANCY, France; [7]Hematolog Kliniken Universitetssjukhuset, LINKOPING, Sweden; [8]La Fe Hospital, VALENCIA, Spain; [9]Russian Scientific Research Institute of Hematology and Transfusiology, SAINT-PETERSBURG, Russian Federation; [10]Johnson & Johnson Pharmaceutical Services, RARITAN, USA

Background. Multiple myeloma (MM) is associated with significant morbidity and mortality. Recent advances in treatment for MM have led to improved outcome and survival benefits in patients with relapsed refractory MM. Bortezomib (VELCADE®) is a proteasome inhibitor indicated for the treatment of MM. The clinical and health economic outcomes in MM patients in clinical practice are captured in an international electronic VELCADE observational study (eVOBS) - a non-interventional study of patients from Belgium, France, Greece, Russia, Spain, Sweden, and Turkey. The study started enrollment in October 2006. We report interim survival analysis of patients enrolled through 21 November 2008 data cut-off. *Aims*. In this analysis we assess survival in patients with relapsed refractory MM treated with bortezomib in real-life settings. *Methods*. Adults scheduled to receive bortezomib for MM are being enrolled in eVOBS. All bortezomib dosages and concomitant treatments (except investigational therapies) are permitted. Survival data are continuously being collected prospectively for 3 years. In this analysis we report stratified Kaplan-Meier survival analysis and multivariate proportional hazards regression for all patients. Patients still alive at the data cut-off date were censored. The current analysis excluded Spain and Russia due to time lag involved in data availability. *Results*. At baseline a total of 447 patients (58% male, median age 64.5years) were reviewed. At data cut-off date, the follow-up time for the majority (55%) of patients was still less than 6 months. 55% of the patients were censored at 6 months and 76% at 12 months The baseline patient characteristics are comparable to the pivotal clinical study of bortezomib versus dexamethasone in the relapsed refractory setting, APEX (Richardson PG *et al.* N England J Med. 2005; 352:2487-98). However, patients enrolled in eVOBS experienced significant renal impairment compared with patients in APEX study. In eVOBS, bortezomib was initiated as 2nd-, 3rd-, and 4+th-line therapy in 45%, 28%, and 17% of patients, respectively. Overall survival was 87% (95% CI: 83-91) at 6 months, 67% (95% CI: 58-74) at 12 months. Statistically significant association was observed between improved survival and patients aged <70 years, line of therapy, albumin >3.5g/dL and creatinine clearance ≥60 mL/min at baseline. *Conclusions*. This non-interventional observational study provides preliminary estimates on survival of bortezomib treated multiple myeloma patients as seen in real-life clinical practice. The clinical data in this study are still maturing and are expected to provide valuable insight to treatment outcome.

0957

THALIDOMIDE OR BORTEZOMIB IN COMBINATION WITH DEXAMETHASONE AS SECOND-LINE THERAPY FOR REFRACTORY/RELAPSED MULTIPLE MYELOMA: A COMPARISON OF EFFICACY AND TOXICITY

M. Varettoni

Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy

Background. Therapeutic options for patients with relapsed/refractory multiple myeloma (MM) have expanded in the recent years with the introduction of novel agents such as thalidomide, bortezomib and lenalidomide. Although their efficacy has been demonstrated in clinical trials, there are no studies comparing these new agents in the setting of relapsed/refractory MM. *Aims*. To compare the efficacy and toxicity of thalidomide or bortezomib, in combination with dexamethasone, as second-line therapy. *Methods*. We analyzed a homogeneous population of MM patients refractory or relapsed after first-line therapy, who were treated either with thalidomide or bortezomib plus dexamethasone. Thalidomide was administered orally at doses of 50-200 mg/daily until progression. Bortezomib 1.3 mg/mq was given intravenously on days 1,4,8,11 every 21 days up to 6-8 cycles. *Results*. The analysis included 59 patients treated with thalidomide and 33 with bortezomib. Age, sex, isotype, Durie-Salmon stage, ISS, cytogenetics, prior transplant, status of disease (relapsed or refractory) were well balanced in the two groups. The median time from diagnosis to initiation of thalidomide or bortezomib was 23 and 20 months respectively (p=0.25). Thalidomide was administered at the median dose of 100 mg/day for a median time of 11 months (1-92). Patients treated with bortezomib received a median number of 4 cycles (1-8). In an intention-to-treat analysis, the overall response rate was similar in the two groups (thalidomide 64%, bortezomib 61%, p=0.13), while the CR+VGPR rate was higher in the latter one (14% vs 33%, p=0.03). The median follow-up was significantly longer for patients treated with thalidomide than with bortezomib (25 vs 11 months, p=0.0001). Overall, progression occurred in 80% of patients treated with thalidomide and 90% of those treated with bortezomib. Patients receiving thalidomide had a significantly better progression-free survival (PFS) (13 vs 4 months, p<0.0001) and overall survival (OS) (26 vs 12 months, p=0.01). The proportion of patients who required dose reduction for any toxicity was similar in the two groups (20% with thalidomide, 32% with bortezomib, p=0.16), while the discontinuation rate was significantly higher with bortezomib (8% vs 24%, p=0.03). Patients receiving bortezomib had a higher incidence of anaemia (12% vs 0%, p=0.01), thrombocytopenia (76% vs 0%, p<0.0001), fatigue (36% vs 12%, p=0.006) as compared to the other group. The incidence of peripheral neuropathy (PN) was similar (54% with thalidomide, 58% with bortezomib, p=0.46), with a trend for a higher incidence of grade ≥2 PN in the latter group (p=0.09). Gastrointestinal toxicity was reported in 44% and 40% of patients, respectively (p=0.41), but grade 3 toxicities occurred only with bortezomib (8%). The incidence of thromboembolic events was similar (7% with thalidomide, 6% with bortezomib, p=0.6). Bradycardia was observed only in patients treated with thalidomide (12%). *Conclusions*. Bortezomib, as second-line therapy, yields significantly higher CR+VGPR rate as compared to thalidomide. These favourable initial results, however, do not translate into better long-term outcome. Patients treated with thalidomide, in fact, have significantly longer PFS and OS. The higher rate of early discontinuation for toxicity in the bortezomib group may account for these results.

0958

INCREASED BONE MINERAL DENSITY IN A SUBSET OF PATIENTS WITH RELAPSED MULTIPLE MYELOMA WHO RECEIVED THE COMBINATION OF BORTEZOMIB, DEXAMETHASONE AND ZOLEDRONIC ACID

E. Terpos,[1] D. Christoulas,[1] P. Kokkoris,[2] M. Gavriatopoulou,[1] G. Boutsikas,[2] M. Migkou,[1] K. Anargyrou,[2] E. Kastritis,[1] K. Tsionos,[2] M.A. Dimopoulos[1]

[1]University of Athens School of Medicine, ATHENS; [2]251 General Air Force Hospital, ATHENS, Greece

Background. Bortezomib is a first-in-class proteasome inhibitor with established antimyeloma efficacy that also showed a beneficial effect on bone metabolism. Bortezomib reduces bone resorption and increases bone formation markers and osteoblast counts in trephine biopsies. However, there are no data for the effect of bortezomib on bone mineral density (BMD) of myeloma patients. *Aims*. To evaluate the effect of the combination of bortezomib plus dexamethasone (VD) and zoledronic acid on BMD of patients with relapsed myeloma. *Methods*. We studied the files of 27 consecutive patients (16M/11F; median age 69.5 years) with relapsed MM who received VD and had BMD before and after 8 cycles of therapy. The median number of previous lines of therapies was 2 (range: 1-5). Bortezomib was given at the standard dose of 1.3 mg/m^2 on D1,4,8,11 of a 21-day cycle, while dexamethasone was given at a dose of 20 mg, p.o., the day of bortezomib administration and the following day. All patients also received zoledronic acid (4mg, iv, monthly). BMD of the lumbar spine (L1-L4, antero-posterior view), and femoral neck (FN) was measured by dual energy X-ray absorptiometry (DXA) using a Hologic QDR-1000 scanner. Evidence of myeloma bone disease at the time of relapse was documented by plain radiography. All patients had measurements of urinary NTX (bone resorption marker) and serum bone alkaline phosphatase (bALP) and osteocalcin (bone formation markers), pre- and every month post-VD. *Results*. Twenty patients achieved an objective response (at least PR), while 2 patients had a minimal response and 5 patients had stable disease after 8 cycles of therapy. Before VD, skeletal survey revealed that 8 patients (29%) had lytic lesions in 1-3 areas (group A), 18 (66%) had lytic lesions in more than 3 areas and/or a pathological fracture (group B), while only one patient had diffuse osteoporosis. DXA measurements showed that 7 patients (25%) had

osteopenia and 14 (51%) osteoporosis at least in one of the evaluated sites at the time of relapse, according to WHO criteria. The combination of VD plus zoledronic acid produced no significant changes in both L1-L4 and FN BMD after 8 cycles of therapy. At the same time, NTX was reduced while bALP and osteocalcin were markedly increased (p<0.001). However, 4 patients (14%) showed at least 10% of increase in L1-L4 BMD (median 16%). All these patients had osteopososis according to DXA measurement, had responded to VD therapy (3 PR and one CR), had received VD as second line treatment and in terms of lytic bone disease 3 patients belonged to group A, while the other one was the only patient who had diffuse osteoporosis. No change in FN BMD was seen in these patients. *Summary and Conclusions*. The combination of VD plus zoledronic acid may increase BMD in a subset of relapsed myeloma patients with low BMD and non-extensive lytic disease who receive this regimen early in their disease therapy. Based on these results, a prospective study evaluating BMD in patients with relapsed/refractory myeloma who receive VD as second line therapy has just started.

0959

COMBINATION OF INTERNATIONAL STAGING SYSTEM AND CYTOGENETICS CAN PREDICT POOR PROGNOSIS IN MULTIPLE MYELOMA AFTER HD-CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION

E. Tóthová,[1] A. Kafková,[1] N. Štecová,[1] E. Švorová,[1] K. Fiedlerová,[2] M. Soska[1]

[1]UPJŠ and University hospital L.Pasteur, KOŠICE; [2]Gendiagnostika, KOŠICE, Slovakia

Backgroud. Multiple myeloma (MM) is one of the key hematologic malignancies in which the impact of dose intensity has been demonstrated. High-dose chemotherapy (HD-CHT) followed autologous stem cell transplantation (ASCT) is performed as a standard treatment for newly diagnosed multiple myeloma. Combinations of prognostic factors such as cytogenetics and international scoring system (ISS) may be useful to stratify prognosis after ASCT. *Methods*. We evaluated transplant outcome among 76 consecutive patients (pts) with newly diagnosed MM who underwent single ASCT between February 2000 and October 2007. Median age was 56 years old and median time from diagnosis to ASCT was 5,5 months. *Results*. The ISS stages at diagnosis were 1 (n=28), 2 (n=28) a 3 (n=20). Cytogenetical analyses of bone marrow at diagnosis detected metaphase abnormalities (including 13 chromosome) in 19 pts, and interphase abnormalities in 14 of 49 (29%) patients, deletion of 17p13 in 3, t(4;14) in 8, and t(14;16) in 3 pts. Patients were defined as high-risk if they had any of these abnormatities or the ISS stage 3. Thirty- one pts (41%) were classified as high-risk. All pts were conditioned with HD melphalan (200mg/m^2). With a median follow up of 2,7 years, overall survival (OS) rates 3 years after ASCT in non-high-risk group were 84% and in high-risk group were 46%, respectively (p=0.006). Progression-free survival rates were 29% and 10%, respectively (p=0.066). Although 23pts achieved complete remission (CR) and 15 achieved VGPR after ASCT, 19 of them relapsed. Of these 19pts, survival rates 1year after relapse in each group were 100% and 34%, respectively (p=0.035). Sixty-five percent of the pts in high-risk group died within 1 year after relapse, although they received salvage chemotherapy containing Velcade or Thalidomide. *Conclusions*. The combination of cytogenetics and ISS can predict prognosis of MM after ASCT. A major problem was a poor prognosis among relapsed pts in high-risk group. The limited duration of responses after HD-CHT for pts with poor prognostic factors highlight the need to develop a risk- adapted treatment strategy. New drugs, alogeneic transplant and combination of these are subjects for future investigation. System (ISS) may be useful to stratify prognosis after ASCT.

THE IMPACT OF FRONTLINE TREATMENT ON SURVIVAL OUTCOMES IN MULTIPLE MYELOMA: THE SGH EXPERIENCE

Z.T. Lao, W.C.N. Wee, Y.S. Lee, S. Su Su, H.C. Wee, A.Q.C. Choo, P. Colin, A.L. Ang, C.Y. Yiu, D. Tan, L.S. Kam

Singapore Health Services/Singapore General Hospital, SINGAPORE, Singapore

Background. Multiple myeloma (MM) is a plasma cell malignancy characterized by an indolent clinical course with recurrent remissions and relapses. The significance of attaining a complete remission (CR) rather than a partial response after frontline treatment, and its impact on overall survival (OS) remains controversial. *Aims*. We sought to evaluate the effectiveness of the various frontline regimens used and whether best responses to frontline therapy are good surrogates for OS. *Methods*. Previously untreated MM patients diagnosed from 2003-2007 with complete clinical data and followed at SGH were included. Criteria for partial response (PR) required reduction of serum myeloma protein level by >50%, while a complete remission (CR) was defined by negative findings on immunofixation. OS curves were estimated by the Kaplan-Meier method and differences were compared using the log-rank test. *Results*. 142 patients with complete treatment data were available for review. The median age was 59 yrs. 36 (24.3%), 61 (41.2%) and 41 (27.7%) patients presented with ISS stage I, II and III disease respectively. Distribution of various induction therapy received are shown in Table 1. 58 (39.%) and 46 (31%) patients attained CR and PR respectively after frontline treatment. The median progression free survival was 3.0yrs and independent of response status. Patients who attained CR however, had a significantly better median OS at 9.1yrs (95% CI: 5.7,12.4) compared to those who achieved PR at 5.6 yrs (95% CI: 4.3,6.9) (p=0.01). No significant differences were observed in the response rates among the different frontline regimes, although bortezomib-based induction showed a trend towards more rapid reduction of M-band. *Summary and Conclusions*. Achievement of CR seems to confer a more favorable survival. Application of a Cox regression model is in progress to better understand the contributions of treatment, particularly bortezomib and transplant, as well as other factors in these patients.

18F-FDG-PET UTILITY IN MULTIPLE MYELOMA. NEW DURIE-SALMON PLUS STAGING SYSTEM. OUR EXPERIENCE

I. Garcia, L. Entrena, C. Ramos-Font, A. Rodriguez-Fernandez

Hospital Universitario Virgen de la Nieves, GRANADA, Spain

Background. Multiple myeloma (MM) is a heterogeneous disease. To standardize the therapy approach is essential to correctly characterize it since diagnosis. Increasing use MR, CT, and FDG-PET have conducted to a new MM classification, Durie-Salmon Plus staging system, according to the number of existing lesions in MR and FDG-PET. Previously, x-ray survey was the gold standard, but up to 25% can be negative in the presence of myelomatous lesions, and its sensitivity is markedly decreased in extramedullary lesions. The advantage of FDG-PET compare to CT or MR, is the ability to discriminate between necrotic or scar tissues and new or old active lesions. It is especially valuable in the evaluation of recurrences and non-secreting myeloma. *Aims*. to evaluate the utility of FDG-PET in MM compare to conventional imaging techniques (CIT). *Methods*. Descriptive analysis of 41 patients with MM, MGUS, and plasmocytomas, and imaging results in the diagnosis and treatment. *Results*. 71 FDG-PET, 25 MR and 36 CT in 41 patients also several X-ray series and bone scintigraphies were performed. When compare to CIT, FDG-PET revealed understaging in 15 patients. In four patients initial staging was change from I to III, and five were up-staged from II to III. The other six showed higher number of lesions but without changing the stage. Interestingly one patient was FDG-PET positive, but in complete remission (CR) considering the rest of diagnostic tools. Myelomatous infiltration was histologically proven. Post treatment FDG-PET was negative. FDG-PET was negative in all eleven patients in CR and the four cases in CR after ASCT. In patients with partial response FDG-PET showed a decrease in the number and intensity

uptake of the lesions. There were seven patients with positive consistent RM, CT, bone scintigraphy and FDG-PET, but in this the number and extension of the lesions were lower, been able to discriminate active from necrotic, scar tissue. All patients with active disease were FDG-PET positive, including a postransplant relapse. When MGUS patients were evaluated, they all were FDG-PET negative. Interestingly there was a patient with a left maxilar plasmocytoma in which CT was the one which defined local disease compare to non specific focal activity described in the FDG-PET. *Summary*. It is necessary to integrate the novel diagnostic tools in the diagnosis and follow up of MM. New Durie-Salmon Plus staging system integrates FDG-PET and MR information in the evaluation of MM. It is essential for further prognostic and therapy evaluation. Like previously published in other series, FDG-PET studies are positive in all active MM and plasmocytomas. It significantly increases the number of lesions and extension of the disease in some cases that conducted to changes in the staging and therapy approach of several patients. It also discriminate the nature of non defined lesions, excluding myelomatous infiltration in some cases. When partial response to treatment occur a decrease of FDG-PET uptake was observed in the lesions. Additionally, all cases with complete response and the case of MGUS were FDG-PET negative.

0962

AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN 5 PATIENTS AFFECTED BY POEMS SYNDROME

L. Laurenti,[1] S. De Matteis,[2] P. Chiusolo,[2] N. Piccirillo,[2] F. Sorà,[2] M. Tarnani,[2] E. Rossi,[2] T. Za,[2] C. Giannotta,[3] E. Nobile Orazio,[3] G. Leone,[2] S. Sica[2]

[1]Institute of Haematology, ROME; [2]Hematology Institute, Università Cattolica Del Sacro Cuore, ROME; [3]IRCCS Humanitas Clinical Institute, ROZZANO, MILAN, Italy

Background. POEMS is a multisystemic paraneoplastic syndrome, the acronym refers to Polyneuropathy, Organomegaly, Endocrinopathy, M protein, Skin changes. This disease is progressive and weakening for patients and lead to death generally for neurological problem without therapy. *Aims and Methods*. We treated 5 pts affected by POEMS syndrome with high dose chemotherapy and autologous peripheral blood stem cell transplantation (aPBSCT). Pts were 3 male and 2 female, median age 54ys (range 44-62). All pts had a severe, rapidly progressive sensory-motor peripheral neuropathy, involving extremities, with inability to walk. All pts had M component IgA-lambda and 1 had also M component IgG-lambda, all had plasmacytosis (7-10%) in bone marrow. Endocrinopathy was present in all pts as thyroid disease and in 1 patient as hypogonadotropic Hypogonadism, in 1 pts as hypophysary adenoma, in 1 pts as glucose intolerance. All pts presented melanosis. 2 patient had splenomegaly, and 3 hepatomegaly. A patient had sclerotic bone lesion. One patient had significantly abnormal pulmonary function before aPBSCT. All pts received Cyclophosphamide 1500 mg/m^2 on day 1,3 and Methylprednisolon 250 mg from day 1-4 for 2 cycles and G-CSF 5 mcg/kg/day was added after 2° cycle for mobilization. 3 pts were previously treated with high dose Ig i.v. and steroids in the neurologic unit. Time from diagnosis to aPBSCT was 4 months (range 3-7). Conditioning regimen was HDMel (Melphalan 100 mg/m^2 for 2 consecutive days). *Results*. Engraftment was rapid and sustained. After a median follow-up of 57 months (range 5-69), all pts are alive with slow but progressive improvement in neurological disease, skin changes, organomegaly, performance status and without evidence of plasmacytosis. Negativization of M component was observed in all patients. Pt with sclerotic bone lesion also received radiotherapy. VEGF level was only performed after aPBSCT, but in our results (see Table 1) this parameter was not correlated with clinical and laboratoristics improvement.

Table 1.

	M component	VEGF value (pg/ml) **
Patient 1	Absent	1701
Patient 2	Absent	1653
Patient 3	Absent	1433
Patient 4	Absent	2400
Patient 5	Absent	12024
Median value		1701

**normal range < 1000 pg/ml; doubt 1000-1500 pg/ml; positive >1500 pg/ml.

Conclusions. Our experience confirms that HDMel and aPBSCT is feasible and efficacious and should be the treatment of choice for POEMS, arresting and even reversing the disease course. Early diagnosis is important to obtain best response and improve clinical outcome. aPBSCT might be safety be performed at experienced transplant centres combined to neurological expertise. We did not observe correlation between VEGF level and clinical improvement, but this data should be confirmed in the follow-up to clarify the role of bevacizumab, anti-VEGF antibody, as new therapeutic option for patients who can not perform transplant or relapse after aPBSCT.

0963

CONTRIBUTION OF THALIDOMIDE MAINTENANCE TO LONG TERM RESULTS OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

Z.N. Özkurt,[1] R. Haznedar,[1] Z.N. Özkurt,[1] Z.A. Yegin,[1] S.Z. Aki,[1] Ö. Çeneli,[2] M. Yagci,[1] G.T. Sucak[1]

[1]Gazi University Faculty of Medicine, ANKARA; [2]Kirikkale University Faculty of Medicine, KIRIKKALE, Turkey

Background. High-dose chemotherapy followed by autologous cell transplantation (ASCT) improves survival in patients with multiple myeloma (MM); however, disease progression after ASCT remains to be problem. Progression free survival (PFS) is shorter in patients who are in partial response (PR) after ASCT compared to the ones achieving complete response (CR). New treatment approaches are required to improve PFS and overall survival (OS). New treatment modalities including maintenance treatment may be beneficial in patients with less than CR. *Aims*. We aimed to analyse contribution to PFS and OS of Thalidomide maintenance treatment in myeloma patients, with a response less than CR after ASCT. *Methods*. Forty six patients [30 male, 16 female; median age 55 (32-71)] who received melphalan 200 mg/m^2 followed by ASCT were enrolled to this study. Median follow-up was 18 (6-65) months. Patients were divided in to three groups; CR,T(-) patients: Patients who achieved CR, 3 months status post transplantation (n=20), who did not require any maintenance; PR,T(+) (n=18): disease status at the third month post-transplant was PR, Thalidomide at 100 mg/day was started at day 100 post-transplantation and PR,T(-) (n=8) patients who were not treated with any maintenance treatment despite a disease response less than CR. *Results*. In CR, T(-) group, 8 patients continued in CR and relapse developed in 12 patients, PFS was 12 (4-65) months. In PR, T(+) group, median Thalidomide maintenance treatment was 12 (4-32) months. The best response under Talidomide treatment was CR in 9 patients, PR in 8 patients, and progressive disease (PD) in 1 patient. During maintenance treatment 10 patients preserved their best disease status, but relapse from CR was observed in 3 patients and PD was identified in 5 patients. PFS was 18(0-48) months. In PR, T(-) group, 4 patients preserved disease status achieved after transplantation, but PD developed in 4 patients. PFS was 12.5 (6-29) months. PFS probabilities were not different between CR, T(-) group (37.0%) and PR, T(+) group (32.9%) (p>0.05). In PR, T(-) group, PFS calculated at first 2 years was lower (46.8%) than PR, T(+) group (74.2%), without statistically significance (p>0.05). Overall survival probability was calculated 85.7%, 94.4%, and 26.7 in CR, T(-), PR, T(+), and PR, T(-) groups, respectively. OS in PR, T(+) patients was not different from CR, T(-) patients (p>0.05), and significantly higher than PR, T(-) patients (p=0.02). *Conclusions*. We found that maintenance treatment with thalidomide after high-dose chemotherapy improves the response rate, and the overall survival in patients with myeloma. In post-transplantation long term period, the patients with PR who received Thalidomide maintenance had a similar PFS and OS ratios to patients in CR. Thalidomide may be a logical approach after post-ASCT setting for treatment of residual disease.

0964

SERUM DKK1 IN SMOLDERING MULTIPLE MYELOMA

M. Hernandez-Martin,[1] R.M. Fisac Herrero,[1] C. Olivier Cornacchia,[1] P. Tajada,[1] M.J. Moro,[1] R. Cuello,[2] A. Martin Garcia-Sancho,[3] C. Aguilera,[4] J. Garcia-Frade,[5] L. Lopez,[6] T. Casadomartin,[1] J.F. San Miguel[6]

[1]Hospital General de Segovia, SEGOVIA; [2]Hospitalclinico de Valladolid, VALLADOLID; [3]Hospital Virgen de la Concha, ZAMORA; [4]Hospital del Bierzo, PONFERRADA-LEÓN; [5]Hospital Rio Hortega, VALLADOLID; [6]Hospital Clinico-Universitario, SALAMANCA, Spain

Background. Dickkopf-1(DKK-1) gene and its protein act as Wnt-sig-

nalling inhibitor in Multiple Myeloma (MM). It has been related with inhibition of osteoblastic function and differentiation. Previously, our group has communicated that the serum concentration of this parameter is higher in MM patients than in Monoclonal Gammopathy of Unknown Significance (MGUS), and is related to the bone lesion in MM. The behavior of DKK1 has not been described in the set of Smoldering Multiple Myeloma (sMM). *Aims*. To study serum DKK1 in sMM patients, comparing it with a series of MM and MGUS patients diagnosed at the same time. *Material and Methods*. 64 MM, 36 sMM y 53 MGUS diagnosed at Hospitals of Castilla-León-Spain between 2003 and 2008. Bone involvement in MM patients was evaluated by conventional Rx; patients were classified in two groups: without lyses (osteoporosis or no bone disease) and with lyses (some lytic lesion or pathological fracture no vertebral). Serum samples were collected at diagnosis and stored at -80ºC before three hours. Serum DKK1 was measured by double-sandwich enzimoimmunoassay (EIA), standardized in our laboratory. We also analyzed CTX (β-crosslaps) in Elecsys' analizator and bone Álkaline Phosphatase (bAP), MIP1 α, OPG and sRANKL by EIA. Results are expressed by median of the values. *Statistical methods*. Non-parametric test (Mann-Whitney U, Kruskal-Wallis and Spearman correlation). *Results*. Serum DKK1 was higher in MM patients (32.5 ng/mL) compared to sMM patients (24.4), and also more elevated in sMM than in MGUS patients (20.6), although no comparison was statistically significant. As previously described, the comparison between MM and MGUS was significant (p<0.01). When analyzed separately, serum DKK1 in MM patients without lytic lesion (n=26) or with lyses (n=37) vs. sMM patients, no significant differences were observed. We analyzed possible correlations between serum DKK1 and the other cytokines, chemokines and biochemical markers, all related with bone disease, in each diagnostic group. Only significant direct correlation between DKK! and bAP was observed in MM patients. *Conclusions*. Serum DKK1 in sMM patients showed values between MM and MGUS patients, but the differences were not statistically significant. This would be consistent with a intermediate biological behaviour regarding bone disease.

Supported by grant Ayudas a la Investigación Clínica2007-CAJABURGOS and Celgene Laboratories

ELEVETED SERUM B-LYMPHOCYTE STIMULATOR LEVELS IN DIAGNOSIS ARE RELATED TO DISEASE AGGRESSIVENESS AND ADVERSE SURVIVAL IN MULTIPLE MYELOMA

D. Maltezas,[1] T. Tzenou,[2] X. Papanikolaou,[1] E. Koulieris,[2] V. Bartzis,[2] A. Gasiamis,[2] T. Iliakis,[2] T.P. Vasilakopoulos,[3] P. Repousis,[1] M. Dimou,[3] G. Georgiou,[3] M.K. Angelopoulou,[3] M. Kotsopoulou,[1] C. Mitsouli - Mentzikof,[1] P. Panayiotidis,[3] G.A. Pangalis,[3] M-C. Kyrtsonis[2]

[1]Hematological Clinic, Metaxa Anticancer Hospital, PIRAEUS; [2]First Department of Propedeutic Internal Medicine, Laikon Hospital, ATHENS; [3]Haematology Department, Laikon Hospital, ATHENS, Greece

Multiple Myeloma (MM) is characterized by the uncontrolled proliferation of monoclonal Plasma Cells. Numerous cytokines participate in the interactions between Plasma Cells and the medullary milleu. B-Lymphocyte-Stimulator (BLyS) is a member of the TNF-superfamily that is important in B-cell differentiation and immunoglobulin production. It has been found of prognostic value in Lymphomas and other Plasma Cell dyskrasias. The aim of the present study was to investigate the relationship of serum BlyS levels in MM patients at the time of diagnosis with disease aggressiveness and survival.88 MM patients were included in our study. Median age was 67 years (42 -84 years). 55% were men, 18,5% were staged I according to Durie and Salmon, 32,5% II and 49% III respectively while 22% were staged I according to ISS, 25% II and 53% III respectively. Myeloma type was IgG in 65,5%, IgA in 19% and light chain in 15,5%. 13% of the patients presented with renal failure, 32% had haemoglobin levels under 10 g/dL and thrombocytopenia (PLT<100×10^9/L) was observed in 4%. Serum LDH and CRP were abnormal in 15% and 47% of the patients respectively. 46% of the patients had bone marrow infiltration over 50% while 28% presented with extensive bone disease. Serum BLyS levels were determined by ELISA (R&D Systems, Quantikine) in duplicate measured in frozen sera drawn at the time of the diagnosis. Values under the median were defined as "low". Statistical analysis was performed by standard methods. Serum BLyS levels ranged from undetectable to 921 pg/mL (median 122 pg/mL). High BLyS levels correlated with low albumin (p=0.037) and high LDH (p=0.012) and had significantly reduced 5-year-survival (50% vs. 82%, p=0.044). No other correlations were found. In conclusion high serum BLyS levels at the time point of the diagnosis are related to aggressive disease and represent an adverse prognostic factor in Myeloma patients. Our findings may be of special interest considering the recent development of anti-BLyS agents.

EPIDEMIOLOGY OF BISPHOSPHONATE USE AND JAW OSTEONECROSIS INCIDENCE IN MULTIPLE MYELOMA PATIENTS IN THE REPUBLIC OF IRELAND

J. McHugh,[1] R.S. Kumar,[2] A. O'Dalaigh,[3] K. Breen,[4] M. McCloy,[5] R. Rajpal,[6] A. Burke,[7] M. Kelly,[8] R. Desmond,[9] C. O'Rafferty,[10] P. Hayden,[11] M. Leahy[1]

[1]Mid Western Regional Hospital, LIMERICK; [2]Waterford Regional Hospital, WATERFORD; [3]Letterkenny General Hospital, LETTERKENNY; [4]Beaumont Hospital, DUBLIN; [5]Our Lady of Lourdes Hospital, DROGHEDA; [6]Mater Misericordiae Hospital, DUBLIN; [7]Sligo General Hospital, SLIGO; [8]Midland Regional Hospital, TULLAMORE; [9]St Vincent's Hospital, DUBLIN; [10]Cork University Hospital, CORK; [11]University College Hospital Galway, GALWAY, Ireland

Background. Osteonecrosis of the jaw (ONJ) is a recently described complication of bisphosphonate therapy. *Aims*. To audit epidemiology of bisphosphonate use and ONJ incidence in multiple myeloma (MM) patients in the Republic of Ireland (ROI). *Methods*. Questionnaires on bisphosphonate use, ONJ incidence and management were sent to the 15 haematology departments in ROI treating MM. *Results*. We received replies from 11 centres. 456 MM patients currently attend these centres with 127 new cases of MM in the last year. 5/11 centres have a written policy on bisphosphonate use. Zoledronic acid is used in 9 centres, pamidronate is used in 7 centres, clodronate is used in 3 centres and ibandronate is used in 1 centre. Patients in 10/11 centres undergo a dental review prior to commencing bisphosphonates. All centres use bisphosphonates for at least 2 years, 6 centres stop at 2 years if MM is stable, 3 reduce to 3 monthly dosing after 2 years and 2 continue monthly dosing indefinitely. 10/11 centres stop bisphosphonates prior to any dental work. 6 centres stop bisphosphonates 1 month prior to dental work, the remainder stopping between 6 weeks and 3 months prior to dental treatment. 6 centres restart bisphosphonates once healing is complete following dental work. 4 other centres specified a time for restarting bisphosphonates ranging from 1-6 months. There have been 24 ONJ cases in MM patients attending these 11 centres. We have data for 21 of these cases. The median age is 62 years (range 43-78 years). The median time since diagnosis of MM at presentation of ONJ was 36 months (range 5-108 months). 14 cases had IgG MM, 3 cases had IgA MM, 4 cases had non secretory MM; none had light chain only MM. 18 patients were on zoledronic acid at the time of diagnosis of ONJ, 3 patients were on pamidronate. The median duration of bisphosphonate use at the time of diagnosis of ONJ was 24 months (range 4-60 months). 13 of the patients were on myeloma treatment at the time of ONJ diagnosis and 8 were on no treatment at that time. 9 patients were on thalidomide, 9 patients were on dexamethasone, 2 patients were on prednisolone, 2 patients were on bortezomib and 1 patient was on melphalan. 9 patients had previously undergone an autologous stem cell transplant prior to ONJ diagnosis. 5/21 cases of ONJ were preceded by dental work. A further case was preceded by a broken tooth. The diagnosis of ONJ was based on clinical findings alone in 6 cases. Radiology was required in the other 15 cases. A histological diagnosis was made in 4 cases. In all cases the bisphosphonate was stopped once ONJ was diagnosed. Antibiotics were administered in 12 cases. Surgery was required in 4 cases. In 2 cases the bisphosphonate was restarted again after ONJ diagnosis. *Conclusions*. There is great variation in bisphosphonate use in MM in ROI. Evidence based national guidelines on bisphosphonate use may help to maximize their benefits in MM whilst limiting their side effects.

THE ASSOCIATION BETWEEN RESVERATROL WITH SIMVASTATIN DECREASES IGM SECRETION IN WALDENSTROM MACROGLOBULINAEMIA

F. Iuliano

U.O di Oncoematologia, ROSSANO, Italy

Background. Waldenström macroglobulinemia (WM) is a distinct B-cell lymphoproliferative disorder characterized by lymphoplasmacytic bone marrow infiltration along with an immunoglobulin M (IgM) monoclonal gammopathy. Despite advances in therapy, WM remains incurable, with 5-6 years median overall survival of patients in symptomatic WM. Therapy is postponed for asymptomatic patients, and progressive anemia is the most common indication for initiation of treatment. Resveratrol (3,4',5-tri-hydroxy-trans-stilbene) is an antioxidant constituent of a wide variety of plant species including grapes. It has gained considerable attention because of its anticancer properties, as shown in solid and hematologic malignancies. Published data show that resveratrol has significant antitumor activity in WM cells line. Moreover, simvastatin, a 3-hydroxy-3-methyl-glutaryl-CoA reductase inhibitor, induced inhibition of proliferation, cytotoxic effect and apoptosis in IgM secreting cell lines as well as in primary CD19$^+$ WM cells. With this background we have treated 4 patients with asymptomatic WM with an association of simvastatin and resveratrol. Aims of this study is to test the efficacy of resveratrol plus simvastatin in asymptomatic Waldenstrom macroglobulinemia. *Methods*. 4 male pts, median age 59.2 yr (range, 42-73) and asymptomatic WM were treated with a schedule containing resveratrol 40 mg/die and simvastatin 20 mg/die for 90 days.At enrollment patients characteristic were hemoglobin level median, 12.1 g/dL, serum β2-microglobulin level median, 2.4 mg/L, and IgM peaks median, 1.8 g/dL. All patients have taken regularly the drugs and there have been no adverse events.CK and LDH serum levels were kept in the normal range. *Results*. In all patients a reduction of more than 50% of the IgM peak was observed after 3 months of therapy and is still maintained at 6 months of foll. *Conclusions*. Our data demonstrate clearly that the association between resveratrol with simvastatin decreases IgM secretion in Waldenstrom macroglobulinaemia and and can be useful in asymptomatic or low risk patients not having any adverse effects.

0968

THE CLINICAL SIGNIFICANCE OF TIMP-1, TIMP-2, MMP-2, MMP-9, OSTEOPROTEGERIN, SRANKL, AND ISS IN MULTIPLE MYELOMA PATIENTS

L.C. Oliveira,[1] J.A. Uzielli,[2] M.S. Baggio,[2] A.P. Lange,[2] J.E. Tanus-Santos,[2] E.M. Rego[2]

[1]Medical School of Ribeirao Preto, University of Sao Paulo, RIBEIRAO PRETO; [2]Medical School of Ribeirao Preto, Univesity of Sao Paulo, RIBEIRAO PRETO, Brazil

Background. Multiple myeloma (MM) is an incurable disease and the outcome highly variable. The ISS is the most useful system based on serum β2-microglobulin and albumin levels. However, this system does not include the evaluation of bone involvement by the disease that is characteristic in MM patients. The OPG/ RANKL system is a critical regulator of bone metabolism. Matrix metalloproteinases (MMP) are a family of zinc-dependent endopeptidases that are inhibited by tissue inhibitors of metalloproteinase (TIMP). MMP-9 is secreted by MM cell lines and MM cells, and may enhance bone absorption in a direct paracrine fashion. Objectives: a) to compare levels of sRANKL, OPG, MMP-2, MMP-9, TIMP-1, TIMP-2 between newly diagnosed multiple myeloma (MM) patients and healthy controls; b) to study the relationship between these parameters and diverse stages of disease according the ISS; and c) to evaluate the relationship between these parameters and bone disease. *Methods*. We studied 38 newly diagnosed and untreated MM patients (24males). The median age was 61years-old (range 39-91). The International Myeloma Working Group criteria and ISS were used to classify patients. Bone involvement was graded according to standard X-ray evaluation into two scores: low score including patients with no lesions, until two bones involved or diffuse osteoporosis and high score including patients with lesions in more than two bones or presence of bone fracture. Ten healthy volunteers were used as controls. MMP-2 and MMP-9 were determined by PAGE gelatin zymography from plasma as previously described. MMP-9 was also measured by ELISA using commercial assay. TIMP-1 and TIMP-2, OPG and sRANKL concentrations were also measured by ELISA. Comparisons among groups were analyzed by ANOVA and the correlation by the Spearman's correlation coefficient. $p<0.05$ were considered to be statistically significance. *Results*. Patients with MM had elevated TIMP-1 and TIMP-2 values compared with controls ($p<0.0001$). Plasma OPG concentration was significantly higher in MM patients compared with controls ($p=0.0012$). No significant difference was found between plasma sRANKL, pro-MMP2, pro-MMP9 and MMP-9 (detected by ELISA) in MM patients and controls. Plasma TIMP-1 correlated positively with OPG (r: 0.64, $p<0.0001$). There were a clearly statistical difference between TIMP-1 and TIMP-2 values and different staging groups ($p=0.0002$, $p=0.0046$, respectively). Plasma levels of OPG were significantly higher in stage III in comparison to the stage I and II ($p=0.012$, $p=0.032$), while no significant difference was found between stage I and II. None statistic significantly relationship was found between patients with low or high score and the measured parameters. For sRANKL, MMP-2 and MMP-9, no difference between patients and controls was detected and no increase of levels was demonstrated with the progression of the disease. We also found a positive correlation between TIMP-1 and OPG, TIMP-1 and serum calcium, and TIMP-2 and serum calcium. None of parameters that we analyzed were influenced by bone disease status. *Conclusions*. We described for the first time in the literature that the values of TIMP-1 and TIMP-2 are increased in MM patients compared with controls and there is a strong relationship between the prognostic staging (ISS) and the levels measured. So, the evaluation of TIMP-1 and TIMP-2 can be considered a prognostic marker in newly diagnosed MM patients.

0969

EVALUATING THE POTENTIAL USE OF RISK CATEGORISATION IN THE MANAGEMENT OF MGUS

M. Almeshhedani,[1] A. Salamat,[2] S. Al-Ismail[2]

[1]Singleton Hospital/ Swansea University, SWANSEA; [2]Singleton Hospital, ABM Trust, SWANSEA, UK

Background. Monoclonal gammopathy of uncertain significance (MGUS) is an increasingly common condition requiring lifelong follow-up due to the risk of progression to a plasma-cell malignancy. Currently, many patients remain under follow-up by haematologists in secondary care clinics. In recent years, a risk stratification model has been proposed which may enable targeted follow-up of high-risk patients.[1] *Aims*. To evaluate the potential use of risk categorisation in the follow-up of MGUS. *Methods*. In the Swansea/Neath Port Talbot region of Wales (population approximately 350,000), all patients with a paraproteinaemia attending haematology clinics between 2003 and 2007 were identified. Clinic letters and laboratory reports were used to ascertain patient diagnosis and obtain results of routine follow-up investigations. MGUS patients who had not progressed to a malignant condition and had undergone serum free light chain (FLC) ratio investigation were identified and risk categorised into four risk groups based on the presence of risk factors (low-risk= 0 risk factors, high-risk= 3 risk factors).[1] The risk factors are: non-IgG MGUS, M Paraprotein>15g/L and an abnormal FLC ratio (<0.26 or >1.65)[1]. A random sample of 40 patients from the high-intermediate and low risk groups, with a follow-up of >2 years, were further investigated to find the number of clinic visits during their follow-up. *Results*. 374 patients had MGUS at presentation, corresponding to 61% of identified paraproteinaemias (n=617). Mean age at presentation was 71 years (SD±12). 342 MGUS patients attended haematology clinics on more than one occasion. The median follow-up was 3.4 years, with a total follow-up of 1292 person-years. Progression to active myeloma/ plasmacytoma occurred in 3.8% (13 cases) whereas progression to other plasma-cell related malignancies occurred in 0.9% (3 cases). In addition, 6 patients progressed to asymptomatic myeloma (indolent/ smouldering myeloma). A group of 147 MGUS patients who had not progressed to malignancy were risk categorised (Figure 1). 31% of patients had no risk factors (low-risk), 47% had 1 risk factor (low-intermediate risk), 21% had 3 risk factors (high-intermediate risk) and 1 patient had all 3 risk factors (high-risk). On average, the frequency of clinic visits was equivalent to one visit every 19 weeks for low-risk patients and one visit every 18 weeks for the high-intermediate risk patients. *Summary and Conclusions*. Using the recently proposed MGUS risk stratification model, we have found that the majority of MGUS patients attending haematology clinics on a frequent basis are in the lower risk categories, which are associated with a low rate of MGUS progression.[1] Furthermore, on average, patients belonging to the lowest risk group (with no risk factors) are being followed up almost as frequently as patients in the high-intermediate risk group (with 2 risk factors). Since routine secondary care follow-up of patients belonging to the lowest risk group may not be necessary[1], implementation of the risk categorisation model would

reduce the number of patients followed-up in clinics and hence reduce costs while helping to free up resources. Lower risk patients may benefit from the introduction of a new system of follow-up e.g. nurse-led clinics.

EFFICATIOUS BUT INSIDIOUS. A RETROSPECTIVE ANALYSIS OF FLUDARABINE-INDUCED MYELOTOXICITY USING LONG-TERM CULTURES -INITIATING CELLS IN 100 FOLLICULAR LYMPHOMA PATIENTS

A. Janikova,[1] Z. Koristek,[1] J. Vinklarkova,[1] T. Pavlik,[2] M. Navratil,[1] Z. Kral,[1] I. Vasova,[1] J. Mayer[1]

[1]University Hospital and Faculty of Medecine Brno, BRNO; [2]Institute of Biostatistics and Analyses, Masaryk University Brno, BRNO, Czech Republic

Background. Fludarabine alone or in combination has been recognized as effective treatment in patients with follicular lymphoma (FL), but can also induce a substantial long-term myelotoxicity. The mechanism of this toxicity has never been studied. *Aims*. To elucidate which compartment of hematopoietic precursors is damaged or not after different chemotherapy. *Methods*. Hundred FL patients were analyzed in this retrospective study. Median age was 55 (32-75) years, 40% had bone marrow involvement and 21 patients were relapsed (1-4 previous course of therapy; 85%immuno/chemotherapy). Myelotoxicity was assessed by cultivation of two types of hematopoietic progenitor cells: colony forming units- granulocyte-macrophage (CFU-GM) and long-term cultures-initiating cells (LTC-IC). The pre-treatment amounts of CFU-GM and LTC-IC were related to age, sex, and stage of disease, bone marrow involvement and previous therapy. The post-treatment comparison of CFU-GM and LTC-IC was performed among different regimens: fludarabine-based (R±FND), procarbazine-based (R±COPP) and R±CHOP-like therapy. *Results*. At baseline, a total number of progenitor hematopoietic cells in both types of cultures varied in wide ranges; LTC-IC of 0- 874 with median 77.71/mL and CFU-GM of 0-531 with median $30{,}58\times10^2$ /mL. Bone marrow involvement, sex, stage of disease or previous therapy had no influence on LTC-IC and CFU-GM counts. Interestingly, we identified an increase in numbers of LTC-IC but not of CFU-GM positively associated with age (p=0.01). In remission (85 pts), the post-treatment numbers of CFU-GM and LTC-IC dropped significantly after R±FND (n=28) and R±COPP (n=16) but not after R±CHOP-like therapy (n=41) compared to baseline value (p<0.01); using paired comparison of samples the differences in LTC-IC only were found to be significant (p=0.019 and p=0.013, respectively). *Conclusions*. Fludarabine as well as procarbazine reduced significantly numbers of LTC-IC in follicular lymphoma patients, which could reflect the impairment of the most immature hematopoietic cells. Even if the both of drugs impair hematopoietic stem cell, regarding its popularity, myelotoxicity of fludarabine should be emphasized. This finding is consistent with clinical observations (poor mobilization and long-term cytopenias) and offers an insight into mechanism of myelotoxicity caused by these drugs in relatively well defined group of FL. We can also hypothetize, the increased number of LTC-IC in elderly patients could be compensatory mechanism of decreasing one-cell function related to aging.

0971

IN MANTLE CELL LYMPHOMA (MCL) THE MCL-INTERNATIONAL PROGNOSTIC INDEX (MIPI) IS A BETTER PREDICTOR OF EVENT-FREE AND OVERALL SURVIVAL THAN INTERNATIONAL PROGNOSTIC INDEX (IPI) IN PATIENTS RECEIVING INTENSIVE 1ST LINE TREATMENT INCLUDING ASCT

C. Geisler,[1] E. Elonen,[2] A. Kolstad,[3] A. Laurell,[4] C. Sundström,[4] J. Delabie,[5] M. Ehinger,[5] M.-L. Karjalainen-Lindsberg,[2] E. Ralfkiaer,[1] P. Brown[1]

[1]Rigshospitalet, COPENHAGEN, Denmark; [2]Helsinki University Central Hospital, HELSINKI, Finland; [3]The Norwegian Radium Hospital, OSLO, Norway; [4]Uppsala University Hospital, UPPSALA, Sweden; [5]Lund University Hospital, LUND, Sweden

Background. The MIPI has been shown to be a better predictor of survival in MCL following conventional treatment than the IPI.[1] It is not known if MIPI can also predict outcome in patients receiving intensive immunochemotherapy with stem cell support. *Aims*. To validate the MIPI in the Nordic MCL2 protocol, in which 160 patients, after giving informed consent, received intensive 1st-line induction therapy of Rituximab (R) + CHOP (R-CHOP) alternating with R-AraC, followed by consolidation with high-dose chemotherapy with BEAM or BEAC + autologous stem cell support.[2] *Methods*. Data allowing MIPI analysis

were available in 155 patients. We compared IPI, MIPI and simplified MIPI (s-MIPI). Regarding the IPI, since the curves of high-intermediate and high risk groups were identical, these were merged into one group. *Results*. MIPI and s-MIPI predicted survival better (p<0.0001) than the IPI (p<0.002). MIPI and s-MIPI did not identify the same patient subgroups, however (Figure 1). By the MIPI most patients were in the low risk group, whereas by the s-MIPI most patients were in the intermediate risk group. The MIPI discriminated significantly between low and intermediate, and intermediate and high risk groups, respectively (p=0.04 and <0.02 respectively), whereas the s-MIPI could not distinguish significantly between low and intermediate risk groups (p=0.13). Regarding vent-free survival, the IPI did not identify significant differences, (p=0.66) in contrast to MIPI (p=0.01) and s-MIPI (p=0.03). The addition to the MIPI of the % Ki-67-positive cells multiplied by its Cox analysis β value (0.02124), did not add further information as it moved almost half (47%) of the patients to the high risk group. *Conclusions*. We confirm that also in MCL patients receiving intensive immunochemotherapy incl. ASCT, MIPI and s-MIPI predict survival better than IPI. However, MIPI and s-MIPI did not group the patients identically. Although MIPI was more discriminative than s-MIPI, the simplicity of s-MIPI may make it preferable.

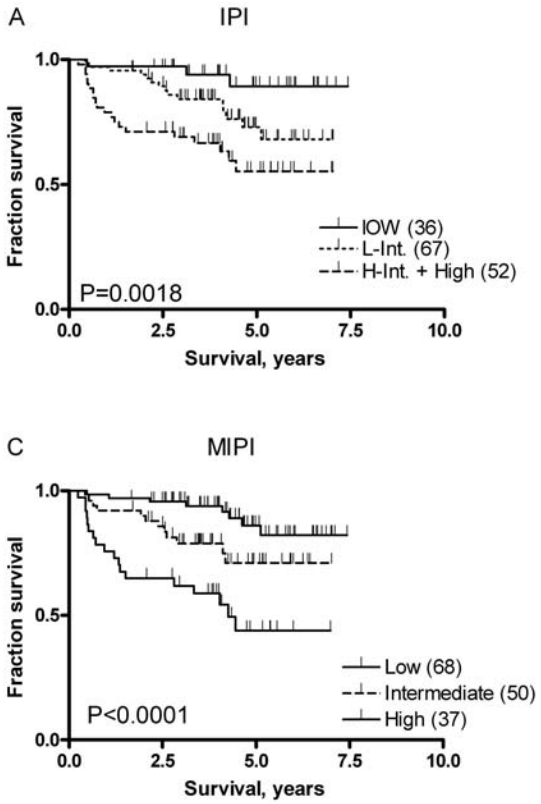

Figure 1. Survival Nodic MCL-2: IPI, MIPI and simplified MIP.

RETREATMENT WITH RITUXIMAB IN 178 PATIENTS WITH RELAPSED AND REFRACTORY B-CELL LYMPHOMAS: A SINGLE INSTITUTION STUDY

M. Johnston, F. Bouafia-Sauvy, F. Broussais-Guillaumont, A.-S. Michallet, C. Traulle, G. Salles, B. Coiffier

Centre Hospitalier Lyon-Sud, LYON, France

Background. The role of rituximab retreatment in patients who have responded to a previous course of rituximab is not well known. For patients who relapse after initial rituximab treatment an important clinical issue is the efficacy of retreatment with rituximab at the time of relapse. *Aims*. To investigate the efficacy and toxicity of retreatment with rituximab with or without chemotherapy in patients with relapsed and refractory B-cell lymphomas. *Methods*. This was a single centre retrospective cohort study. We included patients with relapsed and refractory B-cell lymphomas treated in first line and in first progression with rituximab, with or without chemotherapy. We also attempted to put the results into context by conducting a comparison of the rituximab-retreated patients with a group of matched historical control patients who had not received rituximab in first or second-line therapy but had received approximately identical chemotherapy. *Results*. 178 rituximab-retreated patients were included in the study of which 29% had diffuse large B-cell lymphoma and 28% had follicular lymphoma. The remainder of patients had a variety of B-cell lymphomas. The overall response rate for the first treatment was 81% and for the second treatment was 66%. The median progression-free survival from diagnosis (PFS1) was 13 months and from relapse (PFS2) was 18 months (not statistically different). The 5-year overall survival was 57%. No significant toxicities were identified and the yield of stem cell collection was acceptable in this population. 301 historical controls were identified from the same institution who were well matched with the patients for age, histological subtype and proportion treated with high dose therapy (p>0.05). There was a slight excess of males in the control group and more patients in the rituximab-retreated group had a high or high-intermediate second-line International Prognostic Index. Compared to the historical control patients, the rituximab-retreated patients had a shorter PFS1 (90% progressed at 3 years compared to 78% in the control group, p<0.001). There were no differences between the two groups for PFS2. Despite this, the 5-year overall survival for the rituximab-retreated group was superior (57% versus 40%, p<0.02). *Conclusions*. In conclusion, retreatment with rituximab, with or without chemotherapy, in patients having previously received rituximab yields a high overall response rate in patients with relapsed and refractory B-cell lymphomas. The outcome of retreatment, in terms of progression-free survival, is not inferior to that of primary treatment. Relapse occurring after rituximab-containing therapy may be more aggressive than that occurring after chemotherapy alone.

0973

TEMSIROLIMUS FOR THE TREATMENT OF PATIENTS WITH RELAPSED OR REFRACTORY MANTLE CELL LYMPHOMA: SUPPORTIVE EFFICACY ANALYSES FROM THE PHASE 3 STUDY

G. Hess,[1] J. Romaguera,[2] R. Herbrecht,[3] G. Verhoef,[4] M. Crump,[5] O. Hanushevsky,[6] A. Strahs,[6] B. Hewes,[6] A. Berkenblit,[6] B. Coiffier[7]

[1]Johannes Gutenberg-Universität, MAINZ, Germany; [2]MD Anderson Cancer Center, HOUSTON, TX, USA; [3]Hôpital de Hautepierre, STRASBOURG, France; [4]University Hospital, LEUVEN, Belgium; [5]Princess Margaret Hospital, TORONTO, ON, Canada; [6]Wyeth Research, CAMBRIDGE, MA, USA; [7]Hôpital Lyon Sud, PIERRE BÉNITE, France

Background. Temsirolimus (Torisel®) is a specific inhibitor of the mTOR kinase and is approved in Europe for the first-line treatment of patients with advanced renal cell carcinoma who have at least 3 of 6 poor-prognostic risk factors. Temsirolimus also was evaluated in patients with relapsed or refractory mantle cell lymphoma (MCL). In a phase 3, randomized, open-label study, patients treated with temsirolimus 175 mg weekly 3 times followed by 75 mg weekly (175/75-mg) had significantly longer progression-free survival (PFS) than those treated with investigator's choice therapy (p value temsirolimus: investigator's choice = 0.0009; hazard ratio = 0.44; 97.5% CI = 0.25, 0.78; Hess *et al.* J Clin Oncol. 2008, 26:abs 8513). Patients treated with temsirolimus 175 mg weekly 3 times followed by 25 mg weekly (175/25-mg) showed a trend towards longer PFS than those treated with investigator's choice therapy (p=0.0618; hazard ratio = 0.65; 97.5% CI = 0.39, 1.10). *Aims*. These results were obtained for the intent-to-treat population, which included all ran-

domized patients (n=54 for both temsirolimus groups and the investigator's choice group). We now report the results of sensitivity analyses for the recommended temsirolimus dose, 175/75-mg, compared with those for investigator's choice therapy. *Methods*. The primary endpoint of the study was PFS, the time from the date of randomization to the earlier date of either progressive disease (PD) or death from any cause, if within 4 months of the last valid tumor assessment (per FDA guidance), censored at that assessment. Progression was assessed by independent review of radiographic and clinical data. Progression-free survival was analyzed by Kaplan-Meier estimates and an unstratified Cox proportional hazards model. All patients provided written informed consent. *Results*. Sensitivity analyses for PFS included: 1) evaluable population: those who remained on treatment for at least 8 weeks and did not discontinue early for PD or death, had no major protocol violations, and had at least 1 screening tumor assessment and at least 1 postbaseline independent tumor assessment; 2) all deaths: those patients who had PD or died at any time during the study; 3) all deaths + withdrawal from therapy + initiation of anticancer therapy: those patients who had PD, died, or stopped treatment because of withdrawal from therapy or initiation of other anticancer therapy; and 4) all deaths, excluding patients with blastoid morphology. The latter analysis was performed because 0 patients in the 175/75-mg group and 4 patients in the investigator's choice group had blastoid morphology. The characteristics of PFS for the 4 sensitivity analyses are shown (Table). For each analysis, PFS was significantly longer for the patients treated with temsirolimus 175/75-mg than for those treated with investigator's choice therapy, consistent with the PFS results for the intent-to-treat population. Conclusions: Based on several analyses, patients with relapsed or refractory MCL treated with temsirolimus 175/75-mg showed significant improvement in PFS compared with those treated with investigator's choice therapy. Additional exploratory analyses will be presented.

Table 1. Sensitivity analyses of Temsirolimus 175/75-mg vs. Investigator's Choice Therapy.

PFS Analysis*	Temsirolimus 175/75-mg		Investigator's Choice		p-Value	Hazard Ratio (95% CI)
	n	Median PFS, mo	n	Median PFS, mo		
Evaluable population	29	5.2	26	1.9	0.0002	0.29 (0.15, 0.57)
All deaths	54	5.2	54	2.0	0.0007	0.46 (0.29, 0.72)
All deaths, excluding pts with blastoid morphology	54	5.2	50	2.1	0.0020	0.48 (0.30, 0.77)
All deaths + withdrawal from therapy + initiation of anticancer therapy	54	2.6	54	0.8	<0.0001	0.43 (0.28, 0.65)

*Independent assessment.

Background. Randomised controlled trials (RCTs) reported conflicting results on the impact of high-dose chemotherapy (HDCT) and autologous stem cell transplantation in the first-line treatment of patients with aggressive non-Hodgkin Lymphoma (NHL). *Aims and Methods*. We performed a meta-analysis based on individual patient data (IPD) to assess the efficacy of HDCT compared to conventional chemotherapy in aggressive NHL patients with regard to overall survival (OS) and progression-free survival (PFS). Furthermore, we wanted to determine the efficacy on the intervention in specific subgroups of patients. Particularly we analysed the impact of the age-adjusted International Prognostic Index (aaIPI). We searched the Cochrane Library, MEDLINE and other databases (1/1990 to 12/2007). The RCTs were conducted mainly without Rituximab. Hazard ratios (HR) with 95% confidence intervals (CIs) were calculated using the Cox proportional hazards model stratified by study. The conventional chemotherapy-arm is taken as reference in the analysis. *Results*. Individual patient data were available from 11 RCTs including 2,132 randomised patients. Information on patient characteristics, treatment, events and survival was collected. Overall, there was no evidence for HDCT to improve OS (HR 1.09; 95% CI 0.95-1.24) or PFS (HR 1.04; 95% CI 0.92-1.17) when compared with conventional chemotherapy. In subgroup analysis hazard ratios for OS was 1.34 (95% CI 0.98-1.82) for good risk patients and 1.01 (95% CI 0.87-1.17) for poor risk patients (p value for interaction = 0.10). Subgroup analysis did not indicate differences in terms of PFS between good (HR 1.07, 95% CI 0.84-1.36) and poor risk (HR 0.99, 95% CI 0.87-1.14) patients (p value for interaction = 0.61). *Summary and Conclusions*. Preliminary analyses suggest that there is no evidence for HDCT to improve OS or PFS in NHL patients compared to conventional chemotherapy. There was no evidence for different treatment outcomes in patients with good or poor IPI risk group. Further results will be presented.

0975

PHARMACOKINETICS OF RITUXIMAB AND THE DEVELOPMENT OF ANTIBODIES AGAINST RITUXIMAB IN PATIENTS WITH A B-CELL CD20+ MALIGNANCY

L. Tran,[1] A.D.R. Huitema,[2] L. Aarden,[3] J.H. Beijnen,[2] J.W. Baars[4]

[1]Netherlands Cancer Institute/Slotervaart Hospital, AMSTERDAM; [2]Slotervaart Hospital, AMSTERDAM; [3]Sanquin, AMSTERDAM; [4]Netherlands Cancer Institute/Antoni van Leewenhoek Hospital, AMSTERDAM, Netherlands

Background. Limited information exists about the pharmacokinetics of rituximab in patients with CD20+ B-cell malignancies. In an attempt to increase the therapeutic efficacy, several randomised trials were performed varying the number of infusions, intervals between cycles, duration of treatment, and administration of rituximab in combination with several chemotherapeutic compounds. But still, the optimal dosing regimen has to be elucidated. Additionally, the development of human anti-chimeric antibodies (HACAs) could affect rituximab pharmacokinetics. Although HACAs are observed in patients with auto-immune diseases treated with rituximab, it is rare in patients treated with rituximab for CD20+B-cell malignancies. Most obervations were done in patients during induction, but not on maintenance treatment. It is therefore of interest to determine the presence of HACAs, especially with longer duration of treatment. *Aims*. To get more insight into the pharmacokinetics of rituximab for further improvement of rituximab containing therapies. To assess the development of HACAs against rituximab for patients who are treated with rituximab in combination with chemotherapy or are on maintenance therapy. *Methods*. In this pilot study, patients with a CD20+ B-cell malignancy who were treated with rituximab containing regimens were included. The patients were informed in line with the rules of good clinical practice. Induction treatment schedules consisted of a 2,3,4 weekly schedule of 375 mg/m^2 rituximab intravenously in combination with chemotherapy for 4-8 cycles. Maintenance treatment consisted of a two-three monthly dose of 375 mg/m^2 rituximab intravenously for 2 years. On the day of the treatment with rituximab, preinfusion blood samples were taken. After the end of treatment, selected blood samples were taken. Rituximab levels were measured by enzyme-linked immunosorbent assay (ELISA). The minimum quantifiable concentration was 7.8 ng/mL. An assay for determination of HACAs was designed with a lower limit of quantification of 12 units/mL. *Results*. Eight patients were on induction therapy. Figure 1 shows rituximab levels over the time of treatment. No steady state was reached after four cycles. Trough levels after 4 cycles ranged between 55.7 and 135 μg/mL, with a median of 111 μg/mL. Rituximab levels of 1 patient remained very low after the first course. This patient had a CLL with circulating tumour cells. Apart from 1 patient with mantle cell lymphoma, all patients had a complete response. For all patients, concentration of HACAs was below the quantification limit. Five patients were on maintenance therapy. One patient received two-

monthly maintenance treatment. Trough levels of 4 patients on three-monthly schedule remained constant, with a median concentration of 6 μg/mL (range 0.5-11.7μg/mL). After eight cycles on maintenance therapy, no HACAs were observed. *Summary and Conclusions*. Considerable inter-individual variability of rituximab levels was observed. There were no correlations between rituximab levels, therapy regimen, renal function, solid tumour load and response. For patients with circulating tumour cells, a loading dose could be considered. No HACAs were observed in these patients, which strongly supports the previously described antigen mediated clearance of rituximab.

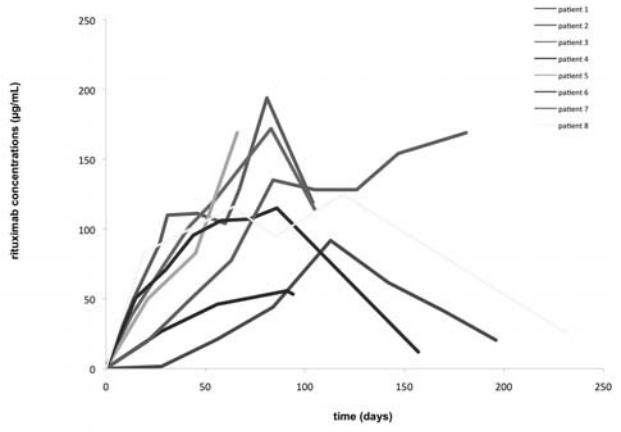

Figure 1. Rituximab levels over the time of treatment

POST-TRANSPLANTATION LYMPHOPROLIFERATIVE DISORDER: REDUCTION OF IMMUNOSUPPRESSION AS INITIAL THERAPY. RETROSPECTIVE ANALYSIS OF CLINICAL CHARACTERISTICS AND PROGNOSTIC VARIABLES

R. Reshef, S. Vardhanabhuti, M.R. Luskin, D.F. Heitjan, E.A. Stadtmauer, D.E. Tsai

University of Pennsylvania, PHILADELPHIA, USA

Background. Post-transplantation lymphoproliferative disorder (PTLD) is a heterogeneous group of lymphoid neoplasms arising in pharmacologically immunosuppressed organ transplant recipients. While it has long been known that reduction of immunosuppression (RI) is an effective therapy, previous reports on RI are of limited value due to small numbers of patients. *Aims*. We sought to estimate outcomes and predictors of outcomes, in patients treated with RI for PTLD. *Methods*. We retrospectively studied 162 organ transplant recipients diagnosed with PTLD at the University of Pennsylvania between 1988 and 2008. Stem-cell transplant recipients were excluded. We analyzed clinical and pathological characteristics, response to therapy, graft outcome and survival of patients treated with RI alone as initial therapy for PTLD in comparison to patients who were treated with other therapies. We used logistic regression to identify predictors of response, and Cox regression to identify predictors of survival, in patients treated with RI. *Results*. 67 patients received RI alone as initial therapy. These patients were similar to those treated with other modalities with respect to demographic parameters, transplanted organ type, immunosuppressive medications, number of previous rejection episodes, pathological subtype, and EBV positivity. 40/67 patients (59.7%) required additional therapy after initial RI; the most common second-line therapies were rituximab (40%), followed by chemotherapy (39%) and radiotherapy (15%). The overall response rate to RI alone was 44% (37% CR, 8% PR), and additional 18% achieved stable disease. Of 23 patients who experienced a CR, only 4 later required therapy for relapsed disease. Median survival was 44 months on RI alone, 24 months on rituximab and 19 months on chemotherapy. We also identified 30 patients who were treated with complete surgical excision of the disease site and received RI as adjuvant therapy. The outcome of these patients was favorable and their median survival was not reached after a mean follow-up of 64 months. In patients treated with RI alone, 41% developed acute allograft rejection. Five of these patients later underwent retransplantation without recurrence of PTLD. Predictors of response to RI: Lack of bulky disease, multiple previous allografting and younger age were associated with better response by univariate analysis. Notably, EBV status, pathological subtype and type of transplanted organ were not associated with significant differences in response to RI. A step-wise multivariate logistic regression analysis confirmed that older age and bulky disease were strong predictors of RI failure. Survival analysis revealed that B symptoms, weight loss, renal failure, dyspnea and liver involvement at diagnosis were associated with worse survival in patients treated with RI alone. *Conclusions*. In our large, single-center series, RI was found to be a powerful tool in controlling PTLD, resulting in responses in 44% of patients, with many patients permanently cured. These findings illustrate once again the role of the immune system in shaping the development of tumors, and support the use of RI, either alone or in combination with other therapies.

Table 1.

Response to RI		
Variable	OR (95% CI)	p-value
>1 previous allograft	0.11 (0.01,0.99)	0.049
Anorexia as initial symptom	3.67 (1.19,11.3)	0.024
Bulky Disease	9.72 (1.15,82.32)	0.037
Survival		
Variable	HR (95% CI)	p-value
Weight loss	2.03 (1.08,3.82)	0.028
B symptoms	2.04 (1.01,4.1)	0.046
Renal failure	2.05 (0.99,4.23)	0.052
Dyspnea	2.68 (1.17,6.13)	0.02
Liver involvement	2.79 (1.26,6.2)	0.012

SERUM B2-MICROGLOBULIN LEVELS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): PROGNOSTIC SIGNIFICANCE UNDER TREATMENT WITH RITUXIMAB-CHOP (R-CHOP)

T.P. Vassilakopoulos,[1] A. Anastasopoulou,[1] N. Constantinou,[2] M.K. Angelopoulou,[1] E. Stavroulaki,[3] C. Kalpadakis,[3] S. Sachanas,[1] V. Pappis,[1] P. Tsirkinidis,[1] M. Moschoyiannis,[1] O. Tsopra,[1] T. Tzenou,[1] A. Gassiamis,[1] X. Yiakoumis,[1] M.C. Kyrtsonis,[1] S.I. Kokoris,[1] M.P. Siakantaris,[1] M. Dimou,[1] G. Georgiou,[1] E. Plata,[1] N.A. Viniou,[1] E. Variamis,[1] K. Konstantopoulos,[1] P. Panayiotidis,[1] H. Papadaki,[3] G.A. Pangalis[1]

[1]Department of Haematology, University of Athens, ATHENS; [2]Haematology Clinic, Theageneion Hospital, THESSALONIKI; [3]Department of Haematology, University of Crete, HERAKLION, Greece

Background. Elevated serum β2-microglobulin levels have been implicated as a prognostic factor in aggressive non-Hodgkin's lymphomas. However they have not been adopted in current prognostic models, partly due to the high rate of missing data in multicenter studies. Given that the introduction of Rituximab has overcome the adverse significance of several prognostic factors, which had been established in the pre-Rituximab era, the extrapolation of the results of prior studies in the Rituximab era is not scientifically acceptable. Therefore, the prognostic significance of serum β2-microglobulin levels in patients with DLBCL treated with R-CHOP has not been adequately investigated. *Aims*. The determination of serum β2-microglobulin levels and the evaluation of their correlation with other baseline features and the outcome of patients with DLBCL treated with R-CHOP. *Patients and Methods*. We analyzed 344 patients with DLBCL, who were treated with R-CHOP or similar anthracycline-based combinations and had available serum β2-microglobulin levels. Baseline patient characteristics were recorded, and failure free survival (FFS) (including early toxic deaths as events) and overall survival (OS) were determined as endpoints for the outcome. *Results*. The median age of the patients was 65 years (18-88), and 59% were males. The distribution of our patients according to the IPI was as follows: Low Risk (L) 49%, Low-Intermediate (LI) 19%, High-Intermediate (HI) 21% and High Risk (H) 12%. According to the R-IPI, 22% were classified as Low Risk (L), 46% as Intermediate Risk (INT), and 33% as High Risk (H). Elevated serum β2-microglobulin levels (>2.4 mg/L) were recorded in 220 patients (64%), being highly correlated with all baseline patient characteristics studied (individual IPI parameters, B-symptoms, haemoglobin, serum albumin; all p values <0.01) with the exception of gender. The frequency of elevated serum β2-microglobulin levels in patients with L, INT and

H R-IPI was 25%, 64% and 90% (p<0.001). The 5-year FFS was 85% vs 70% in patients with normal and elevated serum β2-microglobulin levels (p=0.006). The corresponding 5-year OS rates were 85% vs 79% (p=0.06). A better prognostic discrimination was achieved at the cutoff of 3.5 mg/L: The 5-year FFS was 83% vs 64% in patients with serum β2-microglobulin levels lower or higher than 3.5 mg/L (p=0.0004), with 5-year OS rates of 85% vs 74% (p=0.01). However the prognostic significance of elevated serum β2-microglobulin levels was not retained in multivariate analysis, where it was overcome by R-IPI or its individual components. Conclusions: Approximately 2/3 of patients with DLBCL had elevated serum β2-microglobulin levels, which were highly correlated with all the other baseline adverse features, including IPI and R-IPI. Irrespectively of the cutoff used, the statistically significant effect of serum β2-microglobulin levels on the outcome of DLBCL treated with R-CHOP, which was demonstrated in univariate analysis, was not retained in multivariate analysis. Thus the combination of Rituximab with CHOP appears to overcome the potential adverse prognostic significance of serum β2-microglobulin levels in DLBCL.

0978

LENALIDOMIDE ORAL MONOTHERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY MANTLE-CELL LYMPHOMA: EFFICACY AND SAFETY RESULTS FROM AN INTERNATIONAL STUDY (NHL-003)

P.L. Zinzani,[1] C.B. Reeder,[2] T.E. Witzig,[2] J.M. Vose,[3] R. Buckstein,[4] C. Haioun,[5] R. Bouabdallah,[6] J. Polikoff,[7] D. Pietronigro,[8] M.S. Czuczman[9]

[1]Institute of Hematology and Medical Oncology "L. & A. Seràgnoli", BOLOGNA, Italy; [2]Mayo Clinic, SCOTTSDALE, USA; [3]University of Nebraska, OMAHA, USA; [4]Toronto Sunnybrook Odette Cancer Center, TORONTO, Canada; [5]Hôpital Henri Mondor, CRÉTEIL, France; [6]Institute Paoli-Calmettes Haematology, MARSEILLE, France; [7]Kaiser Permanente Medical Group, SOUTHERN CALIFORNIA, USA; [8]Celgene Corporation, SUMMIT, USA; [9]Roswell Park Cancer Institute, BUFFALO, USA

Background. Mantle cell lymphoma (MCL), which accounts for 5% to 10% of all lymphoid malignancies, is usually characterized by an aggressive course with only short-term remissions after conventional chemotherapy. Historically, the median duration of response ranges between 3 and 4 years indicating a significant unmet therapeutic need to improve patient outcomes. Lenalidomide is an immunomodulatory agent that has demonstrated considerable clinical activity in a variety of hematologic malignancies. A recent sub-analysis of the phase II NHL-002 trial revealed that 15 heavily pretreated patients with advanced MCL achieved an overall response rate (ORR) of 53%, and a median duration of response lasting 13.7 months. A supporting international phase II trial (NHL-003) was initiated to evaluate the clinical utility of single-agent lenalidomide in patients with relapsed or refractory aggressive NHL. Here we present the safety and efficacy results for the MCL subgroup. *Methods*. Key inclusion criteria for patients with relapsed or refractory MCL were ≥1 prior therapy, measurable disease of 2 cm, and an ECOG PS ≤2. The primary endpoint was ORR, and secondary endpoints included duration of response, PFS, and safety. Lenalidomide 25 mg was administered orally once daily on days 1-21 of every 28-day cycle until disease progression or toxicity. Response and progression was measured using the 1999 IWLR Criteria.

Table 1. Response rates with lenalidomide in MCL patients.

Patient sub-group	N	ORR, n (%)	CR/CRu, n (%)	PR, n (%)
MCL	54	**23** (43)	9 (17)	14 (26)
MCL-bortezomib	17	**9** (53)	3 (18)	6 (35)
MCL-stem cell	14	**8** (57)	2 (14)	6 (43)

Results. Fifty-four patients with MCL enrolled on the trial were evaluable for response. Median age for these patients was 69 years (range 33-82), 40 patients (74%) were male, and median time from diagnosis was 3.2 years (range 0.4-10.4). Patients had progressed after a median of 3 prior therapies (range 1-8), which included prior bortezomib for 17 (32%) patients and prior stem cell transplant in 14 (26%) patients. The ORR for the whole MCL cohort was 43%: 9 patients (17%) achieved a complete response (CR) and 14 (26%) achieved a partial response (PR). Responses according to type of prior therapy are summarized in the Table 1. Of the 17 patients who had failed bortezomib, 3 (18%) achieved a CR/CRu and 6 (35%) achieved a PR. Most common grade 3 or 4 adverse events were neutropenia (43%), thrombocytopenia (22%) and anemia (11%). *Conclusions*. Lenalidomide oral monotherapy has demonstrated significant efficacy in treating patients with relapsed or refractory MCL, and has a manageable tolerability profile. These findings are consistent with the previous NHL-002 study, and warrant further investigation of lenalidomide in earlier lines of MCL therapy alone or in combination with other agents.

0979

IMPACT OF TIME-DEPENDENT VARIABLES ON THE OUTCOME OF SPLENIC MARGINAL ZONE LYMPHOMA: A DYNAMIC MODEL ON 84 PATIENTS

S.R. Rattotti,[1] L.A. Arcaini,[2] C.P. Pascutto,[2] F. Passamonti,[2] M. Merli,[2] S. Rizzi,[2] M. Lucioni,[3] E. Boveri,[3] E. Rumi,[2] C. Astori,[2] M. Paulli,[3] M. Lazzarino[2]

[1]Fondazione IRCCS Policlinico San Matteo - Università degli Studi, PAVIA; [2]Fondazione IRCCS Policlinico San Matteo - Division of Hematology, PAVIA; [3]Fondazione IRCCS Policlinico San Matteo - Department of Pathology, PAVIA, Italy

Background. Splenic marginal zone lymphoma (SMZL) is a low grade B-cell lymphoma that represents nearly 2% of lymphoid malignancies. Main manifestations are splenomegaly, lymphocytosis and bone marrow (BM) infiltration. Cytopenias can be present at onset or can develop during the course of disease and are usually a clear indication for treatment. Noteworthy, anemia (defined as hemoglobin level less than 12 g/dL) is one of the 3 parameters included in the SMZL score (Blood 2006). *Aims*. To evaluate the dynamic changes of clinical and laboratory parameters in SMZL and the impact of their modifications on the outcome of disease. *Methods*. From a series of 84 pts with SMZL diagnosed at Division of Hematology of Pavia from 1987 to 2007, we collected clinical and laboratory parameters at onset and at any time during the course of disease. We studied peripheral cytopenias, LDH, β2-microglobulin and serum albumin levels (as categorical respect to normal values and as continuous time-dependent variables), the degree of splenomegaly and BM infiltration (both as continuous variables). Progression-free survival (PFS) was analyzed by univariate and multivariate Cox proportional hazards regression models, with time-dependent covariates. The correlation among clinical and laboratory features was tested with multiple regression model (non-parametric Spearman correlation). *Results*. We studied 84 consecutive pts (38 M, 46 F; median age 62 yrs, range 37-79). Diagnosis of SMZL was established according to WHO classification (2008) and the proposed diagnostic criteria (Leukemia 2008). ECOG PS was 0 in 59%. Twelve pts showed bulky disease. A serum MC was detected in 27 pts (32%). HCV serology was positive in 14 pts (17%). Two pts developed histological shift. 5-years overall survival (OS) was 70% and median PFS was 30 months. In univariate analysis, PFS was influenced at any time during the course of disease by the decrease of hemoglobin (p=0.003) and platelets (p=0.001) and by the increase of LDH levels (p=0.001) and β2-microglobulin levels (p=0.005) (all parameters are predictive as continuous variables). As time-dependent covariates in multivariate Cox model, decrease of platelets (p<0.0001) and raising levels of LDH (p=0.002) are predictive of a shorter PFS. We applied a multiple regression model to evaluate the relationship of cytopenias with other features of SMZL. In this analysis, decrease of platelets is directly related with degree of splenomegaly (p<0.0001), with increase of β2-microglobulin levels (p=0.0001) and reduction of albumin levels (p=0.03). Interestingly, there is no relationship between platelets level and degree of BM infiltration (p=0.1). Levels of hemoglobin and albumin are highly related variables (p=0.0001), but anemia is related neither with splenomegaly (p=0.3) nor with BM infiltration (p=0.1). *Conclusions*. In this dynamic model for SMZL, PFS resulted directly related to time-dependent modifications of lymphoma indexes (LDH, β2-microglobulin) and of hemoglobin and platelets levels. Thrombocytopenia is related to lymphoma mass and its aetiology seems mainly linked to hypersplenism. On the contrary, anemia is not directly caused by hypersplenism or by BM infiltration; its relationship with albumin levels could be explained by a progressive dysregulation of cytokine expression during the course of disease.

RITUXIMAB PLUS CVP (CYCLOPHOSPHAMIDE, VINCRISTINE, AND PREDNISOLONE) COMBINATION CHEMOTHERAPY IN ADVANCED STAGE MARGINAL ZONE B-CELL LYMPHOMA AS A FIRST-LINE THERAPY

B.Y. Ryoo,[1] C. Suh,[2] W.S. Kim,[3] J.S. Kim,[4] J.J. Lee,[5] D.H. Yang,[5] H.J. Kang,[1] S.J. Kim,[3] S.R. Lee,[6] G.W. Lee,[7] H.J. Kim,[8] H.Y. Kim,[8] S.Y. Oh,[9] H. Kim,[10] H.S. Eom,[11] J. Chung,[12] J. Park,[13] Y.M. Park,[13] J.S. Park[10]

[1]Korea Cancer Center Hospital, SEOUL; [2]Asan Medical Center, University of Ulsan College of Medicine, SEOUL; [3]Samsung Medical Center Sungkyunkwan University School of Medicine, SEOUL; [4]Yonsei University College of Medicine, SEOUL; [5]Chonnam National University Hwasun Hospital, JEOLLANAM-DO; [6]Korea University School of Medicine, SEOUL; [7]Gyeongsang National University Hospital School of Medicine, JINJU; [8]Hallym University Sacred Heart Hospital, ANYANG; [9]Dong-A University College of Medicine, BUSAN; [10]Ajou University Hospital, SUWON; [11]National Cancer Center, GOYANG; [12]Pusan National University Hospital, BUSAN; [13]Gachon University Gil Hospital, INCHEON, South-Korea

Background. Although successful results were reported with local treatment or several antibiotics for localized marginal zone B-cell lymphoma (MZBCL), it presents as a disseminated disease in one-third of the cases at diagnosis and relapses involving distant sites after local therapy have been reported. There is no prospective study result for the treatment of advanced stage MZBCL, mainly because of the rarity of this disorder and some difficulties in the differential diagnosis from other low-grade lymphoma subtypes. This is the first clinical trial for advanced MZBCL ever reported. *Aims*. We conducted this multi-center, phase II trial to investigate the efficacy and safety of rituximab plus CVP (R-CVP) combination chemotherapy in patients with previously untreated stage III/IV MZBCL. *Methods*. Patients received rituximab 375mg/m^2 on day1 of each cycle. CVP consisted of cyclophosphamide 750 mg/m^2 and vincristine 1.4 mg/m^2 (maximum 2.0 mg), given intravenously on day 1, and oral prednisolone 100 mg on days 1 - 5. The treatment was repeated every 3 weeks and continued for 6 or 8 cycles until disease progression, withdrawal due to toxicity, or withdrawal of consent. *Results*. Between March 2006 and July 2008, a total of 42 paitents were enrolled with informed consent at this trial from 13 institutes in Korea. Among these patients, 2 patients were dropped out after 1 and 2 cycles of chemotherapy without evaluation. The median age of the evaluated 40 (24 males, 16 females) patients is 56 (range 29-77) years. Thirty patients (75%) had extranodal sites involvement, 17 (43%) of who had 2 or more sites involved. The IPI score were 1 in 10(25%), 2 in 17 (43%), 3 in 11 (27%), and 4 in 2 (5%) patients. The patients received a total of 287 cycles of R-CVP chemotherapy (range 3 - 8 [median 8] cycles/person). There were 24 CR (60%), 11 PR (27.5%), 4 SD (10%), and 1 PD (2.5%), making response rate 87.5% (95% confidence interval, 77.1 - 97.9%). There were 30/287 cycles (10.5%) and 5/287 cycles (1.7%) of grade 3/4 neutropenia and febrile neutropenia, respectively. Non-hematologic toxicities were mild and tolerable. There were 19 cycles (6.6%) of delayed chemotherapy (median 1 week) mainly because of neutropenia (10 cycles) and non-hematologic toxicities (6 cycles). Dose reduction was needed in 9 patients (23 cycles) for cyclophosphamide and in 1 patient (4 cycles) for vincristine. There was toxicity-related hospitalization in 9 patients (22.5%) during treatment. But, there was no treatment-related death. The survival curves will be presented at the conference. *Conclusions*. R-CVP regimen seems rather effective and tolerable in the treatment of advanced stage MZBCL. Longer follow-up period for these patients and other comparative studies are warranted to verify the results of this trial.

0981

MANTLE CELL INTERNATIONAL PROGNOSTIC INDEX (MIPI) AND BIOLOGICAL-MIPI ARE BETTER PREDICTORS OF THE OUTCOME OF MANTLE CELL LYMPHOMA (MCL) PATIENTS THAN IPI: A RETROSPECTIVE ANALYSIS

A. Chiappella,[1] C. Frairia,[1] B. Puccini,[2] B. Botto,[1] L. Arcaini,[3] E. Audisio,[1] I. Baldi,[4] G. Benevolo,[1] C. Boccomini,[1] A. Fabbri,[2] R. Freilone,[1] F. Marmont,[1] L. Orsucci,[1] P. Pregno,[1] L. Rigacci,[2] U. Vitolo[1]

[1]Hematology 2 AOU San Giovanni Battista, TURIN; [2]Hematology, Careggi Hospital, FIRENZE; [3]Division of Hematology, IRCCS Policlinico San Matteo, PAVIA; [4]Unit of Epidemiology, CPO Piemonte, University of Turin, TURIN, Italy

Background. MCL has poor prognosis, with a continuous pattern of relapse and a median Overall Survival (OS) of four years. Clinical MIPI score (including age, performance status, LDH and leukocyte count) seems to be able to give a more reliable estimation of clinical course; cell proliferation (Ki-67) was tested to include a biologic predictive marker in MIPI. *Aims*. To validate MIPI and biological-MIPI on a retrospective group of MCL patients. *Patients and Methods*. Between 1996 and 2008, 102 patients with MCL at diagnosis entered into the study. Clinical characteristics were: median age 62 (37-85) years, 78% stage IV and 17% with blastoid variant. First-line treatments were: high-dose chemoimmunotherapy including Rituximab with autologous stem cell transplantation in 38 patients, Rituximab-Fludarabine based chemotherapy in 18 and Rituximab-CHOP-like in 46. MIPI and biological-MIPI were calculated as published by Hoster 2008. Central pathologist review with Ki-67 evaluation is ongoing. Crude Kaplan-Meier OS and progression-free survival (PFS) curves were estimated both overall and stratified by MIPI, biological-MIPI and IPI score. Differences between curves were tested using the 2-tailed log-rank test. In order to quantify the predictive discrimination of MIPI, biological-MIPI and IPI scores, univariate logistic models (with death and progression event as binary outcomes) were fitted and the area under the receiver operating characteristic (ROC) curves (c-index) was estimated. *Results*. According to MIPI 30 patients (30%) were at low-risk (LR, 0-3), 29 (29%) at intermediate-risk (IR, 4-5), 34 (33%) at high-risk (HR, >5) and 9 missing. Biological-MIPI was calculated on 60 patients with Ki-67 evaluation: 45 patients (75%) were at low-risk (LR, 0-5.699), 6 (10%) at intermediate-risk (IR, 5.7-6.499), 9 (15%) at high-risk (HR, >6.5). According to IPI 29 patients (28%) were at low-risk (LR), 31 (30%) at low-intermediate-risk (LIR), 34 (33%) at intermediate-high and high-risk (IH-HR) and 8 missing. Fifty-two patients achieved a complete-response, 26 a partial-response and 17 did not respond. Failures occurred in 58 patients and 35 of them died, 30 because of lymphoma. With a median follow-up (FU) of 34 months, OS was 69% (95%CI:57%-78%); with a median FU of 28 months, PFS was 61% (95%CI:50%-70%). Thirty-four months OS rates for MIPI were: LR 97%, IR 80%, HR 33% (p<0.00001), for biological-MIPI: LR 89%, IR 75%, HR 26% (p=0.0003) and for IPI: LR 85%, LIR 80%, IH-HR 47% (p=0.0015). Twenty-eight months PFS rates for MIPI were: LR 82%, IR 72%, HR 29% (p<0.00001), for biological-MIPI: LR 82%, IR 28%, HR 22% (p=0.0001) and for IPI: LR 70%, LIR 83%, IH-HR 38% (p=0.0015). MIPI was more predictive than IPI for death event and for failure event: the c-index was 75% and 70% for MIPI, compared to 68% and 65% for IPI respectively. Although assessed on a subsample, biological-MIPI c-index was 71% for death and 67% for failure event. *Conclusions*. in our retrospective series of patients, MIPI and biological-MIPI prognostic scores seem to discriminate among patients with different OS and PFS better than IPI. New therapeutic strategies are warranted to improve the outcome of MCL namely in HR group.

0982

PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE-B-CELL LYMPHOMA TREATED WITH ORAL LENALIDOMIDE MONOTHERAPY: RESULTS FROM THE INTERNATIONAL STUDY NHL-003

C. Haioun,[1] M.S. Czuczman,[2] J.M. Vose,[3] P.L. Zinzani,[4] C.B. Reeder,[5] R. Buckstein,[6] R. Bouabdallah,[7] J. Polikoff,[8] A. Ervin-Haynes,[9] T.E. Witzig[5]

[1]Hôpital Henri Mondor, CRÉTEIL, France; [2]Roswell Park Cancer Institute, BUFFALO, USA; [3]University of Nebraska, OMAHA, USA; [4]Institute of Hematology and Medical Oncology L. & A. Seràgnoli, SERÀGNOLI, Italy; [5]Mayo Clinic, SCOTTSDALE, USA; [6]Toronto Sunnybrook Odette Cancer Center, TORONTO, Canada; [7]Institute Paoli-Calmettes Haematology, MARSEILLE, France; [8]Kaiser Permanente Medical Group, SOUTHERN CALIFORNIA, USA; [9]Celgene Corporation, SUMMIT, USA

Background. Diffuse large-B-cell lymphoma (DLBCL) is the most com-

mon subtype of aggressive lymphoma with considerable biologic and clinical heterogeneity. Despite recent therapeutic advances, up to 50% of patients relapse, and the prognosis remains dismal for those who are not cured with R-CHOP or high-dose chemotherapy with autologous stem cell rescue (SCT). Lenalidomide is an immunomodulatory agent that has demonstrated considerable clinical activity in a variety of hematologic malignancies. In a sub-analysis of a phase II trial (NHL-002) in which 49 patients with relapsed/refractory aggressive NHL received lenalidomide, 26 patients with DLBCL achieved a 19% overall response rate (ORR), and a duration of response lasting a median of 7 months. Here we report on the safety and efficacy results of a subset of patients with DLBCL from the international phase II NHL-003 study, in which patients with relapsed or refractory aggressive NHL who had progressed following ≥1 prior regimen received treatment with single-agent lenalidomide. *Methods*. Oral lenalidomide 25 mg was administered once daily on days 1-21 of every 28-day cycle and continued until disease progression or toxicity. Response and progression was assessed using the 1999 IWLR criteria. *Results*. For the 103 patients with DLBCL who had enrolled and were evaluable for response, the median age was 66 years (21-87), median time from diagnosis was 2 years (0.4-18.6) and 70 patients (68%) of patients were male. Patients had progressed through a median of 3 prior regimens (1-10), and 46 (45%) patients had failed prior SCT. The ORR for the entire patient population was 30% with 7% (7/103) of patients achieving a complete response (CR) and 23% (24/103) of patients a partial response. The ORR was also 30% (14/46) among the 46 patients who had a prior SCT, with 5 patients achieving a CR (11%) and 9 patients a PR (20%). Adverse events were manageable. Most common (>5%) grade 3 or 4 adverse events included neutropenia (34%), thrombocytopenia (18%), asthenia (9%), anemia (8%), leucopenia (7%), back pain (6%) and dyspnea (6%). *Conclusions*. In heavily pretreated patients with relapsed/refractory DLBCL lenalidomide has demonstrated significant clinical activity and a manageable safety profile. Further investigation is warranted to better assess a role for lenalidomide in the treatment of patients with DLBCL.

0983

SURVIVAL IMPACT OF RITUXIMAB COMBINED TO ACVBP (R-ACVBP) IN 209 POOR RISK DLBCL NHL PATIENTS TREATED WITH UPFRONT HIGH-DOSE CONSOLIDATIVE AUTOTRANSPLANTATION (HDC): A GELA PHASE II STUDY

O. Fitoussi,[1] N. Mounier,[2] K. Belhadj,[3] H. Tilly,[4] C. Haioun,[5] O. Casasnovas,[6] C. Ferme,[7] J. Briere,[8] B. Coiffier,[9] P. Feugier,[10] C. Gisselbrecht[11]

[1]Polyclinique Bordeaux Nord Aquitaine, BORDEAUX; [2]CHU Nice, NICE; [3]Service d'Hématologie Clinique,Henri Mondor, CRÉTEIL; [4]Centre Henri Becquerel, ROUEN; [5]Service d'Hématologie Clinique,Hôpital Henri Mondor, CRÉTEIL; [6]CHU Dijon, DIJON; [7]Dept. of Medicine,Institut Gustave Roussy, VILLEJUIF; [8]Service d'Onco-Hématologie,Hôpital Saint-Louis APHP,INSERM U728, PARIS; [9]Service d'Hématologie,Hôpital Lyon Sud,Hospices Civils de Lyon, PIERRE BÉNITE; [10]CHU de Nancy,Hôpital Bradois, VANDOEUVRE LES NANCY; [11]Dept. of Hématology,St Louis Hospital, PARIS, France

Rituximab (R) combined with CHOP improves complete remission (CR) rate and overall survival (OS) in DLBCL patients (pts). More intensive regimen followed by auto transplantation have been used in pts < 60y with 2-3 adverse age-adjusted International-Prognostic-Index (aa-IPI) factors, providing a 5y OS of 65% (CI 60-68%), (Haioun LNH 98-3B, ASCO 2007). The objective of the present study was to assess whether or not combining R (375 mg/m^2) to the dose intense ACVBP (Doxorubicin 75 mg/m^2 d1, Cyclophosphamide 1.200 mg/m^2 d1, Vindesine 2 mg/m^2 and Bleomycin 10 mg d1 and d5, prednisone 60 mg/m^2 d1-d5) also translates into a survival benefit. *Methods*. From 01/2004 to 12/2005, 209 DLCBL pts < 60y with DLBCL and aaIPI 2 or 3 received 4 cycles of R-ACVBP every 15 days supported by G-CSF. Responding patients received a consolidative BEAM and peripheral blood stem cell rescue. Median age was 49 years (range: 18-60), 22% of patients presented with aa-IPI 3, 58% with IPI 3-5 (93% with elevated LDH and 54% with extranodal sites >1). Based on International W Criteria, CR + CRu rate after induction was 61%, PR rate 24% leading to an overall response rate of 84% (176 pts). Deaths occurred in 4% of the pts during R-ACVBP procedure and collection failure was observed in 18 pts (10%). 155 pts received auto transplantation, representing 75% of the study population. A case-controlled study was performed by matching the present R-ACVBP population with ACVBP patients selected from the LNH-98-3 trial. Patients were fully matched (1:1) on histology, aa-IPI score, gender, age and follow-up duration. *Results*. With a median follow-up of 27 months, according to the updated IWC 2007, 3y PFS and OS were estimated at 76% (CI 69-81%) and 81% (CI 75-86%), respectively. There was no significant difference between pts in CR or PR before transplant. 3y PFS was higher in R-ACVBP than in ACVBP patients: 75% (CI 67-81%) vs 58% (CI 50-65%), p=0.0003. 3y OS were estimated at 78% (CI 71-84%) vs 67% (CI 58-74%), p=0.05. The gain in 3y OS was significant in patients who received auto transplantation: 89% (CI 81-93%) vs 77% (CI 67-84%), p=0.02. *Conclusions*. These results with R-ACVBP induction and consolidative auto-transplantation suggest a major survival benefit with an increase remission rate after HDC according the criteria used. An impressive PFS of 76% and OS 81% were observed even with 3 adverse factors. Comparison with previous study without R in induction suggests a major improvement which needs confirmatory prospective study.

0984

CEREBROSPINAL FLUID FLOW CYTOMETRY ANALYSIS IN NEWLY DIAGNOSED AGGRESSIVE NON-HODGKIN LYMPHOMAS AT HIGH RISK FOR LEPTOMENINGEAL DISEASE: A MULTICENTRIC PROSPECTIVE ITALIAN STUDY

G. Benevolo,[1] P. Pioltelli,[2] B. Botto,[2] A. Stacchini,[2] A. Evangelista,[2] M. Spina,[2] F. Mannelli,[2] M. Cantonetti,[2] A. Di Rocco,[2] D. Pietrasanta,[2] V. Pavone,[2] N. Di Renzo,[2] A. Ferreri,[2] M.G. Cabras,[2] U. Vitolo,[2] E. Pogliani[2]

[1]Hematology 2, TURIN; [2]On the behalf of Intergruppo Italiano Linfomi, Hematology 2 ASO San G. Battista, TURIN, Italy

Background. Leptomeningeal disease (LD) is an infrequent but nearly always fatal complication occurring in patients with NHL. The diagnostic standard conventional cytologic examination (CC) of cerebrospinal fluid (CSF), is considered with low sensitivity and low specificity. Recently, studies demonstrated that flow cytometry (FCM) assessment of CSF could increase the proportion of positive cases detected with LD in comparison to CC. It's still unknown if detecting occult LD and consequently changeling prophylactic therapy may improve the outcome in these patients. *Aims*. The aim of this study was to compare CC vs FCM in a large cohort of patients with newly diagnosed aggressive NHL at high risk for LD. We also assessed the impact of detecting occult LD with FCM on progression-free survival (PFS). *Methods*. Patients considered at high risk for LD included: diffuse large B-cell lymphoma (DLBCL) with IPI 2-3, elevated LDH along with at least two extranodal sites or with bone marrow or testis or palate or socket involvement; Burkitt lymphoma (BL); blastoid variant of mantle cell lymphoma (B-MCL); B-cell precursor lymphoblastic lymphoma (B-LL); HIV+ patients. All patients, with no evidence or signs of neurological disease, received intrathecal standard prophylactic therapy. Both FCM and CC were performed and the incidence of positive test for occult LD was compared using the McNemar test for paired data. PFS was defined as the time from diagnosis to any type of progression or death from any cause and compared by the log-rank test. *Results*. From August 2004 to June 2008, 118 patients were enrolled by 10 centres. Clinical characteristics were: 78 males and 40 females, median age 55 years (IQR:43-63); 88 patients (74,6%) with DLBCL, 18 pts (15.2%) with BL, 8 pts (6.7%) with B-MCL and 4 pts (3.4%) with B-LL. Eighteen patients (15.3%) were HIV positive. FCM was able to detect a clonal population in 16 out of 118 patients (13.6%) whereas CC detected abnormal cells only among 7 pts (6%)(p= 0.0002, McNemar's $\chi 2$). Therefore, 9 patients (7.6%) were discordant: FCM positive/CC negative. From date of diagnosis, overall median follow up of survivors was 11 months (IQR:5-18). We observed 22(18.6%) systemic progressions, 5(4.2%) CNS progressions and 19(16.1%) deaths (17 PD, 2 infections). PFS at 6 months was 94% (95%CI:86-97) in pts both negative in FCM and CC, 57% (95%CI:17-84) in pts both positive, 83% (95%CI:27-97) in pts discordant (p=0.0029, log-rank test). *Conclusions*. FCM assessment of CSF in pts with aggressive NHL at risk of LD seems to have an higher sensitivity than CC but, in absence of a gold standard, it's non yet clear what is the clinical relevance of a positive FCM. Our preliminary data suggest that patients both positive for FCM and CC have an higher risk of progression compared with those both negative, whereas discordant cases seem to have an intermediate prognosis. However a longer follow up is needed to further validate these results.

0985

EFFICACY AND SAFETY OF LOW-INTENSITY ORAL AND INTRAVENOUS FLUDARABINE-CYCLOPHOSPHAMYDE WITH AND WITHOUT RITUXIMAB FOR FIRST-LINE TREATMENT OF FOLLICULAR LYMPHOMA

A. Marin-Niebla, E. Rios-Herranz, J.F. Falantes Gonzalez, P. Cerezuela, M.L. Martino Galiana, R. Parody Ruiz-Berdejo, A. Urbano-Ispizua

Hospital Universitario Virgen del Rocio, SEVILLE, Spain

Background. Fludarabine-Cyclophosphamyde (FC) is a potent regimen for untreated and relapsed follicular lymphoma (FL). However, myelosuppression limits its use at standard doses. Oral F appears as effective as intravenously, lowering hospital expenses and favouring compliance. The association of Rituximab (R) with FC improves ORR/OS and PFS in induction, maintenance and salvage regimens, without adding relevant toxicity. *Aims*. 1) To evaluate efficacy and safety of a lower intensity FC ± R in first-line for FL. 2) To assess whether oral administration improves the toxicity profile while maintaining the efficacy. *Methods*. Follicular lymphoma (WHO histological grades 1-2) patients (pts) aged ≥18, previously untreated, WHO-PS≤≤2, ≤2-fold renal and hepatic function values were eligible. *Outpatient treatment*. Intravenous FC and FCR (iv): Fludarabine (F) 25 mg/m^2/d plus Cyclophosphamyde (C) 250 mg/m^2/d (d 1-3), Rituximab (R) 375 mg/m^2 (d1) x 4 28-day cycles; Oral FCR (po): F 30 mg/m^2/d plus C 175 mg/m^2/d (d 1-3), R 375 mg/m^2/ (d1) x 4-6 28-day cycles; R maintenance (advanced stage achieving CR): R 375 mg/m^2 q/3 months x 8 doses. *Results*. From March'99 to January'09, 81 pts were prospectively included: M age: 56 (32-81), M:F 40:41, Stages III-IV: 85.3%, B-symptoms: 28.4%, FLIPI≥2: 81%. Seven (8.6%) pts received FC iv; 28 (34.5%) FCR iv; 46 (56.8%) FCR po. M cycles: 4 (1-4) FC/FCRiv; 5 (3-6) FCRpo. MFU: 29 m (1-116). Seventy-five pts were evaluable for response: ORR rates FCRiv versus FCRpo: 89% vs 97.6% (p<0001). CR/PR rates FCRiv versus FCRpo: 59.3%/29.6% vs 87.8%/9.8% (p<0001). Regarding toxicity, neutropenia was the most limiting AE: 25 neutropenia 3-4 episodes: 15 (55.5%) and 8 (17.4%) in FCRiv and FCRpo respectively (p<0001); grade 3-4 infection rate: 13 (46.4%) and 7 (15.2%) in FCRiv and FCRpo, respectively (p<0001), causing death in 2/28 FCRiv pts. Grade 3-4 thrombocytopenia occurred in 3 FCRiv and 2 FCRpo pts, anemia 3-4 in 2 FCRiv and 1 FCRpo, and 1 case of liver toxicity (FCRiv). Forty pts received R-Maintenance: FCRiv: 20/27 (74%), FCRpo: 20/46. Withdrawal of R-maintenance due to neutropenia and infections: 9 (45%) FCRiv and 3 (15%) FCRpo. Three pts relapsed with a M TTP: 12 m (9-14); and 3 pts died (2 infections, 1 progression). With a MFU: 29 m (1-116), overall survival (OS) was 94.6% (IC al 95%: 88,5 to 100%), and event-free survival (EFS) was 90%, with no significant differences between oral and iv FCR Transformation to aggressive NHL occurred in 2 pts, no cases of myelodysplasia. *Conclusions*. 1) Low-dose FCR is a potent first-line and safe regimen for FL (including pts> 65 yo), with very high ORR and CR rate. 2) The oral low-dose FCR regimen significantly decreases myelosuppression, while achieving a high ORR and CR rates, equivalent to those of FCR iv.

0986

A NEW SHORT-TERM HIGH INTENSIVE PROTOCOL BL-M-04 FOR ADULT PATIENTS WITH BURKITT LYMPHOMA: EFFICACY AND TOXICITY

E. Baryakh, E. Zvonkov, S. Kravchenko, A. Kremenetskaja, A. Magomedova, T. Obukhova, A. Vorobjov

National Hematology Research Center, MOSCOW, Russian Federation

Background. Burkitt lymphoma (BL) is the most aggressive B-cell lymphoid neoplasm, whose growth fraction approximates 100%, with specific chromosomal abnormalities [t(8;14)(q24;q32), rarely - t(2;8)(p12;q32), t(8;22)(q24;q11)]. Despite the rapid proliferative rate, BL is one of the most chemosensitive lymphoid neoplasm.Though it was clear, that high intensive short-term alternating multiagent chemotherapy regimens are most effective in patients with BL, adults have a less favorable outcome than pediatric patients with BL. *Aims*. to evaluate the efficacy and toxicity of the protocol BL-M-04 for adult patients with BL. *Methods*. 37 previously untreated patients with BL were eligible for our study (they had specific translocations involving chromosome 8 [t(8;14)(q24;q32), t(2;8)(p12;q32), and t(8;22)(q24;q11)]. All the patients (23 males and 14 females, mean age 29 years (from 15 to 69 years)) participated in the study performed in the Russian Hematological Research Center between August 2003 and December 2008. The treatment was based on experimental high intensive protocol BL-M-04. BL staging criteria developed by S. B. Murphy were used to stage the patients. Stage I, II, III, IV were diagnosed in 2, 3, 15, 6 patients respectively. B-acute lymphoblastic leukemia (L3) was diagnosed in 11 (30%) patients. B-symptoms (night sweets, fever and weight loss) were present in 30 (81%) patients. Serum lactate dehydrogenase level (LDH) was increased in 30 (81%) patients. Acute renal failure was found in 14 patients: specific renal involvement in 6 patients, ureteral obstruction with postrenal azotemia in 2 patients, and tumor lysis syndrome with uric acid nephropathy in 6 patients. Hemodialysis was used in 5 patients, and urgent nephrostomy in 1 patient. Acute renal failure regressed due to the institution of chemotherapy and intensive care in 8 patients. The main aim of the new treatment regimen was greater efficacy of therapy due to intensification and shorter treatment duration. The new treatment protocol is based on the modified NHL-BFM protocol for high risk patients with a reduced dose of methotrexate from 5000 mg/m^2 to 1500 mg/m^2. As BL, is a chemosensitive tumor that often regresses after 1-2 courses of chemotherapy, we decided to treat patients with BL in 4 courses of chemotherapy (2 induction and 2 consolidation) irrespective of the initial tumor mass. As BL is most sensitive to high dose methotrexate and cytarabine, we used these drugs in the induction phase to achieve to maximize the cytoreductive effect. Courses A and C were used to achieve remission. Doxorubicin was added to course A, and methotrexate to course C. Consolidation courses were similar to induction courses. Hence, we used A and C courses (without course B), intensified with course B drugs (doxorubicin and methotrexate), the interval between the courses being 21 days. *Results*. 34 patients (90%) achieved a complete remission (CR) after 1-2 courses (16 patients - after the 1st course, 18 - after the 2d). 33 are alive in the first CR during 32 months (median 2-62 months). Four patients died. The cause of death in three patietns were chemotherapy related complication. One patient died due to early relapse. The 5-year disease-free survival was 97% with an overall survival of 89%. BL-M-04 therapy resulted in higher CR rates and longer disease-free survival in adult patients with BL and confirmed high efficacy of short-term intensive therapy. Treatment duration was 3-3,5 months. Grade III-IV neutropenia occurred after all courses. Most infectious and hemorrhagic complications occured during the first course (course A), which can be explained by the initial poor condition of the patients. Unfavorable prognostic factors, which increase the number of chemotherapy complications, were stage IV/B-ALL, acute renal failure, and failure of previous treatment (surgery and chemotherapy). *Summary and Conclusions*. BL-M-04 is a highly effective protocol. The 5-year disease-free survival was 97% with 5-year overall survival of 88%. The use of this protocol can achieve rapid tumor regression with a short treatment duration due to chemotherapy intensification and acceptable toxicity. As the majority of relapses occur after 8-12 months of treatment, most of these patients can be considered cured.

Background. Patients with chronic lymphoproliferative disorders (CLD) frequently associate infections with B, C, or D hepatitis viruses, which can also infect and replicate in hematopoietic cells. *Aims*. Analysis of hepatitis viral infection's influence on clinical and biological evolution of CLD - data from patients diagnosed and monitored between December 2007-January 2009; preliminary data of an ongoing multidisciplinary study. *Methods*. Retrospective and prospective study of patients with CLD and hepatitis viral infection. The diagnosis of the CLD was established on lymph node/bone marrow biopsy completed by immunophenotyping analysis, according to WHO classification. All patients had positive serological tests for at least one hepatitis virus; quantitative viremia was determined, by TaqMan PCR method. *Results*. Group of 41 patients: 25 females (60.97%), 16 males (39.02%); median age - 64 years old (min30, max85), with 56.09% between 51-70 years old. B-cell lym-

phoma was found in 28/41 (68.29%) patients: 13/28 (46.42%) - diffuse large B-cell lymphoma, 11/28 (39.28%) - small B-cell lymphoma (marginal/lymphocytic type), 3/28 (10.71%) - follicular lymphoma, 1/28 (3.57%) - lymphoblastic lymphoma. 13/41 patients (31.71%) had: T-cell CLD (2/41), Hodgkin's disease (2/41), CLL (7/41) and Waldenström macroglobulinemia (2/41). Indolent types of CLD were found in 22/41 (53.65%), and aggressive types in 46.35%. HCV was the most frequent virus (24/41-58.53%) and HBV - the second: 14/41 (34.14%); 3 patients presented double/triple viral infection. We observed the association between HBV infection and aggressive histological types (9/14-64.28%), and between HCV and indolent types (15/24-62.50%). Clinical examination revealed adenopathies in 29/41patients (70.73%), hepatomegaly in 38/41 (92.68%) and splenomegaly in 21/41 (51.21%); splenomegaly was found mostly in patients with HCV (12/21-57.14%); 3/41 (7.31%) had diagnostic or therapeutic splenectomy. Extranodal disease was found in 10/41patients (24.39%), especially in patients with indolent CLD and HCV infection. Anemia was present in 9/41 patients (21.95%); autoimmune hemolytic anemia (AIHA) was associated in 4/41 cases (9.75%), all with HCV infection. Thrombocytopenia was revealed in 13/41 (31/70%), mainly associated with HBV infection. The majority of the patients had lymphocytosis (33/41-80.48%), particularly the ones with HCV infection and indolent types of CLD. Serum cryoglobulins were found in 8/41 (19.51%), all with HCV infection. Increased ALT level occurred in 32/41 (78.04%); increased GGT level - 20/41 cases (48.78%); hepatic cytolysis associated predominantly with indolent types of CLD, with HCV infection. Serum LDH level (monitored as prognostic marker), was increased in 17/41 patients (41.46%); of these, 52.94% associated HCV infection. Chemotherapy was given in 32/41 patients with CLD (78%), as monotherapy (5/41 - 13.19%) or combined chemotherapy/chemoimmunotherapy (27/41 - 65.85%); 6/41 patients (14.63%) received interferon and 6/41 (14.63%) - rituximab; antiviral therapy (lamivudin/ribavirin±interferon) was administered in 12/41 patients (29.26%). *Conclusions*. The analysis showed a higher incidence of CLD with hepatitis viral infection in women over 50 years old, with a predominance of HCV infection, which was particularly linked to: indolent CLD subtypes, extranodal disease, splenomegaly, AIHA and cryoglobulinemia, lymphocytosis, liver dysfunction, and high LDH level. The study will further determine how the antiviral and chemotherapy will influence the studied parameters and the clinical and biological outcome of these patients.

Non-Hodgkin lymphoma - Clinical IV

METHOTREXATE RELATED LYMPHOPROLIFERATIVE DISORDER -EXPERIENCE OF A DISTRICT GENERAL HOSPITAL IN THE UK

S. Gupta

Pincess Royal University Hospital, KENT, UK

Patients with Rheumatoid arthritis are estimated to have 2-20- fold increased risk of lymphoproliferative disorder (LPD) in the absence of Methotrexate (MTX) therapy. It remains debated whether MTX per se increases the risk of LPD development. Aim of this study was to evaluate the patient and disease characteristic of LPD in patients of rheumatoid arthritis (RA) who were treated with MTX. The catchments population of this small district general hospital is 300,000. We observed 6 patients of RA treated with MTX who developed LPD. Only one patient was male and the rest were females as RA is more common in females. Mean age was 63 years (range 51-79 years). Mean duration of RA was 13 years while the mean duration of MTX treatment was 7.5 years. Most common type of LPD was diffuse large B cell lymphoma (3) with one each of marginal zone lymphoma, lymphoplasmacytic lymphoma and follicular lymphoma. 4 patients presented with advanced stage disease (>stage II) while one patient had stage IA and the other was limited extranodal disease. EBV stain was positive only in one patient. MTX was withdrawn in all 6 patients after lymphoma diagnosis. 3 patients put on watch and wait approach with continued complete remission in two. Rest of the patient received chemotherapy ranging from rituximab only to high dose combination chemotherapy. All 6 patients are currently in complete remission with mean duration of 16 months post chemotherapy. Our findings were quite consistent with the literature. MTX related LPD is seen generally in older age group with female preponderance as compared to sporadic cases of LPD. EBV positivity is not a consistent finding. MTX withdrawal is effective in small proportion of patient but these patients should have close follow-up. Interesting findings could emerge if patients of RA and LPD with and without MTX are compared with sporadic cases of LPD.

0989

CHLORAMBUCIL WITH OR WITHOUT RITUXIMAB IS AN EFFECTIVE THERAPY IN NON-GASTRIC MALT LYMPHOMAS

C. Kalpadakis,[1] G.A. Pangalis,[2] T.P. Vassilakopoulos,[2] M.C. Kyrtsonis,[2] S. Sachanas,[2] M.P. Siakantaris,[2] F.N. Kontopidou,[2] E.M. Dimitriadou,[2] X. Yiakoumis,[2] P. Korkolopoulou,[2] P. Panayiotidis,[2] H. Papadaki,[1] M.K. Angelopoulou[2]

[1]Department of Haematology, University of Crete, ATHENS; [2]Department of Haematology, University of Athens, ATHENS, Greece

Background. MALT lymphomas are characterized by an indolent clinical course and prolonged survival. Therapy is not standardized. Chlorambucil and rituximab have been shown to be effective. However data is limited regarding the efficacy of their combination. *Aims.* The objective of this retrospective study was to compare the outcome of patients with non-gastric MALT lymphoma who received first line treatment with chlorambucil or rituximab plus chlorambucil. *Patients and Methods.* Patients with a primary non-gastric MALT site of involvement followed in our Departments between 1985 and 2007 were included in the study. Chlorambucil was given at a dose of 10 mg/d for 10d/mo for a total of 12 mos. Combined therapy included rituximab at a dose of 375mg/m^2 every mo for 8 mos plus chlorambucil at the same dose and duration as in the monotherapy schedule. *Results*. 44 of 78 patients who were registered in the database with a diagnosis of non-gastric MALT lymphoma (15 salivary glands, 10 lung, 7 ocular adnexae, 7 intestine, 3 Waldeyer ring, 1 skin, 1 bladder) were included in the present study. 24 received chlorambucil alone and 20 combined treatment. The main clinical characteristics of the two groups are shown on Table 1. Therapy was well tolerated in both groups. Complete remission was achieved in 77% with an overall response rate of 84%. Rituximab plus chlorambucil treatment was superior to chlorambucil in terms of overall and complete response rates (95% vs 79% and 90% vs 75%), without however this difference to be significant (p=0.28). Moreover, no differences were observed in the 5-year FFS and OS between chlorambucil alone and combined treatment (68% vs. 52% and 90% vs 100% respectively). The median follow up of living patients in the chlorambucil arm was 74 months (9-224) vs 21 months (6-97). *Summary and Conclusions.* In this retrospective study the outcome of non-gastric MALT lymphomas was excellent either fol-

lowing chlorambucil or chlorambucil plus rituximab. However imbalances of patients in favor of chlorambucil alone may have an impact on these results. Further studies are needed in order to evaluate the role of rituximab in the treatment of MALT lymphomas.

Table 1. Characteristics of non-gastric MALT lymphoma pts.

Parameter	Chlorambucil 24 pts # (%)	R-Chlorambucil 20 pts # (%)	*p value*
Age >60 years	6 (25)	10 (50)	0.09
Male gender	7 (29)	12 (60)	0.04
Stage IV	7 (29)	10 (50)	0.16

REVIEW OF THE USE OF GDCVP (GEMCITABINE, DACARBAZINE, CYCLOPHOSPHAMIDE, VINCRISTINE AND PREDNISOLONE) COMBINATION CHEMOTHERAPY IN RELAPSED/ REFRACTORY LYMPHOMA IN A LARGE UK HAEMATOLOGY AND BONE MARROW TRANSPLANT CENTRE

S. Choudhuri, R. Griffiths, J. Radford

NHS, MANCHESTER, UK

Introduction. Despite advances in the treatment of Hodgkin's (HL) and Non-Hodgkin's lymphoma (NHL), approximately 50% patients relapse or are refractory to first line chemotherapy. Currently no consensus exists regarding optimal salvage drug regimen. Gemcitabine, a novel nucleoside analogue, has *in vitro*, ability to circumvent MDR secondary to increased P glycoprotein and MDR protein 1 over expression. *Methodology*. We aimed to study the effects of GDCVP combination chemotherapy in these patients. Case notes and computerised data base of patients receiving GDCVP from June 2004 to June 2007 were retrospectively analysed. *Results*. 47 patients (Median age 48 years; 66% male; median Karnofsky score 70; median previous relapses 2; progressive disease documented in all) received GDCVP. Indications comprised Transformed Follicular Lymphoma 9% (4/47), Follicular Lymphoma 4% (2/47), HL 51% (24/47), T NHL 4% (2/47), DLBCL 26% (12/47) and Anaplastic 6% (3/47). 35 (74%) patients had Stage 3B and above disease; 25 (53%) had extra nodal involvement and 35 (75%) exhibited B symptoms. GDCVP (total number of cycles 198; median 4) was used as 1st, 2nd, 3rd and 4th line treatment in 32%, 49%, 15% and 4% patients respectively. Percentage of planned dose delivered was 67%, 66%, 67% and 56% for Gemcitabine, Dacarbazine, Cyclophosphamide and Vincristine respectively. 6 (13%) patients underwent previous stem cell autograft; 16 (34%) received Rituximab, 17 (36%) received Platinum whilst 20 (43%) had radiotherapy. Disease nature prior to GDCVP use was chemosensitive 35 (74%); chemoresistant 12 (26%) of which 10 were Primary Progressive. Myelosuppression was moderate (Grade 3 or 4 anaemia, neutropenia and thrombocytopenia was 12, 63.0 and 48% respectively). Other side effects included nausea 60% (grade 2 -39%), vomiting 26% (grade 2 - 25%), stomatitis 17%, diarrhoea17% (grade2-13%), constipation 11%, alopecia 45%(grade2-24%), sensory loss 13% and infection 32% (grade 2,3 and 4 -73%,13%,13% respectively). Table 1 depicts data on required dose reduction. Dosing was delayed in 4 (9%); GI side effects (2) and severe infection (2) and prematurely stopped in 20(43%) after 1, 2 and 3 cycles in 4, 5 and 11 patients respectively due to progressive disease (17/20) and intolerable side effects(3/20). 39 (83%) patients required G-CSF (Neulasta) prophylaxis (9/39 primary, 30/39 secondary). The overall response rate was 51% - complete 4/47 (8.5%), partial 20/47 (42.5%), stable disease 4 /47 (8.5%) and progressive disease 19/47 (40.4%).Stem cell harvesting occurred in 14 (30%) with median CD34 cell count of 2.3×10^6/kg. 9 (19%) underwent stem cell transplant. 22 (47%) patients died by review completion. Median overall survival was 13.3 months (Kaplan-Meir; 95% CI 14.14 - 1.86) and median progression free survival was 12 months (Kaplan-Meir; 95% CI 16.39 - 7.62). *Conclusions*. GDCVP combination chemotherapy is safe, well tolerated and efficacious in relapsed/refractory lymphoma adding to the evidence underlining the efficacy and minimal toxicity of Gemcitabine based regimens. Importantly it does not interfere with stem cell harvesting and may be of use when patients are unsuitable for or have received prior platinum. We recommend detailed prospective studies to further define the role of GDCVP combination chemotherapy in this setting.

Table 1.

Scheduled dose (G-1g/m2,D-500mg/m2,C-750mg/m2,V-1.4mg/m2,IV,P-40mg/m2 PO) Dose reduction	Reason

VALUE OF 18F-FDG PET/CT FOR THE STAGING OF NON-HODGKIN'S LYMPHOMA: SIGNIFICANT IMPROVEMENT IN THE DETECTION OF NODAL AND EXTRANODAL LESIONS BUT MARGINAL IMPACT ON DISEASE STAGE

T. Papajik,[1] M. Myslivecek,[2] V. Prochazka,[2] H. Mocikova,[3] M. Skopalova,[4] V. Koza,[3] A. Malan,[3] E. Buriankova,[2] K. Chroust,[5] K. Indrak,[2] M. Trneny[3]

[1]University Hospital, OLOMOUC; [2]Palacky University Hospital, OLOMOUC; [3]Charles University Hospital, PRAGUE; [4]Homolka Hospital PET Center, PRAGUE; [5]Masaryk University, BRNO, Czech Republic

Background. An accurate disease staging of patients with non-Hodgkin's lymphoma (NHL) has a fundamental impact on their optimal management and prognosis. 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) combined with computed tomography (CT) is a promising imaging technique that combines metabolic and morphologic data and may markedly enhance detection accuracy in NHL. *Aims*. The aim of this prospective study was to compare PET, CT and PET/CT findings in patients with newly diagnosed untreated NHL, analyze frequency of discrepant images and assess the direct impact of PET/CT on disease stage. *Methods*. 118 patients with biopsy-proven NHL were included in this study (53 DLBCL, 22 FL, 13 T-NHL, 11 MCL, 8 MZL, 3 SLL, 3 LBL, 5 B-cell NHL NS). Whole-body PET/CT was performed in each patient. The PET and CT images were independently evaluated by a nuclear medicine physician and a radiologist who then interpreted the PET/CT images in consensus. A total of 9516 anatomic sites on PET, CT and PET/CT scans were reviewed. For each patient, the true clinical Ann Arbor stage was finally determined by hemato-oncologist with knowledge of histopathologic, laboratory, PET/CT and clinical data. *Results*. Only 1 SLL patient was classified as completely PET-negative (18F-FDG non-avid) case. In 21 patients (18%) PET-negative abnormal lymphadenomegaly according CT criteria was revealed and 15 patients (13%) had PET-positive normal sized lymph node on CT scans. On the other hand, 29 patients (25%) had PET-negative organomegaly and in 22 patients (19%) PET-positive lesion in normal sized extranodal organ was detected. Taken together, PET revealed 87 clinically important changes in 73 patients (62%) in direct comparison with CT. However, PET/CT scans changed Ann Arbor stage only in 13 patients (11%). Using PET/CT results, the disease stage was decreased in 7 patients and increased in 6 patients. *Conclusions*. 18F-FDG PET/CT markedly improves accuracy in initial diagnostic work-up of NHL patients. 18F-FDG PET is superior in the detection of nodal and extranodal lymphoma involvement compared

with CT, but has only limited impact on disease stage. 18F-FDG PET/CT scans may better characterize pathological lesions in patients with NHL.

FRONT-LINE AUTOLOGOUS PURGED TRANSPLANTATION IN INDOLENT NON-HODGKIN'S LYMPHOMAS: A LONG-TERM FOLLOW-UP STUDY

M.T. Hernandez,[1] B.J. González,[1] P. Machado,[1] M. Tapia,[2] M.J. Rodríguez-Salazar,[1] G. González-Brito,[1] R.F. Rodríguez,[1] J.V. Govantes,[2] L. Morabito,[1] J.M. Raya,[1] S. Lakhwani,[1] T. Martín,[1] I. Gómez,[1] M. Fernández,[1] L. Hernández-Nieto[1]

[1]Hospital Universitario de Canarias, LA LAGUNA. S/C DE TENERIFE; [2]Hospital General de La Palma, SANTA CRUZ DE LA PALMA. S/C DE TENERIFE, Spain

Background. Indolent lymphoid neoplasms have a long survival. However, in advanced stages are commonly incurables with conventional chemotherapy. We present our experience with a up-front intensive treatment program which includes chemotherapy until maximum response followed by double-purged autologous hematopoietic stem cell transplantation (HSCT) at a single center. *Methods.* Forty patients with indolent lymphomas were enrolled between 1996 and 2006. The inclusion criteria were (with some minor exception in age): III-IV stages, 18-60 years old, indolent lymphoid neoplasms according to the NCI (PDQ) modification of the WHO classification, adequate hematologic, renal, and hepatic function and informed consent. We followed the principle of maximum response with the induction chemotherapy and the last 14 patients also received rituximab. All patients received an autologous HSCT, 28 cases received a purged product with double immunoselection and 7 cases with only positive immunoselection ($CD34^+$). The conditioning regimen was TBI + an alkylator or BEAM according a predefined procedure. *Results*. Complete response (CR) rate was 30.77% after first line induction chemotherapy, 82.5% before HSCT (after maximum response treatment), and 92.5% after HSCT. Three patients achieved a good partial response (PR) after HSCT, all these patients achieved a CR after a complementary treatment (radiotherapy with or without rituximab), for that the final CR was 100%. With a median followup of 6.5 years the projected overall survival (SV) at 12.5 years was 80% and the projected disease free survival (DFS) at 11 years was 72%. With the univariate analysis (log-rank test) patients with less than 58 years old (p=0.004), follicular lymphoma (vs other indolent lymphomas) (p=0.005), normal range LDH (p=0.045) and those that achieved RC at the time of harvest (p=0.008) or at the time HSCT (p=0.023), showed a significant better DFS. It highlights a projected DFS at 11 years of 88% and an evident plateau after 2 years. Using multivariate Cox regression analysis only the follicular type of lymphoma (OR 9.512; p=0.023) and age less than 58 years old (OR 8.835; p=0.043) remained as independent predictors of superior DFS. At the time of analysis 7 patients have died, 4 (10%) of deaths were transplant related (TRM), of those 1 (2.5%) died before day +100 and 2 (5%) died in the first year. The infections were frequent complications and the cause of TRM. The most frequent infection was herpes zoster. Three secondary malignancies were observed: 1 case of secondary MDS/AML, 1 case of gastric stroma tumor and 1 case of metastatic bladder cancer. *Conclusions.* With this approach a long overall survival and DFS were achieved. A plateau seems showed in both survival curves. This is specially apparent in follicular lymphomas, whereas in other indolent lymphomas it is not so evident.

FRONT-LINE RISK-ADAPTED IMMUNOCHEMOTHERAPY IMPROVES OUTCOME IN INTERMEDIATE/HIGH-RISK PATIENTS WITH FOLLICULAR LYMPHOMA

V. Prochazka, T. Papajik, Z. Kubova, S. Rozmanova, M. Jarosova, K. Indrak

Teaching Hospital in Olomouc, OLOMOUC, Czech Republic

Background. The Follicular Lymphoma International Prognostic Index (FLIPI) is a valuable prognostic tool for risk stratification, but its prognostic power was postulated from retrospective data in the pre-rituximab era. Front-line prognostic stratification of treatment intensity may improve outcome, especially of high-risk patients with follicular lymphoma (FL). *Aims*. To assess whether risk-adapted immunochemotherapy overcomes the negative prognostic impact of the FLIPI score in newly diagnosed patients with FL. *Methods*. The prospective study comprised 137 patients with newly diagnosed FL (grades I-IIIa) who fulfilled the GELF criteria. The median age was 53 years (31-84), 84.7% of the patients had advanced (III/IV) clinical stages, 55% had bulky (>7 cm) disease. The FLIPI scores were as follows: low 33.3%, intermediate 31%, high 35.7%. The front-line treatment was stratified according to the commonly used risk factors (FLIPI, β-2-m and s-TK levels, bulky disease) into 3 treatment groups: (1) patients with FLIPI 0-1 with a maximum of 2 additional risk factors treated with (R)-CHOP, (2) patients under 60 (65) years of age with intermediate-risk disease (FLIPI 2 or less with >2 additional risk factors) indicated for an intensive chemotherapy protocol (ProMACE-CytaBOM or Sequential chemotherapy), and (3) patients under 60 (65) years with high-risk disease (FLIPI ≥3) treated with intensive chemotherapy plus autologous stem cell transplantation (BEAM). (1) 62% of patients were treated conventionally, (2) 13% underwent an intensive chemotherapy protocol, and (3) 25% received intensive chemotherapy with ASCT consolidation. Rituximab was added to chemotherapy in 51% of the patients. The treatment response was classified according to the standard Cheson criteria (1999). Patients who achieved a complete response (CR) or unconfirmed complete response (CRu) plus PCR bcl-2/IgH negativity were classified as molecular CR (CRm). *Results*. Generally, CR or CRu was achieved in 88% of patients, 12% had partial remission (PR). CRm was evaluable in 85 patients: 66% of them achieved molecular CR, 17% CR with bcl-2/IgH positivity and 17% PR. After median follow-up of 52 months, 57% of the patients are still in the 1st CR, 26% relapsed or progressed and 17% of the patients died. Overall survival at 5 years (5y OS) reached 85% (95% CI 0.77-0.92); progression-free survival at 5 years (5y PFS) was 61% (95% CI 0.51-0.72). The FLIPI scores do not stratify risk subgroups for OS (log-rank 0.12). For PFS, the population is divided into only 2 groups: low/intermediate (5y PFS 70%; 95% CI 0.56-0.83) and high-risk (5y PFS 55%; 95% CI 0.38-0.71), log-rank 0.026. Cox regression analysis identified only CRm and s-TK level as independent predictive factors (PFS). *Summary*. Front-line risk-adapted immunochemotherapy improves both the quality of treatment response and survival of FL patients. Some of the conventional prognostic factors lose their power in this population. Further investigation will help to develop the role of FLIPI in current treatment decision-making. New biological factors such as molecular remission and s-TK level identify patients at high risk of early relapse.

THE PROGNOSTIC SIGNIFICANCE OF THE NUMBER OF EXTRANODAL INVOLVEMENT SITES IN THE PATIENTS WITH DISSEMINATED DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP

C. Yoo, B.S. Sohn, J.E. Kim, D.H. Yoon, S. Kim, D.H. Lee, S.W. Kim, C. Suh

Asan Medical Center, SEOUL, South-Korea

Background. The combination of rituximab and CHOP chemotherapy (R-CHOP) has improved survival of patients with diffuse large B-cell lymphoma (DLBCL). Recently, several reports have shown that standard International Prognostic Index (IPI) became less powerful prognostic predictor in patients with DLBCL in the era of R-CHOP. *Aims*. We evaluated the prognostic factors of DLBCL patients treated with R-CHOP. Detailed analysis was planned regarding the number of extranodal sites because of its higher frequency in Korea. *Methods*. Between January

2002 and May 2008, 126 patients with stage III/IV DLBCL treated with R-CHOP were identified. We performed the retrospective analysis of the clinicopathologic factors and verified the predictive power of standard IPI and revised IPI (R-IPI) which was reported by the study group of British Columbia. Various numbers of extranodal sites were analyzed for further stratification and we set E-IPI as the IPI when the number of extranodal sites is stratified in ≤2 vs >2. *Results*. In the univariate analysis, the number of extranodal sites (≤2 vs >2) was a significant prognostic factor for complete response (CR) (p=0.04), event-free survival (EFS) (p=0.01) and overall survival (OS) (p<0.001). Age was also significant for EFS (p=0.03). When the number of extranodal site was stratified differently (0 vs >0, or ≤1 vs >1), these were not associated with CR, EFS and OS. On the multivariate analysis, the number of extranodal sites (≤2 vs >2) remained significant for EFS (p<0.01, HR 2.6) and OS (p<0.01, HR 3.5). The standard IPI identified 3 risk groups with 2-year EFS; 68%, 55%, 56% (p=0.17) and 2-year OS; 85%, 68%, 58% (p=0.04). The R-IPI classified 2 risk groups with 2-year EFS; 65%, 50% (p=0.02) and 2-year OS 76%, 62% (p=0.04). The E-IPI represented 3 risk groups with 2-year EFS; 79%, 56%, 42% (p=0.01) and 2-year OS; 86%, 70%, 39% (p=0.001). The patient group with survival of less than 50% was only recognized by E-IPI. *Conclusions*. The number of extranodal sites (≤2 vs >2) is the most significant prognostic factor of EFS and OS. Although all three indices remain predictive, E-IPI is the best model to identify the prognostic group in this cohort with stage III/IV DLBCL treated with R-CHOP.

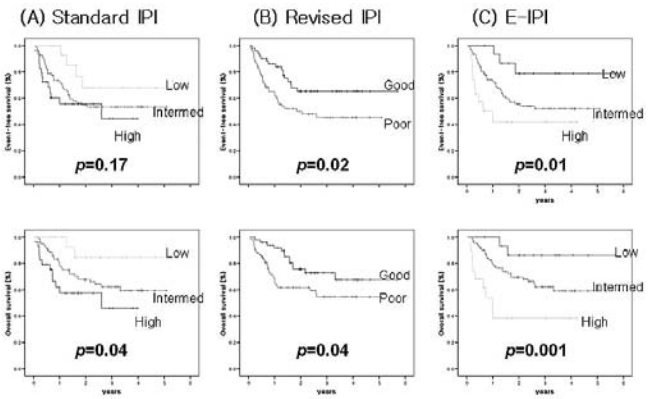

Figure 1. Outcomes according to three prognostic models.

ADDITION OF YTTRIUM-90 IBRITUMOMAB TIUXETAN TO BEAM CONDITIONING PRIOR TO AUTOGRAFTING DOES NOT IMPROVE OUTCOME OF CHEMOREFRACTORY PATIENTS WITH AGGRESSIVE B-CELL NHL

I. Aurer,[1] D. Huic,[1] D. Nemet,[1] Z. Mitrovic,[2] M. Zuvic,[1] R. Serventi-Seiwerth,[1] D. Sertic,[1] M. Mrsic,[1] S. Basic-Kinda,[1] I. Radman,[1] B. Labar[1]

[1]University Hospital Center Rebro, ZAGREB; [2]Medical School, University of Zagreb, ZAGREB, Croatia

Background. The outcome of patients with aggressive B-NHL failing standard front-line and salvage chemotherapy is extremely poor even after autografting. Yttrium-90 ibritumomab tiuxetan (Zevalin®) is a radioimmunoconjugate consisting of an anti-CD20 monoclonal antibody coupled to radioactive yttrium-90. Yttrium-90 ibritumomab tiuxetan is active against B-NHL, has mainly hematological toxicity and is not cross-resistant with chemotherapy. We therefore hypothesized that the addition of yttrium-90 ibritumomab tiuxetan to conditioning might improve the outcome of autografting in these patients. *Aims*. We performed this trial to investigate the feasibility and efficacy of the addition of standard-dose yttrium-90 ibritumomab tiuxetan to the standard pretransplant BEAM chemotherapy conditioning regimen consisting of carmustine, etoposide, cytarabine and melfalan (Z-BEAM) in patients with chemorefractory aggressive B-NHL. *Methods*. Patients with diffuse large B-cell (DLBCL) and mantle-cell lymphoma (MCL) were eligible for the trial provided they have failed front-line antracycline-based chemotherapy and the last salvage regimen, were transplant-eligible and did not have bone marrow infiltration with lymphoma. Yttrium-90 ibritumomab tiuxetan was given at a dose of 14.8 MBq/kg (but not more than 1.26 GBq) on day -10. BEAM was administered between days -7 and -2 and stem cells were reinfused on day 0. *Results*. We identified 18 patients with chemorefractory NHL potentially eligible for the trial, 16 with DLBCL and 2 with MCL. Stem cell collection was successful in 11, all with DLBCL. In 4 out of these 11, rapidly progressive disease precluded autografting. Seven patients received Z-BEAM. Three were men and 4 women; median age was 47 years, range 33-62. All were previously exposed to rituximab. Median number of previous treatment lines was 2, range 2-4, and median disease duration 21 months, range 15-23. Two patients died before engraftment, one due to refractory ventricular fibrillation during stem-cell reinfusion, and the other due to pneumonia caused by a multiresistant Pseudomonas strain. Time to platelet engraftment was 12-39 days (median 18) and time to granulocyte engraftment 8-18 days (median 10). One patient died after engraftment due to multiorgan failure. There were no other cases of serious non-hematological, non-infectious toxicity. None of the four patients surviving to discharge responded and all died within 5 months of transplantation due to tumor progression or complications of further treatment. The trial was stopped prematurely because of lack of efficacy and toxicity. *Conclusions*. In this small series of very high-risk patients with chemorefractory aggressive B-NHL the addition of yttrium-90 ibritumomab tiuxetan to BEAM conditioning prior to autografting was toxic and did not improve outcomes.

0996

A POSSIBLE ROLE OF 18F-FDG PET SCANNING IN THE EARLY DETECTION OF RITUXIMAB-INDUCED PNEUMONITIS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

L. Nieuwenhuizen,[1] F.J. Verzijlbergen,[1] E Wiltink,[1] J.C. Grutters,[1] D.H. Biesma[2]

[1]Sint Antonius Hospital, NIEUWEGEIN; [2]University Medical Centre Utrecht, UTRECH, Netherlands

Background. Rituximab is safe and effective in the treatment of patients with non-Hodgkin's lymphoma (NHL). Recently, rituximab-induced pneumonitis (RP) has been reported as side-effect of rituximab. *Aims*. To evaluate the possible role of 18F-FDG PET scanning in the early detection of rituximab-induced pneumonitis in patients with Non-Hodgkin's lymphoma.

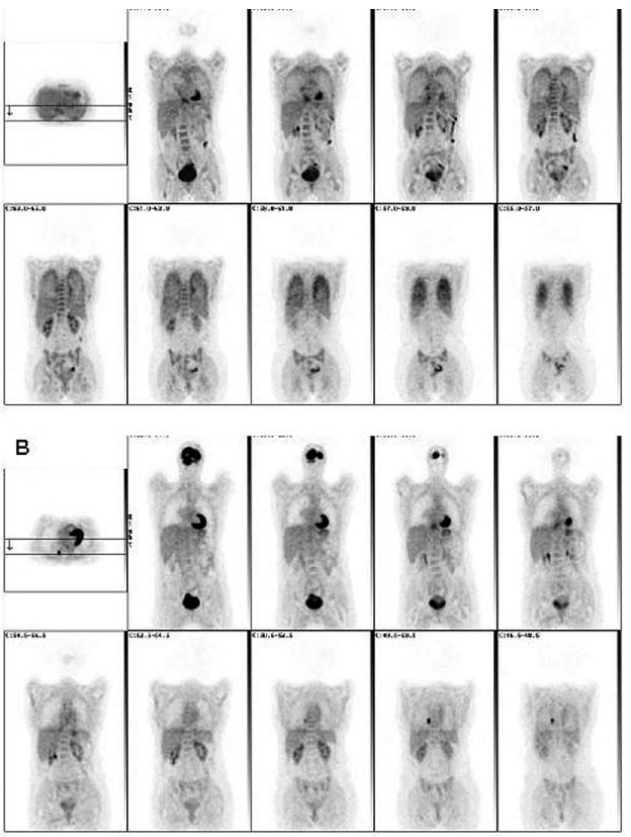

Figure 1. 18F-FDG PET in rituximab induced pneumonitis.

Methods. We performed a single centre, retrospective case-control study of NHL patients treated with C[H]OP-rituximab to investigate

variables associated with RP and to investigate the abnormalities found on 18F-FDG PET. We included patients with a documented 18F-FDG PET before rituximab therapy and in whom a priori the lymphoma response was evaluated by 18F-FDG PET. RP was defined as the presence of characteristic clinical findings and the presence of diffuse unilateral or bilateral pulmonary activity detected by 18F-FDG PET. The diagnosis RP was only made after exclusion of other causes of diffuse lung disease. All subjects were reviewed for treatment schedule, clinical, laboratory, and radiological characteristics. 18F-FDG PET were analysed for activity pattern and maximum standardized uptake values (SUVmax). Patients with RP were considered as cases (case group) and were compared with patients without RP (control group).*Results*. A total of 36 patients were treated with R-C[H]OP, including four patients in which RP was diagnosed. The cases and controls were comparable for age, gender, NHL-classification, Ann Arbor stage and treatment schedule. There were no differences with regard to laboratory parameters, number of administered rituximab doses, interval of rituximab administration and cumulative dose of administered rituximab. All four patients with RP showed bilateral diffuse pulmonary uptake on 18F-FDG PET. The mean SUVmax was 3.5 (range 1.5-7.8). In one patient 18F-FDG PET abnormalities preceeded abnormalities found on HRCT and chest X-ray. The activity on 18F-FDG PET was reversible in all patients. No abnormalities were noted on 18F-FDG PET in the control group. *Conclusions*. In conclusion, we described four patients, in whom 18F-FDG PET imaging proved to be a useful and early diagnostic tool in the detection of RP.

0997

FIRST-LINE TREATMENT WITH RITUXIMAB AND BENDAMUSTINE IN OLD PATIENTS (80 YEARS AND OLDER) WITH AGGRESSIVE B-CELL LYMPHOMAS - AN INTERIM ANALYSIS OF AN ONGOING PHASE II STUDY

E. Weidmann,[1] F. Fauth,[2] A. Atmaca,[1] S.E. Al-Batran,[1] A. Neumann,[1] C. Pauligk,[1] E. Jager[1]

[1]Krankenhaus Nordwest, FRANKFURT/M; [2]Praxis for Hematology and Oncology, HANAU, Germany

Background. Rituximab plus CHOP (R-CHOP) is widely recommended for the treatment of patients with aggressive B-cell lymphomas. There is a paucity of information from clinical studies regarding the management of old patients. A recently published, retrospective analysis in patients aged >80 years reported a median overall survival of 1.2 years (Thieblemont *et al*. Ann Oncol 2008;19:774-9). Bendamustine is a purine analog/alkylator hybrid with single-agent activity in various lymphomas. Acceptable response rates and good tolerability have been achieved with bendamustine in a phase II study in relapsed/refractory aggressive lymphomas (Weidmann *et al*. Ann Oncol 2002;13:1285-9). *Aims*. We initiated a phase II study of first-line treatment with rituximab and bendamustine in elderly patients (≥80 years) with aggressive B-cell lymphomas who were not eligible for R-CHOP or who denied aggressive treatment. Primary objectives were feasibility and efficacy. *Methods*. Judgement whether a patient qualified for R-CHOP was left to physicians. When a decision against R-CHOP was reached, patients with stage I/II disease received 4 cycles of rituximab (375 mg/m^2, day 1) and bendamustine (120 mg/m^2, days 2 and 3) every 21 days, followed by involved field irradiation; patients with stage III/IV disease received 6 cycles of the above treatment followed by 2 consolidating administrations of rituximab. *Results*. To date, 13 patients (9 male, 4 female) with a median age of 85 years (range 80-89 years) have entered the study. The age-adjusted International Prognostic Index was 0 in 6 patients, 1 in 2 patients, 2 in 4 patients, and 3 in 1 patient. Seven patients had stage I/II disease, and 6 had stage III/IV disease. Eleven patients were diagnosed with diffuse large B-cell lymphomas, 1 with mantle cell lymphoma, and 1 with grade 3 follicular lymphoma. Response: Ten patients were evaluable for response (1 patient refused further treatment after the first cycle, treatment was discontinued after the first cycle in 1 patient because of a psychotic episode, and in 1 patient it is too early for response assessment). Nine of the 10 (90%) patients achieved a response: 6 (60%) had a CR, 3 (30%) had a PR, and 1 (10%) had progressive disease. Survival: In an intention-to-treat analysis of all 13 patients, with a mean observation time of 17.3 months (range 1-49 months), the estimated overall survival at 2 years was 56% (Figure 1); the mean overall survival had not yet been reached. Mean progression-free survival was 14.4 months. Toxicity: Toxicity was generally low. Of 46 evaluable treatment cycles to date, only 1 grade 4 toxicity (neutropenia; 2%) was observed. Grade 3 toxicities included leukopenia (7%), neutropenia (4%), thrombopenia (2%), infections (7%), nausea/vomiting (4%), diarrhea (2%), and renal insufficiency (2%). *Summary and Conclusions*. Bendamustine in combination with rituximab may be an alternative treatment for aggressive lymphomas in elderly patients not eligible for R-CHOP. Furthermore, treatment toxicity was low. These results, however, need to be confirmed in larger numbers of patients.

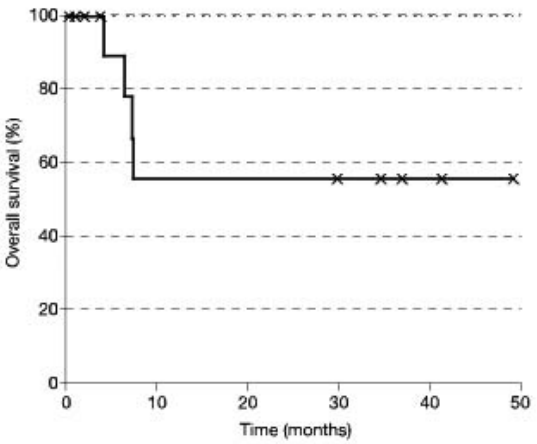

Figure 1.

0998

KI-67 EXPRESSION IS PREDICTIVE OF PROGNOSIS IN PATIENTS OF DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH RITUXIMAB PLUS CHOP

C. Suh, D.H. Yoon, B.S. Sohn, J.E. Kim, C.H. Yoo, S. Kim, D.H. Lee, J.R. Huh

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Tumor cell proliferation as assessed by the Ki-67 expression has yielded conflicting results in predicting prognosis of diffuse large B-cell lymphoma (DLBCL). Furthermore, introduction of rituximab to the treatment of DLBCL has changed significance of previously known prognostic factors. *Aims*. The objective of this study is to investigate the relationship of Ki-67 expression and prognosis in DLBCL treated with rituximab plus cylophosphamide, doxorubicin hydrochloride, vincristine, prednisolone (CHOP) chemotherapy, which is the mainstay of the disease. *Methods*. Between July 2003 and January 2008, 146 adult DLBCL were treated with R-CHOP at Asan Medical Center in Seoul. We retrospectively analyzed their Ki-67 expression and its relationship with prognosis.

Table 1.

	Ki-67 > 80% (n=46)	Ki-67 ≤ 80% (n=100)	P value
Complete remission (CR)	32 (69.6%)	82 (82.0%)	0.092
Relapse after CR	9 out of 32 (28.1%)	8 out of 82 (9.8%)	0.013
2-year overall survival	66.8%	82.3%	0.017
2-year event-free survival	37.4%	74.3%	0.004

Results. There was no significant difference in achieving complete remission (CR) with R-CHOP by the status of Ki-67 expression. Thirty two patients out of 46 (69.6%) achieved CR in the group of high Ki-67 expression (Ki-67 > 80%) and 82 out of 100 (82.0%) gained CR in the group of low Ki-67 expression (Ki-67 <= 80%)(p=0.092). However, more relapse among patients who gained CR after the initial chemotherapy

of R-CHOP was noted in the group of high Ki-67 expression. Nine patients out of 32 (28.1%) who gained CR relapsed in the group of high Ki-67 expression compared to 8 out of 82 (9.8%) in the group of low Ki-67 expression (p=0.013). The group with high Ki-67 expression had a shorter OS and EFS. The 2-year OS rate was 66.8% in the group of high Ki-67 expression and 82.3% in the group of low Ki-67 expression (p=0.017). The 2-year EFS rate was 37.4% in the group of high Ki-67 expression and 74.3% in the group of low Ki-67 expression (p=0.004). Median OS of both groups were not reached at a median follow-up of 25.2 months (range, 5.2-58.8 months). Median EFS in the group of high Ki-67 expression was 22.3 months and it was not reached in the group of low Ki-67 expression. In the multivariate analysis performed with Ki-67 and variables included in the international prognostic index such as age, performance status, Ann-Arbor stage, LDH and extranodal involvement, Ki-67 expression was still found to be an independent prognostic factor for OS (Hazard ratio (HR) = 3.577; 95% CI 1.631-7.845; p=0.001) and EFS (HR = 3.345; CI 1.754-6.378; p<0.001) in this set of patients. *Conclusions*. High Ki-67 expression was associated with more relapse and inferior survival in patients with DLBCL treated with rituximab plus CHOP.

0999

OCULAR ADNEXA NON HODGKIN LYMPHOMAS: A SINGLE CENTRE RETROSPECTIVE STUDY OF CLINICOPATHOLOGIC FEATURES, TREATMENT AND CLINICAL OUTCOME

T. Perrone,[1] F. Gaudio,[2] S. Guerriero,[3] A. Gentile,[4] A. Giordano,[2] A. Spina,[2] F. Laddaga,[2] V. Pavone,[5] A. Guarini,[6] C. Sborgia,[3] G. Specchia,[2] V. Liso,[2] C. de Risi[7]

[1]Hematology, Bari University, BARI; [2]Haematology, BARI; [3]Ophthalmology, BARI; [4]Pathological Anatomy, BARI; [5]Hematology,G.Panico Hospital, TRICASE; [6]Haematology, Oncology Institute, BARI; [7]Haematology, BARI

Background. Ocular adnexa lymphomas account for about 1% of non Hodgkin Lymphomas and 5% to 15% of all extranodal sites. They are the most frequent malignant tumor of the eye and ocular adnexa. *Aims*. Aim of this study was to define histological characteristics, treatment, prognostic factors, and outcome of patients affected by non Hodgkin lymphoma of ocular adnexa. *Methods*. Thirty patients (pts) affected by ocular adnexa non Hodgkin lymphomas were examined in our institution between 1991 and 2008. Median age was 65 years (range 40-90) with an equal gender distribution. A pathologic review of all cases was performed according to the REAL/ WHO classification. The most common histological diagnosis was "Extranodal marginal zone B-cell lymphomas of mucosa-associated lymphoid tissue" (MALT lymphoma) (11 patients, 37%); 9 (30%) cases were "small lymphocytic lymphomas (SLL), 6 (20%) "follicular lymphoma" (FL), 3 (10%) "Mantle cell lymphoma" (MCL) and 1 (3%) Diffuse large B cell lymphoma (DLBCL). Ophthalmologic sites were: intra-orbital in 25 (83%) cases, lachrymal gland in 5 (17%), with bilateral involvement in 1 (3%) case. In 9 (30%) pts extrinsic ocular muscles were involved. The most common symptoms were: palpebral ptosis, exophthalmus and lachrymation. Fifteen 15 (50%) pts had a primary ocular adnexa lymphoma, 2 (7%) had a stage II, while Stage IV was found in 13 (43%) cases: in all cases bone marrow was involved. Four (13%) pts had other extranodal sites: 2 (%) breast, 1 (3%) pharynx, 1(3%) liver. All patients had low LDH values while 7 (23%) pts had a high β2μ value. No pts had a PS>1 and only 2 (7%) referred B symptoms. Twenty four (80%) pts received chemotherapy (11 (37%) with a CHOP-like regimen, 11(37%) a CVP regimen, 2 (7%) a FND regimen), in 14 (47%) pts chemotherapy was in combination with a monoclonal antibody anti CD20 (rituximab). One (3%) pt was treated with Rituximab alone. Five (17%) pts received radiotherapy. Overall response rate was 80%:17 (57%) Complete Remissions and 7 (23%) Partial Remissions. Four (13%) pts had stable disease and 2 (7%) of them progressed. Six (35%) relapses occurred and in 5 (83%) of them there was extranodal involvement:1(3%) breast, 2 (7%) orbit, 1(3%) lachrymal gland and 1 (3%) bone. *Results*. After a median follow-up of 74 (7-220) months, DFS and OS were 72% and 75%. At multivariate analysis, stage IV and histological type (MCL, SLL) had a negative impact on DFS for the overall population. *Conclusions*. In our experience, in accordance with previous studies, ocular adnexa lymphoma is more frequent in elderly pts; the most frequent histological type is MZL, more than 40% of population have a Stage IV disease, and response rate to the treatment is 80%. Stage IV and histological types MCL and SLL are predictive of poorer prognosis, with frequent extranodal relapses. Further studies are needed to evaluate biological and histopathological features of ocular adnexa lymphomas, in order to identify the best therapeutic strategy.

EFFICACY AND TREATMENT COMPLIANCE OF DOSE-DENSE R-CHOP-14 IMMUNOCHEMOTHERAPY PLUS PEGFILGRASTIM FOR FIRST-LINE TREATMENT OF PATIENTS WITH LOW RISK DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): AN OPEN-LABEL CLINICAL TRIAL IN SPAIN

E. Gonzalez Barca,[1] A. Salar,[2] A. Oriol,[3] M.J. Vidal,[4] M. Canales,[5] J. Bargay,[6] S. Gardella,[7] J. Briones,[8] F.J. Tomas,[9] S. Ferrer,[10] D. Caballero[11]

[1]Institut Catalá d'Oncología, BARCELONA; [2]Hospital del Mar, BARCELONA; [3]Hospital Germans Trias i Pujol, BARCELONA; [4]Hospital de Donostia, SAN SEBASTIAN; [5]Hospital La Paz, MADRID; [6]Hospital Son Llátzer, PALMA DE MALLORCA; [7]Hospital Josep Trueta, GERONA; [8]Hospital Santa Creu I Sant Pau, BARCELONA; [9]MD Anderson, MADRID; [10]Hospital U. Dr. Peset, VALENCIA; [11]Hospital Clínico U. Salamanca, SALAMANCA, Spain

Background. Three-weekly R-CHOP has become the standard treatment for DLBCL. Dose-dense immunochemotherapy could improve the efficacy of treatment; however these regimens are worse tolerated due to mielotoxicity. *Aims*. The aim of this analysis was to evaluate the efficacy and treatment compliance of dose-dense R-CHOP supported by pegfilgrastim in patients with DLBCL and IPI 0-2. *Methods*. This is a prospective clinical trial in patients with DLBCL, CD20 positive disease, ECOG PS 0-2, older than 65 with IPI 0-5 or younger than 65 with IPI 0-2. Patients were required to have normal renal, liver and cardiac function. Treatment: 6 cycles of R-CHOP administered every 14 days followed by pegfilgrastim (6 mg per cycle) on day 2. In this intention to treat subanalysis we have selected patients with low or low-intermediate risk IPI to evaluate response after 2° inmunochemotherapy cycle and after 130-days follow up. *Results*. 68 patients with IPI 0-2 were included in this analysis, median age was 58 years old (range 18-82), 24 (35.3%) were older than 65, 37 (54%) were male. Sixty-for (94%) had ECOG 0-1. Characteristics of the disease at diagnosis were as follows: stage III-IV: 33 (49%), bulky disease: 15 (22%), extra nodal involvement: 42 (62%), B symptoms: 13 (19%), elevated LDH: 26 (38%), elevated β-2-microglobulin: 28 (41%), IPI 0-1 33 (49%). Fifty-nine patients completed 6 cycles of treatment. Febrile neutropenia episodes were reported in 10 (14.7%) patients. Overall, 379 inmunochemotherapy cycles were administered and 26 (6.9%) were delayed (6% in younger patients and 8.2% in patients older than 65). The causes of delay were: neutropenia (3), febrile neutropenia (4), hepatotoxicity (1), fever or infection without neutropenia (13) and other adverse events (5). Doses of myelotoxic drugs were reduced in 9 (2.4%) cycles (4 patients). Most cycles (91.8%) were administered as scheduled and most patients (67.7%) completed their full treatment schedule as planned. After second inmunochemotherapy cycle, 30 (45.5%) patients achieved complete remission, 31 (47%) partial remission, 1 (1.5%) stable disease and 4 (6%) were not evaluable. Ten patients did not complete treatment (5 exitus, 1 drop out due to an adverse event, 1 protocol violation, 3 missings). Among patients who completed treatment, 58 patients were evaluated for efficacy after 130-days follow-up, achieving 54 (93.1%) responses of which 49/54 (90.7%) were complete remissions. Responses in IPI 0-1 and IPI 2 patients were 26/29 (89.6%) and 28/29 (96.5%) respectively. *Conclusions*. High remission rate shows that dose-dense immunochemotherapy with pegfilgrastim support is an efficacious treatment for DLBCL in low risk patients. The regimen is well tolerated, treatment compliance is high and most of cycles were administered as scheduled.

NEW VERTEBRAL FRACTURES IN NON-HODGKIN-LYMPHOMA PATIENTS TREATED WITH CHEMOTHERAPY AND HIGH DOSE STEROIDS ARE RELATED TO THE INITIAL VALUES OF BONE MINERAL DENSITY

M.P. Bianchi, M.C. Cox, F. Conti, M. Pietravalle, A. Proietti, L. Vismara, V. David, C. Tatarelli, B. Veggia, G. Antolino, F. Mendicino, R. Camilli, P. Cardelli, B. Monarca, M.A. Aloe Spiriti

A.O.Sant'Andrea-II Faculty of Medicine-La Sapienza-Roma, ROMA, Italy

Background. Osteoporosis and bone fractures are a well known adverse events of steroid therapy: the majority of fractures are described within the first year of steroids administration. Plenty of data are available regarding the effects of low doses of steroids chronically administered in autoimmune diseases, but very few data are available as regards patients with lymphoma and treated with very high doses of steroids (HDS) within few months. *Aims*. To prospectively assess the incidence of pathological bone fractures and bone mineral density loss in a cohort of Non-Hodgkin-lymphoma (NHL) patients treated with R-CHOP-like

chemotherapy and thus receiving 3000-4500 mg of steroids within 3-4 months. *Materials and Methods*. From January 2005 to November 2008, 96 patients with newly diagnosed non-Hodgkin-Lymphoma and elegible for R-CHOP like therapy, were enrolled in this study. Thirthy-three were post menopausal females (34.3%), 9 pre-menopausal females (9%) and 54 were males (56.2%). All patients underwent CT scan of the vertebral spine before and within 1 months by the end of chemotherapy. Forty-one patients were also assessed for bone mineral density (BMD), using a dual-energy X-ray absorptiometer (DXA), at the spine and hip, vitD3 and ostase, before and after chemotherapy, while during chemotherapy bone and urine turnover as plasma β cross laps and urine cross-links, were serially measured. The main outcomes were the incidence of vertebral fractures and changes in bone mineral density of the lumbar spine and proximal femur. *Results*. During the 25 months study, 15 patients (15.6%) underwent vertebral fractures during or shortly after chemotherapy. In 10 cases (73.3%) in post-menopausal females, in 5 cases (33.3%) in males. Fourteen patients who were on oral biphosphonate had to discontinue it during chemotherapy because of gastric intolerance. Mean percentage changes in bone mineral density were -2.5% in the lumbar spine and -1,2% in the hip. New vertebral factures were related to the pre-chemotherapy BMD values, but not to BMD loss during chemotherapy. *Conclusions*. Vertebral fractures are a frequent event in the course of chemotherapy with high dose steroids for lymphoma. Because post menopausal females and older men with low BMD are at very high risk of developing vertebral fractures, specific preventive therapy should be given to patients with osteopenia and osteoporosis, who starts chemotherapy with HDS.

HAEMATOPATHOLOGY DIAGNOSTIC SKILLS ACQUIRED IN A VIRTUAL LABORATORY: PRACTICAL TEACHING IN THE 21ST CENTURY

JM O'Connor,[1] C Burton,[1] J Blase,[2] W Curson,[2] J Doughty,[2] T Lightfoot,[2] A Jack[1]

[1]St James's Institute of Oncology, LEEDS; [2]Epidemiology abd Genetics Unit, YORK, UK

Traditionally, acquiring laboratory skills involved donning a white coat and physically carrying out tests at the bench. There is a need in the age of 'Modernising Scientific Careers' with regional cancer-networks and a 'Knowledge & Skills' based workforce to have higher specialist training for clinicians, clinical scientists and other scientists. Higher specialist training in newly emerging specialist disciplines such as Haematopathology is difficult to acquire, it involves cross-disciplinary knowledge and training remains patchy. Short courses are available for some aspects of specialist training but these often involve attending residential courses away from the site of employment. These short courses serve a useful purpose but there are many key skills that are not covered by training courses and individuals wishing to specialise must create their own training program. Distance learning courses are popular and are successful in delivering traditional academic material. However, these courses whilst good at teaching theoretical knowledge fail to teach practical bench skills. Yorkshire and Humberside cancer network have established a model to teach practical skills via distance learning. The Haematological Malignancy Diagnostic Service (HMDS), St James's Institute of Oncology in partnership with the Epidemiology and Genetics Unit (EGU), York University has developed a Masters degree in Haematopathology that is delivered via a virtual learning environment (VLE). A novel aspect is the teaching of practical skills using a virtual laboratory, SimLab®. The course consists of six modules, three academic and three practical laboratory based. During practical modules students enter SimLab® and carry out their laboratory work using a novel program SimTest®. Students are given a series of cases based on original cases seen in HMDS. Cases cover a wide range of haematological malignancies. The structure of the course is unconventional as case time is allocated according to disease incidence i.e. chronic lymphocytic leukaemia cases are assessed frequently. Students will 'screen' the biopsy by assessing clinical information and looking at morphological images or virtual slides of the tissue biopsy. Students can order a range of tests, raw data/primary results will be available electronically for analysis/interpretation. Tests include morphology, multi-colour flow cytometry, immunohistochemistry, molecular cytogenetics (FISH/karyotype images), and PCR/gene sequencing (gel images or raw sequence text file). Where this course differs from others that provide case studies is that the students have the same starting material that is available in the 'real' laboratory. They are free to make mistakes. To mimic real life as much as possible the students have time and sample constraints imposed. Students should acquire the skills needed in an integrated haematopathology service. We believe that virtual laboratories such as SimLab® and SimTest® offer a solution to some of the problems of delivering higher specialist training.

1003

IMMUNOHISTOCHEMICAL DETECTION OF ZAP-70 IN A SERIES OF MARGINAL ZONE LYMPHOMA (MZL) PATIENTS

C. Kalpadakis,[1] G.A. Pangalis,[2] P. Korkolopoulou,[2] T.P. Vassilakopoulos,[2] G. Levidou,[3] M.C. Kyrtsonis,[2] S. Sachanas,[2] X. Yiakoumis,[2] E.M. Dimitriadou,[2] F.N. Kontopidou,[2] M.P. Siakantaris,[2] E. Patsouris,[3] P. Panayiotidis,[2] H. Papadaki,[1] M.K. Angelopoulou[2]

[1]Department of Haematology, University of Crete, ATHENS; [2]Department of Haematology, University of Athens, ATHENS; [3]Department of Pathology, University of Athens, ATHENS, Greece

Background. ZAP-70 has emerged as a prognostic factor in CLL, since it represents a surrogate marker for the IgVH gene mutational status. ZAP-70 expression in MZL is less well defined. Splenic marginal zone lymphoma (SMZL) display molecular heterogeneity since almost half of the cases carries unmutated IgVH genes, analogous to B-CLL. *Aims*. To evaluate ZAP-70 expression in a series of MZL patients and correlate these findings with other clinical and laboratory features as well as with the mutation status in SMZL patients. *Methods*. Using an immunohistochemical method we evaluated the expression of ZAP-70 in 68 MZL patients diagnosed and followed in our Departments between 1985 and 2008. The study population included 39 SMZL, 21 non-gastric MALT and 8 nodal MZL (NMZL) cases. CD3 staining was also performed in order to exclude normal reactive T-cells being present among the lymphomatous population. Cases demonstrating nuclear staining in greater than 20% of tumor cells were considered positive. For the detection of IgVH somatic hypermutation DNA was extracted from mononuclear cells of spleen tissues or bone marrow in 24 SMZL cases. DNA was amplified using a mixture of six 5' leader region specific primers for each one of the six VH families (VH1-VH6) and a 3'J consensus primer. Amplified products were next ligated and cloned and plasmid DNA was isolated from overnight cultures of randomly selected colonies. At least five plasmids per case were sequenced for both orientations. Clinical, laboratory and outcome data of all patients were recorded and evaluated in relation to ZAP-70 expression. Furthermore in SMZL cases, ZAP-70 expression was evaluated in relation to mutational status of IgVH genes. *Results*. Of the 68 patients studied for ZAP-70 expression only six cases (9%) were found to be positive. Thus, ZAP-70 positivity was detected in three of the 39 (8%) SMZL, in one of the 21 (5%) MALT lymphomas and in two of the 8 (25%) NMZL patients. 24 SMZL cases were simultaneously studied for the detection of their IgVH somatic hypermutation status. 14 (58%) of them were found to be mutated and 10 (42%) unmutated. Of the 3 ZAP-70 positive SMZL cases, all three belonged to the unmutated IgVH group while no positive ZAP-70 cases was detected in the mutated group. Due to the small number of ZAP-70 positive cases in the individual groups studied, it was not possible to perform a meaningful analysis in relation to the clinical and laboratory features as well as survival data of our patients. *Summary and Conclusions*. ZAP-70 is expressed in MZL, although in significantly lower rate than that of CLL. In the present study only 9% of MZL patients were positive for this protein. NMZL presented the higher rate of expression. In SMZL no correlation was found between mutational status and ZAP-70 expression, a finding that clearly shows that ZAP-70 cannot be used as an alternative marker for the mutational status of IgVH genes in SMZL.

1004

OUTCOME OF AGGRESSIVE ATL-HTLV1 PATIENTS AFTER CHOP21 AS FIRST LINE TREATMENT - BUCHAREST EXPERIENCE

D. Cisleanu,[1] A.M. Vladareanu,[2] H. Bumbea,[2] S. Radesi,[3] I. Voican,[2] C. Ciufu,[2] C. Marinescu,[2] M. Onisai,[2] A. Nicolescu,[2] M. Dervesteanu,[1] C. Dobrea,[4] V. Popov,[1] D. Colita,[5] D. Mut-Popescu[5]

[1]Universitary Emergency Hospital Bucharest, BUCHAREST; [2]Hematology Department Universitary Emergency Hospital Bucharest, BUCHAREST; [3]Hematology Deparment Universitary Emergency Hospital Bucharest, BUCHAREST; [4]Victor Babes National Institute of Development and Research, BUCHAREST; [5]Carol Davila University of Medicine and Pharmacy, BUCHAREST, Romania

Background. Adult T-cell Leukemia/lymphoma (ATL) is a peripheral T-cell malignancy caused by a retrovirus, HTLV-1. ATL has the most unfavorable prognosis compared to B-cell non-Hodgkin Lymphoma and

Peripheral T-Cell Lymphoma. Large clinical trails for ATL were conducted in Japan by the Japan Clinical Oncology Group (JCOG). In Europe, the majority of newly diagnosed patients with ATL are treated with CHOP21 as first line therapy, although a large trial to asses the efficiency of this approach in aggressive ATL subtypes does not exist, mainly because the specific geographical distribution of ATL. *Aims*. Evaluating the efficiency of CHOP21 as first line treatment on aggressive ATL-HTLV1 patients. *Methods*. We have retrospectively evaluated 34patients diagnosed with ATL-HTLV1 positive, between January 1998 and January 2007 in Hematology Clinics of the University of Medicine and Pharmacy Carol Davila Bucharest. All patients previously untreated received CHOP21 as first line treatment. We have analyzed the rate of complete response (CR), partial response (PR), rate of response (RR), median time until relapse, median survival time (MST) and 2 years overall survival (OS). Patients' baseline characteristics: median age was 44.5 years (range 19-68), and 20patients (58.8%) were male. Among the 34patients, 19patients (55.9%) were diagnosed with acute ATL, 12patients (35.3%) with lymphoma subtype, and 3patients (8.8%) with chronic ATL subtype. B symptoms were present at 18patients (52.9%). Central nervous system involvement at onset was detected in 4patients (12.5%). 30patients (88.2%) of ATL-HTLV1 positive presented the classic T-helper phenotype ($CD4^+$ $CD8^-$), 3patients (8.8%) presented T-suppressor ($CD4^-$ $CD8^+$) and 1patient (2.9%) had an atypical T phenotype $CD4^+$ $CD8^+$. Hypercalcemia was present at 17patients (50%) and increased serum LDH (over 3times normal value) in 14 patients (41.2%). *Results*. Complete response to CHOP21 was observed in 8patients (23.5%), partial response in 6patients (17.6%), adding up to a 41.1% RR. Regarding the persistence of the response, the median time until relapse was 18 months, range 2.0-60.0. MST was 5months and the 2 years OS was 20.5%. We analyzed the response to CHOP21 in each ATL subtype. In acute ATL, 1patient (5.2%) had CR, and 2patients (10.5%) had PR, with a median time of response of 4months, range 2.0-24.0. In lymphoma subtype, 5patients (41.6%) had CR, 2patients (16.6%) had PR, with a 58.2% RR; median time until relapse was 11months, range 3.0-36.0. In chronic ATL subtype, 2patients (66.6%) had CR, and 1patient had PR, with a median time to response of 48months, range 6.0-60.0. *Conclusions.* CHOP21 is not a satisfactory therapy for aggressive ATL; this approach showed a modest benefit. A literature search revealed that the best results (81% RR, 35% CR) are obtained with JCOG LSG15 (VCAP/AMP/VECP) a multidrug regimen supported by G-CSF which included drugs that are not affected by P-glycoprotein expression. This regimen should be as well a standard therapy for aggressive ATL in Europe. Several reports have demonstrated the clinical benefit of allo-HSCT for ATL patients, the only approach that can cure. Other potential therapeutic compounds are studied.

1005

INTENSIFIED CHOP (ICHOP) ± RITUXIMAB IN PRIMARY MEDIASTINAL DIFFUSE LARGE B CELL LYMPHOMA (PMBCL): THE ROLE OF DOXORUBICIN/ CYCLOPHOSPHAMIDE DOSE-INTENSITY

R. Mazza,[1] M. Spina,[2] M. Magagnoli,[1] M. Demarco,[1] L. Siracusano,[1] L. Castagna,[1] L. Giordano,[1] U. Tirelli,[2] A. Santoro,[1] M. Balzarotti[1]

[1]Istituto Clinico Humanitas, ROZZANO; [2]Medical Oncology A, Centro di Riferimento Oncologico, AVIANO, Italy

Background. PMBCL is a clinical/biological distinct entity, sharing some characteristics with both classical DLBCL and Hodgkin's lymphoma. MACOP B is considered the treatment of choice. *Aims*. To evaluate the role of doxorubicin/cyclophosphamide dose intensity in this setting of patients.Methods Starting from 1997, we treated PMBCL with an ICHOP regimen including cyclophosphamide 1750 mg/mq with MESNA uroprotection, doxorubicin 75 mg/mq, vincristine 1.4 mg/mq with 2 mg cap, and prednisone 100 mg d 1-5 of each 14-day courses, GCSF from day 7 to day 12. Rituximab (R) 375mg/mq/course was added to ICHOP (R-ICHOP) from 2002. Treatment plan included five courses of ICHOP±R. Cases with unfavourable prognosis according to age-adjusted International Prognostic Index (aaIPI2-3) were submitted to high dose chemotherapy (HDT) and peripheral stem cell rescue. Radiotherapy on involved sites was then delivered to all patients if at least partial remission (PR) was reached. Clinical response was evaluated through CT +/- Gallium scan (14 pts) up to 2002, and thorough CT + PET scan (16 pts) thereafter, according to Cheson criteria. *Results*. up to 2006, 30 pts were treated, with the following characteristics: M/F 10/20, median age 34 years (range 22-53), Ann Arbor stage I: 4, II -IIE:19, III: 1, IV: 6; bulky disease: 29; B symptoms: 14; aa IPI 0-1: 24, 2-3: 6; RICHOP / ICHOP 21/9. After ICHOP±R 15 patients achieved complete (CR) or unconfirmed complete remission (CR-U), 14 PR, 1 stable disease. At the end of the whole program 29/30 pts reached CR and one progressed. Seven pts received HDT, six following ICHOP±R and one after II line chemotherapy for refractory disease. After a median observation time of 60 months 1 patient progressed and 1 patient relapsed, respectively. Both died of lymphoma. One patient with stage IIE IPI 0 relapsed 18 months after completion of ICHOP and RT and died after further 5 treatment lines including alloBMT. The other patient with stage II EB IPI 1, progressed shortly after R-ICHOP and RT and died five months later. Five-yr failure free survival and overall survival are 93.2 and 92.8, respectively. ICHOP±R was well tolerated, with neither toxic death or life-threatening toxicity. No patient interrupted the planned treatment because of toxicity. Hospitalization was required in seven cases due to febrile neutropenia (6), hemorrhagic cystitis (3 cases), and pneumonia (1). Five episodes of grade III-IV mucositis were observed in 4 patients. Of 147 delivered cycles, 25 were delayed (13 pts). *Conclusions*. in PMBCL, the results obtained with the ICHOP protocol are better than standard CHOP and comparable to MACOP-B, emphasizing the role of doxorubicin and cyclophosphamide dose-intensity. In this limited series, the impact of adding rituximab is not clear.

Thrombosis and vascular biology II

1006

SUBCLINICAL ATHEROSCLEROSIS IN YOUNG B-THALASSEMIA MAJOR PATIENTS

A. Tantawy, A. A.Abdel Moneim, M. Ghareib, S. Abdel Gelil

Faculty of Medicine, Ain Shams University, CAIRO, Egypt

Background. Although clinical atherosclerosis usually occurs in late age, recent studies have shown that it begins in childhood in the presence of risk factors. Endothelial dysfunction which is an important precursor of atherosclerosis has been demonstrated in β thalassemia major (B-TM) patients, who are subjected to peroxidative tissue injury because of continuous blood transfusions. *Aims*. To assess subclinical atherosclerosis in young β-TM by measurement of carotid intima thickness (CIMT) and the associated risk factors including dyslipidemia in comparison to young type 1 diabetics as a high risk group for premature atherosclerosis. *Study design*. This study is a cross sectional study including 90 children and adolescents divided into 3 groups: 30 β-TM patients of mean age 18.4±6.18 years(Group I); 30 type 1 diabetic patients of mean age 19.23±4.25 years(Group II); and 30 healthy subjects age and sex matched (control group). The followings were done for all studied subjects: history,clinical examination and investigations including: fasting lipid profile assessing serum total cholesterol (TC), HDL-cholesterol (HDL-C), LDL-cholesterol (LDL-C), triglycerides (TG) and lipoprotein (a), Apoprotein A, Apoprotein B; as well as hemoglobin electrophoresis and serum ferritin for thalassemics; random blood sugar and glycosylated hemoglobin for diabetics. High resolution ultrasound for measurement of carotid intima thickness (CIMT)was done for patients and controls. *Results*. There was a significant increase in serum TG and TC levels in thalasemia and type 1 diabetics compared to controls (p<0.001 and p=0.003, respectively). Type 1 diabetics showed the highest level of LDL-cholesterol compared to thalassemic patients and controls (p<0.0001). Patients with TM and type I diabetics had significantly lower HDL-C compared to controls (p<0.0001). Apo A level was significantly higher in thalassemic and diabetic patients compared to controls (p<0.001). Apo B level was significantly lower in thalassemics and diabetics compared to controls (p<0.001). A significant increase in CIMT was found in thalassemics and diabetic patients compared to controls (p<0.001). In TM patients, CIMT was positively correlated with age (r=0.39, p=0.05), HbF (r=0.5, p=0.004), serum ferritin (r=0.73, p=0.001) and serum cholesterol (r = 0.59; p=0.001). In diabetic patients CIMT was positively correlated with age (r=0.52, p=0.003), random blood sugar (RBS) (r=0.43, p=0.02), hemoglobin A1c (HbA1c) (r=0.59, p=0.001) and serum TC (r=0.45, p=0.01). *Conclusions*. Atherogenic lipid profile was prevalent in young β-TM with increased carotid intima thickness (CIMT) suggesting increased risk of premature atherosclerosis. CIMT assessment can be used as a prognostic factor for vascular risk stratification and planning for preventive measures.

1007

SILICA CLOTTING TIME IN LABORATORY DIAGNOSIS OF LUPUS ANTICOAGULANT (LA). AN USEFUL TOOL FOR DIAGNOSIS OF ANTIPHOSPHOLIPID SYNDROME (APS) IN PATIENTS ON ANTICOAGULANT TREATMENT

N. Fernandez-Mosteirin, N. Fernandez-Mosteirin, N. Salvador-Osuna, M. Torres, B. Soria, F. Sevil, N. Padron, A. Godoy, M. Guillen, M. Abio, A. Iborra, C. Sierra, J.F. Lucia, D. Rubio-Felix

Miguel Servet Universitary Hospital, ZARAGOZA, Spain

Background. LA autoantibodies can interfere with phospholipid-dependent clotting tests *in vitro*, and inhibit both the common and intrinsic pathways of coagulation. The activated partial thromboplastin time (APTT), and the dilute Rusell's viper venom time (dRVVT) are currently the most frequently utilized assays. Silica clotting time (SCT) is not affected by oral anticoagulants and could be a very sensitive/ specific test for detecting LA. *Aims*. To evaluate the sensitivity and specificity of the SCT for detecting LA in patients with clinical criteria of APS, with/without associated connective tissue disease or prolonged APTT compared to the results obtained by APTT and dRVVT assays. *Patients and Methods*. Along a period of two months, 220 patients underwent evaluation for suspected hypercoagulability status. In cases with clinical criteria of APS according to the Sapporo International Consensus Statement, the clinical files (demographic, clinical and inherited and acquired thrombophilic risk factors) of patients, were reviewed. PTT-LA, dRVVT and SCT were performed using an ACL TOP-3G automatized coagulometer (Instrumentation Laboratory). *Results*. 220 patients were evaluated for hyperocoagulable status (including LA). Positive result for LA was detected in 43 patients (19.5%) male 18 (41.8%) and female 25 (58.1%) with a median age of 50 years (range: 5-82). Clinical events were deep vein thrombosis/pulmonary embolism 14 (32.5%); cerebrovascular disease 9 (20.9%); arterial ischaemia 5 (11.6%); venous and arterial thrombosis 2 (4.6%); obstetric complications 1 (2.3%); connective tissue disease 8 patients (18.6%) and 4 (9.3%) prolonged APTT. 14 of 43 (32.5%) were under oral anticoagulant treatment (OAT). 17 patients were diagnosed of APS on the basis of clinical and biological data. dRVVT were positive in 40 (93.02%) and 18 patients (41.8%) for SCT. Sensitivity and specificity: SCT relative to dRVVT 50% and 66.6%. PTT-LA relative to dRVVT 42.5% and 66.6%. In the 14 receiving OAT sensitivity and specificity values were: SCT relative to dRVVT 46.1% and 100% respectively. In 17 APS patients sensitivity and specificity values were: SCT relative to dRVVT 70.6% and 100%. In patients with APS receiving AOT sensitivity and specificity values increased: SCT relative to dRVVT 85.7% and 100% respectively. The presence of vascular thrombosis in patients diagnosed of APS was compared to the dRVVT and SCT: 9 patients (53%) showed deep vein thrombosis/pulmonary embolism, 2 (11.7%) showed cerebrovascular disease, 2 (11.7%) showed obstetric complications and 4 (23.5%) showed arterial ischaemia. In 12 patients (70.5%) dRVVT and SCT were both positive, in the remaining 5 patients (29,41%) SCT was negative and dRVVT positive, altough 2 of these patients showed a post-surgical thrombosis. *Conclusions*. 1) In our serie Sensitivity of SCT relative to dRVVT is similar to previously reported, but specificity values are lower. 2) Higher values concerning sensitivity and specificity of SCT relative to dRVVT were obtained in APS patients receiving OAT, according with previously reported data. 3) In our experience SCT seems to be an useful tool in laboratory diagnosis of LA specially in patients on OAT.

1008

POTENTIAL FUNCTION OF EGF1 DOMAIN PEPTIDE IN ANTICOAGULATION THERAPY: BINDING TO TISSUE FACTOR WITHOUT THE ABILITY OF COAGULATION

H. Mei, Y. Hu, H. Wang, X. Zhang, F. Zhou, T. Guo

Institute of Hematology, WUHAN, China

Background. Tissue factor (TF) is exposed to blood upon vascular damage and binds to activated factor VII (FVIIa) to initiate blood coagulation cascade *in vivo*. The first epidermal growth factor-like (EGF1) domain is reported to be important for activation of FVII/TF and we presume that the clone and expression of EGF1 domain peptide would be helpful in studying the anticoagulation drugs based on FVIIa/TF interaction. *Aims*. To explore the potential function of EGF1 domain peptide in anticoagulation therapy.

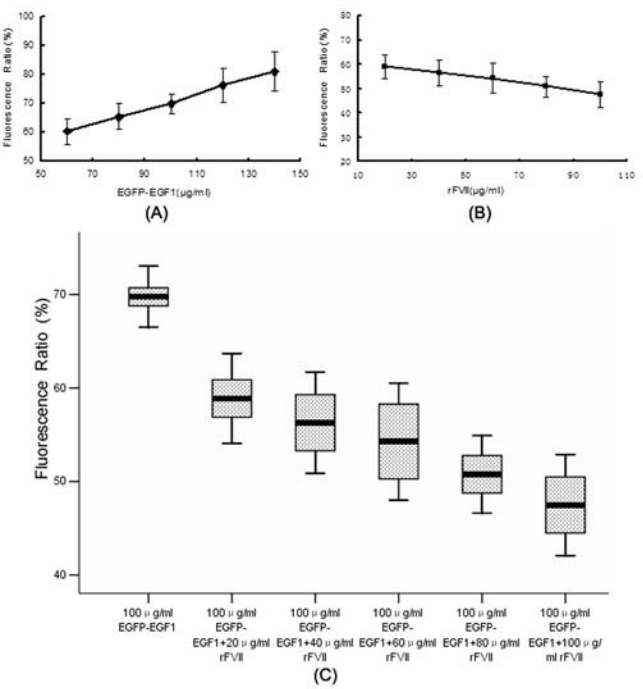

Figure 1. Competition assay of EGFP-EGF1 protein by FASCS.

Methods. We amplified the EGF1 domain from a rat liver and the EGFP-EGF1 fusion proteins were expressed in E.coli BL21. The affinity of rat soluble TF (sTF) was quantitated by surface plasmon resonance (SPR). Subsequently, the model of rat TF (rTF) expression *in vitro* was established by lipopolysaccharide induction. The affinity of TF expressed cells was analyzed by confocal microscope and flow cytometry. Blood clotting activity was tested by prothrombin time assay using FVII depleted human plasma. *Results*. The SPR results indicated the association constant ka of EGFP-EGF1 proteins was higher when compared with rat FVII (rFVII) (8.29±1.39 VS 3.75±0.32, $p<0.01$). The rFVII could definitely depress the integration of EGFP-EGF1 with rTF (69.76±3.29% VS 58.88%±4.81%, $p<0.01$). However, the EGFP-EGF1 proteins lost the activity of coagulation when compared with that of blood plasma of normal SD rats (56.8±3.2s VS 17.8±3.4s, $p<0.01$). *Conclusions*. The rat EGF1 domain peptide could specifically bind to TF without the ability of coagulation, which might be a molecular target for anticoagulation therapy.

1009

RELATIONSHIP BETWEEN INR MEASURED WITH DIFFERENT THROMBOPLASTINS, COAGULATION FACTOR LEVELS AND THROMBIN GENERATION IN PATIENTS RECEIVING ORAL VITAMIN K ANTAGONISTS

K.M.J. Devreese,[1] E. Bailleul[2]

[1]Ghent University Hospital, GHENT; [2]Hematology Laboratory OLV Hospital, AALST, Belgium

Background. The International Normalised Ratio (INR) is the standard method for monitoring oral anticoagulant therapy with vitamin K antagonists. In clinical practice we observe variation in INR measured with different thromboplastins. In contrast to the prothrombin time (PT) thrombin generation (TG) assays offer a more global assessment of coagulation. *Aims*. We evaluated whether differences in INR could be explained by sensitivity of thromboplastins to coagulation factor levels. We studied also the association between INR and parameters of TG. *Methods*. INR was measured with 6 thromboplastins (Coaguchek S®-Roche, Thromborel S®- Siemens, Innovin®- Siemens, Thrombotest®- Axis-Shield, Neoplastine CI Plus®- Stago, Neoplastin R®- Stago) on 83 plasmas of anticoagulated patients (in a range of INR-Coaguchek between 0.9 and 4.7). Innovin and Neoplastin R are recombinant thromboplastins, while all others are not. FII, FVII, FX and FV levels were determined by one stage PT-based clotting assay triggered with Innovin and Neoplastin CI plus. TG was measured by Calibrated automated Thrombinography (CAT) triggered with Innovin. *Results*. Passing and Bablok regression comparing the point of care method (Coaguchek) and the INR by Innovin, Thrombotest and Neoplastin R yielded a slope of 1.077 (95% confidence interval, CI, 1-1.2), 0.967 (95% CI: 0.875-1), 1.008 (95%CI: 0.885-1.118), respectively, and an intercept of -0.096 (95%CI: -0.4 to 0.1), -0.133 (95%CI: -0.2-0.131), -0.108 (95% CI: -0.362-0.229), respectively. Comparison of Coaguchek with Thromborel S and Neoplastin R yielded CI of slope and intercept indicating a difference between methods. Paired Wilcoxon test comparing the FII, FVII and FX PT-based clotting assays triggered with Innovin and Neoplastin CI plus showed significant different levels ($p<0.0001$). Correlation between all INR values and mentioned coagulation factor levels was good, with the highest Pearson correlation coefficient (r) for INR-Thromborel S and factor assays performed with Innovin. A progressive decrease of endogenous thrombin potential (ETP) and peak height (PH) was observed as the INR increases. ETP and PH correlated well with INR values obtained with all thromboplastins (r for ETP ranged from -0.601 to -0.684 and for PH from -0.576 to -0.678). Correlation between coagulation factor levels and ETP and PH was good. FII PT-based clotting level triggered with Neoplastine CI Plus correlated best with ETP (r= 0.873) and PH (r=0.838). No correlation was found with the lag time. 33 samples out of the 83 showed a difference of INR-Coaguchek and INR-Innovin of more than 10% (-22.22 to 24.0%). In this subpopulation coagulation factor levels were comparable with those in the total population (Man Whitney test p= 0.1920-0.8256). ETP correlated well with INR values obtained with all thromboplastins (r from -0.500 to-0.621). *Conclusions*. Our results show that TG and INR are closely correlated. There is no difference in correlation between recombinant and non-recombinant thromboplastins. Despite the efforts of standardisation by expressing results of PT in INR in anticoagulated patients, differences in PT-INR are observed depending on the thromboplastins used. The differences in INR measured with different thromboplastins can not be explained by sensitivity of thromboplastins to coagulation factor levels.

1010

ENDOTHELIAL KLF4 LINKS PRO-INFLAMMATORY LEVELS TO THE EXPRESSION OF PAI-1 AND VWF GENE

L.H. Yang

The Second Hospital of Shanxi Medical University, TAIYUAN, SHANXI PROVINCE, China

Background. The vascular endothelium plays a critical role in vascular homeostasis and maintains blood fluidity. Both biomechanical and biochemical stimuli can affect endothelial gene expression. *Aims*. Identification of factors that mediate the effects of these stimuli on endothelial function is of considerable interest. Pro-inflammatory cytokines can affect prothrombotic properties and regulate blood fluidity. Some studies indicated that endothelial cells can express Krüppel-like factor 4(KLF4), which may have an anti-inflammatory effect. The role for KLF4 in endothelial thrombotic function has not been elucidated. *Methods.* The human umbilical vein endothelial cells(HUVECs), which has been transfected by recombinant adenoviral vector carrying KLF4 antisence RNA, were treated with human IL-1β, TNF-α at final concentrations of 2.5 ng/mL and 10 ng/mL, respectively, for 4 hours. The mRNA expression and the protein diversity of plasminogen activator inhibitor-1 (PAI-1) and von Willebrand factor (vWF) were detected by virtue of Real Time-PCR and Western blot, meanwhile, the expression and location of KLF4 were observed by confocal laser microscope. *Results*. Our study observed that pro-inflammatory mediators significantly up-regulated endothelial KLF4, PAI-1 and vWF expression. Comparing with the control infected cells, in the experimental cells, down-regulated of KLF4 leads to increase of TNF -α and IL-1β induced endothelial cell PAI-1 and vWF expression. Conclusions KLF4 can suppress the expression of PAI-1and vWF under basal and cytokine-stimulated conditions. These observations implicate that, in response to pro-inflammatory stimuli, KLF4 is an anti-thrombotic factors.

1011

THE ANTITHROMBOTIC AND BLEEDING EFFECTS OF DABIGATRAN, A DIRECT THROMBIN INHIBITOR, AS COMPARED TO ENOXAPARIN, HEPARIN AND WARFARIN IN RATS

J. Van Ryn, I. Kuritsch, M. Kink-Eiband, H. Priepke, W. Wienen

Boehringer Ingelheim Pharma GmbH & Co KG, BIBERACH, Germany

Dabigatran etexilate is an orally available direct thrombin inhibitor approved in Europe for the prevention of DVT following orthopedic surgery. Chronic treatment for stroke prevention in patients with atrial fibrillation and VTE treatment Phase III studies are ongoing. Comparators in these studies are not only heparins, but also warfarin. *Objective*. To determine the antithrombotic efficacy of dabigatran as compared to clinically used agents in an arterial venous (AV) shunt model in the rat and compare this to the bleeding potential of these compounds in the same species. *Methods*. The antithrombotic doses of dabigatran, heparin, enoxaparin and warfarin were tested in a rat AV shunt model (determined as ED50). All compounds were given as an iv infusion over 1 hr, except warfarin, which was dosed orally for 4 days. Thrombus formation was measured over 15min within the shunt. Bleeding was measured in the rat tail model using a similar dosing scheme. Standardized cuts were made in the tail of the anesthetized rat following increasing doses of the coagulation inhibitors. The time until bleeding stopped was recorded. Blood sampling for plasma levels and clotting tests were also performed. *Results*. A dose-dependent antithrombotic effect was obtained with all compounds. The dose that resulted in 50% thrombus inhibition (ED50) was 0.07 µmol/kg/hr for dabigatran, 0.02 µmol/kg/hr heparin (~50 U/kg), and 0.07 µmol/kg/hr (~0.3 mg/kg) enoxaparin and 0.58 µmol/kg for warfarin (~0.18 mg/kg oral daily dose). All compounds also had increased bleeding with increased doses. Doses of dabigatran up to 15-fold the ED50 were required before significant bleeding was observed in this model, similar to both heparin and enoxaparin. Doses of warfarin, however, only 2-3-fold the ED50 resulted in significant bleeding. *Conclusions*. Direct inhibition of thrombin by dabigatran is as effective and potent as clinically used antithrombotic agents. Its safety profile is also similar to heparin and enoxaparin, the latter being confirmed in Phase III clinical trials after orthopedic surgery. However, the safety profile in this model was improved vs warfarin, which may be a further benefit for chronic antithrombotic therapy with dabigatran.

1012

MIRNA EFFECT ON THE SEPTIC PHENOTYPE

Y. Alhamdi, M. Perez-Casal, C.H. Toh

University of Liverpool, LIVERPOOL, UK

Background. MicroRNAs are small non-coding regulatory RNAs that control the expression of more than one third of the human genes. Although some studies have explained the role of miRNAs in immunity and inflammation, no information is yet available about their role in sepsis. *Aims*. to identify which miRNA species are involved in regulating the function of the endothelial cells in a state of sepsis and whether activated protein C (APC)- a common treatment in severe sepsis- can affect the expression of these miRNAs. *Methods*. endothelia cells (line EA.hy926) were treated in duplicates as follows: baseline (no treatment), 20 μg/mL LPS, 100nM APC and a combination of 20 μg/mL LPS and 100 nM APC. miRNAs were isolated from the cells using mirVanaTM miRNA Isolation Kit (Ambion). Reverse transcription to cDNA and quantitative real time PCR (qRT-PCR) was performed in an array to show the expression profile of a wide range of miRNAs. *Results*. The following miRNAs showed a fold change of ≥1.5 in a simulated sepsis state (miR-142-5p, miR-142, miR-30d, miR-191, miR-17, miR-130a, let-7i, miR-93, miR-106b, miR-150, miR-186, miR-222, let-7b, miR-27a, let-7f, miR-22, miR-122, miR-302a, miR-7, miR374b, miR-196b, miR-302b, miR-28-3p and miR-302c). The expression of most miRNAs was reduced by APC. Five miRNAs showed dramatic reduction in expression by APC (miR-374b, miR-302c, let-7f, miR-106b and miR-27a). *Conclusions*. several miRNAs are affected by the mimicked sepsis phenotype and they might play a role in controlling endothelial function during sepsis. APC treatment abrogates the effect of LPS on miRNA expression. We propose that these changes will have a functional effect on endothelial cells and this will be our next project.

1013

GENETIC VARIABILITY OF FIBRINOGEN A-CHAIN GENE DEFINES FIBRINOGEN LEVELS BETWEEN HEALTHY INDIVIDUALS AND PATIENTS WITH DOCUMENTED ATHEROSCLEROSIS: EFFECTS ON PROTHROMBOTIC PROFILE

I. Bossinakou, M. Kozanitou, N. Papageorgiou, A. Vlachopoulou, D. Tousoulis, E. Andronopoulou, M. Tsekoura M, C Stefanadis C, E Bossinakou

Hippocratio General Hospital, ATHENS, Greece

Background. Fibrinogen plays an key role in atherogenesis. A genetic polymorphism on fibrinogen a-chain, the G58A, has been associated with fibrinogen levels in healthy individuals, but its effect on patients with coronary artery disease (CAD) is still unknown. In the present study we examined the impact of this polymorphism on fibrinogen levels and its relation to the prothrombotic profile. *Methods*. The study population consisted of 230 subjects, 179 of which with angiographically documented CAD and the rest with angiographically documented absence of any significant coronary stenoses. The G58A polymorphism was detected by Polymerase Chain Reaction (PCR) and appropriate restriction enzymes. Fibrinogen levels were measured by a nephelometric method, while other factors of thrombosis such as plasma levels of D-dimers, factors V, X, plasminogen were measured by standard coagulometry techniques. *Results*. The genotype distribution was GG: 39.6%, AG: 40.2%, AA: 20.2% and GG: 37.3%, AG: 49.0%, AA: 13.7% for CAD patients and healthy individuals respectively. Among the three genotypes there was no significant difference in fibrinogen levels of CAD patients (128.6±32.4 vs 115.8±29.5 vs 127.8±33.4 mg/dL, p=NS for all). Patients with CAD had significantly higher levels of fibrinogen than healthy individuals regarding to the G58A polymorphism (456.3±131.2 vs 385.3±102.0 mg/dL, $p<0.001$). In addition, there were significant differences fibrinogen levels between the same genotypes of the two populations (CAD vs healthy, AA: 477.5±123.1 vs 386.8±62.7, GG: 452.4±146.3 vs. 374.8±114.0, AG: 449.1±119.3 vs 393.6±104.0 mg/dL $p<0.05$ for all). Similarly, d-dimers levels were significantly higher in the CAD than healthy subjects regarding to the G58A polymorphism (555.8±628.7 vs 360.3±336.7 mg/L). On the contrary, levels of thrombotic markers did not differ significantly between CAD and healthy individuals: fV (124.0±31.8 vs 115.0±25.1%), fX (94.2±23.2 vs 90.3±18.7%), plasminogen (109.5±19.0 vs 107.7±14.7 u/mL) p=NS for all. *Conclusions*. Genetic polymorphism G58A on fibrinogen a-chain gene fails to affect the prothrombotic profile as healthy subjects and CAD patients presented with no differences on specific markers. On the contrary, it turns to be effective on fibrinogen levels implying a potential mechanism which promotes atherosclerosis.

1014

THE IMPACT OF THE GENETIC POLYMORPHISM G455A OF FIBRINOGEN B-CHAIN GENE ON FIBRINOGEN LEVELS, LOW-GRADE INFLAMMATORY PROCESS AND ENDOTHELIAL FUNCTION IN PATIENTS WITH ADVANCED ATHEROSCLEROSIS

I. Bossinakou, N. Papageorgiou, M. Kozanitou, D. Tousoulis, Z. Pallantza, A. Vlachopoulou, M. Tsekoura M, C Stefanadis C, E Bossinakou

Hippocratio General Hospital, ATHENS, Greece

Background. The genetic polymorphism G455A on fibrinogen b-chain gene has been associated with fibrinogen levels in healthy individuals, but its effect on fibrinogen levels, low-grade inflammation and endothelial function in patients with advanced atherosclerosis remains unknown. Therefore, in the present study we examined the impact of this polymorphism on fibrinogen levels and other pro-thrombotic molecules, low-grade inflammation and endothelial function in patients with coronary artery disease (CAD). *Methods*. The study population consisted of 293 patients undergoing cardiac catheterization with stable or no CAD. The G455A polymorphism was estimated by PCR and suitable restriction enzymes. Serum levels of C-reactive protein (CRP) and fibrinogen were measured by nephelometric methods. In addition, levels of sCD40-ligand (cd40L) were determined by enzyme-linked immunosorbent assay (Elisa). Endothelial function was measured by estimating flow-mediated dilation of the brachial artery (FMD), with ultrasound. *Results*. The genotype distribution was GG: 51.8%, GA: 37% and AA: 11.2%. There were significant differences among fibrinogen levels across the genotypes of the studied population (AA: 517.4±145.0, GA: 431.5±130.0, GG: 434.2±127.3 mg/dL, $p<0.01$ for AA vs GA and AA vs GG respectively, p=NS for GA vs GG). Among patients with CAD AA patients had significantly higher levels of fibrinogen only than GA patients (AA: 517.5±144.0, GA: 434.0±132.2, GG: 443.0±121.0 mg/dL $p<0.05$ for AA vs GA). C-reactive protein and sCD40L levels did not differ among the study genotypes GG (2.8±4.3 mg/L and 2.4±1.1 μg/mL), GA (3.1±4.5 mg/L and 2.9±2.1 μg/mL) and GG (3.5±3.5mg/L and 2.9±1.3 μg/mL) p=NS for all. Similarly, in patients with established CAD there was no significant difference in CRP or sCD40L levels between GG (2.9±5.2mg/L and 2.5±1.2 μg/mL), GA (2.5±2.5 mg/L and 3.0±2.1μg/mL) and AA (3.1±2.6 and 2.7±1.2mg/L) p=NS for all. Despite the fact that AA patients with CAD had lower FMD than GG and GA this difference did not reach any statistical significance AA (3.3±3.7%) compared to AG(4.7±3.0%) and GG(4.3±4.0%) p=NS for all. *Conclusions*. Our findings suggest that there is a significant correlation between specific genotypes of G455A polymorphism and fibrinogen levels in patients with CAD. On the contrary, this genetic polymorphism fails to affect thrombotic mechanisms, endothelial function and low-grade inflammation in these patients. These findings indicate that the genetic polymorphism G455A on fibrinogen b-chain gene affects fibrinogen levels independently of inflammatory process and endothelial function in patients with CAD.

1015

A NORMAL D-DIMER VALUE, MEASURED BY A HIGH SENSITIVITY ASSAY, RULE OUT A SUSPECTED VENOUS THROMBOEMBOLISM EPISODE INDEPENDENTLY OF PRETEST CLINICAL PROBABILITY

J. Casals-Sole,[1] D. Bernaudo,[2] J. Camp,[3] N. Lozano,[4] E. Ballester,[5] G. Escolar[6]

[1]Hospital Clinic, BARCELONA, Spain; [2]Unita Medicina Generale, Ospedale S. Paolo, NAPOLI, Italy; [3]Family Medicine, Thromboembolism Unit (UFMATE), Hospital Clinic, BARCELONA, Spain; [4]Thromboembolism Unit (UFMATE), Fundacio Clinic, BARCELONA, Spain; [5]Pneumology, Thromboembolism Unit (UFMATE), Hospital Clinic, BARCELONA, Spain; [6]Hemotherapy-Hemostase, Thromboembolism Unit (UFMATE), Hospital Clinic, BARCELONA, Spain

Background. In only 13 to 25% of patients with clinical Venous Thromboembolism (VTE) suspicion, the disease is confirmed by an image study. Academically is recommended, before practice any exploration, to asses the clinical pre-test probability, following explicit rules (ei. Wells criteria); so, when a patient has a low or moderate pretest clinical probability, a normal D-Dimer, measured by a non-necessarily high sensitivity method but previously evaluated, rule-out a VTE episode. However, in general clinical practice, out of clinical trials, these explicit rules are rarely employed. Aims. To prove that the diagnostic strategy to systematically measure D-Dimer levels, whatever the explicit criteria are to all suspicions of VTE, and avoiding the image determination to the patients with normal levels, is safe for them and cost-beneficial for the Institu-

tion. *Methods*. Observational survey and management study, carry out between 12/2006 to 09/2008, in a University Hospital. From all daily D-Dimers orders and image explorations practiced, we register all suspicions of VTE consecutively raised. Deep Vein Thrombosis (DVT) was diagnosed by ultrasounds, while Pulmonary Embolism (PE) was diagnosed by CT or Lung Scan. Blood levels of D-Dimer were measured by a quantitative ELISA by fluorescency rapid assay (D-Dimer Exclusion, VIDAS, BioMerieux, Lyon, France). A cut-off of 500 ngr/mL was chosen. All patients with a normal D-Dimer value were followed by phone calls, for three months, asking for safety to avoid anticoagulants. From these data, a cost-benefit analysis was practiced. *Results*. A total of 3051 suspected VTE episodes were detected. D-Dimer was measured in 2240 cases. From 529 suspicions with a normal D-Dimer value, only one episode of VTE was found (a relapsed DVT) (Table). Similar prevalence in VTE was found, in the suspicion group with high levels of D-Dimer measured (25.07%) that in non-measured group (23.10%). [Chi-square = 1.43, p=0.23, odds ratio 1,13 (CI 95=0.92-1.37)].That's why other criteria, than pre-test clinical probabilities, were used for obviate D-Dimer ordering. D-dimer measurement to all suspicions of VTE is cost-benefit if the prevalence of patients with normal D-Dimer levels is more than 19.7% for DVT or 17,5% in PE suspicions. Increasing age had a lesser probability to found a normal D-Dimer, with values of 29%, 19% and 16% in segments of 60-69, 70-79 and 80-84 years old respectively. Cancer was found in 583 patients in D-Dimer measured group, evidencing a normal D-Dimer value in 138 cases (23.6%). With the strategy to measure D-Dimer to all suspicions of VTE, we compute a saving cost for each VTE episode of 72,6 € for DVT founded, 160,7 € for PE diagnosed by lung scan and 372,2 € for each detected PE when CT is employed. *Conclusions*. D-Dimer determination by this method to all patients with suspicion of VTE, independently of the pretest clinical evaluation, could reject one out of every four patients with safety, providing that the patients in anticoagulant treatment or relapsing episodes are excluded, and also with an important cost reduction in image explorations, if very older patients are excluded.

Table 1.

	Venous Thromboembolism				
		Present	Absent	Total	PPV / NPV (CI 95 %)
D-Dimer	Increased > 500 ngr/ml	**429**	**1282**	1711	PPV **25,07 %** (23,03 – 27,13)
	Normal < 500 ngr/ml	**1**	**528**	529	NPV **99,81 %** (99,79 – 99,83)

ELEVATED LEVELS AND DIFFERENT SUBSETS OF PROCOAGULANT MICROPARTICLES IN BREAST CANCER PATIENTS USING HORMONAL THERAPY

M.C. Trappenburg,[1] M. van Schilfgaarde,[1] H.M. Spronk,[2] H. ten Cate,[2] A. Leyte,[1] W.E. Terpstra[1]

[1]Onze Lieve Vrouwe Gasthuis, AMSTERDAM; [2]Maastricht University, MAASTRICHT, Netherlands

Background. Circulating microparticles (MP) are known to be elevated in cancer and thromboembolic disease. Since breast cancer patients using hormonal therapy have an increased risk for thrombosis, we hypothesized a role for MP in this hypercoagulable state. *Methods*. Plasma samples were collected from 20 breast cancer patients without metastatic disease using adjuvant hormonal therapy, 20 patients with metastatic breast cancer using hormonal therapy and from 20 female controls. The hormonal therapy used was either an anti-estrogen or an aromatase inhibitor. Levels and cellular origin of MP were determined by flowcytometric analysis. In addition, the MP-induced thrombin generation (TG) was determined using the calibrated automated thrombogram method. *Results*. Breast cancer patients had higher levels of MP expressing Annexin V (median 8200 vs 6540×10^6/L, p=0.03) P-selectin (CD62P, median 330 vs 200×10^6/L, p=0.01), Tissue Factor (median 33 vs 15×10^6/L, p=0.001), and of MP derived from epithelial cells (CD227, MUC1) (p=0.005), leucocytes (CD45) (p=0.005) and endothelium (CD144) (p=0.002). MP- associated thrombin generation showed a higher peak height (79 vs 69 nM, p=0.04) and area under the curve (AUC) (1130 vs 1029 nM.min, p=0.006) in breast cancer patients. Both for MP levels and TG parameters no differences were observed between the metastatic and adjuvant group, nor between the anti-estrogens and aromatase inhibitors. *Conclusions*. Altered MP subset characteristics in breast cancer patients using hormonal therapy, especially the higher number of Annexin V and P-selectin positive MP, may induce heightened procoagulant activity. Presence or absence of metastatic disease seemed to have smaller or no impact on these parameters, probably reflecting the inactive disease state of breast cancer patients on endocrine treatment.

1017

ROLE OF JAK2 MUTATION IN PATIENTS WITH SPLANCHNIC VEIN THROMBOSIS: AIIMS EXPERIENCE

S. Rathi, S. Sazawal, B. Sharma, T. Seth, A. Saraya, R. Saxena

AIIMS, DELHI, India

Background. Splanchnic veins thromboses which include portal vein thrombosis and thrombosis of the hepatic veins causing Budd Chiari syndrome are frequent presenting complication of an undiagnosed myeloproliferative disorder (MPD). The recently identified JAK2 V617F somatic mutation that occurs in MPD patients is a risk factor for portal, hepatic and mesenteric venous thrombosis, independently of the presence of overt MPDs. Screening of JAK2 mutation may be useful in identifying patients who should be carefully observed for the subsequent development of overt MPDs. In view of this, we studied JAK2 V617F mutation in patients with splanchnic vein thrombosis. *Materials and Methods*. A total of 26 patients with splanchnic vein thrombosis and without cirrhosis of liver were screened by ARMS technique for JAK2 mutation. These patients presented to hematology and gastroenterology Department, All India Institute of Medical Sciences, New Delhi, India. The distribution of cases was as follows; 11 portal vein thrombosis (PVT), 13 Budd Chiari syndrome (BCS) and two cases having both PVT and mesenteric venous thrombosis (MVT). *Results*. The JAK2 V617F mutation was identified in 3/13 cases with BCS (23%) and 2/11 patients with PVT (18%). None of the patients with MVT were positive for JAK2 mutation. Overall 5/26 patients (19%) with splanchnic vein thrombosis were positive for JAK2 V617F mutation. Patients with JAK2 V617F mutation had higher median TLC as compared to those who were negative for JAK2 mutation (11.2×10^9/L vs. 6.3×10^9/L). The median platelet count in patients with JAK2 positivity was 207×10^9/L and 105×10^9/L in patients who were JAK2 negative. *Conclusions*. This study shows presence of JAK2 mutation in splanchnic vein thrombosis and its association with higher leukocyte count and platelet count. This observation needs to be confirmed in a larger number of patients. Hence screening for the JAK2 V617F mutation may be useful to recognize patients who should be carefully observed for the subsequent development of overt MPD.

1018

A TWO YEAR OBSERVATIONAL STUDY OF PATIENTS ATTENDING A DEEP VEIN THROMBOSIS CLINIC-DEMOGRAPHICS, RISK FACTORS AND ANATOMICAL SITE OF THROMBOSIS

J. Blundell,[1] J. McClure,[2] A. McSorley[1]

[1]Royal Cornwall hospital, TRURO; [2]Royal Cornwall Hopsital, TRURO, UK

Background. Deep venous thrombosis (DVT) is a common clinical problem. There have been marked advances in the diagnostic and therapeutic strategies for management of DVT. The advent of low molecular heparin (LMWH) has led to outpatient therapy for patients presenting with DVT. However our understanding of the epidemiology of DVT is based on studies of mainly hospital based patients. Similarly there is little information on the anatomical distribution of DVT in the outpatient population. It may be important to identify subgroups such as patient with ileofemoral thrombus for consideration of more intensive management. *Aims*. Outpatient management of DVT has been normal practice in our hospital since October 2000. We wished to investigate the demographics and risk factors of the population presenting with DVT to our clinic and to establish the anatomical distribution of thrombi reported. *Methods*. The sex, age and any risk factors of patients present-

ing to the DVT clinic between October 2006 and October 2008 were obtained from the specially designed DVT record sheet. The radiology results (venogram and Doppler ultrasound) were obtained from the PACS system (patient archiving computer system). *Results*. A total of 3600 patients attended as outpatients for investigation of possible DVT, of these there were 366 (10%) who had DVT. There were slightly more men than women 54% as compared to 46%. The age range was wide from 24-86 in the men and 19-91 in women. The majority of patients were over 50 yrs (73%) with only 2% being less than 30 years. Many patients had significant risk factors for DVT; past history was the most common risk factor (23%). Over 21% had a history of surgery within the last 3 months and 18% had a diagnosis of malignancy. Travel was also a common risk factor with 18% having travelled. In the women 5% were taking either the oral contraceptive pill or hormone replacement therapy. The majority of DVTs were above knee -54%, below knee DVTS -30%, ileofemoral.- 5%, axillary vein- 1% and there were 10% of DVTS that were described as extensive. *Conclusions*. Although the majority of patients are elderly with known risk factors for DVTS they can be managed on an outpatient basis. There were at least 15 cases of ileofemoral DVT that may have been suitable for more aggressive management to reduce morbidity. The number of ileofemoral DVTS may have been underestimated as some radiological reports were ambiguous stating extensive DVT. We recommend all radiological reports clearly state the proximal extent of the thrombus.

1019

THROMBOEMBOLISM PREDICTIVE FACTORS IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

A. Bellora, S. Tamiazzo, V. Primon, M. Pini, M.T. Corsetti, E. Cornaglia, M. Demichelis, R. Santi, L. Contino, A. Levis

SS Antonio and Biagio Hospital, ALESSANDRIA, Italy

Background. Polycythemia vera (PV) and Essential Thrombocythemia (ET) are myeloproliferative chronic diseases characterized by the frequent expression of JAK2V617F mutation (90% and 60% respectively). Thromboembolism is a complication that highly impacts on overall survival. A relationship between JAK2+ and Thrombotic events has been suggested. *Aims*. A retrospective study of a group of patients affected by PV and ET, tested for JAK2V617F mutation and classified in accordance with WHO 2008 guide-lines, has been performed. We tried to study potential correlation between thrombotic events and clinical and laboratory variables. *Methods*. We retrospective analysed the incidence of both arterial and venous thrombosis and their relationship with clinical variables. *Results*. We considered 85 patients: 46 female and 39 male. Among 21 patients with PV 16 (76%) were JAK2V617F$^+$ and 5 (24%) JAK2V617F-. Among 64 patients with ET 37 (58%) were JAK2V617F$^+$ and 27 (42%) JAK2V617F-. A thrombotic event occurred in 16 patients during the course of their disease: 5 (24%) within the PV group (3 venous and 2 arterial) and only 11 (17%) within the ET group (7 venous and 4 arterial). The mean and median time between diagnosis and the occurrence of the thrombotic event were 325 and 198 days respectively. The mean and median time between the start of any treatment for the mieloproliferative disorder and the occurrence of the thrombotic event were 220 and 161 days respectively. Platelets (plt), leukocytes (wbc) and haematocrit (ht) at diagnosis were not statistical different between patients who had a thrombotic event and those who did not (Table 1).

Table 1.

Diagnosis	Time	Plt x 10^9	Wbc x 10^9	Ht %
PV without thrombosis	Diagnosis	394	10,8	55,8
PV with thrombosis	Diagnosis	369	10,1	57,9
PV with thrombosis	Event	479	14	51,9
ETwithout thrombosis	Diagnosis	785	9,2	42,1
ET with thrombosis	Diagnosis	1027,2	11,2	42,4
ET with thrombosis	Event	973,2	11,4	46,4

Moreover blood count variables were not different between the diagnosis and the time of the thrombotic event (table 1). JAK2 positivity did not influence the occurrence of a thrombotic event: 15,6% in JAK2- versus 20,8% in JAK2$^+$ patients. At the event time all the 16 patients with thrombosis were treated with ASA, and 12 of them received also cytostatics. Only advanced age showed a significant correlation with the occurrence of a thrombotic event (p=0,004). *Conclusions*. We confirmed the high incidence rate of thromboembolic complications in patients affected by PV and ET. Both JAK2$^+$ and leucocitosis have been suggested as a risk factor for thrombosis, but in our experience none of them statistically influenced the occurrence of a thrombotic event. This can be due to the relative low number of patients analysed. Further cooperative prospective studies on large group of patients are needed in order to better identify risk factors, mainly the role of leukocyte and platelets interaction.

1020

JAK2 MUTATIONAL STATUS, HEMOSTATIC RISK FACTORS AND THROMBOPHILIC FACTORS IN ET PATIENTS

B. Sokolowska,[1] A. Nowaczynska,[2] K. Bykowska,[3] S. Chocholska,[2] K. Wejksza,[4] A. Walter-Croneck,[2] M. Kandefer-Szerszen,[4] T. Gromek,[2] A. Kowalska,[5] A. Dmoszynska[2]

[1]Medical University of Lublin, Poland, LUBLIN, Poland; [2]Department of Hematology Medical University, LUBLIN, Poland; [3]Institute of Hematology and Blood Transfusion, WARSZAWA, Poland; [4]Virology and Immunology, University of Marie Curie-Sklodowska, LUBLIN, Poland; [5]The Children's Hospital of Philadelphia, PHILADELPHIA, USA

Background. The recent discovered of tyrosine-kinase activating JAK 2 V617F point mutation has been found in 50-60% of Essential Thrombocythemia (ET) patients. Increased risk of thrombosis in patients with this mutation has been reported. Other factors that increase the risk of thrombosis arising from ET itself include hereditary thrombophilic factors but also increase or decrease level of coagulation factors. *Aims*. In this study we explored if indeed JAK2 V617F mutation in ET patients coexisted thrombophilic factors that would contribute to thrombotic complication and a higher risk of thrombosis. *Methods*. We have examined 32 patients with ET (24 females and 8 males, mean age 56.0±14.2). This group included: 10 untreated patients, 22 treated with anagrelide, and hydroxyurea. The control group (CG) consisted of 20 healthy persons: 6 males and 14 females (mean age 41.4±8.3). We search for pathogenetic JAK2 V617F mutation and prothrombotic: Factor V Leiden, prothrombin gene and MTHFR gene mutations. We evaluated also plasma levels of: Factors: I,VIII,XII; AT, protein C and S. Urokinase concentration was assessed in plasma and in platelet lysates. Platelet activation was studied using flow cytometry to detect CD61/CD42b and CD61/CD 62P expression on the platelet surface. *Results*. Mean platelet count was 785±32G/l and 250±54G/l for ET and the CG, respectively, p<0.001. WBC count was higher in ET patients than in CG: 8.3±3.7G/l and 5.4±1.4G /l, p<0.001. Concentration of uPA was higher in patient plasma as compared to the CG(0.635±0.232ng/mL versus 0.447±0.115ng/mL, p<0.05). Mean uPA concentration measured in platelet lysates was similar in both group (ET 0.317±0.135ng/109 platelets, CG 0.290±0.065 ng/109 platelets). In 11 patients from ET group thrombotic complications occurred and in 7 ET patients bleeding episodes were noticed. Patients with thrombotic complications as compared to those with bleeding episodes had higher fibrinogen and factor VIII level (420 mg/dL versus 302mg/dL p<0.05, and 115% versus 88% p<0.05 respectively). In patients with thrombotic complications compare to patients without this complications lower CD61/42b expression was detected (1.74% versus 10.00% p<0.05). The JAK 2 V617F point mutation was detected in 18(60%)ET patients. In all cases heterozygous genotypes were determined. In 10(37%) ET patients the MTHFR gene mutation was detected, in 6 patients simultaneously with JAK2 mutation. In 13(65%) persons from CG the MTHFR gene mutation was discovered. No prothrombin G20210A mutation was found in ET patient and in CG. In ET patients with JAK2 point mutation the higher level of red blood cells was found (4.38±0.57T /l and 3.86±0.55T /l, p<0.05 respectively). The activity of factor XII in JAK2 positive patients was lower than in negative ones (83.2±25.5% and 109.0±20.4% respectively p<0.05). In ET patients carrying MTHFR gene mutation (compared to wild type for MTHFR) the higher level of plasma urokinase was observed (0.747±0.3ng/l and 0.547±0.2ng/mL p<0.05). *Conclusions*. Summing up these results in the group of patients with heterozygous JAK2 point mutation we have not observed increase frequencies of thrombotic complications. To evaluate the risk of thrombosis it is necessary to assess not only JAK2 mutational status but also additional risk factors of as well thrombosis as bleeding

1021

ENDOTHELIAL CELLS AND ENDOTHELIAL PRECURSOR CELLS KINETICS IN HAEMATOLOGICAL PATIENTS UNDERGOING CHEMOTHERAPY OR AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Pytlik,[1] L. Kideryová,[1] K. Benešová,[2] R. Veselá,[1] J. Karban,[3] H. Rychtrmocová,[1] M. Trnený[1]

[1]1st Medical Faculty, Charles University, PRAHA 2; [2]Institute of Haematology and Blood Transfusion, PRAHA 2; [3]General University Hospital, PRAHA 2, Czech Republic

Background. Circulating endothelial cells (EC) and endothelial precursor cells (EPC) may reflect tumour load, vessel injury and endothelial healing capacity. Their kinetics during treatment of cancer patients is unknown. *Aims*. To study the kinetics of circulating endothelial cells (EC) and endothelial precursor cells (EPC) in haematological patients during chemotherapy and autologous stem cell transplant (ASCT). *Methods*. 18 newly diagnosed patients and 17 patients undergoing ASCT were studied and compared to healthy controls. ECs were evaluated as $CD146^+CD31^+Lin^-$ cells, while EPCs were evaluated as $CD34^+CD133^+Lin^-$ or $CD34^+VEGFR2^+Lin^-$ cells or CFU-En colony forming units. Numbers of these cells were evaluated before and after treatment, and, in patients treated with ASCT, during mobilization of haematopoietic progenitors. *Results*. Both newly diagnosed patients and patients before ASCT had significantly higher number of $CD146^+CD31^+Lin^-$ cells and significantly lower number of CFU-En colonies than healthy controls. These parameters did not return to normal for at least 3 months after chemotherapy or ASCT. Numbers of CFU-En did not correlated neither with numbers of $CD34^+CD133^+Lin^-$ cells nor with numbers of $CD34^+VEGFR2^+Lin^-$ cells, but they correlated with numbers of $CD4^+$ lymphocytes and NK cells. *Summary and Conclusions*. Haematological patients have higher number of EC and lower numbers of CFU-En than healthy controls. These parameters do not return to normal after treatment, probably as a result of endothelial damage caused by chemotherapy and of ongoing immunological dysfunction.

1022

THE IMPACT OF THE GENETIC POLYMORPHISM G455A ON THE B-CHAIN FIBRINOGEN GENE ON THROMBOTIC PROCESS IN PATIENTS WITH CORONARY ARTERY DISEASE

I. Bossinakou, M. Kozanitou, D. Tousoulis, N. Papageorgiou, E. Andronopoulou, M. Tsekoura M, C Stefanadis C, E Bossinakou

Hippocratio General Hospital, ATHENS, Greece

Background. Evidence suggests that fibrinogen plays a critical role in atherosclerosis. A genetic polymorphism on fibrinogen chain B, the G455A, has been associated with fibrinogen levels in healthy individuals, but its effect on thrombotic process in patients with coronary artery disease (CAD) is unclear. In the present study we examined the effect of this polymorphism on prothrombotic profile of patients with CAD. *Methods*. The study population consisted of 243 individuals, 191 of which with angiographically documented CAD and the rest with angiographically documented absence of any significant coronary stenoses. The G455A polymorphism was detected by PCR and suitable restriction enzymes. Fibrinogen levels were measured by immunonephelometry, while other factors of thrombosis such as plasma levels of d-dimers, factors V and X, plasminogen and thrombin time were measured by standard coagulometry techniques. *Results*. The genotype distribution was GG: 48.2%, AG: 40.3%, AA: 11.5% and GG: 50.0%, AG: 34.6%, AA: 15.3% for CAD patients and healthy individuals respectively. Among CAD patients AA patients had significantly higher levels of fibrinogen than GA patients. There was no difference among other genotypes (AA: 517.5±144.0, AG: 434.0±132.2, GG: 443.0±121.0 mg/dL $p<0.05$ for AAvsGA, p=NS for AAvsGG, GAvsGG). Plasma plasminogen levels did not differ across the three genotypes GG (106.3±19.1 u/mL) compared to GA (112.5±20.0 u/mL) and AA (115.8±11.5 u/mL), p=NS for all. Moreover, there was no significant difference in plasma levels of factor X (AA: 94.1±20.3 vs GA: 91.6±26.1 vs GG: 101.2±23.2%, p=NS for all), factor V (AA: 124.9±28.4 vs AG: 125.7±34.4 vs. GG: 122.0±32.2%, p=NS for all), thrombin time (AA: 19.5±3.2 vs. GG: 20.8±18.4 vs GA: 19.0±1.7 sec, p=NS) and D-dimers (AA: 551.7±321.5 vs GA: 511.4±526.7 vs GG: 616.3±817.4 mg/L p=NS). *Conclusions*. Genetic polymorphism G455A on fibrinogen b-chain gene affects fibrinogen levels, but has no effect on other thrombotic markers. These findings indicate that this polymorphism may play important role in the process of atherothrombosis by affecting only fibrinogen levels, but not other thrombotic parameters.

1023

ASYMPTOMATIC BRAIN MAGNETIC RESONANCE IMAGING ABNORMALITIES IN ADULT PATIENTS WITH THALASSEMIA INTERMEDIA

A. Taher,[1] K. Musallam,[1] W. Nasreddine,[2] A. Inati,[2] A. Beydoun[1]

[1]American University of Beirut Medical Center, BEIRUT; [2]Rafic Hariri University Hospital, BEIRUT, Lebanon

Background. A hypercoagulable state in the thalassemia syndromes has been established. Thromboembolic events are more frequently observed in thalassemia intermedia (TI) patients who are splenectomized and not maintained on regular transfusion regimens. Brain involvement has been poorly studied. Although the incidence of clinically overt stroke in TI is low, silent strokes have been observed in 37% of patients by one study. *Aims*. To evaluate the frequency and risk factors for silent brain abnormality in adult patients with TI who are splenectomized and not maintained on regular transfusion regimens. *Methods*. This was a cross-sectional study on a sample of TI patients attending to the Chronic Care Center, Hazmieh, Lebanon. Patients who are above 18 years of age, splenectomized, not on regular transfusion regimens, and on no antiplatelet or anticoagulant medication underwent brain magnetic resonance imaging (MRI). Patients were initially screened to confirm absence of neurological signs or symptoms and other associated stroke related disease such as diabetes, hypertension, carotid stenosis, cardiac disease, or prothrombotic mutations. Patient charts were reviewed for any previous transfusion history and duration since splenectomy. Blood samples were obtained for assessment of total and fetal hemoglobin, nucleated RBC, platelet, and serum ferritin levels. Written informed consent was provided by all patients. *Results*. A total of 30 patients were included in this study. The mean age was 31.9±11 years (range: 18-54 years) and the male to female ratio was 13:17. The mean duration since splenectomy was 17±9.9 years (range: 2-36 years). Eighteen patients (60%) never received blood transfusions while 12 (40%) had occasional transfusions for transient anemia. A total of 18 patients (60%) had abnormalities on brain MRI. All patients with abnormal MRI had evidence of white matter lesions predominantly involving the frontal and/or parietal subcortical white matter (100%), with less frequent involvement of the external capsule (27.8%), occipital white matter (16.7%), temporal white matter and internal capsule (5.6% each). Four patients (22.2%) had single white matter lesions while 14 (77.8%) had evidence of multiple lesions (mean 5±10 lesions, range: 2 to more than 40 lesions). Most patients had small lesions (<0.5 cm) although 7 patients (38.9%) had lesions ranging in size between 0.5-1.5 cm and 1 patient (5.6%) had lesions greater than 1.5 cm. In addition, 11 patients (61.1%) had evidence of concomitant mild cerebral atrophy. Younger age (p=0.015) and occasional transfusion history (p=0.015) were significantly associated with a lower incidence of MRI abnormality. Moreover, occasional transfusion history (p<0.0001) and a shorter duration since splenectomy (p=0.045) were significantly associated with single, rather than multiple, lesions. Gender, total and fetal hemoglobin, nucleated RBC, platelet and serum ferritin levels had no significant correlations with presence of abnormality or number of lesions detected. *Summary and conclusions.* Silent white matter lesions on brain MRI is a common finding in adult, splenectomized and non-regularly transfused TI patients. Increasing age and a longer duration since splenectomy are associated with a higher incidence and multiplicity of abnormality, respectively; while occasional transfusion history seems to be protective for both.

1024

LOW LEVELS OF PROTEIN Z ARE ASSOCIATED WITH HELLP SYNDROME AND ITS SEVERITY

I.K. Kaygusuz,[1] T.F.T. Firatli Tuglular,[2] T.T. Toptas,[1] M.D. Demir[3]

[1]Marmara University, ISTANBUL; [2]Marmara University School of Medicine, ISTANBUL; [3]Trakya University School of Medicine, EDIRNE, Turkey

Background. Microtrombus formation in the materno-placental circulation and infarcted areas on placenta caused by defects in coagulation cascade have been speculated for the etiology of HELLP syndrome. Protein Z, a cofactor of a vitamin K-dependent protease inhibitor, play a role in the inhibition of factor Xa. Protein Z has been found to be associated with pregnancy complications. However, there is not any data implying an association between HELLP and changes in maternal plasma levels of protein Z. *Aims*. To investigate if HELLP syndrome is associated with maternal plasma concentrations of protein Z. *Methods*. Protein Z levels in 29 women with HELLP syndrome were compared with 29 healthy-nulliparous and 25 pregnant women. Definition and classification of

HELLP syndrome was made according to Tennessee classification. Blood samples were obtained just after delivery in all pregnants. Concentrations of protein Z were determined by a sensitive and specific commercial immunoassays which utilizes sandwich enzyme immunoassay technique (Asserachrom Protein Z®, Diagnostica Stago and Serbio, Asnieres-sur-Saine, France). *Results*. All women were in same ethnicity. The median age was 29 (22-40), 29 (21.40) and 28 (22-47) for healthy, pregnant and HELLP groups, respectively (p=0.893). Median parity, gravidity and mean gestational age in patients with HELLP were 2 (0-9), 3 (1-10), 32.62±3.95 years, respectively. The median protein Z levels in HELLP syndrome were found significantly lower than those of pregnant women [864 (338-2220) ng/mL vs 1732 (726-4000) ng/mL, p=0.0001]. However, no significant difference was found between HELLP and healthy groups (864 (338-2220) ng/mL vs 958 (396-4000) ng/mL, p=0.597). On the other hand, when comparing, protein Z levels were obtained to be higher in pregnant women than those in healthy (1732 (726-4000) ng/mL vs 958 (396-4000) ng/mL, p=0.0001). (Figure 1). Despite protein Z levels in patients with HELLP were comparable with those in healthy women, protein Z levels were observed to be correlated with disease severity in HELLP syndrome. While a positive correlation exists between protein Z levels and platelet counts (rs=0.498, p=0.006), protein Z levels correlated negatively with LDH (rs=-0.458, p=0.012) and AST levels (rs=-0.374, p=0.046). Besides, median protein Z level was higher in partial HELLP than in complete HELLP (74 vs 39.85, p=0.038) (Figure 1). *Conclusions*. Protein Z levels are low in HELLP syndrome and related with its severity. Despite it is not clear whether low levels of protein Z causes HELLP syndrome or its levels lower during disease process, it should be kept in mind that it may play a role in the pathogenesis of HELLP syndrome beside suggested etiological factors like prothrombin 20210A and factor Leiden V mutations.

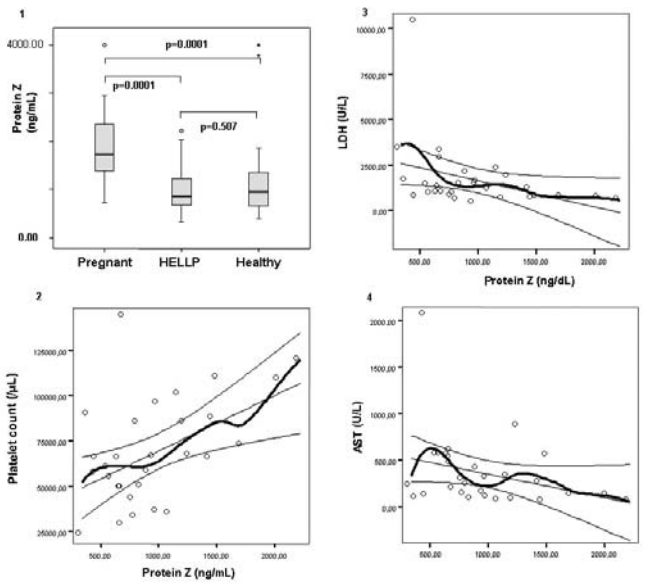

Figure 1. Protein Z levels in groups and its correlations

MOLECULAR TYPING OF P. AERUGINOSA ISOLATES ALLOWS TO TRACE WATER AS THE SOURCE OF AN OUTBREAK OF MULTIRESISTANT PSEUDOMONAS BLOODSTREAM INFECTIONS

C. Chiara,[1] F. Bracchi,[2] E. Casalone,[3] E. Borlenghi,[2] C. Barni,[4] M. Gelmi,[5] G. Ravizzola,[5] F. Donnarumma,[3] G. Mastromei,[3] L. Baushi,[2] N. Manca,[5] L. Jacquot,[4] G. Rossi[2]

[1]Spedali Civili, BRESCIA; [2]Ematologia, Spedali Civili, BRESCIA; [3]Dipartimento di Biologia Evoluzionistica, Università di Firenze, FIRENZE; [4]Direzione Sanitaria, Spedali Civili, BRESCIA; [5]Istituto di Microbiologia, Università di Brescia, BRESCIA, Italy

Background. The effectiveness of systematic surveillance culture is still a matter of debate. Epidemiological surveillance at a Haematology Unit allows to detect changing patterns among isolated pathogens and to discover potential external sources, in order to adopt adequate strategies of environmental control and to better plan empiric antibiotic therapy. Aims. To trace potential environmental sources responsible for outbreaks of bloodstream infections (BSIs) occurring at our haematology unit. Methods. We prospectively analyzed all bacteremic episodes occurring among hematological patients admitted at our Institution over 57 months of observation; to evaluate epidemiological changes occurring over time, we compared the frequency of different species among the pathogens isolated during two consecutive periods (A and B, respectively) of 28.5 months each. When an outbreak (defined as occurrence of an infection at a greater frequency than expected) was observed, pertinent environmental screening were performed, including monitoring of water sources. The genetic correlation between isolates was evaluated by molecular typing by Amplified Fragment-Length Polymorphism (AFLP) on strains isolated from environment and patients. *Results*. During the entire period of observation, 349 BSIs were recorded. Gram-positive (G+) bacteria were responsible for bactaeremias in 134 cases (38.4%), Gram-negative (G-) bacteria in 216 (61.9%) and fungi (all Candida spp) in 10 (2.9%). In 16 cases a mixed BSI was detected. Frequency of G+ and G- BSIs did not significantly differ during the two periods, although, in period B, viridans streptococci (10.5% vs 3.1%, p=0.011) and P. aeruginosa bactaeremias (20.5% vs 9.4%, p=0.0046) significantly increased. Viridans streptococci BSIs were not considered an outbreak as increasing in their frequency was slow and continuous over time. Of the 54 P. aeruginosa observed during the entire period, 18 (33.3%) were multiresistant (MR Pseud) and occurred only during the second period of observation. Eleven out of 18 MR Pseud were observed during the last six months of the study (August 2008 - January 2009), which was considered an outbreak. Therefore, cultures from water of the patients' bathrooms were performed on September 2008 and two P. aeruginosa clusters were detected based on antibiotic resistance pattern, one of which consisting of MR Pseud. AFLP analysis, performed on both water clusters and 6 out of 11 MR Pseud from patients, revealed >85% similarity within patient isolates and the environmental strains belonging to the MR Pseud cluster. Overall a fatal outcome was observed in 33/349 BSIs (9.4%). Mortality increased in the second period (12.6% vs 5.7%, p=0.04). While viridans streptococci BSIs were not associated to a bad prognosis, MR Pseud BSIs significantly correlated with a higher risk of death (p<0.0001), as 10/18 MR Pseud BSIs were associated to death. *Summary and Conclusions*. Genetic analysis of strains isolated from environment and patients revealed that the outbreak of MR Pseud BSIs had a clonal origin and was a consequence of water contamination. Our study confirms the importance of epidemiological observation in order to early detect outbreak and to proceed to specific environmental studies.

1026

CARDIAC BIOMARKERS AND ASSESSMENT OF CARDIAC TOXICITY DURING HEMATOPOIETIC CELL TRANSPLANTATION FOR HEMATOLOGICAL MALIGNANCIES

J.M. Horacek,[1] L. Jebavy,[2] M. Ulrychova,[1] M. Tichy,[1] P. Zak,[1] J. Maly[1]

[1]University Hospital Hradec Kralove, HRADEC KRALOVE; [2]Faculty of Military Health Sciences, HRADEC KRALOVE, Czech Republic

Background. Cardiac toxicity is a potentially serious complication of hematooncology treatment. Preparative regimen (PR) followed by hematopoietic cell transplantation (HCT) represents a high risk for devel-

opment of cardiotoxicity. Various methods including cardiac biomarkers have been recommended for monitoring of cardiotoxicity. Experience with new cardiac biomarkers in this context is very limited. *Aims*. Assessment of cardiac toxicity during HCT with multiple biomarkers of cardiac injury - myoglobin, creatine kinase MB (CK-MB mass), cardiac troponin I (cTnI), heart-type fatty acid binding protein (H-FABP), glycogen phosphorylase BB (GPBB). *Methods*. A total of 53 patients (mean age 49.9±12.3 years, median 54 years, 33 males) transplanted for hematological malignancies were studied. The diagnoses were as follows: AML 27, MM 12, NHL 5, HL 4, ALL 3, CML 1, MDS 1. Thirty transplants were autologous, 23 allogeneic. Cardiac biomarkers were measured on Randox Evidence analyzer the day after completion of PR (after PR) and the day after infusion of hematopoietic cell graft (after HCT). Values above the reference range recommended by the manufacturer were considered elevated. *Results*. The cut-off values of all biomarkers and the number of patients with elevated values are shown in the Table 1. We found significant elevations in GPBB (above 7.30 µg/L) in 8 (15.1%) patients after PR and in 9 (17.0%) after HCT. H-FABP increased slightly above the cut-off (4.50 µg/L) after HCT in 1 (1.9%) patient. Other cardiac biomarkers (myoglobin, CK-MB mass, cTnI) remained within the reference range in all patients. *Conclusions*. Our results suggest that administration of PR followed by HCT could be associated with myocardial injury manifested by increased release of GPBB from cardiomyocytes. These findings could be considered a sign of acute subclinical cardiotoxicity. Whether these acute changes will have predictive value for development of treatment-related cardiomyopathy in the future is not clear and should be evaluated during a prospective follow-up. Further studies in a larger number of patients will be needed to confirm our preliminary results and define the potential role of new biomarkers in this context.

Supported by research projects MO 0FVZ0000503 and MZO 00179906.

Table 1. Elevated biomarkers of cardiac injury in the peritransplant period (n=53).

cardiac biomarkers	1 day after PR	1 day after HCT
myoglobin above 76.0 µg/L	0	0
CK-MB mass above 4.80 µg/L	0	0
cTnI above 0.40 µg/L	0	0
H-FABP above 4.50 µg/L	0	1 (1.9 %)

SERIOUS EBV ENCEPHALITIS IN PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) - SERIES OF 3 CASES

M. Kouba,[1] M. Markova,[1] V. Valkova,[1] M. Hricinova,[1] P. Soukup,[1] C. Salek,[1] J. Mertova,[1] J. Maaloufova,[1] P. Hubacek,[2] J. Cermak,[1] A. Vitek,[1] P. Cetkovsky[1]

[1]Institute of Haematology and Blood Transfusion, PRAGUE; [2]Department of Paediatric Haematology and Oncology, PRAGUE, Czech Republic

Background. Epstein-Barr virus (EBV) infection in alloSCT patients causes various disorders ranging from asymptomatic increase of PCR detected DNA copies in body fluids to highly malignant post transplant lymphoproliferative disease. We show 3 cases of serious encephalitis - a clinical syndrome rarely described in literature. *Aims*. In 3 well-documented cases we describe a clear correlation of neurological status with EBV DNA quantity in cerebrospinal fluid (CSF) as well as prompt improvement of consciousness after receipt of rituximab. *Methods*. In a tertiary haemato-oncological centre we have observed among 344 alloSCT recipients in a period of 6 years (2003-2008) 3 cases of post transplant EBV reactivation with deeply decreased level of consciousness. The three patients recovered their neurological status to normal soon after treatment with rituximab. *Results.* CASE1: 58 years old woman developed abulia, tremor, bradypsychia and nausea on day + 60 of mismatched related alloSCT for high grade myelodysplastic syndrome (MDS) after myeloablative conditioning including anti-thymocyte immunoglobulin (ATG). No gross abnormality was seen on CT scan of her brain. High load of EBV DNA in peripheral blood, bone marrow and CSF (11300 copies/mL) were detected. Shortly after single dose of rituximab the patient improved dramatically. CASE 2: 39 years old woman developed sopor on day +50 of mismatched unrelated alloSCT after myeloablative conditioning (including ATG) for high risk acute myeloid leukemia (AML). Later she developed bilateral fluidothorax. High load of EBV DNA in fluidothorax and peripheral blood and CSF investigations suggesting viral encephalitis lead to therapy by foscarnet and rituximab with prompt recovery of the neurological status and disapearance of fluidothorax. CASE 3: 35 years old man after mismatched sibling SCT for high grade MDS after myeloablative conditioning (including ATG) was readmitted to hospital on day +58 because of fever and vomiting. Mild aGVHD was diagnosed from gastric biopsy. The neurological status of the patient deteriorated rapidly to sopor (without any pathology visible on MRI scan). Lumbar puncture revealed lymphocytosis in CSF and high levels of EBV DNA were detected in both blood and CSF (31200/mL). After first dose of rituximab the neurological status returned to normal within days. *Conclusions*. Our experience suggests that serious encephalitis with sopor without gross morphological changes on CT or MRI scans characterized by high EBV DNA load in cerebrospinal fluid and prompt recovery after rituximab treatment is a distinct clinical syndrome occuring in patients shortly after alloHSCT.

MOLECULAR DIAGNOSIS APPROACH OF BLOOD STREAM INFECTIONS OF THE NEUTROPENIC PATIENT WITH HAEMATOLOGICAL MALIGNANCES

V. Pavone, G. Lobreglio, G. Pasanisi, G. Maggio, M.C. Cosi, C. Zecca, C. Del Casale, A.R. Messa, S. Sibilla, A. Mele, R. Defrancesco

A.O. Card. G. Panico, TRICASE (LECCE), Italy

Background. Life-threatning Infections are a relative common complication in febrile neutropenic patients (pts) with haematological malignancies, mainly due to depth and duration of neutropenia. Therefore, the evidecence of infectious origin during neutropenic fever is the main point in the management of neutropenic patients and for the antibiotic treatment strategy. The current gold standard for the detection of bacterial pathogens in blood is blood culture. Howeverthe blood culture suffers from several limitations, such as lack of rapidity and low sensitivity, especially if the patient has been already treated by empiric antibiotics. *Aims*. We evaluated a novel molecular tool for the diagnosis of bacteriaemia directly from blood samples, comparing its features to those of an automated continuous-monitoring blood culture system. *Methods*. We analyzed 166 febrile episodes in severe neutropenic patients (neutrophil count $<0.5\times10^9$ L^{-1}) admitted to the Haematology Unit. 71 pts with haematological neoplasm were analysed: 21 pts with ANLL, 30 pts with lymphoproliferative disordrers and 20 pts who underwent hemopoietic stem cell transplantation. At the same time a blood culture was requested and five ml of blood was also sampled for the molecular assay (LightCycler SeptiFast Test, Roche Diagnostics). *Results.* 45/166 (27.1%) bacteriemias were documented. In 20/45 (44%), both the methods arranged for systemic infections by Gram-positive or Gram-negative bacteria or fungi. 23/45 (51%) febrile episodes were identified only by the molecular assay (particularly S. aureus, A. baumanni, K. pneumoniae, P. aeruginosa, S. maltophilia, A. fumigatus, C. albicans and C. krusei). 2/45 (4.4%) febrile events were identified only by the blood culture (S. hominis and Burkholderia cepacia), this last not anticipated as target to molecular method. *Conclusions*. Our data confirm the negative and positive predictive value of the molecular assay in monitoring febrile neutropenia. The new molecular tools allow to elaborate new diagnostic algorithms to underline the microbes in the blood stream of the neutropenic patient with haematological malignances. Indeed, the molecular method allowed a faster identification of the pathogens and a more rapid and correct antibiotic treatment.

1029

THE ROLE OF PROPHYLACTIC ANTIMICROBIALS DURING AUTOLOGOUS STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

C. Suh, B.S. Sohn, D.H. Yoon, S. Kim, D.H. Lee, S.W. Kim, J.S. Lee

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Although prophylactic antimicrobials had been used frequently for ASCT, the benefits of antimicrobial prophylaxis in ASCT was controversial, partly because ASCT has a relatively short period of neutropenia compared with allogeneic SCT. However, antibacterial chemoprophylaxis with fluoroquinolones in neutropenic patients has reduced the incidence of Gram negative bacteremia in many literatures. *Aims*. The aim of this retrospective study was to investigate the efficacy of fluoroquinolone based antimicrobial prophylaxis during autologous peripheral stem cell transplantation (ASCT) in patients with multiple myeloma (MM) and non-Hodgkin's lymphoma (NHL). *Methods*. We searched Asan Medical Center Registry for NHL and MM. Total 114 cases received fluoroquinolone based antimicrobial prophylaxis consist-

ed of ciprofloxacin (500 mg twice daily p.o.), fluconazole (100 mg twice daily p.o.) and acyclovir (400 mg every 8hr p.o.). The prophylactic antimicrobials was started 1 day before high dose therapy (HDT), and continued until neutrophil engraftment or switching to intravenous broad spectrum antibiotics at the occurrence of signs of infection. Meanwhile, total 118 cases did not receive antimicrobial prophylaxis during ASCT. *Results.* In prophylaxis group, 80 of 114 (70.2%) patients had experienced febrile episodes at median day +6 after transplantation, which showed statistical difference compared with no-prophylaxis group (p<0.001). In no-prophylaxis group, 111 of 118 (94.1%) patients had experienced at median day +5 after transplantation. Documented infection occurred in 14 of 114 (12.3%) patients in prophylaxis group, and 16 of 118 (13.6%) patients in no-prophylaxis group (p=0.846). In these patients, the positive blood culture was seen in 12 (10.5%) of 114 patients in prophylaxis group, and 12 (10.7%) of 118 patients in no-prophylaxis group (p=1.000). Documented viral infection or reactivation was not observed in prophylaxis group, but observed in 4 patients of no-prophylaxis group. Both groups showed no invasive fungal infection or serious adverse event during ASCT. The day of infection resolved was a median day +15 (range, 3-29) in prophylaxis group and day +14 (range, 2-70) in no-prophylaxis group (p=0.945). The duration of antimicrobial treatment was median 10 days both in prophylaxis group and in no-prophylaxis group (p=0.565). The duration of hospitalization was median 20 days and 21 days, respectively. Three patients had expired during ASCT. In prophylaxis group, one patient had died of veno-occlusive disease followed by hepatorenal syndrome, and 1 patient died of MRSA sepsis. In no-prophylaxis group, 1 patient had died of complications of cardiac amyloidosis. Overall, serious adverse events or infection-related mortality rate was associated with infection was extremely rare at both groups (1.8% vs. 0.8%, respectively). *Conclusions*. In our experience, the antimicrobial prophylaxis seems to decrease the incidence of febrile episodes during ASCT. There was statistical significant lower incidence of febrile neutropenia with unknown origin in prophylaxis group. However, antimicrobial prophylaxis seems to have no beneficial effect on reducing infectious complications. The antimicrobial prophylaxis of our study did not show the difference in the detecting rate of causative organism as an infective agent, duration of antimicrobial therapy and hospitalization between two groups.

1030

EFFECTIVENESS AND SECURITY OF ITRACONAZOL FOR INVASIVE FUNGAL INFECTION (IFI) PRIMARY PROPHYLAXIS IN PATIENTS WITH ACUTE LEUKEMIA

C. Martinez, E. Lopez, I. Heras, A. Fernandez, M.L. Amigo, E. Perez, F.J. Ortuño, V. Vicente

Hospital Universitario Morales Meseguer, MURCIA, Spain

Background. Invasive fungal infection is one of the main causes of morbidity and mortality in neutropenic and acute leukemia patients, therefore an effective pharmacological primary prophylaxis with a low toxicity profile is necessary. *Aims*.To analyze the effectiveness and security of itraconazol in primary prophylaxis in patients with acute myeloid leukaemia (AML) or myelodisplastic syndrome (MDS) in our clinic. *Material and Methods*. We performed a retrospective study of consecutive patients diagnosed of acute myeloid leukaemia, who received itraconazol for antifungal primary prophylaxis, between June 2004 and April 2007. We study each neutropenic episode (NE) individually. Data were collected for the state of the disease, chemotherapy (induction, intensification), previous NE, steroids administration, HEPA filter room, comorbidities (cardiac insufficiency, bronchopathy, diabetes, hepatopathy, chronic renal failure), duration of neutropenia, liver function tests (LFT), duration of prophylaxis, reasons for withdrawn, and others. The statistical analysis consisted on comparison of variables using Kruskal Wallis and Chi2 or exact of Fisher. *Results.* Seventy-nine NE were analyzed. Median age of patients was 51 years (20-79). 67% were men and the rest female. In seventy-six patients the diagnosis was AML, 2 MDS and 1 blast crisis from a chronic myeloid leukemia. On 36 (45.6%) patients the NE coincided with the diagnosis of the disease. Thirty-five (44.3%) of the NE happened during induction chemotherapy. Only 6 had significant comorbidities previous to the NE. Forty-five patients (57%) were at HEPA filter room. All patients received itraconazol prophilaxis, in 49.4 of cases it was administer orally and the rest intravenously. The incidence of probable and proved IFI (by EORTC criteria) was 3.8% (3 patients). No statistically significant relationship was found between IFI and state of disease (p=0.763), chemotherapy (p=0.290) or way of administration of itraconazol (p=0.591). Effectiveness of itraconazol for antifungal prophylaxis was 83.5%. Sixteen patients presented different adverse effects (20.3%), in 10 of them (12.7%) hepatic toxicity attributable to the drug was observed, and digestive intolerance in 6 (7.6%), but withdrawn of prophylaxis because of adverse effects occurred in only 8 cases (10.1%). We observed a tendency for statistically association between bilirrubin high levels at the begining of prophylaxis and posterior hepatic toxicity (p=0.074). 3 patients (3.8%) died during prophylaxis period; no case was attibutable to IFI nor to drug toxicity. *Conclusions*. Itraconazol has demonstrated in our cohort to be an effective drug for antifungal primary prophylaxis in neutropenic patients with acute leukemia, without a significantive adverse effect rate.

1031

PROGNOSTIC FACTORS AND OUTCOME OF PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT (ICU) WITH HEMATOLOGICAL MALIGNANCIES

C. Martinez, E. Lopez, A. Carrillo, E. Perez, J.J. Sanchez, F. de Arriba, I. Heras, V. Vicente

Hospital Universitario Morales Meseguer, MURCIA, Spain

Background. Patients with haematological malignancies present complications that sometimes require the admission to the ICU. Traditionally, in these cases the prognosis and outcome is poor, so the identification of factors that allow physicians to decide the best management for these patients would be of much interest. *Aims*. 1. To analyze survival of patients with haematological malignancies admitted to the ICU in our University Hospital. 2. To identify prognostic factors at the moment of admission to the ICU, and through the stay to the time of discharge. *Material and Methods.* We performed a retrospective analysis of patients admitted to the ICU with diagnosis of hematological malignancy between January 2000 and December 2007. Data were colleceted for disease, cause of admission, previous hospitalization, blood tests, SOFA and SAPSII scales punctuation, mortality at hospital after 30 days and survival after 1 year after admission. *Results.* 169 episodes of admissions to the ICU were included. Median age was 57 (11-88) years, 95 were men (56.2%) and 74 women (43.8%). The diagnosis were acute leukaemia in 36.7%, lymphoproliferative disorders in 34.3% and multiple myeloma, myeloproliferative and myelodisplastic syndrome in 29%. One hundred one (65.6%) received chemotherapy in the previous month and 34 (20%) underwent haematopoietic stem cell transplantation (HSCT) before admission, 21 of them were allogeneic HSCT. The most frequent cause of admission was major acute respiratory failure (35.5%), followed by sepsis (20.7%) and primary heart failure. 72 (42.6%) received respiratory support with non-invasive ventilation (NIV), in 62 (37.6%) orothraqueal intubation was necessary and in 15 patients (8.9%) occurred the nonintubation order. Median stay at the ICU was 6 days (1-72). Overall mortality was 48.5%. Haematological disease was statistically related to mortality at hospital, being greater for the acute leukemia group (p=0.009). Mortality was also higher in patients with longer previous stay at hospital, ventilatory support required, central venous catheter carriers, need of parenteral nutrition and those with higher SOFA and SAPSII punctuation, as well as greater bilirrubin levels and deeper thrombopenia. *Conclusions*. 1.The most frequent cause of admission to the ICU was the respiratory failure followed by sepsis. 2. Mortality at hospital of these patients in our center was similar to the referred previously in the literature. 3. SOFA and SAPSII scales seem to be useful instruments to predict mortality in these patients.

COMPLIANCE TO IDSA-GUIDELINES FOR THE TREATMENT OF INVASIVE ASPERGILLOSIS IN ACUTE MYELOID LEUKEMIA

M. Caira,[1] A. Candoni,[2] M. Offidani,[3] B. Martino,[4] M. Luppi,[5] G. Specchia,[6] C.G. Valentini,[1] M.E. Tosti,[7] F. Aversa,[8] G. Leone,[1] A. Nosari,[9] L. Pagano[10]

[1]Catholic University, ROME; [2]Udine University, UDINE; [3]Ancona University, ANCONA; [4]Reggio Calabria Hospital, REGGIO CALABRIA; [5]Modena University, MODENA; [6]Bari University, BARI; [7]Istituto Superiore di Sanità, ROME; [8]Perugia University, PERUGIA; [9]Niguarda Hospital, MILAN; [10]Cathilic University, ROME, Italy

Background. In February 2008 revised guidelines of Infectious Disease Society of America (IDSA) for the treatment of invasive aspergillosis were introduced. *Aims*. To analyze physician's compliance with IDSA current guidelines and to evaluate guidelines' feasibility and utility in improving patients care. *Methods*. A multicenter registry was conduct-

ed. Patients with acute myeloid leukaemia and proven/probable invasive aspergillosis were evaluated for adherence to the current IDSA-guidelines in terms of choice, dosage and duration of antifungal target therapy. Two groups of patients (IDSA and non-IDSA) were thus defined and compared. *Results.* 136 cases were collected. Treatment choices adhered to IDSA guidelines in 55% of patients only. This cohort of pts was almost identical to that of pts whose treatment deviated from guidelines in terms of the principal epidemiological and clinical carachteristics. Survival analysis at 120th day did not show any difference between the 2 groups, while in terms of 1st line therapy efficacy 24% of patients failed in the IDSA- group versus 41% in remaining patients (p 0.03). *Summary and Conclusions.* Frontline therapy choice remains a crucial point, influencing patients' outcome. Guidelines design cathegories of patients with homogeneous carachteristics and suggest optimal diagnostic and terapeutic options for them. Unfortunatly there are frequent reasons to deviate from these general advises. In this context, our report has a double value: it bears witness of frequent guidelines' inapplicability in clinical daily practice, but it also supports their recommendations, even in a non-selected series.

Table 1. First line antifugal target therapy in the two cohorts of patients (IDSA versus non-IDSA).

	Drug	N° patients	N° failures	*p-value*	N°exitus (AMR)	*p-value*

1033

EFFICACY AND SAFETY OF MICAFUNGIN AS AN EMPIRICAL ANTIFUNGAL AGENT FOR FEBRILE NEUTROPENIC PATIENTS

J.S. Park

Ajou University Hospital, SUWON, South-Korea

Background. Invasive or possible fungal infection is often fatal and increasing the incidence in febrile neutropenic patients with hematologic malignancies. Empirical antifungal agent should be carefully selected. *Aims*. The study was conducted as a prospective multicenter trial to document the efficacy and safety of micafungin (Micamin), a class of echinocandin, in febrile neutropenic patients with hematologic disorders as an empirical antifungal agent. *Methods*. Micafungin was administrated at a dose of 100 mg/day intravenously for sustained fever (>38.4C) at 3-5 days after starting sufficient empirical antibiotic therapy. Overall success rate according to the composite score (no breakthrough fungal infection, survived for seven days beyond the end of therapy, did not discontinue therapy prematurely, had resolution of fever during the period of neutropenia, and successfully treated a documented base-line fungal infection) was evaluated and so was side effects, too. *Results.* AML (18/30), ALL (4/30), MDS (4/30) and lymphomas (4/30) patients were enrolled. The overall success rate according to the composite score was 56.7% (17/30). 93% (28/30) of the patients did not show breakthrough fungal infection, 93% (28/30) survived for seven days beyond the end of therapy, 67% (20/30) did not discontinue therapy prematurely, 67% (20/30) had resolution of fever during the period of neutropenia, and only 2 patients was documented base-line fungal infection and did not respond to micafungin. Two patients (7%) experienced grade 3 anemia and 13% (4/30) showed grade 3 or 4 of elevated transaminase. 23% (7/30) showed grade 3 or 4 hyperbilirubinemia, and four of them resolved. One patient died of hepatotoxicity. The response of ALL patients were superior to those of AML or MDS patients significantly (p=0.002). *Conclusions*. Micafungin documented an excellent efficacy (56.7%) and safety profile when used as an empirical antifungal agent to treat febrile neutropenic patients with hematologic disorders.

1034

MOLECULAR DIAGNOSIS BY LIGHTCYCLER? SEPTIFAST IN THE PREEMPTIVE TREATMENT OF INVASIVE FUNGAL INFECTIONS: A 5 CASES REPORT

D. Clerici,[1] N. Mancini,[2] B. Forno,[1] B. Cappelli,[1] S. Mastaglio,[1] C. Messina,[1] A. Crotta,[1] A. Assanelli,[1] C. Corti,[1] M. Bernardi,[1] J. Peccatori,[1] L. Fumagalli,[1] F. Crippa,[1] F. Ciceri,[1] M. Clementi[2]

[1]San Raffaele Scientific Institute, MILANO; [2]Microbiology Laboratory, University San Raffaele Scientific Institute, MILANO, Italy

Background. Invasive fungal infections (IFI) remain a leading complications with high morbidity in haematological patients undergoing intensive treatment. Despite new drugs active against yeasts and moulds, when the antifungal treatment is started at time of established clinical IFI, the organ damage is leading to severe impairment with significant rate of mortality. An early suspect of incipient IFI is an ideal condition for starting antifungal treatment, thus potentially translating in higher rate of success in infection control. Molecular diagnosis of infections is a new tool for early diagnosis of pathogens circulating in patients with sepsis and neutropenic fever (Mancini, J. Med. Microbiol. 2008). *Aims*. We tested the sensibility and the clinical impact of LightCycler® SeptiFast (Roche Molecular Systems) for molecular diagnosis of invasive fungal infection in a subset of patients at high risk of invasive fungal infections. *Methods*. From January 2007 in cohort of 105 febrile neutropenic patients affected by haematological malignancies each time a blood culture was requested, a small aliquot of blood (1.5 ml) was also sampled for the molecular assay by LightCycler® SeptiFast performed by the Microbiology Laboratory. SeptiFast is a real-time PCR-based assay capable to detect a wide panel of bacterial and mycotic pathogens, and in particular Aspergillus Fumigatus. The time of the PCR-assay is approximately 6 hours. We collected a total of 227 samples and we decided antimicrobial therapy on the LightCycler® SeptiFast result. *Results.* In 5 febrile neutropenic patients (2 AML, 1 ALL, 1 IMF, 1 HD) the SeptiFast was positive for Aspergillus Fumigatus, while the standard blood culture sampled at the same time point was negative in all the patients. The pulmonary CT scan was suggestive for fungal infection in all the 5 patients, while blood sample for detection of the galattomannan antigen was positive only in 2/5 patients. The BAL was performed only in 2 patients, and in 2/2 patients the culture was positive for Aspergillus Fumigatus. In 5/5 patients the SeptiFast result positive for Aspergillus Fumigatus determined a timely switch in the antifungal therapy. We observed in 3 patients the complete resolution of the fungal infection, while in 2 patients the fungal infection became better but they died in the following weeks for progression of the haematological malignancies. *Conclusions*. Molecular diagnosis by LightCycler® SeptiFast is an attractive tool for triggering early pre-emptive therapy for invasive fungal infections, A prospective study with systematic use of SeptiFast in combination with the established galattomannan blood levels and early radiological findings will be run.

1035

MOLECULAR DIAGNOSIS OF BACTERIEMIA IN NEUTROPENIC FEBRILE ONCOHEMATOLOGICAL PATIENTS. PRELIMINARY RESULTS

E. Gimeno,[1] M.L. Sorli,[2] E. Abella,[3] A. Alvarez,[3] J.P. Juan Pablo,[2] M.T. Gimenez,[3] A. Salar,[3] B. Sanchez,[3] C. Pedro,[3] S. Saumell,[3] C. Besses,[3] M. Salvado[4]

[1]Hospital del Mar, BARCELONA; [2]Infectious Disease Deoartment. Hospital del Mar., BARCELONA; [3]Hematology Department. Hospital del Mar., BARCELONA; [4]Laboratori de Referencia de Catalunya, BARCELONA, Spain

Background. The rapid diagnosis of bacteriemia in the course of fever of unknown origin plays an important role for the appropriate therapeutic treatment in neutropenic patients. In daily practice, blood culture helps identify bacterial and fungal bacteriemia. However, the efficacy of culture methods can be limited due to its low sensitivity when the patient is receiving antibiotic therapy and to the long period of time required to get a definitive identification of the pathogen (24-72 hours). Septifast® test (Roche Molecular Systems) is a new molecular technique for the detection of 25 most important bacterial and fungal species reported to cause bloodstream infections. *Aims*. The aim of the study was to compare the real-time PCR assay (Septifast®) with conventional blood cultures from neutropenic febrile oncohematological patients in a single institution. *Methods*. We prospectively tested 45 blood samples from 19 patients (pts), during a period of 5 months. All of them presented fever (>37.8°C) with a neutrophil count <0.5×10^9/L. Seven pts

were diagnosed with acute leukemia, 2pts with chronic lymphocytic leukemia, 5pts with aggressive lymphoma, 1pts with agranulocytosis, 1pts with medullar aplasia, 1pts with multiple myeloma, 1pts with pancreatic neoplasm and 1pts with grade 4 chondrosarcoma. At the moment of the study the patients were receiving antibiotic therapy with piperaciline-tazobactam or imipenem (19pts), vancomicine (7pts), amikacine (3pts), aciclovir (2pts) and antifungal therapy (9pts). Septifast® test (a real-time PCR assay) was applied in wholeblood samples of neutropenic febrile patients, providing results in only 6 hours. At the same time, two blood culture vials for aerobic and anaerobic cultures were drawn. *Results.* Thirty-two percent of patients presented a positive result. Eight of the 45 (17.7%) blood samples studied were positive by PCR assay (2 for Staphylococcus aureus; 3 for Pseudomonas aeruginosa; 1 for Esterichia coli; 2 Coagulase-negative staphyilococci). Two blood samples were positive for Pseudomona aeruginosa and Coagulase-negative staphyilococci by both Septifast® test and conventional blood culture. The entire negative PCR test results correlated with negative blood culture samples. The negative predictive value was 100% with a sensitivity of 100% and a specificity of 86%. (Table 1). *Conclusions*. Septifast® test is an easy and sensitive method for detecting pathogens in severely immunocompromised patients, allowing results in a shorter time than conventional blood cultures, having also higher sensitivity.

Table 1. Comparision results from Septifast® test and conventional blood culture system.

SEPTIFAST®	BLOOD CULTURE		TOTAL SAMPLES
	Positive Samples (%)	*Negative Samples (%)*	
Positive Samples (%)	*2 (4.4)*	*6 (13.3)*	*8 (17.7)*
Negative Samples (%)	0 (0)	37 (82.2)	37 (82.2)
TOTAL (%)	2 (4.4)	43 (95.5)	45 (100)

RESPIRATORY SYNCYTIAL VIRUS INFECTION OUTBREAK IN CHILDREN WITH HEMATO-ONCOLOGICAL DISEASES

A.U. Unuvar, S. Anak, D. Atay, Z. Karakas, G. Ozturk, T. Uzunhan, M. Garipardic, L. Agaoglu, O. Devecioglu

Istanbul University, Istanbul School of Medicine, ISTANBUL, Turkey

Respiratory syncytial virus (RSV) has been reported to cause mortality among adult cancer patients receiving chemotherapy with or without hematopoetic stem cell transplantation (HSCT), but there have been few reports describing the outcome of RSV infection in children with hemato-oncological diseases. Two RSV infection outbreaks developed in hospitalized pediatric patients for various hemato-oncological diseases with or without HSCT between February 20th and April 15th, 2006, and between January 7th and February 25th, 2009. Thirteen of 30 patients developed rhinorrhea, progressive cough and/or dyspnea in these two time periods. A survey of respiratory viruses was done by using direct immunofluorescent antibody assay from nasopharyngeal washing aspirate. RSV antigen was detected in six patients (one high-risk ALL receiving induction, and one standart risk ALL on consolidation chemotherapy (CT); one relapsed ALL, one stage IV neuroblastoma, and one relapsed Hodgkin lymphoma receiving intensive CT; one with post-BMT under treatment for chronic GvHD). In 2009, RSV RNA was assessed in 14 patients with or without symptoms, also. RSV RNA was positive in 9 of 14 patients, two of these nine patients were asymptomatic, and RSV antigen was positive in 3/9 patients with symptoms. The remaining patients with respiratory symptoms in the two different outbreak periods were followed-up for RSV infection, but remained negative during all surveys. Five of six patients with RSV antigen (+), and the sister (RSV antigen was negative) of the boy with hyper-IgM syndrome and RSV antigen (+), who was also transplanted for hyper-IgM syndrome and under treatment for chronic GvHD and pneumonia were all treated with 0.2 g/kg intravenous immune globulin (IVIG) and oral ribavirin. Five patients recovered fully, although two were retreated due to recurrent (+) RSV antigen and respiratory symptoms within two weeks. One of six patients is on ribavirin therapy, now. We did not give oral ribavirin to one patient with (+) RSV antigen due to mild symptoms. All patients are alive. In conclusion, we did not observe any oral ribavirin-related adverse event or mortality in our patients even in post-BMT period. It is possible to give the scheduled anti-neoplastic therapy for not being delayed. However, our study population is too small, and, new studies are needed for cancer patients with RSV infection.

1037

CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHEA IN HEMATOLOGY-ONCOLOGY PATIENTS

S. Delimpasi

Evangelismos Hospital, ATHENS, Greece

Background. Clostridium difficile-associated diarrhea (CDAD) in the cancer patient receiving chemotherapy is a frequent cause of morbidity and prolonged hospitalization. *Objective*. To determine the incidence density and identify risk factors associated with C difficile infection in hematology oncology patients. *Methods*. During a 7 month period (April -October 2007) all patients that were admitted and remained for more 48 hours in a haematology-oncology department in Athens, Greece, were studied. *Results.* The incidence rate of CDAD was 10.8%. The incidence density of C difficile associated diarrhea was 5.0 per 1.000 patient-days (14.2 per 1.000 patient-days at risk. Patients who developed CDAD had significantly longer stay than patients without CDAD (Median 30 vs 17 days, $p<0.001$). The median duration of neutropenia was statistically longer for patients with CDAD compared with patients without CDAD (8 vs 1, $p<0.001$).There was no significant difference in mortality between patients with CDAD and those without CDAD (9,1% vs. 7.7%., $p=0.875$). We found that chemotherapy before admission ($p=0.001$) and number of antibiotics ($p=0.001$) were independently predictive of CDAD by multivariate analysis. *Conclusions*. Special attention should be given to specific practical measures targeted at the practical prevention and control of Clostridium difficile infection.

IN VITRO ANTIBIOTIC SYNERGY ON MULTIDRUG-RESISTANT STRAINS OF PSEUDOMONAS AERUGINOSA ISOLATED FROM ONCOHAEMATOLOGICAL PATIENTS

G. Lobreglio, P. D'Aversa, M. Malagnino, L. Leo, M.J. Monteduro, L. Russo

A.O. Card G Panico, TRICASE, Italy

Background. Pseudomonas aeruginosa is a pathogen of great importance in the context of infections in patients with oncohaematologic desease; it is responsible for high morbidity and mortality of these patients. The strains selected from the broad use of antibiotics are often multidrug-resistant (MDR) or pan-resistant; thus the management of infections caused by P. aeruginosa in these patients is very difficult. *Aims*. Our aim was to evaluate *in vitro* synergy arising from the three different antibiotics pairs association on strains of P. aeruginosa pan-resistant isolates from oncohaematological patients, for all the strains an antimicrobial susceptibility testing had been previously performed by conventional methods in use.

Table 1. Frequencies of the categories for antibiotic association.

ANTIBIOTIC ASSOCIATION	CATEGORY		
	Indifference	Synergy	Antagonism
(CAZ) – (TM)	27/33 (81,82%)	6/33 (18,18%)	0/33 (0,00%)
(MEM) – (TM)	33/33 (100%)	0/33 (0,00%)	0/33 (0,00%)
(CAZ) – (TEC)	21/33 (63,64%)	12/33 (36,36%)	0/33 (0,00%)

Methods. 296 strains of P. aeruginosa isolated from oncohaematological patients, were identified through oxidase tests, catalase, VITEK system 2/GN cards and gallery API-20 NE (bioMérieux, Marcy-l'Etoile, France), 33 (11.15%) of which were pan-resistant, 3 with a mucoid morphotype and 30 non-mucoid. For each strain an antimicrobial susceptibility testing (VITEK system 2/card AST-N022 and Kirby-Bauer) was

performed according to the current CLSI guidelines. Through disc-diffusion in agar (susceptibility disks, Bio-Rad, Marnes la Coquette, France) for the 33 pan-resistant the following antibiotics associations were tested: ceftazidime (CAZ) 30 μg - tobramycin (TM) 10 μg, meropenem (MEM) 10 μg - tobramycin (TM) 10 μg, ceftazidime (CAZ) 30 μg - teicoplanin (TEC) 30 μg. *Results.* The 33 strains included in the assessment of synergy showed a pattern of antibiotic category (resistant 'R' for all antibiotics tested) perfectly superimposable by both methods used. The antibiotic pair ceftazidime - tobramycin showed synergy in 18.18% of cases while no synergy was found for meropenem - tobramycin association. The ceftazidime-teicoplanin association gave surprising results with 36.36% of cases of synergy (Table 1). *Summary and Conclusions*.These observations offer new and interesting therapeutic options for the treatment of this pan-resistant pathogen especially in the severe infections that affect oncohaematological patients.

1039

IFN-GAMMA RELEASE ASSAY RESPONSES IN PATIENTS WITH CLINICAL SUSPICION FOR PULMONARY TUBERCULOSIS, AND IN HEALTH-CARE WORKERS WITH POTENTIAL FOR EXPOSURE TO M. TUBERCULOSIS

G. Lobreglio, P. Barone, P. Errico, G. Maggio, M.C. Cosi, C. Zecca, G.C. Pasanisi

A.O. Card G Panico, TRICASE, Italy

Background. WHO defines tuberculosis as a major cause of illness and death worldwide. Renewed effort to accelerate progress in global TB control in line with the expectations of the Global Plan, supported by intensified resource mobilization from domestic and donor sources, is needed. In many high-income countries with low rates of tuberculosis, serial testing for latent TB infection (LTBI) is recommended for persons at increased risk of TB exposure. In this context, the development of more specific, *in vitro* assays for LTBI, interferon gamma (IFNγ) release assays (IGRAs), is a welcome development. These assays are highly specific, especially in bacillus Calmette Guerin (BCG)-vaccinated populations. *Aims*. To evaluate the tuberculin skin test (TST) and IGRAs responses in patients with clinical suspicion for pulmonary tuberculosis, and in health-care workers who served these patients. All subjects were immunocompetent and HIV negative. *Methods.* We studied TST responses and blood from 29 patients with clinical suspicion for pulmonary tuberculosis, and from 150 health-care workers who had had contacts with patients. The TST was administered by the Mantoux method (5 IU/mL of PPD). T-Spot TB assay was performed on the blood from subjects in study. The assay included two antigen (M. tuberculosis-specific ESAT-6, Early Secretory Antigen Target 6, and CFP10, Culture Filtrate Protein 10). *Results.* 10/29 patients were TST and IGRA positive. Two patients had pulmonary tuberculosis and IGRA prevailing response was directed against CFP10. Eight patients had clinical and/or radiological findings for remote infection and IGRA prevailing response was directed against ESAT-6. 25/69 health-care workers TST and IGRA negative have been vaccinated in past with bacille Calmette-Guérin. 18/50 health-care workers vaccinated were TST positive (induration > or = 10 mm) and IGRA negative and 2/50 were also IGRA positive. Besides, 15/50 TST positive health-care workers were non vaccinated; only three of these subjects were IGRA negative and 22 IGRA positive with prevailing response against ESAT-6 in 21 subjects and one with prevailing response against CFP10 (history positive for pulmonary tuberculosis). *Summary and Conclusions*.The risk of development of active TB has been established in several cohort studies with the TST. Also, from controlled clinical trials, we know that treatment of TST positive persons reduces the risk of active disease. Unfortunately, there are no equivalent data for IGRAs. The association between strong IFNγ response to ESAT-6 and subsequent progression to active TB among household contacts of index cases and the predictive positive value of a positive IGRA result are yet to be determined. Little is known about the response to CFP10. We find a stronger response to CFP10 in cases of pulmonary tuberculosis; moreover, IGRA is a useful diagnostic tool for the surveillance of exposure of HCWs vaccinated with bacille Calmette-Guérin to M. Tuberculosis.

Background. Hairy cell leukemia (HCL) is generally responsive to single-agent Cladribine (2CdA) and only a minority of patients are refractory and with poor prognosis. HCL generally express mutated (M) and, in a minority, unmutated (UM) immunoglobulin heavy chain variable region genes (IGHV). *Aims*. i) to investigate the clinical and molecular parameters predicting response and ii) to investigate the immunogenetic and molecular profile of the refractory patients. *Design and Methods*. In a multicenter clinical trial in newly diagnosed HCL, we prospectively investigated clinical and molecular parameters predicting response and event-free survival (EFS) after single-agent 2CdA. Of 58 HCL, 6 expressed UM-IGHV (UM-HCL) and 52 M-IGHV (M-HCL). Beneficial responses were obtained in 53/58 patients (91%), while treatment failures were observed in 5/58 (9%) patients. Responses correlated significantly with UM-IGHV (5/6 failures, p=0.000001), leucocytosis (3/6, p=0.005), and bulky spleen (4/8, p=0.0007). UM-HCL characteristically had bulky spleen (4/6, p=.002), leukocytosis (3/6, p=.01), TP53 defects (2/6, 33%, p=.03) as documented by mutational analysis and genome wide DNA profile (250K SNP Affymetrix array), and progressed rapidly after first treatment (median EFS 7.5 months, p=0.00000000000004). *Conclusions*. Our data suggest that UM-HCL identify the minor subgroup refractory to 2CdA and with more aggressive disease presentation. High incidence of TP53 disfunction indicates a potential mechanism of resistance to 2CdA in the UM-HCL group. Overall, our data provide new molecular elements for treatment concerns in HCL.

1041

BRIEF CHEMOIMMUNOTHERAPY RITUXIMAB (R)-FND +/- R MAINTENANCE IS EFFECTIVE AND SAFE IN NEWLY DIAGNOSED FOLLICULAR LYMPHOMA ELDERLY PATIENTS: AN INTERGRUPPO ITALIANO LINFOMI (IIL) RANDOMIZED TRIAL

Gallo[1]

[1]On the behalf of Intergruppo Italiano Linfomi, Hematology2, ASO San G. Battista, TURIN, Italy; [2]Roche, MONZA, Italy

Background. In order to maintain efficacy and reduce toxicity of the treatment in elderly follicular lymphoma (FL) patients, we designed a study with a short chemo-immunotherapy. *Aims*. Primary endpoint was

to compare the efficacy of Rituximab maintenance versus observation (control) in elderly FL patients responsive to a short chemo-immunotherapy R-FND plus Rituximab consolidation. *Design and methods*. From January 2004 to December 2007, 241 patients (age 60-75) with untreated advanced stage FL were enrolled into 33 IIL centres and 234 patients were eligible. Treatment plan was: 4 courses of R-FND (Rituximab 375 mg/m2 day 0, Fludarabine 25 mg/m^2 dd 1-3, Mitoxantrone 10 mg/m^2 day 1, Dexamethasone 10 mg dd 1-3) every 28 days followed by 4 weekly Rituximab (375 mg/m^2); responding (CR+CRu+PR) patients were randomized to receive Rituximab maintenance every 2 months for 4 doses or observation. Qualitative and quantitative PCR monitoring for IgH/Bcl-2 rearrangement was performed on bone marrow (BM) at diagnosis, after R-FND and R consolidation and during maintenance/observation. *Results*. Median age was 66 (60-75); advanced stage II 14%, stage III 21% and stage IV 65%; 55% had BM involvement and 18% B symptoms; FLIPI score was: Low 11%, Intermediate 34%, High 55%. One or 2 co-morbidities were present in 36% and 23% of the patients respectively. Qualitative PCR analysis was performed in 222 patients at diagnosis: 51% were Bcl-2 positive. Two hundred and two patients were randomized between maintenance or observation. Thirty-two were not randomized because of: stable/progressive disease (15), adverse events (11) or other causes (6). Overall response at the end of treatment was 86% with 69% CR and 17% PR; PCR negativity at the end of treatment was 74% with PCR negativity associated with CR in 67% of the patients. Rituximab consolidation after R-FND was able to induce CR in 36/88 (41%) PRs and to increase PCR negativity from 61% to 74%. With a median follow-up of 18 months, two-years OS and PFS were: 92% and 73% and shown in the Figure.

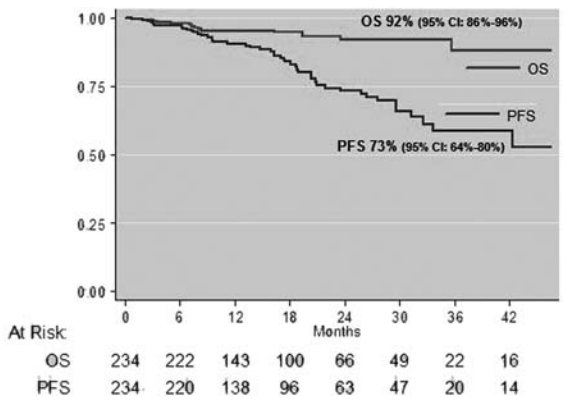

Figure.

Two-years PFS rates according to FLIPI score were: Low/Intermediate risk 85% vs High 65% (p 0.0002). A total of 1119 courses of chemo-immunotherapy were delivered. The most frequent CTC grade 3-4 toxicity was neutropenia in 25% of the courses, with only 13 serious infections. Pulmonary and cardiac toxicities were <1%. Two toxic deaths occurred: 1 HBV reactivation and 1 Steven Johnson Syndrome. Any grade Rituximab related reactions were seen in 6% of the courses with Rituximab discontinuation in only 2 patients. *Conclusions*. The results of this trial, specifically designed for elderly patients, show that a brief chemo-immunotherapy R-FND + Rituximab consolidation is safe and effective with a good 2-yr PFS rate also in patients at high risk FLIPI score. PCR negativity was achieved in the majority of the BCL2-rearranged patients. Further follow-up is needed to validate these observations. The final results of the study will provide insights on the role of Rituximab maintenance after R-chemotherapy.

1042

90YTTRIUM IBRITUMOMAB TIUXETAN (ZEVALIN) COMBINED WITH BEAM (Z -BEAM) CONDITIONING REGIMEN PLUS AUTOLOGOUS STEM CELL TRANSPLANTATION IN RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA. A GELA PHASE II PROSPECTIVE STUDY

C. Gisselbrecht,[1] D. Decaudin,[2] N. Mounier,[3] H. Tilly,[4] V. Ribrag,[5] C. Sebban,[6] N. Milpied,[7] F. Morschhauser,[7] B. Coiffier,[8] S. Le Gouill,[7] P. Lederlin,[7] R. Delarue,[9] G. Laurent,[7] A. Bosly[10]

[1]Institut d'Hématologie, PARIS, France; [2]Institut Curie, PARIS, France; [3]CHU L'Archet, NICE, France; [4]Centre Henri Becquerel, ROUEN, France; [5]Institut Gustave Roussy, VILLEJUIF, France; [6]Centre Léon Bérard, LYON, France; [7]CHU, PESSAC, France; [8]Hôpital Lyon Sud, PIERRE BÉNITE, France; [9]Hôpital Necker, PARIS, France; [10]UCL, YVOIR, Belgium

Background. Autologous stem cell transplantation (ASCT) proceeded by conditioning with intensive high-dose chemotherapy is a standard treatment for patients with low-grade B-cell lymphoma, who have experienced disease relapse or who are refractory to treatment. The long-term outcome of ASCT is better if complete remission (CR) has been achieved at the time of transplant and the duration of response longer than in the last previous chemotherapy treatment. Conditioning regimens therefore include both chemotherapy and total body irradiation to increase the likelihood of CR., 90Y-ibritumomab tiuxetan, has demonstrated pronounced anti-lymphoma activity when given as monotherapy in relapsed/refractory low-grade lymphoma. Consequently, incorporating the CD20-specific antibody as an alternative source of irradiation during conditioning, has generated much interest. *Aims*. The aims of this study were to evaluate the safety and efficacy of conventional dose of 90Yttrium ibritumomab tiuxetan with BEAM conditioning regimen pre autologous stem cell transplantation (ASCT) in chemo-sensitive relapsed or refractory low-grade B-cell lymphomas. *Design and Methods*. From 3/2005 to 8/2006, a phase II study was undertaken, in which 77 patients with relapsed/refractory low-grade B-cell lymphoma were given conventional-dose 90Y-ibritumomab tiuxetan 1 week before starting a standard BEAM regimen (Z-BEAM) as a pre-ASCT conditioning regimen. *Results*. Patients characteristics at last salvage chemotherapy inclusion: 68 follicular lymphoma, 6 marginal zone and 1 mantle cell plus 2 transformed histology after pathological review; median age 53 yr. (31-64), FLIPI low risk 32, intermediate risk 20, high risk 20. First relapse 39; 2nd relapse 10 partial response 21, stable disease 4 and progressive disease 3 after first line treatment. Response rate before ASCT were CR and CRu 77%, PR 22%, stable 1%. Overall, among the 77 pts last salvage chemotherapy regimen included rituximab in 74 pts and ASCT was performed in 75 patients. The haematological reconstitution after Z-BEAM followed by ASCT in 75 pts was : time to neutrophils > 1G/L 12 days (9-35), time to platelets >20 G/L 12 days (3-42). Three months after transplant 88% of the patients were in CR, CRu .With a median follow-up of 28 months (range: 8-38 months), the 2-year EFS and OS were 63% and 97%, respectively. There was a significant difference in EFS post ASCT for patients in favour of 1st relapse 74% versus second relapse 40% (p= 0.005). Using patients as their own control for the duration of last qualifying phase, the 2 years EFS post ASCT, was in favour of ASCT 62% vs 37% (p=0.007). At week 12 and 42 after ASCT, median haemoglobin level were 11.6 g/dl and 11.3 g/dl, median platelets counts was 111G/L and 148 G/L, leucocytes counts 3.48 G/L and 4.80 G/L respectively. There was no evidence of impaired engraftment. Overall toxicities were comparable to standard ASCT conditioning regimens and no toxicity-related mortality was reported. *Conclusion*.This study demonstrated that 90Y-ibritumomab tiuxetan combined with standard BEAM treatment provides a safe, highly active conditioning regimen and need to be evaluated in further randomized study.

1043

RESULTS OF A PROSPECTIVE RANDOMISED TRIAL COMPARING CHLORAMBUCIL, MITOXANTRONE AND DEXAMETHASONE (CMD) VERSUS FLUDARABINE, MITOXANTRONE AND DEXAMETHASONE AS PRIMARY THERAPY FOR ADVANCED STAGE FOLLICULAR LYMPHOMA (REAL GRADES I-III, STAGE III/IV). A REPORT FROM THE UK CENTRAL AND SOUTHERN LYMPH

R.J. Lush,[1] A. Haynes,[2] A. McMillan,[2] A. Jack,[3] W. Qian,[4] I. Jakupovic,[5] P. Smith,[5] A. Prentice[6]

[1]Cheltenham General Hospital, CHELTENHAM, UK; [2]Department of Haematology, City Hospital Campus, Nottingham University Hospitals, NOTTINGHAM, UK; [3]Haematological Malignancy Diagnostic Service, Leeds General Infirmary, LEEDS, UK; [4]Cancer Group, MRC Clinical Trials Unit, LONDON, UK; [5]Lymphoma Trials Office, CRUK & University College London Cancer Trials Centre, LONDON, UK; [6]Department of Haematology, Royal Free Hospital, LONDON, UK

Background. The choice of the most appropriate primary therapy for the de novo presentation of advanced stage Follicular lymphoma (FL) is controversial. The purine analogue Fludarabine has proven activity in FL either as a monotherapy or within combination regimens such as Fludarabine, Mitoxantrone and Dexamethasone (FMD). In this multicentre study 400 patients presenting with de novo advanced stage FL between May 2000 and April 2006 were randomised between FMD (Fludarabine 25 mg/m^2 iv D1-3, Mitoxantrone 12mg/m^2 iv D1 and Dexamethasone 20 mg po D1-5) and CMD (Chlorambucil 10 mg po D1-10 with M and D as per FMD) on physicians' decision to treat for the presence of B symptoms, bone marrow failure, bulk disease or compressive symptoms. Responding patients received a maximum of 8 cycles of therapy. At the time of the study Rituximab (R) was not available for inclusion within primary therapy. Baseline peripheral blood (PB) and bone marrow (BM) samples were provided for PCR analysis to determine the presence of an informative bcl-2/IgH rearrangement and informative patients had further PCR analyses performed at fixed time points during follow-up. *Aims*. The primary end points for comparison of the two regimens were progression-free survival (PFS) and overall survival (OS). Secondary end points were complete (C) and partial (P) remission rates (RR) together with molecular response rates and the impact of molecular response on PFS and OS. *Design and Methods*. 200 patients were randomised to each arm, central histopatholgical review confirming a diagnosis of FL in all cases. The two arms were well-matched for median age, Stage (III vs IV) and IPI / FLIPI.

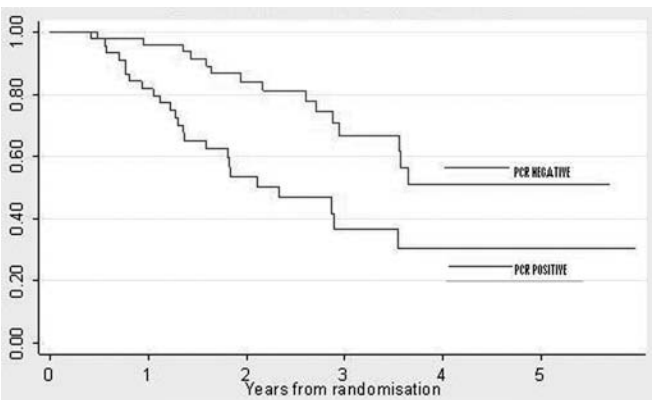

Figure 1. PFS according to PCR result at end of therapy.

Results. At the end of therapy for CMD versus FMD the CRR was 44% and 44% respectively with PRR of 46 versus 47%. Adverse haematological and non-haematological effects were not statistically different between the two arms. 81% of patients allocated CMD received 5 or more cycles of therapy compared with 76% of those allocated FMD. Hazard ratios at 2 years were in favour of CMD for OS at 1.48 (95% CI 0.91-2.31, p=0.11) and for PFS at 1.44 (95% CI 1.08-1.93, p=0.013). Median PFS was 43 months for CMD versus 33 months for FMD. A PCR amplifiable bcl-2/IgH rearrangement was identified in 134 of 267 evaluable patients (50.2%). In a subset analysis of 92 PCR-informative patients 55% of patients receiving CMD and 49% of patients receiving FMD became PCR negative at the end of therapy (p=ns). The achievement of PCR negativity was strongly associated with an advantage in PFS (p=0.03 - see attached figure) but not in OS. The difference in PFS based on molecular response demonstrated utilising a sensitive nested PCR technique could be replicated using a less sensitive single round PCR. *Summary*. In this prospective randomised trial a significant benefit in median PFS was demonstrated for CMD over FMD. Both regimes are deliverable with acceptable toxicity profiles. The PFS demonstrated with CMD compares favourably with other anthracycline-containing regimens without R and with R-CVP. Patients achieving PCR negativity at the end of treatment have a significant PFS advantage.

1044

SINGLE AGENT BORTEZOMIB IS ACTIVE IN RELAPSED/REFRACTORY MALT LYMPHOMAS. FINAL RESULTS OF AN INTERNATIONAL EXTRANODAL LYMPHOMA STUDY GROUP (IELSG) PHASE II STUDY

A. Conconi, G. Martinelli, A. Lopez-Guillermo, P.L. Zinzani, A. Ferreri, L. Rigacci, L. Devizzi, U. Vitolo, S. Luminari, M. Martelli, F. Cavalli, E. Zucca

International Extranodal Lymphoma Study Group (IELSG), BELLINZONA, Switzerland

Background. Bortezomib has shown antitumor activity in different subtypes of non-Hodgkin lymphomas, including both indolent and aggressive diseases. The suggested key role of constitutive activation of NF-KB in MALT lymphoma pathogenesis supported the evaluation of bortezomib in this clinical setting. *Aims*. The IELSG has coordinated a phase II multicenter study aimed to assess the antitumor activity and safety of bortezomib in extranodal marginal zone B-cell lymphoma of MALT-type, relapsed or refractory after prior systemic therapy. *Design and Methods*. Bortezomib 1.3 mg/m^2 has been administered on days 1, 4, 8, and 11 of a 21-day cycle, for up to 6 cycles. Activity has been measured after 6 and 18 weeks of treatment and defined according to the revised NCI response criteria. Toxicity was evaluated according to NCI-CTC (version 3). *Results*. On February 2009, 32 patients (pts) have been enrolled and the pt accrual has been closed. Among the 30 pts in whom the clinical data are available, 16 (53%) pts were male. At time of enrollment median age was 61 years (range, 37-82). Median time from first diagnosis was 3.6 years (range, 0.8-15). Median number of prior systemic therapies was 2 (range, 1-4), in most cases immuno-chemotherapy including rituximab. The Ann Arbor stage distributions were the following: stage I= 7 pts (23%), stage II= 7 pts (23%), stage IV= 16 pts (53%). A primary gastric localization was present in 14 pts, primary cutaneous/subcutaneous in 10, primary lung lymphoma in 3; in the remaining 3 pts lymphoma was primarily localized in the orbit, pharynx, and genital tract. Multiple extranodal sites were present in 8 of these pts (27%). All pts had ECOG PS<2; in 3 cases (10%) elevated serum LDH was reported. Twenty-five pts were assessed for response at the end of treatment plan: the overall response rate was 48% (95%CI: 28%-69%), with 6 complete and 6 partial responses. Seven patients experienced stable disease after study conclusion and 6 progressive disease during therapy; 3 other were not evaluable for response, and in 4 pts, with ongoing therapy, no response data is available yet. All responses were durable lasting from 3+ to 34+ months. At a median follow-up of 2 years, three disease progressions were observed among 2 complete responders and in a single pt in partial response. Five deaths were reported, in 2 cases due to disease progression. No toxicity related deaths were observed. The safety profile of bortezomib is similar to that observed in multiple myeloma and other non-Hodgkin lymphoma entities. The most relevant grade 3 adverse events were fatigue, thrombocytopenia, neutropenia and peripheral neuropathy, which was always reversible, but represented the cause of early treatment stop in 5 patients. *Conclusions*. Bortezomib seems to have relevant clinical activity in patients with MALT lymphomas, with tolerable toxicity. Final results will be presented

Myeloproliferative disorders - Biology

1045

A GERMLINE JAK2 SNP IS ASSOCIATED WITH PREDISPOSITION TO THE DEVELOPMENT OF JAK2 V617F-POSITIVE MYELOPROLIFERATIVE NEOPLASMS

M. Kilpivaara,[1] S. Mukherjee,[1] M Schram,[1] M. Wadleigh,[2] A. Mullally,[3] L Ebert,[4] A. Bass,[5] S. Marubayashi,[1] A. Heguy,[1] G. Garcia-Manero,[6] H. Kantarjian,[6] K. Offit,[1] M. Stone,[2] D. Gilliland,[3] J. Klein1, L. Levine[1]

[1]Memorial Sloan-Kettering Cancer Institute, NEW YORK, NY, USA; [2]Dana-Farber Cancer Institute, BOSTON, USA; [3]Dana-Farber Cancer Institute & Brigham and Women's Hospital, BOSTON, USA; [4]Brigham and Women's Hospital & Broad Institute of Harvard and MIT, BOSTON, USA; [5]Dana-Farber Cancer Institute and Broad Institute of Harvard and MIT, BOSTON, USA; [6]M.D. Anderson Cancer Center, HOUSTON, USA

Background. Polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) are myeloproliferative neoplasms (MPN) characterized by clonal proliferation of one or more myeloid lineages. The presence of the identical somatic activating mutation in JAK2 (JAK2V617F) in over 90% of PV and 50-60% of ET/PMF suggests that there are additional inherited or acquired genetic events that contribute to the pathogenesis of these phenotypically distinct disorders. Moreover, family members of MPN patients are at higher risk for the development of MPN, consistent with the existence of one or more MPN predisposition loci. *Aims*. We hypothesized that germline variation contributes to MPN phenotypic pleiotropy and to MPN predisposition. *Design and Methods*. We carried out a genome-wide analysis of 250000 single nucleotide polymorphisms (SNPs) in 217 MPN samples, and used a series of 324 germline DNA samples from MPN cases to further analyze our findings. *Results*. Analysis of 250,000 SNPs in MPN samples identified an allele in the JAK2 locus (rs10974944) that is enriched in JAK2V617F-positive MPN compared to JAK2V617F-negative MPN or to control populations, suggesting this haplotype predisposes to the development of JAK2V617F-positive MPN. Analysis of germline DNA PV, ET, and PMF patients found that that the GG/CG genotypes at rs10974944 were more common in MPN cases compared to Wellcome Trust Case-Control Consortium (WTCCC) controls (OR=3.1, p=4.1x10-20), consistent with the G allele functioning as a dominant MPN predisposition allele. Germline allelic variation at rs10974944 was strongly associated with JAK2V617F-positive MPN (OR=4.0, p=7.7x10-22) and much less strongly associated with JAK2V617F-negative MPN (OR=1.6, p=0.06). In patients heterozygous (CG) for rs10974944, we showed that JAK2V617F is preferentially acquired in cis with the predisposition allele (G). These data indicate germline JAK2 variation more strongly influences MPN predisposition than MPN phenotype. We identified three additional germline loci that are enriched in PV or in ET, establishing these loci as candidate modifier loci that influence MPN phenotype. *Conclusions*. These data suggest that germline variation is an important contributor to MPN phenotype and predisposition.

Background. Activation of JAK2 by chromosomal translocations or point mutations is a frequent event in haematological malignancies. JAK2 is a non-receptor tyrosine kinase that regulates a number of cellular processes by inducing cytoplasmic signalling cascades including MAPK, PI3K-AKT and the STAT family. Thus far, the focus for understanding the molecular mechanisms of JAK2 mediated oncogenesis have centred around the analysis of these downstream cytoplasmic signalling pathways. *Design and Methods*. Mammalian cell lines and/or primary haematopoietic cells were studied using confocal immunofluorescence (IF), biochemical subcellular fractionation, the generation and development of a histone modification specific antibodies, western blot and immunoprecipitation assays, expression of GST-tagged recombinant mammalian proteins, *in vitro* binding assays, genome-wide expression analysis and chromatin immunoprecipitation (ChIP). *Results*. Using IF and subcellular fractionation our results identify for the first time that JAK2 is present in the nucleus of haematopoietic cells. *In vitro* kinase assays demonstrated that JAK2 phosphorylates histone H3. Modification-specific antibodies were then generated, characterised and used to demonstrate that JAK2 signals directly to chromatin by phosphorylating tyrosine-41 on histone H3 (H3Y41). H3Y41 is conserved throughout phylogeny and has been demonstrated to be an essential amino acid necessary for cell viability. Using a combination of cell fractionation and *in vitro* binding assays we show that this region surrounding H3Y41 is bound by heterochromatin protein 1α (HP1α), an essential component of transcriptionally silent heterochromatin. We present a mechanistic insight into the biological function of JAK2 mediated H3Y41-phosphorylation by demonstrating that this modification prevents the binding of HP1α and thus is likely to modulate multiple aspects of chromatin structure. Finally, the combination of genome-wide expression analysis and ChIP was used to identify the LMO2 oncogene as a previously unrecognised target of JAK2 signalling that is independent of STAT5 binding. JAK2 signalling was associated with increased LMO2 transcription together with increased H3Y41 phosphorylation and reduced HP1α occupancy at the LMO2 promoter. *Conclusions*. These results identify a previously unrecognised nuclear role for JAK2 and reveal the first characterised tyrosine phosphorylation of any core histone. Our data demonstrates that phosphorylation of H3Y41 by JAK2 modulates the structure and function of chromatin by regulating the binding of HP1α, and reveals a previously unrecognised direct link between JAK2 and the LMO2 locus. Taken together these results demonstrate a novel signalling pathway by which JAK2 directly regulates chromatin structure in mammalian cells.

TET2 MUTATION PREVALENCE AND CLINICAL CORRELATES IN A SPECTRUM OF MYELOID NEOPLASMS: A SINGLE INSTITUTION STUDY OF 337 PATIENTS

D. Pardanani,[1] T. Lasho,[1] K. Lim,[1] O. Abdel-Wahab,[2] J. Patel,[2] N. Gangat,[1] C. Finke,[1] S. Schwager,[1] A. Mullally,[3] C. Li,[1] C. Hanson,[1] R. Mesa,[1] A. Pardanani,[1] G. Gilliland,[3] R. Levine,[2] A. Tefferi[1]

[1]Mayo Clinic, ROCHESTER, USA; [2]Memorial Sloan Kettering Cancer Center, NEW YORK, USA; [3]Brigham and Women's Hospital, Dana Farber Cancer Institute, Harvard Medical Sch, BOSTON, USA

Background. Recently acquired loss of heterozygosity (LOH) and somatic deletions at chromosome 4q24 has been described in patients with myeloproliferative neoplasms (MPN). Furthermore, TET2 (TET oncogene family member 2), a putative tumor suppressor gene located in the minimal LOH region of chromosome 4q24 has been shown to harbor loss of function mutations that coexist with JAK2V617F and may predate its acquisition, in patients with myeloid malignancies. *Aims*. To describe the TET2 mutation prevalence and its clinical correlates in a spectrum of myeloid malignancies. *Design and Methods*. High-throughput DNA sequence analysis was used to screen for TET2 mutations in bone marrow-derived DNA from 337 patients with myeloid neoplasms including 239 with BCR-ABL-negative myeloproliferative neoplasms (MPN), 48 with systemic mastocytosis (SM), and 50 with myeloid malignancies other than MPN. *Results*. Among the 239 patients with BCR-ABL-negative MPN, 32 TET2 mutations were identified for an overall mutational frequency of ~13%; specific diagnoses included polycythemia vera (PV; n=89), essential thrombocythemia (ET; n=57), primary myelofibrosis (PMF; n=60), post-PV MF (n=14), post-ET MF (n=7) and blast phase PV/ET/MF (n=12); the corresponding mutational frequencies were approximately 16%, 5%, 17%, 14%, 14% and 17% (p=0.50). Mutant TET2 was detected in ~17% and ~7% of JAK2V617F positive and negative cases, respectively (p=0.04). However, this apparent clustering of the two mutations was accounted for by an independent association between mutant TET2 and advanced age; mutational frequency was ~23% in patients ≤60 years old versus ~4% in younger patients (p<0.0001). Presence of mutant TET2 did not affect survival, leukemic transformation or thrombosis in either PV or PMF. Among the 48 patients with SM, 42 met WHO diagnostic criteria for SM and 6 displayed FIP1L1-PDGFRA; 12 (29%) SM, but no FIP1L1-PDGFRA patients had TET2 mutations. KITD816V was detected by PCR sequencing in 50% or 20% of patients with or without TET2 mutation (p=0.05), respectively. In SM, multivariable analysis showed a significant association between the presence of TET2 mutation and monocytosis (p=0.0003). The remaining 50 patients included 15 with chronic myelomonocytic leukemia (CMML), 16 with myelodysplastic syndrome (MDS), 7 with secondary acute myeloid leukemia (AML), 5 with de novo AML, 3 with MDS/MPN and 4 with MPN, unclassifiable (MPN-

U); the corresponding TET2 mutational frequencies were 20%, 6%, 43%, 20%, 33%, and 50%. A TET2 mutation co-existed with MPLW515L in one MPN-U patient and with PML-RARA in one AML-M3 patient. *Conclusions*. We conclude that TET2 mutations are ubiquitous among myeloid malignancies, are more prevalent in older patients in the context of MPN, display similar frequencies across disease stages, and can co-exist with JAK2V617F, KITD816V, MPLW515L and PML-RARA.

MULTIPLE JAK2 V617F MUTATIONS ARE PRESENT IN MOST PATIENTS WITH ESSENTIAL THROMBOCYTHAEMIA: A NEW DISEASE PARADIGM

J. Lambert, D.C. Linch, R.E. Gale

University College London Cancer Institute, LONDON, UK

Background. Essential thrombocythaemia (ET) is a myeloproliferative disorder characterised by chronic thrombocytosis in the absence of a recognisable cause and is usually an indolent disease with a low rate of transformation to acute leukaemia. The JAK2 V617F mutation is present in approximately 50% of patients with ET and, although its role in the pathogenesis of the disease remains controversial, detection of the mutation is often considered to indicate the presence of a monoclonal process. In most cases, however, the mutation is restricted to a subpopulation of neutrophils and platelets, and production of JAK2 wild-type (WT) platelets remains at normal levels. Non-mutated precursor cells may, therefore, be susceptible to the acquisition of further JAK2 mutations, resulting in multiple independent V617F-positive clones. *Aims*: To investigate the possibility that more than one JAK2 V617F-positive clone is present in patients with V617F-positive ET. *Design and Methods*: We used a common single nucleotide polymorphism (SNP) in exon 19 of the JAK2 coding sequence to genotype JAK2 V617F-positive alleles in 11 ET patients. For each patient, a PCR product spanning exons 14-20 of the JAK2 gene underwent restriction enzyme digestion (RED) to cut only JAK2 WT alleles. The V617F-positive products were then re-amplified and these second round PCR products were used to determine the exon 19 SNP allele (A or G) present. In 5 patients the exon 14-20 PCR products were cloned and V617F status and SNP genotype of individual clones examined. We also determined the inactivated X-allele in *in vitro* cultured JAK2 mutant-positive erythroid colonies from one patient using the human androgen receptor assay. *Results*. Both SNP alleles, in varying proportions, were detected in JAK2 mutant-positive alleles from neutrophils of 10 out of 11 ET patients studied using PCR and RED, indicating the occurrence of at least 2 separate JAK2 mutation events in the majority of ET patients investigated. These results were confirmed in cloned products from all 5 patients analysed. In 3 of these 5 patients, the majority of clones had allele A, in one the A clones and G clones were approximately equal, and in one the majority of clones had allele G. Neutrophil samples taken from one patient 23 months apart showed the ratio of A to G clones remained stable over this period, and in 2 patients the ratio of A to G clones was similar in platelet and neutrophil samples. In a further patient, mutant-positive erythroid colonies with either X-allele inactivated were detected (38% inactivated one allele, 62% inactivated the other), indicating that they could not have arisen from a common clonal precursor. *Conclusions*. These results indicate that the majority of JAK2 V617F-positive ET patients undergo at least two independent JAK2 mutation events and these can occur on a polyclonal background, suggesting that such individuals may have an increased susceptibility to acquiring this mutation. The identification of more than one V617F-positive clone in many mutant-positive ET patients implies an oligoclonal process (analogous to PNH), and the presence of the mutation should not, therefore, be equated with a malignant disease.

1049

TWO ROUTES TO LEUKAEMIC TRANSFORMATION FOLLOWING A JAK2 MUTATION-POSITIVE MYELOPROLIFERATIVE NEOPLASM

P.A. Beer,[1] F. Delhommeau,[2] J.P. LeCouédic,[2] D. Bareford,[3] R. Kukec,[4] M.F. McMullin,[5] C. Harrison,[6] A. Vannucchi,[7] W. Vainchenker,[2] A.R. Green[1]

Background. Transformation to acute myeloid leukaemia (AML) may follow a JAK2-mutant myeloproliferative neoplasm (MPN), although the mechanisms of disease evolution, which may involve loss of the JAK2 mutation, remain obscure. *Design and Methods*. Comprehensive clinical information and blood samples were obtained from 16 patients with AML and a preceding JAK2-mutant MPN (essential thrombocythaemia (ET), polycythaemia vera (PV), refractory anaemia with ringed sideroblasts and thrombocytosis (RARS-T) or primary myelofibrosis (PMF); 15 JAK2 V617F and 1 JAK2 exon 12; see table). Leukaemic blasts (and progenitor colonies where indicated) were assessed for JAK2 mutations, loss of heterozygosity by analysis of single nucleotide polymorphisms within or adjacent to the JAK2 locus, AML-associated mutations (N/KRAS, FLT3, EVI1, NPM, CEBPA, RUNX1 and TP53) and mutations in TET2.

Table 1. Features of 16 patients with post-MPN AML.

Patient	Age/sex	MPN	*JAK2* mutation	Therapy	At transformation to AML	
					JAK2 mutation	Other mutations
#1	65 M	PMF	*JAK2* V617F	HC, AN	heterozygous	NRAS G12S *RUNX1* D171N

#13	93 M	PV	*JAK2* V617F	P32, BU, HC	wild-type	*TP53* C238F
#14	75 M	PV	*JAK2* V617F	HC	wild-type	-
#15	61 F	PV	*JAK2* V617F	HC	wild-type	*TET2* P1549X
#16	86 F	ET	*JAK2* V617F	HC, BU	wild-type	-

M: male; F: female; PMF: primary myelofibrosis; ET: essential thrombocythaemia; PV: polycythaemia vera; RARS-T: refractory anaemia with ringed sideroblasts and thrombocytosis; HC: hydroxycarbamide; AN: anagrelide; IFN: interferon; BU: busulphan

Results. Analysis of highly purified leukaemic blasts demonstrated 6 V617F-homozygous, 1 V617F-heterozygous and 9 JAK2 wild-type leukaemias. Loss of the mutant JAK2 allele by mitotic recombination, gene conversion or gene deletion was excluded in all 9 JAK2 wild-type leukaemias. All 7 patients with JAK2-mutant AML were diagnosed with PMF or myelofibrotic transformation of ET/PV. In marked contrast, only 1 of 9 patients with JAK2 wild-type AML had evidence of preceding myelofibrosis, with the remaining 8 cases transforming directly from ET, PV or RARS-T (p=0.001). This difference in preceding MPN phenotype, coupled with a strong association with the JAK2 mutation status of the leukaemia, indicates the existence of two distinct pathways to leukaemia. No consistent differences were found, however, in the pattern of AML-associated mutations between the two groups: both JAK2-mutant and wild-type leukaemias harboured mutations in RUNX1 (4/7 and 2/9 respectively) or TP53 (1/7 and 3/9 respectively); EVI1 overexpression or oncogenic RAS mutations were detected in JAK2-mutant leukaemias (EVI1: 1/7, RAS: 2/7) and a single JAK2 wild-type leukaemia harboured a FLT3-ITD (see Table 1). Mutations in TET2 may precede acquisition of a JAK2 mutation and could potentially represent a shared clone of origin for JAK2-mutant MPN and JAK2 wild-type AML. Analysis of a patient with a biclonal MPN (JAK2 V617F and MPL W515L mutations in separate clones) identified the same TET2 mutation in JAK2-mutant, MPL-mutant and JAK2/MPL wild-type erythroid colonies, demonstrating that a TET2-mutant founder clone may give rise to phylogenetically related daughter clones bearing dissimilar patterns of genetic mutation. Although TET2 mutations were present in 2/9 JAK2 wild-type leukaemias, in both cases the TET2 mutation was absent from all JAK2-mutant erythroid colonies, demonstrating that in these two patients the TET2 and JAK2 mutations were present in separate clones. *Conclusions*. hese data demonstrate the existence of two routes to AML transformation that are strongly associated with the JAK2 status of leukaemic blasts. Our results are consistent with a model in which JAK2-mutant AML is preceded by accumulation of mutations that give rise to the phenotype of PMF or myelofibrotic transformation of ET/PV. By contrast, JAK2 wild-type AML usually follows directly from ET or PV, implying that different pathogenetic mechanisms underlie transformation to JAK2 wild-type versus JAK2-mutant leukaemia.

GENOME-WIDE SCREENING OF CHRONIC MYELOID LEUKEMIA PATIENTS BY SNP ARRAYS: ALTERATIONS ASSOCIATED WITH DISEASE PROGRESSION

S. Colarossi,[1] A. Gnani,[1] S. Soverini,[1] F. Castagnetti,[1] G. Marzocchi,[1] S. Luatti,[1] A. Astolfi,[2] S. Formica,[2] I. Iacobucci,[1] M. Amabile,[1] A. Poerio,[1] G. Rosti,[3] A. Pession,[2] N. Testoni,[1] M. Baccarani,[1] G. Martinelli[1]

[1]Institute of Hematology and Medical Oncology Seràgnoli, BOLOGNA; [2]Pediatric Oncology and Hematology L. Seràgnoli, BOLOGNA; [3]Insitute of Hematology Seragnoli, BOLOGNA, Italy

BACKGROUND. The expression of BCR-ABL fusion gene in Chronic Myeloid Leukemia (CML) is necessary for malignant transformation but the biologic basis of the progression from Chronic Phase (CP) through accelerated phase to Blast Crisis (BC) is poorly understood. *AIM*. Identifying the genomic imbalances involved in the transition into BC, before clinical features, may provide diagnostic markers of progression; for this reason we planned to use SNP arrays to perform a high-resolution mapping of BC CML patients genomes. *Design and Methods*. We analyzed 11 patients affected by myeloid or lymphoid BC CML disease. Genomic DNA were extracted from bone marrow or peripheral blood mononuclear cells archived both at the time of diagnosis and progression. SNP array-based karyotyping was carried out using Affymetrix GeneChip Human Mapping 250K Nsp arrays. Copy number (CN) and loss of heterozygosity (LOH) analyses were performed using Hapmap normal individuals as reference set and two different softwares: Partek Genomics Suite 6.4 and Affymetrix Genotyping Console 3.0. Genes were recognized according to the March 2008 human reference sequence (NCBI Build 36.3). *Results*. After exclusion of genomic copy number variations (CNVs) by comparison to recorded CNVs in the Genome Variation Database (*http://projects.tcag.ca/variation/*), the following results were achieved: five patients showed huge amplifications and deletions, ranging from 30Mb to 160Mb, on chromosomes 9, 7, 3 and 6. We also found several heterozygous micro-deletions and micro-amplifications spreading all over the genome. This analysis has identified abnormalities in genes involved in apoptosis (e.g., GADD45A, FOXO3A, GAS6), DNA damage response (e.g., MYST as known as Hmof, XRCC2), tumor suppression (e.g., C/EBPdelta, LATS1), chromatin regulation (e.g., HDAC9), and genes belonged to ABC transporters (e.g., ABCB1), cytoskeletal and adhesion molecules (e.g., ITGAL as known as LAF1, SDK1), cytochromes (e.g., CYP3A5), tyrosine kinase (e.g., JAK2), ras family, transcriptional/ translational factors (e.g., ETV1), and zinc finger proteins. Moreover were found copy number changes (gain/loss) in genes associated with malignancy, in particular TNFRSF17, MET, IGFBPL1, EVI1, PTENP1. Other alterations affected key pathways including cell cycle regulation, WNT signaling, and proteasome. Interestingly, we also observed a high frequency of LOH on chromosomes 1, 4, 7,9,11,17 and 19 but in different patients; in addition, inside the altered regions of chromosomes 9, 7, 17, 19, the loss of 12 well-known miRNAs was highlighted. *Conclusions*. The use of the newly genomic tool Genome-Wide Human SNP array 250K allowed us to identify, at submicroscopic level, genetic lesions in patients affected by CML in BC. Our results will be further validated by real-time PCR for the altered genes involved in biological pathways, while sequencing and mutation analysis will be performed on the remaining allele of putative tumor suppressor genes to identify their residual activity. All these validations and the increased number of patients analyzed both at time of diagnosis and progression will provide new insights into the genetic profiling that lead disease progression from CP to BC and consequently new opportunities to develop specific target therapies.

ICSBP DEFICIENCY IN CML CONFERS DIRECT BCR/ABL-INDEPENDENT IMATINIB RESISTANCE BUT RESTRICTS BCR/ABL KINASE POINT MUTATION DEVELOPMENT

A. Chaturvedi, K. Schmidt, A. Neubauer, A. Burchert

Philipps University, Marburg, MARBURG, Germany

Background. Chronic myelogenous leukemia (CML) is a myeloproliferative disorder that is caused by the constitutively activated BCR-ABL tyrosine kinase. Interferon Consensus Sequence Binding Protein (ICSBP) is a transcription factor which is expressed in the bone marrow compartment and predominantly in the lymphatic system. Its expression is down regulated in the peripheral blood of CML patients. Current therapeutic strategies in CML include ABL-specific tyrosine kinase inhibitors (TKI) such as Imatinib (IM), Dasatinib (DA) and Nilotinib (NI). However, resistance and persistence of leukemic (stem) cells under TKI therapy still remains a significant clinical problem. Mutations in ABL kinase domain account for TKI-resistance in about 90% of BCR/ABL positive ALL, but only in ~50% of CML patients. Still little is known about mutation-independent mechanisms of TKI resistance and the nature of kinase mutation emergence. *Aims*. To elucidate mechanism of IM resistance development, we here analyzed the impact of ICSBP deficiency for BCR/ABL-dependent and/or -independent IM and TKI resistance. *Design and Methods*. 32D-BCR/ABL and 32D-BCR/ABL-ICSBP cell lines were generated as described previously. Lineage depleted primary bone marrow (BM) cells of ICSBP-wt and ICSBP-null (-/-) background were transduced with BCR-ABL to yield wt-BA and ICSBP-/- BA cells. Apoptosis was measured with propidium iodide (PI) staining. Viable colonies (CFU) were counted in methylcellulose after one time exposure to TKI. Phosphorylation was analyzed by intracellular staining and immunoblotting. BCR/ABL kinase mutagenesis was studied using the N-ethyl-N-nitrosourea (ENU) mutagenesis assay. *Results*. We demonstrate that wt-BA, when compared with ICSBP-/- BA, are significantly more sensitive to apoptosis induction by IM 4um (40% vs. 19%), DA 150nm (91% vs. 48%), and NI 4um (58% vs. 34%). Similarly, we observed less CFU in wt BA as compared to ICSBP-/- BA when treated with IM 4um (14±5 vs. 66±13), DA 150nm (10±6, 44±4) and NI 4um (8±8, 57±4). The mechanism of reduced sensitivity to TKI treatment in ICSBP-/- BA cells was clearly BCR/ABL-independent, because intracellular FACS analysis revealed no significant differences in the inhibition of phosphorylation (inactivation) of BCR/ABL and its downstream targets Stat5 and CrkL in an ICSBP-/- and ICSBP-wt context after treatment with IM, DA or NI. Likewise, significantly more apoptosis was observed in the myeloid 32D-BA cell system when ICSBP was coexpressed (~80% cell death after 48h) as compared to 32D-BA cells (~25% cell death after 48h). Increased apoptosis induction in 32D-BA-ICSBP cells was associated with a more rapid and more sustained phosphorylation of p38 MAPK - a proapoptotic gene, which has recently been implicated in the control of oncogene addiction. In order to address, whether an increased apoptosis response in the presence of ICSBP also translates into a lower frequency of kinase mutation evolution, we quantitated the rate of IM-induced BCR/ABL-kinase mutations in presence and absence of ICSBP using an established TKI mutagenesis screen. Unexpectedly, significantly more IM-resistant colonies emerged in 32D-BA-ICSBP cells as compared to 32D-BA cells, but only if cells were treated prior to IM-exposure with the randomly acting mutagen, ENU. This suggests that absence of ICSBP expression limits the development kinase point mutations and *vice versa*. *Conclusion*. Lack of ICSBP expression in CML may thus confer BCR/ABL-independent IM drug resistance, but also limit the frequency of point mutation development in a myeloid cell context. This would explain the lower rates of point mutations found in IM-resistant CML as opposed to BCR/ABL positive, IM-resistant ALL.

OMACETAXINE CYTOTOXIC ACTIVITY IN CHRONIC MYELOID LEUKAEMIA STEM CELLS

E.K. Allan,[1] H.G. Jorgensen,[2] S. Michaels,[3] T.L. Holyoake[2]

[1]Scottish National Blood Transfusion Service, GLASGOW, UK; [2]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, GLASGOW, United Kingdom; [3]ChemGenex Pharmaceuticals Inc., MENLO PARK, USA

Chronic myeloid leukaemia (CML) is maintained by a rare population of malignant stem cells which are insensitive to tyrosine kinase inhibitors (TKI) including imatinib, nilotinib and dasatinib, the standard drugs of choice in this disease. We are therefore interested in investigating compounds that inhibit Bcr-Abl independent pathways important for CML stem cell survival. Our long term aim is to find a drug that can be combined with a TKI to improve overall disease response in chronic phase (CP) CML. Omacetaxine mepesuccinate (formerly homoharringtonine), a first in class cetaxine, has been evaluated by clinical trial in TKI insensitive / resistant CML. Omacetaxine is thought to inhibit synthesis of anti-apoptotic proteins of the Bcl-2 family including Mcl-1 and Bcl-XL, leading to cell death. We investigated the *in vitro* response of CP CML CD34+ versus normal stem cells to omacetaxine. Total CD34+ cells and more primitive CD34+38- subpopulations sorted by flow cytometry, were assessed for cell viability (trypan blue exclusion), apoptosis (Annexin-V / Viaprobe), protein expression (Western blotting), stem cell function (colony forming cell and long term culture initiating cell (LTCIC) assays), and cell division (CFSE tracking). For continuous drug exposures, concentration-effect curves established the IC50 for cell viability in total CML CD34+ cells (n=3) to be 62 and 2.8nM at 24 and 72h, respectively, which are clinically achievable concentrations. Following treatment with 10 or 100nM omacetaxine for 0.25, 2, 6, 24, 48 and 72h, the percentage of apoptotic cells (Annexin V+ / Viaprobe +) increased to a maximum of 90% at 72h. It was evident, however, that a minimum exposure time of 24h was sufficient to diminish cell counts at 72h to 30 and 4% of input with 10 and 100 nM omacetaxine, respectively. As we were interested in the mechanism of action as a secondary endpoint, and to ensure sufficient protein for analysis, we selected time points <24h for further investigation. Initial Western results show a reduction in Mcl-1 after 2h drug treatment of CML CD34+ cells and Bcl-2 protein levels also decreased progressively with increasing exposure to 10nM omacetaxine from 6 to 24h. Analysis of protein from the primitive CD34+38- sorted cell population also indicates reduced levels of Mcl-1 compared with no drug control. With respect to untreated CD34+ cells, omacetaxine inhibited colony formation at day 12 by approximately 50% in a dose dependent manner (10 to 100 nM). The effect of this drug on cell division was analysed using the fluorescent marker, CFSE. Omacetaxine exerted an anti-proliferative effect, holding the cells back in early divisions with respect to untreated control. However, when the drug was washed out, some stem cells appeared to recover their proliferative potential and could expand in culture on days 5 to 6. Although omacetaxine is not leukaemia stem cell specific as non-CML CD34+ control cells were found to be sensitive to the drug's activity, its apoptotic inducing functions on leukaemia stem cells differentiates it from TKIs and create the potential of a curative strategy. Further results for LTCIC and mechanism of action will be presented.

BCR-ABL PEPTIDE VACCINATION IN HEALTHY SUBJECTS: IMMUNOLOGICAL RESPONSES ARE EQUIVALENT TO THOSE IN CHRONIC MYELOID LEUKAEMIA PATIENTS

J.M. Rojas,[1] K. Knight,[1] S. Watmough,[1] J. Bell,[1] L.H. Wang,[1] T. Callaghan,[2] R.E. Clark[1]

[1]University of Liverpool, LIVERPOOL; [2]National Blood Service, 14 Estuary Banks, LIVERPOOL, UK

Chronic Myeloid Leukaemia (CML) is characterised by the BCR-ABL oncoprotein. We and others have previously reported that vaccination of CML patients with BCR-ABL junctional peptides can elicit anti-BCR-ABL T cell responses, and that these immune responses correlate with a decrease in BCR-ABL transcript levels. However, the anti-BCR-ABL immune responses we observed were only moderate and transient. To determine whether CML patients may be tolerised to BCR-ABL, here we vaccinated healthy subjects with the same protocol as we have previously reported for CML patients, and compared the intensity of the immune responses obtained in patients and healthy subjects. Vaccinations consisted of a cocktail of 3 BCR-ABL peptides: (1) a 9-mer spanning the e14a2 region, (2) this same 9-mer linked to a PADRE (a 15-mer non-natural peptide shown to activate $CD4^+$ T cells, to which all subjects are immunologically naive), and (3) a 13-mer consensus e14a2 junctional peptide linked to PADRE, administered intradermally at a dose of 600mg each with sargramostim (GM-CSF), on 6 occasions over 2 months. Immune responses were monitored by IFN-γ, Granzyme-B and IL-5 ELISPOT, and proliferation assays to the vaccination peptides by flow cytometry on peripheral mononuclear cells. No subjects showed detectable anti-BCR-ABL or anti-PADRE immune response at entry. All 5 subjects developed a proliferative response to the PADRE-containing peptides used in the vaccine. IFN-α and Granzyme-B production to PADRE was detected in all healthy subjects, demonstrating that the vaccine is capable of eliciting immune responses to novel antigens. Specific IFN-γ and Granzyme-B production to BCR-ABL was also detected in all healthy subjects post vaccination demonstrating that vaccination can elicit anti-BCR-ABL cells in healthy subjects. No IL-5 production was detected, indicating type 1 bias of the immune responses elicited by the vaccine. The specific IFN-γ production to PADRE and BCR-ABL peptides observed in all 5 healthy subjects were compared with those in all 19 CML patients in our previously reported EPIC study. For each timepoint the specific IFN-γ production was compared using a Mann-Whitney test between the healthy subject and patient group. No statistical differences in the intensity or duration of the immune response detectable post-vaccination were found. The present data indicate that CML patients are unlikely to be tolerised to BCR-ABL. The data also suggest that BCR-ABL may be a weak antigen, and this underlines the importance of measuring the immunogenicity of the antigen to be used in immunotherapy. If BCR-ABL has a role in immunotherapy, it may be preferable to use it as part of a multi-epitope vaccination strategy.

BCR-ABL ENHANCES DIFFERENTIATION OF LONG-TERM REPOPULATING HEMATOPOIETIC STEM CELLS

S. Koschmieder,[1] M. Schemionek,[1] C. Elling,[1] N. Bäumer,[1] A. Hamilton,[2] T. Spieker,[1] J. Göthert,[3] M. Stehling,[4] C. Huettner,[5] D.G. Tenen,[6] L. Tickenbrock,[1] W.E. Berdel,[1] H.L. Serve,[7] T.L. Holyoake,[2] C. Müller-Tidow[1]

Background. Recently, we developed an inducible transgenic mouse model in which stem cell-targeted induction of BCR-ABL expression leads to chronic phase CML-like disease. *Aims*: To define the consequences of BCR-ABL expression in hematopoietic stem cells (HSC) *in vivo*. *Design and Methods*. Transplantation studies using inducible transgenic mice. *Results*. Here, we demonstrate that the disease is transplantable using BCR-ABL positive LSK cells (lin-Sca-1+c-kit+). Interestingly, the phenotype is enhanced when unfractionated bone marrow (BM) cells are transplanted. However, progenitor cells (lin-Sca-1-c-kit+) or cells displaying the immunphenotype of mature granulocytes (CD11b+Gr-1+) were not able to transmit the disease or alter the phenotype. The phenotype was largely independent of BCR ABL priming prior to transplant. However, BCR-ABL abrogated the potential of LSK cells to induce full blown disease in secondary recipients. Subsequently, we found that BCR-ABL increased the fraction of multipotent progenitor cells (MPP) at the expense of long term HSC (LT-HSC) in the BM of donor mice. Interestingly, while CML-like disease was reversible and re-inducible in transplanted mice, LSK cells transplanted from reverted BM were not able to re-induce disease in secondary recipients. *Conclusions*. Our results suggest that BCR-ABL induces differentiation of LT-HSC and decreases their self renewal capacities. In addition, they suggest that, although induction of disease is restricted to LSK cells, further cell populations contribute to the phenotype of CML.

Bleeding disorders, platelets and thrombocytopenia

In 2007, a European Network of Rare Bleedings Disorders (RBDs) was established and funded by the European Community. Ten Treatment Centers were enrolled to collect coordinated and consistent clinical, genetic and treatment data using a database with open-source engine and a web-based application. *Design and Methods*. A year after establishment of the project, complete data on 190 patients were analysed. Since the severity of RBDs is not always correlated with the level of coagulant activity, we arbitrary classified the patients as severe (<5%), moderate (6-10%) or mild (>10%). Chi-square or Fisher's tests were used to compare severe patients with moderate or mild ones in order to understand whether <5% of coagulant activity could prevent severe bleeding. A p value <.05 was considered to be statistically significant. *Results*. 43% of patients were severe, 11% moderate and 46% mild; 24% of patients were asymptomatic (10% of severe, 20% of moderate, 36% of mild). The frequency of mucocutaneous (cutaneous, epistaxis, menorrhagia, oral cavity) and GI bleedings were 45%±20 and 27%±8, respectively in all severe RBDs. Hematomas, haemarthrosis and CNS bleeding were more frequent in afibrinogenemia and severe FXIII deficiency. In mild/moderate RBDs, mucocutaneous bleedings were 33%±23, while more severe bleedings were significantly less frequent, but still present in few patients. A significant difference in the number of severe bleeds (haematoma, haemarthrosis, GI and CNS) was observed in severe patients compared to moderates (p<0.05). Comparing severes versus milds, mucocutaneous bleedings were also significantly different (p<0.007). Surprisingly menorrhagia and epistaxis were similar in the three groups. *Conclusions*. These results, coming from the analysis of a large amount of homogeneous data allow us to report that 5% of residual coagulant activity seems to be sufficient to prevent severe types of bleeds, while a higher amount of coagulation factor is required to prevent mucocutaneous bleeds.

RETROSPECTIVE EVALUATION OF DYSFIBRINOGENEMIC PATIENTS AT A SINGLE CENTER: CLINICAL FEATURES AND LABORATORY FINDINGS

C. Santoro,[1] A.P. Leporace,[2] F. Biondo,[2] M. Platè,[3] R. Asselta,[3] F. Peyvandi,[4] M. Menegatti,[4] P. Pignoloni,[2] S. Duga,[3] R. Foà,[2] M.G. Mazzucconi[2]

[1]Hematology, ROME, Italy; [2]Hematology, Sapienza Univeristy, ROME, Italy; [3]Department of biology and Genetics for Medical Sciences, university of Milan, MILAN, Italy; [4]A. Bianchi Bonomi Hemophilia and Thrombosis Center, University of Milan, MILAN, Italy

Background. Dysfibrinogenemia is a very rare bleeding disorder in which the clinical phenotype is unpredictable. The literature consists predominantly of collections of case reports. A relatively recent compilation of over 250 patients, revealed that 53% were asymptomatic, 26% had hemorrhages and 21% had thromboses, some of whom also had hemorrhages. *Aims*. To retrospectively investigate the clinical features and laboratory findings of our dysfibrinogenemic patients and to compare them with the literature data. *Design and Methods*. Over the last 10 years, 27 dysfibrinogenemic patients were diagnosed at our center: 12 were males and 15 females, with a median age at diagnosis of 39.9 years (6.1-80.9); they were grouped in 15 families. The reasons for admission were: reduced fibrinogen activity in routine screening in 10 patients, pre-operative coagulation screening in 7, coagulation screening for bleeding in 1, ischemic symptom in 1, familial study in 8. The laboratory findings were as follows:

	Mean value	Median value	Range
Fibrinogen activity (n.v. 200-400 mg/dL)	37	38	0-112
Fibrinogen antigen (n.v. 200-400 mg/dL)	251	250	140-470
PT ratio (n.v. 0.90-1.14)	1.2	1.2	0.9-1.74
aPTT ratio (n.v. 0.92-1.16)	1.1	1.09	0.9-1.3

Results. "Full" mutational screening of the 3 fibrinogen genes (FGA, FGB, FGG) has, so far, led to a genetic diagnosis in 5 of the 14 studied patients: 1 was heterozygous for the novel FGG Asp330Val (g.7641A>T) mutation, whereas the other 4 were heterozygous for previously reported mutations; 3 carried the FGA Arg16His (g.1203G>A) mutation and 1 the FGG Arg275Cys (g.7475C>T). Sixteen of the 27 patients experienced hemorrhagic symptoms, mostly mild: traumatic cutaneous bleeding in 9; gastro-intestinal bleeding in 3; epistaxis in 7; gum bleeding in 2; heavy menses in 7. One patient experienced cerebral ischemia (concomitant disease: acleisto-cardia). Twenty one patients underwent surgery and 15 dental extractions. Prior to diagnosis carried out at our center, tranexamic acid and plasma infusions were used as prophylactic anti-hemorrhagic treatment before surgery in 2 and 1 cases, respectively. Only 1 patient bled after dental extraction. Eleven spontaneous deliveries and 8 cesarian sections were carried out without any prophylaxis treatment. No hemorrhagic or thrombotic complications were reported. No spontaneous abortions occurred. *Conclusions*. In our case series the prevalence of asymptomatic patients is inferior to literature data (37% vs 53%). Only 1 patient (4%) had a thrombotic event. Most hemorrhagic patients (59%) experienced only mild symptoms. None of them needed red blood cell transfusions. Anti-hemorrhagic prophylaxis of surgery with tranexamic acid and plasma was administered in other institutions, before diagnosis, on the basis of the low fibrinogen activity in pre-operative coagulation screening.

THE CONFORMATIONAL CHANGES OF THE VON WILLEBRAND FACTOR (VWF) TESTED BY NANOBODY AU/VWF-A11 IN A COHORT OF 86 PATIENTS WITH DIFFERENT TYPES OF VON WILLEBRAND DISEASE: AN ADDITIONAL TOOL TO LOCALYZE MOLECULAR DEFECTS OF VWF

A.B. Federici,[1] E. Groot,[2] M. Punzo,[1] P.J. Lenting,[2] F. Rezzonico,[1] L. Baronciani,[1] P.G. De Groot[2]

[1]University of Milan, MILAN, Italy; [2]Dept. of Clin. Chemistry and Hematology, University of Utrecht, UTRECHT, Netherlands

Background. von Willebrand disease (VWD) is the most common inherited bleeding disorder that is caused by quantitative (VWD1 and VWD3) or qualitative (VWD2A. VWD2B, VWD2M, VWD2N) defects of von Willebrand factor (VWF). Several laboratory tests are usually required for a correct diagnosis of these VWD types. A llama-derived antibody fragment (nanobody) recognizing the glycoprotein Iba-binding conformation of VWF (VWF-GPIb:BC) has been developed (Blood 2005;106:3035) and values higher than normal have been found in patients with VWD2B. *Aims, Patients and Methods*. To further explore the usefulness of VWF-GPIb:BC in VWD diagnosis we have tested the nanobody in the plasma obtained from 86 patients with VWD1 (12),

VWD1/2MVIC (6); VWD1/2BNY (12), VWD2A (14); VWD2B (32), VWD2M (10), all characterized by mutations within or outside VWFA1 domain. All the 86 patients enrolled in the study were diagnosed by ristocetin induced platelet aggregation (RIPA) in the platelet rich plasma, ristocetin cofactor activity (VWF:RCo), VWF antigen (VWF:Ag), multimeric structure of VWF. Mutations within or outside VWFA1 domain were searched for and confirmed by sequencing. VWF-GPIb:BC was tested in 40 normal individuals (% of normal plasma = 0.70+0.13), in all VWD (86) at baseline and in 12 cases with VWD1, VWD2A and VWD2M before-1-2 hours after desmopressin (DDAVP). *Results*. VWF-GPIb:BC was high in all VWD2B but the 16 cases with P1266L/Q, R1308L mutations not associated with thrombocytopenia, with values up to 6 times higher than those of healthy controls. Interestingly, high VWF-GPIb:BC was also found in VWD2M(10) patients with mutations (D1277-78EdelInsL, R1315C/L, Y1321C, R1374H) within VWFA1 domain. Values lower than normal were measured in VWD1 and VWD2A, all characterized by mutations outside VWFA1. VWF-GPIb:BC was also measured before-1-2 hours after DDAVP in 12 patients [known mutations] and mean results were as follows: VWD1(6) [R202W, R275C, R1205H, R1583Q, C1927R]=0.5-1.7-1.5; VWD2A(3) [S1506L, V1607D, V1665E]=0.1-0.5-0.4;VWD2M(3) [D1277-78EdelInsL,R1315L,R1374H]=2.2-4.0-3.6. VWF-GPIb:BC levels increased after DDAVP because of the VWF released from endothelial cells, but remain lower than normal in VWD1 and VWD2A. *Conclusions*. Patients with VWD1 and VWD2 showed different results on VWF-GPIb:BC which might reflect the effect of mutations in adjacent domains (D3 and A2) on the GpIb-binding conformation of the A1 domain. Based on these results we conclude that VWF-GPIb:BC can be a useful tool for a rapid identification of different VWD types.

ASSOCIATION OF HEALTH-RELATED QUALITY OF LIFE (HRQOL), BLEEDING, AND PLATELET LEVELS IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP): RESULTS FROM RAISE AND EXTEND

J. Bussel,[1] K.M. Grotzinger,[2] M. Duh,[3] J. Signorovitch,[3] N.L. Stone,[2] A. Brainsky[2]

[1]Weill Cornell Medical College, NEW YORK, USA; [2]GlaxoSmithKline, COLLEGEVILLE, USA; [3]The Analysis Group, BOSTON, USA

Background. Chronic ITP is characterized by autoantibody-induced platelet destruction and reduced platelet production, leading to a low platelet count (<150 Gi/L). Bleeding and bruising signs and symptoms are largely dependent on the platelet count. Eltrombopag treatment is aimed at elevating and maintaining platelets above 50 Gi/L to minimize the risk of bleeding and to improve HRQoL and functioning. *Aim.* To evaluate the association among HRQoL outcomes, bleeding, bruising, and platelet counts in RAISE and EXTEND, long-term trials of eltrombopag. *Design and Methods*. The strength of the correlation among mean HRQoL outcomes, platelet levels, and frequency and severity of bleeding was estimated from linear models using generalized estimating equations methodology in previously reported RAISE and EXTEND studies (Cheng et al. Blood. 2008;112:400; Bussel et al. Blood. 2008;112:3432). Bleeding was evaluated using the WHO Bleeding Scale (Grade 0 = no bleeding through Grade 4 = debilitating blood loss). HRQoL was self-reported at baseline and various points during the study using: 1) the SF-36v2; 2) FACIT-Fatigue subscale; and 3) 6-item subset of the FACT-Thrombocytopenia (FACT-Th), which focuses on concern with bruising and bleeding, and limits to daily physical and social activities. *Results*. RAISE data from 197 evaluable patients suggest that as platelet counts rise and bleeding is reduced, HRQoL improvement is perceived by patients with chronic ITP (Table). All associations between HRQoL and bleeding, and between HRQoL and platelet counts, are statistically significant at $p<0.05$; coefficients are directionally correct. Similar results are observed in EXTEND with 144/207 patients evaluable (data not presented). The increases in platelet counts, decreases in bleeding, and increases in HRQoL were previously reported as independent outcomes in the long-term trials of eltrombopag; selected results are presented below as context. The statistically significant associations presented above suggest that these outcomes are linked. In RAISE, the median platelet count began to rise after 1 week in eltrombopag-treated patients and remained >50 Gi/L throughout the 6-month treatment period, whilst median platelet counts for the placebo group did not rise above 30 Gi/L. Fewer patients in the eltrombopag group had clinically significant bleeding compared with the placebo group. HRQoL improvements were observed in vitality, emotional role, and physical role domains during eltrombopag therapy, whereas no improvements were observed in the placebo group. In EXTEND, approximately 80% of evaluated patients achieved platelet counts >50 Gi/L during the study. In EXTEND, as in RAISE, elevations in platelet counts and reductions in bleeding were accompanied by improvements in HRQoL across multiple domains, measures of fatigue, and activities of daily living. *Conclusions*. HRQoL improvements in the RAISE (and EXTEND) studies are associated with elevation in platelets and reduction in bleeding and bruising symptoms, and improves one or more dimensions of HRQoL.

Table.

HRQoL Domain or Component Score	Covariate	Coefficient[a]	95% CI
SF-36v2			
Vitality	Platelet Count	1.90	0.36 , 3.45

	WHO Bleeding vs No Bleeding	-2.77	-3.99 , -1.55
FACIT-Fatigue	Platelet Count	1.43	0.78 , 2.07
	WHO Bleeding vs No Bleeding	-3.70	-5.22 , -2.18
FACT-Th (6 items)	Platelet Count	0.99	0.62 , 1.37
	WHO Grade >0 vs 0	-2.68	-3.56 , -1.80

CI, confidence interval.
a. The coefficient is estimated from an unadjusted linear longitudinal model and describes the change in mean outcome associated with a one unit increase in the covariate, including only subjects completing baseline assessments. Platelet counts are expressed as log transformations.

1059

EFFICACY AND SAFETY OF ROMIPLOSTIM VERSUS MEDICAL STANDARD OF CARE AS CHRONIC THERAPY FOR NONSPLENECTOMIZED PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

J. Rummel,[1] R. Boccia,[2] B.G. Macik,[3] I. Pabinger,[4] D. Selleslag,[5] L. Gehl,[6] X. Wang,[6] D.P. Berger,[6] D.J. Kuter[7]

[1]Klinikum der Justus-Liebig-Universität, GIESSEN, Germany; [2]Center for Cancer and Blood Disorders, BETHSEDA, USA; [3]University of Virginia, CHARLOTTESVILLE, USA; [4]Medizinische Universitaet Wien, WIEN, Austria; [5]Algemeen Ziekenhuis Sint-Jan, BRUGGE, Belgium; [6]Amgen Inc., THOUSAND OAKS, USA; [7]Massachusetts General Hospital, BOSTON, USA

Background. Chronic ITP is an autoimmune disease characterized by low platelet counts due to both increased platelet destruction and suboptimal platelet production. Conventional ITP therapies that target the immune system have variable response rates and issues regarding toxicity. Romiplostim is an Fc-peptide fusion protein (peptibody) that increases platelet counts by a mechanism similar to thrombopoietin, and has recently been approved in the EU, US, Canada, and Australia for the treatment of chronic ITP. *Aims*. To evaluate the ability of romiplostim versus medical standard of care (SOC) to reduce the incidence of splenectomy and treatment failures in adult nonsplenectomized ITP patients during a 52-week treatment period. *Design and Methods*. Patients provided informed consent and were randomized (2:1) to romiplostim or SOC and stratified by geographic region. Eligible patients either had a platelet count $<50\times10^9$/L or had their platelet count fall to $<50\times10^9$/L during or after a clinically-indicated taper or discontinuation of current ITP therapy. Once-weekly subcutaneous romiplostim was administered with dose adjustments based on platelet count. SOC treatments were prescribed by the investigator according to standard institutional practices or therapeutic guidelines; the only treatments not allowed were investigational agents (rituximab was allowed) or other thrombopoietic agents. The first primary endpoint was the incidence of splenectomy or study discontinuation. The second primary endpoint was the incidence of treatment failure (defined as: platelet count 20×10^9/L for 4 consecutive weeks at the highest recommended dose and schedule, or major bleeding event, or change in therapy due to intolerable side-effect or bleeding symptoms) or study discontinuation. *Results*. In total, 234 patients were randomized (SOC, 77; romiplostim, 157). In romiplostim-treated patients, there was a significantly lower incidence of splenectomy or study discontinuation (OR, 0.169; 95% CI: 0.081, 0.351; $p<0.0001$) and treatment failure or study discontinuation (OR, 0.374; 0.188, 0.744; $p=0.0039$) than in patients receiving SOC. A sensitivity analysis, applied to patients who did not discontinue the study, showed a consistent trend in the incidence of splenectomy and treatment failure with both of the

primary endpoint results. Safety analyses included all patients who received ≥1 dose of romiplostim or 1 type of SOC for ITP. Adverse events were experienced by 92% (69/75) of patients receiving SOC and by 95% (146/154) of patients receiving romiplostim. The most common adverse events in the SOC group were epistaxis (23%), nasopharyngitis (19%), and contusion (19%); and in the romiplostim group were headache (35%), fatigue (27%), and nasopharyngitis (23%). Treatment-related serious adverse events were reported by 8% (6/75) of SOC and 5% (7/154) of romiplostim patients. Three patients died during the 52-week treatment period: 2 SOC patients (cardio-respiratory arrest, hepatic failure), and 1 romiplostim patient (pneumonia). None of the deaths were deemed related to study treatment. Bleeding events with grade ≥3 severity were reported by 8% (6/75) of patients in the SOC group, compared with 3% (5/154) in the romiplostim group. *Conclusions*: Romiplostim significantly reduced incidences of splenectomy and treatment failure in nonsplenectomized ITP patients compared to standard of care. The safety profile was comparable between patients receiving romiplostim and those receiving SOC.

Table. Incidence of splenectomy and treatment failure.

	SOC N = 77	Romiplostim N = 157
Primary endpoints		
Splenectomy or study discontinuation[A]		
Overall	27/77 (35%)	13/157 (8%)
North America	12/31 (39%)	5/64 (8%)
European Union	11/37 (30%)	7/75 (9%)
Australia	4/9 (44%)	1/18 (6%)
Odds ratio, romiplostim/SOC (95% CI)	0.169 (0.081, 0.351)	
p-value	< 0.0001	
Treatment failure or study discontinuation[B]		
Overall	21/77 (27%)	19/157 (12%)
North America	11/31 (36%)	5/64 (8%)
European Union	8/37 (22%)	13/75 (17%)
Australia	2/9 (22%)	1/18 (6%)
Odds ratio, romiplostim/SOC (95% CI)	0.374 (0.188, 0.744)	
p-value	0.0039	
Sensitivity analysis[C]		
Splenectomy	15/77 (19%)	2/157 (1%)
Odds ratio, romiplostim/SOC (95% CI)	0.05 (0.01, 0.24)	
Treatment failure	9/77 (12%)	8/157 (5%)
Odds ratio, romiplostim/SOC (95% CI)	0.4 (0.14, 1.10)	

[A] Patients who received romiplostim or SOC and who discontinued study before reporting a splenectomy were scored as having had a splenectomy.
[B] Patients who received romiplostim or SOC and who discontinued study before reporting a treatment failure were scored as having had a treatment failure.
[C] Sensitivity analysis compared the incidence of patients who actually either reported a splenectomy procedure or met the treatment failure definition, excluding patients who discontinued the study.
Change in therapy to splenectomy, due to intolerable side-effects or bleeding symptoms, was counted as both treatment failure and splenectomy.

[1]Department of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Department of Hematology/Oncology Seràgnoli, University of Bologna, BOLOGNA; [3]Department of Genetics and Microbiology, University of Bari, BARI; [4]Department of Clinical and Biological Science, University of Turin at Orbassano, TURIN; [5]Dept. of Cellular Biotechnologies and Hematology, La Sapienza University, ROME; [6]Pediatric Oncology and Hematology L. Seràgnoli, BOLOGNA, Italy; [7]Ceinge Biotecnologie Avanzate and Dpt. of Biochemistry and Medical Biotechnology, NAPLES, Italy

Background. Recently, in genome-wide analyses of DNA copy number abnormalities using single nucleotide polymorphism (SNP) microarrays, a high frequency of genetic alterations of regulators of B-lymphoid development (Mullighan et al., Nature 2008) was described in B-progenitor ALL. Genetic alterations targeting the B lymphoid transcription factor PAX5 were identified in over 30% of cases. *Aim*. To characterize, by high resolution SNP arrays, the rearrangements on 9p involving the PAX5 locus. *Patients and Methods*. Affymetrix Human Mapping 250K NspI and Genome-Wide Human SNP 6.0 arrays and FISH assay using fosmid probes were used to profile the genomic of 98 adult BCR-ABL1-positive ALL patients. *Results*. The most frequent somatic copy number alterations affecting B-lymphoid development were deletions on 7p12 involving the IKZF1 gene (76/98, 78%), which encodes the transcription factor Ikaros, and mono-allelic copy number changes on 9p chromosome involving the PAX5 gene (31/98, 32%). Overall mono-allelic loss of PAX5 was identified in 28 patients (29%), whereas internal amplification in only 3 cases (3%). Four major PAX5 losses occurred: 1) focal deletions involving only the PAX5 gene in 3 cases (3%) with the minimal overlapping region of 101 kb from 37021876 to 36920536; 2) deletions involving only a portion of PAX5 and flanking genes in 8 (8%) with a median size of 364 kb (range: 154 kb-16395 kb) and ranging from 36603003 on 9p13.3 to 20553365 on 9p21.3; 3) broader deletions involving PAX5 and a variable number of flanking genes in 11 patients (11%) with a median size of 947 kb (range: 567 kb-18208 kb) and ranging from 36948016 on 9p13.3 to 20553365 on 9p21.3; 4) deletion of all chromosome 9 or 9p in 6 patients (6%). In 23 patients (23%) we identified the deletions of both IKZF1 and PAX5; in 51 patients (52%) only the deletion of IKZF1 was found, while the presence of deletion or rearrangements of only PAX5 gene was found in 5 patients (5%). In two cases we identified the loss of IKZF1 and the gain of an internal region of PAX5. According to the type of deletion we could have PAX5 haploinsufficiency or PAX5 mutants with impaired DNA-binding or transactivating activitiy. All these alterations are predicted to result in attenuation, but not complete abrogation of PAX5 activity, suggesting that PAX5 is a haploinsufficient tumor suppressor. FISH analysis with three overlapping BAC probes encompassing the whole PAX5 gene was performed confirming what obtained by SNP-array analysis. To investigate the consequences of genomic PAX5 alteration in BCR-ABL1-positive ALL patients, quantitative PCR (q-PCR) was used to assess the expression of PAX5 in cases with copy number changes on 9p13.2. Q-PCR confirmed the SNP results demonstrating that genomic alterations on 9p13.2 leads to a significant down-modulation at the transcript level of the Pax5. *Conclusions*. PAX5 rearrangements occurred at an incidence of about 30% in adult BCR-ABL1 ALL and its impairment may be associated with the development of this for this poor prognosis subtype of leukemia.

T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive malignancy of thymocytes that accounts for about 15 percent of ALL cases. Leukemic transformation of immature thymocytes is caused by a multistep pathogenesis involving numerous genetic abnormalities providing uncontrolled cell growth. Accumulating evidence suggests the presence of at least 5 different molecular-cytogenetic subgroups in T-ALL, ie. TAL/LMO, TLX1, TLX3, HOXA and MYB. Recently, non-coding microRNAs were discovered as important regulators of gene and/or protein expression and subsequently shown to be directly implicated in cancer. Nevertheless, it is currently unclear in which way deregulated miRNA expression may contribute to the pathogenesis of T-cell acute leukemia. In this study, we investigated whether different genetic subgroups in T-ALL are characterized by distinct miRNA expression patterns. Therefore, we profiled a total of 430 miRNAs using high-throughput quantitative stem-loop RT-PCR in a genetically well characterized T-ALL patient cohort (n=52), including 11 HOXA (3 MLL rearranged, 5 inv(7)(p15q35) and 3 CALM-AF10), 16 TAL/LMO (7 LMO2 rearranged, 8 SIL-TAL1 and 1 LMO2/TAL1 rearranged), 11 TLX3 and 5 TLX1 rearranged patient samples. Since T-ALL blasts originate from maturating T lymphocytes, we also profiled different subsets of sorted T-cell populations ($CD34^+$, $CD4^+/CD8^+/CD3^-$, $CD4^+/CD8^+/CD3^+$, $CD4^+$ single positive and $CD8^+$ single positive). These miRNA profiles of normal T-cells served as a negative control for the identification of deregulated miRNA expression that may be truly leukemia associated. SAM analysis (t-test and Wilcoxon, FDR=0) identified significant and differentially expressed miRNAs between the HOXA, TLX3 and TAL/LMO subgroups whereas no significant differentially expressed miRNAs were obtained for the TLX1 subgroup, probably due to the limited number of patient samples for this latter group. The HOXA subgroup showed specific up-regulation of miR-196a and miR-196b, which are encoded at the HOXB and HOXA cluster, respectively, but no significantly down-regulated miRNAs could be identified in this subgroup. The TLX3 subgroup was uniquely characterized by the up-regulation of miR-99a, miR-125b, let-7c, miR-508 and miR-509, and down-regulation of miR-127 and miR-182. Finally, specific up-regulation of miR-424, miR-148a, miR-422, miR-362, miR-148a, miR-502, miR-10a, miR-200c, miR-31, miR-660 and miR-15b, was identified in the TAL/LMO rearranged subgroup, which was also characterized by the specific down-regulation of miR-99b, miR-155, miR-125a, miR-153, miR-135a, miR-34a and miR-193b. Next, we evaluated the expression pattern of all significant and differentially expressed microRNAs in the different subsets of sorted normal T-cell populations. The expression patterns of these microRNAs could be classified into consistently active, completely absent or temporally regulated during T-cell development. For the microRNAs showing a temporal regulation during T-cell maturation, their differential expression in T-ALL subtypes may reflect differences in the maturation arrest of the T-cell of origin, rather than pointing to an oncogenic event. Nevertheless, their constitutive (in)activation in primary T-ALL patients could still be of oncogenic relevance, similar to transcription factors like TAL1 or LMO2 which also show a temporal regulation during T-cell maturation. In contrast, some other microRNAs showed no expression in any of the T-cell populations, providing strong evidence that their activation in specific T-ALL subtypes may contribute to T-ALL pathogenesis. In conclusion, this study shows that molecular-cytogenetic subgroups in T-ALL are characterized by a specific miRNA expression signature. In addition, correlation of our findings to the expression of these miRNAs in normal T-cell subsets may guide us to the miRNAs with true oncogenic potential. This report paves the way for further investigation directed at the role of these miRNAs in the pathogenesis of T-ALL, which may provide us with further insight in the oncogenic pathways that are (in)activated in different T-ALL subgroups. Ultimately, these deregulated miRNAs may offer new targets for therapeutic intervention.

WILMS' TUMOR 1 GENE MUTATIONS IN ACUTE T-LYMPHOBLASTIC LEUKEMIA

R. Ben Abdelali,[1] A. Renneville,[2] V. Asnafi,[1] J.-B. Micol,[3] O. Nibourel,[2] S. Lenoir,[1] S. Geffroy,[2] M. Cheok,[2] H. Dombret,[4] E.A. Macintyre,[1] C. Preudhomme[2]

[1]Necker Hospital, PARIS, France; [2]Biological Hematology, LILLE, France; [3]Hematology, LILLE, France; [4]Hematology Saint Louis, PARIS, France

The wilms tumor 1 gene (WT1) encodes a transcriptional regulator involved in normal hematopoietic development and is aberrantly expressed in a subset of acute myeloid leukaemia (AML). When it is used for MRD monitoring, failure to normalize WT1 transcript levels after treatment predicted a significantly increased relapse risk. In addition, mutations of WT1 have been found in about 10% of AML patients (pts) and have recently been shown to predict poor outcome. Although Heesch et al. (ASH 2008) reported WT1 mutations in 8% of 239 adult T acute lymphoblastic leukemias (T-ALL), little data is available regarding the frequency, characteristics and clinical impact of WT1 mutations in this disorder. We searched for WT1 mutations in 204 T-ALL pts (128 adults and 76 children). 111 out of 128 adult T-ALLs were enrolled in the French GRAALL or LALA protocols. Diagnostic bone marrow specimens were studied for WT1 mutations by DNA sequencing. All pts were screened for exon 7 and 9 mutations and 46 pts were screened for all WT1 exons (1-10). Mutation status was compared with immunophenotype, T-Cell receptor (TCR) status, WT1, HOX11/TLX1, HOX11L2/TLX3, SIL-TAL, CALM-AF10, NUP-ABL transcript levels by real-time RT-PCR and NOTCH1 and FBXW7 mutational status. Sixteen out of 204 pts (8%) were found to have a WT1 mutation; 13 in exon 7 and 3 in exon 9. WT1 exon 7 mutations were frameshift mutations predicted to result in a truncated WT1 protein whereas exon 9 mutations were missense mutations. All identified mutations were heterozygous. No mutations were detected outside exon 7 and 9 in the 46 pts tested. Frequency of mutation did not differ significantly between adult and pediatric pts. WT1mut and WT1 wildtype (WTwt) pts did not significantly differ with respect to clinical parameters at diagnosis. WT1 was over-expressed in 75% of T-ALL, particularly those of the TCRαβ lineage (p=0.001) and all WT1mut pts demonstrated high WT1 expression levels [WT1mut median: 88.6% (range 17.2%%-557%) vs. WT1wt median: 7.8% (range: 0.001%-774%); p=0.001]. WT1mut were significantly (p=0.02) associated with deregulation of HOXA or TLX1/3 genes (4 TLX3 , 2 TLX1 , 2 CALM-AF10 , 1 MLL-AF6) and 3/9 WT1mut were NUP214-ABL positive vs 7/117 WT1wt (p=0.02). 10/12 WT1mut were NOTCH1 mutated (p=0.05). WT1mut cases were not characterized by particular immunophenotypic features in the EGIL classification , but were preferentially associated with expression of CD79a and with the TCRγδ lineage (5/51 IMδ/IMγ/TCRγδ vs. 2/92 IMb/pre ab/TCR ab cases, p=0.04). No WT1mut were seen in the 8 immature IM0 T-ALLs. Amongst adult T-ALLs, no significant differences were observed in the complete remission rate or overall survival., although 5/7 WT1mut relapsed vs 47/99 WT1wt pt and the DFS tended to be shorter when WT1 is mutated (median 10.8 months) vs. WT1wt (28.5 months). In conclusion, WT1 mutations occur in 8% of adult and pediatric T-ALL and are located in the same region as in AML. WT1mut T-ALLs express relatively high level WT1 transcripts and are found preferentially in T-ALLs of the TCRγδ lineage and/or in those which express HOXA or TLX1/3. Their prognostic impact needs to be tested in a prospective fashion.

ANALYSIS OF GENOMIC BREAKPOINTS INDICATES THAT BCR-ABL IN ACUTE LYMPHOBLASTIC LEUKAEMIA MAY ARISE IN A COMMITTED LYMPHOID PROGENITOR CELL IN A SUBSET OF CASES

J.C. Score,[1] M.J. Calasanz,[2] F. Pane,[3] O. Ottmann,[4] R.-F. Yeh,[5] J. Wiemels,[5] F.H. Grand,[6] N.C.P. Cross[6]

[1]WRGL, University of Southampton, SALISBURY, UK; [2]Department of Genetics, School of Science, University of Navarra, PAMPLONA, Spain; [3]Division of Haematology, Cardarelli Hospital, NAPLES, Italy; [4]Department of Hematology and Oncology, Johann Wolfgang Goethe University, FRANKFURT, Germany; [5]Department of Epidemiology and Biostatistics, UCSF Medical School, SAN FRANCISCO, USA; [6]WRGL, Salisbury and Human Genetics Division, University of Southampton, SALISBURY, UK

Chromosomal translocations in haematological malignancies are believed to result from non-homologous end joining (NHEJ) following two double stranded DNA breaks. In lymphoid disorders, DNA breaks may be a consequence of normal or aberrant RAG and/or AID activity, whereas in myeloid disorders the reasons for breakage are unknown. The paradigm for fusions genes in leukaemia is BCR-ABL, produced as a consequence of the t(9;22). In chronic myeloid leukaemia (CML), breaks within BCR are located in the 5.8 kb major breakpoint cluster region and a region of at least 200 kb in ABL, resulting in a p210 BCR-ABL protein. In Philadelphia chromosome positive acute lymphoblastic leukaemia (Ph+ ALL) the breaks within BCR are frequently located further upstream in the 40 kb minor breakpoint cluster region, resulting in a smaller p190 protein. To determine if the mechanism giving rise to the Ph chromosome is different in CML vs ALL, or p210 vs p190, we developed a FISH and long range PCR strategy to amplify and sequence t(9;22) genomic breakpoints. Forward breakpoints were characterized from 25 cases with p190 ALL, 25 with p210 ALL and 32 with p210 CML and reciprocal breakpoints were identified in a subset of these cases. Statistical analysis of the forward BCR breakpoints revealed 2 distinct clusters in p210 ALL but no significant clusters in CML or p190 ALL. Analysis of the forward ABL breakpoints showed evidence for 2 clusters in p210 ALL and one cluster in p190 ALL, but no clustering in CML. When the forward breakpoints were compared to the proximity of sequence motifs, the only significant association was a deficit of breakpoints falling in repeat regions for p210 BCR breakpoints. No significant differences were found in the distribution of forward breakpoints in ABL between the different subtypes of leukaemia. However, comparison of the patterns at reciprocal breakpoints showed differences between p190 and p210, suggesting that they may be formed by distinct mechanisms. To explore this in more detail, we performed extra-chromosomal recombination assays to test the possibility of RAG involvement in selected cases in which breakpoints were found to be close to cryptic recombination signal sequence (RSS) sites. Of 5 p190 cases tested, one had a 'specific' RSS 4 bp from the forward breakpoint but at the exact location of the reciprocal breakpoint. Involvement of RAG was confirmed by the formation of both coding joints and signal joints, which is the defining feature of V(D)J recombination. In addition 1 of 3 p210 ALL cases tested had a 'specific' RSS at the forward breakpoint, however only a hybrid joint and signal joints were formed therefore the significance of this is uncertain. Neither of the p210 CML cases tested gave 'specific' RSSs. Our data therefore shows that aberrant RAG mediated recombination is involved in a subset of BCR-ABL translocations in ALL, supporting the hypothesis that the fusion may arise in a committed lymphoid progenitor cell, at least in some cases.

Introduction. The BCR-ABL1 fusion gene defines the subgroup of acute lymphoblastic leukaemia (ALL) with the worst clinical prognosis. *Aim and Methods*. To identify oncogenic lesions that combine with BCR-ABL1 to cause ALL, we used Affymetrix Genome-Wide Human SNP arrays (250K NspI and SNP 6.0) and genomic PCR to study 106 cases of adult BCR-ABL1-positive ALL. *Results*. The most frequent somatic copy number alteration was a deletion on 7p12 of IKZF1, which encodes the transcription factor Ikaros and was identified in 80 of 106 patients (75%). Two major deletions occurred: the first one (Δ4-7) was characterised by a loss of exons 4 through 7 (44/106, 42%), and the second one (Δ2-7) that we cloned was characterised by removal of exons 2 through 7 (20/106, 19%). A variable number of nucleotides (patient-specific) were inserted at the conjunction and maintained with fidelity at the time of relapse. The extent of the Δ4-7 deletion correlated with the expression of a dominant-negative isoform with cytoplasmic localisation and oncogenic activity, while the Δ2-7 deletion resulted in a transcript lacking the translation start site. The IKZF1 deletion was also identified in the progression of chronic myeloid leukaemia (CML) to lymphoid blast crisis (66%), but never in myeloid blast crisis or chronic phase CML, or in acute myeloid leukaemia patients. Known DNA sequence and structural features were mapped along the breakpoint cluster regions including heptamer recombination signal sequences (RSS) recognised by RAG enzymes during V(D)J recombination, suggesting that IKZF1 deletions could arise from aberrant RAG-mediated recombination. Using gene-set enrichment analysis to compare the gene-expression signatures of patients with IKZF1 deletion versus not-deleted patients, we identified a unique signatures characterized by down-regulation of genes involved in pre-B-cell differentiation (e.g. VPREB1, VPREB3, IGLL3, BLK) and up-regulation of genes involved in cell-cycle progression (STK17B, SERPINB9, CDKN1A). These findings suggest that genetic alterations of IKZF1 influence the transcriptome and contribute to an impaired B-cell differentiation. We next investigated whether the IKZF1 deletions associated with a poor outcome. Univariate analysis showed that the IKZF1 deletion is a negative prognostic marker influencing the cumulative incidence of relapse (10.1 months for pts with deletion vs 56.1 months for wild-type pts, p=0.0103) and disease-free survival (DFS) (10.1 months vs 32.1 months, respectively, p=0.0229). The negative prognostic impact of the IKZF1 deletion on DFS was also confirmed by multivariate analysis (p=0.0445). *Conclusions*. Deletion of IKZF1 is an important event in the development of BCR-ABL1 B-progenitor ALL which significantly influences clinical outcome. It is likely that Ikaros loss combines with BCR-ABL1 to induce lymphoblastic leukaemia, arresting B-lymphoid maturation.

A MULTICENTER PHASE I-II STUDY OF TOSEDOSTAT IN THE TREATMENT OF PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKAEMIA

G. Ossenkoppele,[1] W. Hooftman,[2] S. Zweegman,[1] E. Davies,[3] G. Morgan,[3] C. Mueller-Tidow,[4] U. Krug,[4] U. Duhrsen,[4] A. Burnett,[5] C. Jenkins,[5] P. Zachee,[6] D. Dierickx,[4] B. Lowenberg,[7] P. Sonneveld,[7] L. Hooftman,[8] A. Richardson[8]

[1]VUMC, AMSTERDAM, Netherlands; [2]Chroma Therapeutics Ltd., OXFORD, UK; [3]Royal Marsden Hospital, LONDON, UK; [4]University Hospital, MUNSTER, Germany; [5]Cardiff University Hospital, CARDIFF, UK; [6]ZNA, ANTWERP, Belgium; [7]Erasmus Medical Centre, ROTTERDAM, Netherlands; [8]Chroma Therapeutics Ltd, OXFORD, UK

The aminopeptidase inhibitor, tosedostat (TSD, CHR-2797,) selectively depletes amino acid pools in malignant cells, causing anti-proliferative, pro-apoptotic and anti-angiogenic effects. In this open label, single-arm, phase I-II study of TSD elderly/previously treated patients with AML/high risk MDS were treated with escalating doses (60-180 mg) of once daily TSD in phase I, and with the recommended dose (130 mg once daily) for 84 days or longer in phase II. Clinical responses were assessed by monthly bone marrow aspirates and weekly haematological assessments. The primary efficacy endpoint was bone marrow complete response (CR). In total, 35 patients with relapsed/refractory AML and 1 patient with relapsed 'high risk' MDS were enrolled in this trial, 10 in phase I, and 26 in phase II. Twenty five patients were male and 11 were female, with a median age of 68 years (range 34-78). The median performance status (ECOG) at baseline was 1 (range 0-2). Of the AML patients, 10 (29.4%) had either secondary leukaemia or adverse cytogenetics or both. For 10 patients (28.6%), treatment with TSD was a second or later salvage attempt. Half of the patients completed the formal 84-day study period, and 17 (16 AML, 1 MDS) continued treatment with TSD after 84 days. MTD (phase I) was 130 mg with 2 out of 4 patients on 180 mg developing DLT (>75% drop in platelet count). Eleven (31.4%) relapsed/refractory AML patients achieved a bone marrow response: 6 CR (<5% blasts in bone marrow), and 5 partial responses (PR, 5-15% blasts); four patients achieved a complete haematological recovery (in remission for up to 12 months), and another patient reached a cytogenetic response. The single patient with MDS RAEB-1 achieved a morphological bone marrow response, and remained stable for more than 6 months. All responders were >60 years at the time of the first dose. Median overall survival was 131.5 days (range 33 - 623) in all AML patients, and 253 days (range 130-470) in AML patients with CR. The most frequently reported adverse events were: thrombocytopenia (61.1%), fatigue (47.2%), diarrhoea (41.7%) and anaemia (38.9%). Three patients (8%) withdrew due to a drug related toxicity. In summary: this study in patients with relapsed and refractory AML/MDS has shown anti-leukaemic activity of TSD in a substantial number of AML patients with very poor prognosis. TSD at 130 mg once daily is also very well tolerated over a long period of exposure (6-12 months). TSD will be tested in a pivotal study in relapsed AML.

Background. Epigenetic therapies in the form of demethylating agents or histone deacetylase inhibitors demonstrate significant clinical activity in patients with acute myeloid leukaemia (AML) and myelodysplasia (MDS) and represent an important new therapeutic modality in myeloid malignancies. Responses however are rarely durable and the great majority of patients will relapse. There is increasing interest in the contribution of leukaemic stem/progenitor cells to disease relapse in AML but the impact of epigenetic therapies on this cellular population has not been examined. *Aims*. We wished to correlate clinical response to combined treatment with a demethylating agent and a histone deacetylase inhibitor with changes in committed and multi-potent leukemic stem/progenitor cell populations in patients with high risk AML and MDS. *Design and Methods*. 45 patients with high risk AML/MDS (30 relapsed/refractory AML, 6 *de novo* AML, 9 high risk MDS) were treated with azacitidine (75 mg/m^2 5 days every 28 days), sodium valproate, all-trans retinoic acid and theophylline. The median age of the patient cohort was 66 years (range 32-85 years). 33 patients had good/intermediate risk cytogenetics and 12 adverse risk cytogenetics. Detailed immunophenotypic analysis, clonal assays (methyl cellulose and cobblestone-area forming colony assays, CAFC) and FISH analysis were performed on stem cell enriched (CD34+CD38-), common myeloid progenitor (CMP), granulocyte-monocyte progenitor (GMP) and megakaryocyte erythroid progenitor (MEP) compartments at diagnosis and during therapy. *Results*. Major clinical responses were observed in 15 patients; 7 achieved a complete remission (CR) or complete remission with incomplete blood count recovery(CRi) and 8 a partial response (PR). The median time to maximal clinical response was 2 cycles (range 1-6). 40% (6/15) of patients achieving CR, CRi or PR had adverse risk cytogenetics.In univariate and multivariate analysis blast percentage at presentation was the only significant predictor of response rate and overall survival. In all diagnostic samples abnormal immunophenotypic CD34$^+$CD38$^-$, CMP, GMP and MEP myeloid progenitor compartments were present. There was an anticipated failure of normal colony and CAFC growth from sorted CD34$^+$CD38$^-$ and myeloid progenitor populations. In responding, but not non-responding, patients there was partial or complete restoration of normal immunophenotypic populations accompanied by normal haemopoietic colony output. Restoration of normal immunophenotypic populations and colony output occurred in advance of clinical responses. In one patient who achieved a CR we were able to demonstrate persistence, in sorted stem/progenitor populations, of clonally abnormal cells. Morphologic relapse was preceded by an increase in clonally abnormal cells in the GMP compartment by 7 months. *Conclusions*. This is the first study to correlate clinical and biological response to epigenetic therapies at a stem/progenitor level and has implications for the use of these agents in the treatment of AML and MDS. These data provide original insights into the cellular kinetics of response and relapse in patients with AML treated with epigenetic therapies and identify potential biomarkers of response. The experimental approach outlined has more general implications for understanding the biological basis of disease relapse in patients with AML and MDS treated with both conventional chemotherapy and novel agents.

Background. In pediatric acute myeloid leukemia (AML), one important subgroup is characterized by translocations of chromosome 11q23, which accounts for 15 to 20% of all cases with an evaluable chromosome analysis. In most cases, 11q23 abnormalities involve the rearrangement of the mixed lineage leukemia (MLL) gene. More than 50 different fusion translocation partners of the MLL gene have been identified. In 11q23/MLL-rearranged childhood AML, the most common translocations are t(9;11)(p22;q23), t(11;19)(q23;p13.1), t(11;19)(q23;p13.3), t(6;11)(q27;q23), and t(10;11)(p12;q23). The 11q23/MLL rearrangements are considered to be associated with poor outcome. However, conflicting data concerning specific 11q23/MLL rearrangements have been reported; for instance some collaborative groups reported better clinical outcome for patients with AML and t(9;11)(p22;q23). Aim. Our aim was to identify differences in outcome between the different translocation partners in 11q23/MLL-rearranged AML in a large cohort of patients collected retrospectively from various collaborative groups. This could lead to a better risk group stratification of these patients in current and future pediatric AML treatment protocols. *Design and Methods*. A total of 756 11q23/MLL-rearranged AML cases were collected from 11 international study groups, representing nearly all recent pediatric AML trials (1993-2005). Survival analysis of the 11q23/MLL subgroups was performed, after central review of karyotypes and/or FISH and PCR results. Patients were assigned to subgroups based on their translocation partner. At least 10 patients had to be included per subgroup; otherwise, they were assigned to the "11q23/MLL-other" group. *Results*. Between the subgroups, age at diagnosis, white blood cell count (WBC), and morphology differed significantly ($p<0.001$). The 5y-pEFS, pOS, and cumulative incidence of relapse (CIR) of the total group with 11q23/MLL-rearranged pediatric AML were 44%, 56%, and 35%, respectively. However, the outcome between the different subgroups varied greatly. Patients with a t(1;11)(q21;q23) had a favorable 5y-pEFS of 92%, whereas those with a t(6;11)(q27;q23) had the worst outcome (5y-pEFS, 11%). Also the subgroups t(10;11)(p12;q23), t(10;11)(p11.2;q23), and t(4;11)(q21;q23) showed a worse 5y-pEFS of 31%, 17%, and 29% respectively (Table 1). Multivariate Cox-regression analysis identified the following independent poor-prognosis indicators for pEFS: t(6;11)(q27;q23) (HR 2.2, $p<0.001$), t(10;11)(p12;q23) (HR 1.5, $p=0.005$), and t(10;11)(p11.2;q23) (HR 2.5, $p=0.005$). The t(1;11)(q21;q23) (HR 0.1, $p=0.004$) was identified as a favorable prognostic indicator. Patients with t(9;11)(p22;q23) represented a heterogeneous group, but the subset with FAB-M5 (HR 0.4, $p<0.001$) was an independent favourable prognostic indicator. *Conclusions*. This retrospective study identified novel independent prognostic subgroups within 11q23/MLL-rearranged pediatric AML It is currently unknown whether other (as yet unidentified) secondary genetic abnormalities play a role in the differential treatment outcome of 11q23/MLL-rearranged AML, or that this is the mere result of the variation in translocation partners. This requires further studies to elucidate the underlying biology. We conclude that identifying the translocation partners in pediatric 11q23/MLL-rearranged AML at diagnosis is essential for effective risk group stratification, especially including t(1;11)(q21;q23), t(10;11)(p12;q23), a t(10;11)(p11.2,q23) and t(6;11)(q27;q23). The patients with a t(9;11)(p22;q23) represent a heterogeneous subgroup, and inclusion of FAB-type in diagnostics is strongly recommended for risk group stratification of patients with a t(9;11)(p22;q23).

Table 1. Survival analysis of subgroups of 11q23/MLL-rearranged AML and prognostic factors for those patients.

AZACITIDINE (AZA) IMPROVES OVERALL SURVIVAL (OS) IN WHO ACUTE MYELOID LEUKEMIA (AML) IN ELDERLY PATIENTS WITH LOW BONE MARROW BLAST COUNTS

P.F. Fenaux,[1] L.R. Silverman,[2] G.J. Mufti,[3] E. Hellström-Lindberg,[4] V. Santini,[5] N. Gattermann,[6] G. Sanz,[7] J.F. Seymour,[8] S.D. Gore,[9] H. Dombret,[10] D. McKenzie,[11] J. Backstrom,[11] C.L. Beach[11]

[1]Hopital Avicenne/Université Paris 13, BOBIGNY, France; [2]Mount Sinai School of Medicine, NEW YORK CITY, USA; [3]Kings College London, LONDON, UK; 4Karolinska University Hospital, STOCKHOLM, Sweden; [5]UF Ematologia Aou Careggi University of Florence, FIRENZE, Italy; [6]Heinrich-Heine-University, DÜSSELDORF, Germany; [7]Hospital Universitario La Fe, VALENCIA, Spain; [8]Peter MacCallum Cancer Centre, MELBOURNE, Australia; [9]Kimmel Comprehensive Cancer Center at Johns Hopkins, BALTIMORE, USA; [10]Hopital Saint-Louis, PARIS, Franc; [11]Celgene, SUMMIT, USA

Background. A subanalysis of the phase-III CALGB 9221 study compared AZA with best supportive care (BSC) in patients with WHO AML, and showed a trend for improved OS: 19.3 vs 12.9 months (Silverman JCO 2006;24:3895). Statistical significance was not achieved (hazard ratio [HR] = 0.70 [95%CI: 0.40-1.23], $p=0.2$), possibly due to small patient numbers and crossover design, patients with progression could crossover from BSC to AZA. A more recent phase-III study, AZA-001, showed AZA significantly prolongs OS in patients with higher-risk MDS vs conventional care regimens (CCR) (Fenaux, Lancet Oncol, 2009). AZA-001 employed FAB, but most RAEB-t patients met WHO criteria for AML. This subanalysis of the AZA-001 study sought to confirm and further elucidate the positive OS trend with AZA in WHO AML patients observed in the CALGB 9221 trial. *Design and Methods*. Patients with higher-risk MDS (FAB: RAEB, RAEB-t, CMML and IPSS: Int-2 or High) were enrolled. Before randomization, investigators preselected (based on clinical status and regional prescribing patterns) 1 of 3 CCR: BSC; low-dose ara-C (LDaraC), or intensive chemotherapy (IC). Subsequently, patients were randomized to AZA (75 mg/m^2/d SC x 7d q 28d) or CCR. If randomized to CCR, patients received their investigator preselected regimen. Karyotypes were reclassified using AML criteria into unfavorable (-7/del7q, 3q abnormality, complex); favorable (t(8;21) and inv16) (none in this analysis); and intermediate (others). OS was analyzed with Cox regression models and Kaplan-Meier (KM) methods. All patients were followed until death or study completion. *Results*. 113/358 (32%) patients met WHO AML criteria (median 23% marrow blasts); 55 were randomized to AZA and 58 to CCR. 53 CCR patients (5 withdrew before treatment) were treated as follows: BSC 47% (25/53), LDaraC 34% (18/53), and IC 19% (10/53). AZA and CCR groups had comparable baseline characteristics. Median age (both arms) was 70 years, with 24% and 72% having an unfavorable or intermediate karyotype (including 46% normal), respectively. Median (range) numbers of treatment cycles were 8 (1-39) for AZA; 2.5 (1-3) for IC; 5.5 (1-14) for LDaraC; and 6 months (2-19) for BSC. Median follow-up for OS was 20.1 months. KM median OS was 24.5 vs 16.0 months in the AZA and CCR groups, respectively, HR=0.47 [95%CI: 0.28-0.79], $p=0.004$ (Figure).

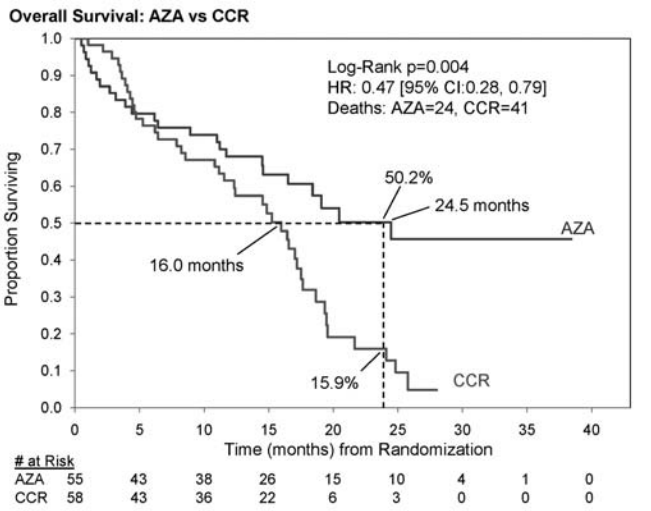

Figure.

At 2 yrs, 50% and 16% of the AZA and CCR groups, respectively, were alive, p=0.0007. OS results in cytogenetic intermediate patients showed a significant HR favoring the AZA group (N=38) over CCR (N=43), HR=0.47 [95%CI: 0.24-0.91], p=0.024. The HR was nonsignificant in patients with unfavorable cytogenetics: AZA (N=14) vs CCR (N=13), median 12.3 months vs 5.3 months, respectively, HR=0.66 [95%CI: 0.26-1.68], p=0.38. *Conclusions*. In the AZA-001 study, outcomes in WHO AML patients are consistent with and support the trend for improved OS observed in CALGB 9221. AZA demonstrates significant activity in elderly patients with WHO AML with low marrow blasts and prolongs OS vs CCR. AZA is currently being more widely evaluated in AML.

1069

PROGNOSTIC SIGNIFICANCE OF CEBPA MUTATIONS IN A LARGE COHORT OF YOUNGER ADULT PATIENTS WITH AML: IMPACT OF DOUBLE CEBPA MUTATIONS AND THE INTERACTION WITH FLT3 AND NPM1 MUTATIONS

C.L. Green,[1] K.K. Koo,[1] R.K. Hills,[2] A.K. Burnett,[2] D.C. Linch,[1] R.E. Gale[1]

[1]*UCL Cancer Institute, LONDON, UK;* [2]*Department of Haematology, School of Medicine, Cardiff University, CARDIFF, UK*

Prognostic markers identified in AML are becoming increasingly important as a means of risk-stratification for therapy. Mutations in the transcription factor CCAAT/enhancer binding protein α (CEBPA) are associated with a favourable prognosis, but a recent study has suggested this may be limited to patients with biallelic mutations. To investigate this we used dHPLC to screen the CEBPA gene in samples from 1049 young adult AML patients, excluding APL, who were entered into the UK MRC AML10 and 12 trials. Three PCR products were analysed, Fragment 1 covered the N-terminus (both start codons and transactivation domain [TAD] 1), Fragment 2 included TAD2 and Fragment 3 covered the C-terminus (DNA-binding and basic leucine zipper domains). Two common polymorphisms (synonymous G/T SNP rs34529039 and p.P194_H195 dup) were clearly identified by their chromatogram and were scored as Wild-type (WT), other samples with abnormal chromatograms were sequenced. Overall, 92 patients (9%) had one/more mutations (MUT); 43 (47%) had a single mutation and 49 (53%) had two mutations, including three that were homozygous. Mutant level ranged between 21% and 59%, median 45% (n=57). The full-length gene was cloned in samples from 11 biallelic MUT patients. In each case the majority of clones (86% overall) had only one mutation, indicating that the two mutations were on different alleles, but a small number (4%) were homozygous MUT. Presence of CEBPA mutations did not correlate with age, white blood cell count or type of leukaemia (de novo or secondary). Cytogenetics was available in 864 patients and the presence of mutations was strongly associated with the intermediate risk group (67 of 73 MUT cases, p=0.003), in particular a normal karyotype (50 of 73 MUT cases, p=0.01). The distribution of monoallelic and biallelic mutations did not differ in the normal versus other intermediate karyotypes (p=0.2). There was some evidence for a lower frequency of FLT3/ITDs in CEBPA MUT patients (29% were CEBPA-/ITD+, 22% CEBPA+/ITD+, p=0.05), which was more apparent in patients with biallelic mutations (32% vs. 13% for monoallelic vs. biallelic). There was a much lower frequency of NPM1 mutations in biallelic CEBPA MUT patients (44% vs. 39% vs. 4% NPM1+ in 0 vs. 1 vs. 2 MUT patients, p<0.0001). In the total cohort, a favourable outcome was restricted to biallelic MUT patients, 5 year overall survival (OS) 37% vs. 41% vs. 61% for 0 vs. 1 vs. 2 mutants (p=0.009) and relapse-free survival (RFS) 36% vs. 41% vs. 55% (p=0.02). This difference was less obvious if only patients in the intermediate risk group were analysed: OS 39% vs. 48% vs. 55% (p=0.05) and RFS 36% vs. 48% vs. 48% (p=0.06) respectively. There was some evidence that the favourable effect of CEBPA MUT was only present in FLT3/ITD- cases (p=0.08 for interaction), OS 41% vs. 46% vs. 68% in FLT3/ITD-, 29% vs. 23% vs. 17% in FLT3/ITD+ patients. These results indicate that the outcome in CEBPA mutated patients is dependent not only on the number of CEBPA mutations, but also on karyotype and other co-operating mutations.

Novel therapeutics and drug resistance

PX-171-006: PHASE IB MULTICENTER DOSE ESCALATION STUDY OF CARFILZOMIB (CFZ) PLUS LENALIDOMIDE (LEN) AND LOW DOSE DEXAMETHASONE (LODEX) IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA (MM) – PRELIMINARY RESULTS

M. Wang,[1] A. Gutierrez,[2] R. Niesvizky,[3] B. Bensinger,[4] M. Vallone,[5] A.A. Gutierrez,[2] M. Kauffman[2]

[1]*M.D. Anderson Cancer Center, HOUSTON, TX, USA;* [2]*Proteolix, SOUTH SAN FRANCISCO, USA;* [3]*Weill Cornell Medical College, NEW YORK, NY, USA;* [4]*Fred Hutchinson Cancer Research Center, SEATTLE, WA, USA;* [5]*Proteolix, Inc., SOUTH SAN FRANCISCO, CA, USA*

Background. CFZ a highly specific proteasome inhibitor that demonstrates promising single-agent activity in relapsed/refractory MM (ASH 2008). The purpose of this study is to evaluate the safety and activity of CFZ in combination with LEN and loDex. *Design and Methods*. This phase Ib trial evaluates 4 dose levels (≥3 subjects each) to define the maximum tolerated dose (MTD) of CFZ/LEN/loDex in relapsed/refractory MM patients who failed 1-3 prior therapies, including prior LEN or bortezomib (BTZ). CFZ is administered intravenously (IV) 15-27 mg/m2 (d1, 2, 8, 9, 15, 16), LEN 10-25 mg po (d1-21) and loDex 40 mg po (d1, 8, 15, 22) in 28-day cycles (C). An additional 10-15 subjects will be evaluated at the highest dose level reached. Overall response (complete response [CR] /stringent complete response [sCR], very good partial response [VGPR] / partial response [PR]) was assessed by the International Working Group Criteria, with secondary assessment by modified European Bone Marrow Transplant Criteria which includes minimal response (MR). *Results*. As of 17 February 2009, 19 subjects have been enrolled in the first 3 cohorts: 8 of the 19 patients were evaluable for response and toxicity. Prior therapies (median = 2) in the evaluable subjects included dexamethasone (8/8), bortezomib (6/8), lenalidomide (7/8), alkylators (6/8), anthracyclines (5/8), stem cell transplant (5/8), and thalidomide (1/8); 6/8 subjects had received both LEN and BTZ. MTD has not yet been reached after the first 3 dose cohorts. No drug-related serious adverse events have been reported. Responses were rapid and occurred within the first 28-day cycle. Dosing regimens and responses to date with a median of 2 cycles (range 1-4) are as follows: i. In cohort 1 (CFZ 15 mg/m2 / LEN 10 mg) all 6 patients were evaluable: 3 PR, 1 stable disease (SD) and 2 progressive disease (PD). ii. In cohort 2 (CFZ 15 mg/m2 / LEN 15 mg) 2 out of 6 subjects were evaluable: 1 PR and 1 SD. iii. Cohort 3 (CFZ 15 mg/m2 / LEN 20 mg) is in dose escalation and enrollment is ongoing. *Conclusions*. CFZ, LEN, and loDex in combination is well tolerated in the first 2 cohorts. There have been no DLTs. The combination has achieved early encouraging responses in subjects who had failed both LEN and BTZ at doses well below the single-agent MTDs of either LEN or CFZ. The overall results from this study support the dosing regimen selected for the Phase 3 study.

Background. In multiple myeloma (MM) molecular remission (MR) is not achieved with autologous transplantation (auto-SCT) as opposed to allogeneic transplantation where it associates to an improved outcome. *Aims*. To assess, by nested and real time-quantitative PCR (RQ-PCR), the impact of a consolidation treatment, including Bortezomib/Thalidomide/Dexamethasone (VTD) on residual MM cells after a good response

to auto-SCT. *Design and Methods*. Inclusion criteria were: complete or very good partial response (CR/VGPR) following first-line auto-SCT; no previous treatment with Bortezomib/Thalidomide; presence of a molecular marker based on the immunoglobulin heavy chain rearrangement (IgH-R). The VTD consolidation regimen has been described (*Palumbo et al., EHA2008*). Minimal residual disease was assessed on bone marrow samples at diagnosis, study entry, after two VTD courses, at the end of treatment and then at six months intervals. Nested and RQ-PCR analysis were performed using IgH-R-derived patient-specific primers as described (*Voena et al,Leukemia1997; Ladetto et al,Biol.BoneMarrow-Transpl.2000*). Results. Thirty-nine patients were enrolled. Twenty percent of patients did not receive the whole planned treatment. Fifty-four percent of patients experienced at least one grade 3-4 toxic event. At a median follow-up (MFU) of 42 months (range 27-75), five patients have died (13%) and 11 have relapsed (28%). Nested-PCR has been performed on the whole population. Eighteen percent of patients converted to stable MR and none of them experienced clinical or molecular relapse at MFU (opposed to 11 clinical relapses among those remaining PCR-positive). RQ-PCR has been performed on the whole population. Following auto-SCT a median tumour burden reduction of 5.51 ln was observed. However a further major decrease of 3.85 ln was recorded following VTD, resulting in an overall median tumour shrinkage of 9.36 ln. Both the tumour reduction attributable to auto-SCT and to VTD consolidation proved statistical significant ($p<0.001$). Considering separately patients in clinical remission from those who relapsed, the level of tumour reduction after VTD was remarkably different: the decrease of marginal medians of ln-PCR was 5.15 ln in the former group but just 0.14 ln in the second one. Moreover the level of response measured by RQ-PCR resulted of clinical relevance as patients showing a tumor burden above the median of ln-PCR values after two VTD courses, at the end of consolidation and after six months were clearly associated to a worse PFS (at MFU 65% vs 94%, $p=0.02$, 57% vs 100%, $p<0.01$, and 77% vs 100%, $p=0.02$, respectively). *Conclusions*. We here document for the first time that persistent MR can be obtained in a proportion of non-allotransplanted MM. We observed a major tumour load reduction by RQ-PCR after VTD consolidation and we proved that the best performances in terms of molecular kinetics are associated to an improved outcome. These findings indicate that impressive levels of tumour cell reduction can be achieved in MM thanks to the introduction of new non-chemotherapeutic drugs.

1072

MECHANISMS OF MSC (MESENCHYMAL STEM/STROMAL CELL) ACCUMULATION AT THE SITES OF TUMORS

R. Uchibori, M. Urabe, H. Mizukami, A. Kume, K. Ozawa

Jichi Medical University, SHIMOTSUKE-SHI, TOCHIGI, Japan

Background. Mesenchymal stem/stromal cells (MSCs) have the ability to accumulate at the sites of tumors when injected into tumor-bearing mice, and therefore MSCs are considered to be an appropriate cellular vehicle for cancer-targeted gene therapy. Intravenous injection of engineered MSCs expressing interferon-β was reported to inhibit the growth of pulmonary metastasis of melanoma and breast cancer in mice, and it also prolonged the survival of mice with glioma xenografts. It is considered that efficient delivery of engineered MSCs to tumor sites improves therapeutic efficacy through reinforced production of antitumor cytokines (transgene products) *in situ*. *Aims*. Although various growth factors and chemokines such as PDGF, HGF, and SDF-1α may be involved, the detailed molecular mechanisms of MSC accumulation at tumors are poorly understood. In this study, we focused on MSC-endothelial cell (EC) adhesion following TNF-α stimulation as a clue to elucidate the mechanisms. *Design and Methods*. To assess tumor tropism of MSCs, GFP-expressing MSCs or fibroblasts transduced with fiber-modified adenovirus vectors were injected into the left ventricular cavity in tumor-bearing nude mice. In addition, luciferase-expressing MSCs or fibroblasts were also injected to the mice, and optical bioluminescence imaging was performed to periodically trace the cells using an *in vivo* imaging system (IVIS). Migration capacity of MSCs and fibroblasts toward growth factors and chemokines was examined by transwell migration assay. The MSC adhesion to ECs was tested with or without TNF-α stimulation *in vitro*. Luciferase-expressing MSCs were injected to the mice treated with parthenolide for reducing TNF-α production, and IVIS imaging was performed to periodically trace the cells. *Results*. Injected GFP-labeled MSCs were detected in tumor tissues, but labeled fibroblasts were not. *in vivo* imaging also revealed that the administration of luciferase-expressing MSCs caused marked accumulation of the bioluminescence signal at the sites of tumors, whereas no accumulation was observed in mice injected with fibroblasts. On the other hand, the factors that induced MSC migration *in vitro* enhanced fibroblast migration as well. It is worthy of note that the stimulation of MSCs with TNF-α enhanced MSC adhesion to ECs *in vitro*. This adhesion was partially inhibited by blocking antibodies against VCAM-1 and VLA-4. The similar phenomenon was not observed for fibroblasts. Furthermore, in the mice treated with parthenolide, the TNF-α level in tumor tissues was reduced, and MSC accumulation at the tumors was significantly inhibited. *Conclusions*. Our data suggest that the MSC-EC adhesion following activation by TNF-α may play a crucial role in MSC accumulation at tumor sites. The present findings would be important to develop efficient MSC-based cancer gene therapy.

1073

FOXO REACTIVATION AS A CONSEQUENCE OF IMATINIB TREATMENT IN CML INDUCES QUIESCENCE IN PH+ PROGENITOR CELLS

D. Cilloni,[1] C. Panuzzo,[1] F. Messa,[1] E. Greco,[1] F. Arruga,[1] E. Bracco,[1] R. Bernardoni,[2] S. Carturan,[1] M. Pautasso,[3] E. Messa,[1] M. Pradotto,[1] C. Maffè,[1] I. Iacobucci,[4] T. Kalebic,[5] G. Martinelli,[4] G. Saglio[1]

[1]University of Turin, TURIN, Italy; [2]University of Bologna, BOLOGNA, Italy; [3]S. Luigi Hospital, ORBASSANO, Italy; [4]Seragnoli Institute, University of Bologna, BOLOGNA, Italy; [5]Novartis Oncology Clinical Development, EAST HANOVER, USA

Background. The FoxO family of transcription factors is regulated by PI3K/Akt induced phosphorylation resulting in nuclear exclusion and degradation. Nuclear FoxO transcribes proapoptotic molecules and cell cycle inhibitors. In CML cells the TK activity of Bcr-Abl leads to the abnormal activation of downstream effectors including PI3K/Akt. The aim of this study was to investigate the role of FoxO3 in Bcr-Abl induced apoptotic arrest and cell growth and the effect of imatinib (IM) induced re-activation of FoxO3 activity in CML progenitor cells. *Design and Methods*: BM cells were collected from 52 CML patients and 20 healthy donors. The expression level of FoxO3 was tested by RQ-PCR. The protein amount and localization was analyzed by Western blot and immunofluorescence, DNA binding activity was measured by EMSA. In addition, FoxO3 was analyzed in CML primary cells and $CD34^+$ cells after IM incubation. Cell cycle and the expression levels of CD47, which has been demonstrated to increased during progression through the cell cycle and stem cell mobilization, was measured by FACS in $CD34^+$ cell population. In addition K562 cells was transfected with pECE-FoxO3 to clarify FoxO3 effects on cell growth and apoptosis. Finally we used our already set up model of Drosophila melanogaster (Dm) transgenic for human Bcr-Abl to study the pathway leading to FoxO3 inactivation. Results: We found that, despite either FoxO3 mRNA levels or protein amount are similar in CML cells compared to controls, FoxO3 protein is equally distributed in the nucleus and cytoplasm in controls but it is completely cytoplasmatic in CML cells and it enters the nucleus during *in vivo* IM treatment or *in vitro* IM incubation. Additionally, FoxO3 DNA binding activity in CML patients is completely absent at diagnosis and reappears after IM treatment. Moreover FoxO3 overexpression in transfected cells results into a 49±9% reduction of proliferation which was further reduced of 75±5% after IM incubation. Furthermore, we demonstrated that IM incubation results into the reactivation of FoxO3 in Ph+ $CD34^+$ cells inducing quiescence into this population as demonstrated by the comparison of cell cycle kinetics and by a decreased expression of CD47. Finally, the progeny obtained from the crossbreeding of Bcr-Abl flies and flies transgenic for FoxO showed a rescue of FoxO phenotype demonstrating that FoxO inactivation is Bcr-Abl mediated. *Conclusions*. Overall, these *in vitro* and *in vivo* experiments suggest that FoxO3 is inactivated in CML cells and its delocalization is mainly dependant from Bcr-Abl activity. The antiproliferative activity of IM may be mediated by FoxO3 re-localization. On the other side, FoxO3 re-activation induced by IM results into a quiescence of Bcr-Abl $CD34^+$ progenitor cells, which raises a hypothesis that FoxO3 could play a role in IM resistance.

1074

PGP - DEPENDENT RESISTANCE TO IMATINIB AT ADVANCED CML IS EXCLUSIVELY DEVELOPED IN AGGRESSIVE MINOR BLAST SUBSET AND CAN BE REVERSED BY PGP MODULATORS

H. Galski, M. Simanovsky, S. Berlinsky, A.R. Nagler

Chaim Sheba Medical Center, TEL HASHOMER, Israel

Background . Although very effective in chronic phase CML, imatinib (IM) and second generation Bcr-Abl tyrosine kinase inhibitors are usually less effective in advanced CML (accelerated and blast crisis phases) since drug-resistant clones inevitably shortly emerge. In a recent study (Simanovsky M et al, Differentiation. 76: 908-922, 2008), we have found that at blast crisis CML (CML-BC), blasts of the same CML clone are heterogeneous, containing a small subset (1-3%) of blasts that are significantly more aggressive than the major malignant population. Briefly, we found that these minor subsets (MS) of blasts (both from patients and human CML-BC cell lines) have highly repopulating ability, increased clonogenicity, and commonly over express BCR-ABL and few other cancer-related genes. *Aims*. To evaluate whether the MS blasts also exhibit differential drug resistance mechanisms toward IM, we also compared the two blast subsets for the level of resistance to IM in relation to expression of a functional Pgp, an ABC transporter that is the product of the ABCB1 (MDR1) gene. *Design and Methods*. RNA expression levels of MDR1 were measured by quantitative RT-PCR. Protein and drug-efflux activity levels of the ABCB1 (Pgp) multidrug transporter were evaluated by Western blotting and by flow cytometry measurements. The anti-proliferative effects of imatinib were measured by MTT proliferation assay in the absence or the presence of the Pgp-specific modulator, R-verapamil (R-VRP). *Results*. The MDR1 gene is significantly (5-7 fold) upregulated in the MS blasts, relatively to the major population. Moreover, while Pgp could not be detected on the cell surface of the major blast subsets, Pgp is exclusively highly expressed in the MS blasts. Moreover, functional Pgp assays in the MS blasts (efflux, dose-dependent competitions, and UIC2 Pgp-specific shift assays) indicated unequivocally that IM is a substrate for Pgp. While IM efficiently inhibited the proliferation of the major blasts in dose-dependent manner, the proliferation rate of the MS blasts was essentially not affected. Furthermore, the anti-proliferative effect of IM on the MS blasts could be restored by addition of the Pgp inhibitor, R-verapamil. While relatively long, gradual selection in culture of the major CML-BC subsets resulted in some Pgp-independent IM-resistant clones, Pgp activity levels were shortly further elevated (by 1-order magnitude) in the MS blasts. Interestingly, FACS analyses, using different monoclonal antibodies that bind specifically to different known extra cellular epitopes of Pgp, indicated differential antibodies-epitopes binding ratios after IM selection. These stoichiometric changes suggest a topological folding shift of Pgp between its moderate to high activity (proposed model, Figure 1).

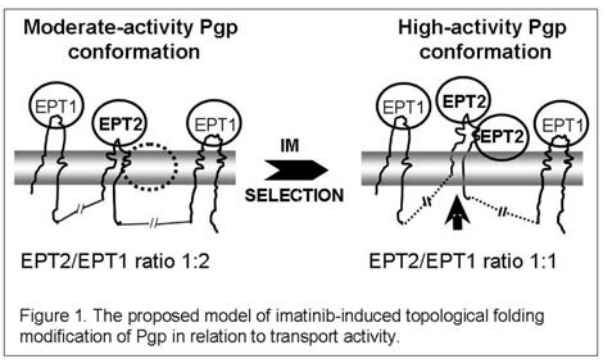

Figure 1. The proposed model of imatinib-induced topological folding modification of Pgp in relation to transport activity.

Figure 1.

Conclusions. The existence of a minor 'pool' of CML blasts of both greater clonogenicity and high expression and activity levels of Pgp, apparently signify clonal evolution toward both increased malignancy and lower therapeutic sensitivity to IM. Moreover, as both IM, dasatinib and nilotinib are transported by Pgp, this study suggests that their combination therapy with Pgp-modulators might also be clinically effective in targeting the MS aggressive blast population.

Red blood cells, iron and granulocytes

NRAMP1 PROMOTES EFFICIENT IRON RECYCLING FOLLOWING ERYTHROPHAGOCYTOSIS IN VIVO

S. Soe-Lin,[1] S. Apte,[1] B. Andriopoulos,[2] M. Andrews,[3] M. Schranzhofer,[1] T. Kahawita,[1] D. Garcia Santos,[1] P. Ponka[1]

[1]McGill University, MONTREAL, Canada; [2]Harvard Medical School, BOSTON, USA; [3]IRCM, MONTREAL, Canada

Background. Natural resistance-associated macrophage protein 1 (Nramp1) is a divalent metal transporter expressed exclusively in phagocytic cells such as macrophages and neutrophils. *Aims*. Based on our earlier *in vitro* study (*Soe-Lin et al. Exp Hematol. 2008;36:929-937*), we intended to determine whether Nramp1 participated in the recycling of iron acquired through the phagocytosis of senescent red blood cells by macrophages *in vivo*. *Design and Methods*. We employed Nramp1+/+ and Nramp1-/- mice and created conditions of accelerated erythrophagocytosis either by the induction of hemolytic anemia, or by hypertransfusion of ospsonized erythrocytes. *Results*. In preliminary characterization experiments of the iron parameters of wild-type (Nramp1+/+) and Nramp1 knockout mice (Nramp1-/-), we found that untreated knockout mice exhibited greater serum transferrin saturation and splenic iron content, with higher duodenal ferroportin (Fpn) and divalent metal transporter 1 (DMT1) expression. Furthermore, hepatocyte iron content and hepcidin mRNA levels were dramatically lower in knockout mice, indicating that hepcidin levels can be regulated by low hepatocyte iron stores despite increased transferrin saturation. In addition, we observed significant iron loading of the reticuloendothelial organs of knockout mice that increased with age. After injection of 59Fe-labeled heat damaged reticulocytes, knockout animals accumulated erythrophagocytosed 59Fe within their liver and spleen, whereas wild-type animals were able to efficiently recycle the phagocytosed 59Fe to the marrow for incorporation into newly formed erythrocytes. In order to further examine the effect of Nramp1 on iron recycling *in vivo*, accelerated erythrophagocytosis was induced in wild-type and knockout mice by administration of the hemolytic agent phenylhydrazine. Following acute phenylhydrazine treatment, Nramp1-/- mice experienced a significant decrease in serum iron levels and hematocrit, while their Nramp1+/+ counterparts were relatively unaffected. Following a month-long phenylhydrazine regimen, Nramp1-/- mice retained markedly increased quantities of iron within the liver and spleen, and exhibited greater splenomegaly and reticulocytosis than wild-type mice. *Conclusions*. The data presented in this report suggest that in the absence of Nramp1, iron accumulates to a greater degree within iron-recycling macrophages in the liver and spleen following erythrophagocytosis. We hypothesize that hepatocytes iron stores are released to compensate for the lack of iron release from macrophages, resulting in a lower production of hepcidin mRNA. Our observation of increased DMT1 and ferroportin within the duodenums of the Nramp1-/- animals imply that the increase in transferrin saturation despite the impaired iron release from erythrophagocytosing macrophages occurs due to a compensatory increase in iron absorption from the diet. These findings are consistent with our hypothesis that Nramp1 promotes the efficient recycling of iron in erythrophagocytosing macrophages.

PREVENTION OF CARDIAC IRON ACCUMULATION WITH ONCE DAILY ORAL DEFERASIROX THERAPY IN REGULARLY TRANSFUSED PATIENTS WITH B THALASSAEMIA MAJOR

D. Pennell,[1] A. El-Beshlawy,[2] P. Sutcharitchan,[3] M. Elalfy,[4] Y. Aydinok,[5] A. Taher,[6] G. Smith,[1] D. Habr,[7] U. Kriemler-Krahn,[8] A. Hmissi,[8] J.B. Porter[9]

[1]Royal Brompton Hospital, LONDON, UK; [2]Cairo University, CAIRO, Egypt; [3]Chulalongkorn University and King Chulalongkorn Memorial Hospital, BANGKOK, Thailand; [4]Ain Shams University, CAIRO, Egypt; [5]Ege University Medical Faculty, IZMIR, Turkey; [6]American University Beirut, BEIRUT, Lebanon; [7]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [8]Novartis Pharma AG, BASEL, Switzerland; [9]University College London, LONDON, UK

Background. Myocardial siderosis as a result of regular blood transfusion therapy is a key cause of cardiac morbidity. Iron chelation therapy with the once-daily oral iron chelator, deferasirox, reduces cardiac iron

levels in patients with cardiac siderosis. Subgroup analysis from the EPIC trial has also allowed assessment of the efficacy of deferasirox in preventing cardiac iron accumulation. Aim. To assess the longitudinal effect of deferasirox over 1 year in preventing myocardial siderosis in non-cardiac iron-overloaded patients with β-thalassaemia major and normal cardiac function. *Design and Methods*. Patients aged ≥10 years with normal myocardial iron content (cardiovascular magnetic resonance [CMR] imaging of myocardial T2* ≥20 ms), serum ferritin (SF) >2500 ng/mL; MR (R2) liver iron concentration (LIC) >10 mg Fe/g dry weight (dw); left ventricular ejection fraction (LVEF) ≥56%; and a lifetime minimum of 50 previous packed red blood cell transfusions were included. Deferasirox was initiated at 20 or 30 mg/kg/day (subsequent dose adjustments of 5-10 mg/kg/day were based on changes in SF, month-6 myocardial T2*, and safety parameters). The primary endpoint was change from baseline in myocardial iron at 1 year. *Results*. 78 patients were enrolled (35 male:43 female; mean age 20.2±7.5 years). Mean baseline (±SD) LVEF was 67.7±4.7%, LIC 28.8±10.2 mg Fe/g dw, median SF 4367 ng/mL, and geometric mean cardiac T2* 32.0 ms ± 25.6%. Transfusion requirements were 133.7 mL/kg in the year prior to enrolment. 76 patients (97%) had received prior chelation therapy (deferoxamine 69.2%; combination deferoxamine/deferiprone 28.2%). Mean deferasirox dose over 1 year was 27.6±6.0 mg/kg/day. After 12 months of therapy, geometric mean myocardial T2* levels remained unchanged (32.5 ms ± 25.1%, +2.0%, p=0.57) and T2* did not fall below 20 ms in any patients. LVEF increased to 69.6% (p<0.0001). Median SF was significantly reduced from baseline at 12 months by 1048 ng/mL (p<0.0001; 20% relative reduction). LIC was also significantly reduced from baseline by 7.2 mg Fe/g dw (p<0.0001; 30% reduction). Change from baseline in T2* was inversely correlated with change in SF (r=-0.2, p=0.05). 75 patients (96.2%) completed the 12-month study; three patients (3.8%) discontinued because of adverse events (AEs) [n=2] or because they no longer required study drug (n=1). Investigator-assessed drug-related AEs were generally mild (78%) and were reported in 31 patients (39.7%), including diarrhoea (n=8, 10%), and rash (n=7, 9%). One patient (1.3%) had a non-progressive increase in serum creatinine >33% above baseline and the upper limit of normal (ULN) on two consecutive visits. No patients had an increase in alanine aminotransferase >10xULN on two consecutive visits. No patients died and no drug-related serious AEs were reported. *Conclusions*. This is the first study to show that iron chelation therapy with deferasirox in patients with β-thalassaemia major and normal baseline cardiac iron levels can prevent accumulation of cardiac iron, whilst significantly reducing body iron burden and improving cardiac function (LVEF). These results demonstrate that prevention of myocardial iron accumulation, in patients who are currently free from cardiac iron loading, is achievable with deferasirox.

1077

RITUXIMAB IN AUTO-IMMUNE HAEMOLYTIC ANAEMIA AND IMMUNE THROMBOCYTOPENIC PURPURA: A BELGIAN RETROSPECTIVE MULTICENTRIC STUDY

Background. Auto-immune haemolytic anemia (AIHA) and immune thrombocytopenic purpura (ITP) may respond to the chimeric anti-CD20 monoclonal antibody rituximab, even when refractory to conventional therapy. *Aims*. To better characterize the effect of anti-CD20 therapy in AIHA and ITP. *Design and Methods*. We retrospectively analysed the use of rituximab in Belgian patients experiencing AIHA and ITP. Belgian hematology centers were invited to fill a questionnaire specifying the major characteristics and quality of response of ITP and AIHA patients given rituximab. For AIHA complete response (CR) was defined by achievement of a normal haemoglobin concentration. Partial response (PR) was defined by transfusion independency in a previously transfused patient or by a 2 gr increase of hemoglobin concentration in patients not given blood transfusion. Other situations were reported as failure (F). In patients with ITP a CR was defined by achievement of a platelet count superior to 100x10^9/L or by maintaining a platelet count >100x10^9/L without immunosuppressive drugs and a PR if the platelet count was 50-100x10^9/L. A F was reported for all other situations. *Results*. 17 centers elected to join the study. 68 courses of rituximab in 53 patients with AIHA and 43 courses in 40 patients with ITP were analyzed. All patients were given rituximab after failing at least one previous line of treatment, including splenectomy in 19% and 72.5% of AIHA-patients and ITP-patients respectively. Overall response rates were 79.2% in AIHA and 70% in ITP, with a median follow up since first rituximab administration of 15 months (range 0.5-62) in AIHA and 11 months (range 0-74) in ITP. As shown in Figure 1 Progression Free Survival (PFS) at one and two years were 72% and 56% in AIHA and 70% and 44% in ITP. In this retrospective analysis we were not able to identify pre-treatment characteristics predictive for response to rituximab. Nine patients with AIHA and three patients with ITP were given one or more additional courses of rituximab. Most of these patients, who had responded to a previous course, experienced a new response comparable to the previous one, both in terms of quality and of duration of response. Finally, the outcome of patients who failed to respond to rituximab therapy was poor both in terms of response to subsequent therapy and in terms of survival. *Conclusions*. This study confirms that rituximab induces responses in a majority of previously treated patients with AIHA and ITP. Response duration generally exceeds one year. Retreatment with rituximab in responding patients is most often successful. The outcome of patients who fail on rituximab is poor. We were not able to identify pre-treatment patient characteristics predicting for response.

INVOLVEMENT OF MATRIX METALLOPROTEINASES AND CXC CHEMOKINES IN LPS-INDUCED AIRWAY INFLAMMATION IN SICKLE MICE

C. Franco-Penteado, M.A.F. Corat, C. Lanaro, D.M. Albuquerque, A.P. Gimenes, L.A.C. Passos, F.F. Costa

UNICAMP, CAMPINAS, Brazil

Transgenic mice expressing exclusively human sickle hemoglobin (SS) are well-established models for the study of vascular inflammation. Previous studies have shown that systemic lipopolysaccharide (LPS) challenge causes exaggerated inflammation, including increased serum and broncoalveolar lavage (BALF) TNF-α and IL-1 cytokines and sVCAM-1 in sickle mice. The goal of this study was to evaluate the contribution of cytokines, CXC chemokines and matrix metalloproteinases (MMPs) in the acute airway inflammation induced by LPS in SS mice. Acute lung inflammation was induced by intranasal administration of LPS (50 mL of 250 mg/mL) in C57BL/6 (control) and Berkeley (SS) mice. BALF was performed 4h (early) and 24h (late) after LPS challenge. qRT-PCR analysis was used to examine gene expression and ELISA protein production. Intranasal instillation of LPS in control and SS mice induced acute airway inflammation after 4 and 24h, characterized by increases in total leukocytes numbers (WBC) and was almost exclusively accounted for by neutrophils (NS); however this influx was significantly greater in SS

mice, when compared with control mice (4h: 1.4±0.06 vs 0.66±0.12 WBC; 1.06±0.1 vs. 0.40±0.12 NS, 24h: 2.9±1.3 vs 1.4±0.2 WBC; 2.6±0.5 vs 1.2±0.2 NS, respectively). Baseline levels, KC and MIP-2 are significantly higher in BAL fluid of SS mice compared to control mice (105.2±14.1 vs 14.1±5.8; 41.2±7.9 vs 11.4±7.3, respectively). After 4h of LPS challenge KC, MIP-2, TNF-α and MMP-9 were significantly higher in SS BALF compared to control mice (2491±454 vs 798.1±98.2; 1726±307 vs 887.3±149.5; 4250±636 vs 1585±263; 187.5±16.7 vs 103.9±16.9, respectively). After 24h of LPS inhalation, BALF levels of these chemokines/cytokine and MMP-9 were significantly decreased in SS mice (217.4±32.5; 125.5±55.6; 30.6±12.1; 29.2±12.8, respectively) and controls (105.1±18.5, 133.5±25.95, 121.7±45.05, 84.07±27.8, respectively) when compared to 4h after LPS inhalation. mRNA levels of KC, TNF-a, IL-1-β, MMP-8, MMP-9 and TIMP-1 in the lungs of control and SS mice in early (4h) LPS-induced lung inflammation were significantly higher when compared to animals that received PBS instead of LPS, whereas LPS-induced KC, MMP-8 and MMP-9 expression was significantly higher in SS mice lung (0.42±0.1; 0.42±0.06; 0.49±0.11, respectively) compared with the control group (0.19±0.047; 0.2±0.06 vs 0.016±0.004; 0.22±0.03, respectively). MMP-2, MMP-12 and TIMP-2 gene expressions were not significantly different between SS and control mice. Increased KC, TNF-α, IL-1-β, MMP-8, MMP-9 and TIMP-1 mRNA levels were detected in the lungs from both 24h mice groups after LPS challenge. Lung MMP-12 expression was significantly increased in SS mice compared to control mice (0.69±0.12 vs. 0.12±0.03). In contrast, TIMP-1 mRNA levels were significantly lower in lung from SS mice compared with control mice (0.08±0.03 vs. 0.19±0.017). Our results provide evidence that local inflammatory mediators and neutrophil recruitment in response to LPS were significantly increased in SS mice and demonstrate that the development of acute LPS-induced airway inflammation in SS mice is associated with enhanced expression of chemokines and MMPs expression in lungs. The findings from this study indicate that these mediators could participate in the lung vaso-oclusive complications in SCD and give further support to the claim that a proinflammatory state is present in SCD.

PROLONGED ADMINISTRATION OF HYDROXYUREA REDUCES MORBIDITY AND MORTALITY IN ADULT PATIENTS WITH SICKLE-CELL SYNDROMES: FINAL ANALYSIS OF A 17-YEAR, SINGLE CENTER, TRIAL

E. Voskaridou,[1] A. Bilalis,[1] D. Christoulas,[2] K. Varvagiannis,[1] K. Sinopoulou,[1] A. Mpalassopoulou,[1] E. Plata,[1] D. Loukopoulos,[3] E. Terpos[2]

[1]*Thalassemia Center, Laikon General Hospital, ATHENS, Greece;* [2]*Department of Medical Research, 251 General Air-Force Hospital, ATHENS, Greece;* [3]*Hematology Res. Laboratory, Biomedical Research Foundation, Academy of Athens, ATHENS, Greece*

Background. Hydroxycarbamide (hydroxyurea; HU) is now considered as the main pharmacological agent used for the management of patients with sickle-cell disease (SCD). Whether HU can prevent the severe chronic complications or modify the mortality of these patients remains still an interesting unresolved question. *Aim*. The present prospective study aims to evaluate the effects of HU in a large number of SCD patients who received HU over long period of time and were followed in a single Center. *Design and Methods*. Since 1991, 330 patients were evaluated: 34 with sickle cell anemia (HbS/HbS), 131 with HbS/β0-thal and 165 with HbS/β+-thal (107 with HbS/IVSI-110 and 58 with HbS/IVSI-6). According to study inclusion criteria 131 patients received HU, while 199 patients were conventionally treated. The usual dosage of HU was 20 mg/kg/day, except for some patients, where toxicity or lack of effectiveness imposed modifications of the dosage in the range of 15- 35 mg/kg/day. The median follow-up period was 8 years for HU patients and 5 years for non-HU patients. *Results*. All HU patients responded to therapy with a median 5-fold increase of HbF at 6-month. Patients who received HU showed a dramatic reduction of: 1) the frequency of severe painful crises (mean±SD: from 7.34±6.5 episodes/year pre-HU to 0.25±0.44 episodes/year post-HU; $p<0.001$); 2) transfusion requirements (from 1.5±5.9/year pre-HU to almost zero during HU treatment; $p<0.001$); 3) hospital admissions (from 2.11±2.96/year pre-HU to 0.07±0.18/year post-HU; $p<0.001$); and 4) the frequency of chest syndrome (from 6.1% pre-HU to 0.8% during HU; $p=0.016$). HU administration produced a significant increase of total Hb and HbF at 6, and 12 months post-HU initiation and at last follow-up along with a significant reduction of leukocyte, platelet and reticulocyte counts, serum bilirubin and LDH levels. The death rate of HU patients was significantly lower than that observed among non-HU patients (13 *vs.* 49 deaths; 9.9% vs. 24.6%; $p=0.001$). The probability of 10-year survival was 86% and 65% for HU and non-HU patients, respectively ($p=0.001$; Figure). The 10-year probability of survival for HbS/HbS, HbS/β0-thal, and HbS/IVSI-110 patients was 100%, 87% and 82%, respectively for HU patients and 10%, 54% and 66%, for non-HU patients. The multivariate analysis showed that HbF values at baseline and percentage change of LDH between baseline and 6-month were independently predicted for survival in the HU group, while in non-HU patients increased levels of Hb and low levels of bilirubin at baseline were independent predictive factors for superior survival. Complications of HU were predictable and easily manageable. Fertility data will be reported in the congress. *Conclusions*. Our study suggests that adult SCD patients who received HU for a long period of time reduce the incidence of acute and chronic complications of SCD, while they have a survival advantage. This seems to be more prevalent in patients with HbS/HbS or HbS/β0-thal, but patients with HbS/β+-thal may be also benefited from HU administration. These results highlight the beneficial effect of HU which seems to modify the natural history of SCD and raise the issue of expanding its use in all SCD patients.

SEX-SPECIFIC EFFECTS OF RITUXIMAB ON TREATMENT OUTCOME OF ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE ANALYSIS OF THE RICOVER-60 TRIAL OF THE GERMAN HIGH-GRADE NON-HODGKIN LYMPHOMA STUDY GROUP (DSHNHL)

N. Murawski, J. Schubert, S. Zeynalova, V. Poeschel, P. Borchmann, A.D. Ho, C. Nickenig, S. Wessendorf, B. Metzner, M. Loeffler, M. Pfreundschuh

DSHNHL, HOMBURG/SAAR, Germany

Background. In the RICOVER-60 trial, where 1222 elderly (61-80 year-old) patients with untreated CD20-positive aggressive NHL were randomized to receive 6 or 8 cycles of CHOP-14 with or without 8 applications of rituximab, best results were obtained with 6xR-CHOP-14 in all subgroups including patients who did or did not receive additional radiotherapy to bulky disease. *Aims*. To study the impact of sex on treatment outcome, patient characteristics and results were analyzed according to the patients´gender. *Design and Methods*. A retrospective analysis has been performed to compare the outcome from female and male patients treated in the RICOVER-60 trial. *Results*. Female patients within the rituximab arms presented a significantly higher LDH and lower performance status compared to the male counterparts (Elevated LDH: 57.2% vs 43.1%, p=0.001; ECOG >1: 18.6% vs. 11.1%, p=0.009). This significance was transferred into the whole population even though the two patient groups did not differ within the non rituximab arms. Female patients experienced more grade 3&4 leukocytopenias than men (64.5% of cycles vs. 45.9%, p<0.001) and the time with median of leukocytes < 2000/mm3 was longer (2 vs. 0 days). This was associated with more grade 3&4 infections (7.4% of cycles vs. 6.0%, p=0.020), but there was no difference with respect to therapy-associated deaths rates (7.2% vs 7.8%, p=0.654). Female patients had a higher 3-year PFS (67.5% vs. 61.0%; p=0.062) and OS (74.2% vs. 68.4% p=0.086). These differences were largely due to a greater improvement by the addition of rituximab on the outcome of females: while the difference in 3-year PFS between female and male patients was 5.2% (p=0.448) in patients receiving CHOP-14 only, this increased to 7.6%(p=0.053) when rituximab was added. Although a less favourable outcome would have been expected for female patients according to the described differences in LDH and performance status. In a multivariate analysis adjusting for the IPI-relevant risk factors LDH, ECOG performance status, advanced stage and >1 extranodal involvement, the relative risk for progression in male compared to female patients was not significantly elevated after CHOP-14 only (1.127; p=0.348), but was significantly higher when rituximab was added (1.592: p=0.004). *Conclusions*. Rituximab improves outcome both in elderly female and male patients treated with CHOP-14; however, the positive effect of rituximab is more pronounced in female patients and renders male sex a significant risk factor. This observation together with the low toxicity of rituximab justifies a trial with higher doses of rituximab for male patients.

A PHASE II TRIAL OF THE ORAL MTOR INHIBITOR EVEROLIMUS IN RELAPSED NON-HODGKIN LYMPHOMA (NHL) AND HODGKIN DISEASE (HD)

E. Witzig, T. Habermann, C. Reeder, I. Micallef, S. Ansell, L. Porrata, P. Johnston, B. LaPlant, B. Kabat, C. Zent, S. Zeldenrust, D. Inwards, J. Colgan, T. Call, S. Markovic, H. Tun

Mayo Clinic, ROCHESTER, USA

Background. The phosphatidylinositol 3-kinase/mammalian target of rapamycin (mTOR) signal transduction pathway integrates signals from multiple receptor tyrosine kinases to control cell proliferation and survival. Everolimus (RAD001, Novartis Pharmaceuticals) is an oral investigational antineoplastic agent that targets mTOR. *Aims*. To learn the anti-tumor activity and toxicity of single-agent RAD001 in pts with relapsed/refractory aggressive or indolent NHL and HD. *Design and Methods*. Patients were eligible if they had measurable disease, a platelet count >75,000, an absolute neutrophil count >1,000, and a creatinine and bilirubin <2x laboratory upper limit of normal. Patients received everolimus 10 mg PO daily and were evaluated monthly. Dose reductions to 5 mg daily and 5 mg every other day were allowed. Response was assessed after 2 cycles and periodically thereafter. Patients could remain on drug until progression or toxicity. *Results*. 145 pts were treated - 77 with aggressive NHL (47 DLBCL; 19 MCL, 8 follicular grade 3, 1 transformed, and 2 high grade); 41 indolent (16 follicular; 22 SLL and 3 marginal zone); 8 T-cell NHL (4 CTCL; 3 PTCL and 1 anaplastic) and 17 HD. The median age was 67 years (range, 27-92). Patients had received a median of 4 prior therapies (range, 1-15). The overall response rate (ORR) was 33% (48/145; 95% CI: 26-41%) with 5 complete responses and 43 partial responses. ORR by disease type is summarized in the Table below. Patients have received a median of 3 cycles (range, 1-29) of therapy. The median time to progression for all 145 patients is 4.3 months (95% CI; 3.6-5.9 months). The median duration of response for the 48 responders is 6.8 months (95% CI; 5.4-11.0 months) and 19 responders remained progression free at 6 months. 18 patients are currently maintaining a response with a median time of 5.5 months (range, 0-32.1 months). Everolimus was well tolerated. The incidence of grade 3/4 anemia, neutropenia, and thrombocytopenia in this heavily pretreated pt population was 16%, 17%, and 35%. Grade 2 hypercholesterolemia occurred in 8% and grade 3 in 1%; grade 2 hyperglycemia in 8%, grade 3 in 4% and grade 4 in 1%; 1 pt had grade 4 hypertriglyceridemia. *Summary*. Everolimus has single-agent activity in relapsed NHL and HD and provides proof-of-concept that targeting the mTOR pathway in NHL is clinically relevant.

Table 1. Overall response rate by disease type.

Disease	n	ORR (95% CI)	CR	PR
DLBCL	47	30% (17-45%)	2%	28%
MCL	19	32% (13-57%)	11%	21%
FL	16	50% (25-75%)	6%	44%
SLL	22	18% (5-40%)	0%	18%
T-cell NHL	8	63% (24-91%)	0%	63%
HD	17	53% (28-77%)	6%	47%

Systemic PTCLs are uncommon malignancies and carry, with the exception of ALK-positive anaplastic large cell lymphoma (ALCL), a poor prognosis when treated with conventional chemotherapy. The role of intensified treatment schedules consolidated by upfront ASCT as 1st line therapy in PTCLs is debated. Therefore, the NLG designed a prospective multicenter phase II study to evaluate the impact of a dose-intensified induction schedule (6 courses of two-weekly CHOEP) consolidated in 1st PR/CR with high-dose therapy (BEAM) followed by ASCT in previously untreated systemic PTCL. With a total of 166 patients enrolled between Oct 2001 and Oct 2007, this is, by far, the largest prospective PTCL clinical trial completed to date. Newly diagnosed systemic PTCL cases aged 18-67 yrs were included. Cases of ALK-positive ALCL, primary cutaneous, primary leukemic and lymphoblastic subtypes were excluded. Of the 166 PTCL cases, 160 were histologically confirmed at referral center level: PTCL unspecified (n=62; 39%), ALK-neg ALCL (n=31; 19%), angioimmunoblastic type (AIL) (n=30; 19%), enteropathy-type (n=21; 13%), panniculitis-like (n=6; 4%), T/NK nasal-type (n=5; 3%), hepatosplenic (n=5; 3%). The M/F ratio was 2.0 and the median age 57 yrs (range 22-67 yrs). The majority of the cases presented with advanced-stage disease (81%), B-symptoms (59%) and/or elevated s-LDH (62%). Nevertheless, 71% of all patients had a good performance score (WHO 0-1) at inclusion. Of the 155 patients with available response assessment after completed induction schedule, 132 (85%) were either in CR/CRu (n=81) or in PR (n=51). Disease refractory to induction treatment was observed in 23 patients. From the original cohort of 160 patients, a total of 112 (70%) had undergone ASCT at the time of the present analysis. Of these, 88 (78%) were in CR/CRu at first assessment 3 months after ASCT, 11 (10%) were in PR and 13 (12%) experienced early post-transplantation disease progression. The reasons for not undergoing ASCT in 20 of the 132 responders were: (i) disease progression between last course of induction and ASCT, (ii) toxicity, (iii) mobilization failures, and (iv) other causes. Treatment-related toxicity following induction and high-dose treatment was predictable and manageable. No subtype-specific toxicity patterns were observed. Of all 160 patients, 87 were alive at last available follow-up. The median follow-up for survival in this cohort is 3 years and 9 months (range 10-81 months). The median follow-up for the deceased patients (n=73) is 8.4 months. Causes of death were: lymphoma n=55 (75%), toxicity n=7 (10%), second malignancy n=2 (3%), other causes n=6 (8%), unknown n=3 (4%). Three- and five year overall survival (OS) for the entire patient cohort was 57% (CI 49%-65%) and 50% (CI 41%-58%), respectively. The corresponding PFS figures were 48% (CI 40%-56%) and 43% (CI 34%-52%). Subtype-specific analysis revealed particularly favorable OS and PFS values for ALCL cases (3yrs: OS 77% and PFS 64%; 5yrs: OS 73% and PFS 64%). AIL and PTCLu had an OS at 3 yrs of 57% and 51%, respectively. The corresponding PFS values were 54% and 42%. As a unique feature, this study included a large number of enteropathy-type PTCL cases (n=21). Their 3-yr OS and PFS were 52% and 47%, respectively. In conclusion, the present data shows that a time- and dose-intensified schedule consolidated by autologous hematopoietic stem cell transplant is effective in previously untreated systemic PTCL. Early treatment failures remain an unsolved problem and novel induction strategies are needed. However, long-term remissions are achieved in a substantial fraction of patients with best PFS values obtained for the ALK-negative ALCL subtype.

8X BEACOPPESC COMPARED TO 4X BEACOPPESC FOLLOWED BY 4X BEACOPPBASE WITH OUR WITHOUT RADIOTHERAPY FOR ADVANCED STAGE HODGKIN LYMPHOMA PATIENTS: FINAL ANALYSIS OF THE HD12 TRIAL OF THE GERMAN HODGKIN STUDY GROUP

P. Borchmann,[1] H. Haverkamp,[2] R.-P. Mueller,[3] H.-T. Eich,[3] H.K. Mueller-Hermelink,[4] T. Cerny,[5] J. Markova,[6] A.D. Ho,[7] L. Kanz,[8] R. Greil,[9] W. Hiddemann,[10] A. Engert,[2] V. Diehl[2]

[1]Internal Medicine I, COLOGNE, Germany; [2]German Hodgkin Study Group, University Hospital of Cologne, COLOGNE, Germany; [3]Department of Radiotherapy, University Hospital of Cologne, COLOGNE, Germany; [4]Institute of Pathology, University of Wuerzburg, WÜRZBURG, Germany; [5]Department of Internal Medicine, Kantonsspital St. Gallen, ST. GALLEN, Switzerland; [6]Department of Hematology, University of Prague, PRAGUE, Czech Republic; [7]Department of Hematology and Oncology, University of Heidelberg, HEIDELBERG, Germany; [8]Department of Internal Medicine, University of Tuebingen, TÜBINGEN, Germany; [9]Third Medical Department of Hematology, Oncology, Hemostaseology, Infectious Dis, SALZBURG, Austria; [10]Third Department of Internal Medicine, University Hospital of Muenchen, MÜNCHEN, Germany

Background. The German Hodgkin Study Group (GHSG) trial HD9 had established a new standard of care for advanced-stage Hodgkin Lymphoma (HL) patients by showing significant superiority of BEACOPP escalated (BE) in terms of failure-free survival (FFTF) and overall survival (OS) over COPP/ABVD and BEACOPP baseline (BB) (each 8 cycles) at the cost of increased toxicity. *Aims*. HD12 aimed to reduce toxicity by deescalating chemotherapy comparing 8 cycles BE with 4 cycles BE followed by 4 cycles BB, and to assess additional radiation (RT) to initial bulk and residual disease. *Design and Methods*. Patients with HL in stage IIB with large mediastinal mass and/or E-lesions or stage III-IV were randomised according to a 2x2-factorial design between: 8BE + RT, 8BE no RT, 4BE+4BB + RT, 4BE+4BB no RT. Reviewing CT-images before and after chemotherapy, fields for RT were centrally planned by a multidisciplinary diagnostic panel blinded for the randomisation arm. Primary endpoint of the trial was FFTF. *Results*. Between 9/1999 and 1/2003, a total of 1.670 patients aged 16-65 were randomized. For this final analysis, 99 patients were excluded (42 HL not confirmed, 20 revision of stage, 20 no study treatment or documentation, 17 other) resulting in 1.571 eligible patients equally distributed between the 4 study arms. Patient characteristics in the 4 groups were comparable with 49% of patients in stage III, 35% in stage IV, 68% reporting B-symptoms and 28% having a large mediastinal tumor. As expected, chemotoxicity was high with 97% of patients receiving at least one WHO grade III or IV toxicity. Most prominent differences between pooled chemotherapy arms were anemia (65% 8BE vs 51% 4BE+4BB) and thrombopenia (65% vs 51%). Death due to acute toxicity was 3% (sepsis, cardiac, pulmonary, infection), with 20 deaths in the 8BE arms and 27 in the 4BE+4BB arms. Treatment outcome was complete remission for 92.4% of patients with another 2.2% experiencing early progression. Total progression/relapse rate was 7.8% (n=52 vs 71) with a median follow up of 78 months. A total of 156 deaths (72 vs 84, 9.9%) have been observed (22 vs 32 due to acute or salvage treatment toxicity; 15 vs 24 HL, 22 vs 13 secondary neoplasia). Secondary neoplasias were observed in 77 patients (4.9%): 12 vs 11 AML/MDS, 11 vs 5 NHL and 20 vs 18 solid tumors/others. OS after 5 years was 91%, 5-year FFTF was 85.5% and 5-year progression free survival (PFS) was 86.2% (Kaplan-Meier estimates). Estimates for the difference at 5 years are -1.8% [-4.7%, 1.1%] for OS, -2.3% (95% CI [-5.9%, 1.3%]) for FFTF and -2.7% [-6.2%, 0.8%] for PFS. The confidence intervals show that while 4BE+4BB is clearly not significantly different from 8BE in all 3 long-term outcome parameters ($p>0.19$, log rank test), a difference of up to -5.9% in FFTF cannot be ruled out statistically. *Conclusion*. BEACOPPescalated remains standard of care for patients with advanced stage HL in our group.

1084

A PROSPECTIVELY RANDOMIZED PLACEBO-CONTROLLED TRIAL OF EPOETIN-A IN PATIENTS WITH ADVANCED-STAGE HODGKIN LYMPHOMA: FINAL ANALYSIS OF THE GHSG HD15-EPO TRIAL

M. Engert,[1] H. Haverkamp,[2] P. Borchmann,[2] A. Josting,[3] M. Fuchs,[2] V. Diehl[2]

[1]Internal Medicine I, COLOGNE, Germany; [2]German Hodgkin Study Group, University Hospital of Cologne, COLOGNE, Germany; [3]Evangelisches Krankenhaus Lippstadt, Medizinische Klinik, LIPPSTADT, Germany

Background and aims. Anemia is frequent among cancer patients and impacts organ function and quality of life of those affected. Anemia has been shown to be a negative prognostic factor in several malignancies including Hodgkin Lymphoma (HL). In addition, the advent of more aggressive treatment regimen such as BEACOPP escalated has resulted in more HL patients needing red-blood-cell transfusion. *Design and Methods*. Thus, apart from the chemotherapy-related question of the GHSG HD15 trial, ie 8 cycles of BEACOPP escalated or 6 cycles of BEACOPP escalated or 8 cycles of BEACOPP14, patients in HD15 were randomized between Epoetin-α and placebo. Study drug was given at 40.000 I.E. weekly with a hemoglobin target level of 12-13g/dL. Primary endpoint was fatigue after the end of chemotherapy (CT) and 6 months later measured with the EORTC QLQ-C30 questionnaire (0-100 scale). With respect to the more recent safety discussion related to erythropoetins (EPOs) in general, we also analysed efficacy and safety endpoints although the trial was not sufficiently powered for time-to-event analyses. *Results*. Between1/2003 and 12/2006 a total of 1.379 patients were randomized for the EPO question of whom 1.329 were eligible. Of these 1.286 (96.8%) are fully evaluable. Patient characteristics were balanced between the placebo and the EPO arm. In those 688 patients who were randomized before 7/2005 and eligible for analysis, the CR/CRu rate was 90,6% with a median follow-up of 28 months, a total of 58 progressions/relapses (8.4%) and 33 deaths (4.8%) without differences between study arms. There was also no difference in terms of freedom from treatment failure (hazard ratio (HR) 0.9, 95%-confidence interval (CI) 0.6-1.4) and overall survival (HR 1.1, 95% CI 0.6-2.3). 51 serious adverse (7.4%) and 35 thrombovascular events (5.1%) were observed with no significant difference between arms. The median number of red blood cell units given significantly favored patients receiving Epoetin-α (2 vs 4; test for trend $p<0.001$). The interim analysis for fatigue gave an average value of 61±25.8 (mean±SD) at the end of treatment and a reduced fatigue score of 33±25.3 at six months after CT. *Conclusions*. This is the largest prospectively randomized, placebo-controlled trial with EPO in cancer patients. So far we found no difference in terms of fatigue, response, relapse or side effects between those advanced-stage HL patients receiving Epoetin-a or placebo. The number of RBC units given was significantly reduced in the EPO group.

RISK FOR AML/MDS TRANSFORMATION IN PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS - A POPULATION-BASED NESTED CASE-CONTROL STUDY IN SWEDEN

J. Björkholm,[1] A.R. Derolf,[1] C. Ekstrand,[1] S.Y. Kristinsson,[1] B. Andreasson,[2] G. Birgegard,[2] O. Linder,[2] C. Malm,[2] B. Markevarn,[2] A. Nilsson,[2] J. Samuelsson,[2] F. Granath,[1] O. Landgren[3]

[1]Karolinska University Hospital, STOCKHOLM, Sweden; [2]Swedish Chronic Myeloproliferative Disorder Study Group, SWEDEN, Sweden; [3]National Cancer Institute, National Institutes of Health, BETHESDA, USA

Background. The clinical course of Philadelphia negative chronic myeloproliferative neoplasms (MPN)s, including polycythemia vera (PV), essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF), is characterized by a variable risk (1-20% after 10 years of disease) for disease transformation into acute myeloid leukemia/myelodysplastic syndromes (AML/MDS). The risk is higher in IMF, intermediate in PV and low in ET. There is no apt way to predict which patient is likely to develop this ominous complication. The use of alkylators and P32 carries a well established increased risk for leukemic transformation. Hydroxyurea (HU) is known to be less leukomogenic. However, its potential long-term effect on AML/MDS development remains controversial. This is due to the relative rarity of MPNs, late appearing transformation events in a long-term disease course, and lack of randomized trials. *Aims*. To define risk factors (treatment, disease and host related factors) for AML/MDS development in a large nested case-control study with a special focus on the leukemogenic potential of HU. *Design and Methods.* 11,039 patients with MPN were identified from the Swedish Cancer Registry and major hematology/oncology units. Through record-linkage with the Cancer Registry patients who developed AML (n=271) and MDS (N=21) were identified. For each patient with a subsequent AML/MDS diagnosis (cases) two control patients (without AML/MDS) matched for MPN disease, age, gender, and calendar period were defined (controls). Information was collected regarding treatment (agent, cumulative dose, duration), disease related factors (laboratory variables) and host-related factors (demographics, co-morbidity). Cases and control patients with prior chemotherapy/radiotherapy for non-MPN, misdiagnosis, no proper match and lack of relevant medical records were excluded from the analysis. Data was analysed by logistic regression conditioned on follow-up time, MPN diagnosis and age. Analyses focusing on treatment effects were mutually adjusted for each other. Results are presented as odds ratios (OR) with 95% confidence interval (CI). *Results*. The final study population consisted of 206 MPN cases (193 AML, 13 MDS; 43% females; PV n=138; ET n=32; MF n=21; MPD NOS n=15) and 225 matched control patients (42% females; PV n=166; ET n=36; MF n=19; MPD NOS n=4). Median time from MPN diagnosis to AML/MDS was 7 years, range 0.5-35 years. Compared to no HU exposure the ORs for 1-499g, 500-999 g, >1000 g of HU were 1.07 (0.42-2.70), 0.90 (0.28-2.89), and 1.01 (0.28-3.60), respectively for AML/MDS development (not significant). In contrast, MPN patients who received P32 >1000 MBq and alkylating agents >1 g had a 3.39-fold (1.28-8.99; $p=0.01$) and 4.46-fold (1.22-16.31; $p=0.03$) increased risk of developing AML/MDS, respectively. Lower exposures to P32 and alkylators were not associated with a significantly increased risk of AML/MDS. *Conclusions*. In this large population-based nested case-control study, the risk of AML/MDS was strongly associated with high exposures of P32 and alkylator treatment. In contrast, HU treatment did not significantly increase the risk for transformation to AML/MDS.

1086

TREATMENT OF PROGRESSION OF MYELOPROLIFERATIVE NEOPLASM TO MDS/AML BY AZACYTIDINE : A REPORT ON 44 PATIENTS

S. Thepot,[1] R. Itzykson,[2] E. Raffoux,[2] C. Recher,[2] B. Quesnel,[2] F. Dreyfus,[2] T. Cluzeau,[2] Y. Chait,[2] S. Harel,[2] J. Delauney,[2] D. Schlaifer,[2] A. Thyss,[2] C. Salanoubat,[2] C. Dartigeas,[2] A. Stamatoulas,[2] A. Marfaing koka,[2] C. Dumontet,[2] B. Cassinat2, C. Zerhouni,[2] M. Roussel,[2] J.J. Kiladjian,[2] C. Gardin,[2] P. Fenaux,[2] L. Ades[2]

[1]Hopital Avicenne, BOBIGNY, France; [2]GFM, BOBIGNY, France

Background. MDS and AML occurring during the course of myeloproliferative neoplasms (MPN) carry a very poor prognosis and current treatments have very limited efficacy. Azacytidine (AZA) significantly

improves survival in higher risk MDS (Lancet Oncol, 2009,online) and in some AML, but its use has not been extensively reported so far in MDS and AML post MPN. *Patients*. The French health agency (AFSSAPS) designed a still ongoing pt named program (ATU) of AZA (75 mg/m²/d x7d every 4w) in higher risk MDS and poor risk AML. 44 pts with MDS or AML post MPN, included in this program in 16 centers, before October 08 and having completed at least 1 cycle of AZA are analysed here. Diagnostic of MPN was based on WHO 2008 criteria, and response to AZA on IWG 2006 criteria for MDS and IWG-AML 2003 criteria for AML. *Results*. Median age was 69.5y (range 37-89), M/F: 27/17. The initial MPN was PV in 17 pts, ET in 16 pts, primary myelofibrosis (MF) in 5 pts, MPN unclassifiable (MPN,U) in 6 pts. 19/44 (43%) pts had JAK2-V617F mutation. Median interval from diagnosis to progression was 6.1 years (3 months-34 years). At inclusion, diagnosis was AML in 21 pts, MDS in 22 pts (RAEB-2 in 16 pts, RAEB-1 in 6 pts) and MDS/MPN U in 1 pt (WHO 2008 classification). Karyotype at transformation was normal in 7 pts, failure in 4 pts, 9 pts had isolated chromosome 7 abn, 5 had +8, 5 had del 20q, and 16 had complex karyotype. Among the 19 pt with JAK2-V6127F mutation at the onset of MPN, 12 were still positive at the time of transformation. The median number of cycles of AZA administered was 6 (range 1-20). Early AZA discontinuation (< 4 cycles) was due to death in 9 pts, restoration of features of MPN in 4 pts and patient decision in 1. Overall response rate (ORR, including CR, PR, CRi, marrow CR, HI for MDS) was 17 (39%). Among the 35 pts who received at least 4 cycles of AZA, 22 (63%) were MDS and 13 (37%) were AML. In MDS pts, 8 (36%) achieved CR (including 2 cytogenetic CR), 2 (10%) achieved PR, and 2 (10%) HI-E leading to an ORR of 54%. In AML pts, 1 achieved CR and 3 achieved CRi (ORR 31%). Median follow up from inclusion was 6 months (2-31). 6 of the 15 responders relapsed after a median time of 9.5 months (5-13) and 9 maintained their responses after a median time of 8 months (4+-26+). 26 pts were still alive after 3 to 26 months (median 7.5). Median survival was 13 months. OS was better in MDS pts than in AML pts (73% vs 15% at 18 months, p=0.0072). Interestingly, in 8 pts with a long history of MPN (median 14 years) response to AZA was associated to recurrence of initial features of MPN requiring restart of cytoreductive therapy in 4 of them. *Conclusions*. 5 AZA gives encouraging results in MDS or AML occurring in the course of MPN

1087

PHASE II STUDY OF CEP-701, AN ORALLY AVAILABLE JAK2 INHIBITOR, IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST POLYCYTHEMIA VERA/ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS

F. P.S. Santos, H. Kantarjian, N. Jain, D. Thomas, G. Garcia-Manero, J. Cortes, S. Verstovsek

University of Texas - M.D. Anderson Cancer Center, HOUSTON, USA

Background. Myelofibrosis (MF; primary or post-essential thrombocythemia/post-polycythemia vera) is one of the Philadelphia chromosome-negative myeloproliferative disorders. There are few treatment options available for patients with MF. Activating mutations of the JAK2 tyrosine kinase (JAK2V617F) are found in 50% of patients with MF, leading to a constitutive autophosphorylated JAK2 protein. CEP-701 is an orally available tyrosine kinase inhibitor that has activity as a JAK2 inhibitor both *in vitro* and *in vivo*. *Aims.* This is a single-center phase II trial evaluating therapy with CEP-701 in patients with JAK2V617F-positive MF. *Design and Methods*. Patients were eligible for this trial if they were at least 18-years of age and had a diagnosis of JAK2V617F-positive MF requiring therapy, including previously treated patients that were relapsed, intolerant, or refractory to therapy or if newly diagnosed then with intermediate or high risk according to Lille scoring system, or with a symptomatic splenomegaly ≥10 cm below costal margin. Patients were treated with CEP-701 at an initial dose of 80 mg twice daily. Responses were evaluated using the criteria developed by the International Working Group on Myelofibrosis Research and Treatment (IWG-MRT). *Results*. A total of 22 patients were treated. Their median age was 61 years (range 38-83 years). Median time from diagnosis to therapy was 28 months (range 0-184 months). Most patients (90%) were previously treated, and the median number of previous therapies was 3 (range 0-6). Splenomegaly was present in 90% of patients, and the median size from left costal margin was 19 cm (range 0-30 cm). Median JAK2V617F / total JAK2 ratio (allele burden) was 53.5% (range 13.5-96.6%). Fourteen out of 21 evaluable patients presented with abnormal cytogenetics. Eight patients (36%) were transfusion dependent. Median time on study was 4 months (range 1-19 months). Responses were seen in 6 patients (27%). All responses were defined as Clinical Improvement by IWG-MRT criteria and consisted of reduction in spleen size alone in 3 patients, transfusion independency in two patients, and reduction in spleen size together with improvement in neutrophils and platelets in one patient. Median time to response was 3 months (range 1-9 months). JAK2 allele burden was unchanged in responders. No patient had improvement in bone marrow fibrosis. No patient had a cytogenetic response. The median duration of response was 14 months (range 3-17 months). Three patients are still on study and have maintained their response for 17, 16 and 6 months, respectively. Main toxicities were anemia (grades 3-4: 18%), thrombocytopenia (grades 3-4: 18%) and diarrhea (all grades: 68%; grades 3-4: 9%). Six patients (27%) required CEP-701 dose reductions because of toxicity. Median time to dose reduction was 3 months (range 1-6 months). Eight patients (36%) had their dose of CEP-701 escalated to 100 mg twice daily. Only one achieved a response after increasing the dose. *Conclusions*. Therapy with CEP-701 was relatively well tolerated and had modest efficacy in patients with MF. Most responses consisted of the reduction in spleen size. There was no improvement in the JAK2 allele burden or bone marrow fibrosis.

1088

TG101348, A JAK2-SELECTIVE INHIBITOR, IS WELL TOLERATED IN PATIENTS WITH MYELOFIBROSIS AND SHOWS SUBSTANTIAL THERAPEUTIC ACTIVITY ACCOMPANIED BY A REDUCTION IN JAK2V617F ALLELE BURDEN

D. Pardanani,[1] J. Gotlib,[2] C. Jamieson,[3] J. Cortes,[4] M. Talpaz,[5] R. Stone,[6] M. Silverman,[7] J. Shorr,[7] D.G. Gilliland,[8] A. Tefferi[1]

[1]Mayo Clinic, ROCHESTER, USA; [2]Stanford University School of Medicine, STANFORD, USA; [3]Moores UCSD Cancer Center, SAN DIEGO, USA; [4]MD Anderson Cancer Center, HOUSTON, USA; [5]University of Michigan, ANN ARBOR, USA; [6]Dana Farber Cancer Institute, BOSTON, USA; [7]TargeGen Inc., SAN DIEGO, USA; [8]Brigham and Women's Hospital, Dana Farber Cancer Institute, Harvard Medical Sch, BOSTON, USA

Background. The discovery of JAK2V617F (VF) has spurred development of JAK2-selective small molecule inhibitors for the treatment of myeloproliferative neoplasms. TG101348 is a potent and selective orally bioavailable JAK2 inhibitor. *Aims*. To assess the safety, tolerability, and pharmacokinetic behavior of TG101348 in a Phase I dose-escalation study. The secondary objectives were evaluation of treatment responses, pharmacodynamic activity of TG101348, and drug effect on VF allele burden. TG101348 was administered orally once daily in 28-day cycles. For patients achieving less than a complete remission after 3 cycles of treatment, escalation was permitted to the highest tolerated dose in the absence of disease progression or unacceptable toxicity. *Results*. Twenty eight patients (median age=66 years) were treated in the dose escalation phase, at 8 dose levels from 30mg to 800mg daily. Nineteen patients had PMF, 7 post-PV MF, and 2 post-ET MF; 89% were VF-positive. Median palpable spleen size was 17cm and 10 patients were transfusion-requiring at the time of study enrollment. The median period of drug exposure to date is 21 weeks (range <1 to 55 weeks). Dose-linear plasma exposures were observed, with mean elimination T1/2 at steady state ranging from 23 to 52 hours across doses. Toxicity. At the highest dose level (800mg), 2 of 6 patients experienced dose-limiting toxicity (asymptomatic grade 3 or 4 amylasemia with grade 4 lipasemia in 1 patient) that was reversible upon holding drug (both patients currently being treated at a lower dose); consequently, the maximum tolerated dose (MTD) was declared at 680mg. The most frequent non-hematological toxicities were grade1/2 nausea/vomiting (64%) and diarrhea (50%), well controlled with anti-emetics and anti-diarrheals or resolving spontaneously; no neurologic toxicities were observed. Grade 3/4 thrombocytopenia was seen in 8 patients (29%; n=6 grade 3, n=2 grade 4); grade 3/4 neutropenia was seen in 3 patients (11%; n=2 grade 3, n=1 grade 4). Efficacy. Six (21%) of the 28 study patients have so far discontinued treatment due to competing comorbidities (n=1), investigator discretion/non-compliance (n=4), or toxicity (n=1; grade 4 neutropenia). The remaining 22 patients are currently at the following dose levels: 680mg (n=17), 520 mg (n=1), 360mg (n=3), and 240 mg (n=1). A reduction in spleen size was seen in all 22 patients (100%) including 5 (23%) whose spleen became non-palpable from a pre-treatment spleen size of 4 to 34cm. A total of 14 patients (64%) have experienced a greater than 50% decrease in spleen size. All 14 patients with leukocytosis at baseline (WBC range 20 to 103x10⁹/L) have experienced a marked reduction in their WBC count (range 6.6 to 28.3). Of the 25 VF-positive patients, 8 (32%) have experienced a greater than 50% reduction in granulocyte mutant allele burden during 2 consecutive readings. *Conclusions*. TG101348 is well tolerated in patients with myelofibrosis and the MTD

is now established at 680 mg/day. Already during the dose-escalation phase of the study, the drug has shown substantial activity in reducing spleen size, leukocyte count, and VF allele burden. The expansion phase of the study at the MTD is scheduled to open in March 2009.

1089

ANAHYDRET: A EUROPEAN MULTICENTER PROSPECTIVE PHASE 3-STUDY: NON-INFERIORITY OF ANAGRELIDE COMPARED TO HYDROXYUREA IN NEWLY WHO-DIAGNOSED ET PATIENTS

E. Petrides,[1] M. Gotic,[2] M. Penka,[3] J. Holowiecki,[4] J. Thiele,[5] H.M. Kvasnicka,[5] R. Kralovics,[6] H. Gisslinger[2]

[1]Hematology Oncology Center, MUNICH, Germany; [2]Institute of Hematology, BELGRADE, Serbia; [3]Department of Clinical hematology, BRNO, Czech Republic; [4]Silesian Medical University, KATOWICE, Poland; [5]Institute of Pathology, COLOGNE, Germany; [6]Center for Molecular Medicine, VIENNA, Austria

Background. Based on the superiority of hydroxyurea & aspirin over anagrelide & aspirin in ET patients in the PT1-trial, guidelines recommend hydroxyurea as first line therapy for ET. However, the diagnosis of ET in the PT1-trial was based on the PVSG classification. Therefore, it remains questionable whether this recommendation is also true for ET patients diagnosed according to the WHO classification. *Aims*. In this European phase 3 study efficacy and tolerability of ANAgrelide and HYDRoxyurea were compared in high risk ET patients diagnosed according to the WHO classification. The study was designed as a non-inferiority trial because of the limited number of treatment naïve ET patients available and the expected low number of ET related events following treatment with a cytoreductive therapy. *Design and Methods*. 258 treatment naïve high risk patients with ET were randomized to anagrelide (n=122) or hydroxyurea (136). The patients characteristics were equally distributed with a median age of 58,1 years (range 19-90 years; 46 male, 76 female) in the anagrelide arm vs. a median age of 56,4 years (range 22-83 years, 47 male, 89 female) in the hydroxyurea arm. *Results*. A central blinded pathology review of 236 bone marrow biopsies revealed a high reproducibility of the ET diagnosis by applying the WHO classification: 194 (82.2%) of patients were classified as having ET, 16 patients (6,8%) were reclassified as PMF-0 and 16 patients (6,8%) were considered having early PVs with an ET-like clinical phenotype. Confirmatory proof of non-inferiority was achieved after a mean observation time of 2,1 years (comprising 539 patient years) based on predefined equivalence criteria for platelet counts, course of hemoglobin levels and white cell count during therapy as well as for the rate of ET related events. In the anagrelide arm 75,4% of the patients developed a complete response of platelet counts (<450.000/µL) compared to 81,7% in the hydroxyurea arm. Neutrophil counts remained unchanged in the anagrelide arm but were significantly reduced by hydroxyurea. No significant differences were observed for the rates of major and minor clinical ET releated events in the anagrelide group (4,29 %, and 16,8 %, resp.) compared to hydroxyurea (4,25 %, and 12,8 %, resp.). During the entire study period 11 major ET related complications occurred in the anagrelide group (5 arterial events, 2 venous thrombotic complications and 4 bleedings) and 12 major events in the hydroxyurea arm (5 arterial events, 5 venous thrombotic events and 2 bleedings). 43 minor ET related events were observed in the anagrelide arm as compared to 36 such events in the hydroxyurea arm. Adverse drug reactions or poor response were reasons for discontinuation of the study drug in 19 patients treated with anagrelide and in 10 patients treated with hydroxyurea. Transformations to myelofibrosis were not reported during the whole study period. The JAK2 mutation status was evaluated in 189 patients with 101 JAK2V617F positive (53,4%) and 88 (46,6%) JAK2V617F negative patients. *Conclusions*. Final analysis of the study proofs non-inferiority of anagrelide compared to hydroxyurea in the treatment of ET diagnosed according to the WHO classification.

Chronic myeloid leukemia - Clinical II

1090

NILOTINIB 800 MG DAILY IN EARLY CHRONIC PHASE CHRONIC MYELOID LEUKEMIA: 12-MONTHS RESULTS OF A PHASE 2 TRIAL OF THE GIMEMA CML WORKING PARTY

G. Rosti,[1] F. Castagnetti,[2] M. Breccia,[3] A. Poerio,[2] G. Gugliotta,[4] L. Levato,[5] F. Palandri,[2] A. Capucci,[5] M. Tiribelli,[6] F. Stagno,[6] G. Marzocchi,[2] S. Luatti,[2] M. Amabile,[2] A. Zaccaria,[5] G. Alimena,[3] F. Pane,[7] G. Martinelli,[2] G. Saglio,[8] M. Baccarani[2]

[1]Department of Hematology and Oncological, BOLOGNA; [2]St. Orsola Hospital, BOLOGNA; [3]Hematology Unit, University of Roma La Sapienza, ROMA; [4]University of Bologna, BOLOGNA; [5]Division of Hematology, CATANZARO; [6]Chair of Hematology, UDINE; [7]Onco-Hematology Unit, University Federico II, NAPOLI; [8]Dpt. of Clinical and Biological Sciences, University of Torino, TORINO, Italy

Background. Imatinib (IM) 400 mg daily is the standard treatment for CML in early chronic phase (ECP). The cumulative rate of complete cytogenetic response (CCgR) in the IRIS trial for the IM 400 mg arm was 51%, 69% and 87% at 6, 12 and 60 months, respectively. One-fourth of all the IM treated pts fail to obtain a stable CCgR due to upfront resistance, refractoriness or intolerance. Nilotinib has a higher binding affinity and selectivity for Abl with respect to IM and is highly effective in IM resistant patients, across every disease phase. *Aims*. To investigate the safety and the efficacy of nilotinib 400 mg BID in ECP, Ph-pos CML patients, the GIMEMA CML Working Party is conducting an open-label, single-stage, multicentric, phase II trial (*ClinicalTrials.gov.NCT00481052*). *Design and Methods.* The primary endpoint is the CCgR rate at 1 year; the kinetic of MR is studied by Q-PCR baseline and after 1, 2, 3, 6, 9 and 12 month. *Results*. 73 patients have been enrolled from 20 Centres between June, 2007 and February, 2008. The median age is 51 years (range 18-83), 45% low, 41% intermediate and 14% high Sokal risk. Median follow-up is currently 410 days (range 185-548).The minimum follow-up is 6 months for all the pts and 12 months for 52 (71%) (complete 12-months data will be presented on site). The cumulative CCgR rate within 12 months is 100%. At 3, 6 and 12 months (ITT), the CCgR rate is 78%, 96% and 90%, respectively (at 12 months, 21 pts with pending results). The achievement of the first MMR, defined as a BCR-ABL:ABL ratio ≤0.1% according to the International Scale, after 1, 2, 3, 6, 9 and 12 months is 3%, 22%, 59%, 66%, 75% and 77%, respectively (15 and 21 pts at 9 and 12 months pending). One patient only progressed at 6 months to ABP with T315I mutation. The dose intensity was high: during the first and second trimester, 58% and 60% of the 73 pts received the full, 800 mg daily dose while 25% and 16% of the pts received a mean daily dose ranging between 600 and 799 mg daily, respectively. Adverse events (AEs) were mostly grade 1 and 2 and manageable with appropriate dose adaptations: the most frequent biochemical AEs were bilirubin increase (53% all grades, 16% grade 3), s-GPT increase (42% all grades, 8% grade 3) and lipase and amylase increase (29% and 18%, all grades, 8% and 4% grade 3+4, respectively); 2 pts went off treatment after 6 and 13 months due to recurrent episodes of amylase and/or lipase increase (no pancreatitis). Hematologic toxicity was recorded in 4 pts (5% - only 1 event grade IV neutropenia); *Conclusions*. The results that have been achieved in these unselected patients and within a multicentric trial, strongly support the hypothesis that in ECP, Ph-pos CML patients the response to nilotinib is faster than the response to IM standard and high dose.

DASATINIB 100 MG ONCE DAILY FOR CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CML-CP) FOLLOWING IMATINIB FAILURE: LONG-TERM FOLLOW-UP FROM STUDY CA180-034

A. Hochhaus,[1] D.W. Kim,[2] H.M. Kantarjian,[3] P. Rousselot,[4] P. Dorlhiac-Llacer,[5] J. Milone,[6] N.P. Shah,[7] Y. Matloub,[8] A. Lambert,[8] R.M. Stone[9]

[1]Universitätsmedizin Mannheim, MANNHEIM, Germany; [2]St Mary's Hospital, The Catholic University of Korea, SEOUL, South-Korea; [3]MD Anderson Cancer Center, HOUSTON, USA; [4]Hôpital Mignot, Université de Versailles et CIC9504, LE CHESNAY, France; [5]Hospital das Clinicas da Universidade de Sao Paulo, SAO PAULO, Brazil; [6]Instituto de Trasplante de Medula Osea, LA PLATA, Argentina; [7]University of California, San Francisco School of Medicine, SAN FRANCISCO, USA; [8]Bristol-Myers Squibb, WALLINGFORD, USA; [9]Dana-Farber Cancer Institute, BOSTON, USA

Background. Dasatinib 100 mg once daily is the recommended and approved dose for patients with CML-CP following resistance, suboptimal response, or intolerance to prior imatinib, based on previous results from CA180-034 - a phase III dose-optimization study demonstrating similar efficacy and significantly minimized toxicity compared with other dose schedules. In a pharmacokinetic analysis, the dasatinib steady-state trough concentration (Cmin) was lower in the 100 mg once-daily arm than in other arms, and lower a Cmin was associated with less frequent key side effects (pleural effusion, neutropenia, and thrombocytopenia), dose reductions, and dose interruptions. *Aims*. To investigate the long-term efficacy and safety of dasatinib 100 mg once-daily treatment and to determine the association of early cytogenetic response with long-term endpoints. *Design and Methods*. Patients were randomized after informed consent using a 2x2 factorial design to one of four treatment arms: 100 mg QD (n=167), 70 mg BID (n=168), 140 mg QD (n=167), or 50 mg BID (n=168). Details of study design and endpoints have been described previously. *Results*. After minimum follow-up of 2 years, the 2-year rate of progression-free survival (PFS) with 100 mg once daily was 80% (vs 75-76% in other arms) and the overall survival rate was 91% (vs 88%-94%). Among responding patients in the 100 mg once-daily arm, excluding Ph-negative BCR-ABL-positive patients, median time to major cytogenetic response (MCyR) was 2.9 months (intolerant: 2.8 months; resistant/suboptimal: 2.9 months) and to complete cytogenetic response was 3.0 months (intolerant: 2.9 months; resistant/suboptimal: 3.1 months), with similar times to response observed in other arms. Among patients treated with dasatinib 100 mg once daily (vs other arms) who had any baseline BCR-ABL mutation following resistance or suboptimal response to imatinib, the 2-year MCyR rate was 57% (vs 47-55%), the CCyR rate was 43% (vs 32-45%), and PFS at 2 years was 75% (vs 58-65%). Dasatinib 100 mg once daily was well tolerated and rates of key side effects showed only a minimal increment in the second year. Across the four treatment arms, significant differences were observed in rates of drug-related pleural effusion (all grades: p=0.049) and cytopenia (p=0.003 for grade 3/4 thrombocytopenia), with lowest rates observed in the 100 mg once-daily arm. Compared with other arms, dasatinib 100 mg once daily resulted in the lowest rates of treatment interruption (62% vs 72-79%), reduction (39% vs 46-62%), and discontinuation (41% vs 47-50%). In addition to 3-year data for PFS, overall survival, and safety, the likelihood of achieving long-term endpoints based on landmark analysis of cytogenetic status at 6, 12, and/or 18 months will be presented. *Conclusions*. This is the first clinical study showing an advantage for intermittent over continuous tyrosine kinase inhibition in terms of maintaining efficacy and improving safety. Extended follow-up from the CA180-034 study confirm that dasatinib 100 mg once daily is the optimal dosing schedule for patients with CML-CP following resistance, suboptimal response, or intolerance to imatinib.

1092

IMATINIB AND DASATINIB TREATMENT RESULTS IN SELECTION OF A POPULATION OF QUIESCENT LEUKEMIC STEM CELLS SHOWING CROSS-RESISTANCE TO CELLULAR IMMUNOTHERAPEUTIC INTERVENTIONS

I. Jedema, L. van Dreunen, R. Willemze, J.H.F. Falkenburg

Leiden University Medical Center, LEIDEN, Netherlands

Background. Tyrosine kinase inhibitors like imatinib and dasatinib are the current treatment of choice for patients with chronic myeloid leukemia (CML). Most patients enter a complete remission during treatment, but recurrence of the disease is seen in the majority of patients upon discontinuation of treatment, and drug resistance may eventually occur illustrating that a fraction of leukemic stem cells is apparently capable of escaping the treatment. In contrast, allogeneic stem cell transplantation (allo-SCT) and application of donor T cells may be a curative treatment. *Aims*. The aim of this study was to investigate whether the leukemic stem cells residing during imatinib treatment are susceptible targets for immunological interventions, and whether allo-SCT performed for persistent CML should be combined with continuous treatment with tyrosine kinase inhibitors. *Design and Methods*. $CD34^+$ positive CML cells were isolated from bone marrow and labeled with the fluorescent dyes CFSE or PKH to allow monitoring of single cell proliferation upon addition of cytokines. CML cells were exposed to imatinib (200-10 μM) or dasatinib (200-10 nM) or to $CD8^+$ minor histocompatibility antigen (mHag) or allo-HLA antigen specific cytotoxic T lymphocyte (CTL) clones. The number, phenotype, and proliferative status of the CML cells residing after single and combined interventions were measured by quantitative flowcytometric analysis. *Results*. In the absence of therapeutic interventions the majority of $CD34^+$ CML cells entered proliferation as determined by dilution of CFSE or PKH. However, a small population of $CD34^+$ CML stem cells residing in the non-dividing peak could be identified in all samples despite the addition of cytokines. Addition of imatinib or dasatinib resulted in efficient dose-dependent induction of cell death in the majority of cells. However, the population of quiescent $CD34^+$ CML stem cells was not affected and appeared to increase compared to the non-treated controls, indicating additional growth arrest of proliferating CML cells by exposure to tyrosine kinase inhibitors. We next tested the capacity of different HLA-A2 restricted $CD8^+$ CTL clones to kill non-treated or imatinib or dasatinib treated CML cells. Whereas the proliferating $CD34^+$ CML precursors were efficiently lysed, the population of quiescent stem cells was capable of withstanding CTL exposure. Detailed phenotypic analysis revealed significant downregulation of HLA-A2 and the adhesion molecules CD49d and CD58 on these quiescent cells, probably resulting in the inability of these target cells to form a high avidity interaction with the T cells. Moreover, the tyrosine kinase inhibitors suppressed T cell proliferation. Removal of the tyrosine kinase inhibitors from the cultures resulted in conversion of part of the quiescent $CD34^+$ CML cells to susceptibility to CTL attack. *Summary and Conclusions*. Treatment with tyrosine kinase inhibitors results in selection of a population of quiescent leukemic stem cells showing cross-resistance to CTL-induced cell death, most likely due to their inability to form a high avidity interaction, indicating that treatment with tyrosine kinase inhibitors may not act synergistically with immunological interventions. The anti-proliferative effect of tyrosine kinase inhibitors on both the leukemic cells and the T cells may potentially even hamper the potentially curative immune response after allogeneic SCT.

1093

MOLECULAR RESPONSES OF THE SPIRIT PHASE III TRIAL OF THE FRENCH CML GROUP COMPARING IMATINIB 400 MG TO HIGHER DOSE IMATINIB OR COMBINATION WITH INTERFERON OR CYTARABINE FOR THE TREATMENT OF NEWLY DIAGNOSED CHRONIC PHASE (CP) CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS

P. Rousselot,[1] C. Preudhomme,[2] J. Guilhot,[3] V. Dubruille,[4] T. Lamy,[4] M. Delain,[4] H. Tilly,[4] P. Cony-Makhoul,[4] C. Allard,[4] H. Jardel,[4] S. Cheze,[4] F.X. Mahon,[2] F. Guilhot[3]

[1]Centre Hospitalier de Versailles, VERSAILLES, France; [2]FI LMC, LILLE, France; [3]CIC 802 INSERM, POITIERS, France; [4]Hematologie, NANTES, France

Background. Imatinib (IM) 400 mg daily is the front-line treatment of CP CML, but provides only 50% major molecular responses (MMR) at 18 months (Mo). *Aims*. we designed a phase III randomized multicenter open-label prospective trial comparing IM 400 mg/d (n=159) with 3 experimental arms: IM 600 mg/d (n=160), IM 400 mg/d combined to s/c cytarabine (Ara-C), (20 mg/m^2/d, d15-28 of 28-day cycles)(n=158) and IM 400 mg/d combined to s/c Peg-IFN2α (90 μg/wk) (n=159). *Design and Methods*. Pts were allocated at a 1.1.1.1 ratio, stratified by Sokal risk groups. Molecular assessments were centralized, blinded and calculated according to the international standardized scale (IS). *Results*. This interim analysis of 636 pts based on an optimal molecular response (OMR = BCR-ABL/ABL ratio ≤0.01) (α=0.85%, β=10%) at 1 year has been planned in order to select the best experimental arm for further comparison to IM-400. Pts were recruited between 9/2003 and 10/2007, median age 51 yrs (18-78), 62% males; Sokal score was low 33%, intermediate 41% and high risk 27%. Median follow-up was 36 Mo. (range 12-62). Overall, at 3 Mo, 88% of pts achieved complete haematological

response. Complete cytogenetic response (CCyR), MMR and OMR rates are described in Table 1 MMR rates at 6 and 12 Mo were higher for IM-PegIFN as compared to IM-400 (p<10-3). At 18 MO the cumulative OMR rates were 22% (IM-400), 28% (IM-600), 25% IM-1ra-c), 43% (IM-PegIFN). Grade 3/4 neutropenia and/or thrombocytopenia occurred during the first year in 8% IM-400, in 14% IM-600, in 41% IM-Ara-C and in 40% IM-PegIFN arms respectively. No significant infection rates were observed between the 4 arms. Grade 3/4 non-haematological toxicities occurred in 19% IM-400 (oedemas, muscle cramps), in 30% IM-600, in 27% IM-Ara-C (diarrhoea) and in 31% IM-PegIFN pts (skin rashes, asthenia). Within the first 12 Mo, discontinuation of experimental treatment occurred in 8% IM-600, 39% IM-Ara-C and in 45% IM+PegIFN pts. *Conclusions*. Although a significant number of pts reduced or stopped PegIFN within the first year, highly significant improvements in the MMR rates were observed in the IM-Peg IFN arm and may translate into survival benefit.

Table 1.

% of 636 pts *(ITT analysis)*	IM-400	IM-600	IM-400 + Ara-C	IM-400 + Peg-IFN2a	P value *(overall)*
At 6 Mo.

Gutenberg Universität, Abt für Hämatologie, MAINZ, Germany; [6]Universitätsklinikum Hamburg-Eppendorf, Klinik und Poliklinik für Innere Medizin, HAMBURG, Germany; [7]Klinikum Großhadern der LMU München, MÜNCHEN, Germany; [8]Medizinische Klinik 5, Universitätsklinikum Erlangen, ERLANGEN, Germany; [9]Krankenhaus München Schwabing, I Med Abteilung, MÜNCHEN, Germany; [10]Klinikum Giessen, Medizinische Klinik IV, GIESSEN, Germany; [11]Kantonsspital Basel, Bereich Innere Medizin I, BASEL, Switzerland; [12]Inselspital Bern, Hämatologisches Zentrallabor, BERN, Switzerland

Background. The introduction of imatinib has significantly changed prognosis of CML patients. Despite favourable hematologic and cytogenetic response (CyR) data, patients (pts) on first line imatinib therapy may relapse. Thus, studies have been conducted to improve initial therapy by dose escalation or combination with other drugs. CML Study IV was designed to compare imatinib in standard dose (400 mg/d) vs high dose (800 mg/d) vs combinations with low dose cytarabine or interferon α. *Aims*. We sought to evaluate the predictive impact of early molecular response for long term progression free (PFS) and event free survival (EFS). *Design and Methods*. 531 pts (60% m, median age 54 years, range 16-84) randomized to imatinib based therapies by December 2005 were investigated, the median follow up was 42 mo (range, 0-74). At baseline, multiplex PCR was applied to determine the dominating BCR-ABL transcript: b2a2 (n=201), b3a2 (n=244), b2a2 and b3a2 (n=78), e1a2 (n=2), e19a2 (n=4), b3a3 (n=1) and e8a2 (n=1). Quantitative PCR from 5,260 peripheral blood samples was performed using the LightCycler technology in two central labs. PCR data were aligned to the international scale (IS) by introduction of conversion factors (Hughes et al., BLOOD 2006). For analysis of prognostic impact, events were defined as (i) loss of complete hematologic response, (ii) loss of major CyR following loss of complete CyR, (iii) accelerated phase, (iv) blast crisis, and (v) death for any reason. Criteria (iii), (iv) and (v) were further regarded as progression. Pts were censored at the time of allogeneic stem cell transplantation or switch to 2nd generation tyrosine kinase inhibitors because of imatinib intolerance or resistance. *Results*. Cumulative molecular response of 531 pts at 3-36 mo after randomization is summarized in Table 1.

Table 1. Cumulative achievement of molecular response levels.

Month	3	6	12	18	24	36
BCR-ABL^{IS}	achieved by % of pts					
≤10%	41	66	79	84	86	89
≤1%	15	40	64	74	77	80
≤0.1% (MMR)	2	16	36	50	59	69
≤0.01%	0	2	9	19	26	39

The molecular response cutoffs with best predictive impact were BCR-ABLIS of 10% after 3 mo (PFS, p=0.053), 10% after 6 mo (PFS, p=0.0095; EFS, p=0.012), 1% after 12 mo (PFS, p=0.011, EFS, p<0.0001), and 1% after 18 mo (PFS, p=0.0045; EFS, p=0.0002) of imatinib based therapies. The achievement of 0.1% BCR-ABLIS (MMR, major molecular remission) was not predictive after 18 mo. In order to investigate the reasons for unsatisfying responses BCR-ABL kinase domain mutations were assessed in 175 pts. 30 pts (17%) harbored 35 mutations affecting 18 different amino acids. *Summary*. Prospective molecular surveillance of CML shows early response predicting stable remissions on first line imatinib therapy. After 3 mo of treatment, residual BCR-ABL transcript levels start to be predictive for PFS. In pts with unsatisfactory response or molecular, cytogenetic and hematologic relapse, BCR-ABL mutations have been detected in 17% of pts. Calculation of molecular response rates dependent on the various imatinib based therapies will be performed after stop of randomization which is expected by the end of 2009.

Infectious diseases, supportive care

RECOMBINANT ACTIVATED FACTOR VII FOR BLEEDING IN THE SETTING OF MALIGNANCY AND HEMATOPOIETIC STEM CELL TRANSPLANTATION.

N. Polizzotto,[1] E. Phillips,[2] F. Cole-Sinclair,[3] S. Dunkley,[4] M. Wood,[1] P. Cameron[2]

[1]Australian Red Cross Blood Service, MELBOURNE; [2]Monash University, MELBOURNE; [3]St. Vincent's Hospital, MELBOURNE; [4]Royal Prince Alfred Hospital, SYDNEY, Australia

Background. Haemorrhage commonly complicates the course of patients with malignancies, resulting from either the disease process or its therapy. Recombinant activated Factor VII (rFVIIa) may have a role in augmenting conventional therapies in this setting. However its safety and impact on transfusion requirements and clinical outcomes has not been explored. *Aims*. To explore the safety and efficacy of rFVIIa in the treatment of haemorrhage associated with malignancy or hematopoietic stem cell transplantation (SCT). *Design and Methods*. Clinical registry data can provide important information, particularly where clinical trials are impracticable. The Australia and New Zealand Haemostasis Registry documents 'off-label' usage of rFVIIa in patients who do not have congenital haemophilia. More than 90 institutions currently participate, capturing an estimated 85% of 'off-label' doses in the region. We analysed episodes where the cause of bleeding was malignancy or SCT. *Results*. 240 eligible episodes were identified in 223 patients (10.7% all registry episodes). Median age was 57 (IQR 43-68); 143 (64.1%) were male. Primary diagnosis was hematological in 119 episodes (49.5%); non-hematological malignancy in 121 (50.4%). 207 (86.2%) were receiving disease-directed therapy, 11 (4.6%) supportive care, unreported in 22 (9.2%). Intent of care was 130 (62.2%) curative, 79 (37.8%) palliative, 31 (12.9%) unreported. 21 (8.8%) were undergoing allogeneic SCT and 4 (1.6%) autologous SCT. Primary sites of bleeding were gastrointestinal 124 episodes (51.6%), pulmonary 28 (11.7%), hepatic 25 (10.4%), genitourinary 23 (9.6%), intracranial 15 (6.2%), others 25 (10.4%). Causes of bleeding were 76 (31.6%) surgical (including resection of tumour or metastases), disease-induced coagulopathy 40 (16.7%), disease invasion 38 (15.8%), mucositis (including graft-versus host disease) 32 (13.3%), others 51 (21.2%); 3 (1.2%) received rFVIIa prophylactically prior to procedures. In 167 episodes (69.6%) a single dose was administered. Median dose was 90 µg/kg (IQR 75-99). Prior to administration median (IQR) haemoglobin was 82 g/L (69-93); platelet count 76 x 109/L (36-132), fibrinogen 2.1 g/L (1.4-3.1), INR 1.4 (1.2-1.9), pH 7.3 (7.2-7.4), temperature 36.8oC (36.0-37.2), and patients had received 5 (2-12) red cells, 2 (1-4) platelets, 4 (0-8) plasma, and 0 (0-8) cryoprecipitate. Bleeding stopped or decreased in 116 (60.7%) episodes where response was reported. Response varied with cause of bleeding, pH and temperature. Transfusion requirements fell to 2 (0-4) red cells, 0 (0-2) platelets, 0 (0-3) plasma, and 0 (0-1) cryoprecipitate following the first dose of rFVIIa. 18 thromboembolic adverse events were reported within 28 days of administration. 132 patients (59.2%) survived to 28 days. *Conclusions*. This is the first comprehensive exploration of rFVIIa in malignancy. LeveIs of 'off-label' use in this setting were higher than anticipated. Reported efficacy and safety were promising in this heterogenous group with difficult bleeding. Response rates were high, with an associated reduction in transfusion requirements following administration. Use of rFVIIa may be an effective adjunct to conventional therapies in uncontrolled malignancy-associated haemorrhage.

1096

INCIDENCE OF FEBRILE EPISODES DURING STEM CELLS MOBILIZATION AFTER HIGH DOSE CYCLOPHOSPHAMIDE CHEMOTHERAPY AND G-CSF (FILGRASTIM OR LENOGRASTIM) ADMINISTRATION IN MULTIPLE MYELOMA PATIENTS: STUDY UPDATE

E. Orciuolo,[1] G. Buda,[1] E. Marturano,[2] E. Mauro,[2] D. Pastore,[3] N. Di Renzo,[4] P. Della Cioppa,[5] G. Pietrantuono,[6] C. Cangialosi,[7] M.P. Petrilli,[8] M. Brunori,[9] G. Irrera,[10] B. Bartolozzi,[11] M. Petrini[1]

Introduction. The G-CSF, primary regulator of granulopoiesis, has shown its efficacy in reducing duration of neutropenia after chemotherapy or myelosuppressive therapy. In these situations G-CSF, accelerating the granulocytous reconstitution, may enable a significant reduction of the incidence, duration and severity of infection. Commercially formulations of rHu-G-CSF include lenograstim, a glycosylated form, and filgrastim, a non-glycosylated form. Glycosylation of the molecule contribute to pharmacokynetis advantages and to higher affinity to specific receptor. Additionally, lenograstim exposed neutrophils unchanged all their functions *in vitro*, while filgrastim exposed neutrophils present functional defects due to higher adhesivity, cytoscheletric alterations and a more immature phenotype. *Aim*. On these bases, we hypothesized that lenograstim may prevent febrile episodes (FE) and reduce their lasting in patients with chemotherapy derived neutropenia more efficiently than filgrastim. Primary endpoint is the incidence of FE. *Patients and Design and Methods.* Starting from April 2005, 132 multiple myeloma patients, achieving high dose cyclophosphamide for stem cells mobilization, were enrolled in 11 Italian centers. Treatment plan consisted in: high dose cyclophosphamide (3 or 4 g/sqm) on day 1, G-CSF (random 1:1 on the base of a generated random list: filgrastim or lenograstim) 30 MU/day from day +4 to +9, 60 MU/day from day +10 to the achievement of an optimal CD34+ cell count for staminoapheresis. FE, significant if equal or higher than 38 oC for at least 2 different determinations, were recorded till day +30. *Results*. All 132 patients underwent post-chemo grade 4 neutropenia and G-CSF was administered starting from day +4. FE were recorded in 23 pts, 14 in the filgrastim arm (66 total patients) and 9 in the lenograstim arm (66 total patients). The global fever incidence was 17.4%, 21.2% with filgrastim and 13.6% with lenograstim. However, to demonstrate functional block of filgrastim exposed neutrophils, FE have been related to neutrophil absolute count. Related to the neutropenia grade, 8 FE are recorded with filgrastim (12.1%) and 1 FE with lenograstim (1.5%) with absolute neutrophil count >500/µL (grade 3) (p=0.0328); this difference is still evident when neutrophils are >1000/µL (grade 2), with 7 episodes with filgrastim (10.6%) versus 1 (1.5%) with lenograstim. *Conclusions*. Lenograstim is associated with a reduced global incidence of FE in multiple myeloma patients undergoing to high dose cyclophosphamide and stem cells mobilization when compared to filgrastim. Additionally, excluding the time frame when neutrophils are not yet recovered (neutrophils <500/µL; grade 4 neutropenia) and G-CSF effects may not be demonstrated, filgrastim treated patients present an higher FE incidence at neutrophil absolute count recovery (12.1% and 10.6%, with neutrophils respectively > 500/µL and 1000/µL), confirming the functional block of filgrastim exposed neutrophils described *in vitro*. On the contrary, lenograstim allows to recovery normally functional neutrophils as demonstrated by the very low incidence of FE (1.5% with neutrophils >500/µL). On these evidences, patients' enrollment will continue to 180 to validate these results.

ENZYME LINKED IMMUNOSPOT (ELISPOT) ASSAY FOR THE DIAGNOSIS OF INVASIVE ASPERGILLOSIS IN HIGH RISK PATIENTS

L. Potenza,[1] P. Barozzi,[1] D. Vallerini1, J. Maertens,[2] A. Candoni,[3] G. Riva,[1] E. Zanetti,[1] C. Quadrelli,[1] R. Bosco,[1] M. Morselli,[1] F. Forghieri,[1] M. Maccaferri,[1] L. Pedrazzi,[1] A. Bonini,[1] R. D'Amico,[1] A. Donelli,[1] M. Codeluppi,[1] G. Rossi,[1] F. Ciceri,[4] P. Comoli,[5] F. Narni,[1] G. Torelli,[1] M. Luppi[1]

[1]University of Modena and Reggio Emilia, MODENA, Italy; [2]Department of Hematology, Universitaire Ziekenhuizen Leuven, LEUVEN, Belgium; [3]Hematology and Bone Marrow Transplantation, UDINE, Italy; [4]Hematology and Bone Marrow Transplantation, S. Raffaele Hospital, MILAN, Italy; [5]Pediatric Hematology/Oncology and Transplantation, IRCCS S. Matteo Hospital, PAVIA, Italy

Background. The high mortality rate of Invasive Aspergillosis (IA) in hematologic and transplant patients is due in part to the limitations of the current diagnostic tools, which do not permit a prompt and undoubted diagnosis. Recent studies in mice and humans have suggested that Aspergillus-specific interferon-γ producing T-cells (IFN-γ-TH1) are protective, while Aspergillus-specific inteleukin-10 producing T-cells (IL-10-TH2) are permissive versus IA. *Aims*. We have evaluated whether the enumeration of Aspergillus-specific IFN-γTH1 and/or IL-10-TH2 through an *ex vivo* ELISPOT assay may be effective in the diagnosis of IA in high risk patients. *Design and Methods*. ELISPOT has been performed, as described [*Potenza et al. Leukemia 2007; 21: 578-81*] on 70 consecutive patients (91% with hematologic malignancies, 9% undergoing solid organ transplantation), classified according to the EORTC/MSG criteria as: 14 proven, 16 probable, 10 possible IA. The remaining 30 patients were considered controls because they were affected with infectious diseases of etiology other than IA, proven by histological or cultural methods. *Results*. At some time during the disease, ELISPOT resulted positive in the 14 proven IA cases. In particular, 13 out of 14 were positive for Aspergillus-specific IL-10-TH2; in 5 out of 14, also for *Aspergillus*-specific IFN-γ-TH1, and in 1 out of 14 only for Aspergillus-specific IFN-γ-TH1. The sensitivity of the test was 100% in proven IA, 50% in probable IA, 20% in possible IA. In the twelve patients in whom ELISPOT was performed at the time of radiological diagnosis, the assay resulted positive in 10 out of 12 (83%). Two patients demonstrated non-reactive in the first collected sample, because their T cells could not be stimulated by phytohemagglutinin. In the 30 control patients, ELISPOT resulted negative in 29 out of 30, with only one patient resulting non-reactive. The overall comparison (considering also nonreactive samples) of proven IA with control patients showed 85.6% sensitivity and 96.6 % specificity of the assay, while the positive predictive value (PV) and the negative PV resulted 100%. Furthermore in 8 proven IA patients with two or more samples collected during the course of the infection, ELISPOT seems to provide the kinetics of the Aspergillus-specific human response in course of IA, *in vivo*, by showing: high number of IL-10-TH2 at the onset, and its persistence/increase in case of progression or death; growing number of IFN-γ-TH1 during stabilization/regression; sustained number of IL-10-TH2 during the growing of IFN-γ-TH1 number to avoid an excessive inflammatory response; persistence of a protective IFN-γ-TH1 response after the resolution of the lesions. *Conclusions*. Our findings demonstrate the potential of ELISPOT in the diagnosis of IA. The ELISPOT assay may complement the other diagnostic tools [e.g. galactomannan antigenemia], enabling a more consistent diagnosis of IA. A larger number of proven and probable IA is necessary to address definitely the diagnostic accuracy of the ELISPOT. The assay may also provide new insights about the dynamic skewing between the Aspergillus-specific IFN-γ-TH1/IL-10-TH2, *in vivo*, during the course of IA, with possible consequences in designing drug and/or cellular therapeutic strategies.

MYELOABLATIVE CONDITIONING PREDISPOSES FOR TOXOPLASMA GONDII REACTIVATION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

S. Meers, K. Lagrou, M. Delforge, T. Devos, D. Dierickx, A. Janssens, G. Verhoef, J. Maertens

University Hospital Leuven, LEUVEN, Belgium

Background. Toxoplasmosis in recipients of allogeneic stem cell transplants (HSCT) is a severe infectious complication and occurs mainly through reactivation of latent Toxoplasma gondii cysts. Monitoring of T.gondii DNA in peripheral blood (PB) by polymerase chain reaction (PCR) has been shown to be an appropriate tool to detect reactivation. *Aim*. To monitor recipients of allogeneic HSCT for T.gondii reactivation by PCR and to identify risk factors for T. gondii reactivation. We also designed this study to evaluate the effectiveness of preemptive treatment before the onset of organ involvement. *Design and Methods*. From November 2001 until December 2008, we prospectively monitored all patients undergoing allogeneic HSCT in our institution that were seropositive (IgG) for T.gondii or from which the donor was seropositive. Patients did not receive trimethoprim-sulfamethoxazole prophylaxis but were monitored with qualitative PCR for T.gondii DNA in PB, weekly until D+100, thereafter two-weekly until 1 year post-transplant. Toxoplasmosis infection (TI) was defined as two positive PCRs in PB without clinical, radiologic or microbiologic evidence of invasive infection. Patients with TI were preemptively treated with pyrimethamine and clindamycine until PCR results were negative in two consecutive samples. *Results*. Two-hundred and eight patients were prospectively monitored. Eighteen patients had toxoplasmosis reactivation (8.7%) and the median time after transplantation was 62 days (range 25-166). One third (6/18) had evidence of invasive disease at first diagnosis (5 central nervous system, 1 cardiac involvement). Three of these patients with invasive toxoplasmosis died, but in only one patient toxoplasmosis was the direct cause of death (two also had concomitant severe invasive pulmonary aspergillosis). Twelve patients (67%) had TI at first diagnosis. Only one of these 12 patients who were preemptively treated, subsequently developed invasive infection but this was only 11 months later (chorioretinitis). Overall, 5 patients had a second reactivation of toxoplasmosis with a median time of 33 days (range 10-318) between termination of treatment and relapse. All but one reactivation occurred in seropositive recipients. The incidence of toxoplasmosis infection/disease was significantly higher in patients conditioned with a myeloablative regimen including total body irradiation ($p<0.01$). All but one patient (94%) had a CD4 T cell count below 200/μL. In our series, the presence of graft-versus-host disease, conditioning with anti-thymocyte globulin or the presence of CMV reactivation did not influence the risk of T.gondii reactivation. Our series contained only 1 patient transplanted with a cord blood graft, but this patient developed fatal cardiac toxoplasmosis at day 64 post-transplant. Finally, HSCT recipients with grafts from seropositive donors had a significantly lower incidence of toxoplasmosis reactivation ($p<0.05$). *Conclusions*. This study represents the largest prospective study on the incidence of toxoplasmosis after allogeneic HSCT. Toxoplasmosis is common with an incidence of 8.7%. All reactivations occurred within the first 6 months after transplantation, except in patients with previous toxoplasmosis reactivation. The majority of reactivations occurred before reconstitution of CD4 T lymphocytes. We demonstrate that myeloablative regimens containing TBI predispose to toxoplasmosis reactivation. Seropositivity of the donor coincided with a lower incidence of toxoplasmosis reactivation in the recipient.

Rituximab improves outcomes for persons with lymphoproliferative disorders and is increasingly used to treat immune-mediated illnesses. Recent reports describe two patients with systemic lupus erythematosus and one with rheumatoid arthritis, who developed progressive multifocal leukoencephalopathy (PML) following rituximab treatment. We reviewed PML case descriptions among patients treated with rituximab from the FDA, the manufacturer, physicians, and a literature review from 1997 to 2008. Overall, 52 patients with lymphoproliferative disorders, one patients with systemic lupus erythematosus, one patient with rheumatoid arthritis, one patient with an idiopathic autoimmune pancytopenia, and one patient with immune thrombocytopenia developed PML following treatment with rituximab and other agents. Other treatments included hematopoietic stem cell transplantation (7 patients), purine analogues (26 patients), or alkylating agents (39 patients). One patient with an autoimmune hemolytic anemia developed PML following treatment with corticosteroids and rituximab and one patient with an autoimmune pancytopenia developed PML following treatment with corticosteroids, azathioprine, and rituximab. Median time from last rituximab dose to PML diagnosis was 5.0 months. Median time to death after PML diagnosis was 2.0 months. The case-fatality rate was 89%. Awareness is needed of the potential for PML among rituximab-treated individuals.

PEG-ASPARAGINASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): EFFICACY AND FEASIBILITY ANALYSIS WITH FOCUS ON LIVER TOXICITY IN THE GERMAN MULTICENTER STUDY GROUP FOR ADULT ALL (GMALL) STUDY 07/2003

N Gökbuget,[1] A. Baumann,[2] J. Beck,[3] J. Boos3, M. Brueggemann,[3] H Diedrich,[4] A. Hüttmann,[3] L. Leimer,[5] T. Lipp,[6] R. Naumann,[3] M. Mohren,[3] A. Reichle,[3] K. Schäfer-Eckart,[7] M. Schmalzing,[3] M. Schmid,[3] N. Schmitz,[8] T. Therwey,[9] D Hoelzer[10]

[1]Goethe University, FRANKFURT; [2]University Hospital München-Groshadern, MÜNCHEN; [3]University Hospital, MAINZ; [4]Medical School, HANNOVER; [5]Robert Bosch Krankenhaus, STUTTGART; [6]Klinikum München-Schwabing, MÜNCHEN; [7]Klinikum Nürnberg-Nord, NÜRNBERG; 8Asklepios Klinikum St.Georg, HAMBURG; [9]Charite University Hospital, BERLIN; [10]Department of Medicine, Hematology/Oncology, Goethe University Frankfurt, FRANKFURT, Germany

Randomised pediatric trials have demonstrated that intensification of Asparaginase (ASP) treatment in ALL can contribute to improvement of outcome. In adult ALL the optimal preparation, schedule and intensity which are effective and feasible have to be defined. The optimisation of ASP treatment is therefore an essential aim of the GMALL. GMALL induction consists of dexamethasone, vincristine, daunorubicine, PEG-ASP (phase I), mercaptopurine, cyclophosphamide and cytarabine (phase II). In the pilot trial 06/99 7x5000U/m^2 *E.coli* ASP given over 14 days were replaced by 1x1000U/m^2 PEG-ASP (500U/m^2 >55yrs). A dose dependent duration of PEG-ASP activity was demonstrated. Based on this correlation in study 07/2003 (Amend 12/06) the dose for PEG-ASP was increased to 2000U/m^2 in induction and consolidation (1000U/m^2 >55 yrs) in order to improve outcome. 1066 pts with a median age of 36 (15-65) yrs were evaluable (8%>55yrs). 799 pts were treated with 1000U/m^2 (cohort 1) and 185 pts with 2000U/m^2 (cohort 2) (reductions >55yrs). 82 pts did not receive ASP in induction due to various reasons. In cohort 1 and 2 91%/92% achieved CR after induction (91%/93% resp. <55 yrs). Data on molecular response (MRD below 10-4) after induction are available in a subset. There is a trend towards earlier and higher molecular CR rate in cohort 2 vs cohort 1 (81% vs 70% after induction). Survival after 1 yr is similar in cohort 1 (79%) vs cohort 2 (81%). Probability of CCR after 1 year shows a trend to improvement with 95% in cohort 2 vs 78% in cohort 1. Toxicity reported here is focused on potentially ASP related oIII-IV (WHO scale) events (734/147 pts in cohort 1/cohort 2). Incidences are as follows: GOT or GPT (29%/29%), bilirubine (10%/14%), thrombosis (4%/3%), bleeding (3%/2%) and hypersensitivity (1%/1%). Details on AEs of all degrees are available in a subset of pts showing an increase of any WHO grade in for bilirubine (81%), GPT (80%), amylase (52%), lipase (29%) and glucose (51%). Bilirubine °III/IV occurred after median 16d, was correlated with age and infections, associated with treatment delays and poorer outcome. PEG-ASP was also feasible in Ph$^+$ ALL combined with imatinib with a trend towards a higher incidence of liver toxicity in cohort 2 and pts with imatinib starting from diagnosis. *Conclusions*. This is the largest cohort of adult ALL treated with PEG-ASP. Overall intensified PEG-ASP was feasible within intensive multidrug induction. Coagulation disturbances occurred frequently but bleeding or thrombosis were rare events. The rate of severe hepatotoxicity was stable after dose escalation however lead to significant treatment delays in individual pts which were prognostically relevant. Lab value changes occurred frequently; it remains open to what extent they are clinically relevant and require interruption of further chemotherapy. It would be an important goal to identify parameters to predict severe ASP related toxicities e.g. by pharmacogenomics. The molecular CR rates after dose escalation and the remission duration are promising and will hopefully turn out into an improved overall survival.

MONITORING OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS WITHOUT KNOWN GENETIC ABNORMALITIES: IMPACT ON PROGNOSIS IN THE GIMEMA LAL-0904 PROTOCOL

Robin Foà on behalf of the GIMEMA Acute Leukemia Working Party

University of Rome Sapienza, ROME, Italy

Background. The evaluation of minimal residual disease (MRD) is becoming always more important in the management of different hematologic malignancies. In childhood acute lymphoblastic leukemia (ALL), monitoring of MRD has a significant prognostic role and influences stratification of patients and treatment. Although MRD is currently incorporated in several clinical protocols for adult ALL patients, data confirming its prognostic significance is scarce and there is no consensus on the time-points for MRD evaluation. *Aims*. The LAL-0904 GIMEMA protocol was designed to evaluate the impact of MRD, at pre-defined times, on achievement of complete remission (CR) and disease-free survival (DFS). The protocol was opened in July 2004 and is still ongoing. We report the results on 123 patients negative for the most important genetic abnormalities (BCR-ABL, ALL1-AF4, E2A-PBX1), with a median follow-up of 22.4 months. *Design and Methods*. All patients were homogeneously diagnosed through a central handling of the samples at presentation and were investigated for morphology, immunophenotype, cytogenetics, molecular biology, and IgH and TCR gene rearrangements. MRD was assessed by both immunophenotype and RQ-PCR analysis of IgH and TCR gene rearrangements during induction at days +35 and +50, and at the end of the consolidation. *Results*. Of the 123 patients, 39 were females and 84 males, with a median age of 31.4 years (range: 15.8 - 59.5), a median white blood cell (WBC) count of $14.8x10^9$/L (range: 0.5 - 300.4); 82 patients had B-lineage ALL and 41 T-ALL. The immunologic subtypes defined according to the EGIL system were as follow: 7% pro-B, 38% common-B and 19% per-B; 3% pro-T, 11% pre-T, 19% cortical-T and 3% mature-T. At the end of the induction, 91.1% of patients were in CR. We failed to observe any significant effect of MRD on the achievement of CR. In univariate analysis, MRD, evaluated by immunophenotype (cut-off at 10-3) and by IgH and TCR gene rearrangement (cut-off at 10-4) at days +35 and +50, showed an impact on DFS: by immunophenotype p=0.067 and p=0.038, respectively, and by IgH and TCR gene rearrangement, p=0.0035 and p=0.0007, respectively. In multivariate analysis, only the results of MRD detected by IgH and TCR gene rearrangement at day +50 had a highly significant predictive impact on DFS (p=0.0013). The evaluation of MRD after consolidation does not seem to add additional information to that obtained after induction therapy. Patients who showed a reduction of at least 10-3 (by immunophenotype) and 10-4 (by IgH and TCR gene rearrangement) had a better outcome. *Conclusions*. In our adult ALL series, the reduction of MRD at the end of induction represents an important prognostic factor both by immunophenotype and by IgH and TCR gene rearrangements. The results of our LAL-0904 protocol clearly indicate that the MRD status during induction should be taken into account when planning the overall therapeutic strategy of adult ALL patients.

1102

PROGNOSTIC IMPLICATIONS OF THE WILMS TUMOR 1 (WT1) GENE MRNA EXPRESSION IN ADULT ACUTE T-LYMPHOBLASTIC LEUKEMIA

S. Heesch,[1] N. Goekbuget,[2] A. Stroux,[3] J. Ortiz Tanchez,[4] C. Schlee,[4] T. Burmeister,[4] S. Schwartz,[4] O. Blau,[4] U. Keilholz,[4] A. Busse,[4] D. Hoelzer,[2] W.-K. Hofmann,[4] E. Thiel,[4] C.D. Baldus[4]

[1]Charité, BERLIN; [2]University Frankfurt am Main, Department of Hematology and Oncology, FRANKFURT/MAIN; [3]Charité, Campus Benjamin Franklin, Department of Biostatistics and Clinical Epid, BERLIN; [4]Charité, Campus Benjamin Franklin, Department of Hematology and Oncology, BERLIN, Germany

The Wilms tumor 1 gene, WT1, encodes a transcription factor involved in normal and malignant hematopoiesis. The role of WT1 in acute leukemias has been underscored by mutations in WT1 found in 10-15% of acute myeloid leukemia (AML) identifying patients with inferior survival. In addition, aberrant expression of WT1 in AML has been associated with an increased relapse risk. Thus far, larger studies have not determined the prognostic impact of WT1 alterations in acute T-lymphoblastic leukemia (T-ALL). Therefore, we have analyzed WT1 mutations and WT1 expression levels in a large cohort of T-ALL that included 239 newly diagnosed adult patients treated on GMALL protocols 06/99 and 07/03. Diagnostic bone marrow specimens were studied for WT1 mutations by DNA direct sequencing and WT1 mRNA expression was determined by real-time RT-PCR. Twenty (8%) of the 239 analyzed T-ALL patients exhibited WT1 mutations (WT1mut) in exon 7. The presence of co-operating gene mutations in WT1mut patients was further investigated. WT1mut patients showed a higher frequency of FLT3 mutations (4/20; 20% of cases) compared to WT1wt T-ALL patients (3/108; 3% of cases). Significant differences were not observed in the complete remission (CR) rate as well as overall survival and relapse free-survival (RFS) between WT1mut and WT1wt patients. Expression levels of WT1 were analyzed in 223 of the 239 T-ALL patients. Three expression groups including patients with WT1 negative (n=97), WT1 intermediate (n=81), and WT1 high (n=45) expression levels were defined. Patients with high WT1 expression were characterized by immature features such as an early immunophenotype, high BAALC expression levels, and aberrant expression of CD13 and HOX11L2. WT1 negative and WT1 intermediate cases had predominantly a thymic phenotype. A strong correlation was observed between the WT1 expression and mutation status: WT1 mutations were predominantly found in the WT1 high expression group (13/41; 29% were WT1mut) compared to only 1/94 (1%) of WT1 negative and 4/74 (5%) of WT1 intermediate cases harboring WT1 mutations (p<0.001). T-ALL patients with aberrant (negative or high) WT1 expression levels showed a higher relapse rate and an inferior outcome as compared to patients with intermediate WT1 expression (4-year disease-free survival: 21.7% for WT1 high, 53.9% for WT1 negative, 75.5% for WT1 intermediate expressers; p<0.001). Interestingly, patients of the high risk groups (negative or high expression) showed an improved survival when consolidated with stem cell transplantation (SCT; 4-year survival: 62%) as compared to chemotherapy only (4-year survival: 36%; p=0.04). In multivariate analysis, WT1 expression was of independent prognostic significance (hazard ratio: 6.8; p=0.003). An interaction was observed demonstrating a favourable impact of SCT for WT1 high risk patients (negative/high expression). Taken together, WT1 gene mutations were identified in a similar frequency and at the same hotspot regions as previously identified in AML but of less prognostic significance in this cohort of T-ALL. Moreover, aberrant WT1 expression was of independent prognostic significance associated with inferior outcome, thus suggesting a role of WT1 in T-ALL. Furthermore, expression analysis could be applicable for a more defined molecularly-based treatment stratification including stem cell transplantation.

1103

GOOD GENERAL MEDICAL CONDITION IN LONG TERM SURVIVORS OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) BUT MORE HEALTH IMPAIRMENT IN OLDER PATIENTS AND PATIENTS AFTER STEM CELL TRANSPLANTATION (SCT): RESULTS OF A SYSTEMATIC ANALYSIS OF GMALL STUDIES

N Gökbuget,[1] K Ihrig,[2] CM Hartog,[2] A Hellenbrecht,[2] H Serve,[2] H Diedrich,[3] E Lange,[4] A Schloen,[5] P La Rosee,[6] R Stuhlmann,[7] D Oruzio,[8] D Hoelzer[2]

[1]Goethe University, FRANKFURT; [2]Department of Medicine, Hematology/Oncology, Goethe University Frankfurt, FRANKFURT; [3]Medical School, HANNOVER; [4]Evang. Krankenhaus, HAMM, Geurnsey; [5]Klinikum Oldenburg, OLDENBURG; [6]Klinikum Mannheim, MANNHEIM; [7]Asklepios Klinikum St.Georg, HAMBURG; [8]Zentralklinikum, AUGSBURG, Germany

Since 1981 the majority of adult pts with ALL in Germany was treated in 7 consecutive trials of the German Multicenter Study Group for Adult ALL (GMALL). Survival was step-wise improved to 50% in the most recent trial with an increasing number of long-term survivors. However so far there is no published evidence about health status and/or late effects in survivors of adult ALL. Therefore the GMALL initiated a retrospective analysis of pts from studies 2/84 - 6/99 alive more than 5 yrs after diagnosis. The questionnaire covered 8 organ systems and 1 category of "specific syndromes", known as potential late-effects of chemotherapy and was directed to treating physicians. It was intended to assess all diseases, appearing after end of therapy. 402 questionnaires were evaluable. Median age at diagnosis was 29 (15-64) years; median observation time was 10 yrs. Pts were included in GMALL-study 2/84 (10%), 3/87 (4%), 4/89 (15%), 5/93 (46%) and 6/99 (25%). 24% had received SCT (4% auto, 20% allo). In 94% of the pts the ECOG status was 0/1 (72/22%); 6% had ECOG 2-4. In 33% of the pts no disease was reported (Table 1). 67% presented a disease in ≥ one organ system; most frequently endocrinium (e.g. infertility, diabetes, osteoporosis), neurologic system (e.g. mood alteration, polyneuropathy, concentration) and skin (e.g.alopecia, erythema); cardiovascular diseases consisted mainly

of hypertension; only 2 pts had heart failure. The most frequently documented category was "specific syndromes" in 39%. Infections, fatigue and osteonecrosis were the most frequent ones. GVHD/sicca syndrome was observed in 10% of all pts and in 44% of SCT pts. Favourable ECOG (0-1) was significantly more often observed in chemo vs SCT pts (97% vs 86%;p=.0003). More pts with chemo had no disease compared to SCT pts (40% vs 9%; p<0.0001). All organ systems were more often involved in SCT pts. They also had more fatigue (p=0.01), and infections (p<.0001). Age was associated with poorer ECOG too. 97% of the pts with diagnosis in adolescent age (15-25 yrs) had ECOG 0-1 compared to 81% in pts > 55 yrs. Fertility was evaluated by a patient-questionnaire (N=487). 58% of the pts (70% of chemo vs 21% of SCT pts; p<0.0001) with desire to have children could realise this wish (medical intervention in 21%). This so far largest data set of medical conditions and late effects of long-term survivors after adult ALL shows favourable results. The observed diseases had only in part a potential correlation to previous ALL therapy (e.g. GVHD, sec. malignancies, osteonecrosis, neurologic diseases). Compared to childhood ALL, the rate of late effects is remarkably low. The impaired health status in pts with SCT compared to chemo underlines that indications for SCT should be made carefully in high-risk patients only. Aftercare should consider specifically the most frequent late-effects i.e. osteonecrosis, fatigue, endocrinology and fertility. These may be cumbersome in individual pts. There is a trend towards more pronounced late effects in the most recent trial with intensified therapy. Therefore the analysis will be carried on.

A RANDOMISED PHASE II STUDY OF PEGYLATED LIPOSOMAL DOXORUBICINE IN ELDERLY PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): THE GRAALL-SA1 STUDY

M. Hunault-Berger,[1] T. Leguay,[1] X. Thomas,[1] O. Legrand,[2] F. Huguet,[1] F. Witz,[1] P. Chevallier,[1] M. Escoffre-Barbe,[1] L. Legros,[1] P. Turlure,[1] F. Larosa,[1] J.Y. Cahn,[1] O. Reman,[1] P. Rousselot,[3] A. Delannoy,[4] N. Dhedin,[5] M. Pochitaloff,[6] M.C. Bene,[7] N. Ifrah,[1] H. Dombret[8]

[1]CHU, ANGERS; [2]Hotel Dieu, PARIS; [3]CHG, VERSAILLES; [4]Hopital de Jolimont, HAAINE SAINT PAUL, Belgium; [5]Pitié-Salpetrière, PARIS; [6]Cytogenetic, MARSEILLE; [7]Immunology, NANCY; [8]Hopital Saint Louis, PARIS, France

The GRAALL-SA1 study aimed to randomly compare the efficacy and toxicity of liposomal pegylated doxorubicin (Peg-Dox) vs continuous infusion doxorubicin (CI-Dox) in elderly patients with Philadelphia chromosome-negative ALL. Induction chemotherapy, supported by G-CSF, comprised either CI-Dox 12 mg/m^2/d and CI-VCR 0.4 mg/d on d1-4 or Peg-Dox 40 mg/m^2 IV and standard VCR 2 on d1, in combination with dexamethasone. A second cycle, reinforced by cyclophosphamide 1 g/m^2, was started at d28. Consolidation included two additional cycles using reduced doses of CI-Dox (12 mg/m^2/d d1-3) or Peg-Dox (30 mg/m^2 d1) with VCR in both treatment arms (5 minutes infusion on d1,8,15) alternating with two cyclophosphamide (650 mg/m^2 d1) / thioguanine (60 mg/m^2 d2-d15) / cytarabine (75 mg/m^2/d4-7 and d11-14) cycles. Maintenance included 6-MP and methotrexate for 2 years. CNS prophylaxis was based on 6 triple ITs and cranial irradiation. From March 2002 to October 2006, 60 patients aged 55 years or more from 26 centers were enrolled in this multicenter study. The median age was 66 years (range 55-80), 17% had initial WBC >30x10^9/L, 2 patients had CNS leukemia and 6.6% had mediastinal involvement. Immunophenotyping showed 85% B-lineage ALL, 12% T-ALL, and 3% aberrant expression of myeloid antigens. Patient characteristics were comparable in the two randomization groups except for a small unbalance with more T-ALL and more steroids resistant leukemia in the Peg-Dox group (6/29 vs 1/31, p=0.05 and 5/29 vs 1/31, p=0.1, respectively). Tolerance was improved in the Peg-Dox arm with less Grade 3-4 infectious events during induction (27% vs 48%; p=0.04), less Gram negative bacteriemia during induction (1 vs 9, p=0.02) and consolidation courses (2 vs 7, p=0.07) and less cardiac toxicities (1/29 vs 6 /31, p=0.12). Duration of neutropenia was reduced from a median of 7 days in the CI-Dox arm to 6 days in the Peg-Dox arm (p=0.06). RBC units transfused were reduced from 7.2 to 4.5 during induction (p= .02) and from 2.9 to 1.1 during consolidation course (p= .003). Days with platelets <50x10^9/L were reduced from 13.4 to 6.4 (p=0.03). After the 2 induction cycles, CR rate was 82%, with 10% failures and 8% induction deaths. With a median follow-up of 40 months, median OS for the entire population was 10 months and 19% of the patients were alive in CR at 3 years (95% CI, 9-30). Despite the better tolerance, there was a trend for a worse 2-year OS in the Peg-Dox arm (11 vs 27%, p=0.07), due to higher induction failure (17 vs 3%) as well as relapse incidence rates (62 vs 39%). Younger age, B-lineage, and steroid sensitivity were the three factors identified for a higher CR rate in multivariate analysis. The decreased toxicity of Peg-Dox over CI-Dox was thus offset by a decreased efficacy. Further studies should evaluated higher doses of pegylated versus conventional formulations of anthracycline in patients with ALL.

Acute myeloid leukemia - Biology II

IDENTIFICATION OF NOVEL MUTATIONS IN ACUTE MYELOID LEUKEMIA USING WHOLE TRANSCRIPTOME SEQUENCING

P.A. Greif,[1] A. Benet-Pages,[2] S. Eck,[2] H. Popp,[3] A. Dufour,[3] A. Vetter,[4] T. Meitinger,[2] T.M. Strom,[2] S.K. Bohlander[1]

[1]Clinical Cooperative Group Leukemia/Helmholtz Zentrum München, MÜNCHEN; [2]Institute of Human Genetics/Helmholtz Zentrum München, MÜNCHEN; [3]Department of Medicine III, Universität München, MÜNCHEN; [4]Clinical Cooperative Group Leukemia, MÜNCHEN, Germany

Background. Acute myeloid leukemia (AML) is a genetically heterogeneous disease. While approximately half of AML patients have at least one chromosomal aberration, the other half classifies as cytogenetically normal (CN-AML). In CN-AML patients an increasing number of recurring somatic mutations have been identified during the last decade. Despite their pathological and prognostic relevance, none of these mutations are sufficient to cause AML on their own. Furthermore, in approximately one quarter of the CN-AML patients none of the known mutations can be detected. *Aims*. To identify novel mutations in AML by transcriptome sequencing using a next generation sequencing machine. *Design and Methods*. The term transcriptome summarizes all mRNA transcripts present in the cells from a certain patient sample. To identify tumor-specific somatic coding mutations, we sequenced the transcriptome of a CN-AML and a remission sample from the same patient using an Illumina GAII machine. Poly-A selected, fragmented RNA was used to synthesize double stranded cDNA, which was then sequenced. SNPs were called with the MAQ software. *Results*. We generated 20.4 and 15.6 million 32 bp paired-end reads of the CN-AML and remission sample, respectively, which mapped to exons of UCSC genes. 8.9% of reads for the AML and 5.0% reads of the remission sample mapped to intergenic regions. Of the 11,178 transcripts with a higher expression than 60 reads per gene (corresponding to approximately 1 transcript per cell), we sequenced 5,911 with an average coverage of greater than seven. By comparing the 63,159 SNPs discovered in the CN-AML sample with the remission sample, we identified 5 non-synonymous mutations not present in either the remission sample or in dbSNP. One of these point mutations affected the RUNX1 gene which forms a well known fusion gene in AML (RUNX1/RUNX1T1) and is a known mutational target in AML. The second mutation affected a gene which encodes a RUNX1 interacting protein, and a third mutation was found in the cellular homolog of a viral oncogene. The two other mutations occurrred in a phospholipase gene and a nuclear chaperon gene. The five genes identified as mutational targets are currently studied in a larger patient cohort of 200 patients with normal karyotype in order to determine the frequency of mutations in these genes. *Conclusions*. Transcriptome sequencing of AML patients is a pioneering application of the latest sequencing technology that may allow the unbiased detecting and understanding of the majority of genetic lesions that contribute to the onset and progression of AML. For mutation screening in the coding regions of expressed genes, whole transcriptome sequencing is currently 5-10 times faster and more cost effective than whole genome sequencing.

SETBP1 OVEREXPRESSION IS A NOVEL LEUKEMOGENIC MECHANISM THAT PREDICTS ADVERSE OUTCOME IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

I. Cristobal,[1] F.J. Blanco,[2] L. García-Ortí,[1] N. Marcotegui,[1] C. Vicente,[1] J. Rifon,[3] P. Aranaz,[4] F.J. Novo,[4] E. Bandres,[1] M.J. Calasanz,[4] C. Bernabeu,[2] M.D. Odero[1]

Acute myeloid leukemias (AML) are clonal malignant disorders that result from multiple genetic alterations in normal hematopoietic stem cells. In recent years, several genetic markers with prognostic impact in AML have been identified, permitting a better understanding of the biology of this disease and, in some cases, providing targets for molecular therapies. However, the outcome of older patients with AML has not improved in the last three decades, due to both patient-specific and disease-specific factors. Here, we describe a novel t(12;18)(p13;q12) involving ETV6 in a patient with AML. The translocation resulted in no functional fusion gene, indicating that a different mechanism might be acting. The SETBP1 gene (18q12), located close to the breakpoint, was overexpressed in the patient, suggesting that expression of this gene was upregulated by the translocation. Overexpression (OE) of SETBP1 through retroviral insertion has been reported to confer a growth advantage in hematopoietic progenitor cells, and SETBP1 interacts specifically with the SET protein, a potent inhibitor of PP2A; however, the role of this gene at the molecular level remained unknown. We demonstrate that SETBP1 OE leads to higher levels of SET due to formation of a SETBP1-SET heterodimer that protects SET of the protease activity, increasing the amount of full-length SET protein of 39 KDa, and decreasing the shorter SET processed forms. We also observed the formation of a SETBP1-SET-PP2A complex that, eventually, results in PP2A inhibition. Furthermore, the deregulation of PP2A activity promotes proliferation of the myeloid leukemic cells. We also analyzed the prevalence of SETBP1 OE in a series of 192 patients with AML at diagnosis. SETBP1 was overexpressed in 28% of patients with AML, and it was associated with unfavorable cytogenetic prognostic group, monosomy 7, and EVI1 OE ($p<0.01$). We found a significant shorter overall survival (OS) in patients with SETBP1 OE. The impact prognosis was especially remarkable in the group of patients older than 60 years in both OS ($p=0.015$) and event free survival ($p=0.015$). In conclusion, our results show a novel leukemogenic mechanism: SETBP1 overexpression would lead to the formation of a SETBP1-SET-PP2A complex that increases the amount of full-length SET protein, resulting in PP2A inhibition and, therefore, promoting the proliferation of the cells. Moreover, we have shown that SETBP1 overexpression is a recurrent molecular event with prognostic impact in AML, especially in the subgroup of elderly patients. Advanced age is the most important prognostic factor for determining outcome in AML, therefore, it is important to identify genetic markers that could categorize cases within this subgroup. Systematic molecular genetic studies in AML patients not only are useful for the evaluation of biomarkers for prognostication, but also for the identification of predictive factors for response to novel therapies. Our data suggest that SETBP1 overexpression could be a predictive factor for response to PP2A activators such as FTY720, which has been proposed as a new alternative for treating blast crisis CML and Philadelphia chromosome-positive ALL.

STUDYING THE ROLE OF PIM KINASES IN FLT3-ITD-INDUCED LEUKEMIA REVEALED PIM1 AS REGULATOR OF CXCL12/CXCR4-MEDIATED HOMING AND MIGRATION

L. Brault,[1] R. Grundler,[2] C. Gasser,[2] A.N. Bullock,[3] S. Ehret,[1] A. Spoo,[4] C. Dierks,[4] A. Biondi,[5] S. Knapp,[3] J. Duyster,[2] J. Schwaller[1]

Background. The PIM1 and PIM2 serine/threonine kinases are overexpressed in most human hematological malignancies. By expression of siRNAs or dominant-negative mutants, we have previously shown that PIM kinases are important for proliferation and survival of hematopoietic cells transformed by oncogenic protein tyrosine kinases such as the FLT3-ITD mutant associated with acute myeloid leukemia (AML). *Aims*. To study the role of PIM kinases in FLT3-ITD mediated leukemogenesis. *Design and Methods*: Reconstitution assays with FLT3-ITD expressing PIM-/- bone marrow cells were performed. We also modulated the function of PIM kinases in cell lines by small molecule PIM inhibitors and isoform-specific siRNAs. *in vitro* kinase assays as well as masspectrometry was used to characterize putative PIM phosphorylation sites. *Results*. Unexpectedly, bone marrow cells deficient for PIM1 failed to reconstitute lethally irradiated wild-type recipients, whereas, the absence of PIM2 did not interfere with the induction of a FLT3-ITD-mediated leukemia-like disease. PIM1-/- bone marrow cells were impaired in early homing to bone marrow and spleen. PIM1-/- but not PIM2-/- bone marrow cells displayed decreased surface expression of the CXCR4 receptor and were defective in migration towards the CXCL12 ligand. By blocking PIM1 function or re-expression in PIM1-/- bone marrow cells, we found that PIM1 activity was essential for proper CXCR4 surface expression and migration towards CXCL12. By expression of wild-type and mutant GST-CXCR4-C-terminal mutants we identified Serine 339 in the CXCR4 intracellular domain as being phosphorylated by PIM1 and essential for proper recycling of the receptor to the surface. In addition, expression of S339 CXCR4 mutants in cell lines functionally

confirmed the importance of this residue. Interestingly, elevated levels of surface CXCR4 in AML blasts were associated with increased PIM1 mRNA expression, and could be significantly reduced by a small molecule PIM inhibitor in 4 out of 6 patients. *Conclusions*. Our data suggest that PIM1 activity is essential for homing and migration of hematopoietic cells through direct modification of CXCR4. Since CXCR4 is also important for homing and maintenance of leukemic stem cells, PIM inhibitors may exert their anti-leukemic effects in part by interfering with interactions with the microenvironment.

EVIDENCE FOR CD34+ HEMATOPOIETIC PROGENITOR CELL INVOLVEMENT IN ACUTE MYELOID LEUKEMIA WITH NPM1 GENE MUTATION: IMPLICATIONS FOR THE CELL OF ORIGIN

M.P. Martelli,[1] V. Pettirossi,[1] E. Bonifacio,[1] N. Manes,[1] D. Cecchini,[1] I. Gionfriddo,[1] A. Liso,[2] M. Delia,[3] L. Giunchi,[1] R. Rossi,[1] R. Pacini,[1] G. Specchia,[3] M.F. Martelli1, B. Falini[1]

[1]Hematology, University of Perugia, PERUGIA; [2]Hematology, University of Foggia, FOGGIA; [3]Hematology, University of Bari,BARI, Italy

Acute myeloid leukemia expressing mutated NPM1 gene and cytoplasmic nucleophosmin (NPMc+ AML) [*Falini B et al, NEJM 2005;352:254-266*] is a new entity of WHO classification that shows distinctive biological and clinical features, including a unique molecular signature characterized by downregulation of CD34 and upregulation of most HOX genes [*Falini B et al, Blood 2007;109:874-885*]. Involvement of HOX genes in the maintenance of the stem-cell phenotype strongly suggest that AML with mutated NPM1 originates from a multipotent hematopoietic progenitor (HSC). This view is also supported by immunohistological findings showing that AML with mutated NPM1 frequently displays multilineage involvement [*Pasqualucci L et al, Blood 2006;108:4146-4155*]. On the other hand, the frequent negativity of NPMc+ AML for the HSC-associated antigen CD34 raises the question of whether the mutation event occurs in a CD34-negative HSC (these cells have been identified in mice) or whether a minimal pool of CD34-positive NPM1-mutated leukemic cells does exist. Currently, the hierarchical level of stem cell involvement in NPMc$^+$ AML is unknown. To address this issue, we purified CD34$^+$ cells from NPMc$^+$ AML patients and detected NPM1 mutant protein in the sorted population by Western blot with anti-NPM mutant specific antibodies [*Martelli MP et al, Leukemia 2008*] (Figure 1A).

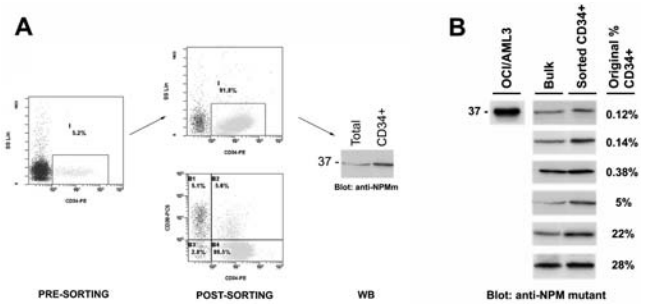

Figure 1.

We investigated 13 NPMc+ AML patients presenting at diagnosis with 0.05 to 28% CD34$^+$ cells in the peripheral blood. In all cases, CD34+ fractions (purity >90%) harboured NPM1 mutant protein, indicating they belong to the leukemic clone (Figure 1B). The percentage of most undifferentiated CD34$^+$/CD38$^-$ cells in the CD34$^+$ fractions ranged from 5 to 97%. Notably, in at least one case, all CD34$^+$ NPM1-mutated leukemic cells were CD38-negative. Moreover in all cases, CD34$^+$ NPM1-mutated leukemic cells appeared to express CD123 (IL-3 receptor), considered a marker of the leukemic stem cell and target of potential therapy. Double staining of bone marrow biopsies with anti-CD34 and anti-NPM antibodies revealed that the rare CD34$^+$ cells expressed NPM1 aberrantly in the cytoplasm. Inoculation of CD34$^+$ NPM1-mutated AML cells into sublethally irradiated NOD/SCID mice resulted into leukemia engrafment in various body sites, especially bone marrow, spleen, lung and liver. Preliminary results showed that CD34$^+$ leukemic cells reacquired the same leukemic phenotype as the original patient's, including CD34-negativity of the leukemic bulk in spite of any lack of differentiation. This finding suggests that NPM1 mutant protein may be involved in downregulation of CD34 antigen, while keeping a gene expression profile typical of the hematopoietic stem cell. These findings suggest the CD34$^+$ fraction contains the SCID-leukemia initiating cells (SL-IC) and point to CD34$^+$/CD38$^-$ HSC as the cell of origin of AML with mutated NPM1.

1109

PROTEIN SYNTHESIS ESCAPES MTORC1 CONTROL AND CONSTITUTES A PROMISING THERAPEUTIC TARGET IN ACUTE MYELOID LEUKEMIA

J.T. Tamburini,[1] A.S.G. Green,[1] V.B. Bardet,[1] N.C. Chapuis,[1] S.P. Park,[1] L.W. Willems,[1] M.U. Uzunov,[2] N.I. Ifrah,[3] F.D. Dreyfus,[4] C.L. Lacombe,[1] P.M. Mayeux,[1] D.B. Bouscary[1]

[1]Institut Cochin, PARIS; [2]Hôpital Pitié-Salpétrière, service d'hématologie, PARIS; [3]Hôpital d'Angers, service d'hématologie, ANGERS; [4]Hôpital Cochin, service d'hématologie, PARIS, France

Background. Acute myeloid leukemia (AML) is a clonal hematological disease characterized by differentiation arrest and by the proliferation of immature myeloid progenitors, both sustained by the deregulation of multiple signaling pathways. The mammalian Target Of Rapamycin Complex 1 (mTORC1) consists of mTOR, raptor, mLST8 and PRAS40. It governs cell growth and regulates cap-dependent translation of mRNAs. Translation is tightly regulated at the initiation level. The eIF4E protein recognizes the 7-methyl-GTP cap structure of mRNA and associates with eIF4G to form the translation initiation complex (eIF4F). The mTORC1 substrate 4E-BP1 inhibits the formation of eIF4F by competitively inhibiting the recruitment of eIF4G and sequestering eIF4E in an inactive complex. Sequential phosphorylation of 4E-BP1 by mTORC1 decreases its affinity for eIF4E and facilitates the assembly of active eIF4E/eIF4G complexes. The rapalogs (e.g. RAD001, rapamycin) are specific mTORC1 inhibitors and have been developed as anti-cancer therapeutics. Despite the rationale for their use as cancer therapeutics, the results of clinical trials are heterogeneous. In AML, mTORC1 is frequently activated but rapamycin is essentially cytostatic and induces apoptosis only when associated with cell-cycle dependent chemotherapies. Thus, its clinical efficacy in monotherapy is limited in AML. *Aims and methods*. As mTORC1 is known to control protein synthesis, the moderate anti-leukemic activity of rapamycin led us to investigate the importance of translation in AML biology. We performed experiments in 24 primary AML samples obtained from patients treated in varying studies of the GOELAMs French group after informed consent according to the declaration of Helsinki. MTORC1 signaling was modulated by RAD001 and raptor siRNA and studied by immunoblot. Cap-dependent mRNA translation was studied by 7m-GTP pulldown assay, polysome analysis, [3H]leucine pulse assay and immunoblot. AML blast cells survival was assessed by methylcellulosis cultures and annexin V fixation in flow cytometry. *Results*. We show herein that directly targeting translation has a marked anti-leukemic potential in primary AML cells. Indeed, specific inhibition of cap-dependent translation was achieved using the small molecule 4EGI-1. This compound dramatically decreased the clonogenic growth of leukemic progenitors and induced massive apoptosis of AML cells, with minimal impairment of normal hematopoiesis. Moreover, we observed that mRNA translation escaped mTORC1 control in AML blasts. Indeed, P70S6K phosphorylation on T389, a typical downstream relay of mTORC1, was abrogated by RAD001 or raptor siRNA whereas 4E-BP1 phosphorylation on S65, essential for translation-initiation control, was unaffected. Therefore, RAD001 failed to inhibit translation. Unlike 4EGI-1, RAD001 did not inhibit the assembly of eIF4F complexes and did not reduce the association of c-Myc mRNA with polysomes. Moreover, we identified the Pim-2 serine/threonine kinase as mainly responsible for the 4E-BP1 phosphorylation on S65 and subsequent cap-dependent translation control in AML. Indeed, pim-2 knockdown and treatment of AML cells by 4EGI-1 strongly reduced the accumulation of oncogenic proteins regulated at the translation initiation level whereas RAD001 failed to modify their cellular levels. *Conclusions*, Our results implicate a rapamycin-insensitive deregulation of oncogenic protein expression in leukemogenesis and strongly support the development of therapeutic strategies that directly target the eIF4F translation initiating complex in AML.

Anemia, aplastic anemia - PNH, Red Blood Cells and Iron

ECULIZUMAB REDUCES PULMONARY HYPERTENSION THROUGH INHIBITION OF HAEMOLYSIS-ASSOCIATED NITRIC OXIDE CONSUMPTION IN PATIENTS WITH PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA

A. Hill,[1] R. Rother,[2] X. Wang,[3] R. Sapsford,[4] P. Collinson,[5] D. Gaze,[5] S. Morris,[6] A. Scally,[7] K. Quinn-Senger,[2] S. Richards,[8] M. Bessler,[9] R. Kelly,[8] P. Hillmen8, M. Galdwin[10]

[1]Bradford Royal Infirmary, BRADFORD, UK; [2]Alexion Pharmaceuticals, CHESHIRE, USA; [3]Pulmomary and Vascular Medicine Branch NHLBI, BETHESDA, USA; [4]Leeds General Infirmary, LEEDS, UK; [5]St. George's Hospital, LONDON, UK; [6]University of Pittsburgh, PITTSBURGH, USA; [7]University of Bradford, BRADFORD, USA; [8]St. James's Institute of Oncology, LEEDS, UK; [9]Washington University, ST. LOUIS, USA; [10]NIH, BETHESDA, USA

Background. Pulmonary hypertension (PHT) has been mechanistically and epidemiologically linked to intravascular hemolysis and NO depletion. Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by chronic hemolysis, as well as elevated cell-free plasma hemoglobin. We have previously reported that ~50% of PNH patients have PHT as measured by Doppler echocardiography. Further, the level of N-terminal pro-B-type natriuretic peptide (NT-proBNP) has been demonstrated to be a strong predictor of PHT and mortality in patients with hemolytic anemias (defined as NT-proBNP ≥160 pg/mL). Eculizumab significantly and rapidly reduces hemolysis. *Aims and Methods*. To evaluate the efficacy of eculizumab in the regulation of cell-free hemoglobin levels, NO depletion, and subsequent cardiovascular morbidities, levels of hemoglobinemia, arginasemia and nitric oxide depletion were assessed in 73 eculizumab- and placebo-treated PNH patients in the phase III randomized, placebo-controlled trial (TRIUMPH). In addition, levels of NT-proBNP as a measure of PHT and systolic and diastolic systemic arterial pressures were examined in eculizumab- and placebo-treated patients.

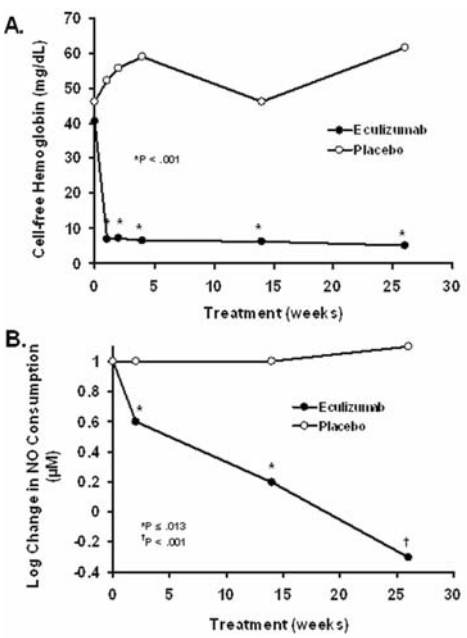

Figure. Effect eculizumab on cell-free plasma hemoglobin and NO consumption.

Results. At baseline, levels of lactate dehydrogenase (LDH), cell-free plasma hemoglobin, arginase 1 and arginase 1 enzyme activity were highly elevated compared to normal values. Levels of hemolysis and NO consumption were shown to be much greater in PNH (more than 6- and 10-fold, respectively) than in patients with other hemolytic diseases. There were significant correlations between cell-free plasma hemoglobin levels and both LDH (R = 0.5094) and plasma consumption of NO (R = 0.9529). Strong correlations between arginase 1 and both cell-free plasma hemoglobin (R = 0.9367) and arginase 1 enzyme activity (R = 0.9081) were also demonstrated. Following eculizumab therapy, measures of hemolysis were significantly reduced from baseline, including LDH (2200±158 to 327±68 U/L) and cell-free plasma hemoglobin (98.8±23.24 to 15.2±5.05 mg/dL), while levels in placebo-treated patients remained unchanged; a concomitant reduction in NO consumption was also observed (see Figure). In addition, at baseline, 46.6% (34/73) of PNH patients in the TRIUMPH study had levels of NT-proBNP ≥160 pg/mL, indicating PHT in these patients. Eculizumab-treated patients showed a 50% reduction in the incidence of PHT over the course of the 26-week treatment period from 52.5% to 26.3%, while PHT did not change with placebo (39.4% to 43.8%; p=0.057). Additionally, eculizumab significantly improved dyspnea (EORTC-QLQ-C30) compared to placebo (Effect size 0.69; p=0.0002). Similarly, eculizumab treatment was associated with a concomitant decrease in systemic arterial blood pressure as compared to patients receiving placebo. *Summary.* In patients with hemolytic anemia, the depletion of NO is associated with the development of cardiovascular morbidities, including PHT. The current data demonstrate that intravascular hemolysis in untreated patients with PNH is associated with high levels of plasma ferrous oxyhemoglobin, which stoichiometrically catabolizes NO, and high levels of plasma arginase 1, which catabolizes arginine - all leading to significant depletion of NO. We show a high prevalence of PHT in untreated patients with PNH as indicated by levels of NT-proBNP. Further, the data demonstrate that in a placebo-controlled study, the antihemolytic effect of chronic eculizumab treatment significantly increases nitric oxide bioavailability and reduces pulmonary hypertension.

1111

UNRELATED CORD BLOOD TRANSPLANTATION FOR ACQUIRED BONE MARROW FAILURE SYNDROMES: A RETROSPECTIVE EUROCORD AND EMBT SEVERE APLASTIC ANAEMIA WORKING PARTY ANALYSIS

D. Purtill

Eurocord, PARIS CEDEX 10, France

Allogeneic haematopoeitic stem cell transplantation is a treatment option for patients with acquired bone marrow failure syndromes (BMFS) who fail immunosuppressive treatment (IST). Unrelated cord blood transplantation (UCBT) offers an alternative source of hematopoietic stem cells for patients lacking a suitable sibling or matched unrelated donor. We studied 59 patients reported to Eurocord who received UCBT as their first allograft for either acquired severe aplastic anaemia (SAA) (n=53) or paroxysmal nocturnal haemoglobinuria (PNH) (n=6). Forty-eight received single and 11 received double UCBT. Median age at transplant was 11,5 years (1-68 years), 59% were children. Most (61%) patients had received more than 20 platelet transfusions by time of transplant, while half (49%) had received more than 20 red cell transfusions. Forty one patients with SAA had received at least one cycle of IST prior to transplant. Among those with sufficient data available (29), 55% had failed one cycle of IST before transplant, 28% two cycles and 7% more than two cycles. Median delay between diagnosis and transplant for patients with SAA was 13 months (2-128 months). Among the 48 single cord transplants, 5 patients (12%) were 6/6 matched, 17 (40%) had one HLA mismatch, 19 (44%) had two mismatches and 2 had three mismatches. For double UCBT, 2 patients had one HLA mismatch, 6 had two mismatches and one had three mismatches when examined according to greatest cord-recipient HLA disparity (2 missing HLA data). Median total nucleated and CD34+ cell doses infused were 3,35*107/kg (1,71 to 16*107/kg) and 1,82*105/kg (0,29 to 13,3*105/kg) respectively for single cords and 6,17*107/kg (3,21 to 9,7*107/kg) and 2,78*105/kg (1,1 to 7,1*105/kg) respectively for double cords. Thirty six patients (64%) received reduced intensity conditioning, although conditioning regimens varied. Twenty-three patients received cyclophosphamide (CY) and fludarabine (FLU) (14 of these had CY dose <100 mg/kg and FLU 120-200 mg/m^2), 12 patients received CY (5 in combination with total body irradiation), 11 patients received CY and busulphan. Forty-five patients (85%) received anti-T-cell immunoglobulins. Median follow-up was 28 months (3-71 months). Median time to neutrophil recovery was 24 days, with a cumulative incidence (CI) of 68 ±7%. No late graft failure was reported. Of those who achieved neutrophil recovery, 29 out of 35 had chimerism results; 26 (90%) had full donor chimerism. The CI of acute graft vs. host disease (GVHD) (grade II-IV) was 31±7%. Of 31 of 45 eligible patients at risk, 14 had chronic GVHD (45%) (limited in 50%). Two year overall survival (OS) estimates were 42±6%. Of 24 patients without engraftment, information on subsequent treatment was available for 14. Ten (71%) of these went on to receive a second allograft, of which 7 were UCBT, and one was alive at last follow-up. Infection remains the most common cause of death (13 patients (38%)). High incidence of graft failure is a problem in UCBT for acquired BMFS; however, the procedure remains a feasible salvage therapy for this group of very high risk patients. More studies with higher patient numbers are required to assess factors affecting transplant outcomes.

1112

COMPARISON BETWEEN LYMPHOGLOBULINE- AND THYMOGLOBULINE-BASED IMMUNOSUPPRESSIVE THERAPY AS FIRST-LINE TREATMENT FOR PATIENTS WITH APLASTIC ANEMIA

C. Vallejo,[1] P. Montesinos,[2] A. Rosell,[3] S. Brunet,[4] E. Pérez,[5] J. Petit,[6] J. Sevilla,[7] A. Martín,[8] R. Arranz,[9] J. Serna,[10] I. Espigado

[1]University Central Hospital of Asturias, OVIEDO (ASTURIAS); [2]Hospital La Fe, VALENCIA; [3]Hospital V. de la Victoria, MÁLAGA; [4]Hospital Sant Pau, BARCELONA; [5]Hospital M. Meseguer, MURCIA; [6]Institut Catalá d'Oncologia, BARCELONA; [7]Hospital Niño Jesús, MADRID; [8]Hospital V. de la Concha, ZAMORA; [9]Hospital La Princesa, MADRID; [10]Hospital Doce de Octubre, MADRID, Spain; [11]Hospital Universitario Virgen del Rocio, SEVILLE, Spain

Background. Immunosuppressive therapy (IST) is considered to be the first-line treatment in patients with severe aplastic anemia (AA) who are not eligible for hematopoietic stem cell transplantation (HSCT). Most IST schemes are based on the combination of anti-thymocyte globulin (ATG) plus cyclosporine A (CsA). Differently from other countries, two ATGs have been approved in Spain for AA from 2003 to 2007: Lymphoglobuline (LG) (raised in the sera of horses) and Thymoglobuline (TG) (produced in rabbits). So, during this period of time, the standard therapeutic protocol of the Spanish study group for AA included both options, and the physicians chose LG or TG based on their own wishes. Most published studies in AA are with LG, which is no longer manufactured. Recent limited data have confirmed therapeutic efficacy of TG, but no randomized studies have been performed comparing both products' activity. The aim of this report is to communicate the outcomes of a group of patients with AA who received either a LG- or TG-based scheme as first-line treatment. *Design and Methods*. We retrospectively investigated the outcome of 101 patients with AA treated with IST at front line between 2003 and 2008. Twenty-nine patients (28%) got LG (15 mg/kg/day/x5 days), and 72 patients (72%) got TG (2.5 mg/kg/day/x5 days). All patients also received methylprednisolone and CsA. Response rate (RR) was assessed at post-IST day +90, day +180, and day +365. If complete response (CR) was not reached, patients received a second course of IST, a second-line therapy (HSCT or androgens), or no treatment. When a second course of IST was employed, it included LG at the same dose as in the first course (15 mg/kg/day/x5 days), or TG at a higher dose (3.5 mg/kg/day/x5 days). CR was defined as a neutrophil count >1.5x10^9/L, a platelet count >100x10^9/L, and a hemoglobin level >120 g/L. Partial response (PR) was defined as a neutrophil count >0.5x10^9/L, a platelet count >20x10^9/L, and a hemoglobin level >80 g/L. Subgroup analyses were conducted and differences in response were tested using the chi-square statistic test. Results: After the first course of IST, 27 patients (27%) reached CR (group A) (LG: 38%, TG: 22%), and 20 patients (20%) reached PR (LG: 10%, TG: 24%). Thirty-one of the patients who did not reach CR after the first IST course, received a second course of IST (5 with LG and 26 with TG) (group B), and 43 patients underwent a different approach (second-line therapy or no treatment) (group C). After the second course of IST, 12 patients (38%) reached CR (LG: 40%; TG: 38%) and 11 patients (35%) reached PR (LG: 40%; TG: 34%). If we exclude patients in group C, the RR among the remaining 58 patients (who underwent 1 or 2 courses of IST) was 86% (67% CR, and 19% PR). No major drug-related toxicities were reported in the whole group of patients. *Conclusions.* ATG-based schemes with both LG and TG were well tolerated as treatment of patients with AA. RR after first course of IST was similar in the LG and in the TG group (48% versus 46%). RR after second course of IST was also similar when LG and TG were employed (80% versus 73%). After excluding those patients who, not having reached CR after the first course, underwent an approach different from a second course of IST, RR to IST was 86%, with 67% of CR. No statistical differences were found based on the type of ATG administered. The results of this study show that TG is, at least, as effective as LG for the treatment of AA patients. Based on these and other recently published data, the current standard therapeutic protocol of the Spanish study group for AA includes TG at the dose of 3.75 mg/kg/day/x5 days for both the first and, if necessary, second course of IST. To our knowledge, no reports are available in the medical literature comparing the outcome of patients with AA who received LG or TG as the first-line therapy for AA. So, in spite of the fact that our study is retrospective and not randomized, we think our data are unique and very useful for helping physicians in switching from LG to TG.

1113

CONDITIONAL INDUCTION OF MKK6-P38 MAPK SIGNALLING IN GRANULOCYTES INDUCES PHENOTYPIC CHANGES TO MONOCYTE-LIKE CELLS

R. Köffel,[1] A. Jörgl,[1] A. Meshcheryakova,[1] M.B. Fischer,[2] C. Scheinecker,[3] H. Strobl[1]

[1]Institute of Immunology, VIENNA, Austria; [2]Department of Transfusion Medicine, VIENNA, Austria; [3]Division of Rheumatology, VIENNA, Austria

How intracellular signalling cascades downstream of cooperating cytokine signals orchestrate transcription factors (TFs) to induce defined myeloid sublineage differentiation programs is so far poorly understood. Lineage instruction by TFs can be demonstrated by over-expression or knock-down experiments. In addition, post-translational modifications such as phosphorylation of TFs by upstream protein kinases are key determinants of their function. MKK6 represents a direct upstream kinase of p38MAPK. The MKK3/6-p38 MAPK signalling cascade is induced by cytokine and immune receptor signals and is constitutively activated in monocytes (Mo) found in rheumatoid arthritis (RA) lesions. How p38MAPK is involved in orchestrating and relaying signal input to the downstream induction of gene activation programs in myeloid cells is poorly defined. We used a retroviral Tet-on system to express genes in primary human hematopoietic cells, and analyzed concomitant cellular and molecular changes. In particular, we asked for the consequences of MKK6-p38 activation in G-CSF-dependent late-stage granulocytes (G) and in immature dendritic cells. We found that conditional induction of dominant-active-MKK6 redirects G-CSF-induced G differentiation to Mo-like cells. Furthermore, conditional induction of MKK6 in immature DCs was sufficient to induce DC maturation. We further analyzed downstream mechanisms in MKK6-induced G to Mo lineage conversion. We observed a rapid p38-dependant induction of Mo promoting TFs c-Jun and concommitant reduction of G lineage associated TF C/EBPα in response to induced MKK6. These changes were followed by the upregulation of MafB and KLF4 as well as by the downregulation of Gfi-1. DOX-titration and pulse chase experiments revealed that G to Mo lineage conversion required low expression levels of MKK6 as well as only a short-term expression of MKK6 (6 h). RA-joint lesional proinflammatory cytokines similarly induced MKK6 in G associated with Mo lineage conversion. *in vivo* validation experiments revealed that Lactoferrin+ late-stage neutrophils from G-CSF-mobilized blood but not from normal blood could be redirected by proinflammatory cytokines to undergo Mo differentiation. Furthermore, these cells could be driven to acquire osteoclast features *in vitro*. Therefore, MKK6-p38 activation by cytokines, microbial products, and stress signals might alter the lineage differentiation of late stage G to monocytic cells. Furthermore, left-shifted Lactoferrin+ G might contribute to the pool of monocytic cells in inflammatory lesions.

THE -509C/T POLYMORPHISM OF TRANSFORMING GROWTH FACTOR-B1 IS ASSOCIATED WITH INCREASED RISK FOR DEVELOPMENT OF CHRONIC IDIOPATHIC NEUTROPENIA

D.G. Eliopoulos, I. Mavroudi, C. Pontikoglou, E. Stavroulaki, K. Pyrovolaki, M. Spanoudakis, M. Psyllaki, G. Goulielmos, H.A. Papadaki

University of Crete School of Medicine, HERAKLION, Greece

Background. Chronic Idiopathic Neutropenia (CIN) is a disorder of granulopoiesis characterized by increased apoptosis of bone marrow (BM) granulocytic progenitor cells. This impaired granulopoiesis has been associated with an inflammatory BM microenvironment consisting of pro-inflammatory cytokines and pro-apoptotic mediators such as tumor necrosis factor (TNF)-α, transforming growth factor (TGF)-β1 and Fas-Ligand (Fas-L). The origin of these molecules is not entirely known. *Aim*. Because genetic polymorphisms of TNF-α, TGF-β1 and Fas-L have been associated with changes in cytokine production in a variety of disease states, we sought to investigate the frequency of TNF-α, TGF-β1 and Fas-L gene polymorphisms in CIN patients and explore their role in excessive cytokine/mediator production and their association with the development of CIN. *Design and Methods*. Fifty-seven patients fulfilling the previously defined diagnostic criteria of CIN and 60 healthy subjects were included in the study after informed consent. All subjects originated from Crete, a well-defined area with genetically homogeneous population. Genomic DNA was extracted from peripheral blood samples and genotype analysis for the detection of TNF-α -308G/A, TGF-β1 -509C/T, +869T/C, +915G/C and Fas-L -844T/C polymorphisms were evaluated using a polymerase chain reaction-based restriction fragment length polymorphism (PCR-RFLP) assay. Cytokine levels in serum and long-term BM culture (LTMBC) supernatants of patients and controls were evaluated by means of an enzyme-linked immunosorbent assay (ELISA). *Results*. The mutant allele T of TGF-β1 -509C/T polymorphism was found in higher frequency in CIN patients compared to controls (p=0.037). This difference reflected mainly the homozygosity for the allele T which was identified in a proportion of 14.0% of the patients versus 1.7% of the controls (p=0.012) whereas no statistically significant difference was demonstrated between patients and controls in the proportion of subjects with CC homozygocity (p = 0.3916) or CT heterozygocity (p=0.423). Compared to wild type genotype, the TT genotype was associated with

increased risk for CIN development (Odds Ratio:12; 95% Confidence Intervals:1.24-115.4; p=0.020) whereas no statistically significant association was demonstrated between the presence of CT genotype and the risk for development of CIN (p=0.593). Compared to healthy controls, patients with CT and TT genotypes displayed increased TGF-β1 levels in serum (p<0.0001 and p=0.0002, respectively) and LTBMC supernatants (p<0.0001 and p=0.0002, respectively) suggesting an association of the mutant allele T with increased levels of TGF-β1 in patients with CIN. No significant difference was found between patients and controls in the frequency of TNF-α-308G/A, TGF-β1 +869T/C and +915G/C, and Fas-L -844T/C polymorphisms. *Conclusions*. The TGF-β1-509C/T polymorphism is associated with increased risk for CIN and contributes to the pathophysiology of the disorder by inducing TGF-β1 overproduction. This is the first study providing evidence that genetic factors may predispose to CIN and may have a role in the pathophysiology of the disorder.

SUCCESSFUL PREGNANCY OUTCOME IN PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA ON LONG TERM ECULIZUMAB

R. Kelly,[1] L.M. Arnold,[1] S.J. Richards,1 A. Hill,[2] C. Bomken,[3] J. Hanley[3] A. Loughney,[3] J. Beauchamp,[4] G. Khursigara,[5] R.P. Rother,[5] E. Chalmers,[6] A. Fyfe Gartnavel,[7] E. Fitzsimons,[8] R. Nakamura,[9] A. Gaya,[10] B. Rotoli,[11] A. Risitano,[11] J. Schubert,[12] P. Hillmen[1]

[1]St James's University Hospital, Leeds, UK; [2]Bradford Royal Infirmary, Bradford, UK; [3]Royal Victoria Infirmary, Newcastle-Upon-Tyne, UK; [4]Alexion Pharmaceuticals Inc, Guildford, UK; [5] Pharmaceuticals Inc, Cheshire, USA ; Queen Mothers Hospital, Glasgow, UK; [7]General Hospital, Glasgow, UK; [8]Gartnavel General Hospital, Glasgow, UK; [9]City of Hope National Medical Center & Beckman Research Institute, Duarte, USA; [10]University of Barcelona, Barcelona, Spain; [11]Federico II University, Naples, Italy; [12]Saarland University Medical School, Homburg, Germany

Background. Paroxysmal nocturnal haemoglobinuria (PNH) is a rare disorder of haemopoietic stem cells resulting in chronic haemolysis and an increased thrombotic risk. During pregnancy, PNH frequently worsens, posing additional risk of morbidity and mortality to mother and fetus. Eculizumab is a terminal complement inhibitor that has been shown to reduce haemolysis, transfusion requirements, thrombotic events, and chronic kidney disease, while improving fatigue and quality of life in patients with PNH. Since pregnancy was an exclusion criteria in the clinical trials, its use in this setting has not been evaluated. *Aim*. The safety and efficacy of eculizumab in the management of PNH during pregnancy. We sought to review the data, to-date, including physician reported adverse events, PK/PD, and distribution of eculizumab, in patients with PNH who received eculizumab. *Methods*. Reports of pregnancy during the eculizumab clinical trial were reviewed for safety, duration of drug exposure during gestation, complications during and after pregnancy, and general health of the newborn. Additionally, two patients were followed who received eculizumab treatment either during the last trimester (started eculizumab at week 27) or throughout gestation to term. Maternal blood, cord blood and breast milk data and PK/PD analyses are presented. *Results.* We present data on 6 pregnancies in patients receiving eculizumab. 1 patient elected termination of the pregnancy and 3 withdrew from eculizumab between 4-16 weeks gestation, as pregnancy was an exclusion criteria in the clinical trials, and continued their pregnancies. All 3 patients delivered healthy babies without complications. One patient received eculizumab throughout her pregnancy. At week 28 and week 30 gestation, she experienced haemoglobinuria and abdominal pain just prior to her eculizumab dose. The 900mg dose interval was adjusted from 14 to 12 days and there were no further breakthroughs. She delivered a healthy boy at term. No eculizumab was detected in the cord blood or breast milk during the first week after delivery. One patient had IVF resulting in a twin pregnancy and started eculizumab at 27 weeks gestation. She also required higher doses of eculizumab to control her haemolysis and delivered healthy babies by elective caesarian-section at 35 weeks gestation. She developed a postpartum haemorrhage needing uterine artery embolisation due to retained products of conception. Cord blood analysis suggested eculizumab was at very low background levels. Both patients on eculizumab were also treated with LMW heparin throughout their pregnancy. *Summary.* Review of these 6 cases of treatment with the complement inhibitor eculizumab during pregnancy does not indicate an apparent safety signal. Further, the first evaluation of eculizumab treatment from conception to delivery in a patient with PNH treated with eculizumab indicates that the pregnancy was successful and eculizumab does not appear to cross the placenta nor is it secreted into breast milk. There were no congenital anomaly/birth defects and no thromboses reported. Eculizumab appears to be well tolerated during pregnancy in PNH and adds to the management during this high risk time but might need to be given at higher doses during the 2nd and 3rd trimesters.

Quality of Life

WHAT HAS BEEN LEARNED FROM MEASURING PATIENT-REPORTED OUTCOMES IN CLINICAL RESEARCH OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES? A SYSTEMATIC REVIEW FROM 1980 TO 2008

F. Efficace,[1] G. Caocci,[2] M. Vignetti,[1] F. Mandelli,[1] P. Fazi,[1] F. Cottone,[1] G. La Nasa[2]

[1]Gimema, ROME, Italy; [2]Ospedale R. Binaghi, Centro Trapianti Midollo osseo., CAGLIARI, Italy

Background. Patient-Reported Outcomes (PROs) are increasingly reported in hematological research and they can potentially provide valuable information to further support clinical decision-making. PROs include a number of parameters (e.g. quality of life and symptom burden) which all have in common the characteristic of being self-reported by the patient. *Aims.* Quality of life (QoL) and other key subjective health status domains, such as fatigue, are very important in the treatment of patients with myelodysplastic syndromes (MDS), but there is currently lack of data regarding the amount of research conducted in this area and the possible added value of using PROs in clinical research (including randomized controlled trials-RCTs) of patients with MDS. The purpose of this work was to systematically investigate traditional clinical and PROs in prospective studies of patients with MDS. *Design and Methods.* A systematic review was performed, broadly following the Cochrane methodology on all prospective studies (including RCTs) having PROs as an endpoint (either primary or secondary) published between January 1980 and July 2008. Candidate articles were identified mainly by PubMed and the Cochrane library. Two reviewers independently assessed all studies to consistently evaluate their methodological quality according to a previously developed protocol reviewer. This included a number of methodological and statistical quality criteria such as PRO missing data documentation, timing of assessment, discussion of outcomes in terms of clinical significance and questionnaire used. Both PROs and traditional clinical outcomes were also systematically analyzed to evaluate their relevance for supporting clinical decision-making. *Results.* Nine prospective studies were identified, four of which evaluated PROs in a RCT setting and interestingly, all the studies were published after the year 2001. Four studies used the EORTC QLQ-C30 to evaluate QoL while five used the FACT-An to also focus on fatigue related problems, in all RCT studies PROs were used as a secondary endpoint. Six out of the nine studies included less than 100 patients thus limiting the interpretation of PROs. In addition to small sample sizes, methodological drawbacks were mainly identified in terms amount of missing data over time and lack of reporting of important details about the design of the PRO assessment. Out of the four RCTs including PROs, important evidence emerged from two studies comparing azacitidine (AZA) and decitiabine versus supportive care. There is robust indication that AZA provide beneficial effects in terms of fatigue, physical functioning, dyspnea, positive affect and psychological distress. Another study also provided a preliminary indication that decitibaine could provide some benefit in terms of QoL compared to supportive care alone. *Conclusions.* The study revealed the paucity of research in this area and some methodological limitations when designing and reporting PROs. However, PROs have become more relevant only in recent years in clinical research of patients with MDS and there is strong evidence of the potential role in providing key outcomes to further support clinical decision-making. Investigators are encouraged to include PROs in future trials of patients with MDS.

1116

PAIN AND EMOTIONAL DISTRESS IN LEUKAEMIA PATIENTS SINCE DIAGNOSIS AND DURING ALL PHASES OF THE DISEASE

M. Luppi,[1] M. Morselli,[1] R. Zanin1, A. Berti,[1] G. Cacciapaglia,[1] R. Fregni,[1] A. Molitierno,[1] E. Checchi,[1] G. Sasso,[1], V. Ricucci,[1] P. Pelloni,[1] L. Galli1, R. Vicini,[1] R. D'Amico,[1] F. Forghieri,[1] L. Potenza,[1] F. Narni,[1] L. Buonaccorso,[1] D. Bolognesi,[2] A. Pietramaggiori,[2] U. Ferrari,[2] F. Artioli,[2] E. Bandieri,[3] C. Ripamonti,[4] G. Torelli,[1] M. Luppi[1]

[1]University of Modena and Reggio Emilia, MODENA; [2]Oncologic Day Hospital, MIRANDOLA; [3]Oncologic Day Hospital, CeVEAS, MIRANDOLA, MODENA; [4]Palliative Care Unit, INT, MILAN, Italy

Background. The few available studies on leukaemia patients have so far addressed only the issue of physical pain and emotional distress in terminally ill patients. *Aim*. We used visual analogue scale (VAS), Edmonton Symptoms Assessment System (ESAS) and Hospital Anxiety and Depression Scale (HADS) to investigate the frequency of physical pain and emotional distress in patients with leukaemia, at diagnosis, during the neutropenia phase (+15), and at discharge, during the various clinical phases (induction, subsequent consolidation, and autologous and allogeneic bone marrow-BM-/peripheral blood stem cell-PBSC- transplantation procedure), as well as in patients with non haematologic cancers, as controls. *Patients and Methods*. 53 patients with acute leukaemia (40 myeloid and 13 lymphoblastic; 36 male, 17 female; median age 50 years-range 32-72-) and 76 patients with solid cancer; 29 female, 47 male; median age 65 years-range 42-83-) were enrolled. The diagnosis of depression and/or anxiety was made with a score of 8 of 21 or more in the HADS questionnaire. In the ESAS analysis, depression and anxiety were considered present with a score of 2 of 10 or more. *Results*. According to the HADS score, during the induction phase, depression was reported in 21%, 36% and 33% of the patients, at diagnosis (time 0), at +15 and at discharge, respectively, while anxiety in 30%, 40%, 36% of the cases, at the same time intervals, respectively. Depression was reported in 32% while anxiety in 38% of all questionnaires, respectively, collected from patients at all time intervals during all clinical phases. According to the VAS score, during the induction phase, mild pain was reported in 39.5%, 27%, and 16.6%, while moderate to sever pain in 11.6%, 20.4% and 5.5% of the cases, at diagnosis, at +15 and at discharge, respectively. According to the ESAS score during the induction phase, depression was reported in 45%, 38.6% and 27.7% of the patients, at diagnosis, at +15 and at discharge, while anxiety in 46.5%, 40.4%, 41.6% the cases, at the same time intervals, respectively. ESAS showed a sensitivity of 57% and 74%, and a specificity of 67% and 67% for depression and anxiety, respectively, when all questionnaires are considered. In solid cancer patients, at diagnosis, mild to moderate to severe pain was reported in 38% of the cases. HADS score was positive for depression in 25% while for anxiety in 19.7% of the cases. ESAS score was positive for depression in 28.9% while for anxiety in 40.7% of the cases, showing a sensitivity of 63% and 86.6% and a specificity of 82% and 70% for depression and anxiety, respectively. *Conclusions*. Contrary to what is generally accepted, not only solid cancer but also leukaemia patients may have physical pain and suffer from emotional distress since diagnosis and during all phases of the disease, as revealed by HADS. ESAS may be a useful tool for the screening of depression and anxiety in leukaemia patients.

1117

QUALITY OF RANDOMIZED CONTROLLED TRIALS (RCTS) IN HEMATOLOGICAL MALIGNANCIES: WHAT WAS REPORTED VERSUS WHAT WAS DONE

B. Djulbegovic,[1] A. Kumar,[2] A. Magazin,[2] H.P. Soares[3]

[1]University of South Florida, Moffitt Cancer Ctr, TAMPA, USA; [2]Moffitt Cancer Center, TAMPA, USA; [3]University of Miami, MIAMI, USA

Background. RCTs are considered the *gold standard* for providing research evidence for interventions in healthcare. However, the validity and reliability of trial results are largely dependent on the study design, analysis and trial conduct. Poorly conducted and reported research seriously compromises the integrity of the research process, especially if biased results receive false credibility. *Aims*. To establish whether reporting of methods in haematological malignancies RCTs conducted by the NCI cooperative groups (CGs), which conducts all publicly sponsored RCTs in cancer in the US, reflect the actual methodological quality. *Design and Methods*. We compared data on methodological quality reported in publications and research protocols. Data were extracted on methodological domains acknowledged as important for minimizing bias in the conduct and analysis of RCTs. We also extracted data on measures that are important to minimize play of chance namely, expected effect size, sample size calculations, α and β error. *Results*. Altogether, between 1955 and 2000, 4 CGs under the ageis of NCI conducted 120 hematological malignancies RCTs enrolling 37, 845 patients. Allocation concealment was adequate in 91% (109/120) of trials but reported only in 18% (21/120) of publications. A priori sample size calculations were performed and reported in 100% of trials. Expected difference in outcome was stated in 98% (118/120) of the trials while it was reported only in 39% (47/120) of the papers. α and β errors were defined and prespecified in 92% (110/120) and 94% (113/120) of the trials but reported in 30% (36/120) and 37% (36/120) of trials, respectively. An intention to treat analysis was done in 98% (118/120) of trials but clearly reported in 23% (27/120) of the trials. *Conclusions*. Reporting of methodological aspects of randomised controlled trials does not necessarily reflect the conduct of the trial. However, to the extent that published records affect the decision-making of physicians and policy makers, our study indicates the need for urgent measures to improve the reporting of RCTs in hematological malignancies.

'PAINLESS' BONE MARROW ASPIRATION BY SLOW SUCTIONING DO NOT AFFECT PERIPHERAL BLOOD CONTAMINATION TO THE SPECIMEN: RANDOMIZED PROSPECTIVE CROSSOVER TRIALS

Y. Asano-Mori,[1] S.I. Mori,[2] T. Ueki,[3] M. Sakai,[4] T. Yamashita,[3] K. Ohashi,[3] H. Akiyama,[3] H. Sakamaki[3]

[1]Toranomon Hospital, TOKYO, Japan; [2]The National Cancer Center Hospital, TOKYO, Japan; [3]Tokyo Metropolitan Komagome Hospital, TOKYO, Japan; [4]Fred Hutchinson Cancer Research Center, SEATTLE WA, USA

Background. The pain during bone marrow aspiration (BMA) can be best explained by negative pressure inside the bone marrow cavity. Although most standard textbooks recommend rapid suctioning with high negative pressure to minimize peripheral blood contamination, this technique might be associated with more pain. To date, there is no evidence that rapid suctioning can reduce peripheral blood contamination. *Aims*. To find a technique that reduces pain without loss of specimen quality, we conducted two trials. *Design and Methods*. The first was a randomized, crossover trial comparing slow aspiration with low negative pressure (L method) and rapid aspiration with high negative pressure (H method). To evaluate pain during the procedure, 49 patients with hematological malignancy who required BMA more than once were randomly assigned to receive either the first aspiration by the L method and the second by the H method or vice versa. Under local anesthesia, a 16-gauge BMA needle was inserted into the BM cavity. A 1-mL syringe (L method) or a 30-mL syringe (H method) was used to aspirate 0.5 mL of BM fluid. To ensure accuracy of aspiration volume in the H method, an extension tube was connected between the 30-mL syringe and needle, and clamped by forceps when the aspirated volume reached 0.5 mL. Pain during each procedure was evaluated using a visual analog scale (VAS), verbal descriptor scale (VDS), and McGill pain questionnaire (MPQ). In the first trial, repeated measures one-way analysis of variance design was used for serial measurement of pain, and the one-tailed Wilcoxon's test was used to compare pain between the two groups. The second trial compared aspirate quality between the L and H methods. Sixteen allogeneic transplantation donors (median age, 33.5 years; range, 22 to 62 years), underwent the first puncture of the harvest procedure under general anesthesia. BMA was drawn simultaneously from the right and left posterior iliac crest with a 1-mL and a 30-mL syringe; the aspiration side and syringe size were randomized. Nucleated cell counts (NCC) of the BM specimens were determined by automated hematology analyses. The non-inferiority margin was defined as less than 25% on the basis of the absolute difference of NCC between the L and H methods. Informed consent for the procedures was obtained from all donors and patients. *Results*. In the first trial, 34 of the 49 patients (67%; 21 men and 13 women; median age, 49 years; age range, 17 to 77 years) completed the study and provided VAS, VDS and MPQ score data after two consecutive BMA. Present pain intensity (PPI) score of the MPQ was significantly decreased with L method when compared with H method (median absolute difference 0, p=0.037) (Table 1). VAS score and total pain rating index (PRI) of the MPQ were also lower with the L method (median absolute differences -0.6 and -0.5), although these results did not reach statistical significance. There was no significant ordinal interaction in repeated measurement of any scores except the

affective-PRI of the MPQ, which was significantly higher at the first aspiration, regardless of the negative pressure intensity (p=0.024). In the second trial, the geometric mean of NCC with the L method was non-inferior to the mean with the H method (p=0.025) (Table 2). *Summary and Conclusions*. These findings indicated that BMA with low negative pressure tended to be less painful, while maintaining specimen quality. There remains difficulty in evaluating the impact of psychological factors on the results. Nonetheless, on the basis of our results we recommend suctioning slowly with low negative pressure using a small syringe in order to reduce pain during BMA.

RISK FACTORS FOR ATTEMPTED SUICIDE AND SUICIDE FOLLOWING A DIAGNOSIS OF HEMATOLOGICAL MALIGNANCY

M. Hultcrantz,[1] T. Svensson,[2] A.R. Derolf,[1] S.Y. Kristinsson,[1] A. Ekbom,[2] F. Granath,[2] M. Björkholm[1]

[1]Karolinska University Hospital, STOCKHOLM, Sweden; [2]Clinical Epidemiology Unit, Karolinska University Hospital Solna and Institute, STOCKHOLM, Sweden

Background. It has been well documented that patients with a diagnosis of cancer are at an increased risk of committing suicide. Male gender, head and neck and lung cancer have been associated with a higher risk of suicide. Psychiatric co-morbidity is also an established risk factor for suicide. However, there is a paucity of literature on the risk of suicide in patients with hematological malignancies *Aims.* To define the incidence and risk factors of suicide and suicide attempts in patients with a broad range of hematological malignancies. *Design and Methods* Through the Swedish Cancer Registry we identified 47,220 patients (54.5% men) diagnosed with a hematological malignancy between 1992-2006. For each patient, five population-based controls (n=235,868) matched by gender and year of birth were chosen randomly from the Swedish Population base. Information on suicide was obtained from the Cause of Death Registry and admissions due to suicide attempts and psychiatric illness from the Swedish Hospital Discharge Register. History of psychiatric illness was measured as having at least one admission with a psychiatric diagnosis prior to the malignancy, or the corresponding time for the controls. Cox-regression was used to analyze the risk of suicide/suicide attempt after a diagnosis of a hematological malignancy. Results are presented as hazard ratios (HR) with 95% confidence intervals (CI). *Results*. The HR for suicide/suicide attempt in patients with hematological malignancies was approximately two times elevated during the first three years after diagnosis, (HR=1.9, CI:1.5-2.3). The overall excess risk was modified by time since diagnosis and no increased risk was seen when three years had elapsed (HR=1.1, CI:0.9-1.4). An analysis only including suicide showed identical risks, HR=1.9 (CI:1.3-2.8) during the first three years after diagnosis, and HR=1.2 (CI:0.8-1.8) after 3 year of follow-up. The overall excess risk associated with malignancy was not significantly modified by age, gender, calendar year or type of hematological cancer. However, data suggests that patients diagnosed up to 1998 were at higher risk (HR=2.2, CI:1.7-2.9) compared to those diagnosed after 1998 (HR=1.6, CI:1.2-2.1). Multiple myeloma was the malignancy associated with the highest estimated risk (HR=3.4, CI:2.3-5.0). In an analysis of the joint effect of malignancy and history of psychiatric illness these factors were shown to interact multiplicatively (Figure). Compared to controls without psychiatric illness, the following risks were seen for the first three years of follow-up: cases without psychiatric illness HR=1.8 (CI:1.4-2.3); controls with psychiatric illness HR=10.8 (CI:8.8-13.2); cases with psychiatric illness HR=23.3 (CI:16.6-32.6). *Conclusions.* Hematological malignancies are associated with an increased risk of suicide and attempted suicide during the first three years after diagnosis. This risk is further increased in patients with a history of psychiatric illness. Patients with multiple myeloma carry the highest estimated risk. These findings have implications for the care and treatment of patients with hematological malignancies.

ANIMAL MODELS FOR THE TWO HYPOTHESES OF TRALI PATHOLOGY

M.B. Tamarozzi,[1] S.G. Soares,[2] A. Sá-Nunes,[3] F.P. Saggioro,[1] J.O. Bordin,[4] A.G. Garcia,[1] E.M. Rego[1]

[1]Medical School of Ribeirao Preto, USP, RIBEIRAO PRETO, Brazil [2]Invent Biotecnologia, RIBEIRAO PRETO, Brazil; [3]NIAID/NIH, BETHESDA, USA; [4]UNIFESP, SAO PAULO, Brazil

Background. Transfusion-Related Acute Lung Injury (TRALI) is a life-threatening complication of blood transfusion. Patients with TRALI present a rapid onset of respiratory failure that typically arises within two hours of the start of blood transfusion, with full presentation of the reaction occurring within six hours. Among the possible molecules triggering TRALI are leukocyte antibodies, present in fresh frozen plasma and platelet concentrates, and neutrophil priming agents released in stored cellular blood components. However, the pathogenesis of TRALI remains controversial. Two proposed pathophysiologic mechanisms for TRALI have received the most attention: the one-event and the two-event hypotheses, both leading to a final common pathway resulting in lung edema. *Aims*. Our aim was to develop mouse models of TRALI that simulated both hypotheses. In the first model we evaluated the role of human neutrophil-specific antibodies anti-HNA-2a in NOD/SCID mice as the single event causing TRALI. The two-event model was developed through the transfusion of Platelet Activating Factor (PAF) in Balb/c mice already primed with endotoxin. *Design and Methods*. In the first model (antibody model) we evaluated the *in vitro* effect of the interaction between human neutrophils and anti-HNA-2a monoclonal antibodies through the production of nitric oxide, hydrogen peroxide, cytokines and adhesion molecules expression. To the *in vivo* assays, human neutrophils expressing HNA-2a antigen, treated or not with anti-HNA-2α antibodies, were injected in NOD/SCID immunodeficient mice. Six hours after cells injection, mice were sacrificed and TRALI was determined by Evans blue dye leak in the bronchoalveolar lavage (BAL), cell influx, cytokines and chemokines (IL-1α, KC, MIP-2 e TNF-α) concentrations in the lung homogenate and the lung histology. In the second model (two-event model), Balb/c mice were treated (primed) or not with LPS and after two hours were i.v. inoculated with PAF. The animals were sacrificed 40 min after and the parameters analyzed were the same used for the first model. *Results*. In the one-event model, we detected an *in vitro* increase of IL-8 production and CD11b, CD18, CD54 e CD66b intensity of expression compared to control. In addition, we observed an *in vivo* increase of the vascular permeability and cell influx, measured by Evans Blue dye leak and lung MPO content, respectively, compared to control. These results were confirmed by histological analysis, which revealed intense vascular congestion neutrophil infiltrates in lungs. There were no significant differences on IL-1 and KC production, but we observed an increase on MIP-2 levels. Regarding to the two-event model there was a significant increase of the cell influx and lung permeability only in animals treated with LPS plus PAF. LPS+PAF treatment induced significant increased levels of TNF-α and MIP-2. Histological analysis revealed inflammatory infiltrates in animals treated with PAF and LPS+PAF. 5. *Conclusions*. The animal models described here support both theories of TRALI, the one and two-event, and demonstrated the essential role of neutrophils to inducing this syndrome. As observed in lungs of both models, the cellular infiltration and histopathological analysis corroborate with the arise of pulmonary permeability, what is similar to human TRALI.

AN ACTIVE HEMOVIGILANCE PROGRAM TO CHARACTERIZE THE SAFETY PROFILE OF 16,631 PLATELET COMPONENTS PREPARED WITH PHOTOCHEMICAL PATHOGEN INACTIVATION TREATMENT TRANSFUSED IN ROUTINE CLINICAL PRACTICE

J.C. Osselaer,[1] J.P. Cazenave,[2] P. Rasongles,[3] F. Knutson,[4] L. Lin,[5] L. Corash[5]

[1]Blood Transfusion Center, Clin Univ de Mont Godinne, Univ Cath de Louvain, YVOIR, Belgium; [2]EFS Alsace, STRASBOURG, France; [3]EFS La Reunion, SAINT-DENIS, France; [4]University Hospital, Clinical and Transfusion Medicine, UPPSALA, Sweden; [5]Cerus Corporation, CONCORD, USA

Background. Inactivation of pathogens and leukocytes in platelet components using amotosalen and UVA light (INTERCEPT') is in routine use in many European blood centers. An active hemovigilance (HV) program was implemented to characterize and extend the safety profile of INTERCEPT Platelets (I-PLT) in routine use. *Aims*. This report summarizes 16,631 I-PLT txn administered to 3,274 pts at 17 different sites in 8 different countries and provides a safety profile of I-PLT transfused in routine practice to a broad patient population. *Design and Methods*. Apheresis or buffy coats platelet components were leukoreduced, suspended in ~35% plasma and 65% InterSol', treated with the INTERCEPT and stored for up to 7 days depending on respective national regulations. INTERCEPT treatment replaced bacterial screening at all sites and γ irradiation for 97.5% (16,325/16,631) of I-PLT txn. Blood centers using INTERCEPT Platelets completed a data form after each txn regardless of whether a reaction occurred. The focus of these studies was response to txn within the first 24 hr regardless of outcome; and there was no time limit on reporting. A common INTERCEPT Hemovigilance Transfusion Report Form was utilized for all 3 studies. Investigators recorded: patient (pt) demographics, primary diagnosis and therapy, and type of I-PLT product. For each txn, the following data were collected: time of adverse event following txn, clinical description of event, objective clinical parameters (vital signs), clinical and laboratory data (radiographs, bacterial cultures), event severity (grade 0-4), serious or non-serious classification, and causal relationship to txn (unrelated, probably unrelated, possibly related, probably related, or related). *Results*. From October 2003 to the present, data from 16,631 I-PLT txn administered to 3,274 pts (60.3% males/ 39.7% females) have been collected. The majority of the recipients were hematology/oncology patients (1,643, 50.2%) many of whom received hematopoietic stem cell transplants s (n=307). The majority of I-PLT were administered in non-intensive care hospital units (13,152, 79.1%), and the remainder were transfused in intensive care units (2,496, 15%) and outpatient clinics (981, 5.9%). Transfusions associated with "related" (possibly related, probably related, or related) adverse events following I-PLT txn were infrequent (110/16,631=0.66%). Eighty-two pts (2.5%) experienced at least one related adverse event following one or more INTERCEPT txn. Most reactions were mild and of grade 1 severity and were representative of the events expected with conventional PLT txn. The most frequently reported signs/symptoms were chills, fever, and urticaria. Eleven SAE's were reported, with one having causal relationship (hypotension possibly related) to I-PLT txn. No cases of Transfusion Related Acute Lung Injury (TRALI), TA-GVHD, transfusion related sepsis or death due to an INTERCEPT txn were reported. *Conclusions*. In this program, 99.34% of I-PLT administrations were without a related txn reactions. Adverse events following I-PLT txn classified as related to txn were infrequent, mild in severity, and representative of the events expected with PLT txn. We believe that the use of an HV program to capture ongoing safety information is a valuable tool to characterize the safety of I-PLT.

1122

UNDERSTANDING AND MEETING CLINICAL PLATELET REQUIREMENTS: AN ANALYSIS OF INDICATIONS AND URGENCY OF PLATELET USE FROM THE PROSPECTIVE UTILISATION OF PLATELETS AND PLASMA (PUPPY) STUDY

N. Polizzotto,[1] N. Waters,[1] M. Comande,[1] G. Grigoriadis,[1] M. Borosak,[1] D. Jolley[2]

[1]Australian Red Cross Blood Service, MELBOURNE; [2]Monash University, MELBOURNE, Australia

Background. Meeting clinical requirements for platelet products requires an understanding of usage, in order to plan for evolving demand. Similarly, ensuring availability during emergencies may require triaging transfusion by restricting supply to clinically urgent cases or deferring elective surgery. However, few data are available to inform supply and contingency planning. *Aims*. To determine indications and urgency of platelet transfusions in Victoria, Australia *Design and Methods*. A random sample survey was performed with methods adapted from the Bloodhound study of red cell utilisation. From August 2008 to February 2009, 1257 platelet units (753 pooled, 476 apheresis, and 7x4 Paediatric Apheresis) were randomly tagged with the case report form (CRF) at production and distributed as usual. When issued for transfusion CRFs were completed by the issuing hospital scientist. *Results*. Interim analysis of the first 706 (56.2%) returned CRFs is presented. 447 (63.3%) were issued for transfusion; 243 (34.4%) expired at hospitals prior to use; 16 (2.2%) recalled or other disposal. Clinical conditions requiring transfusion included haematology/oncology in 287 cases (64.2%; this comprised 118 acute leukaemias [26.4% of total], 43 lymphoma [9.6%], myeloma 25 [5.6%], benign haematology 25 [5.6%] other malignancies 74 [16.6%], platelet disorders 2 ([0.4%]), cardiothoracic surgery 46 (10.3%), urolog-

ical surgery 22 (4.9%), gastroenterology 17(3.8%), solid organ transplant 13 (2.9%), trauma 11 (2.5%) and other or unknown in 51 (11.4%). In 118 cases (26.4%) transfusion supported surgery or an interventional procedure (78 major procedures [66.1%], 20 minor [21.2%], 10 line insertion [8.5%], 10 other or unknown [8.5%]); 37 (31.4%) of these procedures were elective. Clinical urgency of transfusion was acute (required in <1 hour) in 69 (15.4%); urgent (<24 hours) in 288 (64.4%); semi-urgent (<1 week) in 77 (17.2%) and unknown in 13 (2.9%); no transfusions were deferrable for over 1 week. Median platelet count prior to transfusion was $18x10^9$/L (IQR 11 - 45); median platelet count for non-surgical patients $15x10^9$/L, and for surgical patients $67x10^9$/L where reported, and median platelet doses issued was 1 (IQR 1 - 2). The recipient was actively bleeding in 106 cases (23.7%); febrile or septic in 112 (25.1%); receiving anti-platelet agents in 12 (2.7%) and undergoing cardiac bypass or extra-corporeal membrane oxygenation in 40 (8.9%). *Conclusions*. Clinical platelet usage is highly concentrated in specialised areas, predominantly to support patients with haematological and malignant disorders, those undergoing major surgery, and the critically ill. Changes in clinical practice in these areas may have a substantial effect on supply requirements. High levels of urgent transfusion and relatively low numbers of transfusions for elective surgery seen here, demonstrate that in a shortage conventional triage strategies would have little impact on requirements. Additional strategies are required to ensure continued adequacy of supply.

1123

A SELF-OPERATING PRETRANSFUSION BLOOD SAMPLING DEVICE FOR ENHANCED TRANSFUSION SAFETY: PROSPECTIVE PHASE II TRIAL IN EMERGENCY CARE.

M. Notter

Charité, BERLIN, Germany

Although blood safety with respect to infectious complications has reached very high standards, delayed or incorrect blood component administration due to human error still represents the greatest transfusion-associated risk. Pretransfusion blood sampling (PTBS) is a crucial upstream checkpoint in the process chain. In the setting of emergencies or disasters, infusion of colloidal plasma expanders and type 0 Rhesus negative red blood cell (RBC) concentrates potentially interfering with blood typing due to red cell pseudoagglutination or mixed-field agglutination, respectively, in theory ask for collection of the very first blood sample along with IV placement at the site of emergency. Vasoconstriction from hemorrhagic shock and unknown patient identity, however, are factors obviating PTBS. Retrospective analysis of 22 patients presenting with WHO grade 4 hemorrhage to a tertiary care emergency center revealed that the PTBS was performed in no instance at the site of trauma. The median time from admission to completion of blood typing was 26 minutes (range 13-61). 3 out of 7 severely traumatized and massively transfused patients suffering fatal outcome within 24 hours following admission had no pretransfusion sample taken necessitating transfusion with type 0 RBC concentrates throughout treatment. In one incidence, lack of PTBS contributed to delay in transfusion and death from hemorrhage. In order to facilitate PTBS at the scene of primary care a new IV catheter system was invented with an integrated blood reservoir containing EDTA anticoagulans. A flexible plastic band holds the reservoir attached to the patient and exerts a forcing function in a way that self-filling of the reservoir precedes intravenous catheter placement. Upon arrival at the hospital, the reservoir is labeled, disconnected from the patient and immediately sent to the laboratory for blood typing. A prototype version was tested in a randomized controlled phase II clinical trial. Outpatients with traumatic or internal hemorhage, and patients requiring emergent blood typing for other indications (n=90) were randomized to receive IV access using standard IV catheters or the new system. Handling of the self-sampling catheter was rated comparable to the standard in 90% of treatments by emergency physicians. Blood volumes collected with the emergency IV catheter were sufficient to allow for determination of red cell antigens including Rhesus subtypes, isoagglutinins, and irregular antibodies in 100%, 97%, and 60% of cases, respectively. Repeated blood typing from two truly independent venipunctures under emergency conditions occured in 5/6 patients needing immediate transfusions in the experimental arm as compared to 1/11 patients in the control group. The emergency catheter reduced the mean door-to-blood-type-time from 22.5 min (range: 13-121; n=45) to 15 min (range: 7-24; n=45; $p<0.001$).). In conclusion, the novel emergency IV catheter system has the potential to preserve pretransfusion blood sample unaffected by emergency medication at the scene. It thereby can improve transfusion safety by accelerating pretransfusion serology and by avoiding side effects from immunization and mistransfusion, in particular if targeted to areas where treatment is complex and urgent. It may help to protect the supply with valuable type 0 RBC concentrates in emergency and disaster management.

1124

EVALUATION OF THE CLINICAL SIGNIFICANCE AND RISK FACTORS FOR INTRA-VENOUS IMMUNE GLOBULIN INDUCED HAEMOLYTIC REACTIONS.

R. KOTB, J.A. Boisjoly, P. Beauregard

CHU de Sherbrooke, SHERBROOKE, Canada

Background. Hemolysis has been described as a complication of the use of Intravenous Immune Globulin (IVIG). In a report distributed in October 2005 by the IVIG manufacturer Talecris, and endorsed by health Canada, the estimated haemolytic reaction rate was 0.04%. Few other data described the average incidence and possible predisposing factors, and to date, there are no special recommendations to prevent this potentially serious complication. We describe our experience over the last 4 years and analyse the possible predictors of IVIG induced haemolytic reactions. *Patients and methods*. From January 2005 through November 2008, all patients receiving IVIG at the Sherbrooke University Hospital Center were identified, and all patients reported by our internal blood-product surveillance system to have had secondary hemolysis were analyzed. Hemolysis secondary to IVIG was defined as a reduction of haemoglobin with elevation of bilirubin and lactate deshydrogenase and appearance of a positive direct antiglobulin test (DAT) and/or a positive eluate and/or a positive screening for not previously diagnosed allo-antibodies. The hemolysis wasn't explained by other illness. Data collected included patient's demographic data, blood groups, clinical indication for IVIG, type of IVIG, total dose and administration schedule, documentation of IVIG-induced hemolysis and other possible causes that may obscure diagnosis, Hemoglobin (Hb) level changes over the period following administration of IVIG, DAT post IVIG and anti-erythrocyte antibodies specificities. Other biological parameters including serum lactate dehydrogenase, bilirubin, reticulocyte count, haptoglobin, C-reactive protein, ferritin, fibrinogen, albumin and creatinine were also analysed. *Results*. Over a period of 46 months, 359 patients received IVIG in our center. Secondary haemolytic reactions were reported for nine patients (2.5%), 2 males, 7 females, age range 0.7 - 86 years. 3 patients were treated for immune thrombocytopenia, 3 for Kawasaki syndrome, and the others were treated for guillian-barre syndrome, adult-onset still's disease and chronic inflammatory demyelinating polyneuropathy. The average total received IVIG dose was 3.4 g/kg body weight (1.67-6). The average decrease of haemoglobin level was 4.7 g/dL (1.4-6.6), and the average time to Hb nadir was 10.7 days (5-22). Six patients were of blood group A and three were of blood group AB. Eight patients presented positive DAT at the time of hemolysis, and all patients presented anti-A antibodies. One patient of blood group AB presented additional anti-D and anti-E antibodies, and another patient of the same blood group presented additional anti-B antibodies. There was no clear correlation with other analyzed biological parameters including inflammatory serologic markers. *Conclusion*. Our results underline the significance of post IVIG hemolysis in clinical practice. The reported incidence goes with two other recent studies presented late 2008, and reporting an incidence of 1.6 and 4%. This incidence is much higher than the previous data reported in 2005. In this study, patients of blood group A or AB, female patients, and patients receiving high dose IVIG seem to be at higher risk.

PROLIFERATIVE POTENTIAL OF HUMAN MESENCHYMAL STROMAL CELLS

D.A. Svinareva, I.N. Shipounova, N.V. Sats, T.V. Petrova, N.I. Drize

National Haematology Research Centre, MOSCOW, Russian Federation

Background. Mesenchymal stromal cells (MSCs) are multipotent adherent stromal cells, initially isolated from bone marrow (BM), able to differentiate along multiple cell lineages, such as osteoblasts, adipocytes and chondrocytes. Ability of MSCs to self-renew is not proved for human. *Aims*. The aim of the study was to investigate the proliferative potential of human donors MSCs, marked by lentivector, and of MSC from patients with aplastic anemia (AA). *Design and Methods*. BM cells were obtained from donors and AA patients after their informed concern, then 10^5 nucleated BM cells were seeded per cm^2 of culture flask. In 12-15 days confluent monolayer was treated with 0.05% trypsin+0.02 mM EDTA and the cells were reseeded at the density of 4500 per cm^2. The multilineage potential of MSC was evaluated on 1-4 passages by differentiation under proper stimuli. In 2-4 hours after first passage donors MSCs were infected with concentrated (10^8 viral particles/mL) self-inactivating (SIN) HIV vector harboring EGFP under the control of PGK promoter with polybrene for 6 hours. Adherent cell layers (ACLs) of 2-week old long-term BM cultures (LTBMCs) were infected with the same viral stock overnight. To clone MSCs, 1, 2 or 10 cells were seeded per well of 96-well plate. Irradiated with 40 Gy, MSCs were used as a feeder (1000 cells/well). ACL cells were trypsinized and plated 10000 cells/well of 96-well plate 2 weeks after the infection. *Results*. Cell growth kinetics did not differ in GFP-positive and negative MSCs. The number of marked MSCs slightly decreased during passages. The same is true for stromal cells from LTBMCs. The cloning efficiency of GFP-negative MSCs did not differ from GFP-positive (13.7±6.9% versus 14.5±7.0%). All MSCs clones were able to reach the confluence in the well of 96-wells plate after the cloning procedure, and then undergo 5 mitosis, but only 1 out of 22 clones was able to divide once more. Addition of bFGF to cultures did not increase the proliferative potential of MSC. Stromal cells from ACLs showed approximately the same proliferative capacity as MSCs independent of GFP expression. MSC from AA patients and healthy donors did not differ either. Time needed to form confluent monolayer from the initially seeded nucleated BM cells considered as passage zero (Po) was approximately the same for AA and donor cultures, moreover time to each next passage did not differ significantly. Cumulative cell production was also similar in both types of cultures for the first 6 passages. At that point donor MSC almost ceased growth; while AA MSCs continued to proliferate and were able to undergo at least 6 more passages, thus doubling total cell production. This phenomenon could be a consequence of increased bFGF expression in AA MSC when compared with donors (relative expression level in cultures from AA patients was 0.78±0.15, in cultures from donors 0.55±0.09). *Conclusions*. The data suggest that human MSCs have high but limited proliferative potential and are not able to self-renew in culture. MSC of AA patients proliferated longer than donor ones.

1126

SELF-RENEWAL EMBRYONIC GENES EXPRESSION IN ADULT HUMAN MESENCHYMAL STEM CELLS

T. Hassan

University of West of Scotland, PAISLEY, UK

Background. Adult human mesenchymal stem cells characterised by the expression of CD29, CD44, CD73 (SH3), CD90 (Thy-1), CD105 (SH2) and CD166 (ALCAM) were identified in 8 distinct adult tissues including bone marrow, mobilised peripheral blood, arterial endothelium, menstrual blood stroma, adipose tissue, eye conjunctiva and limbal stroma, lung bronchial fibroblasts and exocrine pancreas ductal epithelium. The human mesenchymal stem cells from these adult tissue sources undergo 40-70 doubling populations and differentiate into chondrocytes, osteoblasts and adipocytes in defined culture conditions. Recently, human mesenchymal stem cells from foetal (liver, haematopoietic tissues and amniotic fluid) and neonatal (amniotic epithelium and fluid, placenta decidua, umbilical cord blood and vien) tissues were shown to express key embryonic genes including Oct-4, Nanog-3, Rex-1, Sox-2, SSEA-4 and Bmi-1. *Design and Methods*. Therefore, the expression of self-renewal embryonic genes: Oct-4, Nanog-3, c-Kit and Rex-1 in human mesenchymal stem cells from the 8 adult tissue sources: bone marrow, mobilised peripheral blood, arterial endothelium, menstrual blood stroma, adipose tissue, eye conjunctiva and limbal stroma, lung bronchial fibroblasts and exocrine pancreas ductal epithelium was evaluated using immunoflourescence and immunocytochemistry. *Results*. Immunoflourescence and/or immunocytochemistry staining techniques in the presence of both positive and negative controls revealed the expression of Oct-4 and Nanog-3 in human mesenchymal stem cells from all 8 adult tissue sources, The c-Kit expression was found mainly in in bone marrow-, mobilised blood- and menstrual blood stroma-derived mesenchymal stem cells whilst Rex-1 in bone marrow- and eye conjunctiva stroma-derived mesenchymal stem cells. *Conclusions*. Adult human mesenchymal stem cells possess key self-renewal embryonic genes including Oct-4, Nanog-3, c-Kit and Rex-1 that play crucial role in maintaining their stemness to provide for cell regeneration and repair throughout the years of adult human life.

BONE MARROW ENDOTHELIAL CELLS IN CHILDHOOD MALIGNANCIES AND BLOOD DISEASES

E. Stiakaki, G. Martimianaki, H. Koutala, C. Perdikogianni, L. Kalmanti, M. Pesmatzoglou, M. Kalmanti

University Hospital of Heraklion, University of Crete, HERAKLION CRETE, Greece

Background. Endothelial progenitors cells (EPCs) are a heterogeneous subpopulation of bone marrow mononuclear cells, can differentiate into mature endothelial cells, circulate in the bloodstream, participate in endothelial homeostasis and stimulate the formation of new blood vessels. An increasing interest for their role in angiogenesis of ischemic tissues, tumor microenviroments and the course of hematologic malignancies is recently present. *Aims*. The study of bone marrow progenitors and mature endothelial cells (ECs) of children with blood diseases and cancer as well as the detection and characterization of the immunophenotype of their subpopulations. *Design and Methods*. Bone marrow cells from children with acute lymphoblastic leukemia (ALL) at diagnosis (ALL d, n=8), ALL high risk group under consolidation therapy (ALL HR, n=14), ALL during maintenance (ALL M, n=9), solid tumors at diagnosis without bone marrow involvement (ST, n=13) and children with idiopathic thrombocytopenic purpura (ITP, n=15) were studied. The determination of the putative antigenic phenotypes of EPCs and mature endothelial cells was performed by flow cytometry (Epics Elite Coulter) with the following combinations used: $CD133^+/VEGFR\text{-}2^+$, $CD34^+/VEGFR\text{-}2^+$, $CD34^+$ /VEGFR-2^+ /CD133-, $CD34^+/CD31^+/CD133$, $CD34^+/CD31^+$/ VEGFR-2^+, $CD34^+/CD146^+/CD31^+$, $CD34^+$/ $CD146^+$, $CD146^+/CD31^+$. The differences between groups were evaluated with the non-parametric Mann-Whitney test using the SPSS 16.0 program. *Results*. Endothelial progenitors and mature cells are adequately detected in the bone marrow by flow cytometry. The lower levels of $CD133^+/VEGFR\text{-}2^+$ endothelial progenitors were estimated at ALL diagnosis with statistical significant differences with the ALL -R (0.067±0.016 vs 0.37±0.1, p=0.030), ALL M (0.067±0.016 vs 0.39±0.17, p=0.029) and the solid tumors' group (0.067±0.016 vs 0.64±0.24, p=0.011) in which the highest value was determined. The solid tumors without bone marrow involvement has also the highest levels of CD34+/VEGFR-2+ endothelial cells with statistical difference comparing with the ALL HR (0.33±0.08 vs 0.2±0.08, p=0.026)and ITP (0.33±0.08 vs 0.14±0.037, p=0.007) patients in which group the lowest levels were estimated. The comparison between the ST and ALL HR revealed higher levels in the ST group of the $CD34^+/VEGFR\text{-}2+$ (0.33±0.08 vs 0.2±0.08, p=0.026), $CD34^+/VEGFR\text{-}2^+/CD133-$ (0.16±0.038 vs 0.07±0.019, p=0.047) and $CD34^+/CD31^+/CD133-$ cells (5.02±0.71 vs 1.69±0.34, p=0.001). Between the ST and the ALL M there was no statistical correlation for any endothelial cell subpopulation. The levels of $CD34^+/CD31^+/CD133-$

mature ECs were higher in ITP comparing with the ALL HR(4.36±0.7 vs 1.69±0.34, p=0.003). In the ITP group the lowest levels of the CD34+/VEGFR-2+/CD31+ (0.092±0.034 vs 0.28±0.096, p=0.003) and CD146+/CD31+ (0.45±0.096 vs 0.94±0.28, p=0.046) ECs were estimated and showed significant difference compared with the ALL M. *Conclusions*. A significant decrease of EPCs is evident at diagnosis of ALL, which is reversed in remission. In the ST group without bone marrow involvement the highest values of progenitors and mature endothelial cells are detected without statistical difference compared with ALL M. The role of these findings in the pathogenesis and course of the diseases has to be further investigated.

THE WASHOUTS OF DISCARDED BONE MARROW COLLECTION BAGS AND FILTERS ARE A VERY ABUNDANT SOURCE OF HMSCS EXPANDED IN GMP CONDITIONS

C. Capelli,[1] A. Salvadè,[2] O. Pedrini,[1] E. Gotti,[1] E. Biagi,[2] A. Rambaldi,[3] J. Golay,[1] M. Introna[1]

[1]Lab.Cellular Therapy G.Lanzani, BERGAMO; [2]Division of Pediatrics, Ospedale San Gerardo, MONZA; [3]USC Hematology, Ospedali Riuniti di Bergamo, BERGAMO, Italy

Background. Human Multipotent Mesenchymal Stromal Cells (hMSCs) are considered good candidates for a growing spectrum of cell therapies. We have validated, in two different Cell Factories which operate in strict GMP compliance, a protocol for the production of very large numbers of hMSCs for therapeutic use which makes use of the washouts of normally discarded collection sets left over at the end of the filtration of the bone marrow explants performed for hematopoietic stem cell (HSC) transplantation. This protocol reduces manipulation to a minimum and limits the use of animal and non clinical-grade reagents. *Design and Methods*. Total nucleated cells (TNC) were isolated both from unmanipulated bone marrow aspirates and from washouts of discarded bags and filters, left over after the filtration of whole bone marrow explants which is routinely performed before infusion to patients. Cells were seeded without any manipulation in 5% human platelet lysate (hPL) supplemented α-MEM. After 48 hours nonadherent cells were removed and the adherent cells were expanded for 7-14 days with periodic feeding. The cells were then harvested and seeded at low density (100-200 cells/cm^2) and allowed to expand for additional 10-20 days. Finally the cells were harvested and frozen. *Results*. In a median of 26 days, 14 bags for adult patients and 9 bags for pediatric patients for the standard dose of 1x10^6 hMSCs/kg body weight could be prepared from the expansion of a fraction of the cells recovered from 7 independent washouts. Moreover, 151 vials could be frozen from the remaining cells. The theoretical full expansion of all the frozen vials (validated by the expansion of 2 independent vials) could have allowed the production of 173 bags for adults and 348 bags for pediatric patients. Clinical scale expanded hMSCs identity and purity were assessed by testing viability and expression of CD14, CD34, CD45, CD73, CD90 and CD105. Cytogenetic analysis and clonogenic assay in methylcellulose were performed and no chromosomal alteration or tumorigenic trasformation has been revealed. Bacterial, fungal, mycoplasma and endotoxin contamination were tested by validated tests according to European Pharmacopea guidelines and always found negative. *Conclusions*. The washouts of discarded bags and filters left over at the end of the routine bone marrow explants filtration are a very abundant source of hMSCs precursors which can be easily utilised to produce large numbers of hMSCs clinical bags ready to use under strict adherence to GMP procedures.

1129

MAY THE C-FOS TO BECOME A NEW COMMON MARKER FOR MESENCHYMAL STEM CELLS ?

E. Karaoz, Z. Genç, S. Ayhan, A. Aksoy, A. Okçu, G. Gacar, M. Kasap

Kocaeli University, KOCAELI, Turkey

Background. The characteristics of mesenchymal stem cell (MSC) populations obtained from different organs are very similar, suggesting a closer relationship among them. However, a definitive molecular marker of MSCs remains obscure. The surface proteins such as CD29, CD44, CD90, CD105, CD106 and CD166 in particular, have been used to characterize MSCs. None of these markers are solely specific for MSCs. Transcriptor factor AP-1 (activator protein-1) consists of Fos proteins (c-Fos, Fos B and Fra 2), which are nuclear protein products of c-fos genes belonging to intermediate early genes (IEGs). AP-1 components are specific for some biological processes including cellular proliferation, differentiation, apoptosis and oncogenic transformation. Particularly, c-fos gene has been associated with the coordinated regulation of gene expression during cellular proliferation and differentiation. Therefore, we hypothesized that c-fos may be a good candidate to become a new common marker for MSCs. *Aims*. The objective of this study was to look for a new marker that might be used to characterize the mesencymal stem cells. To reach this objective, the expression of c-fos was analyzed in MSCs from human-derived bone marrow (hBM), cord blood (hCB), dental pulp (from impacted third molars and exfoliated deciduous teeth) (hDP), periodontal ligament (hPDL), adipose tissue (hAT), endometrium (hE), amniotic fluid (hAF) and placenta (hPL) by using RT-PCR and immunocytochemistry. *Design and Methods*. The expressions of CD10, CD11b, CD13, CD14, CD15, CD19, CD33, CD34, CD44, CD45, CD73, CD90, CD117, CD146, CD166, and HLA-DR were analyzed in isolated MSCs from various human derived- organ or tissues by using flow cytometry. Similarly, these cells were analyzed for CD31, CD34, CD44, CD71, CD105, vimentin, fibronectin, β-tubulin, α smooth muscle actin (α-SMA), actin, desmin, and c-fos by using immunohistochemical/immunofluorecence techniques. Total cellular RNA isolated from human derived- MSC cultures (from passage 3) was reverse transcribed the resultant cDNA was used in PCR with the following primers: c-fos forward: AGAATCCGAAGGGAAAGGAA; c-fos reverse: CTTCTCCTTCAGCAGGTTGG. GAPDH was used as an internal control. Potential for multilineage differentiation were determined. *Results*. The expression of surface antigens (hBM, hCB, hDP, hPDL, hAT, hE, hAF and hPL expressed CD10, CD13, CD44, CD73, CD90, CD146 and CD166, but not, CD11b, CD14, CD15, CD19, CD33, CD34, CD45,CD117, HLA-DR) and human tissues expressed specific markers including vimentin, fibronectin, β-tubulin, α-SMA, actin, desmin in MSCs used in this study indicated their undifferentiated state. In addition the cells possessed morphological characteristics and multilineage differentiation potential. The same cells strongly expressed c-Fos as shown by immunohistochemical staining and RT-PCR which were not reported elsewhere. *Conclusions*. In our study, high expression of c-fos antigen in human derived MSC lines when examined with immunohistochemical and molecular methods provided clues that c-fos may be used as a new stem cell marker.

1130

ISOLATION, CHARACTERIZATION AND DIFFERENTATION POTENTIAL OF HUMAN AMNIOTIC FLUID DERIVED MULTIPOTENT MESENCHYMAL STEM CELLS

A. Eker Sariboyaci,[1] A. Okcu,[1] S. Kokturk,[1] G. Gacar,[1] M. Kasap,[1] P. Cetinalp Demircan,[1] E. Caliskan,[2] C. Ozogul,[3] E. Karaoz[1]

[1]Kocaeli University Stem Cell and Gene Therapies Research&Applied Center, IZMIT/KOCAELI; [2]Kocaeli University, Medical Faculty, Department of Obstetrics and Gynecology, IZMIT/KOCAELI; [3]Dokuz Eylul University, Medical Faculty, Department of Histology and Embryology, IZMIR, Turkey

Background. Up to now, some reports exist regarding the characterization of human amniotic fluid cells (hAFCs) that should be considered as an interesting new source of prenatal stem cells (SCs) devoid of ethical issues involved in embryonic SC research. Recent studies reported that hAF obtained by amniocentesis, during treatment of polyhydramnios, and at caesarean section contain fetal MSCs with a multilineage differentiation potential and derived embryonic and extra-embryonic tissue. hAF is significant due to routinely obtain from spare source after birth utilizing minimally invasive or noninvasive tecnique and rich source of SC. Further studies of hAF derived MSCs of classification, characterization, and biology are necessary. *Aims*. To establish a new source of therapeutic cells, we aimed to isolate hAF-MSCs from AF obtained during treatment of polyhydramnios at 27-32 weeks of pregnancy, and to further characterize these cells by investigating their immunophenotypes, the *in vitro* growth kinetics, replicative lifespan, morphology and differentiation potential throughout their existence. *Design and Methods*. Ten millilitres of hAF samples were obtained from polyhydroamnios patients during removal excessive amniotic fluid for routine therapy at 27-32 weeks of pregnancy. hAF samples were centrifuged at 300g for 15 min, and the resulting pellets washed twice with MEM-Earle to remove blood and cell debris. All of the cells isolated from samples were plated in a 25 cm^2 culture flask containing MEM supplemented with 100U/mL penicillin, 0.1 mg/mL streptomycin, and 15% FBS. Viability and proliferation index of the cells were determined using conventional hemocytometric method and MTT Cell Growth Assay. The ability of ex vivo expansion was investigated until senescence, and stem cell-like characteristics were analyzed by examining immunophenotypic features, differentiation potential and messenger

RNA expression (RT-PCR) of the cells at each passage 1-10. Lastly, we analyzed ultrastructural and differentiation characteristics of MSCs. *Results*. Our data indicated that MSCs from hAF expressed CD13, CD44, CD90, CD166 and Oct-3/4, but not, CD11b, CD14, CD15, CD19, CD33, CD34, CD45, CD117, HLA-DR, TR-1-60, TR-1-81, SSEA-4 and consistent with their undifferentiated state. In the IHC examination; hAF-MSC's showed negative immunoreactivity for CD34, CD31, CD71, and showed positive immunoreactivity for CD105, nestin, fibronectin, vimentin, c-fos, tubulin-β, α-smooth muscle actin, desmin, osteocalcin, osteonectin, and γ-enolase. Gene expression studies confirmed this immunophenotypic data. These cells were successfully differentiated into adipogenic, osteogenic, chondrogenic, neurogenic and myogenic lineages. *Conclusions.* Our study has provided evidence that: (i) hAF-MSCs are a promising source due to their high proliferation ability; (ii) hAF-MSCs could differentiate to many kinds of cells including osteocyte, chondrocyte, adipocyte, neuro/glial cell and myocyte, and could be obtained and duplicated easily; (iii) the expression of embryonic stem cell marker such as oct3/4 is required for the maintenance of somatic stem cell properties; (iv) they could be easily used as a convenient resource for future medical trials.

HAEMATOPOIETIC PROGENITOR CELLS (HPC) FROM HUMAN PRENATAL AND POSTNATAL CORD BLOOD

A. Soyano,[1] A. Müller,[2] A.E. Soyano,[3] F. Guevara,[4] B. Martínez[4]

[1]Venezuelan Institute for Scientific Research, CARACAS; [2]Institute of Hematology and Oncology, CARACAS; [3]Clínica Ávila, CARACAS, Venezuela; [4]Cátedra de Obstetricia, CARACAS, Venezuela

Background and Aims. Human haematopoietic progenitor cells (HPC) obtained from adult peripheral blood and from postnatal cord blood have been used to treat several hematological conditions. In this study, the presence of HPCs were evaluated in prenatal (intra uterus) and in postnatal cord blood (obtained immediately after delivery) using hematological and immunological tests. *Design and Methods.* Prenatal cord blood (32 samples) was obtained by cordocentesis through intrahepatic vein puncture guided by ultrasound, from pregnancies of 16-32 weeks of gestational age. In all cases, conditions such as congenital fetal malformation, sensitization due to Rh incompatibility, maternal age over 35 years in the first pregnancy or congenital rubella were suspected. 2. Postnatal cord blood (35 samples) was obtained immediately after delivery from placentas of normal pregnancies. The following tests or parameters were performed or detected on all samples: Hb, hematocrit, Hb electrophoresis, FACS immunophenotyping studies with the following monoclonal antibodies: HLA-Dr, CD2, CD4, CD5, CD8, CD10, CD11b, CD13, CD,14, CD 19, CD20, CD33, CD34, and CD35. To differentiate subtypes of CD34+ cells the following reagents were used: CD34PE / CD33-FITC and CD34PE / HLA-Dr-FITC. Some of the cord blood cell samples were cultured in semisolid medium in the presence of erythropoietin and IL-3. *Results*. Prenatal cord blood (16-32 weeks of gestation) showed higher values of Hb and haematocrit as compared to postnatal cord blood, associated with extensive macrocytosis (mean VCM in 25 samples: 132 fl at 16-20 weeks of age). Immuno-phenotyping of prenatal cord blood cells allowed the identification of leukocytes (CD45+ and HLA-Dr+ cells), T-lymphocytes (CD2+, CD4+ and CD8+ cells), B-lymphocytes (CD10+, CD19+ and CD20+ cells), cells expressing myeloid markers (CD13+, CD14+ and CD33+ cells), and haematopoietic progenitor cells ((CD34+ cells). The number of CD34+ cells showed a maximal value of 4.35% in a sample of 16 weeks of age of gestation, with a tendency to decrease as the pregnancy progressed. In postnatal cord blood the value of CD34+ cells was 0.85%±0.28, most of them of the CD34+ / CD33- phenotype. Both, prenatal and postnatal cord blood, when cultured in semisolid medium, generated erythroid and granulocytic-macrophagic colonies after 7 days of incubation. The earliest samples of cord blood showed more colonies than the older samples. *Conclusions*. Haematopoietic progenitor (CD34+) cells and various types of mature leukocytes can be easily identified in fetal blood obtained from 16-32 week-old pregnancies. The higher value of CD34+ progenitor cells was detected in samples from the 17th week, and the lowest in samples of postnatal blood.

1132

COMPARATIVE ANALYSIS OF MESENCHYMAL STEM CELLS FROM BONE MARROW, DENTAL PULP, ADIPOSE TISSUE AND ENDOMETRIUM

E. Karaoz, A. Aksoy, Z. Genç, S. Ayhan, G. Gacar, A. Okçu, P. Demircan, E. Çaliskan, A. Sariboyaci

Kocaeli University, KOCAELI, Turkey

Background. Several studies have reported the *in vitro* expansion of mesenchymal stem cells (MSCs) from human bone marrow (hBM), dental pulp (from impacted third molars-hDP- and exfoliated deciduous teeth-hSHED), adipose tissue (hAT) and endometrium (hE) and differentiation of these MSCs into multilineage cells. However, MSCs from these different sources have different characteristics. *Aims.* The present study aimed at providing a detailed morphological, immunophenotypical, and growth kinetics of MSCs from five sources using flow cytometry, immunocytochemical techniques and MTT test. *Design and Methods.* MSCs from various human derived- organ or tissues were isolated using appropriate methods. Isolated MSCs analyzed for CD10, CD11b, CD13, CD14, CD15, CD19, CD33, CD34, CD44, CD45, CD73, CD90, CD117, CD146, CD166, and HLA-DR by using flow cytometry. Similarly, these cells were analyzed for CD31, CD34, CD44, CD71, CD105, vimentin, fibronectin, β-tubulin, α smooth muscle actin (SMA), actin, desmin, myogenin, myosinIIa, myoD, osteonectin, osteocalcin, osteopontin, MEPE, BMP-2, BMP-4, collagen type I and II, γ-enolase, βIII-tubulin, neurofilament, GFAP, MAP2a,b, HNK-1ST, nestin and c-fos by using immunohistochemical techniques. Analysis of MTT was made using MTT Cell Growth Kit on passage 3 cultures of MSCs for 1, 4, 7, 11, 14, 17 and 21 days. *Results*. Our data indicated that MSCs from various human derived tissues including hBM, hDP, hSHED, hAT, and hE expressed CD10, CD13, CD44, CD73, CD90, CD146 and CD166, but not, CD11b, CD14, CD15, CD19, CD33, CD34, CD45,CD117, and HLA-DR, consistent with their undifferentiated state. The MCSs of this study isolated from human tissues expressed specific markers including vimentin, fibronectin, β-tubulin, α-SMA, actin, desmin, and possessed morphological characteristics and multilineage differentiation potential. The expression of surface antigens in MSCs agreed with the previous reports regarding MSCs, and indicated that the cells used in our study had the characteristics of MSCs reported elsewhere. In the present study, MSCs expressed some antigens which are indicators of glial and neuronal (γ-enolase, MAP2a,b, βIII- tubulin and GFAP), myogenic (myogenin, myosinIIa, desmin, actin and α-SMA), osteogenic (osteonectin, osteocalcin, osteopontin, type I collagen, BMP-2 and BMP-4) and chondrogenic (type II collagen) differentiations without a need for induction. According to the results of MTT test, MSCs derived from hSHED posses the highest proliferation potential, followed by MSCs derived from hDP, hAT, hBM and hE. *Conclusions*. In our study , MSCs have been conventionally isolated from various tissues and organs including bone marrow, dental pulp, adipose tissue, and endometrium, and these cells had similar morphology and, to a certain extent, immunophenotipic characteristics. Similar findings suggested that these cells were basically the same, although small differences that probably reflect a specialized gene program related to their anatomic localization were observed. When proliferation index was considered, an order of hSHED >hDP>hAT>hBM>hE was observed. Both dental pulp and adipose tissue are attractive to bone marrow as sources for isolating MSCs.

1133

FOXP1 IS PRESENT IN NON-LYMPHOID HEMATOPOIESIS

P. Korac,[1] E. Lovric,[2] K. Horvat,[1] M. Dominis[1]

[1]University Hospital Merkur, ZAGREB, Croatia; [2]County Hospital "Cakovec", CAKOVEC, Croatia

Background. FOXP1 gene is located on chromosome 3, region p14.1. Immunoenzymatic staining of normal tonsil shows FOXP1 in nucleus of mantle zone cells, scatered B-cells inside some germinal centers and few B-cells in T-cell area. After the activation of B lymphocytes higher amounts of its mRNA were observed. It was also suggested that FOXP1 has an essential role in B-cell development and that it is one of the most important transcription regulators in those cells. There are no data about FOXP1 protein presence and/or function in myeloid and erythroid cell linages. *Aims*. To investigate FOXP1 presence in non-lymphoid hematopoiesis. *Design and Methods*. 15 bone marow trephine samples were taken from patients with no hematopoietic malignancies. Immunohistochemical double staining was performed on 4 mm tick, formalin fixed paraffin embedded bone marrow trephine sections according to the protocol provided by the manufacturer of the visualization LSAB/HRP

and LSAB/AP kits (Dako, Glostrup, Denmark). Anti-FOXP1 antibody (JC12) was used in combination with anti-glycophorin C or anti-myeloperoxidase antibodies. *Results*. All 15 samples showed similar results. 60-90% of all cells that had glycophorin C expression showed JC12 immunostaing. 80-90% of all cells that had myeloperoxidase expression showed JC12 immunostaing. All samples with both staining combinations had cells of lymphocyte morphology that were JC12 positive and glycophorin C/myeloperoxidase negative. The reliability of both double staining was confirmed by repeated double blind reading. *Summary and Conclusions*. Presented data suggest presence of FOXP1 protein and its possible function in developmental stages of myelopoiesis and erythropoiesis.

1134

STEM CELL - PLATELET COMPLEXES IN STEM CELL PRODUCTS

S.E. Kraus,[1] Y. van Hensbergen,[2] J.J. Zwaginga[3]

[1]Sanquin / LUMC, LEIDEN; [2]Sanquin Blood bank South West Region, LEIDEN; [3]LUMC / Sanquin Blood bank Northwest West Region, LEIDEN, Netherlands

Background. Activated platelets express P-selectin (CD62P). The binding of this P-selectin to its ligand PSGL-1 , results in complex formation between activated platelets with most white blood cells. Monocytes-platelet complexes(PMCs) in this respect are most known and shown to have a pro-adhesive phenotype by the platelet expressed P-selectin but additionally by increased β1 and 2 -integrin-expression on the monocyte. Stem cell products contain blood platelets in huge quantities; therefore platelet- stem cell complexes (PSCs) may also be formed. We hypothesize that such a platelet binding may similarly influence the adhesion (and homing) capacity of stem cells and possibly their differential behavior. *Aims*. To study:a. the extent of PSC complex formation in different stem cell products and the role of the CD62P-PSGL-1-axis in this respect; and b. the influence of anticoagulation, storage time and the extent of platelet activation on this complex formation. *Design and Methods*. PSC occurrence was measured in citrate anticoagulated mobilized peripheral stem cell transplants (MPSCT) and umbilical cord blood (UCB), as well as in heparin anticoagulated bone marrow (BM). Flowcytometry measured particles that were double positive for CD45, CD34 on one hand and CD61 (platelet glycoprotein IIbIIIa) and CD62P on the other hand were considered to reflect PSC. CD14- CD61 positive events were considered as platelet/ monocyte complexes. Complexes were measured at t=1 and 24 hours. Addition of anti-CD62P or EDTA (15 minutes resp 1 hour incubations) were used to investigate if PSC formation could be blocked or disrupted .

Table 1. PSCs and PMCs in different sources.

	MPSCT	BM	UCB
% PSC ± S.E.M	18,4 ± 6,4	9,4 ± 3,1	7,5 ± 1,6
+ 24 hours	37,4 ± 15,0 *	11,5 ± 3,5	8,5 ± 1,8
+EDTA	16,6 ± 5,2	5,1 ± 1,0	7,8 ± 2,8
+Activation	27,8 ± 13,5 *	16,4 ± 4,4	6,9 ± 0,8
% PMC ± S.E.M	89,4 ± 5,4	71,8 ± 29,4	98,0 ± 1,5
+ 24 hours	97,3 ± 1,4 *	83,4 ± 24,0	99,5 ± 0,6 *
+EDTA	14,3 ± 3,0 *	4,5 ± 2,0*	4,4 ± 2,0 *
+Activation	94,8 ± 5,7 *	73,0 ± 29,3	98,1 ± 1,5

Additional PSC formation was attempted by addition of 10E-4M ADP, a naturally occurring platelet activator. *Results*. All products contained PSCs and PMCs (Table 1). PSC numbers increase about 50% in time (24 hrs) in MPSCT (p=0.002) and to a lesser extent in BM and UCB (both p=0.1). PMCs showed a vast increase in time in MPSCT and UCB (p=0.004 res$p$=0.03) but not in BM (p=0.24). ADP-mediated platelet activation resulted in an increase in both PSC and PMC in MPSCT (p<0.006 resp.p=0.03). No additional effect of platelet activation on PSC or PMC was observed in BM and UCB (p=0.25 resp p=0.7 for PSCs; p=0.3 resp p=0.97 for PMC). PSC-increase in time and after platelet activation was successfully inhibited by anti-CD62P in MPSCT and to a lesser extent in BM and UCB (not shown). In contrast, addition of anti-CD62P effectively inhibited increase in PMC in time as well as after platelet activation in all sources as compared to control samples. No EDTA-effect was found for PSCs in all sources while in all products samples PMCs dissociated after adding EDTA (MPSCT p<0.0001, BM p=0.02 and UCB p<0.001). *Conclusions*. Both PSCs and PMCs are present in different stem cell products. Our results confirm that PSC- formation is CD62P-dependent. Additional platelet activation and longer storage time can increase PSC upto 30-40% in MPSCT products. Further studies are necessary to study the differences between CD34+ stem cells in the different products for their complex forming capacity and the role of PSCs in the efficacy of stem cell transplantation.

1135

COMPARATIVE ANALYSIS OF RAT BONE MARROW-DERIVED MESENCHYMAL STEM CELLS CULTURED UNDER DIFFERENT CONDITIONS

E. Karaoz,[1] S. Köktürk,[1] A. Sariboyaci,[1] M. Kasap,[1] G. Gacar,[1] P. Demircan,[1] A. Okçu,[1] Y. Yazir,[1] C. Ozogul[2]

[1]Kocaeli University, KOCAELI; [2]Dokuzeylül Universtity, Faculty of Medicine, IZMIR, Turkey

Background. Mesencymal stem cells (MSCs) are multipotent cells and can differentia into multiple lineages. These properties allow for an autologous cell source, which in some cases circumvents host immune response issues, and make them a good candidate for potential therapeutic applications such as cellular and gene therapies. In general, MSCs have been successfully isolated by two different culturing techniques: (i) gradient density centrifugation and (ii) direct flushing into culture flask with plastic adherence from the BM of many mammals from human to laboratory rodents. However, culture medium compositions showed differences from one study to another and media like IMDM, DMEM/F12, DMEM, L-DMEM, H-DMEM, α-MEM, and RPMI 1640 were used with different percentages of fetal bovine serum (2, 5, 10, 15 and 20 %). From these studies, contradictory results about the need for the number of passages to obtain the highest immunophenoypically-pure MSC came out. *Aims*. In this study, we cultured MCSs isolated from bone marrows of rats in three different media (RPMI 1640+10% FBS, MEM-Earle+15%FBS and L-DMEM+10% FBS) to determine the number of passages necessary to obtain the highest immunophenoypically-pure MSCs. *Design and Methods*. MSCs have been successfully isolated from femurs and tibias bone marrow of adult Wistar rats by direct flushing method with adherent properties. After each passage, cell suspensions were analyzed by using flow cytometry. Similarly, the cells were analyzed for CD31, CD34, CD44, CD71, CD105, vimentin, fibronectin, β-tubulin, α-smooth muscle actin (SMA), actin, desmin, nestin and c-fos by using immunohistochemical techniques. Viability of MCSs and their proliferation ability were determined with MTT and pulsed BrdU incorporation. Lastly, we analyzed ultrastructural and differentiation characteristics of MSCs. *Results*. When proliferation index was considered, an order of MEM> L-DMEM > RPMI-1640 was observed in MTT analysis. The expressions of the cell surface proteins such as CD29 (positive), CD45 (negative) and CD90 (positive) did not show differences under three different culture conditions throughout passages 1 to 20. However, CD45 expression of MSCs increased significantly in MEM medium after passage 20 and both in RPMI and LDMEM media after passages 30. This increase might be due to *in vitro* maturation of MSCs. In addition, our immunohistochemical studies and differentiation experiments showed that the cells expressed the other markers that were specific for MSCs. These cells were successfully differentiated into adipogenic, osteogenic, neurogenic and myogenic lineages. There was no difference observed in ultrastructural properties when cells were grown in three different media. *Conclusions*. This study clearly demonstrated that cells from early passages should be used in stem cell research due to heterogeneity problem of the cells in late passages. MEM as a culture medium is a good candidate for two reasons; (i) cultured MSCs have high proliferation capacity in this medium (ii) it is much more economical. However, other media (L-DMEM and RPMI) should also be considered when immunophenotypically more stabile passages were aimed at.

Funding: this study was supported by a grant [107S276] of the Scientific and Research Council of Turkey (TUBITAK).

BONE MARROW METASTASES OF NEUROBLASTOMA DETECTED BY IMMUNOHISTOCHEMICAL STAINS: CHROMOGRANIN A, CD56, AND SYNAPTOPHYSIN

S. Park, C.J. Park, S. Kim, S.S. Jang, H.S. Chi, H.J. Im, J.J. Seo

University of Ulsan College of Medicine and Asan Medical Center, SEOUL, South-Korea

Background. Neuroblastoma is one of the most frequently occurring malignant solid tumors in childhood. Evaluation of the bone marrow

(BM) is an important part of clinical staging in neuroblastoma patients because with the presence of BM metastasis, the patient is classified into stage IV or IV-S neuroblastoma. Due to the difficulty in detecting neuroblastoma cells with conventional bone marrow aspirate smears and biopsy specimens, especially in cases where metastases is not prominent, we proposed immunohistochemistry (IHC) as a potential diagnostic tool. *Aims.* The purpose of our study was to evaluate the application of three neuroendocrine markers (chromogranin A, CD56, and synaptophysin) for detecting minimal metastatic neuroblastoma in bone marrow specimes. *Design and Methods*. We studied 59 patients that were newly diagnosed with neuroblastoma between January 1998 and March 2008. A total of 102 BM biopsy and clot sections that consisted of 16 unilateral and 42 bilateral samples were evaluated. Immunohistochemical stains using chromogranin A, CD56, and synaptophysin monoclonal antibodies were done on the Benchmark XT auto-stainer (VENTANA, Tucson, USA). *Results*. Fifteen out of 59 patients (25.4%) had been diagnosed as having bone marrow metastasis. Immunohistochemical staining of clot sections were generally more sensitive than biopsy or aspirate smears for detecting tumor cells. Clot sections stained with chromogranin A identified tumor cells in all H&E-positive specimens as well as 8 additional H&E-negative specimens. Chromogranin also had the lowest false-negative result (H&E positive, IHC negative; n=1) among the three IHC methods. Adding the H&E-/IHC+ cases to the detection rate showed that using a combination of chromogranin A and CD56 was superior in detecting bone marrow metastasis. *Conclusions*. Immunohistochemical analysis of bone marrow specimens is more sensitive than conventional analysis and using a combination of chromogranin A and CD56 appears to be the most sensitive method for detecting neuroblastoma cells. To overcome the discrepancies between routine smears and immunohistochemial stains (H&E negative, IHC positive), immunohistochemical analysis of the bone marrow biopsy and clot sections should be warranted as a routine component in the diagnostic work up of neuroblastoma.

1137

IN VITRO INDUCTION OF FETAL HEMOGLOBIN BY TRANSFORMING GROWTH FACTOR-B AND STEM CELL FACTOR IN ERYTHROID CELLS DERIVED FROM CD133+ CELLS

S. Kaviani,[1] A. Atashi,[1] M. Soleimani,[1] M. Noruzinia,[1] A. Hajfathali[2]

[1]Tarbiate Modares University, Medical Sciences faculty, Hematology Dept., TEHRAN, Iran; [2]Shahid Beheshti Univ. of Medical Scienses, Taleghani Hospital, Hematology Dept., TEHRAN, Iran

Background. Increased fetal hemoglobin (HbF) in β-globin gene disorders, ameliorates the clinical symptoms of the underlying disease. 5-azacytidine, butyrate and Hydroxyurea, have been shown to activate β-globin gene expression. Also, It has been shown that hematopoietic growth factors can influence expression of β-globin in erythroid culture and in animal models. *Design and Methods*. This study was designed for *in vitro* evaluation of stem cell factor (SCF) and transforming growth factor-β (TGF-β) on β-globin gene reactivation of erythroid precursors derived from CD133+ cells *in vitro*. *Results*. The gene expression analysis showed increased expression of β-globin transcript in all groups (the cell culture groups containing TGF- β or SCF or both) as compared with control (2.2, 2.7 and 5.5 folds, respectively) (p<0.01). Also, HbF production in differentiated population was demonstrated using flow cytometry. *Conclusions*. In conclusion, the results of this report suggests that SCF and TGF-β warrant further evaluation as potential therapeutic drugs for treatment of β-globin gene disorders.

1138

DYNAMICS OF DONOR T CELL ACTIVATION DURING EARLY PHASE OF GRAFT VERSUS HOST DISEASE (GVHD): DONOR ANTIGEN PRESENTING CELLS CAN ACTIVATE ALLOGENEIC T CELLS

B. Sadeghi,[1] S. Al-Hashmi,[1] Z. Hassan,[1] C. Lundmark,[1] H. Concha,[1] B. Rozell,[1] M. Abedi-Valugerdi,[2] M. Hassan[1]

[1]Karolinska Institute, STOCKHOLM, Sweden; [2]Stockholm University, STOCKHOLM, Sweden

Background. Bone marrow transplantation (BMT) is increasing rapidly as a curative treatment; however, graft versus host disease (GVHD) is one of the major limiting factors. GVHD is basically an uncontrolled immune response of donor T-cells against host alloantigen. Pre-transplant conditioning is important factor in GVHD initiation; however its occurrence depends mainly on the immune compartments regardless the type of conditioning. The role of host antigen presenting cells in the activation of donor T cells has been reported previously. *Aim*. In the present investigation we tracked host versus donor immune cells in a chorological approach to determine the phenotypical and biological activation pattern at early stage of GVHD. *Design and Methods*. Female and male BALB/c and C57BL/6 mice were used as recipient and donor. Recipient mice were conditioned using busulfan and cyclophosphamide, and were transplanted using allogeneic or syngeneic donors. Recipients were killed at early time points post transplantation (day 0, +1,+3,+5,+7 and +21); immune cells phenotype and function were evaluated in spleen and bone marrow. Cytokine levels in serum were measured using multiplex fluorescence assay. To confirm the emergence of GVHD and T-lymphocyte infiltration, various tissues including spleen were examined utilizing histopathology and immunohistochemistry. *Results*. GVHD occurred 7 days after allogeneic BMT. Donor dendritic cells (DCs) actively expanded and matured early after allo-BMT (day+3) followed by a short period of host DCs expansion. Expansion of donor DCs was significantly higher (p<0.05) compared to host DCs three days after BMT. T-cells repopulation was similar in both allogeneic and syngeneic transplanted groups until day+3. However, five days after BMT donor CD8+ cell expansion in GVHD group was as high as 230% compared to that observed in control untreated group and 700% higher compared to CD8+ cells found in syngeneic transplanted mice. Dramatic expansion of donor T-cells in GVHD mice followed the peak expansion and maturation of donor DCs. IL2, IFN-γ and TNF-α were found to be at the highest level 5 days after BMT which was in agreement with T-cell activation. Following this activation most of naïve T-cells gained effector-memory phenotype and migrated from the spleen to periphery. *Conclusions*. Tracking of host versus donor immune cell at early phase of GVHD have shown that donor DCs has essential role in the activation of alloreactive donor T-lymphocyte. Moreover, during the activation phase of T-cells in the spleen donor naïve cells gain effector-memory phenotype and initiate GVHD.

1139

FACTORS ASSOCIATED WITH SEVERITY OF MUCOSITIS AFTER REDUCED-INTENSITY-CONDITIONING FOR ALLOGENEIC STEM CELL TRANSPLANTATION

W.H. Krüger, H. Wilfert, T. Kiefer, T. Neumann, C. Busemann, G. Dölken

University-Hospital Greifswald, GREIFSWALD, Germany

Chemotherapy-induced mucositis is associated with considerable morbidity. Furthermore, breakdown of the mucosal barrier allows bacteria easy penetration into tissue and bloodstream. Severity of mucositis in allogeneic stem cell transplant (SCT) recipients is less intensive after reduced-intense-conditioning (RIC) protocols compared to classic myeloablative conditioning, however, even after RIC severe mucositis may occur. *Aims*. The aim of the present investigation was to identify factors influencing the severity of oral mucositis after reduced-intense-conditioning for allogeneic stem cell transplantation. *Design and Methods*. 52 patients [male: n=35 (67%), female: n=17 (33%)] with a median age of 62 years (35-73) underwent allogeneic SCT between 2005 and 2008. Conditioning was either TBI(2Gy)/Fludarabine (n=33, 63.5%) or chemotherapy based (treosulfan/fludarabine, melphalan/fludarabine, cyclophosphamide/fludarabine). ATG was given in cases of transplantations from mismatched or unrealated donors (n=44, 85%). GvHD-prophylaxis was carried out with cyclosporine-A and - depending on the protocol - with MMF. Additionally, 45 patients (87%) received short-course MTX. Supportive therapy, anti-infectious therapy and prophylaxis followed standard protocols. Palifermin was given in five cases (10%). Mucositis was graded according the Bearman- and WHO-scale. A variety of clinical and laboratory parameters was correlated with severity of mucositis. *Results*. Both mucositis scales showed an excellent correlation (cc=0,95, p<10e-20, Spearman-rank correlation). The mucositis was significantly more severe after chemotherapy-based conditioning compared to conditiong with TBI(2Gy)/Fludarabin (p<0.002, Mann-Whitney U-test) and when the serum-creatinin was above the upper normal value on day +3 after SCT (p<0.05). Furthermore, the severity of mucositis correlated with time to engraftment of leucocytes (cc=0,26, p<0.02) and thrombocytes (cc=0.38, p<0.001). Other parameters such as the number of preceding therapy lines, the interval from last therapy to conditioning, the use of ATG, voriconazole or TMP-SMZ, a weight gain after SCT, pathological liver parameters or patients age were not associated with the grade of mucositis. *Conclusion*. Mucositis contributes to morbidity after SCT, even after reduced-intensity conditioning. The condition regimen was identified as the sole factor predicting severity of mucositis after RIC and allogeneic SCT. An influence of cumulative toxicity of preceding chemotherapy on mucositis was not observed. Creatinine on day +3 after SCT may help to identify patients at higher risk for severe mucositis in the further course of transplantation.

1140

OPTIMAL TIMING OF G-CSF INJECTION FOR EFFECTIVE PERIPHERAL BLOOD PROGENITOR CELL COLLECTION IN PATIENTS WITH MULTIPLE MYELOMA OR LYMPHOMA

C. Suh, J.E. Kim, D.H. Lee, D.H. Yoon, B.S. Sohn, C.H. Yoo, S.W. Kim, J.S. Lee

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. There have been few attempts to define optimal timing of G-CSF administration for Peripheral blood progenitor cell (PBPC) collection and little is known about short-term kinetics of G-CSF. *Aim*. The objective of this study was to identify better timing of G-CSF administration which improves the efficacy of PBPC collection for autologous stem cell transplantation (ASCT). *Design and Methods*. A total of 262 patients who underwent PBPC collection from January 2000 to March 2008 were included. The patients were diagnosed with Hodgkin's lymphoma, non-Hodgkin's lymphoma and multiple myeloma and eligible for ASCT. PBPCs were mobilized with lenograstim following chemotherapy. Before November 2004, patients received lenograstim injection at a dose of 10 μg/kg subcutaneously at 8 p.m., 13 hours before apheresis (PM group), after then patients received lenograstim at 6 a.m. (AM group), 3 hours before apheresis. *Results*. Injection of lenograstim at 6 a.m. was superior to injection of lenograstim at 8 p.m. with greater numbers of total collected $CD34^+$ cells/kg ($13.29x10^6$/kg versus $8.51 x10^6$/kg, AM and PM group, respectively, p=0.001) in shorter duration of leukapheresis procedures (2 days vs 3 days, p=0.035). The median number of CD34+ cells/kg collected at first leukapheresis was also greater in AM group ($3.94x10^6$/kg vs 2.47 X 106/kg, p=0.001). Stem cell collection efficacy defined as ratio of total collected CD34+ cells per days of leukpaheresis were 5.34 and 2.96, respectively. It was significantly better in the AM group (p=0.001). The median number of patients who achieved a total collected $CD34^+$ cells > $5x10^6$/kg was also greater in the AM group (113 vs 96, p=0.002). *Conclusions*. The present study shows that injection of lenograstim 3 hours before apheresis (AM group) improves the efficacy of stem cell collection with greater number of collected CD34+ cells/kg in shorter duration of leukapheresis procedures compared to that of PM group.

KINETICS OF JAK2 V617F MUTATION IN FIVE JAK2 POSITIVE MDS PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

H. Alchalby, A. Badbaran, M. Lioznov, A.R. Zander, N. Kröger

University Hospital Hamburg, HAMBURG, Germany

Background. JAK2 V617F is a gain of function mutation in the Janus kinase 2 (JAK2) that was described in several myeloproliferative disorders. This mutation was found to exist also in nearly 5% of myelodysplastic syndromes. Recently several groups have further defined a subgroup of myelodysplastic patients who show simultaneously some clinical and pathological characteristics of myeloprolifertive disorders. This group is now referring to the new WHO classification of 2008 diagnosed as myelodysplastic/ myeloproliferative neoplasm, unclassified (MDS/MPN). Another group of patients exhibits features of essential therombocythemia combined with ringed sideroblasts in bone marrow and is now classified according to same system as Refractory anemia with ringed sideroblasts with marked thrombocytosis (RARS-T). JAK2 V617F mutation was detected in the majority of patients from the both previously mentioned groups. *Aims and methods*. We have treated five patients with myelodysplastic syndrome who harbored this mutation with allogeneic stem cell transplantation (ASCT) and monitored the kinetic of JAK2 mutation in peripheral blood after ASCT using a highly sensitive Taqman Polymerase chain reaction method. *Results*. The mean age of the patients was 51y (42-68 y). One of them had an acute myeloid leukemia AML-M1 probably after MDS, 2 had refractory cytopenia with multilineage dysplasia RCMD, 1 had refractory anemia with excess blasts RAEB II, and 1 had a refractory anemia RA which has evolved into RAEB II. Two of these patients showed marked fibrosis in the bone marrow histology. Two patient were conditioned using a standard conditioning regimen, the others received reduced conditioning. JAK2 V617F mutation copies decreased dramatically after transplantation in all patients. In three patients the mutation became negative after a median of 31 (16-46) days after transplantation .The 4th patient hat fluctuating very low values of JAK2 V617F compatible with a chimerism also ranging between 97-99,9 after ASCT, he is alive in a hematologic remission and doing well. In the 5th patient JAK2 V617F burden is decreased steeply but is not negative 4 months after transplantation. *Conclusions*. We conclude that JAK2 V617F mutation status decreases after stem cell transplantation and might be used as a marker of minimal residual disease after ASCT.

This work was supported with an EBMT-AMGEN fellow-ship grant.

CARDIAC STEM CELLS : A NEW POTENTIAL TOOL FOR CARDIAC REPAIR?

J.L.A.J. Rummens,[1] A. Daniëls1, R. Koninckx,[1] P. Steels,[2] M. Hendrikx,[1] K. Hensen[1]

[1]Virga Jesse Hospital, HASSELT, Belgium; [2]Hasselt University, HASSELT, Belgium

Background. The current therapy for myocardial infarction (MI) is not adequate enough, since mortality after MI remains very high. Cardiac repair by injection of stem cells is a promising therapy. Previously, several clinical studies using bone marrow stem cells were undertaken to explore the possibilities of stem cell therapy. Meanwhile, more evidence emerges that cardiac stem cells (CSCs) are present in the adult human heart. These CSCs are claimed to be actual stem cells residing in the heart and not just bone marrow stem cells mobilized to the heart. Therefore, CSCs are probably better suited for cardiac repair, since they are most likely already "pre-programmed" to become cardiomyocytes. *Aim*. To support this hypothesis, the aim of our study was to isolate human CSCs and compare them phenotypically and functionally with human mesenchymal stem cells (MSCs). *Design and Methods*. For the isolation of CSCs the two main methods described by Messina *et al*. and by Anversa *et al*. were followed. Messina *et al*. defines CSCs as cardiosphere derived cells (CDCs), which can be obtained by culturing phase-bright cells that appear after two weeks in a culture of cardiac explants. On the contrary, Anversa et al. consider c-kit+ cells isolated from cell outgrowth from a cardiac explant as CSCs. Upon isolation, CDCs, c-kit+ cells and MSCs appeared to be morphologically very similar in culture. Therefore, different panels of antibodies were used to phenotypically characterize these three cell types. *Results*. CDCs, c-kit+ cells and MSCs were found to be positive for CD13, CD29, CD44, CD55, CD90, CD49c, CD73, CD105 but negative for CD34, CD45 and CD133. The main difference between cells isolated from heart tissue and MSCs was that only MSCs stained positive for CD140b For the functional analysis, cells were subjected to a stem cell differentiation assay. While MSCs could easily differentiate to adipocytes, osteocytes and chondrocytes, CDCs could not. In addition, the possibility of differentiation into cardiomyocytes was examined. Therefore, cells of all three populations were cultured in differentiation medium containing 2% FCS and 5-aza, DMSO or TGF-β respectively. To investigate differentiation, cells were harvested and analyzed for expression of cardiomyocyte specific genes by RT-PCR. Preliminary results from these monocultures indicated that cells isolated from heart tissue had more potential to differentiate into cardiomyocytes than MSCs, because the former cell populations expressed cardiac troponin T and β-actinin in these conditions while the MSCs did not. *Conclusions*. These results indeed suggest that there is a phenotypical and functional difference between CSCs and MSCs, but further investigations have to be performed to show that these CSCs are able to differentiate into cardiomyocytes *in vitro* and *in vivo*.

BORTEZOMIB AND BEAM CONDITIONING REGIMEN FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN MANTLE CELL LYMPHOMA

B. Hebraud, M. Roussel, L. Ysebaert, C. Gaudin, G. Laurent, M. Attal, A. Huynh

CHU Purpan, TOULOUSE, France

Background. Mantle cell lymphoma (MCL) is an agressive non Hodgkin lymphoma with median overall survival (OS) in most series of 3-4 years. Although frontline therapies with autologous stem cell transplantation (ASCT) induce high rates of complete remission (CR), relapse is usual. Bortezomib (VEL) has demonstrated clinical efficacy in relapsed and refractory MCL, a synergistic effect with Cytarabine and a lack of sustained haematological toxicity when combined to high dose Melphalan (in multiple myeloma). The combination of VEL to BEAM could be a logical approach to improve the OS in MCL. *Aims*. The purpose of this monocentric prospective study was to evaluate the feasibility and safety profile of this association. *Design and Methods*. Between 05/06 and 11/08, 13 consecutive patients with MCL were enrolled to receive intensification with VEL-BEAM. VEL (1.3 mg/m^2) was delivered on days - 6,

- 3, + 1, + 4 and BEAM (300 mg/m^2 BCNU, 4x200 mg/m^2 Etoposide, 4x200 mg/m^2 Cytarabine and 140 mg/m^2 Melphalan) on day -7 to -2. Peripheral blood stem cells (median 6.6x10^6 CD34/kg) were infused on day 0. We secondary conducted a retrospective comparison with 8 frontline MCL patients who received "classical" BEAM followed by ASCT. *Results*. Main characteristics of the patients in both groups are resumed in table 1. All patients except 1 were in CR after induction therapy with 3 RCHOP/ alternating RDHAP chemotherapy. VEL did not increase the haematological toxicity observed with BEAM (Table 2). Median duration of neutropenia (<0.5x10^9/L) and thrombocytopenia (<50x10^9/L) was 9 and 13 days respectively. No grade 3/4 extra-haematological toxicity was observed. Two patients were transferred to USIC for septic choc with pneumoniae during neutropenic period. At time of reporting (02/09), only 1 patient relapsed at 18 months (mo). Two patients died: 1 at 3.5 mo of intracerebral hemorragia and 1 because of disease progression at 22 mo. In the classical BEAM group, 2 patients relapsed at 18 and 20 mo respectively with 1 subsequent death. Median follow-up (19 mo) is currently too limited to comment on whether the conditioning regimen with VEL-BEAM will translate into an improved progression free survival and therefore OS. *Conclusions*. These results suggest that VEL (1.3 mg/m^2) and BEAM is a feasible and safe conditioning regimen with promising PFS and OS results in MCL.

IMMUNOPATHOLOGY OF ATG PRIOR TO BONE MARROW TRANSPLANTATION IN MOUSE MODEL

B. Sadeghi,[1] S. Al-Hashmi,[1] Z. Hassan,[1] B. Rozell,[1] M. Abedi-Valugerdi,[2] M. Hassan[1]

[1]Karolinska Institute, STOCKHOLM; [2]Stockholm University, STOCKHOLM, Sweden

Background. Polyclonal anti-thymocyte globulin (ATG) is mainly used in hematopoietic stem cell transplantation, as a prevention for graft rejection as well as for GVHD. Immunosuppressive properties of ATG have been considered primarily from the depletion of peripheral lymphocytes. However direct or indirect effects of ATG on other immune components still is controversial. In the present study we evaluated the immunopathologic effects of ATG on immune system in a mouse model. *Design and Methods*. Ten to fourteen weeks old BALB/c and C57BL/6 mice, were injected intra- peritoneally or intravenously with different doses of ATG (0.2 mg/kg -25mg/kg) at three dosage schedules. Considering bone marrow transplantation as day 0, ATG were given at days -10, -7 and -5 or -7, -5 and -1 or -5, -3 and -1. At day 0, mice were killed; spleen (SP), bone marrow (BM), lymph nodes (LN) and thymus were removed and analyzed for T-, B-, DC, NK-, T-reg and myeloid cells. To evaluate the efficacy of immunosuppressive effect of ATG, a group of BALB/c mice were conditioned using busulfan (Bu) and ATG and compared to a control group of BALB/c conditioned with Bu (80 mg/kg) followed by cyclophosphamide (200 mg/kg). Both groups transplanted with BM and spleen cells from C57BL/6 and followed for engraftment and/or GVHD. *Results*. The administration of ATG (0.2- 4.5 mg/kg) has resulted in an increase in spleen cellularity while in lymph node and thymus a decreased cellularity was observed. We have found that injecting 4.5 mg/kg of ATG at day -7, -5 and -3 significantly decreased T-cell population in spleen and LN compare to Bu-Cy conditioning. The ratio CD4/CD8 increased after ATG treatment showing that CD8 cells are six-fold more sensitive to ATG treatment compared to CD4 lymphocyte. Interestingly T-reg cell population increase after ATG at day 0, however, the increment was negatively correlated with the administration time and positively correlated with the dose. ATG treatment has resulted in an increase in B-cell population by two- and three- fold in spleen and lymph nodes, respectively. Moreover, 1.2- to 3.5-fold increase in DCs, NK and myeloid cells was observed in SP and LN. Thymus cellularity and cell phenotype was less affected while BM cellularity was not affected by ATG treatment. No differences in the ATG effect on cellularity or cell phenotype between IP and IV route was observed. Despite the high immunosuppressive effect observed in T-cell population compared to that seen in Bu-Cy conditioning, no chimerism was observed when Cy was substituted with ATG (4.5-10 mg/kg). *Conclusions*. No donor chimerism could be obtained using ATG as a single agent up to 25mg/kg. ATG dose and the administration time are important factors affecting the repopulation of residual T-cells in spleen and lymph node that have to be considered in bone marrow transplantation setting.

1145

APOPTOSIS-INDEPENDENT ACTIVATION OF CASPASE-3 IN CD34-POSITIVE (CD34+) MOBILIZED CELLS

K. Augeul-Meunier,[1] D. Guyotat,[2] C. Crampe,[1] C. Mounier,[2] L. Campos[1]

[1]CHU de Saint-Etienne, SAINT ETIENNE, France; [2]Institut de Cancérologie de la Loire, SAINT-PRIEST-EN-JAREZ, France

Background. G-CSF mobilized peripheral blood CD34$^+$ cells are now the preferred and major source of hematopoietic stem and progenitor cells harvested for both autologous and allogeneic transplantation. Several mechanisms, like SDF-1/CXCR4 interactions or degradation of adhesion molecules by proteolytic environnement, are involved in the mobilization process. However this phenomenon is still partially understood. Gene expression analysis has identified an overexpression of the caspase-3 gene in CD34$^+$ mobilized cells, compared to CD34$^+$ from normal bone marrow. Caspase-3 is the main effector of the terminal phase of apoptosis. However recent studies have provided evidence of its implication in non apoptotic cellular processes, such as differentiation, migration and cytoskeleton modelling. AIM: The objective was the evaluation of caspase 3 activity compared to apoptosis in peripheral blood mobilized CD34+ cells by flow cytometry, and the determination of an anti apoptotic phenotype in these cells. *Design and Methods*: We evaluated by multicolour flow cytometry the expression of activated caspase-3 in G-CSF mobilized CD34$^+$/CD45$^+$ cells from blood (n=18). CD34$^+$/CD45$^+$ cells from normal bone marrow (n=11) served as control. Caspase-3 activity on fluorescent substrate (PhiPhiLux method) and apoptosis (Annexin V assay) were also evaluated. Finally we analysed the expression of anti apoptotic proteins Bcl-2, Bcl-Xl, and of Heat Shock Proteins HSP27, HSP70 and HSP90 in the same cell population. *Results*. There was significant difference for apoptosis between mobilized and bone marrow CD34$^+$ cells (19,8% versus 32,4% apoptotic cells respectively). Conversely activated caspase-3 levels were higher in mobilized CD34$^+$ cells. This was consistent with cleavage of caspase-3 substrate observed in mobilized cells. A significant increased expression of HSP90 (of which caspase-3 is a client protein), HSP70 and Bcl-Xl was observed in peripheral CD34$^+$ cells, but there was no variation of BCl-2 and HSP27 expression. *Conclusions*. Our results show an activation of caspase-3 in the mobilized peripheral blood CD34$^+$ cells, which appears to be independent of apoptosis induction. The role of this activation and possible control by HSPs warrants further analysis to establish its relationship with mobilization mechanisms.

1146

COMPARISON BETWEEN SPONTANEOUSLY OCCURRING AND POST-TRANSPLANT METABOLIC SYNDROME

C. Annaloro, L. Airaghi, S. Forti, P. Usardi, A. Orsatti, F. Onida, A. Della Volpe, E. Tagliaferri, G. Lambertenghi Deliliers

Fondazione IRCCS Ospedale Maggiore Policlinico Mangiagalli e Regina Elena, MILAN, Italy

Background. Central obesity and insulin resistance, which are linked by low adiponectin levels, play a primary role in the pathogenesis of metabolic syndrome (MS), and obesity-driven subclinical inflammation may contribute to determining the clinical pattern. We have previously observed 29 cases of metabolic syndrome (MS) in 85 adult long-term hematopoietic stem cell transplantation (HSCT) survivors. Aims, To compare common metabolic parameters and adipohormone profiles in post-transplant and "classical" MS patients *Design and Methods* The 29 post-transplant MS patients (15 women and 14 men; mean age 49.8±9.3 years; 17 autologous and 12 allogeneic transplant recipients) were compared with 29 "classical" MS patients (15 women and 14 men; mean age of 52.9±8.0 years) and 39 healthy subjects (19 women and 20 men; mean age 40.1±16.9 years). A record was made for each patient of conventional clinical and metabolic parameters, serum leptin, insulin, quantitative C-reactive protein (CRP), α-TNF and adiponectin Results Serum leptin, CRP, α-TNF and adiponectin levels were all significantly different in the three groups and every post-hoc test was also significant: in comparison with "classical" MS, the patients with post-HSCT MS had significantly higher levels of leptin (22.18 vs 15.3 ng/mL; $p<0.001$), CRP (0.32 vs 0.13 mg/dL; $p<0.05$), α-TNF (7.7 vs 2.8 pg/mL; $p<0.001$) and adiponectin (15.82 vs 9.44 ng/mL; $p<0.001$). There was no significant difference in insulin levels. Serum leptin levels and BMI were related in the patients with "classical" MS but not in those with post-HSCT MS. There were no significant differences between the allogeneic and autologous HSCT recipients. *Conclusions.* Unlike *classical* MS patients, patients with post-transplant MS do not show any physiological relationship between obesity and leptin or adiponectin levels, and so central obesity does not seem to play a primary role in this subset of patients. Conversely, their significantly higher leptin, CRP and α-TNF levels indicate chronic inflammation as an obesity-independent event possibly leading to insulin resistance and MS. The absence of any relationship between MS and allogeneic HSCT or GVHD suggests that chronic inflammation may be a common pathway due to multiple and heterogeneous transplant-related events affecting cytokine expression and immune response. This strengthens the view that post-HSCT and spontaneously occurring MS are separate entities. The former possibly shares some pathogenetic markers with the similar metabolic disorders observed in patients undergoing solid organ transplantation and those with HIV infection.

1147

QUANTITATIVE ANALYSIS OF CHIMERISM BY REAL-TIME POLYMERASE CHAIN REACTION OF INSERTION/DELETION POLYMORPHISM IS A GOOD PREDICTOR OF RELAPSE AFTER ALLOGENIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA

N. Jacque,[1] N. Dhedin,[1] M. Uzunov,[1] S. Nguyen Quoc,[1] J. Lazarovici,[1] L. Sutton,[1] J.P. Vernant1, D. Bories[2]

Background. Quantitative analysis of chimerism after allogeneic stem cell transplantation (allo-SCT) for acute leukemia is helpful to monitor the kinetic of engrafment. Usually, chimerism is assesed by variable number tandem repeat (VNTR) or short tandem repeat (STR) amplification by polymerase chain reaction (PCR), which have a sensitivity of 1 to 5 %. Insertion/Deletion (InDel) polymorphism analysis by real-time quantitative PCR (InDel-QPCR) is a recent and more sensitive method. Aims. As InDel-QPCR is a sensitive method for quantitative analysis of chimerism, it should be able to predict relapse earlier. *Design and Methods*. We conducted a unicentric retrospective study and we evaluated the files of all consecutive patients transplanted from May 2004 to April 2008 which relapsed of an acute leukemia after allo-SCT. Sixteen patients (12 myeloblastic and 4 lymphoblastic acute leukemia) were included in the study. Median age was 45 years (22-60). Conditionning regimen was myeloablative in 12 patients, the source of stem cell was bone marrow in 8 patients. Quantitative analysis of chimerism by InDel-QPCR method was usually performed every month post transplant. *Results*. The median delay between transplant and cytological relapse was 8.5 months (2-32). In three patients the quantification of recipient DNA rate was always superior to 1% at each point post transplant and they presented an early relapse (at 2, 3 and 4 months after transplant). The 13 remaining patients achieved a recipient DNA rate inferior to 1% at a median time of 35 days, in 11 patients recipient DNA rate was less than 0.1% at 56 days and in 7 patients recipient DNA rate was less than 0.01% at a median time of 189 days. The first 13 patients presented an increased chimerism preceding cytological relapse, at a median interval of 52 days (5-154). At the time when an increased chimerism was detected, the peripheral blood count was normal in 12 patients, one had persistent thrombocytopenia since the allo-SCT. *Conclusions*. The 0.01% to 1% range was found to be valuable for an early relapse prediction. Thus, chimerism evaluation by InDel-QPCR is a necessary method for detection of post transplant relapse before cytological abnormalities in acute leukemia, allowing early therapeutic measures.

B CELL RECOVERY AND PLASMATIC BAFF LEVELS IN GRAFT VERSUS HOST DISEASE

L. Yanez, C. Montes, G. Perez, M. Castaneda, A. Bermudez, A. Iriondo

Hospital Universitario Marques de Valdecilla, SANTANDER, Spain

Background. B-lymphocyte activating factor (BAFF), belongs to the tumour necrosis factor (TNF) ligand super family and is expressed by macrophages, dendritic cells and neutrophils especially when there is a proinflamatory stimulation. Its effect is mediated mainly by BAFF receptor (BAFF-R). High levels of this protein are associated with B-cell function and development, but have also seen in B-cell neoplasm, autoimmune diseases and related with chronic Graft versus Host Disease (GvHD). *Aims*. Analyze differences of plasmatic BAFF levels and CD 19 and BAFF-R expression during first 6 months after allogeneic stem cell transplantation (SCT) between patients with and without GvHD. *Design and Methods.* Prospective study of 44 patients who underwent allogeneic stem cell transplantation (SCT) between 2006 and 2008 in our center. Patients characteristics were: 24 male /22 female; Median age: 48 yrs (16-64); Primary disease (AML:39%,ALL:14%,MM:14%, CLL:9%, NHL:7%, HL:5%, MDS: 5%, Aplastic Anemia: 5%, Other: 7%); Donor (MRD:48%; UD: 30%;MmRD:5%; MmUD:18%); Stem Cell source (BM:84%; PB:16%); Conditioning (BUCY: 16%; ICT-CY:2%; Flu-Mel: 32%; FluBu:46%;Other: 5%); GvHD prophylaxis (Csa-MTX:55%; Csa-MMF:43%; Csa alone:2%); ATG infusion: 14%; BAFF plasma levels were analyzed by ELISA test and CD19 and BAFF-R were determined by flow cytometry. Determinations were done before conditioning, in day of stem cell infusion (day 0 of transplant), weekly during first 4 weeks, and then monthly until six months. *Results*. Patients who developed some form of GvHD (acute or chronic) showed significantly higher levels of BAFF after transplantation (378 pg/mL vs 1314 pg/mL, $p= 0,003$) and during the first month post transplant (524 pg/mL vs 1790 pg/mL, $p<0.001$). Plasma BAFF levels were matched between both groups after the fourth month after transplantation. The recovery of CD19+ B cells tends to be significantly slower ($p=0.05$) in patients who develop GvHD during the first six months after transplantation (1m: 0,14% vs 0,31%; 2m: 0.59% vs 1.3%; 3 m: 0,72% vs 3,8%; 4m: 1% vs 3.2%; 6m: 1% vs 4.4%). We have not observed significant differences in the expression of BAFF-R between both groups. *Conclusions*. In our study, we have observed that plasma levels of BAFF are elevated from the beginning of transplantation and in some patients even before receiving conditioning regimen. The presence of high plasma levels of BAFF in the first month post trasplant is related to the subsequent development of acute and/or chronic GvHD. Like the previously published, CD19+ B cells recovery tends to be significantly slower during first six months after transplant. However and despite the differences observed between both groups in plasma levels of BAFF, we did not find differences in expression of BAFF-R.

IMPLEMENTATION OF NEW METHODS INTO INVESTIGATIVE PROTOCOL FOR STANDARDIZATION AND OPTIMIZATION OF LEUKAPHERESIS PROCEDURES

I. Fatorova

University Hospital, HRADEC KRALOVE, Czech Republic

Background. The quality of peripheral blood stem cells (PBSC) depends on the $CD34^+$ cells yield in grafts. Timing of PBSC harvest varies - in patients on the 4th-10th day, in donors mostly on the 4th day after the beginning of growth factor mobilization. The minimal necessary yield for later autolougus or allogenic transplantations is 2 x 10^6 $CD34^+$ cells/kg. At present, the determination of $CD34^+$ cells is per-
